Yes, their first step is step zero. This process was initially described as a five-step process by others (Dawes et al, 2004; Dencso et al, 2005; Craig and Smyth, 2007). The unique features of the Melnyk et al (2010) model are the emphasis on the spirit of inquiry and the sharing of the results of the process.

Step zero involves a curiosity about the interventions that are being applied. Do they work, or is there a better approach? In public health nursing, for example, are there better parenting outcomes if the parents attend classes at the health department? Or are home visits to new mothers and babies more effective for achieving a healthy baby? Step one requires asking questions in a "PICOT" format.

Although Melnyk et al have developed a specific process for the PICOT, the process was first described by Sackett (1996), who discussed the need to define the (*P*)opulation of interest, the (*I*)ntervention or practice strategy in question, the population or intervention to be used for (*C*)omparison, the (*O*)utcome desired, and the (*T*)ime frame. Step two involves searching for the best evidence to answer the question. This step involves searching the literature. In the case of the previous example, a literature search would focus on a search of key terms like *public health nursing*, *parenting of new babies*, *parenting classes*, and *home visits*. Step three requires a critical appraisal of the evidence found in step two.

To appraise the literature found, Melnyk suggests asking three questions about each of the articles found in the literature search: (1) the validity, (2) the importance, and (3) whether or not the results of the article will help you as a nurse provide quality care for your clients. Step four is the step in which the evidence found is integrated with clinical expertise and client values. Institutional standards and practice guidelines, as well as cost of care and support of the health care environment to implement the findings, are all factors considered in this step.

Step five requires an evaluation of the outcomes of practice decisions and changes that were based on the answers to the first four steps. The goal in evaluation is a positive change in quality of care and health care outcomes. In the example of group parenting classes versus home visits to new mothers and babies, current literature suggests improved quality and health care outcomes with home visits (The Pew Center, 2010).

Step six is disseminating outcomes of the results to others, to colleagues, to the employing agency's administration, to faculty and other students, and through a poster or podium presentation of student nurse organizations or professional organizations. Professional organizations often sponsor student presentations for undergraduates as well as graduate students. Sharing of information is most important because it prevents each individual nurse from trying to find the best answer to the same question answered by someone else, and it gives us the basis for asking new questions. Sharing makes practice more efficient and improves quality and health care outcomes.

In a busy community practice setting, it is often difficult for nurses to access evidence-based resources. Using evidence-based clinical practice guidelines is one way for nurses to provide evidence-based nursing care in an efficient manner. Clinical practice guidelines are usually developed by a group of experts in the field who have reviewed the evidence and made recommendations based on the best available evidence. The recommendations are usually graded according to the quality and quantity of the evidence. The Public Health Practice Reference is an example of practice guidelines developed for population-centered nurses' use (AHRQ, 2014).

Approaches to Finding Evidence

Returning to the previous example, the clinical question has been stated and the population has been defined as new mothers and babies. Two interventions will be compared. The outcome is stated as healthy babies and the time frame may be 6 months or 1 year, or another time at which the outcomes of the interventions will be evaluated.

Four approaches are described that allow the nurse to read research/nonresearch evidence in a condensed format. The first, a **systematic review**, is "a method of identifying, appraising, and synthesizing research evidence. The aim is to evaluate and interpret all available research that is relevant to a particular research question" (Cochrane Library, 2014). A systematic review is usually done by more than one person and describes the methods used to search for and evaluate the evidence. Systematic reviews can be accessed from most databases, such as Medline and CINAHL.

The Cochrane Library is an electronic database that contains regularly updated evidence-based health care databases maintained by the Cochrane Collaboration, a not-for-profit organization (<http://www.cochrane.org>). The Cochrane Library is composed of three main branches: systematic reviews, trials register, and methodology database. The Cochrane Library publishes systematic reviews on a wide variety of topics. Systematic reviews differ from traditional literature review publications in that systematic reviews require more rigor and contain less opinion of the author. Systematic reviews for public

health can be found in the Guide to Community Preventive Services, the Cochrane Public Health Group, the Center for Reviews and Dissemination, and the Campbell Collaboration (Box 15-1).

HOW TO Develop an Evidence-Based Practice Guide to a Community Preventive Service

- Form a development team, preferably an interprofessional team, to choose a topic based on a community issue that needs to be addressed.
- Develop a structured approach to organize, group, select, and evaluate the interventions from the literature that work to address the issue.
- Select the interventions the group wishes to evaluate for use.
- Assess the quality of the evidence found in the literature.
- Summarize the findings.
- Make recommendations.
- Write a protocol or step-by-step guide to resolving the community issue.

From Task Force on Community Preventive Services: Guide to community preventive services. 2007. Available at <http://www.thecommunityguide.org/diabetes/default.htm>. Accessed September 26, 2010.

The second approach, **meta-analysis**, is a specific method of statistical synthesis used in some systematic reviews, where the results from several studies are quantitatively combined and summarized (GWU, 2014). A well-designed systematic review or meta-analysis can provide stronger evidence than a single randomized controlled trial.

The **integrative review** is a form of a systematic review that does not have the summary statistics found in the meta-analysis because of the limitations of the studies that are reviewed (e.g., small sample size of the population). **Narrative review** is a review done on published papers that support the reviewer's particular point of view or opinion and is used to provide a general discussion of the topic reviewed. This review does not often include an explicit or systematic review process.

Undergraduate students often perform narrative reviews. However, it is important to learn the process for systematic reviews, especially the use of the results of systematic reviews. Reading systematic reviews that have been completed is helpful in answering the question related to the EBP process.

What counts as evidence has also been argued in the public health literature (Earle-Foley, 2011). RCTs, which are the highest level of evidence used to make clinical decisions, are appropriate for evaluating many interventions in medicine, but are often inappropriate for evaluating public health interventions. For example, an RCT can be designed ethically to test a new medication for diabetes, but not for a smoking cessation intervention. In a smoking cessation intervention, subjects could not be assigned randomly to smoking or nonsmoking groups because a smoking cessation intervention is not appropriate for someone who does not smoke. In this situation, a case-control study would be most appropriate (see Chapter 12). Today there are many community-based clinical trials assisting in finding answers to the questions of which population-level intervention has the best outcomes. (Visit the CDC website to review these trials.)

BOX 15-1 Resources for Implementing Evidence-Based Practice

The following resources can assist nurses in developing evidence-based nursing practice:

1. The *Evidence-Based Practice for Public Health Project* at the University of Massachusetts Medical School Library has developed a website for evidence-based practice in public health (<http://library.umassmed.edu/ebpph/>). Many bibliographic databases, such as Medline, do not list all the journals of interest to public health workers. The project provides access to numerous databases of interest concerning public health. From the project's website, nurses can access free public health online journals and databases.
2. The *Agency for Healthcare Quality and Research (AHRQ)* developed clinical guidelines based on the best available evidence for several clinical topics, such as pain management. The guidelines are accessible via the agency's website (<http://www.ahrq.gov>) and serve as a resource to nurses involved in individual client care.
3. The *National Guideline Clearinghouse* (<http://www.guideline.gov/>), an initiative of the AHRQ, is an online resource for evidence-based clinical practice guidelines. AHRQ also supports Evidence-Based Practice Centers, which write evidence reports on various topics.
4. *PubMed* (<http://www.pubmed.gov/>) is a bibliographic database developed and maintained by the National Library of Medicine. Bibliographic information from Medline is covered in PubMed and includes references for nursing, medicine, dentistry, the health care system, and preclinical sciences. Full texts of referenced articles are often included. Searches can be limited to type of evidence (e.g., diagnosis, therapy) and systematic reviews.
5. The *Cochrane Database of Systematic Reviews* is a collection of more than 1000 systematic reviews of effects in health care internationally. These reviews are accessible at a cost via the website (<http://www.cochrane.org>). Nurses may also have free access from a medical library.
6. The *Evidence-Based Nursing Journal* (<http://ebn.bmjournals.com/>) is published quarterly. The purpose of the journal is to select articles reporting studies and reviews from health-related literature that warrant immediate attention by nurses attempting to keep pace with advances in their profession. Using predefined criteria, the best quantitative and qualitative original articles are abstracted in a structured format, commented on by clinical experts, and shared in a timely fashion. The research questions, methods, results, and evidence-based conclusions are reported. The website for the journal is <http://www.evidencebasednursing.com>.
7. The Honor Society of Nursing, Sigma Theta Tau International, sponsors the online peer-reviewed journal *Worldviews on Evidence-Based Nursing* that publishes systematic reviews and research articles on best evidence that supports nursing practice globally. The journal is available by subscription (<http://www.nursingsociety.org/>).
8. The *Task Force on Community Preventive Services* is an independent, non-federal task force appointed by the director of the Centers for Disease Control and Prevention. Information about the Task Force may be found at the website <http://www.thecommunityguide.org>. The Task Force is charged with determining the topics to be addressed by the CDC's Community Guide and the most appropriate means to assess evidence regarding population-based interventions. The Task Force reviews and assesses the quality of available evidence on the effects of essential community preventive services. The multidisciplinary Task Force determines the scope of the Community Guide that will be used by health departments and agencies to determine best practices for preventive health in populations.
9. The *U.S. Preventive Services Task Force (USPSTF)* is an independent panel of private-sector experts in prevention and primary care. The USPSTF conducts rigorous, impartial assessments of the scientific evidence for the effectiveness of a broad range of clinical preventive services, including screening, counseling, and preventive medications. Its recommendations are considered the "gold standard" for clinical preventive services. The mission of the USPSTF is to evaluate the benefits of individual services based on age, gender, and risk factors for disease; make recommendations about which preventive services should be incorporated routinely into primary medical care and for which populations; and identify a research agenda for clinical preventive care. Recommendations of the USPSTF are published as the *Guide to Clinical Preventive Services*. The guide is available online at <http://www.ahrq.gov/clinic/uspstfix.htm>.
10. The *Centers for Disease Control and Prevention* (www.cdc.gov) publishes guidelines on immunizations and sexually transmitted diseases. Guidelines are developed by experts in the field appointed by the U.S. Department of Health and Human Services and the CDC.
11. *Cochrane Public Health Group (PHRG)*, formerly the health promotion and public health field, aims to work with contributors to produce and publish Cochrane reviews of the effects of population-level public health interventions. The PHRG undertakes systematic reviews of the effects of public health interventions to improve health and other outcomes at the population level, not those targeted at individuals. Thus, it covers interventions seeking to address macroenvironmental and distal social environmental factors that influence health. In line with the underlying principles of public health, these reviews seek to have a significant focus on equity and aim to build the evidence to address the social determinants of health. (Visit <http://www.ph.cochrane.org/>.)
12. *Center for Reviews and Dissemination (CRD)* is part of the National Institute for Health Research and is a department of the University of York. CRD, which was established in 1994, is one of the largest groups in the world engaged exclusively in evidence synthesis in the health field. CRD undertakes systematic reviews evaluating the research evidence on health and public health questions of national and international importance. (Visit <http://www.york.ac.uk/inst/crd/index.htm>.)
13. *Campbell Collaboration*, named after Donald Campbell, was founded on the principle that systematic reviews on the effects of interventions will inform and help improve policy and services. The collaboration strives to make the best social science research available and accessible. Campbell reviews provide high-quality evidence of what works to meet the needs of service providers, policy makers, educators and their students, professional researchers, and the general public. Areas of interest include crime, justice, education, and social welfare. (Visit <http://www.campbellcollaboration.org/>.)

Approaches to Evaluating Evidence

One approach used in evaluating evidence is **grading the strength of evidence**. When evidence is graded, the evidence is assigned a "grade" based on the number and type of well-designed studies, and the presence of similar findings in all of the studies. Grading evidence has been debated so strongly that in 2002 the Agency for Healthcare Research and Quality (AHRQ) commissioned a study to describe existing systems

used to evaluate the usefulness of studies and strength of evidence. The report reviewed 40 systems and identified three domains for evaluating systems for the grading of evidence: quality, quantity, and consistency. The *quality* of a study refers to the extent to which bias is minimized. *Quantity* refers to the number of studies, the magnitude of the effect, and the sample size. *Consistency* refers to studies that have similar findings, using similar and different study designs (Haine-Schlagel et al, 2014). An example of how the *U.S. Preventive Services Task*

HOW TO Develop an Evidence-Based Protocol

Evidence-based protocols are a recognized approach to providing quality client care. Such protocols enhance the abilities of providers and can reduce health care errors. The following are steps to developing a protocol:

- Identify the problem.
- Identify stakeholders.
- Form a team of others to help develop the protocol.
- Develop an action plan with project goals and a timeline.
- Review the available evidence.
- Examine current practice and identify gaps as well as best practices.
- Develop the protocol focusing on gaps.
- Initiate the approval process with the setting.
- Evaluate current practices and modify as needed.
- Educate others who will use the protocol.
- Implement the protocol.
- Evaluate protocol for safety, effectiveness, and adherence (McEuen and Gardner, 2010).

From McEuen JA, Gardner KP, Barnachea DF, et al: An evidence-based protocol for managing hypoglycemia. *AJN* 110(7): 40–45, 2010.

Force 2003 graded the strength of evidence for the *Guidelines for Clinical Preventive Services* can be found at the website at the end of this chapter.

As indicated, many frameworks exist for evaluating the strength and the usefulness of the evidence found in the literature and other sources, such as professional standards. A popular framework was developed by the Agency for Healthcare Quality. Fineout-Overholt et al (2010) have also developed an approach for evaluating evidence. Although these approaches vary in the factors they evaluate, the best approach to choose is one that not only evaluates the strength, but also the usefulness of the

evidence. Table 15-1 provides an example of an approach for evaluating evidence.

The strength of the literature is measured by the type of evidence it represents. For example, the RCT is the evidence that has the greatest strength upon which to make a clinical decision. In contrast, opinion articles, descriptive studies, and professional reports of expert committees have less strength. The usefulness of the evidence is measured by whether the evidence is valid, whether it is important, and whether it can be used to assist in making practice decisions or changes in the community environment and with the population of interest to improve outcomes (Scott and McSherry, 2009).

The best RCT conducted in a hospital setting on using an intervention to prevent falls may not be applicable at all in a community setting. Therefore, although it may be a strong study with outcomes that improve health, it may not have the usefulness for applicability in the community because of the setting in which it was conducted.

Shaughnessy, Slawson, and Bennett (1994) proposed criteria for evaluating the usefulness of evidence, calling the process *patient oriented evidence that matters* (POEM). In general, the reader should ask the following questions: “What are the results? (Are they important?) Are the results valid? How can the results be applied to client care?” (p. 489). Application of POEM (2014) can be found at www.essentialevidenceplus.com. Brownson et al (2009) proposed that the following questions be asked for EBP (plus suggested application examples):

- What is the size of the public health problem? What is the need for improved health outcomes for new mothers and babies in our community?
- Can interventions be found in the literature to address the problem (e.g., home visits or parenting classes)?

TABLE 15-1 Typology for Classifying Interventions by Level of Scientific Evidence

Type/ Category	Strength/How Established	Considerations for the Level of Scientific Evidence—Quality	Quantity/Consistency Data Source Examples
Evidence-based I	Peer review via systematic or narrative review	Based on study design and execution External validity Potential side benefits or harms Costs and cost-effectiveness	<i>Community Guide</i> Cochrane reviews Narrative reviews based on published literature
Effective II	Peer review	Based on study design and execution External validity Potential side benefits or harms Costs and cost-effectiveness	Articles in the scientific literature Research-tested intervention programs (123) Technical reports with peer review
Promising III	Written program evaluation without formal peer review	Summative evidence of effectiveness Formative evaluation data Theory-consistent, plausible, potentially high-reach, low-cost, replicable	State or federal government reports (without peer review) Conference presentations
Emerging IV	Ongoing work, practice-based summaries, or evaluation works in progress	Formative evaluation data Theory-consistent, plausible, potentially high-reaching, low-cost, replicable Face validity	Evaluability assessments Pilot studies NIH CRISP database Projects funded by health foundations

From Brownson RC, Fielding JE, Maylahn CM: Evidence-based public health: a fundamental concept for public health practice. *Annu Rev Public Health* 30:175–201, 2009.

- Is the intervention useful in this community, with this population, or with populations at risk (e.g., the low income or uninsured)?
- Is the intervention the best one or are there other ways to address the problem considering cost and potential health outcomes for the population? (Assess cost and health outcomes of both of the interventions before choosing, including the nurses available to make home visits or who have the skills to teach the parenting class.)

Several variables are considered important in determining the quality of evidence used to make clinical decisions (Polit and Beck, 2011):

- **Sample selection:** Sample selection should be as unbiased as possible. For example, a sample is randomly selected when each subject has an equal chance of being selected from the population of interest. Random selection offers the least bias of any type of sample selection. Other types of sample selection such as convenience sampling contain researcher or evaluator bias.
- **Randomization:** When testing an intervention, randomly assign participants to either the intervention or control group. This type of assignment is less biased than if participants are allowed to choose the group they want to join.
- **Blinding:** The researcher or evaluator should not know which participants are in the experimental (treatment) group or which are in the control group. The researcher or evaluator is “blinded” as to who is receiving the treatment and who is not receiving the treatment.
- **Sample size:** The sample size should be large enough to show an effect of the intervention. In general, the larger the sample size, the better.
- **Description of intervention:** The intervention should be described in detail and explicitly enough that another person could duplicate the study if desired.
- **Outcomes:** The outcomes should be measured accurately.
- **Length of follow-up:** Depending on the intervention, the participants should be followed for a long enough period of time to determine if the intervention continued to work or if the results just happened by chance.
- **Attrition:** Few subjects should have dropped out of the study.
- **Confounding variables:** Variables that could affect the outcome should be accounted for either by statistical methods or by study measurements.
- **Statistical analysis:** Statistical analysis should be appropriate to determine the desired outcome.

APPROACHES TO IMPLEMENTING EVIDENCE-BASED PRACTICE

The first step toward implementing EBP in nursing is recognizing the current status of one’s own practice and believing that care based on the best evidence will lead to improved client outcomes (Melnyk et al, 2010). Since EBP is a relatively new concept, many practicing nurses are not familiar with the application of EBP and may lack computer and Internet skills necessary to implement EBP. Also, implementation will be successful only when nurses practice in an environment

that supports evidence-based care. Public health nurses consider EBP a process to improve practice and outcomes and use the evidence to influence policies that will improve the health of communities.

FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Evidence-Based Practice

Integrate best current evidence with clinical expertise and client and family preferences and values for delivery of optimal interventions.

Important aspects of EBP include:

- **Knowledge:** Describe EBP to include the components of research evidence, clinical expertise and client and family values
- **Skills:** Locate evidence reports related to clinical practice topics and guidelines
- **Attitudes:** Value the need for continuous improvement in clinical practice based on new knowledge

Evidence-Based Practice Question

As a nurse in the community you are working within a Native American community that has a high prevalence of diabetes. As you visit with clients in their homes, you notice that many have a standardized “Diabetes Care” handout they received from the same primary care clinic. Your clients comment that the nutritional recommendations are unrealistic in the context of their regular diet. You decide to initiate a focus group with clients who attend the diabetes clinic at the health department to customize nutritional diabetic guidelines for this community.

1. Go to The National Guideline Clearinghouse website at <http://www.guideline.gov>. This website is an initiative of the Agency for Healthcare Research and Quality and is a reservoir for evidence-based clinical guidelines.
2. On the home page, type “diabetes” in the search box.
3. The second result is: Guideline Synthesis: Nutritional Management of Diabetes Mellitus.
4. Review the various areas of the guidelines: Medical Nutritional Therapy, Carbohydrates, Protein, Fiber, Sucralose, Alcohol Consumption, Dietary Fat and Cholesterol, Micronutrients, Nutritional Interventions for Preventing and Managing Complications, and Physical Activity and Weight Management.
5. What baseline data might you gather from your focus group participants to be best informed in how to tailor the evidence-based recommendation for this community?
6. What might be effective strategies in writing up the community-specific guidelines and distributing them that might enhance their adoption?

Answer

- Understanding the common elements of this community’s diet is a good place to start. What are common carbohydrates, proteins, sources of sugar, dietary fat, and cholesterol that are commonly consumed?
- How does the common diet compare to the National Clearinghouse Guidelines? Are there healthy sources of carbohydrates, healthy fats that are part of the diet that can be emphasized?
- What are common patterns in the community around alcohol consumption? Would educational efforts around the deleterious effects of alcohol on diabetes be helpful?
- Writing up community-based guidelines with assistance from leaders in the community would be a helpful strategy. You could include healthy recipes from community leaders in your guidelines.
Your community-based guidelines might be distributed at a community celebration or gathering by members of the community who helped develop them.

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

CURRENT PERSPECTIVES

Cost Versus Quality

Much of the pressure to use EBP comes from third-party payers and is a response to the need to contain costs and reduce legal liability. Nurses must question whether the current agenda to contain health care costs creates pressure to focus on those research results that favor cost saving at the expense of quality outcomes for clients. Outcomes include client and community satisfaction and the safety of care. Costs can be weighed against outcomes when EBP is used to show the best practices available to reduce possible harm to clients (Makic et al, 2014; Asadoorian et al, 2010).

LEVELS OF PREVENTION

Using Evidence-Based Practice

According to evidence collected by the Task Force on Community Preventive Services, the following are interventions supported by the literature at each level of prevention:

Primary Prevention

Extended and extensive mass media campaigns reduce youth initiation of tobacco use.

Secondary Prevention

Client reminders and recalls via mail, telephone, e-mail, or a combination of these strategies are effective in increasing compliance with screening activities such as those for colorectal and breast cancer.

Tertiary Prevention

Diabetes self-management education in community gathering places improves glycemic control.

From Task Force on Community Preventive Services: *National Center for Chronic Disease Prevention and Health Promotion*. Available at <http://www.cdc.gov>. Accessed December 26, 2010.

Individual Differences

EBP cannot be applied as a universal remedy without attention to client differences. When EBP is applied at the community level, best evidence may point to a solution that is not sensitive to cultural issues and distinctions and thus may not be acceptable to the community. Ethical practice in communities requires attention to community differences.

Appropriate Evidence-Based Practice Methods for Population-Centered Nursing Practice

Gaining a number of perspectives in a situated community is important for nurses using EBP. Nursing has a legitimate role to play in interprofessional community-focused practice and can contribute to its evidence base. Nurses are obliged to ensure that the evidence applied to practice is acceptable to the community. Establishing an EBP culture depends on the use of both qualitative and quantitative research approaches, or the best evidence available at the time. For example, a quantitative research study of a community health center could provide information about patterns of client use, the cost of various services, and the use of different health care providers. However,

when quantitative research is combined with qualitative research, the nurse can gain an understanding of *why* clients use or do not use the services and help the health center be both clinically effective and cost-effective. Evidence from multiple research methods has the potential to enrich the application of evidence and improve nursing practice (Blakely et al, 2013).

The rising cost of health care will demand a more critical look at the benefits and costs of EBP. Finding resources to implement EBP will continue to be a challenge requiring creative strategies. An emphasis on quality care, equal distribution of health care resources, and cost control will continue. Implementing EBP can assist nurses in addressing these issues in the clinical setting. However, EBP can save money by providing the best care possible.

As nurses implement EBP in an environment focused on cost savings, the potential for governments, managed care organizations, or other health care agencies to endorse reimbursement of health care options solely on the basis of cost, without allowing for individual variation or considering environmental issues, will continue to be a concern. Nurses must use caution in adopting EBP in a prescriptive manner in different community environments. One aspect of the new health care reform act (PL 111-148) addresses the development of task forces on preventive services and community preventive services to develop, update, and disseminate EBP recommendations of the use of community preventive services. In addition, grant programs to support EBP delivery in the community are addressed in the Affordable Care Act of 2010.

Although the Internet is one source of evidence data (see Box 15-1), there may be a lack of quality indicators to evaluate the myriad websites claiming to contain evidence-based information. It is essential to evaluate the quantity of the information on the website, whether it comes from a reputable agency or scholar, and whether the source of the website has a financial interest in the acceptance of the evidence presented. (Refer to Chapter 16 on health education, which discusses the Internet as a source of data and how to evaluate its usefulness and reliability.)

HEALTHY PEOPLE 2020 OBJECTIVES

Healthy People 2020 objectives offer a systematic approach to health improvement. See the Healthy People 2020 box for the most recent objectives to improve clients' understanding of EBP and how they can contribute to health care decisions.

EXAMPLE OF APPLICATION OF EVIDENCE-BASED PRACTICE TO PUBLIC HEALTH NURSING

Chapter 9 describes the Intervention Wheel, a population-based practice model for public health nursing. The model consists of three levels of practice at the community, systems, and individual/family levels. It also consists of 17 public health interventions for improving population health. The model was originally developed using a qualitative grounded theory process but did

LINKING CONTENT TO PRACTICE

It is important for nurses to acknowledge and understand EBP. They can participate by applying EBP or they can add to the research base for public health through active programs of research, participating in systematic reviews, or reviewing the best evidence available to them by reading published systematic reviews. Nurses can demonstrate leadership in supporting EBP by becoming change agents, fostering a cultural change in the practice environment, and assisting nurses who do not know how to use EBP to make a difference in practice.

For example, nurses who have recently graduated are knowledgeable about the use of evidence in practice. The new nurses can assist nurses who have been out of school for a while to find sources of evidence upon which to base their practice, such as referring them to the *Guide to Community Preventive Services*. Using evidence in practice will demonstrate its value, but implementation can be difficult because of the sheer volume of evidence and increasing

population needs. Sharing knowledge and engaging in teamwork can help to overcome these barriers.

Nurses have an important role to play in developing and using clinical guidelines for community practices. Use of a community development model and engaging in community partnerships will ensure that the community's perspective is included (see [Chapter 18](#)).

Nurses active in EBP can devote attention to understanding how best to incorporate the guidelines into practice demonstrating practice excellence. EBP offers the opportunity for shared decision making because it can help nurses focus their thinking, observe process outcomes, and thus improve care for clients by communicating with leaders and other nurses what they have observed. Participation in EBP offers continuing professional growth and a feeling of value, recognition for contributions, and respect from peers and administrators ([Bradshaw, 2010](#); [Sandström et al, 2011](#)).

From Bradshaw WG: Importance of nursing leadership in advancing evidence-based nursing practice. *Neonatal Netw* 29(2):117–122, 2010; Sandström B, Borglin G, Nilsson R, et al: Promoting the implementation of evidence-based practice—a literature review focusing on the role of nursing leadership. *Worldviews Evid Based Nurs* Fourth quarter:212–223, 2011.

HEALTHY PEOPLE 2020

Information access is important to assure clients and communities have the correct information to make EBP health care decisions. The *Healthy People 2020* objectives related to providing resources are as follows:

- HC/HIT-6.3: Increase the proportion of persons who use electronic personal health management tools.
- HC/HIT-4: Increase the proportion of patients whose doctor recommends personalized health information resources to help them manage their health.
- HC/HIT-12: Increase the proportion of crisis and emergency risk messages, intended to protect the public's health, that demonstrate the use of best practices.
- HC/HIT-11: Increase the proportion of meaningful users of health information technology.
- HC/HIT-13: Increase the social marketing in health promotion and disease prevention [U.S. Department of Health and Human Services, 2010](#).

From U.S. Department of Health and Human Services: *Healthy People 2020: Roadmap to Improving All Americans' Health*. Washington, DC, 2010, U.S. Government Printing Office.

not include a systematic review of evidence to support the interventions or their application to practice. Initially, the model was developed from an extensive analysis of the actual work of 200 practicing public health nurses working in a variety of settings. The 17 interventions grew out of this analysis, as did the three levels of practice. The authors indicated that the original intent was to provide a description of the scope and breadth of public health nursing practice.

Because of the positive response to the Intervention Wheel, the decision was made to complete a systematic review of the evidence supporting the use of the Intervention Wheel. The goal was to examine the evidence underlying the interventions and the levels of practice. The systematic review involved answering six questions, a comprehensive search of literature, a survey of 51 BSN programs in five states, and a critique (by five graduate

students) of the 665 pieces of evidence found in the literature review for rigor (strength and usefulness). After limiting the final review to 221 sources of evidence, each source was independently rated by at least two members of a 42-member panel of practicing public health nurses and educators. The 42-member panel met to reach consensus on the outcomes of the reviews. The outcomes were field-tested with 150 practicing nurses, and then critiqued by a national panel of 20 experts.

The Intervention Wheel presented in [Chapter 9](#) is the result of this systematic review and critique ([Keller et al, 2004](#)). Although this critique may appear overwhelming, the undergraduate or graduate student may be involved in such a systematic critique as one of many participants contributing to the outcome of such a review. [Table 15-2](#) applies some of the interventions to the core functions of public health.

PRACTICE APPLICATION

A nurse who is the director of a public health clinic is in the process of analyzing how best to expand services to operate as a full-time clinic in the most cost-effective and clinically effective manner. The director gathers evidence from the literature on public health clinics in rural settings to evaluate cost and clinical effectiveness of various models. The nurse also considers evidence from the following sources in the decision-making

process: client satisfaction research data, knowledge of clinic staff, expert opinion of community advisory board members, evidence from community partners, and data on service needs in the state. Having examined the evidence, the nurse decides that incremental (step-by-step) growth toward full-time status is warranted. Evidence of needs in the community and analysis of statistical data indicate that the addition of wellness services

TABLE 15-2 Core Public Health Functions and Related Evidence-Based Nursing Interventions

Core Functions	Related Nursing Interventions
Assessment	Diagnose and investigate health problems and hazards in the community. Mobilize community partnerships to identify and solve health problems. Link people to needed health services. Use evidence-based practice for new insights and innovative solutions to health problems.
Policy development	Inform, educate, and empower communities about health issues. Develop policies and plans using evidence-based practice that supports individual and community health efforts.
Assurance	Monitor health status to identify community health problems. Enforce laws and regulations that protect health and ensure safety. Ensure the provision of health care that is otherwise unavailable. Ensure a competent public health and personal health care workforce. Use evidence-based practice to evaluate effectiveness, accessibility, and quality of personal and population-based services.

PRACTICE APPLICATION—cont'd

for children is a priority and a pediatric nurse practitioner is hired as a first step to assist the public health nurses while planning for full-time status continues.

A. Evaluation of the evidence gathered demonstrates which of the following?

1. Effectiveness of the intervention in communities
2. Application of the data to populations and communities

3. Existence of positive or negative health outcomes

4. Economic consequences of the intervention

5. Barriers to implementation of the interventions in communities

B. Explain how this example applies principles of EBP.

Answers can be found on the Evolve site.

KEY POINTS

- Evidence-based practice was developed in other countries before its use in the United States.
- The Institute of Medicine has indicated that by 2020, 90% of all health care should be evidence based.
- EBP is a paradigm shift in health care and nursing.
- EBP is both a process and a product.
- Application of EBP in relation to clinical decision making in population-centered nursing concentrates on interventions and strategies geared to communities and populations rather than to individuals.
- Nurses at all levels have an opportunity to improve the practice of nursing and client outcomes.
- The EBP process has seven steps.
- Approaches to EBP include systematic review, meta-analysis, integrative review, and narrative review.
- Evaluating the strength and usefulness of evidence is essential to finding the best evidence on which to make practice decisions.
- Cost and quality of care are issues in EBP.
- EBP includes interventions based on theory, expert opinions, provider knowledge, and research.
- Use of a community development model and community partnership model involves community leaders in making decisions about best practices in their community.
- The Intervention Wheel is an example of a result of EBP.
- Health care reform supports EBP.

CLINICAL DECISION-MAKING ACTIVITIES

1. Give an example of how undergraduates can be involved in EBP.
2. Explain how the nurse's knowledge of the community relates to EBP. Give examples.
3. What are the barriers to implementing EBP? How can these barriers be resolved?
4. Is the cost or quality of care more important in EBP? Debate this issue with classmates.
5. When working with a community to improve its health, is it more important to consider the perspectives of the community or those of the provider when defining health problems? Elaborate.
6. Invite the director of nursing from the local health department to speak to your class. Ask if evidence is used to develop nursing policies and practice guidelines. If not, why not?
7. Explain how you can apply evidence to your practice.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Describe the ways in which people learn.
2. Identify the steps and principles that guide community health education.
3. Discuss the importance of understanding the needs of learners including their cultural background, educational and health literacy level, and their motivation to learn and change behavior.
4. Describe how nurses can work with groups to promote the health of individuals and communities.
5. Examine types of health education including written, spoken, and the growing area of social media.
6. Explore ethical issues that arise in the practice of health education.

CHAPTER OUTLINE

Healthy People 2020 Objectives for Health Education Education, Learning, and Change

How People Learn

The Nature of Learning

The Educational Process

Identify Educational Needs and Develop Goals and Objectives

Select Appropriate Educational Methods

Skills of the Effective Educator

Motivational Interviewing

Develop Effective Health Education Programs

Educational Issues

Population Considerations Based on Age and on Cultural and Ethnic Backgrounds

Use of Technology in Learning

Barriers to Learning

Evaluation of the Educational Process

The Educational Product

Evaluation of Health and Behavioral Changes

Groups as a Tool for Health Education

Group: Definitions and Concepts

Stages of Group Development

Choosing Groups for Health Change

Managing the Community Group

Implementing the Educational Plan

One of the best ways to manage health care costs is for people to stay healthy. Nurses are in an ideal role to help individuals, families, and groups learn about health education and health promotion in order to change their behavior. Nurses can help clients by (1) educating across all three levels of prevention: primary, secondary, and tertiary; and (2) working with individuals, families, groups, and communities. The goal is to assist clients to attain optimal health, prevent health problems, identify and treat health problems early, and minimize disability. Education allows individuals to make knowledgeable health-related decisions, assume personal responsibility for their health, change behavior if needed, and cope effectively with alterations in their health and lifestyles. The Levels of Prevention box provides an example of how to use these three prevention levels in health education.

LEVELS OF PREVENTION

Related to Community Health Education

Primary Prevention

Provide education at health fairs about diet, exercise, or environmental hazards.

Secondary Prevention

Provide both education and health screenings at health fairs for such health issues as early diagnosis and treatment of diabetes and hypercholesterolemia in order to shorten the duration and severity of the disease.

Tertiary Prevention

Provide education in rehabilitation centers to teach ways to increase function to individuals who have been in an accident that left them with either an amputation or some paralysis.

This chapter discusses ways to develop individual, group, and community health promotion programs. Specific content in the chapter includes information about how people learn; the sequence of actions that a nurse follows when developing an educational program; the process of making change; literacy, especially health literacy; and the **ethics** related to health education. The role of groups in health promotion is also presented. Many of the objectives of *Healthy People 2020* address the importance of health promotion, and selected objectives are cited in this chapter.

HEALTHY PEOPLE 2020 OBJECTIVES FOR HEALTH EDUCATION

As mentioned in other chapters, *Healthy People 2020* lists national health needs and outlines goals and objectives designed to improve health. The *Healthy People 2020* educational objectives emphasize the importance of educating various populations (based on age and ethnicity) about health promotion activities in the priority areas of unintentional injury; violence; suicide; tobacco use and addiction; alcohol or other drug use; unintended pregnancy, human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS), and sexually transmitted disease (STD); unhealthy dietary patterns; and inadequate physical activity (U.S. Department of Health and Human Services [USDHHS], 2010).

In designing, implementing, and evaluating health education activities, it is useful to understand the primary health problems in the community as well as education principles related to both learning and teaching. Also, effective educational

HEALTHY PEOPLE 2020

Selected examples of *Healthy People 2020* are provided here.

- **ECBP-2:** Increase the proportion of elementary, middle, and senior high schools that provide comprehensive school health education to prevent health problems in the following areas: unintentional injury; violence; suicide; tobacco use and addiction; alcohol or other drug use; unintended pregnancy, immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS), and sexually transmitted infection (STI); unhealthy dietary patterns; and inadequate physical activity.
- **ECBP-3:** Increase the proportion of college and university students who receive information from their institution on each of the priority health-risk behavior areas listed previously.
- **ECBP-8:** Increase the proportion of worksites that offer a comprehensive employee health promotion program to their employees.
- **ECBP-11:** Increase the proportion of local health departments that have established culturally appropriate and linguistically competent community health promotion and disease prevention programs.

ECBP, Educational and community-based programs.

From U.S. Department of Health and Human Services: *Healthy People 2020: Understanding and Improving Health Promotion and Disease Prevention Objectives*. Washington, DC, 2010, U.S. Government Printing Office.

programs are built on the premise that the best approach is to teach what people think they want to learn and in ways that facilitate their learning. For this reason, a core public health principle relates to asking the learners to participate in identifying their learning needs. Then health education programs are designed to meet the health need or problem in that population. In general, these programs involve educating individual members of the population about health promotion, illness prevention, and treatment. For example, in a community where childhood and adolescent asthma is a problem, a community-based asthma education and training program can be developed. If childhood obesity is a major health concern, a program to educate children in their schools and parents and other caregivers in an after-school program about healthy eating, cooking, and exercise may be useful.

To develop a community-based education program, nurses need to follow a set of steps. Typical steps that are discussed in detail throughout the chapter include the following: (1) *identify* a population-specific learning need for the community health client; (2) *select* one or more learning theories to use in the education program; (3) *consider* which educational principles are most likely to increase learning and choose those that are most appropriate and feasible; (4) *examine* educational issues, such as population-specific or cultural concerns, identify barriers to learning, such as limited literacy or limited or lack of health literacy, and choose the most appropriate teaching and learning strategies based on the age, gender, education, and learning needs of the learners; (5) *design and implement* the educational program, using carefully chosen strategies; and (6) *evaluate* the effects of the educational program. The steps used in designing educational programs parallel those of the nursing process.

EDUCATION, LEARNING, AND CHANGE

When helping people change their behavior, remember that people can most easily change knowledge. The next step is to

help people change their attitudes, and the most difficult area to change is behavior. For this reason, nurses provide people with health information so they can improve their decision-making abilities and thereby decide if they will change their behavior. There is a difference between education and learning and between knowing and doing. **Education** is an activity “undertaken or initiated by one or more agents that is designed to effect changes in the knowledge, skill, and attitudes of individuals, groups, or communities” (Knowles et al, 2005, p. 10). Education emphasizes the provider of knowledge and skills. In contrast, **learning** emphasizes the recipient of knowledge and skills and the person(s) in whom a change is expected to occur. Remember that learning involves change.

Change is not easy for most people. To **change** means to move away from one way of thinking, believing, and acting and move toward a new way. Thompson (2010) describes understanding and managing organizational change. Although much of the change regarding health education is directed toward clients, not organizations, the steps he uses also apply to health education. They are as follows: (1) identify the need for change—and this means that the client or clients being served need to believe that they need to make a change; (2) plan how to implement the change—and this step includes explaining the basis for the change, the benefits of the change, and seeking ideas from those being served about the best way to make an identified change; (3) implement the change; and (4) evaluate whether the change made a difference in health. Fielding (2013) offers a similar approach toward health education, consisting of the following five steps: (1) understanding the problem, (2) understanding what works, (3) agreeing on the approach or action, (4) implementing the plan, and (5) evaluating the effect. As nurses work with clients to make health changes, it is important to watch for resistance or reverting back to past behaviors.

HOW PEOPLE LEARN

People learn in a variety of ways. Some people learn better by hearing a message; others learn by observing and/or participating in what is being taught. Learners accept information on the basis of many factors including what they already know, what they believe, and the culture in which they have been raised; as well as how well they can understand and relate to the information that they receive. What a person hears is filtered through his past experiences, the social groups to which he belongs, assumptions, values, level of attention and knowledge, and the respect he has for the person communicating the information. In some cultures, elders are considered to be valued sources of information. In other cultures, people value individuals with more education than they have. Also, because social groups play a critical role in the development of understanding or learning, concepts related to groups are discussed later in this chapter. Effective **health education** is a competency that is included in many documents that describe the role of public health professionals, including nurses. The Linking Content to Practice box illustrates the relationship between health education and selected standards, expectations, and competencies in public health.

LINKING CONTENT TO PRACTICE

Just as objectives in *Healthy People 2020* recommend that health education and promotion be used to provide public health care, so do other key documents such as the American Nurses Association's *Scope & Standards of Practice: Public Health Nursing*. Standard 5b, labeled "Health Education and Health Promotion," says that the "public health nurse employs multiple strategies to promote health, prevent disease, and ensure a safe environment for populations" (American Nurses Association, 2007, p. 23). Similarly, the *Core Competencies for Public Health Professionals* of the Council on Linkages between Academia and Public Health Practice (2010) lists six competencies related to communication skills; five of them relate directly to this chapter. These competencies, listed below, are discussed and illustrated throughout this chapter:

1. Assessing the health literacy of populations served
2. Communicating in writing and orally, in person, and through electronic means, with linguistic and cultural proficiency
3. Soliciting input from individuals and organizations
4. Using a variety of approaches to disseminate public health information
5. Applying communication strategies in interactions with individuals and groups

A variety of educational principles can be used to guide the selection of health information for individuals, families, communities, and populations. Three of the most useful categories of educational principles include those associated with the nature of learning, the educational process, and the skills of effective educators.

The Nature of Learning

One way to think about the nature of learning is to examine the cognitive (thinking), affective (feeling), and psychomotor (acting) domains of learning. Each domain has specific behavioral components that form a hierarchy of steps, or levels. Each level builds on the previous one. Understanding these three learning domains is crucial in providing effective health education (Bloom et al, 1956). First, consider assumptions about how adults learn. Specifically, adults are motivated to learn when (1) they think they need to know something, (2) the new information is compatible with their prior life experiences, (3) they value the person(s) providing the information, and (4) they believe they can make any necessary changes that are implied by the new information (Knowles et al, 2005).

Cognitive Domain

The **cognitive domain** includes memory, recognition, understanding, reasoning, application, and problem solving and is divided into a hierarchical classification of behaviors. Learners master each level of cognition in order of difficulty (Bloom et al, 1956). Start by assessing the cognitive abilities of the learners. This is especially important when learners have a limited level of literacy either of the language used in the instruction or of the content that is presented. A later section discusses both literacy in general and health literacy in particular. Teaching above or below a person's level of understanding can lead to frustration and discouragement. It is therefore important to be sensitive to the value of the cognitive domain in learning. The

cognitive domain consists of the following components (Bloom et al, 1956):

1. **Knowledge:** Requires recall of information
2. **Comprehension:** Combines recall with understanding
3. **Application:** In which new information is taken in and used in a different way
4. **Analysis:** Breaks communication down into parts in order to understand both the parts and their relationships to one another
5. **Synthesis:** Builds on the first four levels by assembling them into a new whole
6. **Evaluation:** In which learners judge the value of what has been learned

Affective Domain

The **affective domain** includes changes in attitudes and the development of values. For affective learning to take place, nurses consider and attempt to influence what learners feel, think, and value. Because the attitudes and values of nurses may differ from those of their clients, it is important to listen carefully to detect clues to feelings or misperceptions that learners have that may influence learning. It is difficult to change deeply rooted attitudes, beliefs, interests, and values. To make such changes, people need support and encouragement from those around them. Affective learning, like cognitive learning, consists of a series of steps that the learner takes:

1. **Knowledge:** Receives the information
2. **Comprehension:** Responds to the information received
3. **Application:** Values the information
4. **Analysis:** Makes sense of the information
5. **Synthesis:** Organizes the information
6. **Evaluation:** Adopts behaviors consistent with new values

Psychomotor Domain

The **psychomotor domain** includes the performance of skills that require some degree of neuromuscular coordination and emphasizes motor skills (Bloom et al, 1956). Clients are taught a variety of psychomotor skills including bathing infants, changing dressings, giving injections, measuring blood glucose levels, taking blood pressures, walking with crutches, as well as many skills related to health promotion exercises.

In teaching a skill, first show clients how to do a task requiring the skill being taught. You can use pictures, a model, or a device, or via a live demonstration, video, CD, or the Internet. Next, have clients practice through a repeat demonstration to validate that what is being taught was actually learned. Also, if the teaching is being done in a class, participants may learn by observing one another master a task. Psychomotor learning is dependent on learners meeting three conditions (Bloom et al, 1956; Dembo, 1994). The learner must have the following:

- The **necessary ability:** This will include both cognitive and psychomotor ability. For example, you may find that a person with Alzheimer's disease can follow only one-step instructions. Thus, you need to tailor your education plan to that person.
- A **sensory image** of how to carry out the skill: For example, when teaching a group of women how to cook heart-healthy foods, ask the women to describe their kitchen and how they would actually go about the cooking process.

- *Opportunities to practice* the new skills: Provide practice sessions during the program to help the client adapt the skill to the home or work environment where the skill will be performed.
- *The following Quality and Safety Education for Nurses box describes the importance of clear and appropriate communication.*

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Client-Centered Care

Important aspects of client-centered care include the following:

Knowledge: Integrate understanding of multiple dimensions of client-centered care: information, communication, and education

Skills: Communicate client values, preferences, and expressed needs to other members of the health care team

Attitudes: Respect and encourage individual expression of client values, preferences, and expressed needs

Client-Centered Care Question

Providing health information in a way that is not understandable or useful to the recipient is a poor form of client-centered communication. If you were teaching a group of four women about wound care after surgery, what steps would you take to assure that the message the women received was the message that you intended to send?

Answer: In general, you would begin by providing the needed information by describing each step; you might include an easy-to-understand handout in the language that the four women understand, or you might give them a CD to take home with them that has the information on it. Next you would demonstrate how to clean the wound. Then you would ask each woman to repeat the cleaning process that you just demonstrated. Finally, you would ask each woman if she had the facilities and supplies to clean the wound at home; and then you would ask if they each had any questions or concerns that you might answer. What else would you do?

Source: Cronenwett L, Sherwood G, Barnsteiner J, et al: Quality and safety education for nurses. *Nurs Outlook* 55:122–131, 2007.

In assessing a client's ability to learn a skill, be sure to evaluate intellectual, emotional, and physical ability, and then teach at the level of the learner's ability. Some clients do not have the intellectual ability to learn the steps that make up a complex procedure. Others may have cultural beliefs that conflict with healthy behaviors. Another client may be tremulous or have poor eyesight, making him incapable of learning insulin self-injection.

THE EDUCATIONAL PROCESS

The educational process builds on an understanding of education, learning, and how people learn. The five steps of the educational process (identify educational needs, establish educational goals and objectives, select appropriate educational methods, implement the educational plan, and evaluate the educational process) are discussed next.

Identify Educational Needs and Develop Goals and Objectives

Begin with a needs assessment to learn about health education needs. The steps of such an assessment are listed in [Box 16-1](#).

BOX 16-1 Steps of a Needs Assessment

1. Identify what the client wants to know. (Consider *Healthy People 2020* educational objectives.)
2. Collect data systematically about learning needs, readiness to learn, and barriers to learning.
3. Analyze assessment data that have been collected and identify cognitive, affective, and psychomotor learning needs.
4. Think about what will increase the client's ability and motivation to learn.
5. Assist the client to prioritize learning needs.

Once you identify the needs, prioritize them to meet the most important needs first. Consider the many factors that influence a person's learning needs and the ability to learn including demographic, physical, geographic, economic, psychological, social, and spiritual factors. Consider also the learner's knowledge, skills, and his or her motivation to learn, as well as what resources are available to support or prevent learning. Resources include printed, audio or visual materials, equipment, agencies, and other individuals. Barriers for the presenter include lack of time, skill and/or confidence, money, space, energy, and organizational support.

When you have identified the learning needs, develop the goals and objectives for the educational program. **Goals** are broad, long-term expected outcomes such as, "Each child in the third-grade class will participate in 30 minutes of daily physical exercise, 4 days per week for 2 months." Program goals should deal directly with the clients' overall learning needs. Regarding the third graders, their learning need is to know how important exercise is to their health and level of fitness.

Objectives are specific, short-term criteria that need to be met as steps toward achieving the long-term goal such as, "Within 2 weeks, each of the children will be able to demonstrate at least two exercises that they have learned." Objectives are written statements of an intended outcome or expected change in behavior and should define the minimal degree of knowledge or ability needed by a client. Objectives must be stated clearly and defined in measurable terms, and they typically imply an action ([Knowles et al, 2005](#)).

Select Appropriate Educational Methods

Educational methods should be chosen to facilitate the efficient and successful accomplishment of program goals and objectives. The methods should also be appropriately matched to the client's strengths and needs as well as those of the presenter. Choose the simplest, clearest, and most succinct manner of presentation and avoid complex program designs. Try to vary the methods in order to hold the attention of the learners and to meet the needs of different learners. Educators also need to be able to deliver presentations, lead group discussions, organize role plays, provide feedback to learners, share case studies, use media and materials, and, where indicated, administer examinations. You will want to think about what content to include, how to organize and sequence the information, what your rate of delivery will be, whether or not you need to include repetition, how much practice time should be included, how you will evaluate the effectiveness of the teaching, and ways that you can provide reinforcement

and rewards. The Internet and use of **social media** have created an entirely new way of providing health information. Sites such as Facebook, YouTube, and Twitter have large numbers of users (Bernhardt et al, 2013). Data from the Pew Internet & American Life Project (Pew Charitable Trusts, 2013) show that laptop computers are used more often than desktop computers and that the use of music players, video game equipment, electronic book readers, and tablet computers has grown rapidly. The most explosive growth has been in the use of mobile phones. These new forms of access to information affect the way in which health education is developed and delivered.

It is important to consider the ethical issues involved in using various forms of teaching tools, especially when using social media. According to the Pew Internet & American Life Project (Pew Charitable Trusts, 2013), 60% of patients seek both support and information online. Of 3,014 survey respondents, 77% said that they used Google, Bing, or Yahoo to find health information. Remember, not all websites are developed by health care professionals, nor have they all been peer reviewed. Also, when nurses use patient cases or data to illustrate a health education point, it is important to clearly understand the guidelines of the Health Insurance Portability and Accountability Act (HIPAA) and avoid privacy ethical violations of the ethics code. When nurses use social media to provide health education, they should consult the *ANA's Principles for Social Networking and the Nurse* (American Nurses Association, 2011) and the National Council of State Boards of Nursing's *White Paper: A Nurse's Guide to the Use of Social Media* (National Council of State Boards of Nursing, 2011). It is essential to protect the privacy of patients and their health data when making presentations in person or via social media or any other medium (Lachman, 2013).

When choosing educational methods, consider age, gender, culture, hearing, sight or developmental disabilities or special learning needs, educational level, knowledge of the subject, and size of the group. For example, clients with a visual impairment need more verbal description than those with no impairment in sight. Persons who have hearing impairments or language deficits need more visual material and speakers or translators who can use sign language or speak their native language. Also, when the learners have limitations in attention and concentration, the educator will need to use creative methods and tools to keep them focused. For example, you might include frequent breaks; simple surroundings with few or no distractions; use of small group interactions to keep learners involved and interested; and the use of hands-on equipment such as mannequins, models, interactive games, and other materials and devices that the learner can physically manipulate. Try to involve the learner appropriately, actively, and creatively in learning. Interactive educational programs may be more effective than noninteractive ones. Interactive strategies include discussion, small group work, games, and role-playing, whereas noninteractive strategies include lectures, videos, or demonstrations. The mnemonic TEACH is a useful way to teach clients. The steps are as follows:

Tune in: Listen before you start teaching. The client's needs should direct the content.

Edit information: Teach necessary information first. Be specific.

Act on each teaching moment: Teach whenever possible. Develop a good relationship.

Clarify often: Make sure your assumptions are correct. Seek feedback.

Honor the client: Respect the client as a partner, share responsibility, and build on the client's experience.

The goal of nurses who use *Healthy People 2020* as a guide in educating clients is to foster healthy communities mainly through primary and secondary prevention. Health fairs are a popular way to provide primary and secondary health education. The objectives of holding health fairs are to increase awareness by providing health screenings, activities, information and educational materials, and demonstrations. A health fair can target a specific population or focus on a specific health issue, as well as target a range of groups and cover a variety of health education and health promotion topics. The fair can be held in many locations and can be either inside or outside. The How To box lists guidelines to assist nurses who chair, co-chair, or serve on a planning committee for a health fair.

HOW TO Plan, Implement, and Evaluate a Health Fair

- Form a planning committee (2-12 people who represent the groups that will be part of the health fair). Possibilities include health professionals, representatives from health agencies, schools, churches, employers, the media, and the target audience.
- Identify the target group; develop a theme.
- Establish goals, expected outcomes, and screening activities consistent with the needs and wishes of the target group. Your primary goal might be to improve the health of a specific population such as workers at one plant or children in one school. You might have secondary goals such as reduced health care costs for the workers and reduced absenteeism for the children.
- Develop a timeline and schedule.
- Choose a site and consider the site logistics: Do this about 1 year ahead. Think about the size of the site you will need and the traffic flow from one booth or demonstration to another, whether parking is available and free or low cost, and whether there are toilets and places to get food and drinks. If the site is inside, consider adequate exits; the possible risks to children, the elderly, or handicapped people; and other safety and security issues. You may need to create maps: one for how to get to the fair and another one to help attendees get from one table, exhibit, or screening station to another. Be sure to include on the map the location of amenities such as toilets and food vendors.
- Plan for supplies that you will need: Tables, chairs, electronic equipment, and accessories such as extension cords, office supplies, sign-in sheets (and what information should be included), release forms for screenings, name tags, bags for attendees to gather the educational information, and evaluation forms. Set your budget. Obtain these supplies in advance.
- Recruit and manage exhibitors: Do this about 4 months ahead. Develop a list of possible exhibitors and sponsors, and contact them via letter, fax, e-mail, telephone, or in person. Follow-up with a confirmation letter (or fax) that outlines the details of the health fair.
- Publicize the health fair: The planning committee will have many good ideas about how to publicize in the specific community.

Examples might include fliers/posters, memos, brochures, e-mail blasts, local print, or radio/television.

- On the day of the fair: Greet health care professionals, agency representatives, sponsors, and members of the population being served.
- Evaluate the health fair: By exhibitors, participants and volunteers. You will need a specific form for each of these groups.
- Between 1 week and 1 month after the fair: Send thank-you letters to health care professionals, sponsors, and agencies, and pay bills associated with the fair.

From Rice CA, Pollard JM: Health fair planning guide, Agri LIFE EXTENSION Texas A&M System, September 16, 2009. Available at <http://fcs>.

Skills of the Effective Educator

The educator needs to understand the basic sequence of instruction. The following steps are useful in planning an educational program. Begin by (1) gaining the attention of the learners and helping them understand that the information being presented is important and helpful to them; (2) tell the learners the objectives of the instruction; (3) ask the learners to recall previous knowledge related to this topic of interest so that they link new knowledge with previous knowledge; (4) present the essential material in a clear, organized, and simple manner and in a way consistent with the learners' strengths, needs, and limitations; (5) help learners apply the information to their lives and situations; (6) encourage learners to demonstrate what they have learned, which will help you correct any errors and improve skills; and (7) provide feedback to help learners improve their knowledge and skills. When you use each of these steps you can help clients increase their learning experiences.

Motivational Interviewing

Sometimes clients do not provide all of the information needed to help promote their health. It is important before developing an implementation plan to carefully assess the need. The goal in health education is to engage the clients in wanting to learn ways in which they can change their behavior. Pay attention to the words you use and avoid medical jargon. Instead, use conversational language. One tool to use in health education is “**motivational interviewing**” (MI), which is a tool designed to help clients state their motivations to change (Miller and Rose, 2009). It is a collaborative partnership between the teacher and the learner designed to help people make their own choices. It seeks to help clients resolve their ambivalence about change and uses the techniques of elaboration, affirmation, reflection, and summary to engage people in talking about change. MI often is used in conjunction with other communication techniques. MI has four essential steps: engaging, which includes person-centered, empathic listening; guiding, which includes a particular identified target for change; evoking of the client's own motivations for change; and planning (Motivational Interviewing Network of Trainers, 2013).

MI was initially designed to treat problem drinkers and is used often with individuals rather than groups. However, the principles can be applied to health education. For example, if a public health nurse determines that she has four women in a

community group she leads who are overweight, eat high-calorie foods, and indicate they exercise little if any on a regular basis, how could the nurse use MI? First, the nurse needs to form a partnership with each of the women, in which she and the clients can communicate easily and in which each woman trusts the nurse. The nurse draws each woman out and learns what, if anything, each wishes to change. The nurse also learns about each one's motivation to change and ability to do so. Consider the client, Anna, and examine her motivation to change her eating and activity patterns. Anna says that her family will eat only fried foods, so to get her husband and children to eat a meal she fries their meats and vegetables. The family does eat fresh fruit and drink milk. Anna says that she gets exercise by walking to the bus stop en route to work and cleaning her home. She has not considered other forms of regular exercise. If you want to use MI with Anna and incorporate these principles in designing your nursing plan you could begin as follows:

1. Expressing empathy by trying to see the world through Anna's eyes
2. Building on Anna's strengths and helping her believe that she has the ability to make a change (self-efficacy)
3. Rolling with resistance when Anna is ambivalent about her ability to change
4. Developing discrepancy by helping Anna recognize that her current actions conflict with her expressed goals of eating healthy foods and exercising regularly

You could incorporate into your strategy the counseling skills that are part of MI: open-ended questions, affirmations, reflections, and summaries (OARS). These communication skills are useful in any nurse-client interaction. Open-ended questions refer to those that are not easily answered with yes or no or a short answer. These questions invite elaboration and more thinking about what is being asked. In helping Anna prepare healthier meals, ask her to describe the dinner she cooked the previous night. Affirmations are designed to recognize client strengths; they must be genuine and correct. Once Anna begins to explore the idea of preparing more nutritious food, you would affirm her progress and encourage her to continue working toward that goal. Reflections or reflective listening is possibly the most critical skill in that it conveys empathy because you are listening carefully. You can then guide Anna toward dealing with her ambivalence about change by examining the positive and negative aspects of the present situation. Using reflective listening, if Anna expresses concern or difficulty in her goal of preparing different meals, you can focus on her concern and possible ambivalence about sticking to the plan for change.

MI uses the term *change talk* to refer to statements by clients that they are motivated and willing to make change. An easy-to-use mnemonic is “DARN-CAT,” which refers to the following:

Preparatory Change Talk

Desire (I want to change)
Ability (I can change)
Reason (It's important to change)
Need (I should change)

Implementing Change Talk

Commitment (I will make changes)
Activation (I am ready, prepared, willing to change)
Taking steps (I am taking actions to change)

Apply the DARN-CAT mnemonic to the goal you and Anna have for her to learn ways to prepare more nutritious meals. Although MI is a set of skills that requires training to use completely, nurses can incorporate some of the MI techniques into their communication with clients. See the website www.motivationalinterviewing.org for more information on motivational interviewing.

Develop Effective Health Education Programs

All programs, including sessions using MI skills, should include a clear message conveyed in a format appropriate to the learners and in an environment that is free from distractions and consistent with the message. Emotions such as anxiety, stress, anger, or fear can interfere with the listener actually hearing the message being sent. Also, provide information that is understandable to the listener. Use plain language and avoid jargon, multisyllable words, slang, and complex medical terms. Use words that the listener will know and recognize. For example, some people are more familiar with terms like *high blood pressure* and *high blood sugar levels* rather than *hypertension* and *increased glucose levels*. On the other hand, be careful not to oversimplify your terms if your audience is knowledgeable about health care. You want to avoid “talking down” or “over the head” of your listeners.

The type of learning format that you select will depend on the learners. If they are young, you will want an interactive format and many of your options will include the use of technology. You could use a game such as developing a bingo game with food groups to teach about healthy eating. The old adage “A picture is worth a 1000 words” still holds true. People tend to remember what they see or hear; a lively format rather than a passive one encourages learning. Most people have a short attention span, so you need to make your point quickly and directly. It may help to provide take-home written materials or a CD for further reminders and follow-up of what is taught. Because people often learn better when they are actively engaged in the learning, small group discussion, role-playing, and question-and-answer sessions may reinforce learning. See Box 16-2 for examples of types of learning formats.

Pontius (2013) offers many useful suggestions for developing both verbal and written messages. Her audience is composed of school nurses; however, her messages fit many areas of health education. For written material, first limit the content and make it relevant; use an active voice and conversational tone so that you engage the learner in the process; make the material easy to read and write the way you talk. You do not want to use a thesaurus to find terms to use, so say what you mean in understandable words. As has been mentioned, make the content relevant to the age, gender, and culture of the learner. For online and social media messages, send out one message at a time. Use 12-point print size for most people and 14 point for older people. Use bullets or numbers to easily catch the attention of the reader, and put your most important points early in the list. Leave some white space on the page and choose ink that contrasts clearly with the background of the paper. Use examples to show the desired behavior. Figure 16-1 shows a community

BOX 16-2 Examples of Learning Formats

Presentation: This method can be used when the group is large and you want to be consistent in the message that is delivered to all participants. Remember, people tend to have a short attention span, so what can you do to keep them engaged? You might ask them to spend some time talking with one another in small groups and then have the group respond to questions, or ask attendees to write answers to questions and invite several to share their answers. The presentation can also be a webinar or similar electronic tool, including Skype.

Demonstration: Use the demonstration technique to show attendees how to perform a task. You could demonstrate insulin injection, heart-healthy food preparation, and exercise.

Small Informal Group: Because learners often learn as much from one another as from the instructor, small groups can be valuable. For example, in working with women in a shelter for abused women, participants may share actions they took to remove themselves safely from the violent environment. They might also be able to jointly plan how each might move to the stage of independent living outside the shelter.

Health Fair: See the How To box on ways to plan, implement, and evaluate a health fair. For example, you might offer a health fair in a senior center and have displays such as posters; videos; live demonstrations; handouts on such topics as reducing fat in selected recipes (including samples) and age-appropriate exercises for flexibility; as well as screenings for elevated blood pressure, glucose, or cholesterol or for osteoporosis and vision.

Non-native Language Sessions: You could adapt the health fair approach for a Hispanic group by holding the session in Spanish and providing all of the materials in Spanish. Then ask Spanish-speaking nurses to staff each of the stations for health learning.

FIG 16-1 Educating a community group about environmental health issues and gathering their concerns. (From [Centers for Disease Control and Prevention \[2009\]](#); courtesy Dawn Arlotta.)

group being educated, and Box 16-3 lists ways to design clear educational programs.

EDUCATIONAL ISSUES

There are three important educational issues to consider when you are planning educational programs. First, different populations of learners require different teaching strategies. Second, be prepared to overcome barriers to learning. And

BOX 16-3 Ways to Design Clear Educational Programs

1. Develop the content for your message.
2. Identify the most appropriate format and location for the program, taking into account your budget, location, and other available resources and constraints. See [Box 16-2](#) for examples of formats.
3. Organize the learning experience to fit the audience; consider how to engage the learners in the process.
4. Plan how you will deliver the material, using the following points:
 - Limit the number of points that you wish to cover to the most important ones.
 - Begin with a strong opening and close with a strong ending; people remember most what is said first and last.
 - Fit your use of language to the learners; use an active voice and emphasize the positive. For example, “Many people are able to lose weight by reducing their intake by 500 calories a day and exercising 45 minutes at least four times a week.”
 - Use examples, stories, and other vivid messages. Limit statistics and complex terminology.
 - Refer to trustworthy sources. In general, government, educational, or professional association sources are peer reviewed by professionals and dependable. The Centers for Disease Control and Prevention, National Cancer Institute, American Public Health Association, and the American Academy of Pediatrics are four examples of sites that offer useful information.
 - Use aids to highlight your message. For example, you might have posters, handouts, or CDs to give to attendees. You might also incorporate a clip from a website such as www.YouTube.com to emphasize your point. Be sure to verify that the content on the site is accurate; not all information is provided by professionals.
5. Don't forget to plan the evaluation when you are initially planning the program.

third, consider the appropriateness of using technology in the programs.

Population Considerations Based on Age and on Cultural and Ethnic Backgrounds

Nurses are an important source of health education in the community. The increase in populations of varying cultural and ethnic backgrounds and the aging of baby boomers require that community health education cross age and cultural boundaries. In terms of age, children, adults, and older adults have different learning needs and respond to different educational strategies. In each age group, learners vary also in their cognitive ability, personality, and prior knowledge. Some people learn better with more direct instruction, supervision, and encouragement than do other people.

Learning strategies for children and individuals with little knowledge about a health-related topic are characterized as [pedagogy](#). In the pedagogical model of learning, the teacher assumes full responsibility for making decisions about what will be learned, and how and when it will be learned. This form of learning is teacher directed. Learning strategies for adults, older adults, and individuals with some health-related knowledge about a topic are called [andragogy](#). In andragogy, learners play an important role in deciding what they need and want to learn.

Andragogy is a more transactional way of learning than is the pedagogical model. Each model has useful elements ([Knowles et al, 2005](#)). For example, when learners are dependent and entering a totally new content area, they may require more pedagogical experiences. In addition to considering the age of the population to be educated, think about the learning needs of the population and use the pedagogical and andragogical principles that will best meet these needs. In educational programs for children, provide information that matches the developmental abilities of the group. The following age-specific strategies may help the nurse tailor educational programs for children.

- *With younger children use more concrete examples and word choices.* You might tell a group of 3-year-old children that it is good to brush their teeth two times a day. With 10-year-olds, you can explain to them the benefits of brushing their teeth and the risks of not brushing and talk about issues such as the care of their teeth with braces.
- *Use objects or devices, rather than just discuss ideas, to increase attention.* When teaching a group of children with asthma how to use inhalers, it is better to hand out inhalers to each participant and have them practice proper technique with the inhalers rather than just giving them a handout with instructions or demonstrating how to use an inhaler while they watch you.
- *Incorporate repetitive health behaviors into games to help children retain knowledge and acquire skills.* Singing songs while acting out healthy activities such as washing hands before eating helps children get in the habit of washing their hands and makes this health promotion behavior fun. For example, the time a child should wash his or her hands is about the same amount of time it takes to sing “Twinkle, Twinkle Little Star.”

In thinking about culture, it is important to know that by 2050 approximately 50% of the U.S. population will consist of ethnic minorities such as Asians, African Americans, Hispanic Americans, Native Americans, and Pacific Islanders. Culture influences family structure and interactions as well as views about health and illness. These demographic changes present new challenges to nurse educators. Nurses need to understand the health belief systems of the ethnic populations being served and be familiar with populations who are prone to develop certain health problems. When presenting seminars or providing written, audio, or visual information, provide information in a culturally competent manner.

For example, in a rural farming area, there might be a large population of Mexican migrant crop workers. Knowing that this Spanish-speaking group is more likely to have tuberculosis than other segments of the community, nurses may visit the migrant worker camp to present information on tuberculosis such as prevention, symptom identification, early diagnosis, and treatment. An interpreter may accompany the nurses and provide oral content in Spanish. Written handouts can be in Spanish and designed to be read and understood on a second- or third-grade reading level.

Think also about the generation of the learner. The generation born between 1980 and the present time have always had

digital media and access to the Internet and are called the *net generation* (Billings and Kowalski, 2004). They are connected and use mobile devices for many purposes including learning. They typically prefer to work in groups or teams, are active learners who seek innovation, want an immediate response to their questions, and are able to multitask. They like simulations and virtual reality forms of learning. *Generation X* members were born between 1960 and 1980, and they tend to be self-directed, like to work in teams, and may need to develop skills because they may not be as tech savvy as the net generation. Members of this group can tolerate delayed gratification; they want clear information with practical value; and they can engage in games and activities when appropriate. The *boomers*, born between 1940 and 1960, are accustomed to being dependent on the teacher, want to be in charge of their own learning, respond positively to feedback, and want to do a good job. They like to be connected to other people.

Use of Technology in Learning

Many kinds of technologies such as computer games and programs, videos, CDs, and Internet resources can increase learning. These technologies may enable the learner to control the pace of instruction, offer flexibility in the time and location of learning, present an appealing form of education, and provide immediate feedback. You may want to use a variety of technological applications in your teaching. It is also important to be aware that people increasingly are using the Internet as a source of health information. Why do people use the Internet? A major benefit is its convenience: It is available 24 hours a day, 7 days a week, and there is no need to drive there, take public transportation, or find a parking place.

Educating people through the Internet has been shown to be more effective in fostering treatment adherence than in-person counseling, telephone counseling, or self-directed learning (Dauz et al, 2004). Clients may ask nurses to provide them with information about ways to evaluate the quality and reliability of this information. The following list provides some criteria for assessing the quality of Internet health information (Agency for Healthcare Research and Quality, 1999; VanBiervliet and Edwards-Schafer, 2004):

- **Authorship:** Are the authors and contributors listed with their credentials and affiliations?
- **Caveats:** Does the site clarify whether its function is to provide information or to market products?
- **Content:** Is the information accurate and complete, and is an appropriate disclaimer provided?
- **Credibility:** Does the site include the source, currency, relevance, and editorial review process for the information?
- **Currency:** Are dates listed for when the content was posted and updated?
- **Design:** Is the site accessible, capable of internal searches, easy to navigate, and logically organized?
- **Disclosure:** Is the user informed about the purpose of the site and about any profiling or collection of information associated with using the site?
- **Interactivity:** Does the site include feedback mechanisms and opportunities for users to exchange information?

- **Links:** Have the links been evaluated according to back-linkages, content, and selection? The Evidence-Based Practice box below describes the effective use of a smartphone app for health promotion.

EVIDENCE-BASED PRACTICE

The authors describe the development and formative evaluation of a smartphone app that deals with physical activity promotion. They say that physical inactivity is the fourth leading risk factor for global mortality and that self-monitoring of physical activities levels can support a healthier life. Because the Internet is easily accessed by many people, the authors used "10,000 Steps," which is an online physical activity health program to encourage the use of step-counting pedometers to track daily exercise. Their goal was to evaluate the design and usability of this smartphone app. They used both qualitative (video-taping and having participants "think aloud") and quantitative (a four-item usability questionnaire that used a 5-point Likert-type scale followed by a semistructured interview) measures. During the project they made modifications to the app. The results showed that the design changes significantly reduced the time it took for participants to complete their tasks. The study demonstrates the relevance of testing the design and then modifying a smartphone app designed for health promotion.

Nurse Use

Smartphones and their apps are an innovative medium for the delivery of health messages and health care interventions. It is a good idea to test the app before launching it to work out any areas that could be improved in terms of ease of use.

Kirwan M, Duncan MJ, et al: Design, development, and formative evaluation of a smartphone application for recording and monitoring physical activity levels: the 10,000 Steps "iStepLog." *Health Educ Behav* 40:140–151, 2013.

Barriers to Learning

Barriers to learning fall into two broad categories: one concerning the educator and the other concerning the learner.

Educator-Related Barriers

Some common educator-related barriers to learning, together with strategies to minimize them, follow (Knowles et al, 2005):

- **Fear of public speaking:** Be well prepared, use icebreakers, recognize and acknowledge the fear, and practice in front of a mirror or video camera or with a friend.
- **Lack of credibility with respect to a certain topic:** Increase your confidence by carefully preparing for the talk so that you have included useful information and you understand the information; avoid apologizing for lack of expertise, and instead convey the attitude of an expert by briefly sharing your personal and professional background.
- **Limited professional experiences related to a health topic:** You may want to describe personal experiences (brief ones), share experiences of others, or use analogies, illustrations, or examples from movies, current news, or famous people.
- **Inability to deal with difficult people who need to learn health-related information:** One strategy that may help with handling difficult learners is to confront the problem learner directly. Other strategies include using humor, using small groups to foster participation of timid people, asking

disruptive people to give others a chance to speak, or, if this does not work, asking them to leave.

- *Lack of knowledge about how to gain participation:* You can foster participation by asking open-ended questions, inviting participation, and planning small group activities whereby a person responds based on the group rather than presenting his own information.
- *Lack of experience in timing a presentation so that it is neither too long nor too short:* Plan ahead and practice the presentation by speaking during the practice at the same pace that you will speak to the group.
- *Uncertainty about how to adjust instruction:* You can more easily adjust instruction when you know the participants' needs, request feedback, and redesign the presentation during breaks, based on what you have learned about the participants.
- *A sense of discomfort when learners ask questions:* Try to anticipate questions, concisely paraphrasing questions to be sure that you correctly understood the question, and recognizing that it is appropriate to admit that you do not know the answer to a question.
- *Lack of feedback from learners:* Solicit informal feedback during the program and at the end with program evaluation.
- *Concern about whether media, materials, and facilities will function properly:* Test the equipment before the program to make sure it runs and also that you know how to use it. Also, have back-up plans for how to get help if you have a problem.
- *Difficulty with openings and closings:* Strategies to foster successful openings and closings include developing several examples of openings and closings, memorizing the opening and closing, concisely summarizing information, and thanking participants for attending.
- *Overdependence on notes:* You may wish to use note cards or visual aids as prompts; also, practicing in advance is a proven way to increase skill at presenting.

Learner-Related Barriers

Two of the most important learner-related barriers are low literacy and lack of motivation to learn information and make needed behavioral changes.

Low Literacy Levels. Nurses often deal with individuals and populations who are illiterate or who have low literacy levels. These individuals may be embarrassed to admit this deficit to health care providers and educators and may try to appear to understand when they really do not. Specifically, they may not ask questions to clarify information even when they do not understand it. As society becomes more multicultural, the problem of low literacy can increase due to limited use of the primary language as well as limited education. One of the Core Competencies for Public Health Professionals listed in the 2009 revisions by the Council on Linkages between Academia and Public Health Practice is to “assess the health literacy of populations served” (Council on Linkages, 2010). The next paragraphs describe the significance of this problem and the need for nurses to address health literacy.

The National Assessment of Adult Literacy (NAAL) is the largest literacy assessment study done in the United States. This

assessment was first conducted in 1992. At that time, out of five levels in the assessment, 50% of American adults were in the top two levels and 50% were in the bottom three levels of literacy. The minimal standard needed to function in the workplace is that of level 3 proficiency. In 2003, the tool measured literacy in four levels: *Below Basic*, *Basic*, *Intermediate*, and *Proficient*. The literacy scales used in 2003 were as follows: prose literacy, document literacy, and quantitative literacy. Prose examples include searching, comprehending, and using information from editorials, news stories, brochures, and instructional materials. Document literacy refers to searching, comprehending, and using information from documents such as job applications, payroll forms, transportation schedules, maps, tables, and drug and food labels. Quantitative literacy is the ability to identify and perform computations such as balancing a checkbook, completing an order form, or determining the interest on a loan from an advertisement. The 2003 test is more than just a survey and actually asks the test takers to perform tasks to demonstrate their literacy (Kutner et al, 2006). The 2003 NAAL included information about health literacy, which is an important topic for nurses.

Health literacy is gaining considerable attention for many reasons including the costs of health illiteracy when people are unable to follow directions about health care. *Healthy People 2020* defines **health literacy** as “[t]he degree to which individuals have the capacity to obtain, process, and understand basic information and services needed to make appropriate health decisions” (USDHHS, 2010). Health literacy includes a range of abilities including being able to “read, comprehend, and analyze information; decode instructions, symbols, charts and diagrams; weigh risks and benefits; and, ultimately, make decisions and take action” (National Institutes of Health [NIH], 2014). “Literacy skills are a stronger predictor of an individual’s health status than age, income, employment status, education level, or racial/ethnic group” (Weiss, 2007, p. 13). A person with limited literacy may be unable to understand instructions on prescription bottles, interpret health appointment cards, fill out health insurance forms, and read and understand self-care or hospital discharge instructions. What happens when someone has health illiteracy? A person with limited literacy may:

- Have a limited vocabulary and general knowledge and does not ask for clarification
- Focus on details and deal in literal or concrete concepts versus abstract concepts
- Select responses on a survey or questionnaire without necessarily understanding them
- Be unable to understand math (which is important in calculating medications)

In the past few years a great deal of federal and local attention has been paid to health literacy. Box 16-4 summarizes a sample of websites available to guide people in learning more about how to provide information in a way that learners who have varying levels of literacy can understand. The *Plain Writing Act of 2010* requires the federal government to write all new publications, forms, and publicly distributed documents in a “clear, concise, well-organized” manner and according to plain writing guides (see Public Law 111-274 at <http://www.gpo.gov/>

[fcdsys/pkg/PLAW-111publ274/pdf/PLAW-111publ274.pdf](#)). Similarly, the National Institutes of Health has developed materials on health literacy and clear communication and calls attention to the enormous costs associated with health illiteracy and how clear, understandable communication is needed for health care professionals (NIH, 2014). An especially helpful document is *Simply Put: A Guide for Creating Easy-to-Understand Materials* developed by the Centers for Disease Control and Prevention (2009). This 43-page guide is filled with information on how to create materials that will increase knowledge or change beliefs, attitudes, and behaviors by sending messages that are clear, relevant, and appropriate for the intended audience. Box 16-5 summarizes key sections in the guide.

Nurses may use pictures including comic books, slides and videos including YouTube presentations, and models in educating clients with low literacy. Some people learn better in a series of educational sessions. For example, at the first session, identify learning capacity and provide a small amount of foundational information. During subsequent sessions, new information that builds on existing knowledge and skills is provided and evaluated. Give additional information when you believe that the information has been understood and can be incorporated into learners' lives. To evaluate whether a person has limited health literacy, listen for the following clues: "I forgot my reading glasses," "I can read this when I get home," or "I will talk about this with my family—may I take the instructions home?" These comments may be quite straightforward or be a clue that the person actually cannot read the material.

Some people do not engage in learning because they have low levels of motivation to do so. Although adults respond to some external motivators, the most powerful motivators are internal. People are motivated to learn if they value the information and feel that they will benefit from the outcome, if they think they can follow through on what is being taught, and if it will improve their situation in life or increase their self-esteem (Ota et al, 2006).

As discussed in Chapter 17, models can be used to structure health education and health promotion plans. One model, the **health belief model** (HBM), is an individual-level model. This model can be useful in planning programs in which the motivation of learners might be a concern. Specifically, the HBM was one of the first theories of health behavior. As is discussed in Chapter 17, it began in an interesting way when people failed

BOX 16-5 Excerpts from *Simply Put*

A Guide for Creating Easy-to-Understand Materials

Make Your Message Clear

1. Give the most important information first and limit the number of messages.
2. Tell audiences what they need to do and what they will gain from understanding and using material.
3. Choose your words carefully.

Text Appearance Matters

1. Use font sizes between 12 and 14 points; for headings use a font size at least 2 points larger than that in the main text.
2. Font style: Do not use all caps; limit use of light text on a dark background.

Visuals Help Tell Your Story

1. Choose the best type of visual for your material.
2. Use visuals to help communicate your messages in a culturally relevant and sensitive manner.
3. Make visuals easy for your audience to follow and understand and of high quality.
4. Sometimes drawings can help your audience understand.
5. Use realistic images to illustrate internal body parts or small objects.

Layout and Design

1. Design an effective cover.
2. Organize your messages so they are easy to act on and recall.
3. Organize ideas in the order that your audience will use them.
4. Make the text easy for the eye to follow and invite the audience into the text.

Consider Culture

1. Use terms that your audience uses and/or is comfortable with.
2. Target messages to each cultural or ethnic group or subgroup.

Translations Take Your Message Further

1. Messages that work well with an English-speaking audience may not work for audiences who speak another language.
2. Design material for minority populations based on subgroups and geographic locations.
3. Get advice from community organizations in the areas you wish to reach.
4. Carefully select your translator and avoid literal translations.
5. Use the back-translation method and field-test your materials with members of the intended audience.

Test for Readability

1. Reduce reading level before using formulas; test a document's readability level (CDC, 2010, pp. 5-27).

Source: Centers for Disease Control and Prevention (CD): *Simply Put: A Guide for Creating Easy-to-Understand Materials*, ed 3, Atlanta GA, 2010, CDC.

to use free chest x-rays in the 1950s. A group of social psychologists were asked to try to explain the failure to use this screening. Specifically, what would motivate people to seek health care?

As discussed in Chapter 17, the HBM includes six components that attempt to answer the question of what motivates an individual to do something. These components are as follows: (1) perceived susceptibility ("Will something happen to me?"),

(2) perceived severity (“If something does happen to me, will it be a big problem?”), (3) perceived benefits (“If I do what is suggested, will it really help me?”), (4) perceived barriers (“Assuming I do what is suggested, will there be barriers that will be unpleasant, costly, and so forth?”), (5) cues to action (“What might motivate me to actually do something?”), and (6) self-efficacy (“Can I really do this?”). This model has been applauded and criticized. It does offer guidance in planning health education programs in that it reminds nurses to think carefully about what motivates people to change. To understand motivation, it is important to learn (1) how the people involved feel about the health problem, (2) whether they think it is serious, (3) whether they believe that action on their part will make a difference, and (4) whether they think that they can both manage the barriers and actually perform the action.

Consider the following example of how the HBM might be applied to a person in the community who has recently been diagnosed with diabetes. The person, June, is 25 years old and was diagnosed 2 months ago with diabetes mellitus. She has found it difficult to follow the recommendations of the public health nurse who has seen her in the community clinic. When the nurse asked June what seemed to be getting in the way of her complying, June said that she had asked herself these questions:

1. If I do not follow the nurse’s advice about diet, exercise, and taking my insulin, will something really happen to me?
2. If I do not follow the advice and something does happen, will it really be a problem?
3. On the other hand, if I take my medicine, eat a diet that will keep my diabetes under control, exercise as recommended by the nurse, and take my insulin according to the nurse’s directions, will I really reduce the seriousness of my disease?
4. How much will it cost me to purchase the foods in order to follow the diet? How much time will it take each week to exercise as recommended? Will it hurt me to give myself insulin injections?
5. I did see that my friend, Sue, who was diagnosed about 2 years ago with diabetes was careful about what she ate at the party, and she did talk about her exercise program where she walks 50 minutes 5 days a week. Sue did look better than she did when I saw her last year.
6. Is it possible for me to take care of myself like Sue does?

Two additional models that are especially useful in health promotion are discussed in Chapter 17. They are the **transtheoretical model** (TTM) and the **precaution adoption process model** (PAPM). Both models deal with change that occurs in stages and over time.

Further details about health promotion models can be found in Chapter 17.

Evaluation of the Educational Process

Evaluation is as important in the educational process as it is in the nursing process. Evaluation provides a systematic and logical method for making decisions to improve the educational program. You will need to evaluate the educator, the process, and the product.

Feedback to the *educator* provides the person an opportunity to modify the teaching process and enables the educator to better meet the learner’s needs. The learner’s evaluation of the educator occurs continuously throughout the educational program. The educator may receive written or verbal feedback from learners. Educators can get feedback by using return demonstrations to see what learners have mastered (Palazzo, 2001).

The educator should assume that inadequate learner responses reflect an inadequate program, not an inadequate learner. If the evaluation reveals that the learning objectives are not being met, the nurse must determine why the instruction is not effective. At this point, the educator will want to present the material creatively and meaningfully in new ways that will increase learner retention and the learner’s ability to apply the new knowledge. Ultimately, the educator must assume responsibility for the success or failure of the educational process and the development of learner knowledge, skills, and abilities.

Process Evaluation

Process evaluation examines the dynamic, ongoing components of the educational program. It follows and assesses the movements and management of information transfer and attempts to make sure that the objectives are being met. Use process evaluation throughout the educational program to determine whether goals and objectives are being met and the time required for their accomplishment. Ongoing evaluation also allows the teacher to correct misinformation, misinterpretation, or confusion (Palazzo, 2001).

Periodically review program goals and objectives, and ask whether the desired health behavior change is really necessary. Such a question inevitably leads back to the original learning objectives and enables the nurse to rethink the practicality and merit of each of the objectives. If teaching seems not to be working, re-examine the factors that influence learner readiness and motivation. Process evaluation uses information gathered from the educator as well as from learner evaluations and assesses the dynamics of their interactions (Knowles, 1990).

THE EDUCATIONAL PRODUCT

The educational product is the outcome of the educational process, and the product can be measured both qualitatively and quantitatively. For example, a qualitative assessment should answer the question, “How well does the learner appear to understand the content?” A quantitative assessment should answer the question, “How much of the content does the learner retain?” Thus, the quality of the product is measured by improvement and increase, or the lack thereof, in the learner’s knowledge, skills, and abilities related to the content of the educational program. Selected outcomes for the population of interest need to be identified when the educational program is conceived. Measurement of changes in these outcomes determines the effectiveness of the program. In nursing, the educational product is assessed as a measurable change in the health or behavior of the client.

Evaluation of Health and Behavioral Changes

Many approaches, methods, and tools are used to evaluate health and behavioral changes. Examples include questionnaires, rating scales, surveys, checklists, skills demonstrations, testing, subjective client feedback, and client repeat demonstration. Whether you use qualitative or quantitative strategies depends on the expected educational outcome. Evaluation of outcomes measured includes changes in knowledge, skills, abilities, attitudes, behavior, health status, and quality of life. Approaches to evaluating health education effects will vary, depending on the situation. For example, when considering a client's ability to perform a psychomotor skill such as changing a dressing, observing the client doing the skill is the most appropriate means of evaluation.

If evaluation of the educational product shows positive changes in health status and health-related behaviors, the educator can expect good results in similar health educational programs. If evaluation shows no changes or negative changes in health status and health-related behaviors, then re-examine and modify the program to attain better results in the future.

It is important to evaluate short-term health and behavioral effects of health education programs and to determine whether they are really caused by the educational program. Short-term objectives are often easy to evaluate (Babcock and Miller, 1994). For example, a **short-term evaluation** of whether a client can perform a return demonstration of a process being taught requires minimal energy, expense, or time; skill mastery can be determined within a matter of minutes. If the short-term objective is not met, the nurse determines why and identifies possible solutions so that successful learning can occur. If the short-term objective is met, the nurse can then focus on long-term evaluation designed to assess the lasting effects of the education program.

The goal of health education is to help clients make lasting behavioral changes that will improve their overall health status. Long-term follow-up with clients is a challenging task. **Long-term evaluation** is geared toward following and assessing the status of an individual, family, community, or population over time. The tools of evaluation are designed to assess whether specific goals and objectives were met. Also, monitor the extent and direction of client changes in health status and health behaviors (Kleinpell and Mick, 2001).

Often, for nurse educators, the goal of long-term evaluation is an analysis of the effectiveness of the education program for the entire community, not the health status of a specific client. Nurses track the achievement of community objectives over time, but not that of the individual community members. Thus, in a changing population, long-term evaluation of the results of an education program is still possible. The percentage of objectives and goals met by sampling the target population gives valid statistics for program assessment, even though the population of individuals may have experienced a complete turnover (Kleinpell and Mick, 2001).

For example, a nurse notes that according to annual health department data, 60% of all pregnant women in the nurse's catchment area received some prenatal care. Wanting to increase

this percentage to 100%, the nurse tries an educational intervention in which radio and television stations make public service announcements (PSAs) about the importance and availability of prenatal services.

After 1 year, the nurse discovers that 80% of all pregnant women now receive prenatal care. The nurse continues to use PSAs the next year because good results are evident. However, the long-term goal of the education program to influence the behavior of 100% of the pregnant women in the community has not yet been met. The nurse enlists volunteers to put informational posters in shopping malls, grocery stores, public transportation stops, laundries, and public transportation vehicles. In the second year after implementing the revised educational program, again using the statistics from the health department, the nurse finds that 95% of all pregnant women in the target area now receive prenatal care. The nurse can now evaluate and modify a community educational program over time to increase the rate, range, and consistency of progress made toward meeting the long-term goals of the project. It will be important and often difficult to keep track of clients; e-mail, telephone calls, and text messages may be useful.

Because health education is often conducted in the community in groups rather than provided to one person at a time, the use of groups in health education is discussed.

GROUPS AS A TOOL FOR HEALTH EDUCATION

People are part of a variety of groups, and each can influence health behavior and support useful or poor health practices. Groups are an effective and powerful medium by which to initiate and implement changes for individuals, families, organizations, and the community. People naturally form groups in the home, and groups in the community dramatically influence the community's health. They may form for a clearly stated purpose or goal, or they may form naturally as shared values, interests, activities, or personal characteristics attract individuals to each other.

Community groups represent the collective interests, needs, and values of individuals; they provide a link between the individual and the larger social system. Throughout life, group membership influences thoughts, choices, behaviors, and values as people socialize and interact. Through groups, people may express personal views and relate them to the views of others. Groups serve as communication networks and can help organize various aspects of communities.

Community groups may be informal or formal. **Formal groups** have a defined membership and a specific purpose. They may or may not have an official place in the community's organization. In **informal groups**, the ties between members are multiple, and the purposes are unwritten yet understood by members. These groups often form spontaneously when participants have a common interest or need. You can find out about what formal and informal groups exist in a community by reading the local newspaper, listening to public service information on the radio or television, reading items on the Internet, and asking residents about the groups to which they belong. Nurses often serve as a catalyst for

forming new groups or by creating linkages among groups that currently exist.

Group support often helps people make needed health changes. Skillful use of group methods can help a person analyze the problem, sustain motivation for change, experience support during vulnerable periods, and receive quick interpersonal feedback. The discomfort associated with change can be reduced through the relationships with others in beneficial groups. Many of the *Healthy People 2020* priorities can be addressed in health promotion and disease prevention groups, where individuals learn healthier behaviors and gain support from others in changing from risky to healthy lifestyle choices. For example, groups may support physical activity and fitness, sound nutrition, and safe sexual practices. Through group support, individuals may conquer smoking, drug abuse, or abusive relationships. They may identify and reduce exposure to environmental hazards and promote safer physical settings for all. Also, one of the core competencies for public health professionals is to “use group processes to advance community involvement” (Council on Linkages, 2010, p. 10).

Group: Definitions and Concepts

An understanding of several group concepts facilitates group work in the community. Some of the core concepts answer the following questions: (1) What is a group? (2) What is the purpose of the group? (3) How do groups develop and function? (4) What are their stages? and (5) What roles do members typically play in the group?

Definitions

A **group** is a collection of interacting individuals who have common purposes and are influenced by one another. Groups form for a variety of reasons. Families are an example of a community group. Families share kinship bonds, living space, and economic resources. They have many purposes such as teaching their members as well as providing psychological support and socialization. Groups also form in response to community needs, problems, or opportunities. For example, community residents may form a neighborhood association to protect their health and welfare. Community groups occur spontaneously because of mutual attraction between individuals and obvious and keenly felt personal needs such as those for socialization and recreation. Health-promoting groups may form when people meet to work together to support one another in achieving health goals such as weight loss, exercise, dealing with loss, and giving up smoking, gambling, or drinking.

Concepts

Groups need to identify a clear purpose. Having a clear purpose helps in establishing criteria for member selection and determining the action plan. For example, a clear statement of purpose proved valuable in forming a new group in one city’s housing development. The local department of social services had received numerous reports of child abuse and neglect. Routine home visits for well-child care documented high stress between parents and their offspring, and some parents requested teaching and guidance from the nurse in child discipline. The

nurse proposed that a parent group address this community need, and she chose this purpose for the group: dealing with kids for child and parent satisfaction. The purpose indicated both the process (to help parents deal with children) and the desired outcome (satisfaction for parents and children). As potential members were approached, this statement of group purpose helped them decide if they wanted to join.

Cohesion is the attraction between individual members and between each member and the group. Individuals in a highly cohesive group identify themselves as a unit, work toward common goals, endure frustration for the sake of the group, and defend the group against outside criticism. Attraction increases when members feel accepted and liked by others, see similar qualities in one another, and share similar attitudes and values. Group effectiveness also improves as members work together toward group goals while still satisfying the needs of individual members.

Members’ traits that increase group cohesion and productivity include the following: (1) compatible personal and group goals, (2) attraction to group goals, (3) attraction to some members of the group, (4) a mix of leading and following skills, and (5) good problem-solving skills.

Groups have both task and maintenance functions. A **task function** is anything a member does that deliberately contributes to the group’s purpose. Members with task-directed abilities become more attractive to the group. These traits include strong problem-solving skills, access to material resources, and skills in directing. Of equal importance are abilities to affirm and support individuals in the group. These functions are called **maintenance functions** because they help other members stay with the group and feel accepted. Other maintenance functions are the ability to help people resolve conflicts and create social and environmental comfort. Both task and maintenance functions are necessary for group progress. Naturally, those members who provide these functions are attractive, and an abundance of such traits within the membership tends to increase group cohesion.

The following group members’ traits may decrease cohesion and productivity: (1) a sense of conflict between personal and group goals, (2) lack of interest in group goals and activities, (3) poor problem-solving and communication abilities, (4) lack of both leadership and supporter skills, (5) disagreement about types of leadership, (6) aversion to other members, and (7) behaviors and attributes that others do not understand.

Usually, the more alike group members are, the stronger a group’s attraction, whereas differences tend to decrease attractiveness. Members’ perceptions of differences can create marked competition and jealousy. At the same time, personal differences can increase group cohesion if they support complementary functioning or provide contrasting viewpoints necessary for decision making. Cohesive factors are complex and many factors influence member attraction to each other and to the group’s goal. High group cohesion positively affects productivity and member satisfaction. The following example illustrates factors that influence group cohesion. A nurse initiated a group for clients who had been treated for burns. Ten residents, all from one town, had been discharged after a month in the local

burn unit. The stated purpose for the group was to teach coping skills to assist members in the difficult transition from hospital to home. Each person had been treated for extensive burns in an intensive care treatment center; each had relied heavily on health care workers for physical, social, and emotional rehabilitation; and each had faced the challenge of resuming work and family roles. Individuals shared some similar experiences and hopes for the future but varied in the amount of trauma and stress experienced. They also differed widely in psychological readiness for return to ordinary daily routines. One woman in the group was able to return quickly to her job as a cashier in a large supermarket. The strength of her determination to overcome public reaction to her scars, coupled with an ability to “use the right words” and an empathy for others, distinguished her from others in the group. These differences proved attractive to other members, inspiring them to work toward a return to their own roles in life. These members saw her differences as attainable.

This group’s cohesion was provided by the members’ attraction to the common purpose of returning to successful life patterns and managing relationships with others. Members also believed that interaction with others with similar burn experiences could help them reach that goal. This example shows that certain member experiences such as crises or traumas may help individuals identify with each other and may increase member attraction.

Being different from the general population and similar to the other group members can be positive for some members and negative for others. Some members may not want to be identified by an aversive characteristic such as disfigurement. Empathy for another’s pain, learned only through mutual experience, may provide a person with a required perspective for problem solving or affirming another’s view. This group was effective, and the nurse helped members use common experiences and learn from their differences.

Members’ attraction to the group is influenced by factors such as the group programs, size, type of organization, and position in the community. Attraction to the group is increased when members view goals clearly and see group activities as effective.

The concept of cohesion helps to explain group productivity. Some cohesion is necessary for people to remain with a group and accomplish the set goals. Attractiveness positively influences members’ motivation and commitment to work on the group task. Group cohesion may be increased as members better understand the experiences of others and identify common ideas and reactions to various issues. Nurses facilitate this process by pointing out similarities, contrasting supportive differences, or helping members redefine differences in ways that make those dissimilarities compatible.

Norms are standards that guide, control, and regulate individuals and communities. Group norms set the standards for group members’ behaviors, attitudes, and perceptions. Norms suggest what a group believes is important, what it finds acceptable or objectionable, or what it perceives as of no consequence. This commonly held view of what ought to be motivates members to use the group for their mutual benefit (Northen

and Kurland, 2001). All groups have norms and mechanisms to accomplish conformity. Group norms serve three functions: (1) to ensure movement toward the group’s purpose or tasks; (2) to maintain the group through various supports to members; and (3) to influence members’ perceptions and interpretations of reality.

Although certain norms keep the group focused on its task, some diversion can be present if members respect goals and feel committed to return to them. The **task norm** is the commitment to return to the central goals of the group, and its strength determines the group’s ability to adhere to its work.

Maintenance norms create group pressures to affirm members and maintain their comfort. Individuals in groups seem most productive and at ease when their psychological and social well-being is nurtured. Maintenance behaviors include identifying the social and psychological tensions of members and taking steps to support those members at high-stress times. For example, maintenance norms often refer to things such as scheduling meetings at convenient times and in an accessible and comfortable space with parking as well as seating, refreshments, and toilets.

Groups also have **reality norms**, where members reinforce or challenge and correct their ideas of what is real. Groups can examine the life situations confronting individuals and help to make sense of them. As individuals gather information, attempt to understand that information, make decisions, and consider the facts and their implications, they can take responsible action, not only in relation to themselves and their group, but also for the community. Group (task, maintenance, and reality) norms combine to form a group culture. Although working with a group does not mean dictating its norms, the nurse can support helpful rules, attitudes, and behaviors. Norms form when these rules, attitudes, and behaviors become part of the life of the group, independent of the nurse. Reality norms influence each member to see relevant situations in the same way the other members see them. For example, suppose a group of individuals with diabetes defines an uncontrolled diet as harmful; members may try to influence one another to maintain diet control. The nurse’s role in this group is to provide accurate information about diet and the disease process while continually displaying a belief that health through diet control is attainable and desirable.

Group members with similar backgrounds may have a limited scope of knowledge. For example, women in a spouse abuse group may believe that men are exploitive and harmful on the basis of common childhood and marriage experiences. Such a stereotypical view of men could be reinforced by similar perceptions in other members; this might lead to continuing anger or fear of interactions with men, and a hostile or helpless approach to family affairs. Nurses or group members who have known men in loving, helpful, and collaborative ways can describe their different and positive perceptions of men, thereby adding information and challenging beliefs. The health and condition of members improve as their perceptions of reality are based on a more complete range of data. Nurses bring an important perspective to groups in which similar backgrounds limit the understanding and interpretation of personal concerns.

BOX 16-6 Examples of Group Role Behavior

(There are many examples; this is a representative list of the types of roles members assume.)

- **Follower:** Seeks and accepts the authority or direction of others
- **Gatekeeper:** Controls outsiders' access to the group
- **Leader:** Guides and directs group activity
- **Maintenance specialist:** Provides physical and psychological support for group members, thereby holding the group together
- **Peacemaker:** Attempts to reconcile conflict between members or takes action in response to influences that disrupt the group process and threaten its existence
- **Task specialist:** Focuses or directs movement toward the main work of the group

The role structure of a group refers to the expected ways in which members behave toward one another. The role that each person assumes serves a purpose in the group. Examples of roles are leader, follower, task specialist, maintenance specialist, evaluator, peacemaker, and gatekeeper. Box 16-6 includes descriptions of each of these group roles.

Stages of Group Development

Tuckman (1965) developed a model of the stages of group development that has remained useful over time. He contended that any group, regardless of its type or setting, went through four stages: forming, storming, norming, and performing. In 1977 Tuckman and Jensen determined that there was actually a fifth stage: adjourning. This model can be used for health-related groups to identify in what stage the group is and what may be the next stage. Specifically, in the “forming” stage, members become acquainted with one another and the leader, become oriented to the group, and try to determine what their behaviors should be in relation to one another and to the goal of the group. In the “storming” stage, members begin to express their own individuality, which may run counter to that of others, and they may express hostility to one another and polarize because of interpersonal issues. In the third, or “norming,” stage, members start to accept one another; develop some cohesion, norms, and roles; and become comfortable in expressing their opinions and offering ideas. Members begin to trust one another and their interaction takes on more depth. In the fourth stage, “performing,” the group uses its interpersonal structure to accomplish its goals, and group energy is directed toward the tasks. In the fifth stage, “adjourning,” the group engages in separating from one another.

Leadership is a complex concept. It consists of behaviors that guide or direct members and determine and influence group action. Positive leadership defines or negotiates the group's purpose, selects and helps implement tasks that accomplish the purpose, maintains an environment that affirms and supports members, and balances efforts between task and maintenance. An effective leader pays attention to communications and interactions among the members. Attention is paid to both spoken words and body language, and this information provides continuous feedback about the members and the group process. By

BOX 16-7 Examples of Leadership Behaviors

- **Advising:** Introducing direction on the basis of knowledgeable opinion
- **Analyzing:** Reviewing what has occurred as encouragement to examine behavior and its meaning
- **Clarifying:** Verifying the meanings of interaction and communication through questions and restatement
- **Confronting:** Presenting behavior and its effects to the individual and group to challenge existing perceptions
- **Evaluating:** Analyzing the effect or outcome of action or the worth of an idea according to some standard
- **Initiating:** Introducing topics, beginning work, or changing the focus of a group
- **Questioning:** Generating analysis of a view or views by questions that support examination
- **Reflecting behavior:** Providing feedback on how behavior appears to others
- **Reflecting feelings:** Naming the feelings that may be behind what is said or done
- **Suggesting:** Proposing or presenting an idea to a group
- **Summarizing:** Restating discussion or group action in brief form, highlighting important points
- **Supporting:** Giving the kind of emotionally comforting feedback that helps a person or group continue ongoing actions

paying close attention to communications and interactions, members detect changing group needs, and they can take responsibility and pride in their own involvement. One or more members may lead the group or many may share leadership. Shared leadership may increase productivity, cohesion, and satisfying interactions among members.

After initiating or establishing a group, nurses may facilitate leadership within and among members, frequently relinquishing central control and encouraging members to determine the ultimate leadership pattern for their group. In some settings and circumstances, a single authority seems necessary (e.g., when members have limited skills or limited time, or when groups claim discomfort with shared responsibility for leading). A leadership style that shares leading functions with other group members is effective when there are many alternatives and when issues of values and ethics are involved in the group's action. Examples of leadership behaviors are shown in Box 16-7. Leadership can be described as patriarchal (paternal), or democratic. Each of these styles has a particular effect on members' interaction, satisfaction, and productivity. Groups may reflect one or a combination of styles.

A patriarchal or paternal style is seen when one person has the final authority for group direction and movement. A person using **patriarchal leadership** may control members through rewards and threats, often keeping them in the dark about the goals and rationale behind prescribed actions. Paternal leaders win the respect and dependence of their followers by parent-like devotion to members' needs. The leader controls group movement and progress through interpersonal power. Patriarchal and paternal styles of leadership are authoritarian. These styles are effective for groups such as a disaster team in which immediate task accomplishment or high productivity is the goal. Group morale and cohesiveness are typically low

under sustained authoritarian styles of leadership, and members may not learn how to function independently. Also, issues of authority and control may disrupt productivity if the group members challenge the power of the leader.

Democratic leadership is cooperative in nature and promotes and supports members' involvement in all aspects of decision making and planning. Members influence each other as they explore goals, plan steps toward the goals, implement those steps, and evaluate progress.

Choosing Groups for Health Change

Nurses choose the type of group that will be used after studying the overall needs of the community and its people. Such a study is based on client contacts, expressed concerns from various community spokespersons, health statistics for the area, available health resources, and the community's general well-being. These data point to the community's strengths and critical needs.

The nurse can identify goals for the community and for various groups through media reports, from community informants, and from colleagues. Goals may include visions for change as perceived by the people living and working in the local community. Data may be organized according to the opinions and behaviors of the identified groups. Such information about community groups and assessment data are used with community representatives to plan desired interventions. Alliances or coalitions unite diverse interest groups who share a common interest in perceived threats to community health, and nurses may work with groups both for community analysis and vehicles for change.

Deciding whether to work in **established groups** or to begin new ones is based on the clients' needs, the purpose of existing groups, and the membership ties in existing groups. There are advantages to using established groups for individual health change. Membership ties already exist, and the existing structure can be used. It is not necessary to find new members because compatible individuals already form a working group. Established groups usually have operating methods that have proved successful; an approach for a new goal is built on this history. Members are aware of each other's strengths, limitations, and preferred styles of interaction and may be comfortable working with and may be able to influence one another. If you choose to work with an established group, be sure to determine whether the new focus is compatible with the existing group purposes. [Figure 16-2](#) shows a breakout session during a community forum.

Groups can be used during a community assessment for information. Groups such as health-planning groups, better business clubs, women's action groups, school boards, and neighborhood councils are excellent information resources because part of their purpose is to determine and respond to community needs. In addition, they are already established as part of the community structure. When a group representing one community sector is selected for community health intervention, the total community structure is studied. Groups reflect existing community values, strengths, and norms.

How might nurses help established groups to work toward community goals? The same interventions recommended for

FIG 16-2 Breakout session in a community forum on environmental health concerns. (From [Centers for Disease Control and Prevention \[2009\]](#); courtesy Dawn Arlotta.)

groups formed for individual health change can be used for groups focused on community health. Such interventions include the following:

- Building cohesion through clarifying goals and individual attraction to groups
- Building member commitment and participation
- Keeping the group focused on the goal
- Maintaining members through recognition and encouragement
- Maintaining member self-esteem during conflict and confrontation
- Analyzing forces affecting movement toward the goal
- Evaluating progress

When nurses enter established groups, they need to assess the leadership, communications, and normative structures. This facilitates group planning, problem solving, intervention, and evaluation. The following example illustrates working with a community group. A nurse was asked to meet with a neighborhood council to help them study and “do something about” the number of homeless living on the streets. Residents knew this nurse from a local clinic and from his consulting work at a shelter for the homeless in an adjacent community. In their invitation to the nurse, council members said “our intent is to be part of the solution rather than part of the problem.” The nurse accepted the invitation to visit. He learned that this council had addressed neighborhood concerns for 20 years—protecting zoning guidelines, setting up a recreational program for teens, organizing an after-school program for latchkey children, and generally representing the homeowners of the area. The neighborhood was made up of low-income families who took great pride in their homes. After meeting with the council and listening to their description of the situation, the nurse agreed to help and joined the council.

As the first step in addressing the problem, the council conducted a comprehensive problem analysis on the homeless situation. All known causes and outcomes of homeless persons on

the street were identified, and the relationships between each factor and the problem were documented from literature and from the local history. The nurse brought expertise in health planning and knowledge of the homeless and their health risks. He suggested negotiation between the council and the local coalition for the homeless, recognizing that planning would be most relevant if homeless individuals participated. The council was cohesive and committed to the purpose, had developed working operations, and did not need help with group process. They made adjustments in their usual group operation to use the knowledge and health-planning skills of the nurse. Interventions for the homeless included establishing temporary shelters at homes on a rotating basis, providing daily meals through the city council or churches, and joining the area coalition for the homeless.

This example shows how an established, competent group addressed a new goal successfully by building on existing strengths in partnership with the nurse. Community groups, because of their interactive roles, are logical and natural ways for people who work together for community health change. As the decision-making and problem-solving capabilities of community groups are strengthened, the groups become more able representatives for the whole community. Nurses improve the community's health by working with groups toward that goal.

How can the nurse enter existing groups and direct their attention to individual health needs? One nurse employed by an industrial firm noted the harmful effect of managerial stress on several individuals. They had elevated blood pressure, stomach pain, and emotional tension. The nurse learned that the employees with stress were all members of a jogging team that met weekly for conversation in addition to regular workouts. High-level health had been a value shared by all team members, but although jogging was seen as an enjoyable and health-promoting activity, they had never talked about a shared purpose for improved health. The nurse saw a need for stress reduction, thought that the individuals at risk could achieve stress reduction if supported through a group process from valued friends, and proposed that a new purpose be added to the jogging team's activities. All in the group readily accepted and began to focus more on their stress levels as they jogged.

When it is neither desirable nor possible to use existing groups, the nurse can initiate a selected membership group. Choose members who have common health needs or concerns. For instance, individuals with diabetes can meet to discuss diet management and physical care and to share problem-solving remedies; community residents can meet for social support and rehabilitation after treatment for mental illness; or isolated older adults can meet to socialize, eat nutritious meals, and exercise.

Consider members' attributes when composing a new group. Members are attracted to others from similar backgrounds, with similar experiences, and with common interests and abilities. Members' behavior is influenced by the membership, purpose, attraction, norms, leadership, and group structure, and by memories of prior groups. Select members so that common ties or interests balance out dissimilar traits. Try to have members with expressive and problem-solving skills and

others who serve in supportive roles; try to have a mix of people with both task and maintenance functions, and others who can develop these skills.

The size of the group influences effectiveness; generally, 8 to 12 is a good number for group work focused on individual health changes. Groups of up to 25 members may be effective when their focus is on community needs. Large groups often divide and assign tasks to subgroups, with the original large groups meeting less frequently for reporting and evaluation. Setting member criteria can facilitate recruitment and selection of the most appropriate members for any group. The criteria usually suggest a mixture of member traits, allowing for balance for the processes of decision making and growth.

Managing the Community Group

As soon as the group forms, begin to work on the stated purpose. Help members interact by paying attention to maintenance tasks of attending, eliciting information, clarifying, and recognizing contributions of members. Begin by talking about what brought each person to the group. Encourage each one to participate; recognize and support them as they take on leadership functions. The new group begins to take shape in the early sessions as members try out familiar roles and test their individual abilities. The core competency skills for communication recommended by the Public Health Foundation ([Council on Linkages, 2010](#)) are useful to nurses working with community groups. [Box 16-8](#) lists these competencies. Subsequent steps are then planned not only according to the nurse's skill and preference, but also according to the group composition and the skills brought by members.

Conflict is normal in human relations. People may see conflict as the opposite of harmony and try to guard against it. This is an unfortunate view because the tensions of difference and potential conflict actually help groups work toward their purposes. Conflict occurs when members feel obstructed or irritated by one or more other group members ([Northen and Kurland, 2001](#)). Conflict signals that antagonistic points of view must be considered and that one must reexamine beliefs and assumptions underlying relationships. Some people are

BOX 16-8 Core Competencies for Communication Skills of Educators

Communication Skills

- Communicates effectively both in writing and orally, including via e-mail
- Solicits input from individuals and organizations
- Advocates for public health programs and resources
- Leads and participates in groups to address specific issues
- Uses the media, varied technologies, and community networks to convey information
- Effectively presents accurate demographic, statistical, programmatic, and scientific information for professional and lay audiences

Attitudes

- Listens to others in an unbiased manner
- Respects points of view of others
- Promotes the expression of diverse opinions and perspectives

concerned about security, control of self and others, respect between parties, and access to limited resources. In groups, members may express frustrations about trust, closeness and separation, and dependence and independence. These themes of interpersonal conflict operate to some extent in all interactions and are not unique to groups.

People tend to repeat the same patterns of behavior in conflicts. Sometimes the pattern works; other times it does not. The best approach is to match the response style to the situation (Sportsman and Hamilton, 2007), which requires personal awareness and awareness of others. Specifically, when you respond with avoidance, forcing with power, capitulation, and exclusion of a member, the behaviors fail to satisfy the concerns of participants. Assertiveness (attempting to satisfy one's own concerns) and cooperativeness (attempting to satisfy the concerns of others) can be positive responses to conflict. Behaviors that reflect either assertiveness or cooperativeness and that may satisfy the frustrated parties include confrontation, competition, compromise, reconciliation, and collaboration. Resolving conflict within groups depends on open communication among all parties, diffusion of negative feelings and perceptions, concentration on the issues, and use of fair procedures and a structured approach to the process.

Conflict can be overwhelming, especially when members view the expression of controversy as unacceptable or unremitting. Conflict suppressed over time tends to build up and finally explode out of proportion to the current frustration. A group that repeatedly avoids expressing conflict becomes fragile, is unable to adapt and helpless to face challenges. Conflict may be destructive if contentious parties fail to respect the rights and beliefs of others.

Approaches for acknowledging conflict and solving problems that respect others and represent self-concerns are first learned in families and other small groups. These lessons teach people to embrace conflict as a natural occurrence that supports growth and change. Other people learn to avoid conflict or to

disregard others in the promotion of self. Teams that try to be harmonious and avoid conflict may hinder collaboration and personal growth (Gerow, 2001).

It is important to evaluate individual and group progress toward health goals. Early in the planning, specify the action steps that should be taken to meet the goals. These small steps may be responses to learning objectives (listed as action steps designed to support facilitative forces and deal with resistive forces), or they may reflect the group's problem-solving plan. The action steps and the indicators of achievement are discussed and written in a group record. Recognition of accomplishments in the group and of the group is built into the group's evaluation system. Recognition may include concrete rewards such as special foods and drinks, or it may be the personal expression of joy and member-to-member approval. Celebration for group accomplishments marks progress, rewards members, and motivates each person to continue.

Implementing the Educational Plan

Once educational methods have been selected, they should be implemented through management of the educational process. Implementation entails the following: (1) control over starting, sustaining, and stopping each method and strategy in the most effective and appropriate time and manner; (2) coordination and control of environmental factors, the flow of the presentation, and other contributory parts of the program; and (3) keeping the materials logically related to the core theme and overall program goals (Knowles, 1990). Administrative and political support is essential to successful program implementation.

Educators must be flexible and modify educational methods and strategies to meet unexpected challenges that confront both the educator and the learner. External influences (such as time limitations, expense, and administrative and political factors) and learner needs require an ongoing evaluation of their impact on the educational program. Implementation is a dynamic element in the educational process.

PRACTICE APPLICATION

During Kristi's BSN student public health practicum at a local health department, the health department got many calls from people wanting information about H1N1 virus. For Kristi's community health intervention project, she decided to do an educational piece on this topic. What is her best course of action?

A. Develop a poster presentation to have on display at the health department.

B. Make an educative pamphlet to mail to anyone calling with questions.

C. Work with the health department staff to develop a community forum presentation and information brochures on H1N1.

D. Develop an in-service program for health department staff on potential spread of the virus and ways to prevent its spread.

Answers can be found on the Evolve site.

KEY POINTS

- Health education is a vital part of nursing because the promotion, maintenance, and restoration of health rely on clients' understanding of health care topics.
- Nurse educators identify learning needs, consider how people learn, examine educational issues, design and implement educational programs, and evaluate the effects of the educational program on learning and behavior.

- Nurses often use the *Healthy People 2020* educational objectives as a guide to identifying community-based learning needs.
- Education and learning are different. Education is the establishment and arrangement of events to facilitate learning. Learning is the process of gaining knowledge and expertise and results in behavioral changes.

KEY POINTS—cont'd

- Three domains of learning are cognitive, affective, and psychomotor. Depending on the needs of the learner, one or more of these domains may be important for the nurse educator to consider as learning programs are developed.
- Nine principles associated with community health education are gaining attention, informing the learner of the objectives of instruction, stimulating recall of prior learning, presenting the stimulus, providing learning guidance, eliciting performance, providing feedback, assessing performance, and enhancing retention and transfer of knowledge.
- Often theory can guide the development of health education programs. Two useful ones are the health belief model (HBM) and the transtheoretical model (TTM), the latter discussed in connection with the precaution adoption process model (PAPM).
- Principles that guide the effective educator include message, format, environment, experience, participation, and evaluation.
- Educational issues include population considerations, barriers to learning, and technological issues.
- Two important learner-related barriers are low literacy, especially health literacy, and lack of motivation to learn information and make the needed changes.
- The five phases of the educational process are identifying educational needs, establishing educational goals and objectives, selecting appropriate educational methods, implementing the educational plan, and evaluating the educational process and product.
- Evaluation of the product includes the measurement of short- and long-term goals and objectives related to improving health and promoting behavioral changes.
- Working with groups is an important skill for nurses. Groups are an effective and powerful vehicle for initiating and implementing healthful changes.
- A group is a collection of interacting individuals with a common purpose. Each member influences and is influenced by other group members to varying degrees.
- Group cohesion is enhanced by commonly shared characteristics among members and diminished by differences among members.
- Cohesion is the measure of attraction between members and the group. Cohesion or the lack of it affects the group's function.
- Norms are standards that guide and regulate individuals and communities. These norms are unwritten and often unspoken and serve to ensure group movement to a goal, to maintain the group, and to influence group members' perceptions and interpretations of reality.
- Some diversity of member backgrounds is usually a positive influence on a group.
- Groups also go through a set of stages in order to form, operate, and adjourn.
- Leadership is an important and complex group concept. Leadership is described as patriarchal (or paternal), or democratic.
- Group structure emerges from various member influences, including members' understanding and support of the group purpose.
- Conflicts in groups may develop from competition for roles or member disagreement about the roles ascribed to them.
- Health behavior is greatly influenced by the groups to which people belong and for which they value membership.
- An understanding of group concepts provides a basis for identifying community groups and their goals, characteristics, and norms. Nurses use their understanding of group principles to work with community groups toward needed health changes.

CLINICAL DECISION-MAKING ACTIVITIES

1. Think about an educational interaction that you had with each type of client (individual, family, community, and population) that did not seem to go well. For each type of client and on the basis of how people learn, identify what might have been the problem. Develop a plan for ways in which the interaction could have been improved, based on how people learn.
2. Recall a learning experience in which the message, format, environment, experience, participation, or evaluation was unsatisfactory. Then develop a plan for how the problem could have been overcome and turned from a negative or neutral learning situation into a positive one.
3. Review the phases of the educational process. Apply this process to a population of individuals with hypertension, a community in which tuberculosis is on the rise, and families with a child who has attention deficit disorder.
4. Select one of the *Healthy People 2020* educational objectives and design a population-specific education program to meet that objective. Consider how people learn, educational issues, educational process including teaching strategies, and evaluation procedures that you would use.
5. Consider three groups of which you are a member. What is the stated purpose of each group? Are you aware of unstated but clearly understood purposes? What is the nature of member interaction in each group? How do purpose and interaction differ in the three groups?
6. Observe two working groups in session, from the community, a health care agency, or a school. Notice the attractiveness of each group through the eyes of its members.
7. List actions that nurses may take to assist groups in various aspects of their work, such as member selection, purpose clarification, arrangements for comfort in participation, and group problem solving.
8. Observe a nurse working with a health promotion group. Does the nurse function in the way you anticipated? What nursing behavior facilitates the group process? List the areas of skill and knowledge that groups consisting of community residents would most likely expect of the nurse.

Building a Culture of Health through Community Health Promotion

Pamela A. Kulbok, DNSc, RN, PHCNS-BC, FAAN

Pamela A. Kulbok earned her BS and MS from Boston College and her doctorate at Boston University and did postdoctoral work in psychiatric epidemiology at Washington University in St. Louis. She was a U.S. Navy nurse; has worked in a visiting nurse service; and has directed a hospital-based home health agency. She is the Theresa A. Thomas Professor of Primary Care Nursing, Professor of Public Health Sciences, and Chair of the Department of Family, Community, and Mental Health Systems at the University of Virginia, School of Nursing. Dr. Kulbok is a Robert Wood Johnson Foundation, Executive Nurse Fellow (2102-2015). She was the Principal Investigator of an interprofessional, cross-institution, community-based participatory research project to design a youth substance use prevention program and of a series of studies of youth nonsmoking behavior. She has taught undergraduate and graduate courses in public health nursing, health promotion research, and nursing knowledge development. She was Co-Chair of the American Nurses Association (ANA) workgroup that revised the *Public Health Nursing: Scope and Standards of Practice* (2013), a member of the American Public Health Association (APHA) PHN Section, Definition Task Force that updated the *Definition of Public Health Nursing* (2013), President of the Association of Community Health Nursing Educators, and Chair of the Quad Council of Public Health Nursing Organizations. She was a member of the ANA—Congress on Nursing Practice and Economics. She is Fellow in the Center for Health Policy at the University of Virginia.

Nisha Botchwey, PhD, MCRP, MPH

Nisha Botchwey earned her doctorate degree at the University of Pennsylvania and completed her Masters of Public Health at the University of Virginia. She taught Urban and Environmental Planning and Public Health at the University of Virginia. She is an Associate Professor of City and Regional Planning in the College of Architecture at the Georgia Institute of Technology. Dr. Botchwey specializes in public health and the built environment and community engagement. She teaches Public Health and the Built Environment, Community Engagement and the Citizen Participation and Health Impact Assessment, courses subscribed by community design and public health students from Emory and Georgia State University. Dr. Botchwey is author of *Health Impact Assessment in the United States* (Springer, 2014). She is also Director of the *Built Environment and Public Health Clearinghouse* (www.bephc.gatech.edu), an online resource supported by the Centers for Disease Control and Prevention and the National Prevention Strategy, offering training resources and multisector community building for public health, planning, architecture, transportation engineering, and health impact assessment. Dr. Botchwey is co-lead of the *Atlanta Dashboard*, an interactive tool that collects, analyzes, and displays quality of life and health data at the sub-county level to aid in evidence-based decision making. Dr. Botchwey is Co-Director of the National Academy of Environmental Design's Research Committee, a member of the Centers for Disease Control and Prevention's Advisory Committee to the Director, and an NSF ADVANCE Woman of Excellence Faculty award recipient.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Describe a culture of health and community health promotion in the context of the ecologic model and social determinants of health (SDOH).
2. Analyze participatory approaches and the interrelationships among communities, populations, and interprofessional health care providers in the application of community health promotion strategies.
3. Describe evidence-based practice using the integrative model of community health promotion at multiple levels of the client system: individual, family, aggregate, and community.
4. Analyze nursing and interprofessional roles that are essential to build a culture of health through community health promotion.

INTRODUCTION

The Robert Wood Johnson Foundation (RWJF) (2013) recently introduced the idea of a **culture of health**. Recognizing that health and health care are in the forefront of national debate and dialogue about health reform, nurses and other providers are questioning the foundation of our health care system. There is a significant shift away from acceptance of the status quo, and toward building a culture of health. Such a shift puts emphasis on the pursuit of long, healthy lives for all Americans and is consistent with the national health vision and goals proposed in *Healthy People 2020* (U.S. Department of Health and Human Services [USDHHS], 2014a) and the National Prevention Strategy (National Prevention Council [NPC], 2011). The RWJF foresees "... a vibrant American culture of health: where good health flourishes across geographic, demographic, and social sectors; where being healthy and staying healthy is an esteemed social value; and everyone has access to affordable, quality health care" (2013). While most people recognize the need to exercise regularly, maintain their weight at recommended levels, and manage stress in their lives, modifiable health behaviors remain the major contributors to deaths in the United States (U.S.) (National Center for Health Statistics [NCHS], 2012). For example, tobacco use remains the leading cause of premature deaths in the United States, with 480,000 deaths annually attributed to cigarette smoking (USDHHS, 2014b). Nurses,

other health professionals, and the public recognize that initiating and maintaining a healthy lifestyle is difficult and requires different approaches directed toward individuals, families, communities, populations, and the environments in which they live.

In this chapter, we describe the historical underpinnings of health and health promotion for communities and populations including the concepts of community and social determinants of health (SDOH). In addition, we describe community health promotion models and frameworks including those specific to public health nursing and health promotion models from the social sciences. These concepts and models and the ways they are related are critical to building a culture of health and determine the nature of nursing practice with communities and populations. We emphasize an ecologic approach to community health promotion and population health, which integrates multilevel interventions to promote the health of the public. The integrative model of community health promotion (Laffrey and Kulbok, 1999) can help nurses plan care for clients including communities and populations. The model synthesizes knowledge from public health, nursing, and the social sciences. The chapter describes studies that illustrate community-based participatory research (CBPR) and multilevel interventions. Applications of the integrative model of community health promotion show that the way nurses view these concepts is important in their approach to practice.

HISTORICAL PERSPECTIVES, DEFINITIONS, AND METHODS

Health and Health Promotion

Health is the key term in the process of building a culture of health through community health promotion. Beginning with Nightingale's efforts to discover and use the laws of nature to enhance humanity, nursing has taken an active role in promoting the health of communities and populations. The way one defines health shapes the process of nursing and health care, including making decisions about what to assess, with what level of client, and how to evaluate the outcomes of care. For example, health from a medical perspective as alleviating an individual's illness symptoms, involves assessment of the duration, intensity, and frequency of specific symptoms. Intervention focuses on symptom relief and treatment of the cause of symptoms. Evaluation consists of determining the extent of symptom alleviation. On the other hand, health defined from an ecologic or environmental perspective as maximizing a community's physical recreation opportunities, may involve assessment of existing recreation facilities, accessibility to the population, and beliefs and knowledge related to recreation and land use in the community as resources for healthy living.

The holistic or ecologic view of health is not new. The ancient Greeks viewed health as the influence of environmental forces on human well-being and healing from illness. Scientific medicine emerged slowly and in the twentieth century, professional care took precedence over self-care. During the last five decades, the concept of self-care as derived from a positive idea of health has reemerged to compete with professional care. Some proponents of self-care emphasize lay diagnosis and self-treatment, whereas others focus on teaching people how to work with their health care providers. As a result, health care system changes include the renegotiation of roles and emphasize collaboration between consumers and providers, as well as recognition of the health impact of the conditions in which people live.

Many health professionals believe that individuals are in a position to produce health. This idea is not new. In 1974, **Fuchs** suggested that the "greatest potential for improving health lies in what we do and don't do for and to ourselves" (p. 55). In the political arena, **LaLonde** introduced a similar idea in *A New Perspective on the Health of Canadians* (1974). LaLonde identified four major determinants of health: human biology, environment, lifestyle, and health care. In 1976, policy makers in the United States reinforced these determinants of health and supported efforts to improve health habits and the environment as the best hope of achieving any significant extension of life expectancy (**U.S. Department of Health, Education and Welfare [USDHEW], 1976**, p. 69). The fundamental ideas of these landmark documents about the determinants of health emerged during the era of social ecology (**Bronfenbrenner, 1977 and 1979**). **Box 17-1** lists some landmark initiatives in health promotion and disease prevention.

The **ecosocial or social-ecological** perspective, initially presented by Bronfenbrenner in 1977, described human-environment interaction and health outcomes over a life span.

The environments are described as the micro-, meso-, and macro-system levels. **McLeroy et al (1988)** translated these levels of the ecologic model to actionable layers of influence that include intrapersonal (characteristics of the individual), interpersonal (formal and informal social networks and social support systems), institutional (social institutions), community (mediating institutions, relationships and power), and public policy (multilevel laws and policies).

The U.S. Public Health Service established the first national objectives involving disease prevention, health protection, and health promotion strategies in the surgeon general's *Healthy People* report. Disease prevention strategies focus on services such as family planning and immunizations delivered in clinical settings. Health protection strategies include environmental measures to improve health and quality of life. Health promotion strategies focus on achieving well-being through community and individual lifestyle change measures (**USDHEW, 1979**).

As described in **Chapter 2**, the health objectives for the nation outlined in *Healthy People 2020* build on initiatives that have been pursued since 1980. Designed for use by individuals, communities, states, and professional organizations, these health objectives provided a guide for community and population programs to improve health. The release of *Healthy People 2020* in 2010 included a national vision, mission, and overarching goals. The four goals emphasized prevention, health equity, environments conducive to health for all, and healthy development across the life span. Information on *Healthy People 2020* objectives and action plans (**USDHHS, 2014c**) is available at <http://www.healthypeople.gov/2020/default.aspx>.

FIG 17-1 Determinants of Population Health (From Centers for Disease Control and Prevention: *Social determinants of health*. Available at <http://www.cdc.gov/socialdeterminants/faq.html#b>. Accessed April 26, 2014.)

The **National Prevention Strategy** (NPS) published through the U.S. Surgeon General's Office by the National Prevention Council (NPC, 2011) seeks to "improve the health and quality of life for individuals, families, and communities by moving the nation from a focus on sickness and disease to one based on prevention and wellness" (NPC, 2011, p. 7). To realize this vision for children, youth, adults and the elderly, the NPS targets interventions in multiple settings. These include healthy and safe community environments, clinical and community preventive services, empowered people, and elimination of health disparities. A focus on safe and healthy communities recognizes the power of the social, economic and environmental factors that have a stronger influence on health and well-being than does the health care setting (see Figure 17-2 for National Prevention Strategy).

This idea that the health of communities and populations is shaped by multiple determinants has been reinforced in the national (Institute of Medicine [IOM], 2003) and international (World Health Organization [WHO], 2014a) health policy literature. The current focus is on determinants of population health (Figure 17-1), which include genes and biology, health behaviors, medical care, total ecology, and social/societal characteristics (Centers for Disease Control and Prevention [CDC], 2014a; IOM, 2006). In Figure 17-1, genes, biology, and health behavioral choices account for 25% of population health; and social determinants of health including medical care, the physical and social environment account for the remaining 75%. Although recent trends reveal improvement in determinants of population health such as healthier living conditions and a decrease in smoking, these positive trends are associated with persistent socioeconomic disparities worldwide (WHO, 2014a) (see **Healthy People 2020** box).

Definitions of Health

The WHO (1948) reflected a holistic perspective in its classic definition of health as a state of complete physical, mental, and social well-being, and not merely the absence of disease and infirmity. Terris expanded the WHO definition: "Health is a state of physical, mental and social well-being and the ability to function and not merely the absence of illness and infirmity" (Terris, 1975, p. 1038). By deleting "complete" and adding "ability to

HEALTHY PEOPLE 2020

Tobacco Use

Selected objectives from *Healthy People 2020* that pertain to tobacco use:

- TU-1: Reduce tobacco use by adults.
- TU-2: Reduce tobacco use by adolescents.
- TU-3: Reduce the initiation of tobacco use among children, adolescents, and young adults.
- TU-6: Increase smoking cessation during pregnancies.
- TU-7: Increase smoking cessation by adolescent smokers.
- TU-11: Reduce the proportion of nonsmokers exposed to secondhand smoke.

From U.S. Department of Health and Human Services: *Healthy People 2020*. Available at <http://www.healthypeople.gov/2020/default.aspx>. Accessed January 15, 2011.

function," Terris placed the WHO definition in a realistic context, providing a useful framework for health promotion.

Smith (1981), a nursing scholar, suggested that the "idea of health" directs nursing practice, education, and research. She defined health along a continuum, allowing for "more" or "less" health. Smith proposed four models of health, ordered from narrow and concrete to broad and abstract: clinical health, or absence of disease; role performance health, or ability to perform one's social roles satisfactorily; adaptive health, or flexible adaptation to the environment; and eudaemonistic health, or self-actualization and attainment of one's human potential.

Population health is a term widely used in several IOM reports and in contemporary health care policy. Recently, the IOM Roundtable on Population Health Improvement defined population health as "the health outcomes of a group of individuals, including the distribution of such outcomes within the group" (Kindig and Stoddart, 2003, p. 381). Though not a part of the definition itself, population health outcomes are the product of multiple determinants of health, including genetics, behaviors, public health, medical care, and environmental and social factors (Adler et al, 2013; IOM, 2014).

It is important for nurses and health care providers to reflect on their own definition of health and recognize how their definition influences the care they provide. Likewise, it is equally important for nurses to assess clients' personal health definitions. Only through knowledge of their own health definition, together with assessment of clients' health definitions, can nurses create interventions tailored to achieve the clients' health goals. Nurses and health care providers who emphasize health promotion and population health that is congruent with the beliefs, health definitions, and goals of the population also acknowledge the importance of illness prevention. Nurses must strive to understand health policies and the consequences of these policies on vulnerable populations whose living conditions may include few determinants of good health.

Definitions of Health Promotion

Health promotion is an aim of nursing and health care, although explicit definition of health promotion and differentiation from disease prevention or health maintenance is rare. Leavell and Clark (1965) strongly influenced the evolution of health promotion and disease prevention strategies through their classic definitions of primary, secondary, and tertiary

levels of prevention that were rooted in the biomedical model of health and epidemiology. The application of preventive measures, according to Leavell and Clark, corresponds to the natural history or stages of disease (see [Chapter 12](#)). Primary preventive measures apply to “well” individuals in the prepathogenesis period to promote their health and to provide specific protection from disease. Secondary preventive measures apply to diagnosis or to treatment of individuals in the period of disease pathogenesis. Tertiary prevention addresses rehabilitation and the return of people with chronic illness to a maximal ability to function (see [Levels of Prevention](#) box).

LEVELS OF PREVENTION

Diabetes

Primary Prevention

For a person with identified risk factors for diabetes, the goal is to maintain a normal weight, to exercise regularly, and to reduce the intake of carbohydrates.

Secondary Prevention

Have regular blood glucose level testing done and be alert for any symptoms of the onset of diabetes. If the blood glucose level indicates that the client has diabetes, begin treatment.

Tertiary Prevention

For a person diagnosed with diabetes, monitor blood glucose levels and maintenance of a diabetic diet, regular exercise, and medication.

Even though primary, secondary, and tertiary levels of prevention had their origins in the medical model, [Leavell and Clark \(1965\)](#) moved beyond the medical model. They conceptualized primary prevention as two distinct components: health promotion and specific protection. Health promotion focuses on positive measures such as education for healthy living and promotion of favorable environmental conditions as well as periodic examinations including, for example, well-child developmental assessment and health education. Specific protection includes measures to reduce the threat of specific diseases or injury, such as hygiene, immunizations, use of seat belts, and the elimination of workplace hazards.

Health promotion and specific protection, when used as sub-concepts of primary prevention, stem from a definition of health as the absence of disease. However, health promotion and specific protection strategies are not the same. Some terms used to describe health promotion are linked to a positive view of health (e.g., *health habits* or *health practices*), whereas other terms are linked to the negative view of the absence of disease (e.g., *disease* or *illness prevention*). Using the terms *health promotion*, *health protection*, and *disease prevention* interchangeably, as indicators of preventive behavior, leads to confusion ([Kulbok et al, 1997](#)). Interestingly, similar confusion exists today in the field of health education regarding definition of the terms *health behavior*, *health education*, and *health promotion* ([Simons-Morton, 2013](#)). As interprofessional practice opportunities increase, public health nurses need to have clear definitions in mind when they use terms associated with community health promotion.

The WHO described health promotion as a process that enables individuals to increase control over and improve their

health ([WHO, 2014b](#)). According to the 1986 Ottawa Charter, health promotion combines both individual- and community-level strategies to build healthful public policy, create supportive environments, strengthen community action, develop personal skills, and reorient health services. Health is a resource for daily living. For individuals or communities to realize physical, mental, and social well-being, they must become aware of and learn to use the social and personal resources available within their environment.

There is considerable evidence supporting a positive view of health underlying health promotion activities directed toward individuals, communities, and populations. The WHO's definition of health promotion as a process and the current focus on an ecologic approach to determinants of population health are grounded in the perspective of positive health. These approaches view health promotion in the context of a holistic healthy lifestyle, as well as involving simultaneous interaction with the social and physical environments. Clearly, health promotion and population health are consistent with the goals of public health nursing.

Disease Oriented versus Process and Environmentally Oriented Health and Health Promotion. Nurses have long recognized the importance of an emphasis on wellness and health promotion in health care. In public health nursing (PHN) practice, it is clear that many factors, beyond illness, affect the health of individuals, communities, and populations. The biomedical model, in which health is defined as absence of disease, does not explain why some populations exposed to illness-producing stressors remain healthy, whereas others, who appear to be in health-enhancing situations, become ill. Viewing clients from the perspective of the biomedical model alone makes it difficult to identify health potential beyond the absence of disease in the individual. For example, most at-risk populations such as the frail elderly have at least one diagnosed chronic disease. Limiting the definition of health potential to the absence of disease, nurses would never perceive this population as healthy. Defining health as the absence of disease is a pessimistic and individual-level definition; nursing actions can help older and chronically ill persons become healthier if a broader definition of health is used.

[Laffrey, Loveland-Cherry, and Winkler \(1986\)](#) describe two perspectives from which the key concepts of nursing science (e.g., person, health, environment) and nursing can be viewed. The first is the **disease-oriented perspective** that views health objectively, and defines it as the absence of disease as discussed previously. This perspective assumes that humans are composed of organ systems and cells; in this instance, health care focuses on identifying what is not working properly with a given system and repairing it. In this context, health behavior begins with patient compliance with health professionals' recommendations. The second perspective defines health subjectively as a process, not as a presence or absence. In this **health-oriented perspective**, humans are complex and ever-changing systems, and are interconnected with others and the environment. Health behavior within this latter health-oriented perspective involves a holistic view of lifestyle and interaction with the environment and not simply compliance with a prescribed regimen.

Both perspectives support the aims and processes of population-focused nursing. The disease-oriented approach directs nursing toward illness prevention, risk appraisal, risk reduction, prompt treatment, and disease management of individuals. However, the health-oriented approach directs nursing practice toward promotion of positive health for a larger segment of the population. Defining health broadly as the life process, taking into account the mutual and simultaneous interaction of humans and their environment, views illness as a potential manifestation of that interaction. Because positive health does not exclude any part of the life process (it includes illness prevention and illness care), it goes beyond the disease perspective to include positive and holistic health (Laffrey and Kulbok, 1999).

Community

Another concept essential to building a culture of health through community health promotion is **community**. The emphasis on community as the target of practice gained increased attention since the mid-1970s when the U.S. and Canadian governments and health researchers attributed declining mortality and morbidity rates to better standards of living, such as sanitation, clean air and water, and wider availability of healthy foods. Again, these approaches were consistent with emerging ideas about social ecology during the same period. The IOM's seminal report on the future of public health highlighted the importance of community in its statement that the "mission of public health is to assure conditions in which people can be healthy by generating organized community effort to prevent disease and promote health" (National Research Council [NRC], 1988, p. 7). (See Chapter 18 for more on the concept of community.)

As discussed previously, national health goals emphasize that environment and community are central to achieving health. *Healthy People in Healthy Communities: A Community Planning Guide Based on Healthy People 2010* (USDHHS, 2001) (Box 17-2), outlines practical recommendations for coalition building, creating a vision, and measuring outcomes to improve the health of communities. Communities can tailor these recommendations to their own local needs, and health professionals in public and private organizations can work together with community members to develop programs that fit the needs and resources of their own communities. The National Prevention Strategy also offers recommendations on what can be done to improve population health in specified contexts and across goal areas (NPC, 2011). Nurses participate in this collaborative and interprofessional process through community assessments, community development activities, and identification of key persons in the community with whom to build partnerships for health programs. Nurses working with nonprofit hospitals can also directly engage in improving health of communities through completion of a Community Health Needs Assessment (CHNA) as required under the Affordable Care Act (Rosenbaum, 2013).

One of the four overarching goals of the *Healthy People 2020 Framework* is to create social and physical environments that promote good health for all (USDHHS, 2014d). Community-wide program planning provides a strategy to achieve this goal. *Healthy People 2020* highlighted a community framework called

BOX 17-2 *Healthy People 2010: A Strategy for Creating a Healthy Community*

To achieve the goal of improving health, a community must develop a strategy supported by many individuals who are working together. The MAP-IT technique helps you to map out the path toward the change you want to see in your community. This guide recommends that you MAP-IT—that is, **mobilize, assess, plan, implement, and track**.

Mobilize individuals and organizations that care about the health of your community into a coalition.

Assess the areas of greatest need in your community, as well as the resources and other strengths that you can tap into to address those areas.

Plan your approach: start with a vision of where you want to be as a community; then add strategies and action steps to help you achieve that vision.

Implement your plan using concrete action steps that can be monitored and will make a difference.

Track your progress over time.

From U.S. Department of Health and Human Services: A strategy for creating a healthy community: MAP-IT. In *Healthy people in healthy communities: A community planning guide using Healthy People 2010*, Washington, DC, 2001, U.S. Government Printing Office.

BOX 17-3 *Milio's Propositions for Improving Health Behavior*

- Health status of populations is a function of the lack or excess of health-sustaining resources.
- Behavior patterns of populations are related to habits of choice from actual or perceived limited resources and related attitudes.
- Organizational decisions determine the range of personal resources available.
- Individual health-related decisions are influenced by efforts to maximize valued resources in both the personal and societal domains.
- Social change is reflective of a change in population behavior patterns.
- Health education will impact behavior patterns minimally without new health-promoting options for investing personal resources.

Modified from Milio N: A framework for prevention: changing health damaging to health-generating life patterns, *Am J Public Health* 66:435, 1976.

MAP-IT (USDHHS, 2014e) as a guide to using *Healthy People 2020* in your community (see <http://healthypeople.gov/2020/implement/mapit.aspx>). MAP-IT stands for Mobilize, Assess, Plan, Implement, and Track; and communities can use the guide to evaluate public health interventions designed to implement the goals of *Healthy People 2020*.

Nurses and interprofessional health care providers have many opportunities to participate in community-wide health care. To address community problems, these professionals need to integrate concepts of health and illness, individual and population, public health and health care, health promotion and disease prevention, and ecology and environmental health. This integration means that nurses must consider the complex relationship between personal and environmental forces that affect health. Over 35 years ago, Milio (1976) offered a set of propositions for improving health behavior by considering personal choices in the context of available societal resources. These propositions (Box 17-3) remain relevant today. They constitute

a fitting model for health promotion that addresses both personal and societal resources for this and future decades.

COMMUNITY HEALTH PROMOTION MODELS AND FRAMEWORKS

Numerous models and frameworks have **community health promotion** as the goal. The following sections provide brief descriptions of models specific to community and/or health promotion that are useful to public health nurses practicing at a basic or advanced level.

Public Health Nursing Community Models and Frameworks

Although theoretical frameworks developed within nursing and other health disciplines are traditionally oriented toward individuals, there is increasing recognition of the importance of community and person–environment interactions that go beyond social cognitive theory and other interpersonal frameworks (USDHHS, 2005) in promoting health. PHN defined community as “... persons in interaction, being and experiencing together, who may or may not share a sense of common purpose” (ANA, 2013, p. 65). Nurses realize that the community is more than the sum of the individuals, families, aggregates, and organizations within it and that interaction is essential for any real change to occur. The following are examples of public health nursing models focused on interventions with communities or populations.

Choporian (1986) was among the first to acknowledge that nurses could strengthen their position with communities by focusing on the social, economic, and political structures that make up the community, as well as the social relations and patterns of everyday life in the community. Within this perspective, interventions targeted to public health policy can have far-reaching health benefits. Shuster and Goepfinger (2012) asserted that definitions of *community* vary widely and that nurses working with communities learn quickly that there are many different types. Shuster and Goepfinger highlighted the importance of person, place, and function, as well as interaction among systems within a community. Nurses must examine the complexity and dynamic nature inherent in the process of community building, rather than viewing the community as a geographic, racial, or cultural group that is static.

Despite the ideal, it is not easy to integrate the concept of the community as client into practice. Consequently, the provision of care to individuals *in the community* may still overshadow nursing practice and health promotion directed *to the community*. Bekemeier and Jones (2010), in a study of local public health agency (LPHA) functions, leadership, and staffing, reported that the proportion of nursing staff in an LPHA related strongly to provision of services involving individual-level care. They found that the staff nurses were most likely to perform individual-family interventions, and that both the staff nurses and the managers rated individual-family interventions as more important than community- or system-level interventions. These findings suggest that there is an ongoing need to expand “... education and outreach to nurses regarding their roles and

responsibilities to assure environmental health protection, community assessment, and health improvement planning” (Bekemeier and Jones, 2010, p. E16).

Anderson and McFarlane (2000, 2010) and Salmon (1993, 2009) developed system models based on the assumption that assessing the various components of the system (i.e., individual, family, community, and society) facilitates a healthy community. Anderson and McFarlane’s community-as-partner model includes eight major community subsystems. The basic core of the community, according to these authors, is its people, described by their demographic characteristics and their values, beliefs, culture, religion, laws, and more. Within the community system, the people interact with the other subsystems. A community health assessment must include information about the subsystems and the pattern of interactions among the subsystems and of the total community with the systems external to it.

Salmon’s model (1993, 2009) focused on the public health mission of organized efforts to protect, promote, and restore health. It embraces multiple determinants of health and is consistent with the IOM’s perspective on population health (IOM, 2014). According to Salmon’s model, nursing includes health promotion, illness prevention, and health protection strategies. Systems models provide important guidance for assessing communities and populations and indicate that system-level interventions require participation with relevant subsystems. However, systems models may not provide the guidance needed for intervention development.

Keller et al (1998, 2004) proposed a population-based intervention model based on the scope of PHN practice that crosses multiple levels of care; this model defines the population-focused underpinning of PHN practice and provides guidance for PHN interventions at the individual, community, and system levels. The model was later termed the “Intervention Wheel” (Keller et al, 2004, p. 453). The Intervention Wheel includes community, systems, and individual/family levels of practice. (See Chapter 9 for more information on the Intervention Wheel.) It is population based and identifies 17 public health interventions. The models proposed by Anderson and McFarlane (2000, 2010), Salmon (1993, 2009), and Keller et al (1998, 2004) focus on stability and equilibrium. They emphasize protecting the community from specific disease risks; less attention is directed toward factors that promote an optimally healthy community. A few of the classic community-wide epidemiologic studies focused on **multilevel interventions** or community health promotion are described next.

Influential Multilevel Community Studies

Two significant community studies of health risks, morbidity, and mortality are the Framingham Heart Study, initiated in 1949, and the Human Population Laboratory’s longitudinal survey in Alameda County, California, initiated in the early 1970s. The Framingham Heart Study followed 5209 adults over their life span to identify factors contributing to coronary heart disease (CHD). Collecting periodic health assessments and morbidity and mortality data, major risk factors associated with CHD mortality were identified (e.g., elevated systolic blood

pressure, elevated serum cholesterol level, and cigarette smoking). The investigators used health risk appraisals to relate the risk factors in well individuals to the probability of future cardiovascular disease (Lieb et al, 2009). The Framingham study continues today (see <http://www.framinghamheartstudy.org/>).

The Alameda County study measured the relationships of health and social behaviors to mortality in a community sample of 6928 individuals over 4 years. The behaviors included eating three meals daily, eating breakfast, sleeping 7 to 8 hours a night, using alcohol moderately, exercising regularly, not smoking, maintaining a desirable weight-to-height ratio, and maintaining social networks. There was a positive relationship between smoking and excessive alcohol use and mortality. There was an inverse relationship between physical exercise, 7 to 8 hours of sleep, optimal weight in relation to height, and social networks and mortality (Berkman and Breslow, 1983). These findings led to the emphasis on social and environmental variables, in addition to personal behaviors, in strategies for community health promotion.

Findings from these early large-scale surveys prompted a number of public health multilevel intervention programs. Examples include the Stanford Five-City Heart Disease Prevention program (Farquhar et al, 1990), the North Karelia study (Puska et al, 1983), the Pawtucket Heart Health program (Lasater et al, 1984), the Minnesota Heart Health program (Luepker et al, 1994), and the Dutch Heart Health Community Intervention (Ronda et al, 2005). These programs provided beginning scientific evidence for the implementation of community-level risk reduction programs, although the results were modest and often not statistically significant. However, these studies made major contributions to theory and practice in building community partnerships, establishing social marketing, developing behavior change strategies, and evaluating health programs. Results of these studies make it clear that multiple levels of intervention are necessary to reach the community in a meaningful way. Nurses have close relationships with individuals, families, high-risk groups, organizations such as schools, congregations and workplaces, and other health care professionals. They can contribute to health promotion by participating in community projects such as the ones described here. It is important that nurses develop health programs and document improved outcomes for high-risk groups with whom they interact.

Health Promotion Models and Frameworks

There are a variety of theoretical approaches that can be used to help public health nurses design and implement health promotion programs for individuals and communities. The National Cancer Institute's seminal document, *Theory at a Glance* (USDHHS, 2005), organized these health promotion models and frameworks into three levels, which are consistent with the ecologic perspective used in this chapter. The first level is intrapersonal or individual, including models focused on knowledge, attitudes, personal beliefs and values. The second level is interpersonal, including models that emphasize processes and groups such as family, friends, and peers who may

provide support. The third level is community, which includes institutional structures and policies that may enhance or inhibit health behavior. Brief descriptions of selected models and frameworks are provided in the following sections.

Individual Health Promotion Models

There are several intrapersonal or individual level models including the health belief model, the theory of reasoned action and the theory of planned behavior, the stages of change or transtheoretical model, and the precaution adoption process model (Edberg, 2013). The **health belief model (HBM)** can be used to plan programs to increase an individual's motivation to take a positive health action. Specifically, the HBM was one of the first theories of health behavior. It began in the 1950s, when the U.S. Public Health Service sent mobile units to communities to provide chest x-rays as a way to screen for tuberculosis (Rosenstock, 1974). The chest X-rays were free, convenient, and painless, yet people did not take advantage of the service. A group of social psychologists tried to explain the failure to use this screening, or more specifically, to determine what would motivate people to seek health care.

The HBM includes six components that attempt to determine what motivates an individual to adopt a health behavior. These components are (1) perceived susceptibility ("Will something happen to me?"); (2) perceived severity ("If something does happen to me, will it be a big problem?"); (3) perceived benefits ("If I do what is suggested, will it really help me?"); (4) perceived barriers ("If I do what is suggested, will there be barriers that will be unpleasant or costly?"); (5) cues to action ("What might motivate me to take the recommended action?"); and (6) self-efficacy ("Can I really do this?"). This model has been praised and criticized. It provides guidance in planning health promotion programs because it reminds nurses to think carefully about what motivates people to change. To understand motivation, it is important to learn (1) how people involved feel about the health problem, (2) whether they think the problem is serious, (3) whether they think that action on their part will make a difference, and (4) whether they think they can both manage the barriers and actually perform the action (Edberg, 2013; USDHHS, 2005).

The **transtheoretical model (TTM) or stages of change (SOC)**, and the precaution adoption process model (PAPM) are discussed together because they both deal with the process of change that occurs in stages and over time. The TTM or SOC has six stages:

1. **Precontemplation**, in which the person does not plan to change; this may be because the person does not know there is a problem or does not want to do anything about it. For example, a person may not know that potential exposure to radon, a cancer-causing radioactive gas that he cannot see, smell or taste in his home, is a health risk.
2. **Contemplation**, in which the person begins thinking about making a change in the future and examines the pros and cons of doing so. The person may have heard about home radon exposure on the local news and is considering whether his home may have unsafe levels of radon and whether he should test for radon.

3. **Preparation**, in which the person intends to do something. In the example about radon exposure, the person might contact the environmental office of the local health department for advice about radon testing.
4. **Action** occurs when the person actually buys a radon-testing kit and uses it in his home.
5. **Maintenance** is when the person decides to test for radon and to take measures to reduce radon to acceptable levels.
6. **Termination** is when the person has adopted and sustained the behavior change process. For most behaviors, this stage is rarely accomplished and individuals stay in the maintenance stage (Edberg, 2013; USDHHS, 2005).

Although the terms used are slightly different, the intent of the PAPM is much like that of the TTM or SOC. The stages are (1) unaware of the issue, (2) unengaged by the issue, (3) deciding about acting, (4) deciding not to act, (5) deciding to act, (6) acting, and (7) maintenance. You can apply the cooking example later in this chapter to these stages, as well (Edberg, 2013).

Interpersonal Health Promotion Models

Interpersonal-level models generally involve interaction between individuals and the social environment. These models focus on the reciprocal or mutual nature of interaction; that is, the person's thoughts, feelings or actions are influenced by and also exert influence on his or her immediate environment. The social environment typically involves family, friends, peers, co-workers, health providers and others (USDHHS, 2005). Social learning theory, social cognitive theory, social network theory, and social support (Edberg, 2013) are examples of interpersonal-level frameworks that are useful for health promotion. **Social cognitive theory (SCT)** is one of the commonly used interpersonal theories. It evolved from Bandura's social learning theory (SLT), which proposed that individuals learned from their own behaviors and from observations of the behaviors of others and the benefits of those behaviors. Bandura expanded SLT by adding the construct of self-efficacy, which addresses the degree of confidence individuals have in their ability to perform a behavior (Edberg, 2013; USDHHS, 2005).

Continuing with the example of radon exposure, an individual would need to believe that he was capable of obtaining a radon test kit, understanding the directions for radon testing, and using it properly to test radon levels in his home. Note that there are incremental, small steps involved in a behavior seemingly as simple as using a radon testing kit. Bandura stressed the importance of understanding the target behavior in order to plan potential strategies to assist an individual in the process of behavior change. In addition to understanding the target behavior, change strategies based on SCT include (1) verbal persuasion, (2) role modeling, (3) positive affective response, and (4) positive reinforcement of the behavior. Strategies that public health nurses can use to change behavior include (1) communication skills to persuade a person to test his home for radon, (2) modeling the radon testing behavior, (3) emphasizing the positive emotional response associated with reducing the health risk for his family, and (4) providing positive encouragement and affirmation when the person has completed the radon testing in his home.

Community Health Promotion Models

The **social ecological model** is another model used to guide public health nursing interventions for community health promotion (USDHHS, 2005; Edberg, 2013). The social ecological model (SEM) guides health promotion as well as illness prevention interventions. According to this model, health care and health-related behavior are a function of individual, interpersonal, organizational, community, and population factors. Thus, interventions are specific to each of these levels. In one of the first comprehensive studies using the SEM to assess factors related to the uptake of influenza vaccine, researchers examined vaccine uptake during the 2009 H1N1 pandemic. Of the 2079 adults surveyed, only 18.4% reported that they received the 2009 H1N1 vaccine. The results indicated that variables at all SEM levels influenced acquiring the vaccination: intrapersonal level explained 53%; interpersonal explained 47%; institutional level explained 34%; and, the policy and community levels each explained 8% of the variance related to influenza vaccine uptake. Together the SEM levels explained 65% of the variance in vaccine uptake. This data indicated that interventions aimed at multiple levels might be more effective than those targeting a single level (Kumar et al, 2013) (see **Evidence-Based Practice** box).

EVIDENCE-BASED PRACTICE

A study of leisure time physical activity (LTPA) in black adults, which used the social ecological model, helped to clarify relationships between LTPA and social-ecological factors such as self-efficacy, self-regulation, social support, outcome expectations, and policy beliefs (Li et al, 2012). The results suggested that self-regulation and intention to organize personal time for routine PA may yield successful results and that a PA intervention may succeed if participants in the intervention include people in their close network who support each other. In addition, the results suggested that planning policies to enhance the built environment and satisfy the community have the potential for wide-reaching effect on PA levels of African Americans. Several other major community-wide studies have drawn on concepts such as those presented in these models.

Li K, Seo DC, Torabi MR, et al: Social-ecological factors of leisure-time physical activity in black adults. *Am J Health Behav* 36:797-810, 2012.

THE ECOLOGIC APPROACH TO COMMUNITY HEALTH PROMOTION

Ecologic Perspectives on Population Health

Because individuals ultimately make decisions to engage in healthy or risky behaviors, lifestyle improvement efforts have focused typically on the individual as the target of care. Following the health belief model (Rosenstock, 1974), individuals generally concentrate on immediate personal rewards or threats when deciding whether to engage in specific behaviors; in this context, they may convince themselves that their immediate personal risks from certain behaviors such as smoking are low, or that the immediate rewards outweigh the risks. However, from a public health perspective, smoking in the United States has resulted in more than 480,000 deaths annually in the United

States, approximately 20% of all deaths (USDHHS, 2014b). Though still alarming, the percent of American adults who smoke today is 18%, down from 43% in 1964. However, we continue to increase spending on smoking-related medical care for adults, \$132 billion in 2014, and lose more money in worker productivity costs, \$157 billion, a 50% increase from just six years ago (CDC, 2008; USDHHS 2014b). Therefore, it is clear that health behaviors extend beyond the individual or the intra-personal and the interpersonal levels, having multiple determinants both internal and external to individuals and communities, as well as determinants within the society.

For example, adolescents' decisions not to smoke are associated with their individual attributes (e.g., positive self-image), family characteristics (e.g., parent-child connectedness), aggregate characteristics (e.g., peer influence), and community factors (e.g., living in a tobacco-growing region) (Kulbok et al, 2008a). As a result, interventions to initiate or maintain healthy behaviors have greater potential for success when directed systematically toward the multiple targets of the individual, family, group, community, and society—that is, when they use an ecologic approach to community health promotion.

The Social Determinants of Health

Current trends in public health and health promotion emphasize the ecologic perspective on interaction between individuals and the environment. The ecologic approach also addresses the SDOH (McQueen, 2009) through social networks, organizations, neighborhoods, and communities (Navarro et al, 2007). According to the World Health Organization (WHO), SDOH “are the conditions in which people are born, grow up, live, work and age, including their health. These circumstances are in turn shaped by a wider set of forces: economics, social policies, and politics” (2010, p. 1). The WHO is an important contributor to defining and developing strategies to address the SDOH, and has outlined ten components of SDOH. (Box 17-4 lists the 10 components.)

There is increasing awareness that to achieve lasting gains in population health, assessments and interventions must be directed to multiple levels of the client system like those outlined in the SDOH. For example, a multilevel analysis of depressive symptoms in a national sample of 18,473 adolescents in the United States (Wight et al, 2005) showed that individual, family, aggregate, and community characteristics accounted for significant differences in adolescent depression. The American Academy of Pediatrics (2005) issued a statement urging pediatricians to increase their partnerships with communities in developing programs to improve child health. Examples of pediatrician-community partnerships (Sanders et al, 2005) include establishing a child health consultant program, working with a community to repair and fund sites to facilitate safe physical activity for children, developing dance programs for overweight and obese adolescent girls, and arranging a program for community leaders to learn about the Medicaid enrollment process. Traditional interventions that target only an individual's risk or illness are not as effective as interventions and programs developed using an ecologic approach that can affect all levels of the client system that contribute to good or ill health

BOX 17-4 The Social Determinants of Health

1. *The Social Gradient:* Life expectancy is shorter and most diseases are more common further down the social ladder in each society.
2. *Stress:* Stressful circumstances—making people feel worried, anxious, and unable to cope—are damaging to health and may lead to premature death.
3. *Early Life:* The health impact of early development and education lasts a lifetime.
4. *Social Exclusion:* Hardship and resentment, poverty, social exclusion, and discrimination cost lives.
5. *Work:* Stress in the workplace increases the risk of disease. People who have more control over their work have better health.
6. *Unemployment:* Job security increases health, well-being, and job satisfaction. Higher rates of unemployment cause more illness and premature death.
7. *Social support:* Friendship, good social relations, and strong supportive networks improve health at home, at work, and in the community.
8. *Addiction:* Individuals turn to alcohol, drugs, and tobacco and suffer from their use, but use is influenced by the wider social setting.
9. *Food:* Because global market forces control the food supply, healthy food is a political issue.
10. *Transport:* Healthy transport means less driving and more walking and cycling, backed up by better public transport.

(Navarro et al, 2007). More studies are needed to design and test these ecologic, multilevel community health interventions.

Farley and Cohen (2005) introduced the curve-shifting principle. This principle complements the ecologic model and calls for targeting health interventions at the population level. They built on representations of the relationship between individual and group behavior (Rose, 1992), with individual behavior being the foundation of the total population distribution. The median of this normal distribution represents prevailing social norms that govern health behavior. Traditional approaches to health behavior interventions for public health problems like obesity focus on the intrapersonal and interpersonal levels for high-risk populations—people at the extremes of the population curve. Although treating high-risk populations may be effective for selected individuals and may move them closer to the center or the prevailing social norm, this approach does little to prevent others from becoming the extremes of the distribution. Therefore, a focus on the total population, not just the high-risk group, with efforts to change the social norm so that everyone is consuming less sugar or participating in more hours of moderate to vigorous physical activity, exemplifies the curve-shifting principle.

Consider another example of the curve-shifting principle that involves the built environment. The built environment includes the physical parts of the environment where we live and work (e.g., homes, buildings, streets, open spaces, and infrastructure) (CDC, 2013). Prentice and Jebb (1995) were among the first to report the association between obesity and the built environment by measuring inactivity, car ownership, and television viewing.

Instead of simply teaching children the importance of walking and biking to school, the Safe Routes to Schools initiative improved the environment and the walkability of areas near schools, which correlates with increased local resident walking (Owen et al, 2004). Increased walking among local adult residents is evidence that "... increasing neighborhood walkability may affect people in the larger community, not just schoolchildren" (Watson et al, 2008, p. 5). As a result, the population living nearest to walkable areas will walk more, thereby shifting the population social norms about walking and biking, including to school. People's behavior will change based on targeted interventions to the environment in which they live, a concept advanced by B.F. Skinner (1978), a behavioral psychologist in the 1950s. In following this curve-shifting principle in health promotion and illness prevention, the ecologic model works at the population level to shift social norms governing health behavior and ultimately health outcomes.

AN INTEGRATIVE MODEL FOR COMMUNITY HEALTH PROMOTION

Laffrey and Kulbok (1999) developed an integrative model for community health promotion to guide nursing and health care. The intent of the model was threefold. First, the model assists nurses to see the continuity of care at multiple levels. Second, it helps nurses describe their own areas of expertise within the complex health care system. Third, the model provides a basis for collaboration and partnership among nurses, other health care

providers, and the population. Each of these collaborators brings expertise to the client system. Important assumptions underlying the model include the need for integration of care in the complex health care system; the inseparable nature of individuals, families, aggregates, and community systems; and the maximization of health potential through health promotion interventions. In addition, the model builds upon complementary health and disease perspectives described previously (Figure 17-2). The health perspective focuses on promoting health as a dynamic and positive quality of life and includes the promotion of physical, mental, emotional, functional, spiritual, and social well-being considered in the context of ecologic and environmental factors. The disease perspective includes both the care and prevention of illness (disease and disability) and focuses on reducing risks and threats to health. Although some clinical strategies may be similar in the two perspectives, their ultimate goals differ fundamentally. The difference in these two perspectives is seen in the specific purpose of nursing and health care, as it is applied to health promotion, illness prevention, or illness care.

The integrative model (Laffrey and Kulbok, 1999) includes two dimensions: **client system** and **focus of care**. The client system is multidimensional with nursing and health care targeting the multiple levels of clients. The simplest level of the client system is its most delimited target, the individual. When the individual is the client, the environment includes the family, the broader aggregate, and the community of which the individual is a part. The nurse and health care provider are concerned with how these environments affect the individual's health.

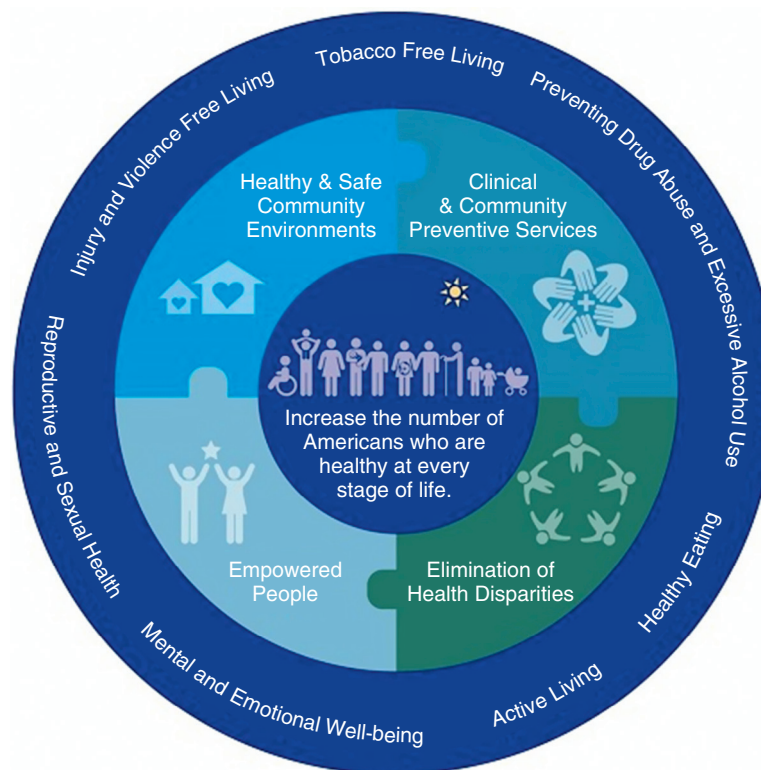

FIG 17-2 National Prevention Strategy (From National Prevention Council, *National Prevention Strategy*, Washington, DC, 2011, U.S. Department of Health and Human Services, Office of the Surgeon General. Available at <http://www.surgeongeneral.gov/initiatives/prevention/strategy/>. Accessed on May 16, 2014.)

Each succeeding level of the client system is more complex, since the client can also be the family, an aggregate, or the community. The aggregate and community make up the environment for the family, and the community is the environment for the aggregate. Examples of different types of assessments and interventions appropriate at each level of client within the system are discussed later in this chapter. It is important to remember that community-oriented care is holistic in nature and is population focused in that it addresses multiple levels of clients and multiple levels of care within the total system. The integrative model of community health promotion is consistent with the ecologic approach described earlier, which addresses SDOH through social networks, organizations, neighborhoods, and communities (Navarro et al, 2007).

Focus of care in the integrative model includes health promotion, illness (disease or disability) prevention, and **illness care**. Each focus is appropriate for some aspects of nursing and health care. It is even more important to remember that the goal of health care is a healthier community, achieved through health promotion interventions. No matter where care begins, it ultimately leads to health promotion of the community. It underscores the need for nurses and health care providers to have a good understanding of care requirements at all client levels. The individual, family, aggregate, and community each have characteristics, strengths, and health needs that are unique and that differ from those at the other levels.

INTERPROFESSIONAL APPLICATION TO NURSING AND PUBLIC HEALTH

The integrative community health promotion model reflects the basic beliefs and values of holistic nursing and health care practice and is consistent with the current emphasis on building a culture of health (RWJF, 2013) and the ecologic perspective on multiple determinants of health (IOM, 2014; WHO, 2014a). The model depicts continuity and expansiveness of the client systems and foci of care. Health promotion is the central axis, or core, of the model. At its narrowest focus, individuals receive illness care. According to the model, at the broadest level of care, nurses work with community leaders, other community residents, and health professionals to plan programs to promote optimal health for the community and its people. The goals of nursing and health care actions in the integrative model, at any client level from the individual to the community, are to identify health potential and achieve maximal health. To achieve these goals it is essential to have an active partnership between the nurse, health care providers, and the client system. By facilitating an active partnership with the client system, whether the focus of care is health promotion, illness prevention, or illness care, nurses involve clients in each step of the process of managing care from the assessment of their health needs and resources to implementation and evaluation of outcomes. In the following sections, strategies such as community-based participatory research and Photo-voice that are useful in interprofessional community health promotion interventions are discussed.

Community-Based Participatory Research (CBPR)

The aim of PHN is to create partnerships with individuals, families, groups, and communities to promote their health. **Community-based participatory research**, grounded in epistemology and critical social theories (Minkler and Wallerstein, 2008), provides the philosophical and theoretical basis for forming partnerships and for collaboration with the community. Researchers have used CBPR to conduct ecologic, community, and environmental assessments. This approach to community assessment allows understanding of sociocultural contexts, systems, and meaning through a collaborative research process. In CBPR, partnerships are active and community members are involved in assessing, planning, implementing, and evaluating change. Both professionals and community residents determine health needs and plan interventions. As residents increase their awareness, they are better able to determine what they want for themselves, their families, and their community and they are more likely to take leadership roles in program development, using health professionals as consultants.

Just as early PHN roles extended beyond disease prevention and illness care to encompass advocacy, community organizing, health education, political and social reform (Kulbok and Glick, 2014), contemporary PHN roles emphasize collaboration with community organizations and community members. Recently, Kulbok, Thatcher, Parks, and Meszaros (2012) examined emerging PHN roles that address complex, multicausal, community problems. They utilized a community participatory and ethnographic community assessment model and provided a PHN exemplar from their CBPR project, Youth Substance Use Prevention in a Rural County. The project involved an interprofessional team (i.e., the community participatory research team [CPRT]), including an advanced practice public health nurse, a human development specialist, a psychologist, an architecture and urban planning specialist, a nurse anthropologist, graduate students, and youths, parents, and leaders from the rural community. The CPRT used community participatory strategies, Geographic Information Systems (GIS) mapping, and Photo-voice to design a substance use prevention program in a rural tobacco-growing county in the South. The CPRT completed a comprehensive community and environmental assessment of the county, its rural ecology, context, and culture, and reviewed evidence-based prevention programs as the foundation for designing and implementing a youth substance use prevention program that was acceptable, effective, relevant, and sustainable by the rural county.

In another example of a CBPR project, the community residents of the East Side Village Health Worker Partnership (ESVHWP) on Detroit's East Side developed a community-based program titled Healthy Eating and Exercising to Reduce Diabetes (HEED) (Schulz et al, 2005). The purpose was to increase community awareness about diabetes and prevention. Community groups and individuals with expertise in diabetes served as the project steering committee. They developed training protocols and recruited and trained community advocates. After training completion, the HEED advocates developed activities to promote healthy diets and physical activity. The

advocates and other community residents identified important barriers to healthy dietary choices, such as lack of access to grocery stores and fresh produce. Members of the HEED project established a monthly mini-market at a community site with a few retail outlets carrying high-quality produce. The project was successful in fostering a strong interest among participants in healthy cooking demonstrations and cooking techniques. Subsequently, the HEED project joined forces with another community initiative to obtain funding to expand the mini-markets and food demonstrations.

The Physical Activity and Neighborhood Resources in High School Girls study (Pate et al, 2008) followed an ecologic model based on the social cognitive theory for adolescent females in urban, suburban, and rural communities. Researchers hypothesized that physical activity is influenced by a comprehensive set of personal, social, and physical environmental factors. Using GIS mapping, mixed regression models on BMI, and environmental variables, as well as 3-day physical activity recall, they found that the physical environment explained less than 5% of the variance in physical activity among adolescent girls. However, after adjusting for race, BMI, socioeconomic status (SES), and household income, there was an association between churches and vigorous physical activity. An additional study by Botchwey (2007) showed that up to 80% of congregations and faith-based organizations offer health services to their community, with a greater variety of services than secular non-profit organizations. Therefore, as nurses work with communities, it is important to consider the social and physical components of the environment, especially those actively engaged in health promotion.

Photovoice Method and Projects

Photovoice is a novel method used in CBPR projects that integrates the strengths of social support and engagement, building local capacity to identify and address community concerns. Wang and Burris (1997) developed this methodology in 1997 by expanding the use of “photo novella” (Wang and Burris, 1994) as a means to empower communities while gathering qualitative data. It is a grassroots community method of gathering information by using photography. By using Photovoice participants photograph, contemplate, and then verbalize stories or simple descriptions about their photo(s) taken in response to a particular prompt, thereby allowing their voices to be heard. This process prevents written text from hindering communication and is effective in a society that uses oral tradition to preserve its culture (Riley et al, 2004). Health care researchers have used Photovoice as an assessment tool (Lacson, 2007; Strecher, 2004; Thompson et al, 2008).

This study by Kulbok et al (2008b) addressed gaps in the youth tobacco prevention literature. The purpose was to identify attitudes, beliefs, values, strategies, and shared meanings associated with tobacco-free behaviors of rural-dwelling male adolescents and their parents. The study examined differences in the meaning attached to nonsmoking and nonuse of smokeless tobacco among groups of African American and white male adolescents and their parents from two tobacco-growing counties in Virginia. In addition, the study assessed whether a

modified Photovoice method would enhance the contribution of male adolescent participants and parents in individual and group interviews. Photovoice is a qualitative approach that uses images to promote effective ways of sharing beliefs about a specific topic. Researchers have used Photovoice to facilitate group conversations and to encourage participants to share their thoughts among themselves. In this study, Photovoice was a concrete way for youth and parents to express their perceptions about being tobacco-free, amplified through photographs that respond to questions about this topic. This approach was particularly effective with the male adolescents, who were hesitant to share their thoughts and feelings, and had a hard time articulating their thoughts.

The Ngudo Nga Zwinepe (NNZ) Learning through Photos projects use Photovoice to understand water perceptions and innovations as well as health in the Limpopo Province of rural South Africa where water resources are scarce and frequently contaminated (Cunningham et al, 2009). In one Photovoice project, community members took pictures documenting their perception of water and their water system. In contrast to the researchers’ expectations, there was little mention of the deleterious health effects of contaminated water. Instead, the participants listed infrastructure/storage, community, money, and food as their top priorities; health/hygiene ranked fifth overall. Photovoice provided data to characterize the water priorities of this community and to implement an intervention that meets the community’s primary concerns in the shorter term while developing educational strategies regarding the health risks of contaminated water.

The projects described in the previous paragraphs show the importance of multiple approaches to reaching the population. In multilevel intervention approach to community-oriented programs, it is important to pay attention to all client levels (i.e., individual, family, aggregate, and community). For example, in nutritional programs, it is important to address the individual, the household, grocery store accessibility and environment, the community, and the food environment. No one individual can address all of these levels, but there is increasing emphasis on working in teams and in developing partnerships consisting of residents, health providers, and other professionals outside the health field as specified through the National Prevention Strategy. In addition, it is important to frame and initiate interventions based on participants’ priorities, not the priorities of experts. This approach promotes increased buy-in to projects and the necessary compliance by community participants to adhere to healthy behaviors. Nurses have many opportunities to work with and to lead these multidisciplinary teams to conduct assessments, develop strategies with the community and its populations, and facilitate the empowerment of community residents and recommended change. It is increasingly important that nurses integrate these intervention strategies with the epidemiologic evidence base for practice.

APPLICATION OF THE INTEGRATIVE MODEL FOR COMMUNITY HEALTH PROMOTION

In the previous sections we described the importance of multiple levels of nursing and health care aimed at health promotion and

illness prevention of individuals, families, aggregates, and the total community. In the remainder of this chapter, we present an example using the integrative model to apply these concepts.

Obesity and the Built Environment

Illness Care

In this case example (Table 17-1), a young woman recently diagnosed with obesity is referred for care. The nurse's immediate goal is to provide care that will help this client resolve her illness. Obesity rates have doubled over the last 20 years, with 16.9% of children ages 2 to 19 years and 34.9% of U.S. adults considered obese (Ogden et al, 2014). These rates are the result of a built environment that promotes increased unhealthy food consumption and decreased physical activity. Our built environment includes all of the places we live, work, learn, worship, and play and that are created or modified by people. According to the CDC, in order for people to make healthy choices to combat obesity, both policy and environmental changes are needed to assure affordable healthy food and safe places for activities (CDC, 2014b). Therefore, teaching the client about the effects and side effects of her medications, and how to monitor her weight, nutrition, and physical activity at home, are important interventions. Since predisposing genetic, lifestyle, and environmental factors related to obesity exist, it is important to give family members information about this illness, including early recognition of signs and symptoms for themselves. Other important aspects of illness care include assessing the prevalence of obesity among high-risk aggregates in the community and teaching obesity prevention and treatment classes in community-wide settings that high-risk groups frequent. An example is providing cooking classes in churches to at-risk women in the community. At the community level, it is important to assess whether there are adequate and available providers and resources for healthy food and safe physical activity in the community.

Illness/Disease Prevention

Prevention care is also addressed at the individual level by teaching measures such as healthy nutrition, progressive

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Teamwork and Collaboration

Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality client interventions and outcomes. Important aspects of teamwork and collaboration include:

- **Knowledge:** Know the scopes of practice of teammates and support them in practicing to their fullest level.
- **Skills:** Clarify roles when necessary to avoid duplication of efforts and to gain the most comprehensive approach to client care.
- **Attitudes:** Respect the unique perspectives and contributions of team members.

Teamwork and Collaboration Question

Consider the role of partnerships with the community to reduce childhood and adult obesity in the community in collaboration with school health, public health, occupational health, and home health. Are other team members needed to launch a community program to focus on obesity? If so, who would you include and what is your rationale?

exercise, and lifestyle techniques to prevent additional weight gain. Healthy nutrition and regular moderate to vigorous exercise are important preventive measures for all family members. Aggregate-level preventive interventions include providing showers at workplaces to encourage exercise before or during the workday. Community intervention examples include year-long multimedia campaigns to provide intensive education to the community about prevention of obesity.

Health Promotion

Health promotion can motivate a person to adopt a less sedentary and more active lifestyle. Health promotion includes encouraging individuals to adopt a health-promoting lifestyle and helping them to become aware of their own power and self-efficacy to do so. Nurses can encourage families to make health-promoting activities a part of their daily lives. This might include taking walks, swimming together, or joining an

TABLE 17-1 Community Health Levels of Care: Obesity and the Built Environment

Focus of Care	CLIENT SYSTEM			
	Individual	Family	Aggregate	Community
Illness care	Administer medications Monitor weight as well as adherence to nutrition and physical activity recommendations of individual client in the home setting	Teach family members about nutrition and physical activity practices to lose weight and prevent the onset of obesity-related diseases	Assess prevalence of obesity in the community Teach obesity classes community-wide in settings that high-risk groups frequent	Assess community for accessibility and adequacy of healthy food and safe physical activity venues in the local environment
Illness/disease prevention	Teach nutrition, progressive exercise, and lifestyle techniques to prevent additional weight gain	Teach nutrition and importance of regular exercise to all family members to prevent additional cases of obesity	Develop classes about obesity risk reduction for targeted high-risk groups and their community	Participate in community-wide multimedia education for obesity risk reduction
Health promotion	Empower individual to adopt a less sedentary and more active health promotion lifestyle	Plan with family to incorporate health promotion activities into lifestyle	Provide group education (classes) regarding benefits of regular exercise and healthy eating	Work with community leaders and citizens to establish safe physical activity space and healthy food options

intergenerational baseball or bowling team in which families compete with other families. Aggregates can also benefit from heart-healthy classes or activities that are culturally specific to particular subgroups, such as older Hispanic women or African American teenage girls. These activities can include stress management, well-balanced nutrition, exercise, dance classes, sports, or any other topic that can promote heart health. When looking at the total community, an example of a health promotion intervention is participating in a coalition to plan for supermarkets and community gardens, as well as parks or recreation areas within the community that are safe and accessible to the population.

In summary, the concepts of health, health promotion, and community are inextricably linked; it is difficult to discuss one without including the others. It is also important that nurses examine their definitions and beliefs about each concept as the basis for their practice. The essence of public health is the ability to see the totality of community while addressing its component parts and, at the same time, to see the total needs for health promotion, health protection, illness and disease prevention, and illness care and management. The integrative relationship among these components distinguishes public health nursing from nursing in more circumscribed settings, such as hospitals and clinics.

LINKING CONTENT TO PRACTICE

In this chapter, we describe the origins of the integrative model of community health promotion (Laffrey and Kulbok, 1999) and its application in public health nursing practice. The integrative model addresses the multiple determinants of population health and is consistent with the ecologic framework (IOM, 2014) and social determinants of health (SDOH) (Commission on Social Determinants of Health [CSDH], 2008; WHO, 2014a). The ecologic approach provides a basis for understanding population health and the challenges of building a culture of health (RWJF, 2013). It emphasizes that multiple social determinants of health influence the conditions that promote health on multiple levels

(i.e., individual, family, aggregate, community, and society). The central focus of public health nursing practice is health promotion. Health promotion is also central and dominant in the integrative model of community health promotion. Public health nurses strive to improve the health status of communities and populations. Whether the client system is the family or a vulnerable population, and the focus of care is illness prevention or illness care, health promotion remains the central goal. No matter where public health nursing care begins, it ultimately leads to health promotion of the community and population health.

PRACTICE APPLICATION

A rural health outreach program serves migrant workers, their families, and other vulnerable populations in the local community. The program's goals include increased knowledge about risk factors, services, and self-care; improved community health; increased access and affordability of individual- and community-level health promotion services; and reduced barriers to health services. The program offers health promotion and disease prevention educational materials and classes in English and Spanish throughout the region in churches, schools, community centers, fire departments, and migrant camps. In addition, clinics in eight local sites across the county provide services. Clinic services include health risk assessments, disease screening, immunizations, health education, counseling, and referral. The program staff trained community health workers (CHWs) from the migrant community to deliver basic health education and resource information. Funding from a variety of public and private sources supports the program. It is essential that the program show effective outcomes if it is to sustain funding.

Mary Ann Jones, a nurse with a bachelor of science in nursing degree, works for the outreach program. She is a member of a group asked to evaluate whether the outreach program (including the eight clinics) is effective in meeting the stated objectives.

- A. Using the integrative model for community health promotion as a guide, how might you organize a comprehensive approach to assessment and data collection?
- B. What are sources of data you might use for assessing individual, aggregate, and community health indicators?
- C. What is the value of interviewing rural residents, migrant workers, and clinic participants about their perceptions of health and the value of health services?
- D. Who else can you interview to elicit important information about the usefulness of the outreach program?
- E. How can you best use CHWs to increase participation and partnership among concerned health professionals, community residents, and migrant families and to sustain the program?

Be creative and comprehensive in your approach, and consider how you might build a culture of health using the ecologic perspective, the social determinants of health, and cultural factors associated with rural and migrant populations in the United States. Current spending limits on federal and state programs for health promotion and disease prevention require that nurses deal effectively with issues of outreach, sustainability, and success of community health programs.

Answers can be found on the Evolve site.

KEY POINTS

- The goals of a culture of health for America are for good health across geographic, demographic, and social sectors; for being healthy and staying healthy as a social value; and for everyone to have access to affordable, quality health care.
- The idea of health shapes the process of population-focused nursing practice, from assessment of health-related needs of individuals, families, aggregates, and communities to evaluation of health outcomes.

KEY POINTS—cont'd

- The National Prevention Strategy foresees a prevention-oriented society where public and private sectors value health for individuals, families, and society and work together to achieve better health for Americans.
- The greatest benefits in public health are likely to come from efforts to improve individual and family lifestyles through community and population interventions that address the social determinants of health including social conditions and the built environment.
- Public health nurses have a history of commitment to primary health care and to enhancing levels of wellness in communities and populations.
- When nurses examine their own definition of health, they recognize how this health definition directs the nursing care they provide.
- When nurses examine the client's definition of health, they are more likely to tailor care to the client's culture, needs, lifestyle, and social and physical environment.
- The Framingham Heart Study has provided more than 50 years of research about risk factors and lifestyle habits; Framingham researchers are currently studying how genes contribute to common disorders such as obesity, hypertension, and diabetes.
- The Stanford Heart Disease Prevention program, the North Karelia Project, the Pawtucket Heart Health program, and the Minnesota Heart Health program contributed to the scientific knowledge base for the design, implementation, and evaluation of community- and population-level risk-appraisal and risk-reduction programs.
- Public health nurses function beyond resolving a specific illness to preventing the illness and promoting optimal health for the individual, the family, the aggregate, and the total community. All of these levels are important to promote the health of the community and populations.

CLINICAL DECISION-MAKING ACTIVITIES

1. Write your own definition of health, and interview a nurse, client, and physician about their definitions of health. How are these definitions similar or different? How do they "fit" with your understanding of what nurses and health care providers need to do to build a culture of health?
2. What are some challenges encountered when you consider different definitions of health and health promotion from a disease oriented versus an environmental or social-ecologically oriented perspective? Illustrate these challenges and opportunities with examples of strategies that are health promoting and will contribute to building a culture of health.
3. Discuss the importance of the built environment in community health promotion, and provide examples of environmental health promotion indicators for a specified community.
4. Develop a nursing care plan for addressing childhood obesity using the propositions of [Milio \(1976\)](#) as a frame of reference.
5. Use the integrative model for community health promotion and social determinants of health to identify the most important strategies in a community-wide plan for childhood obesity.
6. Illustrate community health levels of care including the client system and the focus of care:
 - A. For teenage pregnancy: begin with community-level health promotion
 - B. For childhood obesity: start with community-level illness prevention

Issues and Approaches in Population-Centered Nursing

In the report brief, “For the Public’s Health: Investing in a Healthier Future,” The Institute of Medicine says “In 1914, New York City Commissioner Herman M. Biggs remarked that ‘public health is purchasable’, adding that within natural limitations, a community can determine its own death rate” ([Committee on Public Health Strategies, 2012, p. 1](#)). It is embarrassing that over a century later, the United States has not done a good job of determining its own death rate. We spend huge amounts of money on clinical care and too often neglect public health and population-based efforts to improve health care. The primary orientation of health care delivery has been toward care and cure of the individual. There is increasing evidence that lifestyle and personal health habits influence the health of individuals, families, populations, aggregates, and communities.

Although it is necessary to identify health risk factors among individuals and groups in the community, nurses should also identify and work with health problems of a defined population or the total community. Healthy communities provide greater resources for growth and nurturing of individuals and families than do the communities that ignore the need for an emphasis on the health of their populations.

Certainly, nurses can use a public health approach to work with individuals and families in promoting health, intervening in disease onset or progression, and assisting with rehabilitation. Likewise, nurses often find that strategies used to introduce health behaviors directed at illness prevention and lifestyle changes are applicable to groups in the community and the community at large. Concepts for promoting health behaviors through groups, identifying community groups and their contributions to community life, and helping groups work toward community health goals are essential to population-centered nursing practice.

Healthy communities/healthy cities is an approach to helping communities organize and strive to provide environments for healthful living for their populations. In this approach, health is described as encompassing the physical and mental health of individuals and families plus the social, political, economic, educational, cultural, and environmental settings of the total community.

Nurses can help communities attain their health goals by understanding the organization of communities, the effects of rural versus urban settings on health issues, how and why programs are managed, and how to evaluate programs for quality and effectiveness. A community assessment provides the basis for helping communities establish their goals. The use of a nurse-managed clinic is one approach nurses have found to be successful in meeting the needs of aggregates, or vulnerable at-risk populations. These needs must be considered when trying to improve the health of a community. Case management is an approach that has been used by nurses since its inception to match the most appropriate services and health care delivery interventions to population needs.

Although all communities strive to protect their populations and provide a safe living environment, natural and man-made disasters may occur; nurses can play a significant role in helping a community through crises. However, as the Institute of Medicine report points out “to improve health outcomes in the United States, we will need to transform the way the nation invests in health to pay more attention to population-based prevention efforts, remedy the dysfunctional manner in which public health funding is allocated, structured, and used; and ensure stable funding for public health departments” ([Committee on Public Health Strategies, 2012, p. 4](#)).

Community As Client: Assessment and Analysis

Mary E. Gibson, PhD, RN

Dr. Mary E. Gibson was a public health nurse in Albemarle County, Virginia, early in her career. Since that time she has practiced in a variety of Maternal Child Health settings. Mary was involved in the Virginia Department of Health's early initiative to regionalize high risk pregnancies and has worked as an outpatient nurse, childbirth educator, Perinatal Outreach nurse including systems work with regional hospitals and nurses, and outreach education; and as a labor and delivery and perinatal nurse. Her master's degree concentration was community health. Her doctoral work at University of Pennsylvania focused on nursing history, and this continues to be her research focus. At the University of Virginia, Mary's teaching experience includes graduate level Community Assessment, undergraduate Obstetric and Neonatal Nursing and clinical undergraduate Community Health Nursing. She currently leads a local nonprofit's board that serves at-risk, underserved children and families.

Esther J. Thatcher, PhD, RN, APHN-BC*

As a BSN nursing student, Esther volunteered in El Salvador several times with a group called Nursing Students Without Borders. After graduating, she continued to work with Latinos as a migrant farmworker outreach nurse in rural Virginia. She then worked in adult Internal Medicine settings, where she became interested in preventing chronic diseases in underserved populations. Later, as a public health nurse, Esther reignited her interest in how community environments affect health outcomes. Her PhD research at the University of Virginia was to describe community influences on healthy food access in rural Appalachia. She is currently a postdoctoral fellow at University of North Carolina—Chapel Hill.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Analyze the importance of community assessment in nursing practice.
2. Select and utilize a method and model for assessment of a community.
3. Appraise various online data sources for reliability and accuracy of information.
4. Utilize the nursing process to create a community assessment for a selected community.
5. Interpret concepts basic to community nursing practice: community, community client, community health and partnership for health.
6. Develop a prioritized community problem list and nursing diagnosis, and a care plan for a community.

KEY TERMS

active participation, p. 400
 aggregate, p. 398
 coalitions, p. 399
 community, p. 398

community as client, p. 398
 community as partner, p. 407
 community health, p. 399
 community health workers, p. 401

*With gracious thanks to Elayne Kornblatt Phillips, MPH, PhD, RN, FAAN for careful reading and critique. A special thanks to George Shuster for his contributions to this chapter through many editions of this text.

"I believe that the community—in the fullest sense: a place and all its creatures—is the smallest unit of health and that to speak of the health of an isolated individual is a contradiction in terms."

Wendell Berry

INTRODUCTION

Communities are the environments where we live and work. Naturally, the community's ability to serve the needs of its members defines key aspects in the health of the community. The public health nurse (PHN) is in an ideal position to view the "community as client," and to begin to identify and work with the strengths present in the community and to help harness these strengths to meet the challenges faced by the community. Health is a broadly defined and interdependent concept. As defined by the World Health Organization, "Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (WHO, 1948). Therefore, the health of the community involves many aspects besides the absence of disease. The influence of environment, public

services and policies along with economics play a large role in the health of the community.

We use the nursing process from assessment through evaluation to promote a community's health. This process begins with community assessment (sometimes called community needs assessment)—one of the core functions of public health nursing—which involves getting to know the community inside and out. It is a logical, systematic approach to identifying community strengths and resources. In this chapter we will clarify specific community concepts including community as client, provide a snapshot of the nurse's role in communities, and outline the process for undertaking a comprehensive community assessment using a hybrid of the nursing process.

COMMUNITY DEFINED

"Boston Strong" was a phrase that spread quickly after the 2013 Boston Marathon bombing. Like many communities in the immediate aftermath of a major disaster, residents of Boston and beyond rallied together in a declaration of solidarity and shared community identity. The community spirit and hope

implied in “Boston Strong” is an example of the comfort and reassurance that a strong community identity can provide to individuals (Lin, 2014). But what do we mean by *community*, and how might being part of a community influence a person’s health?

There are many definitions of community. At its simplest, a **community** is a group of people that share something in common, such as geographic location, interests, or values (Obst & White, 2005, p. 127). The World Health Organization defines community as “a group of people, often living in a defined geographical area, who may share a common culture, values and norms, and are arranged in a social structure according to relationships which the community has developed over a period of time” (World Health Organization, 2004, p. 16). One study that aimed to define community among a diverse U.S. population reached the consensus definition of “a group of people with diverse characteristics who are linked by social ties, share common perspectives, and engage in joint action in geographical locations or settings” (MacQueen et al, 2001).

A community is a system, not just the sum of the characteristics of its inhabitants. In most definitions, the community includes three factors: people, place, and function. *People* are the community members or residents. An **aggregate** is a population or group of individuals who share common personal or environmental characteristics. *Place* can be a geographic location or other shared spaces such as the Internet. *Function* refers to the aims and activities of the community.

Community is a concept rather than simply a specific place, and individuals living in the same place may describe their community differently. When an organization asks a nurse to perform a community assessment, community usually refers to a specific population, an aggregate with specific characteristics that lives within the area that an organization serves, such as a school district, or a geographic area such as a county. However, it is important to remember that individuals within this defined area could view the community through a different lens. Understanding the many identities of community is part of the community assessment and is best done through talking with residents and stakeholders.

COMMUNITY AS CLIENT

Nursing Care of the Community As Client

Population-focused health care is highly relevant in our current health care environment, and the community as client is important to nursing practice for several reasons. The community is the client when the nursing focus is on the collective or common good of the population, instead of on individual health. When focusing on the **community as client**, direct clinical care can be a part of population-focused community health practice (Radzynski, 2007). For example, sometimes direct nursing care is provided to individuals and family members because their health needs are common community-related problems. Changes in individual health will ultimately affect the health of the community (O’Donnell et al, 2009).

Improved health of the community remains the overall goal of nursing intervention. This is often accomplished through

individual treatment; for example, addressing intimate partner violence, child or elder abuse is intended primarily to impact the effects of abuse on society and ultimately on the population as a whole. Similarly, treating a client for tuberculosis reduces the risk to other community members, thereby reducing the risk of an epidemic in the community. Since 1965, large-scale campaigns to encourage smoking reduction or cessation among groups and individuals, and laws that prohibit smoking in specific public spaces have resulted in significantly lower smoking rates in the adult population (42% in 1965 compared to 19% in 2011) (CDC, *Trends in Current Cigarette Smoking Among High School Students and Adults, United States, 1965-2011*).

Focusing on the community client highlights the complexity of the change process. Change for the benefit of the community client must often occur at several levels, ranging from the individual to society as a whole. For example, health problems caused by lifestyle, such as lack of exercise, overeating, and speeding, cannot be solved simply by asking individuals to choose health-promoting habits. Society must also provide healthy choices. Most individuals find changing their habits independently extremely difficult; indeed, sometimes impossible. The support of family members, friends, community health care systems and relevant social policies are necessary for success. Individuals who have lifestyle health problems are often blamed for their illness because of their choices (e.g., to smoke), often referred to as “blaming the victim.” In his classic work, Ryan (1976) points out that the “victim” cannot always be blamed and expected to correct the problem without changes also being made in the helping professions and public policy. Figure 18-1 illustrates the continuum of care from the individual to global health.

Commitment to the health of the community client requires a process of change at each appropriate level on the continuum. One nursing role emphasizes individual and direct personal care skills, another nursing role focuses on the family as the unit of service, and a third centers on the community. The most successful change processes often arise from collaborative practice models that involve the community and nurses in joint decision making. (Bencivenga et al, 2008). Nurses must remember that collaboration means shared roles and a cooperative effort in which participants want to work together (Ndirangu et al, 2008). Participants must see themselves as part of a group effort and share in the process, beginning with planning and including decision making. This means sharing not only the power but also the responsibility for the outcomes of the intervention. Viewing the community as client and thus as the target of service means a commitment to two key concepts: (1) community health and (2) partnership. These two concepts form not only the *goal* (community health), but also the *means* of population-centered practice (partnership).

FIG 18-1 Health on a population continuum.

Community As Client

Population-centered practice seeks healthful change for the whole community's benefit (Radzynski, 2007). Although the nurse may work with individuals, families or other groups, aggregates, or institutions, the resulting changes are intended to affect the whole community. For example, an occupational health nurse's target typically includes preventing illness and injury and maintaining or promoting the health of an entire company workforce. Because of this focus, the nurse might help an individual disabled worker become independent in activities of daily living. The nurse could also take action to make the whole community better able to support persons with disabilities. These actions might include promoting vocational rehabilitation services in the community and advocating for local policies that improve equal opportunities for disabled workers.

Community health nurses join professionals from many other fields in fulfilling the **core public health functions**: assessment, assurance, and policy development (National Research Council, 1988). The community assessment process described in this chapter is a key role of PHNs. The findings of the assessment process guide actions of *assurance*, or ensuring that all community members have access to high-quality health services. *Policy development* includes informing and mobilizing community members to advocate for business and government policies that improve health.

The community as client perspective guides decisions about allocation of resources and services to create the greatest benefit for the community. Sometimes this means spreading the benefit to as many people as possible in the community. For example, clean air and water are resources needed by everyone in a community. At other times, the community will experience the greatest benefit if resources are prioritized for groups within the community who are in high-risk categories. For example, supplies of vaccine for the 2009 H1N1 influenza pandemic were limited at first. Population groups at highest risk for complications from the disease were vaccinated before making the vaccine available to the general population (Shim, Meyers, & Galvani, 2011).

Two main ethical concepts that guide the community as client perspective are utilitarianism and justice. **Utilitarianism** means doing the greatest good for the greatest number of people. **Distributive justice** means treating people fairly, and distributing resources and burdens equitably among the members of a society. **Social justice** means ensuring that vulnerable groups are included in equitable distribution of resources. The outcome of social justice should be a reduction in health disparities between privileged and marginalized social groups. Nurses can use these concepts to carefully consider how to best allocate scarce resources, such as health services and funding, in ways that benefit the whole community. More information on ethics in community practice is found in other chapters of this book.

Community Health

Community health is reflected in the health behaviors and subsequent outcomes of its residents and also by the ability of

the community as a system to support healthy individuals. The **socio-ecological model** views individuals as having dynamic interactions with social and environmental features of communities, for example social networks, organizations such as schools and businesses, media, government policies, and natural and built environments (Richard, Gauvin, & Raine, 2011). Nurses caring for the community as the client identify effects that these complex community parts have on individuals' health; they work with all parts of a community to achieve the goal of a healthy community. Betty Neuman's Health Care Systems Model illustrates this system well (Neuman, 1980).

Neuman's model views systems as greater than the sum of their parts; the strength of each part of a community and the synergy between these parts contribute to the ability of its residents to be healthy. Community systems provide stability and protection from chronic or sudden stressors such as homelessness, health declines, disease outbreaks, or disasters. Another community model, Community-As-Partner, identifies major community systems as physical environment, health and social services, economy, transportation and safety, politics and government, communication, education, and recreation (Anderson & McFarlane, 2011).

The World Health Organization's (WHO) Healthy Cities program is an international leader in promoting health through community systems. It defines a healthy community as "one that is continually creating and improving those physical and social environments and expanding those community resources which enable people to mutually support each other in performing all the functions of life and developing to their maximum potential" (World Health Organization, 2014). The WHO describes four aims of healthy communities as (1) supporting individual health, (2) promoting quality of life, (3) distributing the resources needed for basic sanitation and hygiene, and (4) creating accessible health care services.

Community Partnerships for Assessment

Partnering with community members is a key element of a successful community health program or intervention. Involving community members not only in the data collection process, but in all phases of the assessment, ensures that the data collected are more accurate and more relevant to the concerns of the community. Partnerships also promote community members' investment in the success of the assessment and in the resulting projects to improve community health. Therefore, successful strategies for improving community health must include community partnerships as the basic means or key for improvement. Some community assessment models feature community partnerships as a central activity, such as **Mobilizing for Action through Planning and Partnerships (MAPP)** (NACCHO, 2014).

Nurse-community partnerships can take many forms. A successful democratic partnership requires hard work from all parties and is usually achieved only through a long-term commitment to the process, wherein diverse community members and health care professionals share all resources and work equitably (D'Alonzo, 2010). **Coalitions** are formal partnerships in which individuals and organizations serve in defined capacities

BOX 18-1 Partnerships

The three main characteristics of a successful partnership are the following:

1. *Being informed.* Community member and professional partners must be aware of their own and others' perceptions, rights, and responsibilities.
2. *Flexibility and acceptance.* Community member and professional partners must recognize the unique contributions that each can make to a given situation. For example, professionals often contribute important knowledge and skills that laypersons lack. On the other hand, laypersons' definitions of community health problems are often more accurate than those of professionals.
3. *Negotiation.* Because contributions vary and each situation is different, the distribution of power must be negotiated at every stage of the change process.

Data from Jackson EJ, Parks CP: Recruitment and training issues from selected lay health advisor programs among African Americans: a 20-year perspective [review], *Health Educ Behav* 24:418–431, 1997.

such as steering committees, advisory committees, and work groups. Coalitions are *active partnerships*, in which all participants share leadership and decision making to some degree. Unfortunately, some community health efforts view community residents only as sources of information and receivers of interventions; this limits residents to *passive participation*. **Passive participation** is the antithesis of the partnership approach most valued in nurse-community partnerships, in which all partners are actively involved in and share power in assessing, planning, and implementing needed community changes (Ndirangu et al, 2008; Timmerman, 2007).

Community members who are recognized as community leaders (whether professionals, pastors, government officials or interested citizens) possess credibility and skills that health professionals often lack. The community member–professional partnership approach specifically emphasizes **active participation**. O'Donnell (2009) wrote that partnership means the active participation and involvement of the community or its representatives in healthy change. For example, a partnership between Native American community members and academic researchers ensured the development of an effective ongoing program to address breast cancer disparities in this community (Christopher et al, 2008) (Box 18-1).

Partnership, as defined here, is an essential concept for nurses to know and use, as are the concepts of community, community as client, and community health. Experienced nurses know that partnership is important because health is not a static reality but is continuously generated through new and increasingly effective means of community member–professional collaboration. Other active professional service providers such as school teachers, public safety officers, and agricultural extension agents play a large part in the overall health of the community. Partnership in identifying strengths and problems and in setting goals is especially important because it brings commitment from all persons involved, an essential component of successful change (Biel et al, 2009).

Partnerships involving nurses working with community organizations offer one of the most effective means for interventions because they actively involve the community and build

on existing community strengths. Nurses working with community groups and organizations can fulfill many different roles including media advocacy, political action, community-based health communication, social marketing, and outreach facilitation. Regardless of what roles nurses fulfill as their contribution to the partnership, they must remember to “start where the people are” (Severance & Zinnah, 2009).

Shoultz et al (2006) looked at the challenges and possible solutions in developing partnerships with communities. Community partnerships involve both influence and power. Nurses must focus on where and how health professionals and the community can work together, respecting voices of all community members. This approach requires nurses to do *with* rather than *to* the partner, while the partner's role throughout the process is active and empowered, not passive. Mutually determined goals and plans of action, and the assignment of roles and responsibilities, are negotiated. Through this model, community partners become more effective at working independently to solve their own problems and make their own decisions.

Prioritizing the problems through the lens of the participants may not match the identified priorities defined by other sources of data. In the language of community empowerment advocates, community participants must have an active role in the change process. The PHNs must work hard to include members of a setting, neighborhood, or organization while developing trust and providing the community with a central role throughout the process (Christopher et al, 2008; Hanks, 2006).

One historical example of a nurse-community partnership remains an inspiring story of this important work. Nancy Milio was a young, white PHN when she began working with an inner-city African American community in Detroit during the 1960s. Together, she and community members identified needs and designed a program to meet them. Milio's painstaking process of working *with* the community to create a Mom's and Tot's Center where mothers and children could access primary health care and child care is a sentinel example of community partnership. The true value of this partnership was demonstrated when the Detroit riots occurred in 1967, and the storefront where the clinic was located remained intact while surrounding structures burned; the local rioters had spared the clinic because it “belonged to the people” (Milio, 2000; DeGuzman & Keeling, 2012). Thus, working within the community to develop priorities and to create programs promotes longstanding ownership and at the same time assures the probability for sustainability.

The Nurse's Role in the Community

The nurse's ability to establish credibility and trust in the community is important in doing a thorough community assessment. The nurse may be considered to be an *insider* if he or she grew up in the community, has personal ties to the people there or comes from a similar cultural or ethnic background. This insider status may increase community members' willingness to speak openly and partner with the nurse. However, sometimes this insider status can be a disadvantage if it compromises the nurse's impartiality or objectivity (Ochieng, 2010). Nurses who

are new to the community or have few insider connections can increase their familiarity with the community and its residents through taking part in informal community activities, such as shopping, attending church, or participating in organizations. They can also partner with trusted insiders in the community, such as *gatekeepers* and *community health workers*.

Gatekeepers refer to formal or informal community leaders who create opportunities for nurses to meet diverse members of the community (Sixsmith, Boneham, & Goldring, 2003). Gatekeepers can confer credibility to the nurse. For example, a church pastor may act as a gatekeeper by introducing a nurse to the congregation, thus increasing the likelihood that the church members will trust the nurse enough to provide information or to serve as partners in the assessment and throughout any program planning, intervention, and evaluation.

Community health workers (CHW) are not professional or licensed health care providers but are community members from diverse backgrounds who receive training to do health outreach work. CHWs can assist nurses in doing community health assessments in several ways. They extend the reach of the nurse by being able to do many activities that are part of the community assessment process. They can also serve as gatekeepers, using their own insider status to engage community members in the assessment process.

COMMUNITY ASSESSMENT

Community assessment put quite simply is taking detailed stock of a community both from the outside in and from the inside out for the purpose of identifying and analyzing conditions therein. Community assessment, sometimes called community needs assessment, is one of three core functions of public health. This process requires clinical judgment and critical appraisal of multiple types of data from a variety of sources, and it requires a clear knowledge and understanding of the community as client. People, place, and function are the foundational dimensions of a community and need to be defined as part of the assessment process. These dimensions guide the gathering of data. Data can be primary or secondary. **Primary data** are collected directly through interaction with community members, which may include community leaders or interested stakeholders. **Secondary data** are obtained through existing reports on the community including census, vital statistics, and numerical reports (e.g., morbidity and mortality information) or information from reference books.

There might be many reasons for conducting a community assessment but for public health nursing the purpose is usually to identify community health needs and to develop strategies to address them. The purpose of this section is to provide a clear method for completing a comprehensive community assessment, using the tools of the nursing process adapted to communities. CDC (2013) offers a clear set of common elements that constitute a community assessment (see Box 18-2). An example of Santa Cruz's very comprehensive and ongoing community assessment (2009) can be accessed at http://www.appliedsurveyresearch.org/projects_database/quality-of-life/santa-cruz-county-community-assessment-project-cap.html.

BOX 18-2 Common Elements of Assessment and Planning Frameworks

1. Organize and plan
2. Engage the community
3. Develop a goal or vision
4. Conduct community health assessment(s)
5. Prioritize health issues
6. Develop community health improvement plan [in this case Nursing Diagnosis]
7. Implement and monitor community health improvement plan
8. Evaluate process and outcomes

Source: CDC *Assessment and Planning Models, Frameworks and Tools* 2014A, www.cdc.gov/stltpublichealth/ch/assessment.html.

Why Community Assessment?

Community assessments may be done for various reasons. For example, a PHN in a community may want to conduct an assessment to learn more about community needs or strengths, or may want to locate confirmation data to address a recognized community problem. Recently a new directive resulting from the Affordable Care Act requires charitable hospitals to perform a community needs assessment of their catchment area every three years and plan an implementation strategy to address any identified needs (Barnett, 2012).

In some cases administrators will perform these assessments, but PHNs are ideal choices to lead the community in this required activity. Public health personnel are the recognized experts in this arena. The recent formation of the Public Health Department Accreditation Board placed responsibility to implement standards for uniform performance with health departments in the United States. These standards include enhanced surveillance of community health services through regularly conducted community assessments (Riley, Bender, & Lownik, 2012).

Assessment is one of the three core functions of public health (CDC *Core Functions*, 2011). Public health nursing places assessment at the forefront of PHN competencies. The Quad Council of Public Health Nursing Organizations is a coalition that includes the Association of Community Health Nursing Educators (ACHNE), the Association of Public Health Nurses (APHN), the American Public Health Association—Public Health Nursing Section (APHA), and the American Nurses Association's Congress on Nursing Practice and Economics (ANA). In 2011, the Quad Council revised the core competencies for public health nursing and adopted a three-tiered structure describing the skills expected of nurses as the generalist, specialist, and executive levels of public health nursing practice (Swider et al, 2013). The **Public Health Nursing Competencies** include eight major domains: analytic and assessment skills, policy development/program planning skills, communication skills, cultural competency skills, community dimensions of practice skills, public health sciences skills, financial management and planning skills, and leadership and systems thinking skills. The domain of analytic and assessment skills (Table 18-1), details the competencies specific to community assessment across all tiers of public health nursing practice.

TABLE 18-1 Public Health Nursing Competencies, Domain 1: Analytic and Assessment Skills

Tier 1: Generalist	Tier 2: Specialist/Mid-Level	Tier 3: Executive/Senior-Level
<ol style="list-style-type: none"> 1. Identifies the determinants of health and illness of individuals and families, using multiple sources of data. 2. Uses epidemiologic data and the ecological perspective to identify the health risks for a population. Identifies individual and family assets and needs, values and beliefs, resources, and relevant environmental factors. 3. Identifies variables that measure health and public health conditions. 4. Uses valid and reliable methods and instruments for collecting qualitative and quantitative data from multiple sources. Develops a data collection plan using appropriate technology to collect data to inform the care of individuals, families, and groups. 5. Identifies sources of public health data and information. Collects, interprets, and documents data in terms that are understandable to all who were involved in the process, including communities. 6. Uses valid and reliable data sources to make comparisons for assessment. 7. Identifies gaps and redundancies in data sources in a community assessment through work with individuals, families, and communities. 8. Applies ethical, legal, and policy guidelines and principles in the collection, maintenance, use, and dissemination of data and information. 9. Describes the public health nursing applications of quantitative and qualitative data. 	<ol style="list-style-type: none"> 1. Assesses the health status of populations and their related determinants of health and illness. Partners with populations, health professionals, and other stakeholders to attach meaning to collected data. 2. Develops public health nursing diagnoses for individuals, families, communities, and populations. Uses a synthesis of nursing, public health, and system science/theory when characterizing population-level health risks. Assures that assessments identify population assets and needs, values and beliefs, resources, and relevant environmental factors. Derives population diagnoses and priorities based on assessment data, including input from populations. 3. Utilizes a wide variety of relevant variables to measure health conditions for a community or population. 4. Develops a data collection plan using models and principles of epidemiology, demography, and biostatistics, as well as social, behavioral, and natural sciences to collect quantitative and qualitative data on a community or population. Uses methods and instruments for collecting valid and reliable quantitative and qualitative data. 5. Uses multiple methods and sources when collecting and analyzing data for a comprehensive community/population assessment. Assures that assessments are documented and interpreted in terms that are understandable to all who were involved in the process, including communities. 6. Critiques the validity, reliability, and comparability of data collected for communities/populations. 7. Identifies gaps and redundancies in data sources used in a comprehensive community/population assessment. Examines the effect of gaps in data on PH practice/program planning. 8. Assures the application of ethical, legal, and policy principles in the collection, maintenance, use, and dissemination of data and information. 9. Synthesizes qualitative and quantitative data during data analysis for a comprehensive community/population assessment. Uses various data collection methods and qualitative and quantitative data sources to conduct a comprehensive, community/population assessment. 	<ol style="list-style-type: none"> 1. Conducts comprehensive, in-depth system/organizational assessment as it relates to population health. 2. Uses organizational and other theories to guide development of system-wide approaches to reduce population-level health risks. Designs systems that identify population assets and needs, values and beliefs, resources, and relevant environmental factors. 3. Utilizes a comprehensive set of relevant variables within and across systems to measure health conditions. 4. Develops systems that support the collection of valid and reliable quantitative and qualitative data on individuals, families, and populations. 5. Designs systems that assure that assessments are documented and interpreted in terms that are understandable to all who are involved in the process, including individuals, communities, and populations. Designs data collection system that uses multiple methods and sources when collecting and analyzing data to ensure a comprehensive assessment process. 6. Designs systems to assure the validity, reliability, and comparability of data. Revises systems to assure optimal validity, reliability, and comparability of data. 7. Identifies gaps and redundancies in sources of data used in a comprehensive organizational assessment. Strategizes with relevant others to address data gaps. 8. Ensures information disseminated is understandable to the community and stakeholders. Establishes systems that incorporate ethical, legal, and policy principles into the collection, maintenance, use, and dissemination of data and information. 9. Synthesizes qualitative and quantitative data during data analysis for a comprehensive organizational assessment. Uses multiple methods and qualitative and quantitative data sources for a comprehensive system/organizational assessment.

TABLE 18-1 Public Health Nursing Competencies, Domain 1: Analytic and Assessment Skills—cont'd

Tier 1: Generalist	Tier 2: Specialist/Mid-Level	Tier 3: Executive/Senior-Level
10. Collects quantitative and qualitative data that can be used in the community health assessment process. Assesses data collected as part of the community assessment process to make inferences about individuals, families, and groups.	10. Incorporates an ecological perspective when analyzing data from a comprehensive community/population assessment. Partners with groups, communities, populations, health professionals, and stakeholders to review and evaluate data collected.	10. Incorporates ecological perspective when analyzing data from a comprehensive, system/organizational assessment as it relates to population health.
11. Utilizes information technology to collect, analyze, store, and retrieve data related to public health nursing care of individuals, families, and groups.	11. Utilizes information technology effectively to collect, analyze, store, and retrieve data related to care of communities and populations.	11. Collaborates with others in the design of data collection processes and applications that facilitate the collection, use, storage, and retrieval of data.
12. Practices evidence-based public health nursing to promote the health of individuals, families, and groups.	12. Practices evidence-based public health nursing to promote the health of communities and populations.	12. Practices evidence-based public health nursing to create and/or modify systems of care. Utilizes data to address scientific, political, ethical, and social public health issues.
13. Uses available data and resources related to the social determinants of health when planning care for individuals, families, and groups.	13. Collects data related to social determinants of health and community resources to plan for community-oriented and population-level programs. Analyzes those data. Incorporates the results of those analyses into program planning.	13. Evaluates organization/system capacity to analyze the health status of the community/population effectively. Allocates organization/system resources to support the effective analysis of the health status of the community/population.

From Swider SM, Krothe J, Ryes D, and Cravetz M (working group for the QUAD Council): [The QUAD Council practice competencies for public health nursing](#), *Public Health Nursing* 30(6):519-526, 2013.

Assessing the health of the community requires a broad definition of health, including consideration of the economic, social, physical, and mental health of the population. Access to resources that provide for these broad needs and services will be part of the assessment process.

The PHN should place the assessment of community strengths as high on the list as recognized problems in the development of an assessment plan. It is important to value both in the assessment, planning, implementation, and evaluation process.

...Healthy Communities initiatives are better served by assets-oriented methods than by standard “problem-focused” or “needs-based” approaches. An assets orientation allows community members to identify, support and mobilize existing community resources to create a shared vision of change, and encourages greater creativity when community members do address problems and obstacles (Sharpe et al, 2000).

Communities have both resources and needs. We recommend a balanced approach to the assessment, highlighting community assets as well as problems to identify the community vehicles already present for positive change. Community strengths can later be called upon in the planning and intervention phases of the process to address the challenges the community faces. This strength-based approach may be better received by communities and funders, and promotes the inclusion of key informants and interested stakeholders; it can make strategic planning a part of the process.

Data Sources

Health Status Indicators

Measures of health status take more than one form. Numerical data put out by a recognized agency (such as the U.S. Census Bureau or Centers for Disease Control and Prevention, or Robert Wood Johnson Foundation) are referred to as *secondary* data (collected by someone else). Information that is gleaned from telephone surveys, personal interviews, or focus groups conducted by those who are assessing the community—any data derived from personal connections or key informants—are considered *primary* data (collected by the assessor[s]). Both types of data are required for the community assessment and both types of data will be included when analyzing the assessment data.

Secondary Sources of Data

Even before setting foot in the community it is possible to learn a great deal about its residents' health status. **Health indicators** are numerical measures of health outcomes, such as morbidity and mortality, as well as determinants of health and population characteristics. Generally, these data are from *secondary* sources such as websites or printed materials. [Table 18-2](#) lists several of these sources.

Creation of a set of health indicator data during a community health assessment serves several purposes. First, it creates a “snapshot” of health conditions that can guide the assessment team during the analysis and problem prioritization phases. Second, it is an important and easily comprehensible means of communicating the results of the assessment to the larger

U.S. Census	http://www.census.gov	Demographic and economic data

community. Third, it is an effective way to compare the current health status in the community with the same community at different time points, with other communities, or with larger populations such as state or national data. Table 18-3 lists health indicators that are frequently included in community health assessments.

There are two important considerations for selecting which indicators to include in an assessment: the priorities of the community, and comparability to other data. Ideally, diverse community **stakeholders** should participate in identifying health indicators that address their interests or concerns. Stakeholders include anyone with a personal or occupational interest or concern in a community's life. If the health indicators will be compared with other assessments, then use similar measures when possible. For example, the total number of deaths in a community is different from the annual rate of deaths per 100,000 population. The box below gives additional tips on obtaining high-quality data.

SECONDARY SOURCE DATA

Questions to ask about data from secondary sources:

1. How current is the reported information?
2. When was the site last updated?
3. How credible is the data source?
4. Is an author identified?
5. Are demographic data reported about the people?
6. Are data reported about different community systems?
7. Is there any obvious bias in the reporting of data?
8. Are community voices represented?

Shuster, G: *Community as client* assessment and analysis. In Stanhope and Lancaster (editors), *Public Health Nursing, Population-centered health care in the community*, ed 8, 2012 Elsevier, St. Louis, Mo.

Healthy People 2020 and County Health Rankings are useful resources for health indicators. *Healthy People 2020* identifies national health priorities, providing baseline data as well as

health indicator goals. For example, the baseline rate of injury-related mortality was 59.7 deaths per 100,000 population and the *Healthy People 2014* goal rate is 53.7 deaths per 100,000 population (www.healthypeople.gov). The County Health Rankings report is updated annually, and provides county-level data for a wide variety of health indicators and also compares county rankings within and across states (www.countyhealthrankings.org).

Primary Sources of Data

Primary data involve the researcher or community members at the community level. Various methods can be used to collect the data, such as participant observation, key informant interviews, surveys, town hall meetings, focus groups, Photovoice, spatial data, or windshield surveys. The researcher or the community members experience the events or interact directly with the community as a group, with individuals, or by observation.

Participant observation refers to the deliberate sharing in the life of a community, for example, participating in a local fair or festival or attending a political or social event. Just as you would assess a hospital patient's room upon entering and note details about the environment (family members, emotional tone, patient's level of consciousness, IV access or vital signs, cleanliness, organization), visiting or attending an event can be a window through which to view the community. In addition, participant observation can be a fun way to experience community events.

Key informants can be identified through formal or informal channels in the community. They might be leaders in a sector of the community such as a church congregation, civic club, governmental body or neighborhood. They need not hold any formal title, but are generally viewed as community leaders by other community members and often have a long history in the community. Meeting with key informants and identifying local issues, strengths, and concerns from their viewpoint constitutes an important component of the overall assessment. See **How To box** for more information.

TABLE 18-3 Health Status Indicators: Frequently Recommended Health Metrics

HEALTH OUTCOME METRICS		HEALTH DETERMINANT AND CORRELATE METRICS			
Mortality	Morbidity	Health Care (Access & Quality)	Health Behaviors	Demographics & Social Environment	Physical Environment

HOW TO Identify a Key Informant

- Talking to key informants is a critical part of the community assessment.
- Key informants are not always people who have a formal title or position.
- Key informants often have an informal role within the community.
- County health department nurses and church leaders are often key informants. They also know many community members and can identify other key informants.

Shuster, G: *Community as client* assessment and analysis. In Stanhope and Lancaster (editors), *Public Health Nursing, Population-centered health care in the community*, ed 8, 2012 Elsevier, St. Louis, Mo.

Town hall meetings are opportunities for local constituents to come together, usually to discuss a particular issue or proposal that influences all members of the community. Many town hall meetings have been held recently, for example,

to address the issue of health care reform. The following photo represents one town hall meeting held for that purpose in Hartford, Connecticut, in 2009. Political rallies and delegate forums are often held in this format.

A **focus group** is similar to an interview, in that it collects data mainly through asking open-ended questions to participants but to a small group rather than an individual. Focus groups are useful for situations where the interaction between participants is likely to prompt discussions or generate ideas that individual interviews might not. Focus groups work well when the topic is not a sensitive one and participants feel comfortable speaking out about the issue with the group. For example, an assessment of the role of a parks and recreation department used focus groups to prompt discussions about individual experiences as well as perceptions about the larger community (Henderson et al, 2001).

Focus groups should be structured to balance a diversity of perspectives with opportunities for in-depth understanding of the chosen topics. The design of the question guide should address the goals for the data: for example, do you want to generate a free-flowing discussion of ideas or obtain specific information from each participant? Participants should be recruited through community channels such as churches, associations, and other places where people gather. An ideal number of participants is between six and eight, though smaller or larger groups can work in different circumstances (Rabiee, 2004).

Each focus group should be organized so that its participants are fairly homogenous in key characteristics. For example, in an assessment to compare different neighborhoods, each focus group might contain residents from one neighborhood. In an assessment of community barriers and resources for physical activity, focus groups might be divided among participants who identify themselves as exercisers, and non-exercisers (Lees et al, 2005). A typical format for a focus group is that one moderator leads the discussion, while an assistant takes written notes, and the session is often audio recorded. The recording is then transcribed and included in the analysis.

Photovoice

Photovoice, also called photo elicitation, is a community assessment technique in which community members take photos to represent a topic or theme about community health. For example, a study on childhood obesity asked rural youth to take photos on the theme of assets and barriers to healthy diets and physical activity (Findholt, Michael, & Davis, 2010). Photovoice has been used with many types of community participants, but can be especially useful in working with groups that may be marginalized or have little power such as youths, the elderly, individuals living in poverty, or those involved in substance abuse. Photovoice is a way for participants to communicate powerful messages about their experiences, without the need for words.

Photography is a relatively easy group activity because devices to take photos are relatively common and inexpensive. Disposable cameras and the participants' cell phones are examples of devices with minimal added cost. Video, sound recording, and other forms of media can also be used in ways similar to Photovoice. For example, a group of New Orleans residents used Videovoice to create their own documentary to advocate for housing, education, and economic development after Hurricane Katrina (Catalani et al, 2013).

The basic process to incorporate Photovoice into a community assessment is as follows:

1. **Train participants:** Participants receive training in Photovoice methods, including the topic of interest, basic photography techniques, and ethical and safety issues. Participants may need to learn how to obtain written consent before photographing people, businesses, or other identifiable subjects. Training is especially important when the topic of interest is sensitive or illegal, such as substance abuse.
2. **Take photos:** Participants take the cameras into their communities and take photographs that reflect the topic. Equipment should be modified to fit the participants. For example, adolescents may be very comfortable with a variety of mobile devices, whereas older adults may prefer simpler cameras with modifications for low vision or manual dexterity (Novek et al, 2012).
3. **Display photos:** The photos are collected from the participants, and then printed or digitally projected for group participants, and sometimes members of the public, to view them.
4. **Discuss photos:** Viewing the photos is meant to spark discussions that provide additional information about the topic of interest. These discussions may take place as focus groups with the Photovoice participants. If the photos are displayed in public, the aim may be to raise awareness and to start conversations among diverse stakeholders.
5. **Analyze and report results:** The information gathered through these discussions, as well as the photos themselves, can be included in the data analysis phase. The photos can also be part of the report to the community about the findings of the community assessment (Catalani & Minkler, 2010).

Photovoice can be useful at different stages of a community assessment, but may be especially useful in the early stages of data collection. The “insider” knowledge gained through this type of activity can guide subsequent community assessment activities. For example, if the Photovoice topic is “barriers to healthy lifestyles” and the majority of photos focus on places that make pedestrian or bike travel difficult, then the later stages of the assessment should give additional attention to walkability and transportation.

Spatial Data

Everything is related to everything else, but near things are more related than distant things.

Tobler's First Law of Geography (Sui, 2004)

Most of the information gathered in a community assessment has a spatial component: it is located somewhere in the community. The location of places like health care services, food stores, schools, bus routes, factories, highways, bodies of water, and parks can affect residents' access to health benefits or exposure to health threats. Demographic data can also be spatial. We can look at a neighborhood or other area and learn about its residents, such as age, racial or ethnic background, health characteristics, income, home value, and crime rates. Having this information can be very helpful for assessing health resources

and risks for specific neighborhoods. By assessing the spatial distribution of health resources and disparities, we can place programs in neighborhoods where the impact will be greatest.

Maps have several uses in community assessments. Maps are a place to compile **spatial data** from primary or secondary sources. During the problem analysis and prioritization phases, these maps can support decision making about community health priorities. Later, maps can be used to plan programs and interventions. Like the idea that “a picture is worth a thousand words,” a map can also be an effective means of communicating the findings of a community health assessment to a wide range of stakeholders, and encouraging their participation in discussions about the findings.

Map-making is very flexible, depending on the resources that are available. A map can be as simple as a hand-drawn sketch of features in a community or neighborhood. Drawings or graphics can be added to commercially produced paper or online maps. **Geographic information systems (GIS)** is a set of software and technology that can create maps electronically. The amount of training to use GIS software varies. Some free websites allow users to build GIS maps without any prior training. For example, www.communitycommons.org has demographic, health, and economic data that can be used to build a map of a specific place. More powerful software, such as ESRI ArcGIS, can analyze spatial data and display it using a variety of visual options. This type of software is sometimes expensive and time-consuming to learn, but is very useful for those who want to use maps regularly in their work.

During a community assessment spatial data can be collected in several ways. One low-tech approach is to note the address or nearest street intersection of a place and later draw it onto a map. A higher-tech approach can involve a smart phone or other mobile device that has *global positioning system (GPS)* capabilities. While walking around a community, these devices can be used to note locations by recording the latitude and longitude coordinates. Some smart phones and other devices can take photographs that store the GPS location. These photos can later be incorporated into GIS maps as images or hotlinks.

GIS can pull together multiple types of assessment data that, when viewed on a map, can identify areas of a community with a particular set of characteristics. For example, nurses used GIS to look for patterns between traffic pollution and childhood asthma (Newcomb & Li, 2008). They found that children living near a major roadway were much more likely to experience hospital admissions for asthma.

Using Primary Data

Informant interviews, focus groups, and participant observation are good ways to generate information about a community's unique beliefs, norms, values, power and influence structures, and problem-solving processes. These primary data can be time-consuming and challenging to collate and interpret. However, it is worthwhile to make the effort to systematically collect primary data in the community and to avoid drawing conclusions from limited observations or unconfirmed intuitions.

Contradictions within the data collected are common. If there are disconnects or the two types of data do not match, this is important information to consider for your assessment and program planning. Reports from different members of a community may not agree. Information from primary data should be compared to secondary data which can provide context about a community's assets and needs. What is important is that the voice of the informant or group is heard and that the assessor in the community takes all information into account at the time of data analysis. In addition, the priorities of the community members must be included in any planning or implementation of interventions.

Community Health Assessment Models

There are many existing models of community health assessment, making it possible to conduct an assessment without the need to design the process from scratch. Table 18-4 provides examples of commonly used models that assess for a broad array of community health concerns. The WHO's Healthy Cities initiative offers another approach to population-centered health assessment. An example of the assessment data that support this approach is found at <http://www.healthycity.org>. For additional information on Healthy Cities see Chapter 20.

Other assessment models focus on specific topics. For example, the CDC (2014b) developed the Community Assessment for Public Health Emergency Response (CASPER) toolkit for rapid needs assessment of communities affected by disasters or other emergencies (retrieved from <http://www.cdc.gov/nceh/hsb/disaster/casper.htm>). The Community Food Security Assessment Toolkit profiles food availability and accessibility by collecting data from focus groups, food stores, and secondary data sources (Cohen, Andrews, & Kantor, 2002). Another example is the Neighborhood Environment Walkability Survey (NEWS), a toolkit to assess the physical and social aspects of a community related to walking and bicycling (Saelens & Sallis, 2002).

The selection of an assessment model and whether to use an existing model or design your own can be guided by several criteria (Ervin, 2002). What are your goals for the assessment? What are the resources available for the assessment project, such as time, people, budget, and access to the community? Is there an existing model that aligns with your goals, and is feasible in terms of your available resources?

COMMUNITY AS PARTNER

The **community-as-partner** model is based on nursing processes and theories, and emphasizes the dynamic nature of community systems as integral to the health of residents (Anderson & McFarlane, 2011). A key feature of this model is its division of the community structure into subsystems that can serve as an organizational structure for community health assessments. The subsystems of the community structure consist of physical environment, health and social services, economy, transportation and safety, politics and government, communication, education, and recreation. Each of these subsystems represents distinct functions and organizations within the community that can be assessed separately. However, they also interact to create

TABLE 18-4 Interprofessional Community Health Assessment Models

Assessment Model	Example
<p>Health Impact Assessment (HIA) is a process to predict the effects on health from projects or policies such as land use, community design, transportation, or industrial facilities. The outcome of an HIA is to provide recommendations to minimize negative health impacts, and monitor results. <i>Learn more at http://www.naccho.org/topics/environmental/health-impact-assessment/</i></p>	<p>An interdisciplinary group of public health experts, health care professionals, and community planners used an HIA to estimate the impact of a proposed multibillion-dollar project in Atlanta, GA, to redevelop a 22-mile loop into transit, parks, and improved neighborhoods. One HIA recommendation was to develop parks and green spaces first, in order to maximize health benefits (Ross et al, 2012).</p>
<p>Mobilizing for Action through Planning and Partnerships (MAPP) is a strategic planning process to select high-priority public health issues and to match them with resources. Public health agencies lead the MAPP, but participation of community members and agencies is a major focus. <i>Learn more at http://www.naccho.org/topics/infrastructure/mapp/</i></p>	<p>A public health department in Virginia assessed the 5 counties and independent city in its district to identify top health issues needing action. Through partnerships with 61 agencies and gathering data from more than 2,000 residents, the MAPP process selected top priorities as obesity, mental health and substance abuse, pregnancy outcomes, and tobacco use (Thomas Jefferson Health District, 2012).</p>
<p>Community Health Assessment and Group Evaluation (CHANGE) is a tool to help communities annually gather and organize data about community health, plan programs, and monitor changes over time. Five community sectors are assessed: community at large, community institution/organization, health care, school, and work site. <i>Learn more at www.cdc.gov/HealthyCommunitiesProgram (CDC 2010)</i></p>	<p>Researchers in a rural Missouri county used the CHANGE tool to assess why rates of chronic disease were high. Through interviews with representatives from each of the 5 sectors, they identified challenges, assets, and potential partnerships for addressing chronic disease (Stewart, Visker, & Cox, 2013).</p>
<p>Community Health Needs Assessment (CHNA) is a set of guidelines for nonprofit hospitals to assess the communities they serve, and is a requirement under the Patient Protection and Affordable Care Act (ACA). Community input and other sources provide data on priority health problems, barriers to health care access, and vulnerable populations. <i>Learn more at http://www.cdc.gov/policy/chna/ (Rosenbaum 2013)</i></p>	<p>Nursing students partnered with a hospital in rural Minnesota to complete the CHNA. They gathered data through surveys and interviews with residents and organizational leaders. They identified 3 priority health problems, and differentiated assets and barriers to addressing these problems in different community institutions serving vulnerable populations (Madelia Community Hospital & Clinic, 2013).</p>

the complex community environment in which people live and function. Each subsystem may protect the health of community members by addressing a particular need. Understanding the relative success of each of these subsystems in promoting health and safety can provide important insights about the community's ability to respond to health problems

HOW TO CONDUCT A COMMUNITY ASSESSMENT

Getting Started

In the previous section several models of community assessment are outlined. This section will offer a step-by-step method to complete a community assessment. In beginning the assessment the nurse should identify one model that will guide the assessment. We incorporate the steps for the assessment in Figure 18-2, but this process can be adapted to any model used.

The community assessor(s) should plan to visit and interact in the community and collect data about *people, place, and function* over a month or more to get a feel for the community and create as full a picture as possible. A “feet on the ground” approach will yield rich data and visiting the community and interacting with its members is essential to the process. Very comprehensive assessments will require community coalitions and inclusion of key stakeholders, such as those included in MAPP assessments; expanding the participant group may extend this stage over many months or years (NACCHO, 2014;

www.naccho.org). See Box 18-3 for information on personal safety while assessing communities.

Windshield Survey

Windshield surveys are a method of simple observation. They provide a quick overview of a community and can be used along with photographs and interviews to get a general overall sense of the community (Table 18-5). This can be the first step in the process of generating data that help to identify the community, trends, stability, and changes that all serve to define the health of the community (Stanhope & Knollmueller, 2000). The nurse riding in a vehicle can observe many dimensions of a community's life and environment through the windshield, but walking the streets can also provide similar information. Under those circumstances, one can readily observe common characteristics of people in the community, neighborhood gathering places, the rhythm of community life, housing quality, and geographic boundaries (see How To box and Table 18-5). A windshield survey can be used by itself for a short and simple assessment. However, it is used here as one part of the longer, more complex comprehensive community assessment.

Community “Place” and “People” Identified

Using Figure 18-2, the first step of the community assessment is to define the community. To do this, geographic boundaries, the population within the boundaries, the purpose of the assessment, and a data collection plan will be identified. Census

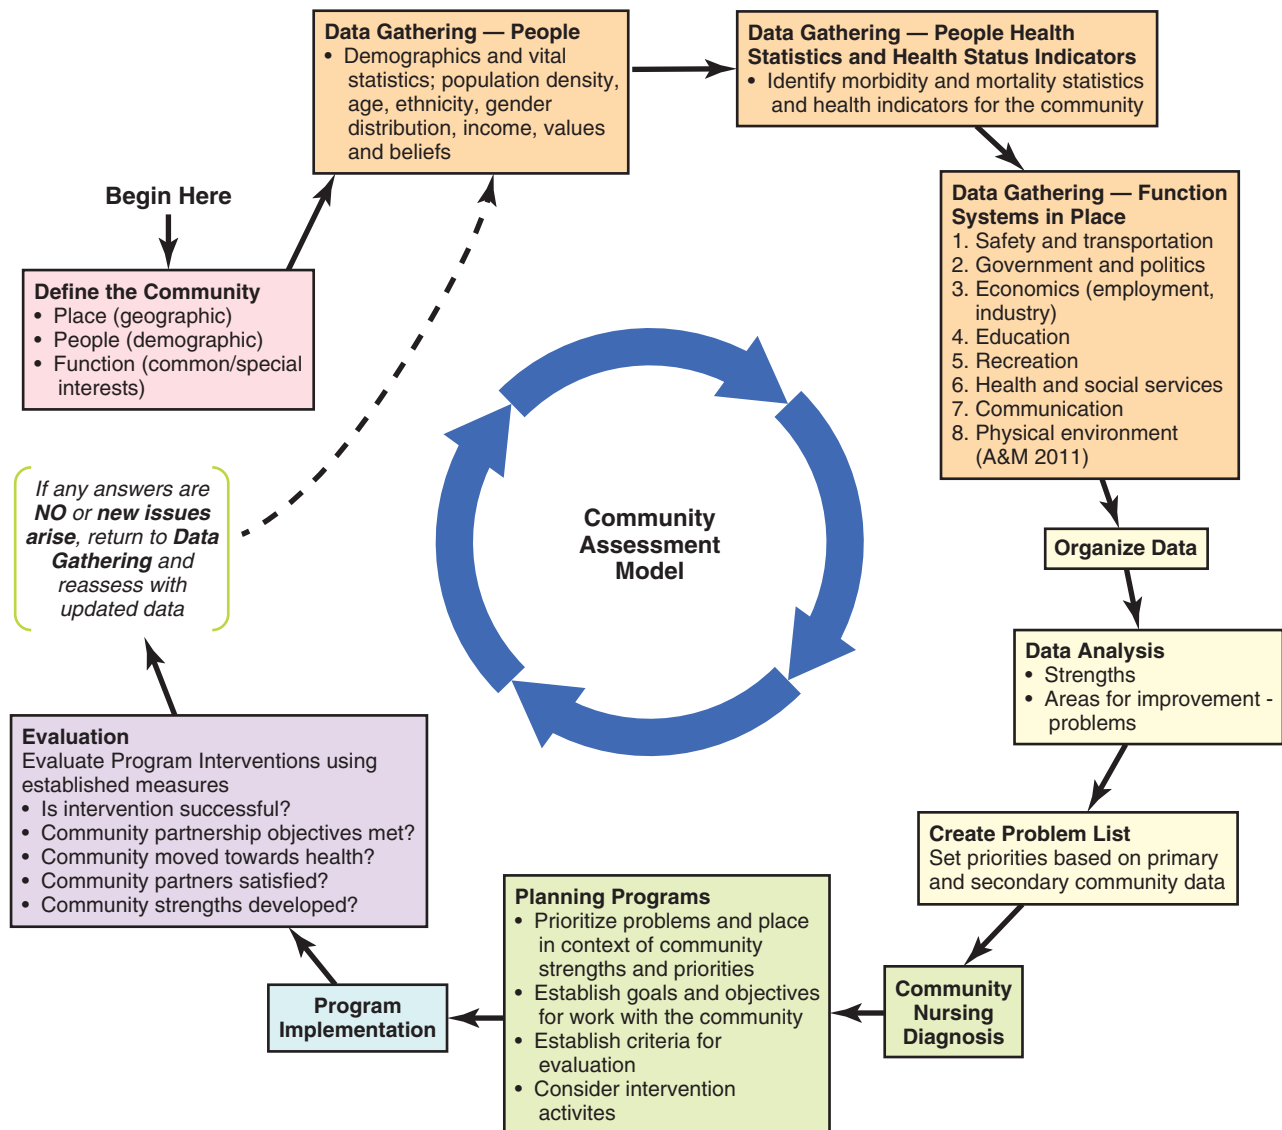

FIG 18-2 Community assessment model.

BOX 18-3 Personal Safety in Community Practice

Effective nursing practice starts with personal safety, and this remains important throughout the process. An awareness of the community and common sense are the two best guidelines for judgment. For example, common sense suggests not leaving anything valuable on a car seat and not leaving your car unlocked. Similar guidelines apply to the use of public transportation. Calling ahead to clients to schedule meetings will help prevent delays or confusion, and it gives the nurse an opportunity to lay the groundwork for the meeting. If there is no telephone and no access to a neighbor's telephone, plan to establish a time for any future meetings during the initial visit. Regardless of whether there has been telephone contact, there are rare situations when a meeting is postponed because the nurse arrives at a location where people are unexpectedly loitering by the entrance and the nurse has concerns about personal safety.

For nurses who either are just beginning their careers in the community or are just starting a new position, three clear sources of information will help answer many questions about personal safety:

1. *Other nurses, social workers, or health care providers who are familiar with the dynamics of a given community:* They can provide valuable insights into when to visit, how to get there, and what to expect, because they function in the community themselves.
2. *Community members:* The best sources of information about the community are the community members themselves, and one benefit of developing an active partnership with community members is their willingness to share their insight about day-to-day community life.
3. *The nurse's own observations:* Knowledge gained during the data collection phase of the process should provide a solid basis for an awareness of day-to-day community activity. Nurses with experience practicing in the community generally agree that if they feel uncomfortable in a situation, they should trust their instincts and leave.

TABLE 18-5 Windshield Survey Guidelines

Each community has its own characteristics. These characteristics along with demographic data provide valuable information in understanding the population that lives within the community and the health status, strengths/limitations, risks and vulnerabilities unique to the “population of interest.” Once you have defined a “community of interest” to assess, a **windshield survey** is the equivalent of a community head-to-toe assessment. The best way to conduct a windshield survey is with more than one person, allowing for one to observe and take notes. Having one pair of eyes on the road, you can benefit from having other individuals notice the unique characteristics of the community; a shared experience provides additional insight. As you analyze your findings, it may be necessary to make a second tour to fill in any blanks. Many of us take these characteristics for granted in our own community, but they provide a rich context for understanding communities and populations and often have significant impact on the health status of the community in general.

Elements	Description
Boundaries	What defines the boundary? Roads, water, railroads? Does the area have a name? A nickname?
Housing and zoning	What is the age of the houses? What kind of materials are used in the construction? Describe the housing including space between them, general appearance and condition, and presence of central heating, air conditioning, and modern plumbing.
Open space	Describe the amount, condition, use of open space. How is the space used? Is it safe? Attractive?
Commons	Where do people in the neighborhood hang out? Who hangs out there and at what hours during the day?
Transportation	How do people get from one place to another? If they use public transportation, what kind and how effective is it: How timely? Personal autos? Bikes, etc? Are there pedestrians? Does the area appear to be safe?
Social service centers	Do you see evidence of recreation centers, parks, social services, offices of doctors, dentists, pharmacies?
Stores	Where do residents shop? How do they get to the shops? Do they have groceries or sources of fresh produce? Is this a “food desert”?
Street people and animals	Who do you see on the streets during the day? Besides the people, do you see animals? Are they loose or contained?
Condition of the area	Is the area well kept or is there evidence of trash, abandoned cars or houses? What kind of information is provided on the signs in the area?
Race and ethnicity	What is the race of the people you see? What do you see about indices of ethnicity? Places of worship, food stores, restaurants? Are signs in English or other languages? (If the latter, which ones)?
Religion	What indications do you see about the types of religion residents practice?
Health indicators	Do you see evidence of clinics, hospitals, mental illness, and/or substance abuse?
Politics	What indicators do you see about politics? Posters, headquarters?
Media	Do you see indicators of what people read? If they watch television? Listen to the radio?
Business & industry	What type of business climate exists? Manufacturers? Light or heavy industry? Large employers? Small business owners? Retail? Hospitality industry? Military installation? Do people have to seek employment elsewhere?

Adapted and revised by J. Lancaster from: Mizrahi TM: School of Social Work, Virginia Commonwealth University, Richmond VA, September 2008; Stanhope MS, Knollmueller RN: *Public and Community Health Nurse's Consultant: A Health Promotion Guide*, St. Louis, 1997, Mosby.

HOW TO Obtain a Quick Assessment of a Community

- One way to get a quick, initial sense of the community is to do a windshield assessment using a format like the example provided in Table 18-5.
- Nurses interested in conducting a windshield assessment need to take public transportation, have someone else drive while they take notes, or plan to stop frequently to write down what they see.
- The windshield survey example is organized into 15 elements with specific questions related to each element.
- Nurses who use this approach will have an initial descriptive assessment of the community when they are finished.
- If interventions are planned, the more thorough and more comprehensive process described in this chapter will be necessary.

Shuster, G: *Community as client* assessment and analysis. In Stanhope and Lancaster (editors), *Public Health Nursing, Population-centered health care in the community*, ed 8, 2012 Elsevier, St. Louis, Mo.

blocks or tracts and geopolitical boundaries such as city or county lines will allow for collection of consistent data about the region under study. Included in “place” is the type of terrain or environment, the climate, the history of the area, and its size. The population is the next identifier. How does your assessment define those within the community? Are they members of a specific group or the population in general? What data are available for the assessment and where will you seek your sources? In essence, the identification of the community’s members comprise the “client” within these boundaries.

What is the local history? Who were the original settlers and how has the community developed over time? Is it an area of growth or decline? Are original families still living in the area or has the early population been replaced? History can reveal a lot about customs and mores that could influence the health of the community.

PLACE

- Boundaries
- Environment
- Size
- Climate
- History
- Population

People

Those inhabiting the community are a primary focus of the assessment. Various strategies can be used to identify this central core of the community. The first step often involves the use of secondary data. Using census data clarifies the population density and the demographics of the population under study. Suggested websites for the collection of these data are provided in Table 18-2. Some demographic measures include the population composition—racial and ethnic groups present, ages, socioeconomic status and poverty rates as related to geographical area; educational attainment; and the distribution of the population over census areas. Next, review this information in the context of previous census data (e.g., look back 20 years) to demonstrate how age groups are shifting. For example, if particular age groups are increasing in numbers, that can help to predict needs; if the area is shrinking or growing in population, that will predict different needs.

For quick information estimates on a specific area, consult American FactFinder (<http://factfinder2.census.gov>). Perhaps one racial or ethnic group inhabits a particular area of the community. Census data will help identify this information. That may be important later in the PHN's assessment process for understanding morbidity and mortality data. Many states have websites that can help to predict population projections for localities. In Virginia, for example, one can visit www.virginialmi.com to see projections and historical census data for each county or independent city, helping to visualize trends.

As a next step, the PHN will identify formal and informal structures within the community. What formal and informal groups exist in the community? What structures are present that unite or separate people in the society? This will require interviews and delving into the community. For example, local government, schools, churches, and health care organizations may represent formal structures. Clubs (e.g., Rotary Club, garden clubs, country club, YWCA or libraries) may reflect informal groups that could form in neighborhoods, where an informal leader could be the advisor to that group on matters of all kinds, including housing, health or legal matters. These informal leaders can be identified through interaction with the community members and by visiting community agencies. There are likely crossovers between formal and informal groups. Pay attention to advocacy groups and those that have goals of improving the community or some subset of the community in some way. This can help to identify community assets.

Carefully examine the formal and informal structures that exist and consider if they unite the population of the community or support only a specific portion of the population. Who are the leaders? For example, a private school might support only a more prosperous portion of the community or the school might reach out into the community to offer scholarships for those in different socioeconomic strata. Public schools might have broad support and funding or garner limited resources from local coffers. Some of this information may be evident but some may require deeper investigation and interviews with key informants. Leaders of formal groups may be key informants, but leaders of informal groups should be considered key informants as well.

The assessment would not be complete without an inventory of the community belief systems in place, including identifying places of worship. This could be accomplished through both primary and secondary data, by speaking to community members or by looking in the phone book. Traditions and values of the community may be classified according to portions of the community if it is heterogeneous, or in general if it is more homogenous. How the religious climate in the town might influence other goods or services should be investigated. For example, a community may have a religiously conservative population that could influence the availability or access to abortion counseling or certain birth control services for residents.

PEOPLE

- Size and density of population
- Demographic structure of population (e.g., race, ethnic groups, gender, and age) currently and in historical context
- Educational attainment
- Informal groups
- Formal groups
- Linking structures
 - Schools
 - Neighborhood associations
 - Civic clubs
- Values and beliefs
 - Churches
 - Synagogues
 - Mosques
 - Political affiliations

Community Systems in Place

Using a systems approach, the PHN can explore the organizing structures in place within the community that may serve the needs of the people. Community systems contributing to community function or dysfunction include safety and transportation; politics and government; economics (including industry, employment, and commerce); education; recreation; health and social services; communication; and physical environment (Anderson & MacFarlane, 2011). Each of these functional systems influences the health of the community and requires full assessment.

COMMUNITY SYSTEMS IN PLACE

- Safety and transportation
- Politics and government
- Economics (employment, industry)
- Education
- Recreation
- Health and social services
- Communication
- Physical environment

Source: Anderson and MacFarlane (2011), *Community as partner*, Philadelphia, Lippincott Williams & Wilkins.

Safety and Transportation. Safety requires a broad assessment. Road maintenance and presence of interstate highways or curvy mountain roads will influence the safety of the community. The PHN should identify statistics on highway safety and find information about motor vehicle fatalities and moving violations, seatbelt use, and child safety seat use in the area. For example, in Virginia one can go to the state Division of Motor Vehicles site and locate the sites of most frequent motor vehicle accidents according to cause and location (http://www.dmv.state.va.us/safety/#crash_data/). Likewise, many county websites have information about motor vehicle accidents or fatalities in their jurisdictions. Safety also includes crime rates, issues such as sidewalks or guard rails along roadsides, crosswalks in intersections, safe playgrounds, and bike paths. Police, fire protection, and emergency services also fall under the umbrella of safety, as do laws requiring helmets for motorcyclists.

Following the crime statistics for the area or individual neighborhoods in your community can provide good evidence of the effectiveness of the police force and an overall measure of citizen safety. In addition, qualitative information gained from speaking to locals and service providers can add valuable perspectives about their experience with community safety.

Community residents frequently depend on public transportation to access community services. When doing a community assessment, the PHN should survey the availability of affordable community transportation for all income levels. To do this, one should look at whether transportation options such as buses, commuter trains or cabs are present to allow access to central places in the community. What percent of the population have cars? It is also helpful to know if there are railroads and airlines available to connect to more regional or national sites. This can provide insight on potential community permeability to outside influences or community isolation.

Politics and Government. The PHN will need to identify the type of government structures in place in the geographic area. Many communities have websites that will help clarify this community governance. Is there a mayor or board of supervisors? Who are the identified formal leaders in the government? A visit to the community's office building will provide a perspective on the accessibility of the governing body. Political affiliation in the community may be relevant to certain priorities, so identifying the mix of party allegiance in past presidential, state, or local elections is a useful measure to obtain.

Government buy-in to community needs is essential for health progress to occur. For example, what dollar amount does the community spend on child health or elderly care? Take a look at the most recent budget of the community. How does that compare with other regions of the state or United States? For example, are government-supported programs in place to enhance early childhood education? There may be overlaps with economic systems of the area as well, which affect taxation and community wealth.

Economics. Regional economic prosperity frequently influences all citizens in the population. The existing jobs, the unemployment rates, and the types of industry in the community are

all important. Identify the average income and wages for types of jobs available and identify the industries that operate within the community and what percentages of skilled and unskilled jobs exist.

In an optimal community, the jobs that are available and the educational level needed for those jobs should mesh. Frequently, community colleges identify community employment needs and promote educational programs to meet the needs of the local job market. Virginia's Labor Market Information (www.virginialmi.com) website, for example, provides detailed data on unemployment and economic indicators for each county. Data availability will relate directly to where your assessment is taking place.

The state of the job markets in the community could influence the availability of health insurance associated with employment, and the need for assistance in registering for health insurance through Affordable Care Act–created exchanges. If there are migrant workers in the community you are assessing, the issue of immigration is likely to be present. If so, what local programs or services are available for these legal or illegal immigrant workers within the community?

Education. When considering the educational systems in the community, the PHN should first identify all the schools in the area, including preschools, school readiness programs, primary and secondary schools and, if possible, visit some or all of them to observe the condition of the buildings and the children at recess or at the end of the day. What resources for nutrition, physical activity, and health care do the schools have? What percentage of the children receive free or reduced cost meals? Are there Head Start or sponsored preschool programs available for lower income families? Are there measures in place to identify school readiness? If different ethnic groups are part of the community, what is the language literacy? Coordinating this information with government spending on education in the locality will help to clarify the value that the community places on education.

The educational attainment of the population is relevant to the type of educational programs that are present in the community. Examining the high school dropout rates, standardized testing results, and the pupil/teacher ratios within the locality will help to evaluate the quality of the schools within the district. General educational development (G.E.D.) classes for students who need a high school diploma and adult literacy programs in place would indicate that the community places a high value on the education of its citizens. Higher education institutions, such as community colleges, four-year colleges, professional and technical schools, and universities will also influence the overall educational level of the community, which ultimately influences the economic prosperity of the citizens.

Recreation. Safe indoor or outdoor recreation areas for children and adults can provide the community access to healthy exercise. State, city or county parks, their condition and use, along with organized sports teams, bike paths or public gymnasiums would be indicators of public promotion of physical activities, and the importance of those to the community. If the community has hiking trails, are they well maintained? Are swimming pools open to the public? If there are lakes or rivers

nearby, do they provide guarded beaches or lifeguards? Part of the assessment of recreation addresses for whom it is available.

Identifying how the residents spend their leisure time will help to clarify recreational opportunities. Local youth and adult sports teams, movie theaters, availability of cable TV, bowling alleys, prevalence of X-rated book stores, and local statistics on drug use will contribute to the information obtained on the community.

Health and Social Services. Location of and population access to health services in the form of health care providers, emergency services, hospitals, and hospice programs are key elements in the assessment of community health. The proportion of providers who accept Medicaid or Medicare, or proportion of services available to immigrants influences the access of certain populations to services. Number and type of medical practices available can identify gaps or gluts in services for the population when compared with age groups in the community. For example, the proportions of pediatricians, obstetricians, and geriatricians should somewhat mirror the related population's age groups. Private versus nonprofit hospitals, insurance coverage, sliding scale payments, and means to reach services (proximity and transportation) all influence how health services might be used in a community. While in some communities abundant resources may be present, access to the services may be inhibited by hours of operation or limited provision of services through insurance or payment restrictions.

Number of hospitals, clinics, offices, and mental health facilities are important, but how the community uses them is a critical element in the success of health care delivery. Health care in vulnerable populations often requires care coordination, which may include home visiting, appointment arranging and transportation, development of a medical home, and the introduction of vulnerable families to resources including early childhood education, child or elder abuse prevention, and family support services. Social services in the form of community programs and state or local agencies such as community action coalitions or social service departments should be assessed. The presence of these types of services in a community would reflect positive inclinations toward holistic health for that community. Gaps in certain services represent an opportunity for program development.

Physical Environment. The climate and overall geographic description of the community contributes to health and well-being. Tendencies toward flooding, drought or hurricanes, and mountainous, ocean or riverside locations will carry concurrent health consequences. The availability of good water and air supplies and locally produced food are positive indicators for health, and should be explored within your community. Industries with poorly managed runoff of chemicals, unsafe dams or chemical waste would provide negative health indicators. Environmental pollution of any kind requires further assessment. The Environmental Protection Agency (EPA) lists information about Superfund sites throughout the country on its web-site (<http://www.epa.gov/superfund/sites/index.htm>). Scorecard (<http://scorecard.goodguide.com/>) compares localities in terms of pollutants.

The built environment, including housing and neighborhoods, provides a potential health indicator. What is the condition and age of local housing? Does the area seem prosperous? While new and energy efficient housing, including housing for low income families, can imply a positive indicator of health, older, less efficient homes appearing run down may be an indicator of less positive neighborhood conditions. For example, houses built before 1978 can contain lead paint, which represents a significant health risk for young children (Figure 18-3).

An additional important element related to housing is the average cost of owning or renting a home in the area. This information can identify housing availability and affordability for community members.

Communication. Communication in the United States has become intricately tied to Internet availability. Identifying the methods of communication within the community you are assessing will help to articulate the information available to the public and how they receive it. At which sites within the community is Internet available? Local libraries often provide free Internet access. Are there Internet providers for the community? Rural areas can sometimes have limited Internet access, thereby restricting communication with those inside or outside their locality through e-mail or Internet-based social media.

The cell phone has become a primary source of communication. Once again, looking at the availability of cell phone coverage in the community may help reveal access to those outside and within the community. While landlines are almost

FIG 18-3 Older homes are more likely to contain lead-based paint.

FIG 18-4 Cell phone ownership.

universally available and can provide communication within and outside of communities, young members of the community rely heavily on social media and texting for communication with their peers. Those sources of communication require both Internet and cell phone coverage in many cases. Today one can hardly imagine limitations on these methods, yet there are rural areas that still do not have good access to them.

Cell phones and mobile devices such as tablets, iPads, and laptops are increasingly becoming vehicles for health messages, advertising, and political messages. While ten years ago only 66% of adults had cell phones, now the number is 91%. In addition, many homes in areas of good cell coverage have disconnected their landlines and use cell coverage for all phone communication (Rainie, 2013). See Figure 18-4, which illustrates rates of cell phone ownership in the United States during the past 10 years.

In areas where tornadoes or hurricanes are prevalent, individual communities may have systems in place for communicating early warning of weather events. Such systems usually include a siren that is tested at a regular time each week and otherwise sounds only when the threat is imminent. If your community is in a high risk weather or topographic area, knowing the disaster plan can be helpful in understanding the community.

Radio or television can also provide information about imminent events. Radio or television also may provide news and advertise events to the local community. Local news can clue the community assessor into pertinent current events or community issues that are at the forefront. Newspapers can also provide interesting insights into the community's current events or issues. Some communities have numerous papers reflecting

BOX 18-4 Using the 7 "A's"

1. Is the community *aware* of its needs and of the service?
2. Is it *accessible* to community members?
3. Is the service *available* when the community needs it?
4. Can the community members *afford* the service?
5. Does the community find the service *acceptable*?
6. Is the service *adequate* to meet the needs of the community?
7. Are the services *appropriate* to meet the needs of the community?

different political viewpoints, or may target certain subsystems or aggregates in the community. They may be issued on a daily or weekly basis.

Informal methods of communication, such as signs and bulletin boards, may offer some means of transferring information at central locations in communities. Churches, local stores, and government offices such as the post office or town hall, may continue to be relevant communication hubs in small or rural communities. U.S. Postal Service, Fed Ex, and other carriers are common links to outside sources of goods and services for communities.

When these systems are robust, they afford degrees of protection for the community and its health. Weaknesses in the systems may permit health threats to enter the community. For example, a lack of sidewalks on a main street could result in pedestrian injuries or fatalities. The stronger and more focused the services/systems in place are toward individual community needs, the stronger the community resilience will be against outside threats to optimal health (Figure 18-5). Assessing the strength of systems can be a measure of the strengths of the community. When the systems are not intact or are insufficient to meet the needs of the community, the possibility of poorer overall health of the community increases. The systems in place may act as protective factors against negative outside forces that could threaten the community. For example, a strong school immunization program could offset a measles epidemic. Table 18-6 provides more information on assessing these systems.

The Seven "A's"

Once the PHN has identified and cataloged the systems of the community, then it is most helpful to measure their effectiveness. One method that can be used to evaluate adequacy of services or systems in a community is the "7 A's." A series of queries about a service or system's effectiveness in reaching the community can be used with any of the above listed community components. The 7 "A's" are *awareness*, *access*, *availability*, *affordability*, *acceptability*, *appropriateness*, and *adequacy* (Truglio-Londrigan & Gallagher, 2003). Asking questions about an agency or service using the 7 "A's" can help to identify how well the service or system is meeting the needs of the community. Box 18-4 explains how to use the 7 "A's" to craft questions to assist in gauging the value of existing services, or in identifying assets in the community or opportunities for improvement.

FIG 18-5 Optimal community systems in place to protect the public. (Data from Anderson ET and MacFarlane J: *Community as Partner: Theory and Practice in Nursing*, ed 6, Philadelphia, 2011, Lippincott Williams & Wilkins.)

Data Analysis

Once the data are assembled, you will have stacks of papers and multiple computer files. One systematic way to organize your data is to follow a pattern of collating the information according to the section of the assessment and the systems. Follow the model that you have chosen to order your information. You can create tables of census and **demographic data**, indicating a comparison of your community's data to state data and national data. Identify ages, gender, marital information, births and infant deaths, race or ethnicity, and density of the population and assemble the information into a table. This helps you to see the information at a glance. Identify whether the population in your community is on the rise or declining and which age and ethnic/racial groups are increasing or decreasing. How many families live below the poverty level? These items of information can pinpoint areas where needs may be increasing. Census data provide rich information about how many people live in your community and historic data about population size, composition, and income. Be sure that your data are the most recent and that when you compare data that you are comparing data reported in the same format and from a reliable source.

Next, organize all data, primary and secondary, related to each of the systems. You may decide to make tables about these data as well and make a report on the data available for each system. Be sure to include the community assets you have identified for each system, as well as any observed deficiencies. Do the perceived issues of the community match your secondary data? Synthesize the data into a coherent report based on each system (See **QSEN** box).

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Client-centered Care

Recognizes the client or designee as the source of control and as a full partner in providing compassionate and coordinated care that is based on the preferences, values and needs of the client

Knowledge: understanding of multiple dimensions of client-centered care

Skill: for individual, family, aggregate, or community elicits values, preferences, and expressed needs as part of clinical interview

Attitude: support care for each client level whose values differ from one's own

Question

The Quad Council core competency of analytic and assessment skills indicates the beginning PHN should collect data, both quantitative and qualitative, to be used in community assessment. The PHN then assesses data collected as part of the community assessment process to make inferences about clients (values, culture, preferences for health care)

In order to develop, revise, or even improve community health care delivery, how would the PHN use the outcomes of the community assessment? What steps would the nurse take to make change based on client choice?

Morbidity and **mortality** data should be tabulated identifying the top three causes of morbidity and mortality and also comparing the local data to the state, national, and previous years' local data. Are there conditions in the causes of illness or death that are rising or declining? Looking at this information and linking with the information derived from primary data

TABLE 18-6 Community Systems: Potential Measures**Safety and Transportation**

- Crime rates and trends
- Traffic accidents and fatalities
- Fire stations and emergency responders and response times; publicly paid or volunteer?
- Police protection and public perception thereof
- Highway system and road conditions
- Availability of public transportation in, out of, and around the community
- Commuters to and from the community and methods of commute
- Child car seat assistance

Politics and Government

- Type of local government
- Budgets for public services/systems
- Diversity in government offices match to community diversity (e.g., mayor, board of supervisors, etc.)
- Local tax base and taxes levied
- Party affiliation of county majority

Economics

- Average income
- Percentage of families who own their homes
- Automobile ownership
- Number of children eligible for free lunches
- Unemployment figures/types of jobs available
- Families on unemployment compensation
- Percentage of food stamp recipients
- Poverty statistics
- Industries in place/largest employers/size of most businesses
- Available child care

Education

- Number and types of primary and secondary schools (public vs. private)
- Number and access to community and four-year colleges or universities
- Preschool classes available
- Early intervention home visiting programs
- Average educational achievement of population
- Primary and additional languages of community

Recreation

- Local parks and park management
- Safe playgrounds
- Type of recreational businesses (bowling alleys, adult bookstores, movie theaters)
- Sports teams, youth and adult; sports arenas/fields
- Biking trails/lanes
- Track or running trails, tennis courts
- Activity clubs (garden, hiking)
- Senior center(s)
- Local festivals/fairs

Health and Social Services

- Hospitals, health clinics/medical offices, specialists
- Health department and programs
- Free clinic
- Social service department
- In home care provision (i.e., hospice, maternal child programs)
- Statistics on child and elder abuse, sexual assault
- Immunization status of community members
- Home health care team
- Percentage of Medicaid families in community
- Percentage of population on disability and ages of those disabled
- Obesity rate: adults and children
- Mental health clinic(s)

Communication

- Newspapers
- Cell phone carriers and availability of service
- Internet connections
- Radio and TV stations
- Community bulletin boards (check post offices and central places)
- Informal sources of information and communication

Physical Environment

- Age and condition of housing
- Physical terrain and potential for environmental disaster (hurricanes, tornadoes, etc.)
- Proximity to Superfund sites (pollution)
- Water and air quality
- Industrial pollution
- Natural environment

will help focus priorities. Identifying health indicators such as obesity rates, smoking rates, and causes of morbidity and mortality can clarify the needs of the community.

Identification of Health Assets and Challenges

Once you have pulled together your data into an organized format, the community problems and strengths should emerge. Using a targeted form like Santa Cruz County's "snapshot" (see [Figure 18-6](#)) will help you to see these in a clear way. While the "snapshot" addresses six systems, you can expand this to the size needed to reference your community. With the resulting "list" of identified problems and assets, you will be ready to prioritize your results.

Prioritizing

Once the data are collated and clarified on paper, the themes can be placed in the context of the earlier identified community priorities reflected in your primary data. In this way, community involvement and input in the assessment process will make your assessment and planning relevant to the community, and create the opportunity to meet the community's identified needs. At the same time, try to identify within your secondary data a rationale for the community's identified need. In other words, you might compromise. Attempting to implement programs that are not recognized as most relevant by the community can result in lack of community buy-in and ultimate program failure.

Section	Indicator	Measurement	Data	Year	Trend	Direction	Page
Economy	Unemployment Rate	Santa Cruz County	10.6%	June 2009	↑		33
		Watsonville	22.2%	June 2009	↑		33
	Affordable Housing	Median sale price, all home types – Santa Cruz/Watsonville area	\$347,000	2009	↓		44
	Foreclosures	Number of notices of default – Santa Cruz County	1,537	2008	↑		50
Education	Test Scores	Percent of 3rd grade students scoring proficient or above in the English-Language Arts subject area on the California Standards Test – Santa Cruz County	40%	2009	↑		62
	High School Dropout Rates	Adjusted four-year derived dropout rate – Santa Cruz County	14.0%	2007/08	↓		83
Health	Health Insurance	Percent of children ages 0-17 with health insurance – Santa Cruz County	97.9%	2007	↑		111
	Obesity	Percent of children ages 5-19 who are overweight or obese – Santa Cruz County	25.9%	2008	↑		133
Public Safety	Adult Crime	Property crime rate – Santa Cruz County (<i>per 1,000 residents</i>)	29.9	2008	↓		158
	Elder Abuse	Rate of reported cases of elder abuse – Santa Cruz County (<i>per 1,000 elders ages 65 and older</i>)	21.0	2008	↑		176
Social Environment	Quality of Life	Percent of telephone survey respondents who reported being “very satisfied” with their overall quality of life	72.0%	2009	→		211
	Food Insecurity	Number of people served by the Second Harvest Food Bank – Santa Cruz County	48,161	2008	↑		199
Natural Environment	Concern for Natural Environment	Percent of telephone survey respondents who said water availability most concerned them about the natural environment	18.1%	2009	—		218
	Health of Waterways	Number of bodies of water added to the 303(d) impairment list – Santa Cruz County	6	2008	↑		227

FIG 18-6 Snapshot of Santa Cruz County. (http://www.appliedsurveyresearch.org/storage/database/quality-of-life/santacruzcap/cap15_2009/CAP15_Full_Report.pdf).

For example, though secondary data may document that increased mortality due to heart disease should be the community's highest priority, as evidenced by higher than average mortality from heart disease, the community might see a different need, such as elder care or child care, as the highest priority. There is no clear guide in this prioritizing process, but testing ideas about perceived need and actual data-driven information with community stakeholders and key informants helps the PHN come to an optimal way to prioritize problems and identify target areas for improvement. Just as in the hospital setting, make the patient (in this case the community) the center of your focus. **Box 18-5** can assist you in steps to prioritize the community problem list. Identifying the top three community

BOX 18-5 Problem Priority Criteria

Criteria that have been helpful in ranking identified problems include the following:

1. Community awareness of the problem
2. Community motivation to resolve or better manage the problem
3. Nurse's ability to influence problem solution
4. Availability of expertise to solve the problem
5. Severity of the outcomes if the problem is unresolved
6. Speed with which the problem can be solved

Shuster, G: Community as client" assessment and analysis. In Stanhope and Lancaster (editors), *Public Health Nursing, Population-centered health care in the community*, ed 8, 2012 Elsevier, St. Louis, Mo.

problems or needs should then lead to creating the priority nursing diagnoses (see Use of Secondary Data Sources).

The ethical concepts of utilitarianism and justice can help you navigate the negotiations and advocacy inherent in prioritizing one health problem over another. Utilitarianism means doing the most good for the most people, so a priority problem would ideally be one that affects a large proportion of the community. However, justice focuses on the fair distribution of resources among all people. Social justice means advocating for the most vulnerable populations in a community, to ensure that their problems receive higher priority than the problems found throughout the general population. For example, secondary data might find that infant mortality occurs rarely in the community; but if there is a wide disparity among racial groups in infant mortality rates, social justice would call for this problem to be given higher priority in order to address underlying determinants of health that may cause the disparity.

Nursing Diagnosis

The community health nursing diagnosis in this phase of the process helps clarify the prioritized problems and is an important first step to planning. Community diagnoses clarify the target population for care and identify the factors contributing to the identified problem. As the analysis of the data proceeds, the nursing care plan can be formed. In the planning phase, community-focused interventions are identified, along with ways to measure outcomes.

There are several standardized classification systems to accommodate this diagnosis formation. North American Nursing Diagnosis Association (NANDA) and the Omaha system are two prominent systems of classification. **NANDA** may require some adaptation to the community for certain diagnoses; Carpenito's *Nursing Diagnosis: Application to Clinical Practice* (based on NANDA) does recognize several community diagnoses and health seeking behaviors that can apply to communities (Carpenito, 2013, pp. 797-816). The Omaha system includes domains and problem classifications that are specific to community health.

The NANDA system outlines the systematic nursing diagnosis process by identifying the (1) problem or potential problem; (2) its relation to factors, stressors, or health issues; and (3) then supporting data that document the problem. The identification of the problem in the NANDA classification has strict parameters dividing problems into categories and systems. This can be confining when working within the community as client, since even though the NANDA classification system does offer several community-based diagnoses, it is more focused on individuals or families. For more information on NANDA nursing diagnosis, please consult Carpenito (2013), <http://www.nanda.org> or the nursing diagnosis text recommended by your faculty.

The **Omaha system** was developed by visiting nurses and expands beyond the physiological domain and includes environmental, psychosocial, and health-related behaviors domains. In addition to the problem, the Omaha system addresses the intervention scheme and the problem rating scale for outcomes. Omaha-based computer software applications are available to

streamline electronic records (Omaha System, 2014). The Omaha system website, <http://www.omahasystem.org>, contains case studies and full explanation of the use of its standardized taxonomy and problem oriented approach.

Community nursing diagnosis language must describe at the aggregate level—in other words, the community level—responses to actual and potential illnesses and life processes. This also means that the defining characteristics for community diagnoses must be observable and measurable at the aggregate level. To do this, community-level data must be used. Epidemiologic supporting data or community survey data are two examples of community-level data. The comparison of local data with state, regional, or national data, as rates and across multiple years, is one key means of identifying community-level problems, as well as patterns and trends.

The community nursing diagnosis, no matter which classification system the PHN uses, then leads to expected outcomes and evidence-based health promotion strategies to address and improve the problem identified in the diagnosis. This becomes the nursing care plan. The expected outcomes and evaluations derived from the nursing diagnosis systems suggest subsequent evaluation measures for identified needs or problems. Just as problems are recognized and prioritized, so can strengths be identified that may offer avenues through which the PHN can address existing challenges facing the community.

LINKING CONTENT TO PRACTICE

In this chapter, the focus is placed on the partnership between the public health nurse and the community throughout the process of community assessment, problem identification, planning, intervention, and evaluation. One of the Institute of Medicine's (IOM) three core functions of public health is assessment. The process of community assessment outlined and described in this chapter closely follows The Council on Linkages' *Core Competencies for Public Health* (adopted June 11, 2011). This includes the need for public health nurses to "maintain partnerships with key stakeholders." Among other identified competencies for public health providers, including public health nurses, is the ability to "assess the health status of populations and their related determinants of health and illness." This chapter presents the means by which public health nurses can construct a composite database containing assessment data from a wide variety of sources. This initial community assessment phase also directly links with The Quad Council Domains of Public Health Practice: Domain #1: Analytic Assessment Skills; Domain #5: Community Dimensions of Practice Skills; and Domain #6: Basic Public Health Sciences Skills. The Council on Linkages: Core Competencies for Public Health also emphasizes the public health nurse's ability to describe "the characteristics of a population-based health problem." Development of goals and objectives along with their problem correlates as part of the community health assessment directly relates to this competency; whereas another Council on Linkages competency—"Develops a plan to implement policy and programs"—directly relates to the development of intervention actions described in this chapter.

Program Planning, Implementation, and Evaluation

Once interventions and evaluation measures are identified through the nursing diagnosis framework, the PHN arrives at a new step in the nursing process—the program planning phase. This includes analyzing and establishing priorities among

community health problems already identified through nursing diagnosis, establishing goals and objectives, and identifying intervention activities that will accomplish the objectives. These interventions must be clearly supported by the community stakeholders in order for the community to buy in to the identified program plans. Intervention activities, the means by which objectives are met, are the strategies that clarify what must be done to achieve the objectives or the ways change will be effected. The next phase of the nursing process is program implementation. This involves enacting the plan for improved community health using the identified goals and objectives.

Finally, upon implementation of the program and by using the established evaluation measures, the PHN can measure the

success of the program and determine community satisfaction with the outcome. These evaluation criteria will already be identified through the nursing diagnosis format chosen.

Program planning and implementation should be based on the community's problems AND its strengths, as well as the priorities of the community members. If the identified problem is not resolved to the satisfaction of the community at large following program implementation, the PHN will return to the data-gathering phase and begin the process again using the updated data. As shown in [Figure 18-2](#), this can be an ongoing, circular process, just like the nursing process. Program management, encompassing program planning, implementation, and evaluation is discussed in detail in [Chapter 25](#).

PRACTICE APPLICATION

Lily, a nurse in a small city, became aware of the increased incidence of respiratory diseases through contact with families in the community and the local chapter of the American Lung Association. During family visits, Lily noticed that many of the parents were smokers. Because most of the families Lily visited had small children, she became concerned about the effects of secondhand smoke on the health of the infants and children in her family caseload.

Further assessment of this community indicated that the community recognized several problems, including school safety and the risk of water pollution, in addition to the smoking problem that Lily had identified during her family visits. Talks

with different community members revealed that they wanted each of these identified problems “fixed,” although these same community members were uncertain about how to start. In deciding which of the three identified problems to address first, which criterion would be most important for Lily to consider?

- A. The amount of money available
- B. The level of community motivation to “fix” one of the three identified problems
- C. The number of people in the community who expressed a concern about each of the three identified problems
- D. How much control she would have in the process

Answers can be found on the Evolve site.

KEY POINTS

- Most definitions of community include three dimensions: (1) networks of interpersonal relationships that provide friendship and support to members, (2) residence in a common locality, and (3) shared values, interests, or concerns.
- A community is defined as a locality-based entity, composed of systems of formal organizations reflecting societal institutions, informal groups, and aggregates that are interdependent and whose function or expressed intent is to meet a wide variety of collective needs.
- A community practice setting is insufficient reason for stating that practice is oriented toward the community client. When the location of the practice is in the community but the focus of the practice is the individual or family, the nursing client remains the individual or family, not the whole community.
- Population-centered practice is targeted to the community—the population group in which healthful change is sought.
- Community health as used in this chapter is defined as the meeting of collective needs through identification of problems and management of behaviors within the community itself and between the community and the larger society.
- Most changes aimed at improving community health involve, out of necessity, partnerships among community residents and health workers from a variety of disciplines.
- Assessing community health requires gathering existing data and interpreting the database.
- Five methods of collecting data useful to the nurse are analysis of existing secondary data, and primary data collection through informant interviews, participant observation, surveys, and windshield surveys.
- Nurses should identify and partner with gatekeepers, formal or informal community leaders, to gain entry or acceptance into the community.
- The planning phase includes analyzing and establishing priorities among community health problems already identified, establishing goals and objectives, and identifying intervention activities that will accomplish the objectives.
- Once high-priority problems are identified, broad relevant goals and objectives are developed; the goal is generally a broad statement of the desired outcome while the objectives are precise statements of the desired outcome.
- Intervention activities, the means by which objectives are met, are the strategies that clarify what must be done to achieve the objectives, the ways change will be effected, and the way the problem will be interpreted.
- Implementation, the next phase of the nursing process, means transforming a plan for improved community health into achieving goals and objectives. This essentially is the implementation of the program.
- Simply defined, evaluation is the appraisal of the effects of some organized activity or program.

CLINICAL DECISION-MAKING ACTIVITIES

1. Observe an occupational health nurse or public health nurse, school nurse, family nurse practitioner, or emergency department nurse for several hours. Determine which of the nurse's activities are population centered. Give specific examples and present your reasons for considering them population centered.
2. Using your own community as a frame of reference, develop examples illustrating the concepts of community, community client, community health, and partnership for health. What are some of the complexities of this question?
3. Read your local newspaper and identify articles illustrating the concepts of community, community client, community health, and partnership for health. How does your article specifically relate to the concept?
4. Using any two of the conditions of community competence given in the chapter, briefly analyze your own community. Give examples of each condition.
5. Search the Boone County, Iowa, website (<http://www.co.boone.ia.us/>) for information on county festivals. Ask yourself the following question: To what extent do the county festivals depicted on the website reveal community cohesion?
6. Search the Washtenaw County, Michigan, website (<http://www.ewashtenaw.org/>) for information about "county conversations." Identify which issues are being addressed, and read the local newspaper for additional information. Did you find other countywide issues when you read the newspaper? Are there positions on the issues that are not presented?

Population-Centered Nursing in Rural and Urban Environments

Angeline Bushy, PhD, RN, FAAN, PHCNS-BC

Dr. Angeline Bushy, Professor and Bert Fish Endowed Chair at the University of Central Florida, College of Nursing holds a BSN degree from the University of Mary in Bismarck, North Dakota; an MN degree in rural community health nursing from Montana State University in Bozeman; an MEd in adult education from Northern Montana College in Havre; and a PhD in nursing from the University of Texas at Austin. She is a Fellow in the American Academy of Nursing and a Clinical Specialist in Public Health Nursing. Dr. Bushy has worked in rural health care facilities located in the north-central and intermountain states; presented nationally and internationally on various rural nursing and rural health issues; published six textbooks and numerous articles on that topic; and, is a Lieutenant Colonel (Ret.) in the U.S. Army Reserve.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Compare and contrast definitions of *rural* and *urban*.
2. Describe residency as a continuum, ranging from farm residency to core inner city.
3. Compare and contrast the health status of rural and urban populations on select health measures.
4. Analyze barriers to care in health professional shortage areas and for underserved populations.
5. Evaluate issues related to the delivery of public health services for rural underserved populations.
6. Describe characteristics of rural and small-town residency.
7. Examine the role and scope of public health nursing practice in rural and underserved areas.
8. Evaluate two professional-client-community partnership models that can effectively provide a continuum of health care to residents living in an environment with sparse resources.

KEY TERMS

farm residency, p. 424

frontier, p. 428

health professional shortage area (HPSA), p. 428

medically underserved, p. 436

metropolitan area, p. 424

Building Professional-Community-Client Partnerships in Rural Settings

Case Management
 Community-Oriented Primary Health Care

Access to health care is a national priority, especially in regions with an insufficient number of health care providers. Recruiting and retaining qualified health professionals can be a challenge in underserved communities, particularly inner cities and rural areas of the United States. Until recently, however, only limited research has been undertaken on the special challenges, problems, and opportunities of nursing practice—especially public health nursing in rural settings. This chapter presents major issues surrounding health care delivery in rural environments, which sometimes differs from that in urban or more populated settings. Common definitions for the term *rural* are discussed, as are its associated lifestyle, the health status of rural populations, barriers to obtaining a continuum of health care services, and public health nursing practice issues. Strategies are discussed to help nurses deliver more effective population-focused nursing services to clients who live in more isolated environments with sparser resources. This chapter describes rural public health nursing practice and can be used by students, nurses who practice in rural public health departments, and those who work in agencies located in urban areas that offer outreach services to rural populations in their catchment area.

HISTORIC OVERVIEW

Formal rural nursing originated with the Red Cross Rural Nursing Service, which was organized in November 1912. The Committee on Rural Nursing was directed by Mabel Boardman (Chair), Jane Delano (Vice-Chair), and Annie Goodrich along with other Red Cross leaders and philanthropists (Bigbee and Crowder, 1985). Before the formation of the Red Cross Rural Nursing Service, care of the sick in a small community was provided by informal social support systems. When self-care and family care were not effective in bringing about healing, this task was assigned to healers, who often were women who lived in the local community. Historically, the health needs of rural Americans have been numerous, and although not necessarily unique, they are different from those of urban populations. Consistent problems of maldistribution of health professionals, poverty, limited access to services, ignorance, and social isolation have plagued many rural communities for generations.

The history of the Red Cross Rural Nursing Service shows a consistent movement away from its initial rural focus, as demonstrated by its frequent name changes. Unfortunately, concern for rural health is similarly often temporary and replaced by other areas of greater need. It can be hoped that health care

reform initiatives will ensure equitable access to care for rural and urban residents alike (NACRHHS, 2012).

DEFINITION OF TERMS

Rurality: A Subjective Concept

Everyone has an idea as to what constitutes rural as opposed to urban residence. However, the two cannot be viewed as opposing entities. With the increased degree of urban influence on rural communities, the differences may not be as distinct as they may have been even a decade ago (Bureau of the Census, 2011, 2012, 2013; Meckler & Chinni, 2014). In general, **rural** is defined in terms of the geographic location and population density, or it may be described in terms of the distance from (e.g., 20 miles) or the time (e.g., 30 minutes) needed to commute to an urban center. See Box 19-1 for selected terms and definitions.

Both urban and rural communities are highly diverse and vary in their demographic, environmental, economic, and social characteristics. In turn, these characteristics influence the magnitude and types of health problems that communities face. Urban counties, however, tend to have more health care providers in relation to population, and residents of more rural counties often live farther from health care resources (Bushy, 2013).

BOX 19-1 Terms and Definitions

Farm residency: Residency outside area zoned as “city limits”; usually infers involvement in agriculture

Frontier: Regions having fewer than six persons per square mile

Large central: Counties in large (1 million or more population) metro areas that contain all or part of the largest central city

Large fringe: Remaining counties in large (1 million or more population) metro areas

Metropolitan county: Regions with a central city of at least 50,000 residents

Non-farm residency: Residence within area zoned as “city limits”

Micropolitan county: Counties that do not meet SMSA (see below) criteria

Rural: Communities having fewer than 20,000 residents or fewer than 99 persons per square mile

Small: Counties in metro areas with fewer than 1 million people

Standard metropolitan statistical area (SMSA): Regions with a central city of at least 50,000 residents

Suburban: Area adjacent to a highly populated city

Urban: Geographic areas described as non-rural and having a higher population density; more than 99 persons per square mile; cities with a population of at least 20,000 but less than 50,000

Some equate the idea of rural with **farm residency** and **urban** with **non-farm residency**, whereas others consider *rural* to be a “state of mind.” For the more affluent, rural may bring to mind a recreational, retirement, or resort community located in the mountains or in lake country where one can relax and participate in outdoor activities, such as skiing, fishing, hiking, or hunting. For the less affluent, the term can impose grim scenes. For example, some people may think of an impoverished Indian reservation as comparable to an underdeveloped country, and other people may think about a migrant labor camp with several families living in a one-room shanty with no access to safe drinking water or adequate sanitation.

Just as each city has its own unique features, also it is difficult to describe a “typical rural town” because of the wide population and geographic diversity. For example, rural towns in Florida, Oregon, Alaska, Hawaii, and Idaho are different from one another, and quite different from those in Vermont, Texas, Alabama, or California. Also, there can be vast differences between rural areas within one state. Still, descriptions and definitions for *rural* tend to be more subjective and relative in nature than those for *urban*.

For example, “small” communities with populations of more than 20,000 have some features that one may expect to find in a city. Then again, residents who live in a community with a population of less than 2000 may consider a community with a population of 5000 or 10,000 to be a city. Although some communities may seem geographically remote on a map, the residents who live there may not feel isolated. Those residents believe they are within easy reach of services through telecommunication and dependable transportation, although extensive shopping facilities may be 50 to 100 miles from the family home, obstetric care may be 150 miles away, or nursing services in the district health department in an adjacent county may be 75 or more miles away (Bolin & Bellamy, 2014; Gamm et al, 2003).

RURAL-URBAN CONTINUUM

Frequently used definitions to describe rural and urban and to differentiate between them are provided by several federal agencies (Bureau of the Census, 2011; USDA, 2013a; 2013b) (see Box 19-1). These definitions, which in many cases are dichotomous in nature, fail to take into account the relative nature of ruralness. Rural and urban residencies are not opposing lifestyles. Rather, they must be seen as a **rural-urban continuum** ranging from living on a remote farm, to a village or small town, to a larger town or city, to a large metropolitan area with a *core inner city*. See Figure 19-1, which describes the continuum of rural-urban residency.

Several federal agencies classify U.S. counties and county equivalents (N = 3007) according to population density, specifically, metropolitan counties (84% of the total population) and non-metropolitan counties (16% of the total population) (USDA, 2013b). The terms **metropolitan area** and **micropolitan area** (metro and micro areas) refer to geographic entities primarily used for collecting, tabulating, and publishing federal statistics. Core-based statistical area (CBSA) is a collective term for both metro and micro areas. A metro area contains a core urban area of 50,000 or more population. A micro area contains an urban core of at least 10,000 (but less than 50,000) population. Each metro or micro area consists of one or more counties containing the core urban area. Likewise, adjacent counties have a high degree of social and economic integration (as measured by commuting to work) with their urban core (USDA, 2013b).

Demographically, micro areas contain about 60% of the total non-metro population, with an average of 43,000 people per county. In contrast, **non-core areas**, with no urban cluster of 10,000 or more residents, have on average about 14,000 residents. In general, lack of an urban core and low overall population density may place these counties at a disadvantage in efforts to expand and diversify their economic base. The designation

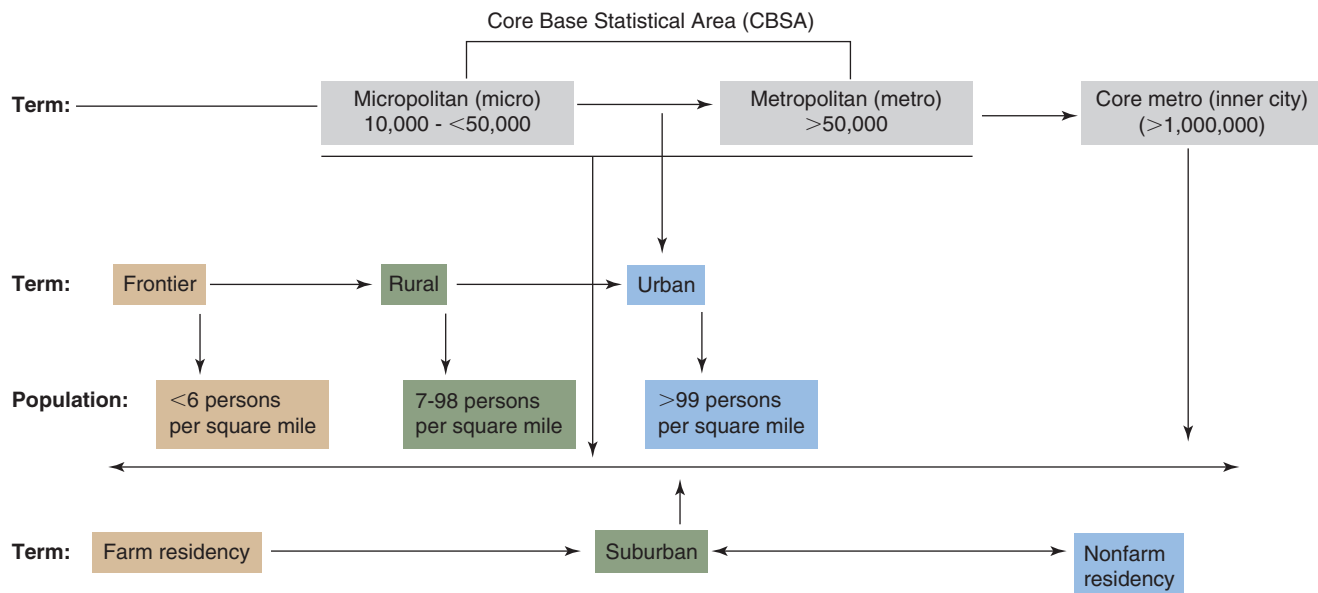

FIG 19-1 The continuum of rural-urban residency.

of micro areas is an important step in recognizing non-metro diversity. The term also provides a framework to understand population growth and economic restructuring in small towns and cities that have received less attention than metro areas. Nationally and regionally, many measures of health, health care use, and health care resources among rural populations vary by the level of urban influence in a particular region.

Micro areas embody a widely shared residential preference for a small-town lifestyle—an ideal compromise between large highly populated urban cities and sparsely populated rural settings. As information about these places makes its way into government data and publications alongside metro areas in the coming years, hopefully the notion of “micropolitan” will draw increased attention from policy makers and the business community.

In the past two decades there has been a steady population shift from urban to less-populated regions of the United States. Demographers metaphorically refer to this demographic phenomenon as the “doughnut effect.” That is to say, people are moving away from highly populated areas to outlying **suburbs** of urban centers. Most of the population growth has been in rural counties with a booming economy coupled with the geographic area to expand, such as in many western and southern states (USDA, 2013a, 2013b).

Clearly, a notable population shift will also affect the health status and lifestyle preferences of communities in which the shift occurs. As beliefs and values change over time, urban-rural differences narrow in some aspects and others become more pronounced. Depending on the definition that is used, the actual rural population might vary slightly. According to **Bureau of the Census estimates** (2011, 2012, 2013), almost 20% of all U.S. residents live in rural settings. In this chapter, rural refers to areas having fewer than 99 persons per square mile and communities having 20,000 or fewer inhabitants.

CURRENT PERSPECTIVES

Population Characteristics

Adding to the confusion about what constitutes rural versus urban residency are the special needs of the numerous under-represented groups (minorities, subgroups) who reside in the United States. In general, there are a higher proportion of whites in rural areas than in urban areas. There are, however, regional variations, and some rural counties have a significant number of minorities. Little is documented on the needs and health status of special rural populations (AHCPR, 2013a, 2013b; Bolin & Bellamy, 2014; USDHHS, 2013). Anthropologists are quick to report that, within a group, there often exists a wide range of lifestyles. Consequently, even in the smallest or most remote town or village, a subgroup may behave differently and have different values about health, illness, and patterns of accessing health care. Also, a group’s lifestyle may be associated with health problems that are different from those of the predominant cultural group in a given community. Background information on selected populations can be found in **Chapters 7** and **32**.

Demographically, rural communities include a higher proportion of younger and older residents. Nurses can expect to

encounter more residents under the age of 18 and over 65 years of age in rural areas compared with an urban setting. Rural residents 18 years of age and older are more likely to be, or to have been, married than are their urban counterparts. As a group, rural adults are more likely to be widowed and have fewer years of formal education than urban adults (Meckler & Chinni, 2014; USDA, 2013a).

Although there are regional variations, rural families in general tend to be poorer than their urban counterparts. Comparing annual incomes with the standardized index established, more than one fourth of rural Americans live in or near poverty, and nearly 40% of all rural children are impoverished. Compared with those in metropolitan settings, a substantially smaller proportion of rural families are at the high end of the income scale. Accompanying the recent population shifts from urban to formerly rural areas, one can speculate that average income level might also change; however, no data are available at this time to substantiate this estimate. Regardless, level of income is a critical factor in whether a family has health insurance or qualifies for public insurance. Consequently rural families are less likely to have private insurance and more likely to receive public assistance or to be uninsured.

The working poor in rural areas are particularly at risk for being underinsured or uninsured. In working poor families, one or more of the adults are employed but still cannot afford private health insurance. Furthermore, their annual income is such that it disqualifies the family from obtaining public insurance. Several factors help explain why this phenomenon occurs more often in rural settings (Bushy, 2013). For example, a high proportion of rural residents are self-employed in a family business, such as ranching or farming, or they work in small enterprises, such as a service station, restaurant, or grocery store. Also, an individual may be employed in part-time or in seasonal occupations, such as farm laborer and construction, in which health insurance often is not an employee benefit. In other situations, a family member may have a preexisting health condition that makes the cost of insurance prohibitive, if it is even available to them. At present it remains to be seen if this situation will change with the recent health care reform. A few rural families fall through the cracks and are unable to access any type of public assistance because of other deterrents, such as language barriers, compromised physical status, the geographic location of an agency, lack of transportation, or undocumented worker status. Insurance, or the lack of it, has serious implications for the overall health status of rural residents and the nurses who provide services to them (AHCPR, 2013a, 2013b; NCHS, 2014).

Health Status of Rural Residents

Even though rural communities constitute about one fourth of the total population, the health problems and the health behaviors of the residents in them are not fully understood. This section summarizes what is known about the overall health status of rural adults and children. The health status measures that are addressed are perceived health status, diagnosed chronic conditions, physical limitations, frequency of seeking medical treatment, usual source of care, maternal–infant health, children’s health, mental health, minorities’

health, and environmental and occupational health risks (Bolin & Bellamy, 2014; OSHA, 2013). Residents of rural areas suffer some of the same health problems as migrant farmworkers, as described in Chapter 34, including exposure to environmental factors and accidents.

Perceived Health Status

In general, people in rural areas have a poorer perception of their overall health and functional status than their urban counterparts. Rural residents over 18 years of age assess their health status less favorably than do urban residents. Studies show that rural adults are less likely to engage in preventive behavior, which ultimately increases exposure to risk. Specifically, they are more likely to use tobacco products and self-report higher rates of alcohol consumption and obesity; furthermore, they are less likely to engage in routine physical activity during leisure time, wear seat belts, have regular blood pressure checks, have Pap smears, complete breast self-examinations, and have colorectal screenings. Ultimately, failure to participate in health-promoting lifestyle behaviors impacts the overall health status of rural residents, their level of function, physical limitations, degree of mobility, and level of self-care activities (American Legacy Foundation, 2013; Crosby et al, 2012; NCHS, 2014).

Chronic Illness

Rural adults are more likely than urban adults to have one or more of the following chronic conditions: heart disease, chronic obstructive pulmonary disease, hypertension, arthritis and rheumatism, diabetes, cardiovascular disease, and cancer. Nearly half of all rural adults have been diagnosed with at least one of these chronic conditions, compared with about one fourth of non-rural adults. Also, the prevalence of diagnosed diabetes in rural adults is about 7 out of 100 as opposed to 5 out of 100 in non-rural environments. Rural adults are more likely to have cancer (almost 7%) compared with urban adults (about 5%). Although most cases of acquired immunodeficiency syndrome (AIDS) are still found in urban areas, the rate is increasing in some rural populations (Smalley, Warren, Rainer, 2012; South Carolina Research Center, 2013).

Rural-urban health disparities have been documented in health status (Box 19-2) and for health behaviors (Box 19-3). For example, there are disparities in the proportion of rural adults who receive medical treatment for both life-threatening illness and degenerative or chronic conditions compared with urban adults. The proportion of rural residents who receive these treatments is high in rural versus urban areas. Life-threatening conditions include malignant neoplasms, heart disease, cardiovascular problems, and liver disorders. Degenerative or chronic diseases include diabetes, kidney disease, arthritis, and chronic diseases of the circulatory, nervous, respiratory, and digestive systems. In essence, chronic health conditions, coupled with their poor health status, limit the physical activities of a larger proportion of rural residents than of their urban counterparts (Bolin & Bellamy, 2014; NCHS, 2014).

Physical Limitations

Limitations in mobility and self-care are strong indicators of an individual's overall health status. Specific assessed measures on

BOX 19-2 Disparities Among U.S. Urban (Metropolitan) and Rural (Micropolitan) Residents' Health Status

Residents of fringe counties near large metro areas have the following:

- Lowest levels of premature mortality, partly reflecting lower death rates for unintentional injuries, homicide, and suicide
- Lowest levels of smoking, alcohol consumption, and childbearing among adolescents
- Lowest prevalence of physical inactivity during leisure time among women
- Lowest levels of obesity among adults
- Greatest number of physician specialists and dentists per capita
- Lowest percentage of the population without health insurance
- Lowest percentage of the population who had no dental visits

Residents in the most rural counties have the following:

- Highest death rates for children and young adults
- Highest death rates for unintentional and motor vehicle traffic-related injuries
- Highest death rates among adults for ischemic heart disease and suicide
- Highest levels of smoking among adolescents
- Highest levels of physical activity during leisure time among men
- Highest levels of obesity among adults
- Highest percentage of adults with activity limitations caused by chronic health conditions
- Fewest physician specialists and dentists per capita
- Least likely to have seen a dentist
- Highest percentage of the population without health insurance

From Centers for Disease Control and Prevention: *United States, 2001—Urban and Rural Chartbook*, Washington, DC. Available at <http://www.cdc.gov/nchs/data/hus/01.pdf>. Accessed December 22, 2010; Gamm L, Hutchison L, Dabney B, Dorsey A: *Rural Healthy People 2010: A Companion Document to Healthy People 2010* (Vol. I, II, III), 2003. Available at <http://www.srph.tamhsc.edu/centers/rhp2010/publications.htm>. Accessed June 28, 2005.

a national health survey included walking one block, walking uphill or climbing stairs, bending, lifting, stooping, feeding, dressing, bathing, and toileting. In fact, almost 10% of rural adults report at least three or more of these physical limitations, compared with about 6% of metropolitan adults. The increased prevalence of poor health status and impaired function is not necessarily attributable to the increased number of older adults found in rural areas. Similar patterns are evident in adults 18 to 64 years of age. Rural adults under 65 years of age are more likely than urban adults to assess their health status as fair to poor, and a greater percentage have been diagnosed with a chronic health condition (NCHS, 2014; USDHHS, 2013).

Based on data from national health surveys, the overall health status of rural adults leaves much to be desired. This is attributed to a number of factors, including impaired access to health care providers and services, coupled with other rural factors. Thus nurses who practice in rural areas are essential in providing a continuum of care to their clients. Specifically, nurses can help clients have healthier lives by teaching them how to prevent accidents, engage in more healthful lifestyle behaviors, and reduce the risk of chronic health problems. Once clients in rural environments have been diagnosed with a long-term problem, nurses can help them manage chronic conditions to achieve better health outcomes and functioning (Gamm et al, 2003; Bolin & Bellamy, 2014).

BOX 19-3 Rural-Urban Disparities: Lifestyle and Health Behaviors

- Residents in any rural areas are more likely to report fair to poor health status (19.5%) than were residents of urban counties (15.6%).
- Rural residents are more likely to report having diabetes (9.6%) versus urban adults (8.4%).
- Rates of diabetes are markedly higher among rural American Indians (15.2%) and African American adults (15.1%).
- Rural residents are more likely to be obese (27.4%) versus urban residents (23.9%).
- Rural black adults are particularly at risk for obesity; ranging from 38.9% in rural micropolitan counties to 40.7% in remote rural counties.
- Rural residents are less likely to meet CDC recommendations for moderate or vigorous physical activity (44%) versus urban residents (45.4%).
- Rural African American adults are less likely to meet recommendations for physical activity than other rural residents; this difference persists across all levels of rurality.

Access to Health Care Services

- Rural residents are more likely to be uninsured (17.8%) versus urban residents (15.3%).
- Hispanic adults are more likely to lack insurance, with uninsured rates ranging from 40.8% in rural micropolitan counties to 56.1% in small remote counties.
- Most rural residents (81%) and urban residents (79.4%) report having a personal health care provider. However, residents in remote rural counties were least likely to have a personal physician (78.7%).
- Rural white adults are more likely to have a personal health care provider than were other adults. Among Hispanic adults, the proportion with a

personal provider ranged from 60.4% in rural micropolitan counties to 47.7% in remote rural counties.

- Rural adults are more likely than urban adults to defer seeking health care because of cost (15.1% vs 13.1%).
- Rural adult African Americans, Hispanics, and American Indians are more likely to report having deferred care due to cost compared with white rural residents.

Receipt of Preventive Services

- Rural women are less likely (70.7%) than urban women (77.9%) to be in compliance with mammogram screening guidelines.
- Rural women are less likely (86%) than urban women (91.4%) to have had a Pap smear within the past 3 years.
- Rural residents over age 50 years are less likely (57.7%) to have had a colorectal screening versus urban counterparts (61.4%).

Quality of Diabetes Care

- The proportion of adults with diabetes who reported receiving at least two hemoglobin A1c tests within the past year was low among both rural (33.1%) and urban residents (35%).
- White rural residents with diabetes were more likely than African American or Hispanic residents to receive at least two hemoglobin A1c tests in the past year.
- Only 64.2% of rural and 69.1% of urban residents with diabetes reported receiving an annual dilated eye examination.

Patterns of Health Service Use

When the use of health care services is measured, it is found that more than three fourths of adults in rural areas received medical care on at least one occasion during a year. Despite their overall poorer health status and higher incidence of chronic health conditions, rural adults seek medical care less often than urban adults. In part, this discrepancy can be attributed to scarce resources and lack of providers in rural areas. Other reasons for this phenomenon are discussed later under Rural Health Care Delivery Issues and Barriers to Care (AHCP, 2013a, 2013b; NACRHHS, 2012). Nurses must be especially thorough in their health assessment of rural clients who may not receive regular care for chronic health conditions.

Availability and Access of Health Care

The ability of a person to identify a usual source of care is considered a favorable indicator of access to health care and a person's overall health status. Essentially, a person who has a usual source of care is more likely to seek care when ill and adhere to prescribed regimens. Having the same provider of care can enhance continuity of care, as well as a client's perception of the quality of that care. Rural adults are more likely than urban adults to identify a particular medical provider as their usual source of care. Rural adults are more likely to receive care from general practitioners and advanced practice registered nurses (APRNs) compared to urban adults who are more likely to seek care from a medical specialist. However, this trend may

be changing with health care reform, which emphasizes the importance of primary care (BHPR, 2013a, 2013b; Bushy, 2012; IOM, 2010; Krey, 2014).

Another measure of access to care is traveling time and/or distance to ambulatory care services. Rural persons who seek ambulatory care are more likely to travel more than 30 minutes to reach their usual source of care. Extended commuting time may also be a factor for residents in highly populated urban areas and those who must rely on public transportation. Once the person arrives at the clinic or physician's office, no differences between rural and urban residents are found in the waiting time to see the provider.

In general there is a maldistribution of health professionals among rural and urban counties. For instance, 1 out of 17 rural counties is reported to have no physician. Among rural respondents on national surveys, the ability to identify a usual site of care or a particular provider often stems from a community or county having only one, perhaps two, health care providers. The limited number of health care facilities is reinforced by the finding that nearly all rural residents who seek health care use ambulatory services that are provided in a physician's office as opposed to a clinic, community health center, hospital outpatient department, or emergency department (NACRHHS, 2012). One can speculate about the indicator of *usual place and usual provider*; that is to say, it suggests that rural residents are at least as well off as urban residents in regard to access to care. However, this finding may be related to the fact that rural

physicians tend to live and practice in a particular community for decades, thus providing care to multigenerational families who seek care from this particular provider.

Moreover, in a **health professional shortage area (HPSA)**, a physician or a nurse practitioner may provide services to residents who live in surrounding counties. One or two nurses in a public health department usually offer a full range of services for all residents in a rural catchment area, which may span more than 100 miles from one end to the other end of a county or health district. Consequently, rural physicians and nurses frequently report, “I provide care to individuals and families with all kinds of conditions, in all stages of life, and across several generations.” It should not come as a surprise that rural respondents who participate in national surveys are able to identify a usual source and a usual provider of health care (Woolston, 2010).

Maternal–Infant Health

Reports in the literature conflict regarding pregnancy outcomes in rural areas. Overall, rural populations have higher infant and maternal morbidity rates, especially counties designated as HPSAs, which often have a high proportion of racial minorities. Here one also finds fewer specialists, such as pediatricians, obstetricians, and gynecologists, to provide care to at-risk populations. There are extreme variations in pregnancy outcomes from one part of the country to another, and even within states. For example, in several counties located in the north-central and intermountain states, the pregnancy outcome is among the finest in the United States. However, in several other counties within those same states, the pregnancy outcome is among the worst. Particularly at risk are women who live on or near Indian reservations, are migrant workers, and are of African American descent residing in rural areas in southeastern states (Bolin & Bellamy, 2014; Leipert, Leach & Thurston, 2012; USDHHS, 2013).

Public health nurses appreciate the interactive effects of socioeconomic factors, such as income level (poverty), education level, age, employment-unemployment patterns, and use of prenatal services, on pregnancy outcomes. There are other, less well-known health determinants, such as environmental hazards, occupational risks, and the cultural meaning placed on child-bearing and child-rearing practices by a community. The interaction effects of these multifaceted factors vary and often are difficult to measure (Nelson, 2009; Warren & Smalley, 2014).

Health of Children

Reports on the health status of rural children show regional variations and conflicting data. Comparing rural children with urban children under 6 years of age on the measures of access to providers and use of services reveals the following (AHCPR 2013a, 2013b; Bolin & Bellamy, 2014; USDHHS, 2013):

- Urban children are less likely to have a usual provider but are more likely to see a pediatrician when they are ill.
- Like rural adults, rural children are more likely to be cared for by a general practitioner who is identified as their usual caregiver.

School nurses play an important role in the overall health status of children in the United States. The availability of school

nurses in rural communities also varies from region to region. More specifically, in **frontier** and rural areas of the United States, school nurses usually are scarce. In part, this deficit can be attributed to limited resources associated with very low local tax revenues and shortages of health personnel in those counties. In other words, there are fewer taxpayers living in those large geographic areas. Some frontier areas have fewer than four persons per square mile and a few areas have fewer than two persons per square mile. Consequently, rural county commissioners, like their urban counterparts, are forced to prioritize the allocation of scarce resources, in particular for essential public services such as maintaining the infrastructures of utilities, roads, bridges, and education; supporting a financially suffering county hospital; hiring a county health nurse; and offering school health services. In rural communities there are fewer resources overall, yet certain public services must be provided to local residents—albeit in many situations with aging and outdated infrastructures.

Clearly, creativity is required by both community residents and local public health care providers to resolve health care and school nursing needs. Partnership arrangements, for example, have been negotiated by two or more counties that agree to share the cost of a “district” public health nurse. Other county commissioners have forged partnerships with an agency in an urban setting and contracted for specific health care services. In both of these situations, it is not unusual for the nurse to provide services to *all* children attending *all* schools in the health district’s participating counties. In some frontier states, schools may be situated more than 100 miles apart and as many miles or more from the district health office. Because of the number of schools and distances between them, the county nurse may be able to visit each school only once or twice in a school term. Usually the nurse’s visit is to update immunizations and perhaps teach maturation classes to students in the upper grades.

The health status of rural women, infants, and children is less than optimal. In part this can be attributed to inadequate preventive, primary, and emergency services to meet their particular health care needs. On one hand, scarce resources can pose a challenge to a nurse who provides care to rural residents, especially those in underserved areas. On the other hand, resource deficits encourage creativity and innovation; both of these behaviors are characteristic of nursing in general and of rural nurses in particular.

Mental Health

Like many other measures of health, the facts about the mental health status of rural people are also ambiguous and conflicting (AHCPR, 2013a, 2013b; Crosby et al, 2012; NCHS, 2014). Stress, stress-related conditions, and mental illness are prevalent among populations who are economically deprived. Increasing federal regulations imposed on agriculture, timber, and marine- and mining-related industries in the past two decades led to many job losses in rural communities. The term *farm stress* is associated with the economic downturn in the agriculture industry as it affects an individual, family, and the community. This same term or diagnosis could be applied to other

communities experiencing economic recessions in their predominate enterprises, such as marine-, automobile-, and timber-related industries. Economic factors also contribute to a family's being underinsured or uninsured. Interestingly, even if mental health services are available and accessible, rural residents delay seeking care when they have an emotional problem until there is an emergency or a crisis. This behavior is reflected in the lower number of annual visits for mental health services and chronic health conditions by rural residents.

Mental health professionals who serve rural populations report a persistent, endemic level of depression among residents in economically stressed rural areas. They speculate this condition is exacerbated by high levels of poverty, geographic isolation, and an insufficient number of mental health services. Depression may also contribute to the escalating incidence of accidents and suicides, especially among rural male adolescents and young men. These incidents have increased dramatically over the last decade and continue to rise within this group, to the point of being epidemic in some small communities. Likewise, the stigma associated with mental illness remains, especially in communities having fewer health care providers to educate the public about mental and behavioral health conditions (Smalley et al, 2012).

There are conflicting reports on the prevalence of interpersonal violence and alcohol and substance use among rural populations. These behaviors are less likely to be reported in areas where residents are related or personally acquainted. Over time, destructive coping behaviors in small, tight-knit communities may be accepted by local residents as "business as usual" for a particular family. Family problems may also be ignored if formal social services and public health services are sparse or nonexistent, or if residents do not trust the professionals who provide services at a local agency. In underserved rural areas, there are gaps in the continuum of mental health services, which, ideally, should include preventive education, anticipatory guidance, screenings, early intervention programs, crisis and acute care services, and follow-up care. As with other aspects of health care, nurses in rural areas play an important role in community education, case finding, advocacy, and case management of client systems experiencing acute and chronic emotional and behavioral health problems (Bushy, 2012, 2014; Smalley et al, 2012).

Health of Minorities

As mentioned previously, a significant number of at-risk minority groups in rural America have some rather distinctive concerns (particularly children, older adults, Native Americans, Native Alaskans, Native Hawaiians, migrant workers, African Americans, and the homeless) (CDC, 2013b; NCFH, 2014; USDHHS, 2013). The rural homeless, for example, may be migrant farmworkers or local families whose homes were foreclosed. Sometimes the family may be allowed by law to continue living in the house that once was theirs. The family no longer has a means of livelihood and often remains hidden in the community with insufficient income to purchase food or other necessary services. The particular health problems of these at-risk groups are discussed in Chapters 7 and 27 through 38. Nurses

should be aware, however, that at-risk and underrepresented groups may experience some unique challenges associated with rural social structures, lifestyle, and sparse resources.

Environmental and Occupational Health Risks

A community's primary industry or industries are a determinant in the local lifestyle, the health status of its residents, and the number and types of health care services it may need. For example, four high-risk industries identified by the Occupational Safety and Health Administration (OSHA) and found in predominantly rural environments are forestry, mining, marine-related fields, and agriculture. See Table 19-1 for a description of rural groups, their typical health care needs, and their health risks or conditions. Associated health risks of these industries are machinery and vehicular accidents, trauma, selected types of cancer related to environmental factors, and allergies and respiratory conditions associated with repeated exposure to toxins, pesticides, and herbicides (NCFH, 2014; NCHS, 2014; OSHA, 2013; USDA, 2013b).

For example, agriculture production industries such as farming and ranching are often owned and operated by a family. Small enterprises with a low number of employees do not fall under OSHA guidelines. For that reason safety standards are not enforceable on most farms and ranches, since these often are family enterprises. Moreover, small businesses, such as farms, are not covered under workers' compensation insurance. Additional concerns arise because family members participate in the farm or ranch work. This means that some adults and children may work with animals and operate dangerous machinery with minimal operating instructions on the hazards and on safety precautions. Also, many agriculture workers do not speak or read English. Consequently, agriculture-related accidents result in a significant number of deaths and long-term injuries, particularly among children and women. The morbidity and mortality rates associated with agriculture vary from state to state. The rising incidence of these injuries and deaths, however, has become a national concern. Nurses in rural settings can help address this problem by including farm safety content in school and community education programs (NCFH, 2014; OSHA, 2013).

In summary, it is risky to generalize about the health status of rural Americans because of their diversity coupled with conflicting definitions of what differentiates rural from urban residences. Many vulnerable individuals and families live in rural communities across the United States, but little is known about most of them. This information deficit therefore is a potential area of research for nurses who practice in rural environments.

RURAL HEALTH CARE DELIVERY ISSUES AND BARRIERS TO CARE

Although each rural community is unique, the experience of living in a rural area has several common characteristics (Bushy & Winters, 2013; Hurme, 2009; Molinari & Bushy, 2012). Barriers to health care may be associated with these characteristics (e.g., whether services and professionals are available,

TABLE 19-1 Select Health Care Needs, Risks/Conditions of Select Rural Aggregates

Rural Aggregates	Health Care Needs	Health Risks/Conditions
Farmers/ranchers	Advanced life support/emergency services Oral/dental care Obstetric/perinatal/pediatric services Mental/behavioral health services Agricultural health nurses Geriatric specialists	Agricultural chemicals and environmental hazards Dermatitis Stress/depression/anxiety disorders Respiratory conditions (i.e., farmer's lung) Accidents (vehicular/machinery) Trauma-related chronic conditions Dental caries/loss Interpersonal/domestic violence
Native Americans	Advanced life support/emergency services Oral/dental care Obstetric/perinatal/pediatric services Mental/behavioral health services Culturally appropriate substance abuse treatment programs Epidemiologists Diabetes screening and educators Community health workers/education	Infectious diseases (e.g., hepatitis, TB) Sudden infant death syndrome (SIDS) Interpersonal/domestic violence Diabetes Alcohol/substance abuse Cirrhosis of the liver Vehicular accidents Hypothermic/environmental injuries Trauma-related injuries/chronic conditions Dental caries/loss
African Americans	Community nursing health promotion and screening services Diabetes screening and educators Hypertension screening/education Prenatal and perinatal health care services Oncology services (education/screening/follow-up interventions) HIV/AIDS prevention education/screening/follow-up care Mental/behavioral health services	Diabetes Hypertension Sickle cell anemia Infectious diseases (e.g., hepatitis, HIV/AIDS) Cancer (e.g., prostate, breast) Dental caries/loss Depression Interpersonal/domestic violence
Migrant farmworkers	Environmental protection policies (safe drinking water/sanitation) Community nursing/migrant health services (primary, secondary, tertiary prevention) Diabetes screening and educators Hypertension screening/education Maternal/child services Oncology services (education/screening/follow-up interventions) Mental/behavioral health services	Infectious diseases (e.g., hepatitis, typhoid, TB, HIV/AIDS, STDs) Exposure effects of pesticides/herbicides Otitis media (children) Substance abuse (alcohol, recreational drugs, imported medicinal/herbs) Dental caries/loss Interpersonal/domestic violence
Native Alaskans	Advanced life support/emergency care services Medical transport services Oral/dental care Obstetric/perinatal/pediatric services Mental/behavioral health services Culturally appropriate substance abuse treatment programs Epidemiologists Diabetes screening and educators	Infectious diseases (e.g., hepatitis, TB) Dental caries/loss Depression Interpersonal/domestic violence Environmental health risks (e.g., exposure to toxic substances/contaminants, hypothermia) Diabetes Alcohol/substance abuse Cirrhosis of the liver Vehicular accidents/trauma/long-term chronic residual effects
Coal miners	Occupational Safety and Health Administration policy/standards Mental/behavioral health services Emergency/advanced life support services Occupational health nurses Grief counselors	Depression/substance abuse Occupational-related accidents/trauma Respiratory conditions (e.g., black lung, chronic obstructive pulmonary disease) Interpersonal/domestic violence

affordable, accessible, or acceptable to rural consumers). Box 19-4 lists common barriers to health care in rural areas.

Availability implies the existence of health services as well as the necessary personnel to provide essential services. Sparseness of population limits the number and array of health care

services in a given geographic region. Lacking a critical mass, the cost of providing special services to a few people often is prohibitive, particularly in frontier states where there are an insufficient number of physicians, nurses, and other types of health care providers. Consequently, where services and

BOX 19-4 Characteristics of Rural Life

- More space; greater distances between residents and services
- Cyclical/seasonal work and leisure activities
- Informal social and professional interactions
- Access to extended kinship systems
- Residents who are related or acquainted
- Lack of anonymity
- Challenges in maintaining confidentiality stemming from familiarity among residents
- Small (often family) enterprises; fewer large industries
- Economic orientation to land and nature with industries that are extractive in nature (e.g., agriculture, mining, lumbering, marine-related; outdoor recreational activities)
- More high-risk occupations
- Town as center of trade
- Churches and schools as socialization centers
- Preference for interacting with locals (insiders)
- Mistrust of newcomers to the community (outsiders)

BOX 19-5 Barriers to Health Care in Rural Areas

- Lack of health care providers and services
- Great distances to obtain services
- Lack of personal transportation
- Unavailable public transportation
- Lack of telephone services
- Unavailable outreach services
- Inequitable reimbursement policies for providers
- Unpredictable weather and/or travel conditions
- Inability to pay for care/lack of health insurance
- Lack of “know how” to procure publicly funded entitlements and services
- Inadequate provider attitudes and understanding about rural populations
- Language barriers (caregivers not linguistically competent)
- Care and services not culturally and linguistically appropriate

personnel are scarce, these must be allocated wisely. Accessibility implies that a person has logistical access to, as well as the ability to purchase, needed services. Affordability is associated with both availability and accessibility of care. It infers that services are of reasonable cost and that a family has sufficient resources to purchase these when needed. Acceptability of care means that a particular service is appropriate and offered in a manner that is congruent with the values of a target population. This can be hampered by a client's cultural preference and the urban orientation of health professionals (Bushy, 2013; NACRHHS, 2012). Box 19-5 lists barriers to health care in rural areas.

Providers' attitudes, insights, and knowledge about rural populations are also important. A patronizing or demeaning attitude, lack of accurate knowledge about rural populations, or insensitivity about the rural lifestyle on the part of a nurse can perpetuate difficulties in relating to those clients. Moreover, insensitivity fosters mistrust, resulting in rural clients' perceiving professionals as outsiders to the community. Some nurses in rural public health practice settings express

feelings of professional isolation and community nonacceptance. To address disparate views, nursing faculty members should expose students to the rural environment and the people who live there. Clinical experiences must include opportunities to provide care to clients in their natural (e.g., rural) setting to gain accurate insight about a particular community.

To design population-focused programs that are available, accessible, affordable, and appropriate, nurses must implement interventions that mesh with clients' beliefs. This implies that a family and a community are actively involved in planning and delivering care for those who receive it. Nurses must have an accurate perspective on rural clients. Although the importance of forming partnerships and ensuring mutual exchange seems obvious, to date, most research about rural communities has been for policy or reimbursement purposes. Empirical data about rural family systems are sparse in terms of their health beliefs, values, perceptions of illness, and health care-seeking behaviors as well as what is deemed to be appropriate nursing care. Therefore, nurse scholars must assume a more active role in implementing research on the needs of rural populations for nursing services to expand the profession's theoretical base and subsequently implement community-oriented, empirically based clinical interventions (deValpine, 2014; Williams, 2012; Williams et al, 2012).

NURSING CARE IN RURAL ENVIRONMENTS**Theory, Research, and Practice**

Information on nursing practice in small towns and rural environments is growing, and several themes have emerged as shown in Box 19-6. A nurse who practices in this setting can view each of these dimensions either as an opportunity or as a challenge.

Researchers from the University of Montana contend that existing theories do not fully explain rural nursing practice (Long & Weinert, 1989; Winters, 2013; Winters & Lee, 2009). Their focus has been on the key concepts pertinent to nursing theory (health, person, environment, and nursing/caring) and proposed relational statements that are relevant to clients and nurses in rural environments (see the Evidence-Based Practice box). Because the focus of their research was primarily with non-Hispanic whites living in the Rocky Mountain area, care must be taken about generalizing those findings to other geographic regions and minorities. These researchers propose that rural residents often judge their health by their ability to work. They consider themselves healthy, even though they may suffer from several chronic illnesses, as long as they are able to continue working. For the rural person, being healthy is the ability to be productive. Chronically ill people emphasize emotional and spiritual well-being rather than physical wellness.

Distance, isolation, and sparse resources characterize rural life and are seen in residents' independent and innovative coping strategies. Self-reliance and independence are demonstrated through their self-care practices and preference for family and community support. Community networks provide support but still allow for each person's and family's

BOX 19-6 Characteristics of Nursing Practice in Rural Environments

- Variety/diversity in clinical experiences
- Broader/expanding scope of practice
- Generalist skills
- Flexibility/creativity in delivering care
- Sparse resources (e.g., materials, professionals, equipment, fiscal)
- Professional/personal isolation
- Greater independence/autonomy
- Role overlap with other disciplines
- Slower pace
- Lack of anonymity
- Increased opportunity for informal interactions with clients/coworkers
- Opportunity for client follow-up upon discharge in informal community settings
- Discharge planning allowing for integration of formal and informal resources
- Care for clients across the life span
- Exposure to clients with a full range of conditions/diagnoses
- Status in the community (viewed as prestigious)
- Viewed as a professional role model
- Opportunity for community involvement and informal health education

From Bushy A: Conducting culturally competent rural nursing research. In Merwin B, editor: *Annual Review of Nursing Research: Focus on Rural Health*, 26:221–236, 2008; Hurme E: Competencies for nursing practice in a rural critical access hospital, *Online J Rural Nurs Health Care* 9(2):67–81, 2009. Available at <http://www.rno.org/journal/index.php/online-journal/article/viewFile/198/256>. Accessed January 8, 2011; Nelson W, editor: *Handbook for Rural Health Care Ethics*, Lebanon, NH, 2009, Dartmouth. Available at <http://dms.dartmouth.edu/cfm/resources/ethics/>. independence. Ruralites prefer and usually seek help through their informal networks, such as neighbors, extended family, church, and civic clubs, rather than seeking a professional's care in the formal system of health care, including services such as those provided by a mental health clinic, social service agency, or health department.

Although nursing is generally similar across settings and populations, there are some unique features associated with practice in a geographically remote area or in small towns where most people know one another. The following paragraphs highlight a few of the variations that nurses in rural practice report (Roberge, 2009; Winters, 2013; Woolston, 2010).

A nurse's professional and personal boundaries often overlap and are diffuse. It is not unusual for a nurse to have more than one work-related role in the community. For example, a nurse may work at the local hospital or in a physician's office and may also be actively involved in managing the family farm, a local grocery store, or pharmacy. For nurses, this means that many, if not all, clients they encounter are known also as neighbors, as friends of an immediate family member, or as part of one's extended family. Associated with social informality is a corresponding lack of anonymity in a small town. Some rural nurses say, "I never really feel like I am off duty because everybody in the county knows me through my work." In part, this can be attributed to nurses being highly respected and viewed by local

EVIDENCE-BASED PRACTICE

Nurse researchers at Montana State University proposed the following theoretical concepts and dimensions of rural nursing practice: (Long & Weinert, 1989; Winters, 2013; Winters & Lee, 2009).

- **Health:** Defined by rural residents as the ability to work. Work and health beliefs are closely related for rural Montana sample.
- **Environment:** Distance and isolation are particularly important for rural dwellers. Those who live long distances neither perceive themselves as isolated nor perceive health care services as inaccessible.
- **Nursing:** Lack of anonymity, outsider versus insider, old-timer versus newcomer. Lack of anonymity is a common theme among rural nurses who report knowing most people for whom they care, not only in the nurse–client relationship, but also in a variety of social roles, such as family member, friend, or neighbor. Acceptance as a health care provider in the community is closely linked to the outsider/insider and newcomer/old-timer phenomena. Gaining trust and acceptance of local people is identified as a unique challenge that must be successfully negotiated by nurses before they can begin to function as effective health care providers.
- **Person:** Self-reliance and independence in relationship to health care are strong characteristics of rural individuals. They prefer to have people they know care for them (informal services) as opposed to an outsider in a formal agency.

Nurse Use

In working with rural residents, it is important to know how they define their health and their environment, because their definitions may differ from yours. Understand that you may not find acceptance and trust immediately; rural residents often trust informal caregivers more than those in a formal organization.

Long K, Weinert C: Rural nursing: developing a theory base, *Sch Inq Nurs Pract* 13(3):275–279, 1999; Winters C, Lee H: *Rural Nursing: Concepts, Theory and Practice*, ed 3. New York, 2009, Springer Publishing.

people as experts on health and illness. Often rural residents informally ask a nurse's advice before seeing a physician for a health problem. Rural residents may ask health-related questions when they see a local nurse (who may be a neighbor, friend, or relative) in a grocery store, at a service station, during a basketball game, or at church functions (Bushy, 2012).

Nurses in rural public health practice must make decisions about the care of individuals of all ages with a variety of health conditions. They assume many roles because of the range of services they provide in a rural health care facility and because of the scarcity of nurses and other health professionals. Nurses who work in rural areas need to have skills that include technical and clinical competency, adaptability, flexibility, strong assessment skills, organizational abilities, independence, interest in continuing education, sound decision-making skills, leadership ability, self-confidence, and skills in handling emergencies, teaching, and public relations. The nurse administrator is also expected to be a jack-of-all-trades (i.e., a generalist) and to demonstrate competence in several clinical specialties in addition to managing and organizing staff within the facility for which he or she is responsible (Hurme, 2009; Roberge, 2009; Woolston, 2010).

Rural nursing practice provides challenges, opportunities, and rewards. The way in which each factor is perceived depends on individual preferences and the situation in a given

community. Challenges of rural practice sometimes include professional isolation, limited opportunities for continuing education, lack of other kinds of health personnel or professionals with whom one can interact, heavy workloads, an ability to function well in several clinical areas, lack of anonymity, and, for some, a restricted social life (Molinari & Bushy, 2012; Smalley et al, 2012; Warren & Smalley, 2014).

The most often cited opportunities and rewards in rural nursing practice are close relationships with clients and coworkers, diverse clinical experiences that evolve from caring for clients of all ages who have a variety of health problems, caring for clients for long periods of time (in some cases, across several generations), opportunities for professional development, and greater autonomy. Many nurses value the solitude and quality of life found in a rural community personally and for their own family. Others thrive on the outdoor recreational activities. Still others thoroughly enjoy the informal, face-to-face interactions coupled with the public recognition and status associated with living and working as a nurse in a small community. Disease prevention is also an important consideration in rural communities. The **Levels of Prevention** box shows the levels of prevention that nurse in a rural locale might use.

LEVELS OF PREVENTION

Rural Health

Primary Prevention

- The public health nurse partners with a women's organization in a faith community located in a small Midwestern town to instruct members on meal planning as a strategy to offset the tendency to develop diabetes in family members.
- The public health nurse advocates for policy changes regarding sexual education content (to include information on contraception that goes beyond abstinence) in the schools with the district commissioners of education.

Secondary Prevention

- The public health nurse screens congregation members of the faith community in the Midwestern town for the presence of diabetes.
- The public health nurse partners with the local critical access hospital to offer free cholesterol, blood pressure, and blood sugar screening as well as the influenza vaccine to adults attending the annual county health fair.

Tertiary Prevention

- The public health nurse collaborates with the senior center in the small community town, which provides meals on a routine basis to the elderly, to reach individuals with a diagnosis of diabetes.
- The public health nurse provides consultation on diabetic nutrition, exercise habits, foot care, and, if needed, assists clients in obtaining medications through a mail-order pharmaceutical vendor.

Although most of the publications about rural health care and nursing focus on hospital practice, much of that information is applicable to both community agencies and community-focused nursing (Davis and Droe, 1993; Molinari and Bushy, 2012). There are some work-related stressors of nursing in rural communities. Case (1991) in the 1990s identified stressful experiences of nurses working in rural Oklahoma public health

FIG 19-2 A hospital-sponsored health fair is one example of a community event to provide health services to individuals in a rural area.

departments as including: political/bureaucratic problems and intraprofessional and interpersonal conflicts associated with inadequate communication; unsatisfactory work environment and understaffing; difficult or unpleasant nurse–client encounters, such as with relatives who refuse to deliver needed care to clients, and with clients who are hostile, apathetic, dependent, or of low intelligence; fear for personal safety; difficulty locating clients, and clients falling through the cracks of the health care system. These same stressors continue to be cited by nurses who work in rural as well as urban public health agencies. Anecdotal reports describe specific stressors associated with geographic distance, isolation, sparse resources, and other environmental factors that characterize rurality.

Nursing in rural areas is characterized by physical isolation that may lend itself to any one of the following: professional isolation; scarce financial, human, and health care resources; and a broad scope of practice. Associated with personal familiarity with local residents, nurses often possess in-depth knowledge about clients and their families. Along with the acknowledged benefits, informal (face-to-face) interactions can significantly reduce a nurse's anonymity in the community and at times be a barrier to completing an objective assessment on a client. Like urban practice, rural community nursing as shown in **Figure 19-2** takes place in a variety of locations, including homes, clinics, schools, occupational settings, and correctional facilities, and at community events such as county fairs, rodeos, civic and church-sponsored functions, and school athletic events.

Research Needs

Recent empirical studies on rural nursing practice reinforce anecdotal reports by nurses (Bushy & Winters, 2013; Graves, 2009; Hurme, 2009; Merwin, 2006). Specific research topics of importance to nursing practice in rural environments include the following:

1. Most nurses indicate that they enjoy practicing in rural areas and are proud of what they do. They believe that their work deserves more recognition by professional nursing organizations. Also, the retention rate of nurses in some practice

settings is poor. The perspective of nurses who are dissatisfied with rural nursing provides a more complete picture of the rural experience. This information can be useful to a variety of people: other nurses who are considering rural practice, nurse managers in need of better screening tools to assess the fit between the nurse and the environment when interviewing applicants, planners of continuing nursing education programs, and faculty members who teach public health to undergraduate and graduate students.

2. More information is needed about the stressors and rewards of rural practice, in particular public health nursing. These data could lead to the development of stress management techniques to be used by nurses and their supervisors to retain nurses and to improve the quality of their workplace environment.
3. With the increasing number of rural residents in all regions of the United States, empirical data are needed on the particular nursing needs of rural client systems, especially under-represented groups, minorities, and other at-risk populations that vary by region and state.
4. A need also exists for the international perspective on the health of rural populations, and on nursing practice within the rural community. Australian, New Zealand, and Canadian nurse scholars have provided some insights into rural practice in these nations. Information is needed from less-industrialized nations as well as from those that are highly industrialized.
5. Technology increasingly is used in health care and seems to hold great potential in improving access to health care in rural and underserved areas. However, research is needed to determine the most efficient and effective way to meet the needs and preferences of rural clients, and to ensure quality.
6. Communication technology increasingly is used by institutions of higher learning to deliver educational programs to nurses who live and work some distance from campus. Empirical studies are needed to measure the most effective modalities to achieve desired learning outcomes and the impact on recruitment and retention of nurses in rural settings.
7. Rural-urban disparities in health status and health behaviors need closer examination from the nursing perspective. Evidence-based practice nursing guidelines are needed that take into consideration the rural context and preferences of residents who obtain health care in these settings.

Preparing Nurses for Rural Practice Settings

Nurses in rural practice need broad knowledge about nursing including health promotion, primary prevention, rehabilitation, obstetrics, medical-surgical specialties, pediatrics, planning and implementing community assessments, and understanding the public health risks and needs for emergency preparedness in a particular state. A community's demographic profile and its principal industry(ies) can provide a snapshot of local social determinants that can affect health. Using demographic information, a nurse can anticipate the particular nursing skills that will be needed to care for clients in a catchment area (U.S.A. Center for Rural Health Preparedness, n.d.). In rural areas

nurses use their knowledge of resources and their ability to coordinate formal and informal services to coordinate a continuum of services for clients even when resources are sparse and fragmentation exists in the health care delivery system.

Technology has great potential for connecting rural public health providers and consumers with resources outside of their community. The concept of *telehealth* is an expansion of the term *telemedicine*. Essentially, telemedicine more narrowly focuses on the curative aspect of health care, whereas telehealth encompasses preventive, promotive, and curative aspects of health care and can include delivery of education/information to a more distant site. Telehealth uses a variety of technology solutions such as a health care provider communicating by e-mail with clients, ordering medications from a pharmacy, consulting with other health care providers, or accessing advanced or continuing education offered by a university located some distance from the receiving site. More specifically, telecommunication technology could be as simple as nurses in two or more different public health settings consulting over the telephone or via computer video conferencing coordinating local health fairs, or as complex as nurse scholars collaborating with international peers on a community health-focused research project or a medical specialist located at a health science center using complex robotic surgical technology on a client who is located in another country. Regardless of the practice setting, the nurse must be computer literate and be proficient in using the communication technology that is available in that community. Increasingly, the Internet is linking nurses in rural public health practice with nursing colleagues, educators, and researchers in urban-based academic settings, thereby addressing often-cited concerns associated with professional isolation (ANCC, 2013; Molinari & Bushy, 2012; Bushy & Winters, 2013).

FUTURE PERSPECTIVES

It is important for all people involved in providing health care in rural areas to understand the possible problems they might encounter when trying to provide the continuum of needed services in an area with a disproportionately high number of underserved persons. Those who should be involved include residents, their elected representatives, the administrators of public and private health care agencies, and members of the media. The media need to focus on public health as well as hospital care and the lack of primary care providers in rural areas (deValpine, 2014). As discussed later, both case management and community-oriented primary health care (COPHC) are effective models for dealing with some of the care deficits and resolving rural health disparities.

Scarce Resources and a Comprehensive Health Care Continuum

The current fragmented health care system makes it difficult to provide a comprehensive continuum of care to populations living in areas having scarce resources, such as money, personnel, equipment, and ancillary services. In rural communities, the most critically needed services are usually preventive services, such as health screening clinics, nutrition counseling, and

BOX 19-7 Health-Related Priorities for Many Rural Communities

- Access to care
- Cancer (screening, early intervention, oncology services)
- Diabetes (prevention, screening, tertiary care)
- Maternal–infant and children services
- Mental illness and behavioral health services
- Nutrition/obesity
- Drugs, alcohol, and substance abuse
- Use of tobacco products
- Education and an array of community-based programs
- Public health infrastructures
- Immunizations and infectious diseases
- Injury and violence prevention
- Family planning
- Environmental and occupational health
- Emergency medical services infrastructures
- Long-term care/assistive living facilities

From Bennett K, Olatosi B, Probst J: *Health Disparities: A Rural–Urban Chartbook*, 2008. Available at [http://rhr.sph.sc.edu/report/\(7-3\)%20Health%20Disparities%20A%20Rural%20Urban%20Chartbook%20-%20Distribution%20Copy.pdf](http://rhr.sph.sc.edu/report/(7-3)%20Health%20Disparities%20A%20Rural%20Urban%20Chartbook%20-%20Distribution%20Copy.pdf). Accessed January 8, 2011; Gamm L, Hutchison L, Dabney B, et al: *Rural Healthy People 2010: A Companion Document to Healthy People 2010*, Vol I, II, III, College Station, TX, 2003, The Texas A&M University System Health Science Center, School of Rural Health, Southwest Rural Health Research Center. Available at <http://www.srph.tamhsc.edu/centers/rhp2010/publications.htm>. Accessed January 8, 2011.

wellness education (Bolin and Bellamy, 2014; Gamm et al, 2003). Box 19-7 lists several health related priorities for rural communities.

Although the nursing needs vary by community, there is generally a need in most rural areas for the following:

- School and parish nurses
- Family planning services
- Prenatal and postpartum services
- Resources for individuals diagnosed with HIV/AIDS and their families
- Emergency medical services
- Resources for families of children with special needs, including those who are physically and mentally challenged
- Mental health services
- Resources for older adults (especially the frail elderly and those with declining mental capacity) to include a continuum of residential and respite services, including adult day care, hospice, homemaker assistance, and provision of nutritional meals along with public transportation for those who remain at home

Providing a continuum of care has been further hindered by the closure of many small hospitals in the past two decades. Of those that remain, many report financial problems that could lead to closure (NACRHHS, 2012). A shortage or the absence of even one provider, most often a physician or nurse, could mean that a small hospital must close its doors. Closure of the hospital has a ripple effect on the health of local residents, other health care services, recruitment and retention of health

professionals, as well as on economic development efforts in a small community (USDA, 2013a, 2013b; USDHHS, 2013).

The short supply and increasing demand for primary care providers in general, and nurses in particular, will continue for some time. To help solve this problem, elected officials and policy developers need nurses, especially those in advanced practice roles, to provide vital services in underserved areas. In an effort to effectively respond to this opportunity, nurses must be creative to ensure delivery of appropriate and acceptable services to at-risk and vulnerable populations who live in rural and underserved regions. Nurses must be sensitive to the health beliefs of clients, and then plan and provide nursing interventions that mesh with the community's cultural values and preferences.

Healthy People 2020 National Health Objectives Related to Rural Health

Because the demographic profile varies from community to community, each state has variations in the health status of its population. *Healthy People 2020* has important implications for nurses in that a significant number of at-risk populations cited in that policy-guiding document live in rural areas across the United States (Bolin and Bellamy, 2014; AHCPR, 2013a, 2013b). Consequently, priority objectives vary, depending on population mix, health risks, and health status of residents in the state.

HEALTHY PEOPLE 2020

These selected objectives pertain to residents of both rural and urban areas:

- AHS-3: Increase the proportion of persons with a usual primary care provider.
- IVP-13: Reduce motor vehicle crash–related deaths.
- MHMD-9: Increase the proportion of adults with mental disorders who receive treatment.
- HDS-2: Reduce coronary heart disease deaths.
- IVP-1: Reduce fatal and nonfatal injuries.

From U.S. Department of Health and Human Services: *Healthy People 2020*, 2010. Available at <http://www.healthypeople.gov/2020/default.aspx>. Accessed January 9, 2011.

At the local level, communities have been using *Healthy People* as a guide for action and to identify objectives and establish meaningful goals. The three-volume *Rural Healthy People 2010: A Companion Document to Healthy People 2010* focused on the particular concerns relative to vulnerable populations in rural environments (Gamm et al, 2003). A parallel rural compendium is being developed for *Healthy People 2020* (Bolin and Bellamy, 2014).

The Center for Disease Control's (CDC, 2013a) *Healthy Communities Initiative* mobilized rural as well as urban communities to focus on chronic disease prevention. Individuals and groups at the local level collaborated with state health departments, the CDC, and other organizations to implement programs that promote and support good health in their community. This CDC initiative is a useful tool for state and local officials and health care planners to use to tailor *Healthy People*

objectives to fit a community's specific needs, both rural and urban. Translating national objectives highlighted in *Healthy People 2020* (USDHHS, 2013) into achievable community health goals requires integration of the following components to ensure that services will be acceptable and appropriate for rural clients:

- Health statistics must be meaningful and understandable, and they must include appropriate process and outcome objectives that can be readily measured.
- Strategies must be designed that involve the public, private, and voluntary sectors of the community to achieve agreed-on local objectives.
- Coordinated efforts are needed to ensure that the community works together to achieve the goals.

Consider, for example, general objectives in developing a health plan for a rural county having a large population of young people. *Healthy People 2020* objectives for the county should target women of child-bearing age, children, and adolescents. Priority objectives should include offering accessible prenatal care programs, improving immunization levels, providing preventive dental care instructions, implementing vehicular accident prevention and firearm safety programs, and educating teachers and health professionals for early identification of cases of interpersonal violence. On the other hand, consider a rural county that has a higher number of residents over the age of 65 years, compared with the national average. Priority objectives in the health plan should target health risks and problems of older adults in that community. Specific objectives might include developing health-promoting programs to prevent chronic health problems, or establishing community programs to meet the needs of those having chronic illness, specifically cardiovascular disease, diabetes, hypertension, and accident-related disabilities; or, organizing a partnership to build progressive/assistive care residential facilities in the community. In general, the objectives in *Healthy People 2020* are pertinent to people living in all areas and not unique to rural residents. The *Healthy People 2020* box illustrates selected objectives that fit people in rural as well as more urban areas.

When implementing community-focused health plans that emerge from *Healthy People 2020*, consideration must always be given to the rural context, such as sparse population, geographic remoteness, scarce resources, personnel shortages, and physical, emotional, and social isolation. In addition to being actively involved in empowering the community and planning and delivering care, nurses play an important role in representing their community's perspective to local, state, regional, and national health planners and to their elected officials.

BUILDING PROFESSIONAL-COMMUNITY-CLIENT PARTNERSHIPS IN RURAL SETTINGS

Health care reform initiatives are focusing on cutting costs while improving access to care with equitable quality for all citizens, especially vulnerable and underserved populations. State and local grassroots organizations must be actively involved for health care reform to succeed in rural areas. Specifically, professional-client-community partnerships are essential to accomplish reform at the local level. As seen in the *Linking*

Content to Practice box, nursing practice in rural areas is comprehensive and incorporates skills from nursing and public health. Two models have been found to be particularly useful for nurses in rural environments: case management and Community-Oriented Primary Health Care (COPHC).

LINKING CONTENT TO PRACTICE

As discussed, practice in rural areas relies on excellent nursing and public health skills in assessment, communication, cultural competency, problem solving, coalition building, coordination, and policy development, among others. Documents that guide the practice include the American Nurses Association Standards of Nursing Practice, the core competencies as identified by the Council on Linkages, and the Quad Council Public Health Nursing Competencies. As one example of the congruence, consider assessment. The Council on Linkages' Core Competency of "Assess the health status of populations and their related determinants of health and illness" under their analytic assessment skills is then elaborated on by the Quad Council as a public health nursing skill of "Conducts thorough health assessments of individuals, families, communities and populations" and the public health nursing practice standard under assessment of "the public health nurse collects comprehensive data pertinent to the health status of populations" (p. 15). The relationship among these three sets of standards continues through all phases of the public health care provision process.

From American Nurses Association: *Public Health Nursing: Scope and Standards of Practice*, Silver Spring, MD, 2007, Available at <http://www.nursebooks.org>; Public Health Foundation: *Council on Linkages: Core Competencies for Public Health Professionals*, 2008, Washington, DC, Author. Available at <http://www.phf.org/link/index.htm>. Accessed June 24, 2010; Quad Council: *Public Health Nursing Competencies*, 2009. Available at <http://www.astdn.org/publication/squadcouncilphncompetencies.htm>. Accessed January 17, 2011.

Case Management

Case management is a client-professional partnership that can be used to arrange a continuum of care for rural clients, with the case manager tailoring and blending formal and informal resources. Collaborative efforts between a client and the case manager allow clients to participate in their plan of care in an acceptable and appropriate way, especially when local resources are few and far between. The Practice Application at the end of this chapter demonstrates how nursing case management can allow an older adult resident to stay at home in a rural environment if adequate supports can be provided. Outcomes are often remarkably different when case management is used. Additional information on case management is found in *Chapter 22*.

Community-Oriented Primary Health Care

COPHC is an effective model for delivering available, accessible, and acceptable services to vulnerable populations living in *medically underserved* areas. This model emphasizes flexibility, grassroots involvement, and professional-community partnerships. It blends primary care, public health, and prevention services, which are offered in a familiar and accessible setting. As shown in *Box 19-8* the COPHC model is interprofessional, uses a problem-oriented approach, and mandates community involvement in all phases of the process (Graves, 2009; Molinari & Bushy, 2012).

BOX 19-8 Community-Oriented Primary Health Care (COPHC): A Partnership Process

The steps in the COPHC process include the following:

- Define and characterize the community.
- Identify the community's health problems.
- Develop or modify health care services in response to the community's identified needs.
- Monitor and evaluate program process and client outcomes.

Building professional-community partnerships is an ongoing process. At various times, nurses, other health professionals, and community leaders must assume the role of advocate, change agent, educator, expert, or group facilitator to gain both active and passive support from the community. Partnerships involve give-and-take negotiations by all participants to reach consensus. Essentially, the process begins with professionals gaining entrance into a community, establishing rapport and trust with local people, and then working together to empower the community to resolve mutually defined problems and goals. As mentioned previously and discussed also in [Chapter 20](#), the *Healthy Communities Initiative* is an excellent resource for developing, defining, and responding to the stated goals. Because of the importance of churches and schools in a rural community, leaders from those institutions often are key players in building provider-community partnerships. The organizational phase is a priority because it forms the foundation for all other activities related to planning, implementing, and evaluating community initiatives.

As was described for case management, professional-community partnerships allow more effective identification of existing informal support systems that are accepted by rural residents. The goal is to integrate community preferences with new or existing formal services. Public input should be encouraged early in the planning process and must continue throughout the process to allow the community to feel that it has ownership in the project. This strategy can go a long way to address local residents viewing the process as outsiders bringing another bureaucratic program into town. Strategies that nurses can use to enhance the building of partnerships in rural environments are listed in the [How To Build Professional-Community-Client Partnerships](#) box.

HOW TO Build Professional-Community-Client Partnerships

1. Gain the local perspective.
2. Assess the degree of public awareness and support for the cause.
3. Identify special interest groups.
4. List existing services to avoid duplication of programs.
5. Note real and potential barriers to existing resources and services.
6. Generate a list of potential community volunteers and professionals who are willing to assist with the project.
7. Create awareness among target groups of a particular program (e.g., individuals, families, seniors, church and recreation groups, health care professionals, law enforcement personnel, and members of other religious, service, and civic clubs).

8. Identify potential funding sources needed to implement the program.
9. Establish the community's health care priority list, and involve many community members in considering and selecting their health care options.
10. Incorporate business principles in marketing the program.
11. Measure the health system's local economic impact.
12. Educate residents about the important role the local health care system plays in the economic infrastructure of the community and the consequences of a system failure.
13. Develop local leadership and support for the community's health system through training and providing experience in decision making.

From McGinnis P: Rural Policy Development: A Community Leadership Development Approach, Kansas City, MO, 2003, National Rural Health Association.

Partnership models, such as case management and COPHC, have proven to be highly effective in areas with scarce resources and an insufficient number of health care providers. Individuals and communities who are informed, active participants in planning are more likely to develop consensus about the most appropriate solution for local problems. Subsequently, involved participants are more likely to use and support that system after it is implemented. Partnership models enhance the ability of rural communities to do what they historically have done well (i.e., assume responsibility for the services and institutions that serve their residents). Knowledge about partnership models and the skills to effectively implement them are useful for nurses who coordinate services that are accessible, available, and acceptable for rural populations in their catchment area.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES**Targeted Competency: Quality Improvement**

Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems.

Important aspects of quality improvement include:

- **Knowledge:** Explain the importance of variation and measurement in assessing quality of care.
- **Skills:** Use quality measures to understand performance.
- **Attitudes:** Value measurement and its role in good client care.

Quality Improvement Question:

Examine health statistics and demographic data in your geographic area to determine which vulnerable groups are predominant. Look on the web for examples of agencies you think provide services to these vulnerable groups. If the agency has a web page, read about the target population they serve, the types of services they provide, and how they are reimbursed for services. Learn about different agencies and share results during class. Based on your findings, identify gaps or overlaps in services provided to vulnerable groups in your community. Which data do these agencies collect to demonstrate the efficacy of their services? How could you deal with these gaps and overlaps to help clients receive needed services?

Prepared by Gail Armstrong, DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

PRACTICE APPLICATION

Mrs. Jones, an 89-year-old widow, was diagnosed over 10 years ago with progressive congestive heart failure. She continues to live in her beloved home of 60+ years in spite of being on continuous oxygen the last 3 years. She also has “bad knees” and gets around her house and yard with the use of a walker. Her husband of more than 60 years suddenly died 4 years ago of a heart attack while working on their farm. Their two married daughters live in California and Arkansas. The Midwestern town where she lives has about 1000 residents. The nearest hospital is more than 60 miles away from this town. Mrs. Jones’s 82-year-old widowed sister, Lydia Thomas, lives a few blocks from her. Their 76-year-old brother recently entered the county nursing home located in a town 20 miles away.

Even with her dyspnea and physical limitations, Mrs. Jones is able to live alone with her dog and cat, and insists that she will not relinquish her independent lifestyle as has her brother. Yet, in the past year she has been hospitalized three times: for a bad chest cold, for a kidney infection, and after a neighbor found her lying unconscious by the picnic table in her yard. Her doctor says this episode was related to a “heart problem.”

Upon being discharged from the hospital, Crystal Moore, the local home health nurse, was assigned to visit Mrs. Jones. Ms. Moore’s office is based in the County Senior Center near the nursing home where the brother is a resident. He is also a client of Ms. Moore and she visits him every Wednesday. The nurse provides outreach services to all the residents in the county referred to her by a large homehealth agency located in the city 70 miles away. As a case manager, she works closely with the hospital’s discharge planners to arrange a continuum of care for clients in the county. Nursing-related activities

include coordinating formal and informal services for clients, including biomedical supplies, oxygenation, nutrition, hydration, pharmacological care, arranging for personal care, homemaker assistance, writing checks, home maintenance, emergency respite services, and home delivery of meals.

- A. Describe the nursing roles that Ms. Moore uses in coordinating a continuum of care for Mrs. Jones in terms of nutrition, oxygenation, pharmaceutical and biomedical equipment, transportation, and homemaker assistance.
- B. Identify formal health care and support resources that can be accessed for Mrs. Jones.
- C. Identify informal support resources that might be available in the small community that could help to ensure that Mrs. Jones is safe.
- D. Identify three outcomes for Mrs. Jones that can be achieved by using nursing care (case) management.
- E. Select a rural community in your geographic area. Create hypothetical situations, or select real clients with real health problems (e.g., an older adult with Alzheimer’s disease, a middle-aged person with cancer requiring end-of-life care, a child who is dependent on technology as a result of a farm accident). Prepare a list of services and referral agencies in that community that could be used to develop a continuum of care for each of these cases. How are these the same as, or different from, the case described in this chapter?
- F. How could a public or home health nurse who is new to the community learn about formal and informal resources that could be accessed to develop a continuum of care for a rural resident for whom she cares?

Answers can be found on the Evolve site.

KEY POINTS

1. There is wide diversity in the demography, economy, and geography of rural communities.
2. Not all rural communities are based on an agricultural economy; most are not!
3. Although many are struggling, not all rural communities are suffering economically. Some rural communities only need more extensive economic development for sustainability.
4. Some rural towns are located in urban counties.
5. There are wide variations in the health status of rural populations, depending on genetic, social, environmental, economic, and political factors.
6. There is a higher prevalence of working poor in rural America than in more populated areas.
7. There are rural-urban health disparities. Rural adults 18 years and older overall are in poorer health than their urban counterparts; nearly 50% have been diagnosed with at least one major chronic condition. However, they average one less physician visit each year than healthier urban counterparts.
8. More than 26% of rural families are below the poverty level; more than 40% of all rural children younger than 18 years of age live in poverty.
9. General practitioners and nurse practitioners are usual providers of care for rural adults and children.
10. Rural residents must often travel more than 30 minutes to access a health care provider.
11. Nurses must take into consideration the belief systems and lifestyles of a rural population when planning, implementing, and evaluating community services.
12. Barriers to rural health care include the lack of availability, affordability, accessibility, and acceptability of services.
13. Partnership models, particularly case management and community-oriented primary health care (COPHC), are effective models to provide a comprehensive continuum of care in environments with scarce resources.

CLINICAL DECISION-MAKING ACTIVITIES

- Compare and contrast the terms *urban*, *suburban*, *rural*, *frontier*, *farm*, *non-farm residency*, and *metropolitan* and *micropolitan areas*.
- Describe residency as a continuum, ranging from farm residency to core metropolitan residency.
- Discuss economic, social, and cultural factors that affect rural lifestyle and the health care-seeking behaviors of residents who live there.
- Identify factors that affect the accessibility, affordability, availability, and acceptability of services in the health care delivery system.
- Compare and contrast the health status and lifestyle behaviors of rural and urban residents.
- Summarize key nursing concepts in terms of practice in the rural context.
- Examine the characteristics of rural community nursing practice and describe how these might differ from those of practice in more populated settings.
- Compare and contrast challenges, opportunities, and benefits of living and practicing as a nurse in the rural environment.
- Evaluate case management and community-oriented primary care as partnership models that can help nurses enhance the continuum of care for clients living in an environment with sparse resources.
- Propose potential areas for rural nursing research activities. Specify research questions that focus on the professional and clinical concerns of public health nurses who practice in the rural context.

Promoting Health Through Healthy Communities and Cities

Jeanette Lancaster, PhD, RN, FAAN

Dr. Lancaster is Professor and Dean Emerita of Nursing at the University of Virginia. She has edited this book with Dr. Marcia Stanhope through its previous eight editions.

Loren Kelly, RN, MSN

Ms. Loren Kelly is a Clinician Educator at the University of New Mexico College of Nursing. She is also the Interprofessional Education Coordinator for the College at the University of New Mexico Health Sciences Center. She earned her BA in Political Science from the State University of New York at Potsdam; the Associate degree in Nursing at Castleton State College in Castleton, CT, her MSN in Community Health Nursing from the University of New Mexico, College of Nursing.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Discuss the history of the Healthy Communities and Cities movement.
2. Discuss the Centers for Disease Control and Prevention Healthy Communities Program.
3. Describe the core concepts and principles that guide the development of a healthy community program.
4. Describe the steps used when working with communities in the Healthy Communities and Cities process.
5. Apply the steps in working with Healthy Communities and Cities to the concepts of health promotion.
6. Explain the role nurses can assume in working with Healthy Communities and Cities.

CHAPTER OUTLINE

History of the Healthy Communities and Cities Movement
 Definition of Terms
 Assumptions About Community Practice
 Healthy Communities and Cities in the United States

Healthy Communities and Cities Around the World:
 Selected Examples
 Developing a Healthy Community
 Models for Developing a Healthy Community

The **Healthy Communities and Cities (HCC)** initiative, or movement, began with the **World Health Organization (WHO)** in 1986 with the signing of the *Ottawa Charter for Health Promotion*. The initiative has grown and changed since 1986. This initiative, originally called *Healthy Cities*, has assumed a healthy communities focus in recent years. Some locales use the term *healthy communities and cities*, whereas other locales talk about *healthy municipalities and cities*, and still others use the term *healthy communities*. The Centers for Disease Control and Prevention (CDC) in the United States initiated work in this area in 2003, and called their program the *steps program*. The CDC program is now called *Healthy Communities*. The term *healthy communities* is used in this chapter; however, reference is made to other terms in order to describe the history of the movement and to refer to specific programs that use a term other than *healthy communities and cities*. The goal of this movement is to promote health through community engagement and collaboration to activate and diffuse local changes that support good health. The premise is that community members must be involved in identifying the need for health programs and in developing programs to meet those needs. Building healthy communities relies on broad-based participation to make systems change in communities that can improve the health of the residents. The overall goals are to build community capacity, prevent chronic diseases, reduce health risk factors and attain health equity.

This chapter provides an introduction to the history of the HCC movement and to the basic terminology related to the movement. It describes various models in which communities have structured their programs both in the United States and selected other countries. Key facilitators and barriers to the Healthy Communities process are discussed, as is the role for nurses in supporting the development and sustainment of healthy communities.

HISTORY OF THE HEALTHY COMMUNITIES AND CITIES MOVEMENT

HCC is found in many regions of the world. The movement began in 1986 when the WHO's *Ottawa Charter* became the first worldwide action plan for health promotion. At that time, the delegates to the conference declared that the following broad categories were prerequisites to health: peace, shelter, education, food, income, a stable ecosystem, sustainable resources, social justice, and equity. This is a much different approach to viewing health than the individualistic approach that holds that each person is responsible for his or her own health. Although 1986 seems to be in the distant past, the

areas for action that were determined by the *Ottawa Charter for Health Promotion* are highly relevant today (WHO, 1986). They are as follows:

- *Building healthy public policy:* Many countries around the world have begun to recognize the need to integrate health considerations into policy making and programming across sectors to achieve better health and health equity. One example of this is the Health in All Policies (HiAP) approach to improve population health. What this means is that health and equity must be embedded into governmental decision making at local, state, and national levels for collaboration across all of the sectors that influence health. Intersectoral collaboration includes policies in the areas of education, housing, transportation, land use, and neighborhood safety to promote health equity.
- *Creating supportive environments:* For example, when communities are being revitalized or developed, places should be designated as “green areas,” and made accessible to the public with parks, walking or bike paths, and fitness facilities. Both work and leisure should be a source of health for people. See [Chapter 17](#), Integrating Multilevel Approaches to Promote Community Health for a discussion of how the environment, especially the built environment affects health.
- *Strengthening community action:* The *Ottawa Charter* states (and this continues to hold true) that health promotion is most effective in communities when residents are fully engaged in the development and implementation of programs. This requires a “tried and true” public health approach in which nurses listen to and respond to the needs of the community. Community members need to be involved in setting priorities, making decisions, planning strategies, and implementing them in order to attain better health.
- *Developing personal skills:* This includes providing information and teaching people the skills that they need in order to be healthy, such as regular and competent hand washing, choosing the right foods, engaging in regular age-appropriate exercise, and learning to avoid risk factors and increase their protective factors. This step increases the options available to people so they can have more control over their own health and their environments.
- *Reorienting health services:* This involves health care systems emphasizing health promotion and prevention, beyond providing clinical and curative services. Individuals, community groups, health practitioners, health care institutions, and the government share responsibility for health promotion (WHO, 2010). The following Quality and Safety Education for Nurses box describes the importance of safety in community care.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

As described in earlier chapters of the text, including [Chapter 2: History of Public Health and Public Health Nursing](#), there are six Quality and Safety in Nursing competencies. All of the competencies could easily apply to Healthy Communities and Cities. However, safety is especially important for a healthy community program. Safety is an important competency for public health nurses who work in rural, suburban, and urban areas and for nurses who care for clients and communities in developed and less-developed countries. Aspects of community safety include but are not limited to the following:

1. **Knowledge:** Learn about the potential threats to safety including from the physical and social environments including those at home, school, and at worksites.
2. **Skills:** If a safety threat is identified, such as toxic materials from a factory being channeled into a water source, organize appropriate community leaders, workers, and volunteers to work toward reducing the pollution.
3. **Attitudes:** Be aware of the various conflicting points of view and goals in a situation in which industrial pollution affects the health of the community.

Safety Question

If you think that a particular industry is emitting noxious chemicals into the air or water of the community, how do you get specific information to inform your actions?

Answer: Start by going to the Environmental Protection Agency (EPA) website (<http://www.epa.gov>) and search for pollutants by categories including ZIP code, address, or facility name. See Envirofacts Multisystem Search User Guide at http://www.epa.gov/enviro/facts/multisystem_user_guide.html.

As discussed in [Chapter 17](#), health promotion is a process designed to help people increase control over, and improve, their health. Health promotion is not just the responsibility of the health sector but rather includes individuals, families, groups, and communities. Strategies and programs should be customized to meet local needs and take into account different cultural needs, economies, customs, resources, and priorities. The original goals of the Ottawa Conference continue to be areas of concern, and work must continue to achieve the goals. [Chapter 4](#) also addresses, from a global health perspective, the need for a healthy community approach in selected countries around the world.

HCC began in the United States in 1988, with Healthy Cities Indiana and the California Healthy Cities project. Healthy Cities Indiana adapted the European experiences to the American context. The concept of Healthy Communities was used to include localities that were not cities but rather smaller communities such as towns or counties. In recent years, many U.S. communities have initiated the HCC process with the result that thousands of communities have taken local action to promote health. Several of these communities are featured in the chapter as examples of what a focus on health promotion at the community level would look like.

In other parts of the world, HCC has different names, including Healthy Islands, Healthy Villages, and, in Latin America, Healthy Municipalities and Communities. In addition, national networks have developed in Australia, Canada, Costa Rica, Iran,

and Egypt. Other regional networks have been developed in Francophone Africa, Latin America, Southeast Asia, and the western Pacific. Particular attention is given later in the chapter to Healthy Municipalities and Communities in the Pan American Health Organization (PAHO) region, since PAHO's work is long-standing and well developed and has demonstrated effective results.

Some claim that the concept of a healthy community or city is not new ([Hancock, 1993](#)). It is based on the belief that the health of the community is largely influenced by the environment in which people live and that health problems have multiple causes: social, economic, political, environmental, and behavioral. The HCC process has been applied to rural and metropolitan areas. The HCC process engages local residents in action and is based on the premise that when people have the opportunity to work out their own locally defined health problems they will find sustainable solutions to those problems. This concept is integral to good public health practice, which is to engage those for whom programs are being developed in the identification of need for, planning, implementing, and evaluating the programs. The *Healthy People 2020* process is consistent with the way healthy communities and cities have developed their priorities and plans. One of the four goals of *Healthy People 2020* is to create physical and social environments that promote good health for all. This goal relies on an ecologic perspective that says that health and health behaviors are determined by many influences including personal, organizational, environmental, and policy factors. Many of the goals of *Healthy People 2020* will be challenging to meet in light of the poor economic conditions in the United States and many other countries. For example, it is difficult to increase the income of low-income persons in an era in which people continue to lose their jobs and where unemployment, especially unemployment of youth, is high. See the [Healthy People 2020](#) box for objectives that relate to healthy communities and cities.

HEALTHY PEOPLE 2020

Selected Goals That Pertain to Healthy Communities

- ECBP-8: Increase the proportion of worksites that offer a comprehensive employee health promotion program to their employees.
- ECBP-9: Increase the proportion of employees who participate in employer-sponsored health promotion activities.
- ECBP-11: Increase the proportion of local health departments that have established culturally appropriate and linguistically competent community health promotion and disease prevention programs.
- PA-13: Increase the proportion of trips made by walking.
- PA-1: Reduce the proportion of adults who engage in no leisure-time physical activity.
- PA-4: Increase the proportion of the nation's public and private schools that require daily physical education for all students.
- OSH-9: Increase the proportion of employees who have access to workplace programs

From U.S. Department of Health and Human Services, *Healthy People 2020*, Washington, DC, 2010, U.S. Government Printing Office.

DEFINITION OF TERMS

There are many definitions of a healthy community. The *Healthy People 2010* document described a healthy community as one that included those elements that enable people to maintain a high quality of life and productivity (USDHHS, 2000). To expand on this definition, consider what was stated in the document *Healthy People in Healthy Communities: A Community Planning Guide Using Healthy People 2010*: that a healthy community would include access to health care services that include both treatment and prevention for all community members; the community would be safe; and there would be adequate roads, schools, playgrounds, and other services to meet the needs of the people in the community; and that the environment would be healthy and safe (USDHHS, 2001).

The CDC defines a healthy place as one that is “designed and built to improve the quality of life for all people who live, work, worship, learn, and play within their borders—where every person is free to make choices amid a variety of healthy, available, accessible, and affordable options” (CDC, 2014, p. 201). The CDC also points out that a healthy community is one that continuously creates and improves both the physical and social environments and expands community resources to enable people to mutually support each other in carrying out essential life functions as well as in developing to their maximum potential. A healthy community seeks to improve the quality of life of its people and does this through collaboration, partnerships, diverse and extensive citizen ownership, and partnership in the process.

The principles of primary health care (WHO and UNICEF, 1978) and the Ottawa Charter for Health Promotion (WHO, 1986) were instrumental in the development of the Healthy Cities movement. **Primary health care** refers to meeting the basic health needs of a community by providing readily accessible health services. Because health problems transcend international borders, **international cooperation** is important to ensure health. The principles of primary health care include equity, health promotion, community participation, multisectoral cooperation, appropriate technology, and international cooperation.

Equity implies providing accessible services to promote the health of populations most at risk for health problems (e.g., the poor, the young, older adults, minorities, the homeless, and immigrants and refugees). As discussed in [Chapter 17, health promotion](#) and disease prevention focus on providing community members with a positive sense of health that strengthens their physical, mental, and emotional capacities. Individuals within communities become involved in health promotion through **community participation**, whereby well-informed and motivated community members participate in planning, implementing, and evaluating health programs. **Multisectoral cooperation** is the coordinated action by all parts of a community, from local government officials to grassroots community members. **Appropriate technology** refers to affordable social, biomedical, and health services that are relevant and acceptable to individuals’ health, needs, and concerns.

ASSUMPTIONS ABOUT COMMUNITY PRACTICE

There are different models of community practice, and the assumptions that professionals have about communities shape the implementation of the HCC process. The classic work of Rothman and Tropman (1987) describing these different models and some of the key assumptions continue to be relevant today, as shown in the examples used in this chapter. The key models for community practice include the following:

1. Locality development is a process-oriented model that emphasizes consensus, cooperation, and building group identity and a sense of community.
2. Social planning stresses rational-empirical problem solving, usually by outside professional experts. Social planning does not focus on building community capacity or fostering fundamental social change.
3. Social action, on the other hand, aims to increase the problem-solving ability of the community with concrete actions that attempt to correct the imbalance of power and privilege of an oppressed or disadvantaged group in the community.

Effective models of community practice use a partnership between citizens and professionals in which there is delegated power and citizen control (Rothman and Tropman, 1987). A partnership approach, considered a bottom-up approach, incorporates the concepts of a multisectoral approach as well as community participation. A partnership approach contrasts with the top-down approaches in which professionals and experts tell the citizens what to do rather than involve and ask them.

HEALTHY COMMUNITIES AND CITIES IN THE UNITED STATES

In the following paragraphs, HCC initiatives in various regions of the United States are discussed. These examples show the different models of community practice that are being implemented. Specifically, the CDC’s Healthy Communities Program emphasizes policy, systems, and environmental changes that focus on chronic diseases and that encourage people to be more physically active, eat a healthy diet, and not use tobacco. The rationale is based on the fact that about 50% of Americans are affected by chronic disease, and these diseases account for 7 of the 10 leading causes of death in the country. Also, there are many direct and indirect costs associated with being obese and overweight. Many chronic diseases are preventable. By preventing a chronic disease from occurring, people can enjoy a higher quality of life, communities have a decreased burden of illness, and both the state and federal governments are able to reduce the amount they spend on health care (CDC, 2011). Some examples of chronic diseases cited by the CDC include the fact that heart disease and stroke account for 30% of all deaths in the United States; that nearly 26 million Americans have diabetes; and one of every 3 adults and 1 of 5 children aged 6–19 in the United States are obese (CDC, 2011, p. 2). The CDC said also that more than half of all adults fail to meet

recommendations for aerobic physical activity based on the *2008 Physical Activity Guidelines for Americans*; that tobacco is the single most preventable cause of disease, disability, and death; and that excessive alcohol use is the third leading cause of death related to lifestyle (CDC, 2011, p. 2).

These chronic disease facts support the priority that the CDC has placed on funding projects that will interrupt chronic diseases in communities around the country. Since 2003, the CDC's Healthy Communities Program has funded more than 330 rural, urban, and tribal communities to support their goals. Specifically, their programs include Strategic Alliances for Health Communities, ACHIEVE (Action Communities for Health, Innovation, and Environmental Change), REACH U.S., Pioneering Healthy Communities (in collaboration with the YMCA of the USA), and Steps Communities (CDC, 2014). Also, Communities Putting Prevention to Work (CPPW) is a locally driven program that supports 50 communities as they tackle obesity and tobacco use. The CDC (2014) says that over 50 million people, or one in six Americans, live in a city, town, county or tribal community that benefits from these programs.

The CDC has also developed a set of “tools for community action” that can be used in developing healthy communities. Some of these tools are as follows:

1. Community Health Online Resource Center: formerly the Community Health Resources Database: see http://cdc.gov/DCH_CHORC/ to find assistance in planning, implementing, and evaluating community health interventions and programs that address their focus on chronic disease.
2. The Community Guide: see <http://www.thecommunityguide.org/index.html> to find evidence-based public health and community health interventions.
3. Community Health Assessment and Group Evaluation (CHANGE) Tool: Community leaders can use this tool to see what local policy, systems, and environmental strategies are currently in place in their communities and identify areas where health strategies are needed. CHANGE assists communities to define and prioritize areas for their own improvement. See <http://www.cdc.gov/nccdphp/dch/programs/healthycommunitiesprogram/tools/change/pdf/changeactionguide.htm>. Accessed August 15, 2014.
4. Action Guides: *The Community Health Promotion Handbook: Action Guides to Improve Community Health* (Partnership for Prevention, 2008). In collaboration with the Partnership for Prevention program, the CDC has developed a set of “how-to” guides for five community-level health promotion strategies related to its chronic disease prevention target areas of diabetes self-management, physical activity, and tobacco-use cessation. See <http://www.prevent.org/Initiatives/Action-Guides.aspx> for a listing of specific guides. Also, see the CDC website for the other five guides to help communities develop health programs.

Given the usefulness of the CDC *Community Health Promotion Handbook*, further discussion is warranted here. The recommendations for the five guides that the CDC chose came from the Task Force on Community Preventive Services (TFCPS, 2005). The handbooks primarily target public health

professionals but also can be used by community leaders. The Task Force on Community Preventive Services continually updates its recommendations. See www.uspreventiveservicestaskforce.org. The current task force is called the U.S. Preventive Services Task Force (USDHHS, 2014). This guide provides health professionals with an authoritative source for making decisions about preventive services. The guides build on a socio-ecological model that recognizes that social and physical environments affect health and health behavior. This model divides the environment into five areas that affect health behavior: individual, interpersonal, organizational, community, and policy. Using the *Handbook* relies on the same process used in the assessment of a community. In other words, before deciding which of the five areas to target in your work, follow these steps:

1. Conduct a needs assessment and set health priorities.
2. Find out what social and environmental factors may affect each health priority as well as what options are available for dealing with the chosen health priorities.
3. Think about the acceptability (to the community) and the feasibility (are resources available, etc.) to implement the project(s).

As you work with the action guides, remember to take small steps and do first things first; involve the appropriate people and do not be reluctant to make changes as you go based on what you learn and the outcomes you have (Partnership for Prevention, 2008).

HEALTHY COMMUNITIES AND CITIES AROUND THE WORLD: SELECTED EXAMPLES

As mentioned earlier, PAHO in collaboration with the WHO has a long-standing involvement in developing healthy communities that they call the Healthy Municipalities and Communities Movement. The mission of this movement is to “strengthen the implementation of health promotion activities at the local level, making health promotion a high priority of the political agenda; fostering the involvement of government authorities and the active participation of the community, supporting dialogue, sharing knowledge and experiences and stimulating collaboration among municipalities and countries” (PAHO, 2012). Other key concepts in their approach include multisectoral partnerships to improve social and health conditions and advocacy for developing **healthy public policy**, maintaining healthy environments, and promoting healthy lifestyles. PAHO believes that creating a healthy municipality involves a process that relies on strong political commitment and support that is aligned with equally strong communities who are determined to achieve their goals and who participate actively in the process of goal achievement (PAHO, 2012).

PAHO recommends a participatory development framework to gain commitment from the mayor, local government (all sectors), and representatives of community groups and organizations. PAHO has found this process to be the most effective in the Americas. The phases are as follows:

1. Aspects in the initial phase of the process
 - Meet with local government authorities and community leaders to gain their perspectives about such things as

healthy spaces and health promotion and to request that they make a public statement as well as a joint declaration of their commitment.

- Create an intersectoral, community planning committee.
 - Conduct a needs assessment including analysis of problems and needs.
 - Build consensus and decide on priorities for action.
2. Steps in the planning process
 - Train the committee and task forces to ensure that they understand the concept of healthy community, the settings approach to health promotion, and participatory methods including needs assessment, planning, evaluation, and health education.
 - Develop an action plan.
 - Mobilize resources needed to implement the plan and develop a detailed work plan.
 3. Moments in the consolidation phase of the process
 - Implement activities that are included in the plan. Examples might be establishing health-promoting schools, workplaces, markets, hospitals, and other healthy environments.
 - Evaluate the results as well as the quality of participation.
 - Share knowledge and experiences with others.

PAHO notes that the steps that work in its region may be somewhat different from those that have been successful in Canada, the United States, and Europe. Later in this chapter, the 20 steps that PAHO says have been used by these other countries are cited as a way for nurses and other public health workers to develop a healthy community strategy. Interestingly, PAHO has found that it must start its process by gaining support from the mayor of the community and from other community leaders. These individuals must understand the concept of health promotion and the healthy municipalities process before they will offer their support. PAHO has also found that it must have a strong and knowledgeable support group who can envision a healthy municipality and convey that vision to opinion leaders (PAHO, 2012).

There are many excellent examples of Healthy Communities and Cities around the world. PAHO says that in some countries in their region, such as Mexico, Costa Rica, Chile, and Cuba, national networks have been established and been producing good results for many years (PAHO, n.d.). A few examples are highlighted here with information on how to locate their websites and learn more about the work being done around the world.

- *Ontario (Canada) Healthy Communities Coalition:* They focus on “What makes a healthy community.” Their website, www.ohcc-ccso.ca, is filled with useful resources.
- *Horsens, Denmark:* One of their key foci is on “safe community Horsens.” Their website, www.horsenssundby.dk, is in Danish, but the button to choose English is clearly marked and they provide an overview of the work they are doing.
- *Community Builders of New South Wales, Australia:* They have an interactive electronic clearinghouse for persons involved in community level, social, economic, and environmental renewal, including community leaders, community and government workers, volunteers, program managers,

academics, policy makers, youth, and seniors. They include rural and regional communities (www.communitybuilders.nsw.gov.au).

- *Association for Community Health Improvements:* This organization’s website includes many healthy community tools and organizations in the United States and internationally. Similarly, www.healthycommunities.org hosts a website with valuable information about healthy communities and extensive links to other sites.

Selected examples of healthy communities in the United States are discussed later in this chapter. Also see Chapter 4 for examples of Healthy Cities Toronto, Canada, and Chengdu, China.

DEVELOPING A HEALTHY COMMUNITY

What do people want from a healthy community? We know that each community is different and its challenges, goals, resources, competencies, problem-solving skills, and practices are different. As discussed throughout the chapter, many organizations in the United States and other countries have worked to help communities become healthier (Figure 20-1). One of these organizations in the United States is the National Civic League (2007). (See www.communitycommons.org/tag/nation-civic-league). In 2014, the National Civic League partnered with Community Commons to celebrate 25 years of Healthy Communities and to spread the ideas and insights in published and new online media. They emphasize the complexity of developing healthy communities and have identified five principles that they think should be applied in community work if the goal is to find solutions using a broad-based inclusive process. These principles are as follows:

1. A broad definition of health that goes beyond the absence of disease to address the root problems in communities and

FIGURE 20-1 Community participation for developing a healthy community involves a representative community planning committee. (From CDC, PulseNet News, 2004. Available at: http://www.cdc.gov/pulsenet/newsletter/Spring_2004.htm. Accessed January 10, 2011.)

includes economy, education, parks and recreation, arts, mental health, and community spirit and unity.

2. A collaborative, consensus-based approach to problem solving that involves a diverse group of citizens from the community.
3. An assets-based approach to problem solving that defines people and relationships by their skills and abilities rather than their needs and deficits.
4. Addressing challenges at a systems level in the community rather than implementing another short-term, low-impact project.
5. Creating a shared vision for the future that captures the hopes and dreams of the community and that guides collaborative work.

Other principles will guide the development and implementation of a healthy community. Examples of useful principles include the following:

- The whole is greater than the sum of the parts; in other words, most communities have limited resources, and no one agency can do all that is needed. However, if agencies work together, the outcome of the whole can be much bigger than the outcome of the aid provided by one agency.
- A change in one part of the system affects the others. For example, if the public transportation workers in a large city go on strike and there is no public transportation for many days, many areas of the community will be affected.
- Collaboration is central to the development of a healthy community.
- All systems have feedback loops whereby information from one area is fed back to the whole and provides an opportunity for change or “course correction.” For example, you might establish a helping program for dependent older adults where daycare is provided at low cost. This would enable the family members with whom the elder lives to provide safe care while they worked. However, if the family has no transportation of their own and the facility is not accessible by public transportation, the program would not be as helpful as hoped.

The National Civic League also asked hundreds of communities across the country “What would your community look like if it were a really healthy place to live?” The replies shown in [Box 20-1](#) come as no surprise. You might ask yourself that

same question before looking at [Box 20-1](#) and see how close your replies are to those of the respondents.

This chapter indicates that a healthy community has involvement, inclusiveness, cooperation, and collaboration, among other qualities. Collaboration can help make the best use of resources, reduce duplication and competition, increase effectiveness, and develop more sustainable resources. It is like a recipe in that each agency in the collaboration brings one or more ingredients to the product. Putting all the ingredients together leads to a better product. Collaboration involves doing things differently than in the past and developing different kinds of partnerships and relationships. Organizations that work together effectively have generally achieved three things:

1. High levels of trust
2. Serious time commitment from the partners
3. A diminished need to protect their own turf ([Torres & Margolin, 2003](#))

Collaboration requires the same mix of behaviors and goals as those associated with the development of a healthy community—that is, a group of participants including those who are paid and volunteers who bring different skills and talents to the process and who work together to do the following:

1. Address a specific problem or opportunity
2. Work on a broad agenda of mutually beneficial goals
3. Provide a forum to discuss and respond to community concerns, interests, and resources
4. Recognize that there are roles in a partnership and they will be different from the role the person had in the parent organization.

As mentioned earlier, Indiana and California have the longest history of Healthy Communities and Cities in the United States. Healthy Cities Indiana began as a pilot program in 1988 with a grant from the W.K. Kellogg Foundation as a collaborative effort among Indiana University School of Nursing, Indiana Public Health Association, and six Indiana cities. On the basis of this project’s success, the W.K. Kellogg Foundation funded the dissemination phase, called CITYNET-Healthy Cities, in cooperation with the National League of Cities through their network of 19,000 local officials ([Flynn, Rider, & Ray, 1991](#)). This was an extensive project that initially involved six cities (Gary, Fort Wayne, New Castle, Indianapolis, Seymour, and Jeffersonville). Activities in these cities focused on problems of diverse populations. For example, actions were consistent with local priorities that included problems of children, teen parents, the homeless, access to health care, crime and violence, and older adults. Action was also taken on the broader environmental policy issues, including management of solid waste and promotion of air quality. For each of these projects, the Community Health Promotion process was followed, thereby providing a broad base of community participation at all stages of community planning. This was a process developed at Indiana University School of Nursing, and it was consistent with many of the other U.S. and international processes for implementing healthy community initiatives.

An early example of the use of the Community Health Promotion process was the New Castle Healthy City community

BOX 20-1 What Is a Healthy Community?

- A clean and safe environment
- A diverse and vibrant economy
- Good housing for all
- Good roads and good public transportation
- Parks, playgrounds, and recreational facilities
- People who respect and support each other
- A place that promotes and celebrates its cultural and historical heritage
- A place where citizens and government share power and where citizens feel a sense of belonging
- A place that has affordable health care for all
- A place that has good schools
- A place that has and supports strong families

EVIDENCE-BASED PRACTICE

This case study examined how lack of access to basic health care affects the health of poor, rural people in Gambia and what strategies including extensive use of nurses can help alleviate some of the health problems. Although this study was carried out in an African country, the information learned by the researchers has application in any country in which people live in rural areas and have difficulty accessing health care. The authors point out that poor people in developing countries tend to suffer “from a phenomenon known as the poverty penalty (the additional cost paid for goods and services by the poor relative to the more affluent)” (Sanneh et al, 2013, p. 126).

Sub-Saharan Africa, including Gambia, has a higher under-five mortality rate than anywhere else in the world. The 2007-2020 National Health Policy Framework of Gambia, entitled “Health is Wealth” aimed to address health issues through both preventive and curative services. They developed a health pyramid that placed primary care (village health services) at the base; secondary care (minor and major health centers) as the next two types of care delivery moving up the pyramid; and tertiary care (hospitals) at the peak of the pyramid.

Their case study took place in Kiang West, in the Lower River Region of Gambia, which has a 50% poverty rate among its population ratio of 30,000 people per primary health care facility. Roads are not well developed and there is little economic activity. This was the work of a multistakeholder group including representatives from the government, Medical Research Council, World Health Organization, and the United Nations International Children Emergency Fund. The representatives of the health sector and a range of stakeholders initiated various activities to improve care, including improving staffing at the Karantaba Health Centre with more traditional birth attendants and village health workers who worked with the community health nurses to provide primary health care. They expanded programs for immunizations, providing children with two high doses of Vitamin A (which is critical to child health and immune function), surveillance of infectious disease, and mid-wifery services. Nurses play a key role in health care in this country. They documented improvements in the primary care services that they increased.

Nurse Use

What the collaborators in the multistakeholder group learned is that “no single organization, sector, nor approach can provide answers for underdevelopment, poverty, and ill health.” They noted that “the importance of cooperation, both within a specific sector and across sectors, cannot be stressed enough” (p. 132).

Sanneh EJ, Hu AH, Njai M, et al: Making basic health care accessible to rural communities: A case study of Kiang West District in rural Gambia, *Public Health Nursing* 31(2):126–133, 2013.

assessment. The community committee found that there were high death rates in the community from cancer, chronic obstructive pulmonary disease, and heart disease. The committee asked the following questions: Why were rates higher in this area than in the state and the nation? What were the lifestyle choices of people in the community? What in the environment supported or inhibited healthy choices?

The committee worked with the staff at Indiana University School of Nursing to develop a survey to obtain baseline data on health behaviors in the community. Staff at the University trained local volunteers in survey data collection. They distributed 1000 door-to-door surveys using a system that ensured appropriate geographic coverage in the community. The response rate of 50% demonstrated the community’s interest in health concerns. They then compared their findings with the national health objectives (USDHHS, 1991). They found high

levels of unhealthy behaviors, such as cigarette smoking and inadequate exercise, compared with the *Healthy People 2000* national objectives.

They used the survey results to determine the focus of their Healthy City initiatives. Using the data, they testified before the county commissioners about the need for health education and to support the employment of a health educator in the local health department. The cigarette smoking results were used by the committee to testify before the city council in support of an ordinance banning smoking in city buildings. The committee also sponsored community health awareness programs including a family fitness walk, safety checks of bicycles, and presentations on healthy food preparation emphasizing reduced fat and salt in meals.

New Castle has expanded its focus and is now known as Healthy Communities of Henry County. They focused on developing a network of walking trails throughout the county on the Trans-Indiana National Road Heritage Trail (NRHT) (Figure 20-2). Their 15th Annual Raintree Ride was held September 2014. (See www.hchcin.org for more details on this worthy project and the implied enthusiasm for its accomplishment.) The process for the walking trails initiative, which began in 2002, is consistent with that of other successful healthy community projects. Specifically, consultants worked with the committee to conduct a feasibility study and write a grant. Over the years, the committee obtained broad community support and cooperation, not only in defining local problems, but also in setting priorities and implementing their initiatives. Their interventions integrated individual lifestyle changes and policy changes aimed at promoting supportive environments for health.

FIGURE 20-2 Walking trails in Indiana help people engage in health-promoting exercise. (From indianatrails.org, 2010. Courtesy of Beverly Matthews. Available at: <http://www.indianatrails.org/NRHT/photos.htm>. Accessed January 12, 2011.)

Another example in Indiana is the Healthy Communities Initiative in Bartholomew County. The Initiative began in 1994 with a goal of improving health and quality of life for residents of the county. They have remained true to their original concept of collaboration across the community. Their Guiding Principles are as follows:

- Collaboration
- Community Ownership
- Inclusive/Broad Based
- Benchmark & Measure Outcomes
- Long-Term Commitment
- Continuous Learning
- Positive Motivation

The current collaboration is between Columbus Regional Hospital, schools, businesses, local government, churches, and others working together to address identified health needs. See more at <http://www.crh.org/community-involvement/healthy-communities.aspx#sthash.vUfQc1D7.dpuf>. They have action teams in community medication assistance, caring parents, domestic violence, Proyecto Salud, healthy lifestyles, tobacco awareness, volunteers in the medicine clinic, and a breast feeding coalition (Columbus Regional Hospital, 2014).

The second state to be featured is California. The California Healthy Cities and Communities (CHCC) is a program of the Center for Civic Partnerships, a part of the Public Health Institute. For the past 25 years, the Center has assisted and supported over 100 cities and communities in the state to develop community health improvement initiatives (Center for Civic Partnerships, 2014). They work with communities of varying sizes and have developed strategies to curtail exposure to tobacco, increase opportunities for physical activity, encourage better nutrition, and improve public safety. This network is built on the premise of shared responsibility among community members, local officials, and the private sector. Community participation is the cornerstone of the projects, and the mission is to reduce inequities in health status that exist among diverse populations in communities. They publish a newsletter called *Connections* that can be accessed on their website: <http://www.civicpartnerships.org/#/ca-healthy-cities-and-communities-progra/cjhg>.

In 1989 Pasadena became a charter city of the California Healthy Cities project and produced a quality-of-life index with extensive input from residents, technical panels, and neighborhood groups. The index included over 50 indicators affecting community life, such as safety, education, substance abuse, recreation, economy, and housing. The index guided policy development in tobacco control, alcohol availability, and infant health education. It also assisted city and community agencies in planning, priority setting, resource development, and budgeting. In 2008, Pasadena engaged a consulting group to help them update these indicators so they might continue their growth as a healthy city.

Another example of California Healthy Cities and Communities is in Chico. A Healthy Chico Kids 2000 community-wide initiative was started, focusing on nutrition and health promotion. Nutrition education was provided for students in kindergarten through sixth grade. A dietary assessment was conducted

that led the school district to reduce fat calories in school lunches. The initiative was expanded to increase awareness of cardiovascular risk factors among elementary school students, and the work is ongoing.

In California, Building Healthy Communities is a ten-year comprehensive community effort to help Californians think about and support the health of the community. This work is funded by the California Endowment Building Healthy Communities fund. The Endowment distributed \$1.7 billion in its first decade of operations. The Endowment thinks that a specific focus helps them have a great impact, and they are focusing on healthy community building. Specifically, they are targeting “a nexus of community, health, and poverty to advance a ‘prevention movement’ in California” (California Endowment, 2010, p. 1). The Endowment plans to focus on this area for the next decade to develop “places where children and youth are healthy, safe and ready to learn” (California Endowment, 2010, p. 2). They think that the health of children is a primary indicator of the health of its communities (Figure 20-3). For news and information about Building Healthy Communities. See www.calendow.org/healthycommunities/building-healthy-communities/.

FIGURE 20-3 Supportive communities provide playgrounds where children can play and exercise in a safe location. (From Metro Regional Government, 2010. Available at: <http://www.oregonmetro.gov/index.cfm/go/by.web/id/149>. Accessed January 10, 2011.)

There are thousands of Healthy Communities and Cities programs in the United States seeking local solutions to complex problems. Nurses often play key roles in the work of Healthy Communities and Cities programs.

MODELS FOR DEVELOPING A HEALTHY COMMUNITY

There are many models to guide the development of a healthy community. The models have a considerable amount of commonality. This section discusses how a nurse could either lead or be part of a team responsible for designing, implementing, and evaluating a healthy community. As has been seen, most of the successful healthy communities or cities establish priorities that are identified after careful assessment and enormous amounts of community involvement. Nearly 20 years ago, faculty at the Indiana University School of Nursing under the leadership of Beverly Flynn developed a **Community Health Promotion Model** by adapting the European model of cities to the United States. This section discusses the key steps needed to develop a healthy community and compares them to the model developed at Indiana University. The steps of a general model that PAHO describes as common to models in the United States, Canada, and Europe are as follows (PAHO, 2012):

1. Build a local support group
2. Know about the Healthy Cities idea
3. Know the city or community
4. Gain financial support
5. Decide where the organization for the project will be located
6. Develop the proposal
7. Appoint a project steering committee
8. Analyze the environment in which the project will take place
9. Define clearly the work of the project
10. Set up the project office
11. Plan a long-term strategy
12. Build project capacity
13. Establish accountability mechanisms

Now compare the previous 13-step model to the nine steps in the Community Health Promotion Model (Produced by the Institute for Action Research for Community Health/Indiana University, 1994) (Flynn, 1997):

1. Orient the community to the idea of community health promotion. For example, meet with formal and informal leaders to identify persons in the community who have an interest in and the capability to support the community development process. You could hold an informational community forum, or establish a task force to plan. The key is to find people who are committed to the process.
2. Build the partnership. Learn who the formal and informal community leaders are so you know who is listened to in the community. Be sure to have broad-based representation on your planning committee. Remember that people participate when they think there is a need, feel a sense of community, see their involvement as helpful and worth their time, and think the benefits outweigh possible costs (CDC, 1997).

BOX 20-2 Principles of Community Engagement

Before starting a community engagement effort:

- Be clear about the purposes or goals of the engagement effort, and the populations and/or communities you want to engage.
- Become knowledgeable about the community in terms of its economic conditions, political structures, norms and values, demographic trends, history, and experience with engagement efforts. Learn about the community's perceptions of those initiating the engagement activities.

For engagement to occur, it is necessary to:

- Go into the community, establish relationships, build trust, work with the formal and informal leadership, and seek commitment from community organizations and leaders to create processes for mobilizing the community.
- Remember and accept that community self-determination is the responsibility and right of all people who comprise a community. No external entity should assume it can bestow on a community the power to act in its own self-interest.

For engagement to succeed, you need to:

- Partner with the community to create change and improve health.
- Recognize and appreciate all aspects of community engagement and respect community diversity. In order to effectively design and implement approaches for community engagement, be aware of the various cultures and other areas of diversity of a community.
- Realize that you can only sustain community engagement by identifying and mobilizing community assets, and by developing capacities and resources for community health decisions and action.
- Be prepared to turn over control of actions or interventions to the community, and be flexible enough to meet the changing needs of the community.
- Make a long-term commitment to the engaging organization and its partners.

From Centers for Disease Control and Prevention: Principles of community engagement, Atlanta, 1997, CDC. Available at <http://www.cdc.gov/phppo/pce>. Accessed April 4, 2010.

Box 20-2 describes principles of community engagement that need to be considered in the community engagement process.

3. Develop a structure in the community for health promotion. This step is similar to the PAHO stage of assembling a steering committee that will plan and coordinate the work. Some ways to collaborate and get the work done that support the HC process are (1) the whole local partnership deliberates and shares information, but subgroups make decisions and implement them; (2) the local partnership serves as a single advisory board for multiple agencies; and (3) the whole local partnership makes decisions, but subgroups take action together (Veazie et al, 2001). The steering group might develop and communicate a clear vision and mission that is broadly understood by all participants and not just by health professionals. The mission should define the problem and acceptable solutions in such a way as to engage (not blame) those community members most affected and not to limit the strategies and environmental changes needed to address the community-identified concern. Ongoing action planning should identify specific community and system changes that can lead to widespread behavior change and community health improvement. The committee should develop widespread leadership, engaging a broad group of members and

allies in the work of the community organization, mobilization, and change (Roussos & Fawcett, 2000). The membership of the working group should be diverse and clearly reflect the community's composition.

4. Determine who will lead the health promotion work. You may need to provide some leadership development work at this stage, such as sending members to conferences or workshops or using consultants or online training programs.
5. Assess the community. The steps here follow those in the chapter on community assessment. Start by clarifying the purpose of the assessment and what you will do with the data you collect. The assessment provides the frame of reference for identifying the community's strengths, needs, and resources.
6. Plan for community-wide health. Many of the skills for working with groups that are discussed in Chapter 16 will be used in this step of the process, as will models for planning in Chapter 25 that discusses program management.
7. Develop community action for health. The interventions at this stage should be designed to achieve the outcomes cited in Box 20-3. These nine areas can guide the selection of actions and provide a focus for the evaluation.
8. Provide information based on data to policy makers. Effective development of public policy relies on dialogue between those making the policies and the members of the public who will be affected by them. The aim is to link policy makers, professionals, and citizens together to achieve commonly agreed on health goals. Examples of healthy public policies include seat belt legislation, no-smoking policies,

motorcycle helmet laws, handgun laws, and immunization policies for school-age children. Providing information is a way to serve as an advocate. Nurses may be asked to testify or assist others to prepare testimony that will give the city council, county commissioners, or other members of planning groups the information they need to promote the development of healthy public policy.

9. Monitor and evaluate the progress. This step is similar in all problem-solving processes. You must watch the progress, make sure you stay on track, or make a course correction if needed and then evaluate the outcome.

As can be seen, both models use a problem-solving approach, and the latter is clearly similar to the use of the nursing process in the community with a goal of promoting health. In the following box a brief case illustrates how a model such as the ones listed previously are used to guide the development of a healthy community.

HOW TO Work with a Healthy Community Initiative: A Case Example

The Crooked Creek Quality of Life Initiative (CC QOLI): A Community Development Experience took place in Indianapolis, Indiana. The purpose of the initiative was to improve the quality of life of residents of a geographically defined neighborhood in an Midwestern city in the United States. An advisory board provided oversight for a comprehensive assessment conducted by nursing students. The assessment results were used for developing a proposal that funded an advisory group appointed by the mayor of the city. The PAHO Healthy Cities and Municipalities model was used to bring diverse sectors of the community together to collaborate in order to address the conditions responsible for health and well-being. Organizations involved included a hospital, social service agency, housing development agency, and university.

The goal of the CC QOLI was to improve the quality of life of Crooked Creek residents through:

1. Revitalization of built environments (such as in commercial and community buildings, housing, roads, and sidewalks)
2. New collaborations among health, education, and social service organizations
3. Engagement of the residents in community improvement

Initiatives implemented to achieve these goals were investment in a housing program for low- and moderate-income residents; construction of a Family Pavilion to address the civic, social, intergenerational, cultural, and recreational needs of Crooked Creek individuals and families; and a School Health Program for area students.

Results Achieved

The Fay Biccard Glick Family Pavilion at Crooked Creek was constructed and now provides a wonderful space for community gatherings, youth and family activities, recreation, and an affordable venue for wedding receptions, family reunions, graduation ceremonies, open houses, and religious services. The School Health Program moved health care delivery beyond traditional hospital walls and is now part of a broader vision to build healthier communities. School corporations have adopted healthier school policies and are able to address chronic issues of asthma, obesity, and absenteeism. Investments in housing have resulted in completion of three congregate living homes providing a home for 12 disabled residents, and the most recent home uses "green" building practices. Additional results have been the provision of costly repairs to the homes of 33 elderly homeowners; education of 60 potential homebuyers about the home-buying process; and down payment

BOX 20-3 Designing Interventions and Evaluating Results of Healthy Municipalities and Cities

- **Health education:** Health knowledge, attitudes, motivation, intentions, behavior, personal skills, and effectiveness
- **Influence and social action:** Community participation, community empowerment, social standards, and public opinion
- **Healthy public policies and organizational practices:** Political statutes, legislation, and regulation; location of resources; organization practices, culture, and behavior
- **Healthy living conditions and lifestyles:** Use of tobacco, availability of food and food choices, physical activity, consumption of alcohol and drugs, relationship between protective factors and risk factors in the physical and social environment
- **Effectiveness of health services:** Delivery of preventive services, access to the health services, and quality of services
- **Healthy environments and spaces:** Restricted sale of tobacco and alcohol; restrictions on illicit drug use; positive environments for children, young people, and older adults; and sanctions for abuse and violence
- **Social results:** Quality of life, social support networks, positive discrimination, equity, development of life skills
- **Health outcomes:** Reduction of morbidity and mortality, disability, and avoidable mortality; psychosocial and life skills
- **Capacity building and development:** Measures of sustainability, community participation and empowerment, human-resources development

From Pan American Health Organization: Healthy municipalities and communities: mayor's guide for promoting quality of life, Washington, DC, n.d., World Health Organization, p 24. Available at <http://www.paho.org/english/ad/sde/hs/mayorsguide.htm>. Accessed January 21, 2011.

assistance for 12 first-time buyers who purchased homes in Crooked Creek.

Factors Affecting and/or Hindering Success

A major barrier occurred when the contractor for the Family Pavilion project walked off the job midway through the project, resulting in an 8-month delay and cost overruns. Another contractor was hired and funds were raised to complete the project. The School Health Program became more complex when partners realized that the unique nature of each school required that interventions be tailored for each particular school's student population. The investments in housing programs found the cost of projects were sustainable only to the degree that the organization continued to successfully compete for public and private funds to underwrite projects.

Summing Up

Lessons learned across initiatives include:

1. Collaboration makes individual organizations stronger—a new organization without a track record benefits from partnering with an established organization, which gives others “permission” to be supportive. Established organizations benefit from the energy and entrepreneurial aspects of start-ups.
2. Having a good plan based on good data is crucial to securing funding and support.
3. Program operators need to ensure that senior leaders (senior executives and board members) stay informed and engaged over time in order to sustain initiatives over the long term. Otherwise they risk being replaced by the next new (and not necessarily better) thing.

Authors: Alicia Chadwick with Crooked Creek Northwest Community Development Corporation, Helen Lands with Fay Biccard Glick Neighborhood Center, Mary Beth Riner with Indiana University School of Nursing, and Marty Rugh with St. Vincent Health.

Because nurses naturally work with community people from different walks of life and are respected health professionals in the community, they are well suited to promote Healthy Communities (HC). Look for opportunities within existing community partnerships that you work with and that are also interested in promoting the community's health. Plan how to introduce them to the HC process, and work together to find ways to initiate the process with your combined network of contacts to develop activities that support improved health.

Nurses may work with the healthy community process in a variety of ways and in many stages. It is important to remember that evaluation and research are important parts of the process. Specifically, nurses may initiate, coordinate, or be part of a research team conducting program evaluation research. Providing data relevant to changes in health status through short-term impact evaluation and long-term outcome evaluation is valuable in creating the knowledge base for validating the field of community health promotion. The following How To box describes the steps to use in organizing a community meeting to plan a healthy community.

The Linking Content to Practice box applies many of the key public health documents to the work of developing a healthy community. Remember that the ultimate goal is to promote the community's own leadership for health. In other words, the nurse must not do for the community what it can do for itself. The role of the nurse and of other health professionals in Healthy Communities is to work in partnership with community leaders (Flynn, 1997). John Ashton (1989), one of the

founders of the European Healthy Cities project, summarizes the role of health professionals in Healthy Cities as being “on tap, not on top.” The Levels of Prevention box provides suggestions for how to foster community education and action, and the How To box describes how to organize a community meeting related to the HC model.

LINKING CONTENT TO PRACTICE

Health promotion using the healthy community model relies on key public health skills and core competencies. Such an approach includes the core functions of assessment, policy development, and assurance, which is making sure that there is a competent workforce available to meet the needs of the community. See Chapter 1 for details on the public health core functions.

Specifically, the *Public Health Nursing: Scope and Standards* uses a community-focused problem-solving process that is consistent with the steps in developing a healthy community (ANA, 2013). Throughout the Quad Council Public Health Nursing Competencies document are competencies that also fit this process. For example, in many of the domains, there is an emphasis on collaboration with others for determining health priorities and in using the policy-making process to achieve health goals (Quad Council, 2011). Also, the steps in healthy community development are congruent with the Intervention Wheel discussed in Chapter 9.

LEVELS OF PREVENTION

Healthy Communities

Primary Prevention

Develop a community forum to initiate communication about health promotion.

Secondary Prevention

Assess needs and strengths in the community to detect ways to address health problems.

Tertiary Prevention

Initiate community action when problems have occurred and evaluate and monitor progress of programs and policies.

HOW TO

Organize a Community Meeting About Healthy Communities

1. Identify who should be included in the community meeting. It is critical that all sectors and population groups in the community be involved.
2. How will they be invited to the meeting? Who will invite them? Allow at least 2 weeks so people can arrange their schedules.
3. Who will convene the meeting?
4. Set the date and time for the meeting and arrange for a neutral meeting place.
5. Plan the meeting agenda:
 - a. Introduction of participants
 - b. Introduction to Healthy Communities (HC)
 - c. Identification of community people who should be there (“Whom did we miss?”)
 - d. Questions and discussion about HC, and about community issues that are important
 - e. Commitment to the HC process
 - f. Formation of the HC committee (obtain names and addresses of those interested)
 - g. Other suggestions

PRACTICE APPLICATION

Because nurses work in partnership with the community in Healthy Communities, the examples of outcomes of HC initiatives reflect that partnership rather than a specific nursing intervention. An example of an outcome of a HC initiative that used the Community Health Promotion process is Fort Wayne, Indiana, Healthy City.

Committee members of the Fort Wayne, Indiana, Healthy City project collaborated in a community-wide program to address the fact that only 65% of Fort Wayne preschool children were immunized. Access to immunization services was expanded to five sites throughout the city at three different times in a program called Super-Shot Saturday.

A nurse, along with other members of the Fort Wayne, Indiana, HC committee, would be using which of the following principles of health promotion to provide access to immunizations for preschool children?

- A. Promoting healthy public policy
- B. Creating supportive environments
- C. Strengthening community action
- D. Reorienting health services
- E. Improving personal skills

Answers can be found on the Evolve site.

KEY POINTS

1. Although Healthy Cities began in 1986 in Europe, it is now an international movement of communities and cities focused on mobilizing local resources and political, professional, and community members to improve the health of the community.
2. The principles of primary health care and health promotion guide the Healthy Communities movements.
3. The name used for the Healthy Community activity varies from one locale to another.
4. The models of community practice most frequently found in the Healthy Communities movement are that of working with the local people to plan via community partnerships that will best meet their needs.
5. Community participation can be gained in many ways; it is often helpful to have a local person on the planning committee to advise on how to best enlist the aid and support of the residents.
6. The CDC has become involved in the Healthy Communities work in its efforts to reduce the amount of chronic illness.
7. The CDC has developed a wide range of tools to help communities improve their health; these tools are available on its website at no charge.
8. The concept of healthy communities is used in the United States as well as in many other nations. One region that has a well-developed set of programs is that covered by the Pan American Health Organization (PAHO). The steps that are used in PAHO countries are included in the chapter.
9. The steps for developing a healthy community including the use of the PAHO model or the Community Health Promotion model developed at Indiana University School of Nursing can be used by nurses working with communities to improve their health capacity.
10. The first two states to develop Healthy Community projects were Indiana and California. These two states have ongoing active and responsive programs; some are discussed in the chapter.
11. The *Healthy People 2020* objectives incorporate many of the key concepts of healthy communities including providing access to health services; combating chronic illnesses, and providing safe food, a safe and healthy environment, opportunities for fitness, immunizations, and reduction in injuries and violence, to name a few.

CLINICAL DECISION-MAKING ACTIVITIES

1. In collaboration with a community group, conduct a community assessment. Identify the community's assets and problems.
2. Evaluate the effectiveness of a current approach to a health problem in your community (e.g., teen pregnancy). Describe how the approach would change if you were to use the steps in developing a healthy community such as the Community Health Promotion process.
3. Discuss the role of the nurse in health promotion within a healthy community model.
4. Identify city council members, the president of the chamber of commerce, the director of family services, the mayor, a religious leader, and other community leaders who are the "movers and shakers" in getting things done. Generate a list of questions that will help these leaders describe the major assets and problems of the community. Interview several local leaders and summarize their responses.
5. You are asked by the health commissioner to organize a community coalition for orientation to the Healthy Communities process. Outline the steps you would take.
6. Describe your philosophy of community leadership development for health promotion.
7. Discuss ways in which the *Healthy People 2020* objectives can incorporate community participation. Select one topic area within *Healthy People 2020* and outline a community inclusive approach that you could use.

The Nurse-led Health Center: A Model for Community Nursing Practice

Katherine K. Kinsey, PhD, RN, FAAN

Dr. Katherine K. Kinsey is the Nurse Administrator and Principal Investigator of the Philadelphia Nurse-Family Partnership (NFP), the Mabel Morris Family Home Visit Program, and other special projects including early childhood initiatives. Dr. Kinsey earned the BS from Millersville University in Pennsylvania and the BSN and MSN from the University of Pennsylvania School of Nursing. She earned the PhD from the Graduate School of Education with a speciality in Health Professions Education also from the University of Pennsylvania. Dr. Kinsey previously directed a nationally recognized academic-based nurse-managed health center. She is a past chairperson of the American Public Health Association, Public Health Nursing Section. Dr. Kinsey serves on several nonprofit boards and is the president of the Kingsley Family Foundation, which is dedicated to improving the well-being of vulnerable, underserved populations.

Mary Ellen T. Miller, PhD, RN

Dr. Mary Ellen T. Miller is an Associate Professor at De Sales University School of Nursing in Center Valley, PA, and teaches in the undergraduate, graduate, and doctoral nursing programs. She earned the BSN and MSN from LaSalle University and the PhD from Temple University. Both universities are in Philadelphia, Pennsylvania. Dr. Miller serves as Chair of the Wellness Center Committee of the National Nursing Center Consortium. Previously, she served as the Associate Director of Public Health Programs for an academic nursing center. Dr. Miller has published works about nurse-managed centers and presents regionally and nationally on topics related to her work, as well as about student involvement with community service and learning, and about nurse-managed wellness centers.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Describe key characteristics of nurse-led center models.
2. Explain community collaboration.
3. Identify interventions that address *Healthy People 2020* goals.
4. Determine the feasibility of establishing and sustaining a nurse-led center.
5. Describe the roles and responsibilities of the advanced practice nurse in a nurse-led center.
6. Discuss the future of population-centered nursing practice, education, and research.

Positioning Nurse-Led Health Centers and Advanced Practice Nurses for the Future

Considerable data document that nurse-led health centers (NLHC) improve health **outcomes**. The **nurse-led health center (NLHC)** model increases access to care; provides a more comprehensive approach to health and illness; decreases racial, ethnic, and geographic disparities in health status; and can potentially reduce the overall costs of health care. NLHCs, as safety net providers, reach out to and engage underserved, vulnerable populations in public health and primary health care initiatives. This chapter describes NLHCs and their origins, evolution, and future directions. Emphasis is placed on the *Healthy People 2020* framework, **community collaboration**, and **multi-level interventions** to improve access and reduce health disparities. This chapter describes nursing roles and responsibilities in delivering client-centered, community-based services, managing center operations, and expanding initiatives for practice, research, and education in public health and primary care settings. Economic, social, political, national health care reform, and global factors influencing NLHC operations and population-centered nursing practice are discussed.

WHAT ARE NURSE-LED HEALTH CENTERS?**Overview and Definition**

The terms *nurse-led health center*, *nursing center*, *nurse-managed health center*, and *nurse-managed health clinic* are interchangeable in this chapter and are used to describe this model of health care. The citations in this ninth edition of *Public Health Nursing: Population-Centered Health Care in the*

Community include historical references noted in earlier editions and current references regarding the evolution of NLHCs. The references frame the decades-long NLHC movement. However, the ways in which we gain knowledge is changing. The introduction of new Internet-based technology and communication venues regarding public health programs and NLHCs will grow exponentially (Khan et al, 2010). Access to NLHCs initiatives, public health practice examples, and career opportunities are now featured on social media websites, wikis, and blog communities. These venues, and others still in the research and development phases, will add rich content as NLHCs continue to transition into mainstream health care provider status.

In the past, the most frequently cited and referenced definition of nurse-led health centers was the one developed by the American Nurses Association (ANA) Nursing Centers Task Force in the mid-1980s and shown in **Box 21-1**. However, the Nurse-Managed Health Clinic Investment Act of 2009 (Senate Bill 1104/House of Representatives Bill 2754) of the 111th Congress provides a more current and functional definition of nurse-managed health clinics with an amendment to Title III of the Public Health Service Act (42 U.S.C. 241 et seq.) as seen in **Box 21-2**.

NLHC provide unique opportunities to improve the health status of individuals, families, and communities through direct access to nurses and nursing models of care (Lancaster, 1999). All NLHCs possess characteristics that reflect the values, beliefs, and scientific knowledge and skills inherent in **nursing models of care**. Furthermore, each is guided, managed, and primarily

BOX 21-1 American Nurses Association Nursing Centers Task Force: Nurse-led Center Definition

Nurse-led centers—sometimes referred to as nursing centers, community nursing organizations, nurse-managed centers, nursing clinics, and community nursing centers—are organizations that give the client direct access to professional nursing services. Using nursing models of care, professional nurses in these centers diagnose and treat human responses to actual and potential health problems, and promote health and optimal functioning among target populations and communities. The services provided in these centers are holistic and client centered and are reimbursed at the reasonable fee level. Accountability and responsibility for client care and professional practice remain with the professional nurse. Overall accountability and responsibility remain with the nurse executive. Nurse-led centers are not limited to any particular organizational configuration. Nurse-led centers can be free-standing businesses or may be affiliated with universities or other service institutions such as home-health agencies and hospitals. The primary characteristic of the organization is responsiveness to the health needs of the population.

From Aydelotte MK, Barger S, Branstetter E, et al: *The nursing center: concept and design*, Kansas City, MO, 1987, American Nurses Association, p 1.

BOX 21-2 Nurse-Managed Health Clinic (NMHC) Investment Act of 2009 Definition

The term “nurse-led health center or clinic” or “NLHC” means a nurse-practice arrangement, managed by advanced practice nurses, that provides primary care or wellness services to underserved or vulnerable populations and is associated with a school, college, university, or department of nursing, federally qualified health center, or an independent nonprofit health or social services agency.

Source: Nurse-managed Health Clinic Investment Act of 2009. Senate Bill 1104 and House of Representatives bill 2754. For exact language see Title V, section 2512 of the House bill (HF 3962) and Title V, Subtitle c, section 5208 of the Senate bill (HR 3590).

staffed by nurses, thus ensuring that decision making and ultimate accountability for this model of care rest with professional nurses (Kinsey and Gerrity, 2005).

The NLHC is supported by the ANA seminal position paper titled *Health Promotion and Disease Prevention* (ANA, 1995). The paper recognizes health promotion strategies as pivotal points of any health care system designed to control costs and reduce human suffering. It acknowledges nursing’s scope of practice and underscores its efforts to focus on disease prevention interventions (ANA, 1995).

Nurse-led center models combine human caring, scientific knowledge about health and illness, and understanding of family and community characteristics, interests, assets, needs, and goals for health promotion, disease prevention, and disease management. NLHC models de-emphasize illness-oriented and institutional care that has dominated health care since World War II and subscribe to a holistic perspective on improving personal, community, and societal well-being.

Nurse-led Models of Care

NLHCs are strategically positioned to improve the health and well-being of vulnerable populations (Kinsey, 1999) and reduce

health disparities by providing access to comprehensive primary health care and health promotion and disease prevention services (Hansen-Turton, Miller, & Greiner, 2009). Interdisciplinary staff achieves success through shared vision, positive attitudes, and respect for team members (Phillips, 2009). Social determinants of health (Wilensky & Satcher, 2009) as well as the integration of time, tact, talent, trust, caring, personal respect, equity, and social justice perspectives serve as the foundation from which health is viewed as essential for everyday life (Plowfield, Wheeler, & Raymond, 2005). Efforts of the center focus on enhancing people’s capacity to meet their personal, family, and community responsibilities and interests and typically include the following:

- *Community-based culturally competent care* that is accessible, acceptable, and responsive to the populations being served
- *A holistic approach* to care based on complex and interrelated bio-psychosocial factors
- *Interorganizational and interdisciplinary collaboration* that crosses health and human service systems and increases opportunities for comprehensive and seamless services among care providers, agencies, and payers
- *Multilevel interventions* that acknowledge organizational, environmental, health, economic, and social policy contributions to health, health problems, and issues of access to care
- *Community partnerships* in establishing and supporting the center’s health efforts
- *Relationship-based practice* with individuals, families, organizations, and communities that fosters understanding of context, interests, and needs for health care

Nurse-led center models combine people, place, approach, and strategy in everyday life to develop appropriate health interventions. **Advanced practice nurses** (APNs) work in close partnership with the communities they serve to provide public health programs, community-wide health education, and primary health care services. They establish relationships with families, community representatives, policy makers, and others in designing, implementing, and evaluating appropriate health intervention strategies, services, and programs (Zimmerman, Mieczkowski, & Wilson, 2002; Hansen-Turton, Miller, & Greiner, 2009).

A nurse-led center’s *health* and *community* orientation builds strong connections to the population served. These strong relationships with community leaders, residents, and clients foster a deep awareness of local factors that influence daily life (Lundeen, 1999). This orientation builds on Lillian Wald’s community work more than a century ago. Wald’s work to establish The Henry Street Visiting Nurse Service and a cadre of public health nurses who treated social and economic problems—not just infections, diseases, and providing care to the chronically ill—is part of the nursing center legacy (Fee & Bu, 2010). *Figure 21-1* depicts the opening of a nurse-led center.

TYPES OF NURSE-LED HEALTH CENTERS

There are many types of nurse-led centers. Each has a “personality” of its own (Gerrity and Kinsey, 1999). A center should be

FIG 21-1 Donna Torrisi, MSN, Nurse-Managed Health Center Director with community leaders at the 2008 Grand Opening of the Family Practice and Counseling Health Annex, Philadelphia, PA. (From Family Practice and Counseling Network Clients, Philadelphia, PA.)

based on community assets and perceived needs with a clearly stated mission and vision as well as its commitment to community well-being, contributing to its profile (Hansen Turton, Miller, & Greiner, 2009). Organizational structure (academic, non-academic), federal tax status (profit or nonprofit), and **reimbursement systems** (fee for service, sliding scale fee rates, or no charge) also define centers. Other types will evolve as a result of national health care legislation. The legislative initiatives include maximizing federally qualified health center services; increasing access to **primary health care** for people of all ages; introducing new public health, preventive health, and home visiting programs; and implementing and using electronic medical records. To date, most nurse-led centers fit into the types described in Box 21-3.

Wellness Centers

Wellness centers focus on health promotion, disease prevention, and management programs. APNs and others provide outreach and public awareness services, health education, immunizations, family assessment and screening services, home visiting, and social support (Hansen-Turton, Miller, & Greiner,

BOX 21-3 Nurse-led Center Typologies

Service Model

- *Wellness centers:* Provide health promotion and disease prevention programs
- *Comprehensive primary care centers:* Provide health-oriented primary care and public health programs
- *Special care centers:* Provide programs targeting specific health conditions (such as diabetes) or population groups (such as the frail elderly)

Organizational Structure

- *Academic nurse-led center:* Housed within a school of nursing
- *Free-standing center:* Independent center with its own governing board
- *Subsidiary:* Part of larger health care systems, home-health agencies, community centers, senior centers, schools, and others
- *Affiliated center:* Legal partnership association with health, human services, or other organization

Internal Revenue Service Designation

- *501(c)3:* Non-profit business
- *Proprietary:* Incorporated as a for-profit business

Reimbursement Mechanism

- *Fee-for-service:* Payment at time of service; may include sliding-fee scale
- *HMO provider:* Payment at contracted rates by health maintenance organization
- *Federally Qualified Health Center (FQHC):* Federal designation that allows cost-based reimbursement per encounter
- *Third-party reimbursement:* Client billing to public program or commercial/private insurance
- *Contributions:* Individual donations, philanthropic gifts, fund-raising activities to support a program

2009). Public health education and support programs may include smoking cessation (Lakon, Hipp, & Timberlake, 2010) and management of chronic conditions such as diabetes, asthma, and hypertension. Many centers also provide dental, behavioral health, environmental health risk reduction, and parenting education (Hansen-Turton, Bailey, Torres, & Ritter, 2010). “Enabling” services help people access language translation, registration for entitlement programs, transportation vouchers, and specialty services. *Healthy People 2020* goals and objectives provide direction to services planned, implemented, and evaluated through the wellness center model.

These centers complement existing primary care services. The staff maintains strong relationships with local health care providers in community health centers, clinics, private practices, long-term care facilities, and other organizations. In general, financial support for center programs comes from public health department and other service contracts, foundation grants, fee for services, voluntary contributions, and shared resources from affiliated organizations (Hansen-Turton, Miller, & Greiner, 2009). In addition, these centers often serve as venues for community service learning activities for graduate and undergraduate students from multiple disciplines. Nursing centers extend learning beyond the classroom and into the community, providing a legitimate experience whereby students apply theoretical content to a community setting (Miller & Guigliano, 2006).

Special Care Centers

Some nurse-led centers focus on a particular demographic group or on those with special health care needs. **Special care centers** provide services and specialized health knowledge and skills to a particular group, and they are an adjunct to comprehensive primary health care models. Examples of special care centers are those that focus on the needs of people with diabetes or HIV/AIDS, adolescent mothers, the frail elderly, and support services for people with mental disorders (Alakeson, Frank, & Katz, 2010). Other centers are the hub for public health nursing practice in home and community settings. These include Nurse-Family Partnership models across the nation as well as other early childhood home visiting models including Parents As Teachers and Early Head Start.

Comprehensive Primary Health Care Centers

In many communities, nurse-led centers offer **comprehensive primary health care**. In addition to the health and wellness programs described previously, these centers also serve as the primary care (medical) home for families in the communities where they are located. In the centers, nurse practitioners, other advanced practice nurses, and allied health professionals provide both physical and behavioral health care services. These centers address the needs of individuals and families across the life span, ensuring access to specialized health care as indicated. **Public health nurses** and community workers provide outreach, social support, and an array of public health programs. Public health programs include health education, screening, immunizations, lead poisoning prevention, home visitation such as in the **Nurse-Family Partnership**, environmental health initiatives, and other preventive community-based health services (Figure 21-2).

Comprehensive primary health care centers face the challenge of establishing systems for documenting clinical care and utilization patterns. These systems include demographic profiles, accounting support, billing mechanisms, reimbursement

protocols, quality improvement strategies, and client satisfaction measures (Sherman, 2005). Nursing centers must meet standards established by government, insurers, health maintenance organizations, and other payers.

Increasingly, the Bureau of Primary Health Care (BPHC) of the U.S. Department of Health and Human Services (USDHHS) designates nurse-led primary health centers as **federally qualified health centers** (FQHCs). Their purposes are to (1) provide population-based comprehensive care in medically underserved areas and (2) maintain the appropriate mission, organizational, and governance structure according to the FQHC designation. These designations include community health center, public housing center, homeless center, or school-based center.

The FQHC designation is important from a number of perspectives. Most importantly, it supports a primary care center's efforts to serve low-income and uninsured populations and remain fiscally solvent. FQHCs receive federal grant funds from the Health Resources and Services Administration (HRSA) to support operational expenses. They also receive cost-based payment for services provided to Medicare and Medicaid patients, Federal Tort Claim coverage, and 340b drug pricing, and they have the option to participate in the National Health Services Corps.

Many nurse-led centers need to overcome internal and external organizational hurdles to initiate the FQHC application process and receive funding approval (Torrisi & Hansen-Turton, 2005). The **National Nursing Centers Consortium** (NNCC), with offices in Pennsylvania, Washington, DC, and California, provides regional training for the FQHC application processes. The recent passage of the Nurse-Managed Health Clinic Investment program by the 111th Congress holds great potential for additional NLHC-affiliated academic institutions to be eligible for FQHC status.

Many NLHCs are in nonprofit academic settings. They are housed within or closely affiliated with schools of nursing. These NLHCs actively integrate service, education, and research in their model. They build on public health and primary care nurse practitioner educational programs, draw on the knowledge and skills of faculty, and provide rich learning experiences for nursing students at all levels. Furthermore, they use the knowledge, skills, and resources of other schools of health professions, business, communications, and law to expand the center's service capacity (Shiber & D'Lugoff, 2002). Academic nursing centers have documented benefits to communities served, specifically regarding the strengths of nurse practitioners and the centers' ability to provide outreach to the community (Pohl et al, 2007).

One example of an academic nurse-led center is the Lewis and Clark Community College Nurse-Managed Health Center located in Godfrey, Illinois. The college also has a mobile health unit. This NLHC was the first to open to the public on a U.S. community college campus. The center provides nonemergency, low-cost primary care services and partners with the Southern Illinois Healthcare Foundation for referrals and specialty care. Nursing students have clinical rotations through the NLHC and its mobile unit. Students and faculty are involved in client education and illness prevention services. This model introduces

FIG 21-2 Investing in the future: public health nurses and programs like Nurse-Family Partnership, Early Head Start, Parents As Teachers, and others improve family health and mother-child (or maternal-child) well-being. (Used with permission of Philadelphia Inquirer Copyright © 2010. All rights reserved.)

students to the expanding roles and responsibilities of APNs in community settings and career options (Weller, 2010).

Other centers may be affiliated with freestanding organizations, subsidiaries of health care or other human services organizations, or sponsored by an affiliate of such entities. Each of these organizational arrangements requires carefully established legal agreements. To conduct business, these organizations must become incorporated; apply to the Internal Revenue Service (IRS) for a tax status designation; and receive a Statement of Tax Status Determination. Organizations are generally categorized as a nonprofit (501(c)3) entity or some form of proprietary (for-profit) organization. The majority of nursing centers are with nonprofit organizations; others fit within a proprietary business model, and others operate as subsidiaries of established organizations. In all cases, staff must be familiar with the particular laws and regulations associated with the IRS tax status under which they operate.

Another way to describe nurse-led centers involves the health care system's financial reimbursement methods that support services and programs. These include fee-for-service, designated HMO provider, Medicaid provider, Medicare provider, and FQHC status. Each designation requires a center to possess certain characteristics, meet a set of standards, and possess identification numbers that allow them to participate in billing and reimbursement systems.

Regardless of the type of center, a wide array of social determinants, personal, social, educational, economic, and environmental concerns, indicate the need for and expansion of nursing centers. Increasing population density and diversity, challenging community conditions, and long-standing and emerging health problems indicate the role such models of care can play (Kinsey, 2002). The 2010 national health reform law, the **Patient Protection and Affordable Care Act**, holds the potential for NLHCs to work with like entities to help improve the nation's health. This law and the 2013-2014 "roll-out" focuses on reforming the health care system, increasing disease prevention initiatives and access to services, and containing or reducing health care expenditures (Thorpe & Ogden, 2010). The national commitment to build integrated delivery systems offers nurse-led centers and academic health systems new opportunities to demonstrate effectiveness, efficiency, and cost savings (Dentzer, 2010).

With the anticipation of NLHCs expansion grants, it is essential to work with like-minded individuals and groups to share knowledge, resources, and lessons learned. Several organizations dedicated to the promotion and sustainability of NLHCs are in place to support its members through these expansion phases. The NNCC is one nationally recognized organization dedicated to this work. As of 2014, NNCC represents more than 250 members and is the largest national repository of member nurse-led health centers. Its members represent organizations, programs within parent organizations, free-standing entities, and individuals invested in the nurse-managed center model. (A current membership list is available at <http://www.nncc.us>). Members have the benefits of NNCC monthly newsletters, grant updates, current legislative and advocacy work, and its Annual National Conference. NNCC reaches out to nonprofit organizations and individuals interested in establishing or expanding a nurse-led (clinic) model.

The Consortium often links members with potential members to share expertise and consult on program design and implementation. See the **Linking Content to Practice** box.

LINKING CONTENT TO PRACTICE

This chapter discusses the ways in which nurses provide primary care and public health services within the context of a nurse-led center. The skills of assessment, planning, implementation, evaluation, and policy development are integral to this role. In order to effectively practice in a nurse-led center, nurses use the standards of nursing practice from many specialty areas as well as the core competencies for both public health nursing and public health. Specifically, the nurse working in this setting would incorporate the following core competencies from the *Quad Council of Nursing (QCN) Public Health Nursing* (2011) and the *American Association of Colleges of Nursing (AACN)*, supplement to the 2010 *Essentials of Baccalaureate Nursing Education for Professional Nursing Practice* titled *Recommended Baccalaureate Competencies and Curricular Guidelines for Public Health Nursing* (2013). The QCN competencies are built on those of the Council on Linkages (PHF, 2014) and their core competencies for public health professionals. For example, Domain #1 in both documents describes analytic assessment skills and Competency #1 is "conducts thorough health assessments of individuals, families, communities and populations." There are 10 additional skills that nurses would use from this domain in nursing centers. As has been discussed throughout this chapter, nurses working in nursing centers use the policy process in providing care. Domain #2 is that of policy development/program planning skills and each of the 11 competencies/skills are used in a nursing center. The AACN supplemental competencies are based on the nine essentials from the original AACN recommendations and focus on primary and secondary prevention strategies in population health, including interprofessional collaboration.

From Public Health Foundation, Council on Linkages: *Core competencies for public health professionals*, Washington DC, 2009, PHF; Quad Council: *Domains of practice*, 2009. Available at <http://www.sphc.org/phncompetenciesfinalcomb.pdf>. Accessed July 29, 2010.

THE FOUNDATIONS OF NURSE-LED CENTER DEVELOPMENT

The foundations for integrating primary care and public health services through the NLHC model include the perspective of the World Health Organization (WHO) and the *Healthy People 2020* systematic approach to improving individual and community health. The WHO's definition of health and its framework to address global health supports an NLHC's integration of primary care and public health services in community settings (WHO, 1978).

The *Healthy People* initiative has framed the nation's health promotion and disease prevention agenda since 1980. Its framework, vision, mission, goals, and objectives are developed to achieve better health for all by 2020. *Healthy People* represents a collaborative federal, public, and stakeholder process and accounts for global and national environmental, social, demographic changes, and trends such as the increasing older populations. *Healthy People* accommodates the escalating technological influences on personal and population health status, and incorporates anticipated changes in the U.S. sickness-oriented health system. **Chapter 2** describes the history of *Healthy People*, and chapters throughout the text apply the

objectives of *Healthy People 2020* to their content. The concept of *Healthy People 2020* builds on shared responsibility to improve the nation's health. Communities, individuals, and systems have the potential for change, yet no one person or organization can do this alone. Powerful, productive partnerships among diverse people and groups and long-term commitments to community collaboration are needed to achieve *Healthy People 2020* goals. NLHCs can help to achieve the goals and objectives of *Healthy People 2020* and would emphasize those goals and objectives that fit the target populations' needs. For example, an NLHC associated with an elementary school where more than 40% of the students are obese would select *Healthy People 2020* objectives relative to childhood nutrition, physical activity, and exercise. The NLHC would also implement communication strategies that address the need to reduce childhood obesity in school-age children.

Community Collaboration

Nurse-led centers and APNs are well positioned to guide and facilitate community collaboration and engagement (Keefe, Leuner, & Laken, 2000; Bechtel & Ness, 2010; Thompson & Feeney, 2004). Productive collaboration requires staff expertise and commitment from many to change communication patterns, professional agendas, and speak in a common voice to generate positive community transformation (Cross & Prusak, 2002). The community transformations occur through policy, legislative, and funding changes that improve the health status of many and help design the patient-centered medical homes that include NLHCs (Landon et al, 2010).

Individuals, families, groups, organizations, policy makers, and staff are involved in the process. Referred to as stakeholders, each entity brings a unique perspective. Their particular knowledge and skills enhance the community's efforts to address critical needs, solve problems, and recognize unique strengths and resources. **Stakeholders** facilitate or undermine strategic efforts to improve health. It is impossible to fully know and address issues and concerns in a community without having all perspectives heard and every stakeholder respectful of different opinions and experiences (Bechtel & Ness, 2010). The following *Healthy People 2020* box lists a sample of goals that affect nurse-led centers.

HEALTHY PEOPLE 2020

The following objectives are examples that pertain to the work of nurses in nurse-led centers:

- ECBP-3.3: Advocating for personal, family, and community health (skills).
- HC/HIT-2: Increase the proportion of persons who report that their health care providers have satisfactory communication skills.
- AHS-7: Increase the proportion of persons who receive appropriate evidence-based clinical preventive services.
- MICH-10: Increase the proportion of pregnant women who receive early and adequate prenatal care.
- MICH-21: Increase the proportion of infants who are breastfed.

From U.S. Department of Health and Human Services: *Healthy People 2020: understanding and improving health*, Washington, DC, 2010, U.S. Government Printing Office

Collaboration takes time, effort, and resources. It requires nurturing and support to make it work. Relationships among

people and organizations serve as the foundation for the collaborative process and for community change. Relationships begin with introductions and open discussion to listen to and learn from one another. From this, relationships grow toward a collective willingness to work together toward a common purpose, sharing *risks, responsibilities, resources, and rewards* along the way. The seminal definition of collaboration developed by Mattessich and Monsey (1992) describes the work involved; they view collaboration as a relationship entered into by two or more groups to achieve common goals that are well defined and beneficial to all. There must be a respectful commitment to these goals with mutual accountability and authority that allows for shared responsibilities, resources, and successes. See Resource Tool 21.A: Factors Influencing the Success of Collaboration.

Nurse-led center staff needs to have skills in networking, coordination, and cooperation in order to collaborate (Hansen-Turton, Miller, & Greiner, 2009). A number of basic agreements and interview strategies help set the stage for a long-term process of discussion, decision making, and action (Rollnick, Miller, & Butler, 2008). Once established, they are reviewed and rigorously adhered to throughout the life of the collaboration. These agreements are as follows:

- Regular meetings where diverse perspectives are heard and respected
- A mutually agreed on decision making process
- Consistent and accurate communications so all participants have the necessary information to make decisions
- Agreement by all participants to support collaborative decisions once they are made—within the groups or organizations they represent and publicly in the community

Mattessich and Monsey (1992) have identified six critical elements that contribute to the success of a collaborative endeavor: the environment, membership characteristics, process and structure of the group, communication patterns, purpose of the collaboration, and resources within and outside the group.

Perhaps the most important feature in community collaboration is the capacity of those involved to enhance the capacity of *another* person, group, or organization to achieve the common purpose. For instance, rather than the nurse-led center serving as the lead organization, different participating organizations will serve from time to time in the leadership role, or hold greater responsibility, or perhaps receive additional funds to achieve the common purpose to which they all have subscribed. This cooperation allows participants to achieve a mutual benefit (Goffe & Jones, 2001).

Each nurse-led center develops its philosophy, goals, and activities through a process of community collaboration, community assessment, and strategic planning. **Strategic planning** recognizes multiple levels of intervention required for bringing about and sustaining change. Often, community collaboration and assessment are concurrent activities.

Community Assessment

Nurse-managed centers must conduct periodic community assessments. This chapter reemphasizes the importance of data and analysis of community needs and assets in determining the

FIG 21-3 Neighborhood walks provide insight into the community's health.

type of nursing center to establish or expand. Through the assessment process, nurses learn both the community's formal and informal infrastructure and the communication networks through which everyday life takes place (Baker, White, & Lichtveld, 2001). Neighborhood walks, bus rides, car trips, and discussions with elected officials, administrators of health care systems, public health department staff, and community members provide insight into the community's health and the many other influencing factors. Figure 21-3 depicts a nurse doing a neighborhood walk. Also, historical, ethnographic multimedia news features add context to the community assessment (Anderson, 1999).

Assessment activities identify community assets and health problems. For example, there may be a rich network of block captains who serve as leaders and communication liaisons with the community. There may be a local community college that can provide space and support for meetings. If high rates of childhood asthma are discovered, there may be human service organizations that can help in disease prevention and management efforts (Kawachi & Berkman, 2003).

As nurses conduct individual interviews and focus groups, develop surveys, review health care data, and examine social determinants of health (social, educational, employment, economic, housing, and others), they gather detailed information about the overall well-being of the community. These sources of information build an understanding of the community and its traditions, strengths, interests, concerns, problems, needs, and preferences. The assessment process includes sharing current health data, historical trends, and future projections with the community. Center staff can discuss the findings, share perspectives and ideas, and encourage involvement in the collaborative process. From this, the nursing center's overall direction, services, and programs emerge (Anderko, 2000).

Sociopolitical systems

FIG 21-4 Multilevel intervention model.

Multilevel Interventions

As the community and the center work together for comprehensive community health, a multilevel approach is needed. Some behavioral decisions or changes occur at the individual and family level. However, for comprehensive community health improvement, strategies are needed at organizational, community, and sociopolitical levels. Nursing center staff may focus their efforts on system issues, community capacity, and family and individual health care access concurrently. Alternatively, the staff may concentrate programmatic efforts solely at the individual or family level and later address system and community issues. There is no one approach. Figure 21-4 presents the “big picture” perspective that the majority of center interventions take place in community rather than institutional settings. In the twenty-first century, innovative and disruptive preventive health models are challenging the status quo of institutionally driven primary care practices (Lawrence, 2010).

APNs involved in public health and nurse-managed center services are strategically positioned to communicate, adapt, and influence change to improve and support individual, population, and community health outcomes (Vermeulen, Puranam, & Gulati, 2010). The multilevel intervention approach helps people enter the health care system earlier, with greater ease and confidence, and continue in care long enough to realize positive outcomes (Berkman & Lochner, 2002). This approach also recognizes that one size (static, rote services) does not meet all the needs and interests of the target population.

Nurses keep in mind the **prevention levels** that improve the health of the public. *Primary, secondary, and tertiary prevention* are not terms the general population understands. In fact, the idea of prevention at different levels requires thoughtful investigation and analysis. One of multiple national resources regarding prevention levels and agendas is Partnership for Prevention (www.prevent.org). The **Levels of Prevention** box is one example that a NMHC might use.

LEVELS OF PREVENTION

Nursing Center Application

Primary Prevention

Assess home for lead dust; educate family on lead poisoning prevention strategies.

Secondary Prevention

Conduct blood lead level screenings on a regular basis for children younger than age 6.

Tertiary Prevention

Treat child who has an elevated blood lead level with appropriate therapies and eliminate environmental lead toxicity exposures.

The foundations of nursing center development are rooted in public health nursing history and the evolution of the nursing profession (Fee & Bu, 2010). Other chapters in this text provide historical details and factors that have influenced nursing education, practice, service, and research throughout the twentieth century.

Most nursing center models as currently known emerged from academic nursing programs in the 1970s through 2000s. At that time, opportunities did not exist within the traditional health care system for faculty or their nurse practitioner students to apply their knowledge and skills in a nursing framework of care. Bold ideas in the schools of nursing at the University of Wisconsin-Milwaukee, Arizona State University, Columbia University, and others established practice settings that simultaneously provided health care to the community and learning experiences for students. Many of the academic centers focused on the underserved populations in nearby communities. Over time, centers have achieved national recognition as essential safety net providers to vulnerable populations (Sherman, 2005).

The success of these early efforts supported the establishment of other academic nursing centers across the nation. Interest in this model of practice grew rapidly among community

service organizations, schools, churches, public housing facilities, and others (Bellack & O'Neil, 2000). Although there continues to be no historical or current databank regarding the absolute number of nursing centers that have been developed, NNCC surveys document that models have been developed in every state, and in urban, suburban, and rural communities. Some nurse-managed centers have curtailed services or closed because of factors such as funding challenges, changes in institutional commitment, scarcity of qualified advanced practice nurses, and population losses resulting from natural catastrophes (Pohl et al, 2010).

Resource Tool 21.B highlights the evolution of nursing centers over the past century, and lists educational, political, legislative, and funding factors that have influenced the development and **sustainability** of nursing centers. This evolutionary trend will be altered with the implementation of the Patient Protection and Affordability Care Act and committed funding to NLHCs.

THE TEAM OF A NURSE-LED CENTER

Nurses, including APNs, other health and allied health professionals, support staff, and the community at large, comprise the nurse-led center team. The center type and its services determine staff patterns and roles, responsibilities, and reporting lines. Every center must have an organizational chart that clearly shows staffing positions and reporting responsibilities. The **organizational framework** must be dynamic in nature and adaptive to new community-focused initiatives.

A fundamental premise to any NLHC is that the community in which the model is placed has the most power and influence on model development and team composition. The demand for services will be community driven. A rural NLHC model may have different staff needs than one situated in a distressed urban area (Jacobson, 2002).

A center's success also relates to how well the team works together to ensure the delivery of high-quality health care to target populations (Heifetz & Linsky, 2002). Positive collegial and professional relationships set the tone for the work. Critical center clinical and management positions are briefly highlighted in the following section. Resource Tool 21.C presents actual or potential nurse-led center positions and extensive descriptions of staff and adjunct roles.

Director: Nurse Executive

The director or nurse executive is an APN who is committed to the NLHC model. The roles and responsibilities of the nurse executive are dynamic and diverse. The director has a current knowledge of the target community, the ability and willingness to work with many community organizations and groups, and a background in organizational planning, administration, and fiscal management. The nurse executive is responsible for oversight of contracts and **grants**, annual reports, and development of the advisory board or board of directors. Other responsibilities include hiring and retention of highly qualified staff.

Directors are visionary leaders and planners. They constantly use data, collaborative feedback, existing resources, and

partnerships to modify and adjust the overall direction of the nursing center (Salmon, 2007; Torrisi & Hansen-Turton, 2005). As NLHCs have evolved and third-party reimbursement opportunities for nurse practitioner services increase, APN practitioners have assumed leadership positions in center practices. Likewise, advanced practice public health nurses have led the NLHC movement and employed nurse practitioners as advanced practice providers. For the most part, public health nurse directors have implemented a holistic service model. This model incorporates public health service and community-based programs that complement the primary care services.

There are NLHCs that started with public health programs and then established primary health care services. These public health programs include maternal–child home visitation funded by Title V federal funds, Nurse-Family Partnership (NFP), and Environmental Protection Agency (EPA) grants focusing on lead poisoning prevention, asthma triggers prevention, and many others. Other centers started with primary health care services at one location and later on incorporated client-centered public health services.

Advanced Practice Nurses

Advanced practice nurses (APNs) have additional education and training beyond their basic nursing program and are certified or licensed in a specialty area such as women's health nurse practitioner. They provide an expanded level of health services to individuals and families. These nurses are responsible for the oversight of clinical staff as well as program services and outcome measures.

Nurses with advanced preparation in community or public health nursing are essential to the advancement of NLHCs and integrated health services (Dentzer, 2010). These nurses use nursing and public health principles to promote and sustain the health of populations in neighborhood and community settings. Their work is diverse. Nurses are responsible for assessing populations' needs and interests in health care, developing grant proposals to expand services, and managing contracts for preventive and early intervention programs in community settings. Nurses implement group health education classes and screenings, and provide individual case management in community and home settings. Health advocacy is an essential component of their work (ANA, 2007).

In comprehensive primary care centers, nurse practitioners provide on-site services. As APNs, nurse practitioners can be generalists (i.e., family nurse practitioners who provide services to people of all ages) or specialists. The specialist nurse practitioner has skills with particular age groups (e.g., pediatric, adolescent, or geriatric) or skills developed to meet the interests and needs of particular population groups such as women's health; menopausal health; and wound, ostomy, and continence management (Horrocks, Anderson, & Salisbury, 2002).

Naylor and Kurtzman's article in *Health Affairs* (2010) discusses nursing workforce issues, and the need to support the work of APRNs in primary care settings. In 2008, APRNs represented about 8% of the 3.1 million licensed registered nurses in the United States (ANA, 2011). The majority of APNs

practice in primary care and public health settings. These settings include FQHCs, local and state health departments, NLHCs, and **convenient care clinics** (retail clinics).

National health reform legislation supports increasing the advanced practice workforce in primary care patient-centered medical homes. As discussed in Chapter 5, on March 23, 2010, the Patient Protection and Affordable Care Act was signed into law. The act makes a significant investment of \$50 million to expand nurse-managed health centers to serve vulnerable, at-risk populations. In addition, it also supports faculty scholarship programs to expand nursing school enrollment and student loan repayment programs.

Other Staff

Community health workers are essential staff in many NLHCs. Typically, they are neighborhood residents who have completed high school or 2-year associate degree programs and who want to work with others in their community. The workers are trained in community outreach, family case management, or on-site services (Rosenthal et al, 2010).

The operations of any center require support staff. Staff members include a business or operations manager and data operations personnel. A parent organization may dedicate a portion of staff lines, including human resources and public relations, to assist the director and senior staff. The operations manager handles contracts and grant budgets, advertising for staff, personnel hires, and billing. Personnel management, staffing patterns, and site management including data collection are also responsibilities of an operations manager.

Data operations personnel are essential. Client-based and population-based outcomes are necessary for program evaluation, proposal development, and funding purposes. Rapid changes in technology related to billing and reporting requirements, and federal regulations regarding protection of information about an individual's health care status, require data operations personnel on site or as consultants. In today's litigious society, the operation of any NLHC involves ensuring privacy of client records and securing access to computerized data.

At present and into the future, information systems (IS) and technology support (TS) personnel must be in place to meet the escalating expectation to institute and effectively use a computerized client-centered database. Computerized systems require upgrades and maintenance. Also, as hardware and software programs become obsolete and new programs are introduced, staff will need training and support to adapt to new data systems.

Staff may also be needed for public relations and multimedia campaigns to gain support as the center expands. Other multidisciplinary providers are engaged in nursing center work and share responsibility in outreach and educational campaigns. Provider representation is diverse. Staff includes physician collaborators, family therapists, mental health counselors, students, faculty, administrators, and clinical social workers. Other professionals include dentists, podiatrists, lactation specialists, and clinicians with interests in holistic health (Lutz, Herrick, & Lehman, 2001).

Educators, Researchers, Students, and Other Members

The education and research roles held by faculty, staff, and consultants are essential if the NLHC model is to advance in today's health care system (AACN, 2002). The opportunity for faculty involvement through clinical training of students as well as community-focused research programs is evident and promising for community collaboration and well-being (Greiner & Knebel, 2003).

NLHC programs are client and student oriented. Nursing students can learn about the intersection of health care economics, service, education, and research (Thies & Ayers, 2004). Students also have opportunities to promote social justice while engaging in community service learning activities with underserved, vulnerable populations (Hansen-Turton, Miller, & Greiner, 2009; Thompson & Feeney, 2004). If the center is part of a school of nursing, faculty roles include clinical oversight of graduate and undergraduate students assigned to the center or involved in related community projects, such as adult influenza inoculation campaigns.

Other members include community advocates, board of directors/advisory board members, and organizational partners. Community advocates are frequently known as key stakeholders. Community voices are often the most influential and listened to by elected officials and their staff.

Every NLHC should have a board of directors or advisory board. The organizational structure of a center as part of a larger institution or a freestanding entity dictates the type of board members that govern or advise staff on the direction of the center. A board of directors has oversight responsibilities, including fiscal management, for the NLHC model. An advisory board guides the work of an NLHC but holds no fiduciary or voting responsibilities. The board should represent diverse professions and occupations and be knowledgeable about the target community and its residents.

In addition, organizational partners are valued members. Centers that develop and maintain organizational relationships will benefit through service agreements and contracts with one or more of the partners.

THE BUSINESS SIDE OF NURSE-LED CENTERS: ESSENTIAL ELEMENTS

Nurses who work in nursing centers are committed to working with diverse people in noninstitutional settings. The nurses use community characteristics, population profiles, health indexes, epidemiologic findings, and positive working relationships with professionals and the public at large to develop the model (Hansen-Turton, Miller, & Greiner, 2009). The model requires careful planning and structure to be a successful education, service, and business enterprise. During the planning and implementation phases, interrelated elements must be considered. Resource Tool 21.D outlines essential elements in nursing center development. These elements serve as an annual checklist to measure growth of a nursing center and guide sound decisions regarding sustainability and future planning.

Start-up and Sustainability

In planning and establishing a nursing center (Schultz, Krieger, & Galea, 2002), nurses and others need to seek expert advice and support. This includes having financial advisors. It is important to remember that this work is a business enterprise in which the art and science of nursing is practiced. Final decisions about establishing a nursing center are made after exploration of the following essential areas:

1. Organizational goals, commitments, and resources
2. Community interests, assets, and needs
3. Feasibility study, internal and external to the parent organization
4. Strategic plan
5. Business plan
6. Information management plan and resources
7. Existing social policy and health care financing
8. Legal and regulatory considerations
9. Mission, vision, and commitment of the lead organization

The initial work of assessing the interests, resources, and capacity of an organization to undertake the nursing center model is interrelated yet separate. For example, conduct a feasibility study before developing a business plan and incorporate elements of the feasibility study into the business plan. A strategic plan builds on feasibility data as well as economic principles and practices. Planners must also consider workforce needs, personnel management, public information and outreach campaigns, community capacity, and the health care environment relative to funding streams. In 2015 and beyond, any feasibility study must analyze the national health care reform legislation dollars committed, and funded programs. As a cautionary note, dollars committed do not guarantee funding at that level. Regardless of the federal funding level, there will be widespread competition for program support.

Feasibility Study

A **feasibility study** identifies the strengths, limitations, and capacity of an organization and the community to support the establishment and continuation of a nursing center. It requires interviews with key individuals, surveys and data collection, focus groups, and community forums. It is necessary to consider epidemiologic, environmental, and other community assessments as well as data from public health agencies. Local agencies and tertiary care institutions can provide data about health needs and gaps in care for targeted groups. The study must consider legal and regulatory policies. States vary in their regulations for APNs, particularly nurse practitioners. The planners must investigate required professional credentialing, site accreditation, state Medicaid waivers, physician collaborative agreements, and any local or state requirements (Naylor & Kurtzman, 2010). The overall processes of community collaborations, assessment, and feasibility studies support the development of business plans, strategic plans, and timelines.

A sound business plan considers all aspects of establishing a nursing center and describes the development and direction of the nursing center and how goals will be met (see the **How To Develop a Business Plan** box). A **business plan** is built on the

known or more predictable sources of funding at the time the plan is developed. In today's uncertain economic health care environment, it may be necessary to modify the business plan at a moment's notice (Torrisi & Hansen-Turton, 2005). Legislative changes and reimbursement regulations can significantly alter the business plan. In addition, no grant allocation should ever be included in the business plan until the grant is awarded.

HOW TO Develop a Business Plan

1. Cover page includes date, name, address, and phone number(s) of the person(s) responsible for the nursing center and any consultants to the business plan.
2. Executive summary. This is a one- or two-page overview of the center and the plan.
3. Table of contents.
4. Description of the business plan that details what the center is and what services it will provide.
5. Survey of the industry. This summarizes the past, present, and future of the local and regional health care market.
6. Market research and analysis. This description outlines existing competition and the potential market share and identifies target groups.
7. Marketing plan. This details how the center will reach its targeted clients.
8. Organizational chart with a description of the management team.
9. List of supporting professional staff (e.g., accountants).
10. Operations plan. This describes how and where services will be provided.
11. Research and development. This projects program improvement and opportunities for new initiatives.
12. Overall schedule. The timeline establishes the start date and development phase of the nursing center.
13. Critical risks and problems. This examines the internal and external threats to the center and how these will be addressed.
14. Financial plan. The fiscal projections for the first 3 to 5 years are presented. A budget, cash flow forecast, and break-even point are included.
15. Proposed funding. Specific sources are listed that can provide funding.
16. Legal structure of the center. This describes the status of the center, such as free-standing, a corporation, or part of a larger organization.
17. Appendixes and supporting documents

The strategic plan complements the business plan. A strategic plan looks into the future and guides the work of the nursing center in that direction. Strategic plans have a regular timeline and may change as indicated by local, national, and global events. Strategic planning meetings are periodically scheduled to review and refine the plan. The plan includes goals, objectives, and target timelines for implementation and evaluation of projected and ongoing services. The strategic plan should answer these questions: (1) What resources will the center need after start-up? (2) What economic and legislative factors may influence center productivity and sustainability? (3) What will be the center's core functions in 5, 7, and 9 years? (4) How can

the staff move the center in the appropriate direction? (5) How will staff process and handle change?

Feasibility studies, business plans, and strategic plans lay the foundation for strong nursing centers. These components are crucial to the day-to-day functioning of a newly opened nursing center and reflect the abilities of the management team to build community coalitions and collaboratives. In addition, the management team must be knowledgeable about federal regulations, acts, and funding changes, especially Medicaid and Medicare reimbursement, and grant opportunities. One resource tool that should be on site for reference is the NNCC Guide: *Nurse-Managed Wellness Centers: Developing and Maintaining Your Center*, a National Nursing Center Consortium Guide and Toolkit (Hansen-Turton et al, 2009).

Once the community assessment, feasibility study, business plans, and organizational networking are completed, it is important for key people to ask the following questions:

- Why would the organization want to do this?
- What will be the immediate and long-term outcomes for the organization and the community at large?
- Can the investment (that is, staff, money, time, and space) be made?
- Does the community truly want and need a nursing center model?

The organization cannot drive the desire for the nursing center. The center must be person- and community-centric, not provider-centric. If the establishment of a nursing center is solely done from the organization's vantage point, the possibility of long-term sustainability may be jeopardized. The final question is the most critical one: Does the community truly want and need a nursing center model? No assessment, study, or plan can ignore this question. If the answer is not clear, more time must be invested to find out if there is a match in need, interest, and a center's potential capacity. For example, if the community is focused on helping young women move from public assistance into jobs and the immediate need is daycare, a nursing center that offers linkages with daycare providers and on-site physical examinations and childhood immunizations will be an essential community resource. However, if the nursing center offers only senior citizen services, the immediate and expressed community need was ignored.

The establishment of a nursing center is warranted if the model reflects the needs, interests, and strengths of the target population and is economically feasible. There should be long-term commitments by all involved in the planning process, including any parent organization. The parent organization's mission, vision, and commitment influence the viability of the nursing center model. Planners must determine the support of the parent organization before investing the time, effort, and collaborative work necessary to develop the model. If there is uncertainty at the administrative level, it is foolhardy to move forward until there is strong and documented commitment from the organization that matches the community commitment.

It is challenging for those involved in the planning process to forecast programs, determine service patterns, integrate outcome measures, and project costs. The planning process over

time can be difficult. Planners may not devote sufficient time to the matter of nursing center revenue sources (Torrisi & Hansen-Turton, 2005). If money matters are not thoroughly considered, any nursing center's future will be compromised and may not withstand the stresses of changing funding streams, political decisions, and policy changes (Kinsey & Gerrity, 2005).

The business plan provides information that forecasts the minimum funding necessary to begin a nursing center and project income 1, 3, and 5 years from inception. A break-even analysis is essential. A business plan must be periodically modified when legislation regarding Medicaid and Medicare reimbursement rates occurs. In addition, a business plan must accommodate a state's reimbursement parameters for APNs.

Potential income sources include fee-for-service, commercial reimbursement, and self-pay. Fee-for-service may be the most viable of economic strategies. Commercial reimbursement includes private health care insurers with established fee schedules. Clients without a source of health insurance are characterized as self-pay. Costs and charges for services must be established. Nursing centers located in medically underserved areas or working with medically underserved populations (migrants) have sliding-fee schedules based on published federal poverty guidelines. Managed care contracts with particular insurance companies, particularly Medicaid contractors, are other sources of income; however, the monthly Medicaid reimbursements do not cover the cost of providing health care to the most vulnerable and underserved in society (Torrisi & Hansen-Turton, 2005). **Cost-effectiveness** and **quality care** are key concerns as providers deal with the instability of reimbursement rates and the variable number of underinsured people seeking a medical home.

Financial support for nursing centers may also come from foundations, charitable contributions, private giving, and fund-raising. Fund-raising can take the form of direct mailings, pledges, and events that raise money. Grants are a source of initial and ongoing funding. The funding organization generally releases guidelines of what the organization will fund. The guidelines are frequently released as a request for proposals (RFP). A proposal developed in response to the RFP specifies how the nursing center would meet the goals of the granting organization in the given timeline. The description of services and client outcomes must be presented in relation to the RFP guidelines.

Nursing centers have agreements and contracts in place for specific services. Agreements and contracts may have different language as well as reporting and fiscal management requirements; however, the basic premise is similar. The nursing center enters into a written agreement to provide services to a select population group or develop a program that targets a specific area. For example, a center may have an agreement with the American Cancer Society to develop a cancer education program for minority seniors in a low-income senior housing complex. The agreement is for a defined time period, has target goals and objectives, and outlines staff assignments and expectations, but there is no budget related to the program. A contract is a legal document that lists the purchase of services, reporting requirements, invoicing, and expected client outcomes. An

example would be a city health department that issues a contract to a nursing center to immunize 100 adults against influenza for a specified sum per vaccine. Each nursing center may have one or many contracts and agreements; however, a nursing center should enter into each arrangement with clear understanding of the business side of the model. Any contract or agreement should be fiscally sound and not deplete center resources.

EVIDENCE-BASED PRACTICE

Evidence-based practice represents the clinical application of particular nursing (health care) interventions and documented client and population outcome data over time (Deaton, 2002). Trends in health care services, client responses, and changes in community characteristics must be documented and summarized periodically (Oros et al, 2001). Assessments of sources of ill health, including noncommunicable conditions, and community influences on economic, environmental, behavioral, and physical health are conducted periodically and reported (Lancaster, 2005). Outcome measurements include client use of on-site services, childhood and adult immunizations patterns, pregnancy outcomes, emergency department and hospital use, and other health indexes including client satisfaction and quality-of-life measures.

The cost of collecting and documenting outcome measures must be included in the NLHC budget (Tudor, 2005; Bates & Bitton, 2010). Measurement instruments require technological support and staff expertise and ongoing monitoring and analyses (Garrett & Yasnoff, 2002; Browne et al, 2010). The Patient Protection and Affordable Care Act includes the prevention and wellness national strategy to fund and support evidence-based and community-based services. This act should provide support to NLHCs with defined outcome measures and electronic medical records (EMRs) in place (Forrest & Whelan, 2000).

Defined outcome measures (evidence) will enable NLHC staff to determine program effectiveness and cost savings associated with clinical outcomes (Resick et al, 2011). The challenge is how to define the criteria, develop measurements and collection methods, compare the evidence with broader community findings, interpret the data to funders, and disseminate findings to the wider health care community. Nursing center staff can use a variety of forums to share findings including professional conferences and publications, popular press, multimedia venues, and testimonies at public hearings (Callahan & Jennings, 2002).

Evidence-based Practice Model

In the twenty-first century health care market, research focusing on **evidence-based practices** demonstrating meaningful client and family outcomes will drive grant calls and investment decisions by public and private entities. An outstanding example relevant to advanced practice nurses and nurse-led models of care was published online July 7, 2014 in the *Journal of the American Medical Association (JAMA) Pediatrics*. Dr. David Olds et al reported on the *Effect of Home Visiting by Nurses on Maternal and Child Mortality*. He and colleagues found that the

Nurse-Family Partnership reduces preventable death among both low-income mothers and their first-born children living in urban, disadvantaged neighborhoods. Primarily African American low-income mothers and children residing in Memphis, Tennessee, were engaged in a randomized, clinical trial of this early intervention program for more than two decades (1990-2011). In earlier studies, mothers participating in the NFP program, when compared with those in the control group, were found to have received better prenatal care; reduced short-interval second pregnancies; decreased use of public assistance programs; and had less substance abuse. Their nurse-visited children, compared to children not receiving nurse home visits, were less likely to be hospitalized with injuries through age two years; more likely to be school ready; and less likely to reveal depression, anxiety, and substance abuse at age 12. This study reports on the findings that mothers in the control groups who did not receive nurse home visits were nearly three times more likely to die than mothers receiving nurse home visits. The relative reduction in maternal mortality was even greater for deaths related to external causes including drug overdose, suicide, and homicide. Children in the control group not receiving nurse home visits had a mortality rate of 1.6% for preventable causes such as sudden infant death syndrome, unintentional injuries, and homicide. There were zero preventable deaths among nurse-visited children.

For more than 37 years, Dr. Olds and colleagues continued to study the long-lasting maternal and early childhood outcomes of those involved in Nurse-Family Partnership. NFP is the most rigorously studied maternal and early childhood health program of its kind. The data demonstrate that NFP public health nurse home visitors, in partnership with their enrolled mothers, contribute to multigenerational health and family stabilization. These outcomes also have measurable economic and societal benefits that reduce long-term social service expenditures. The Nurse-Family Partnership National Service Office (www.nursefamilypartnership.org) helps communities and nurse-led models of practice implement and sustain this evidence-based public health program. The Philadelphia Nurse-Family Partnership is highlighted later in this chapter.

Health Insurance Portability and Accountability Act (HIPAA)

Staff committed to evidence-based practice, outcome measures, EMRs, data collection, and analyses must be knowledgeable about the Health Insurance Portability and Accountability Act (HIPAA). HIPAA, which is Public Law 104-191 passed by the 104th Congress to protect the privacy of individually identified health data referred to as protected health information (PHI). The regulations took into consideration the shift to paperless, electronic medical records. Electronic records increase the potential for individuals to access, use, and disclose sensitive personal health data. The act enables consumers to have more control over their health information, establishes boundaries about the use and release of health records, sets safeguards about provider protection of private health information and penalizes violations of same, and enables consumers to obtain and/or make informed decisions about how their health

information is used and disclosed. According to current regulations, all staff must monitor and keep secure client records, have mechanisms to transfer client information securely and appropriately, and strictly adhere to client confidentiality (Thorpe & Ogden, 2010).

Nurses in NLHCs are required to comply with HIPAA regulations, as well as be responsive to and report public health threats such as tuberculosis, disease outbreaks related to food contaminations, and influenza. Reference resources for staff include the HIPAA website of the Office for Civil Rights (<http://www.hhs.gov/ocr/hipaa/>) (USDHHS, 2010b) and the CDC website on Privacy Rule guidelines (<http://www.cdc.gov/privacyrule/>) (CDC, 2010b). Other chapters further detail public health responsiveness and HIPAA documentation challenges.

Outcomes and Quality Indicators

Quality health indicators and related performance measures are priorities in any type of nursing center (Stryer, Clancy, & Simpson, 2002). These data are presented to the nursing center's board, funders, and the community at large and document the center's contributions to the health and welfare of the community. Outcome measures and quality indicators can be preset, or staff may determine that there are outcome measures that were not predetermined, but at time of review have meaningful results. For example, the nurse practitioners may have set up a callback system that improves timely use of primary care services. This can now be documented through client satisfaction, adherence to advised health practices, and changes in health behaviors. Such outcomes can be considered quality indicators that emerged from the day-to-day practices.

Center staff must carefully consider and determine what outcome measures and quality indicators have meaning for the community and the health care system. Despite a staff tendency to want to measure everything, begin with particular indicators and measures and incrementally add as information is indicated. Excessive measures consume staff time and resources and valid measurements may not emerge.

The Quality Care Task Force of the NNCC has developed *Guidelines for Quality Management for Nursing Centers with Standards for Community Nursing Centers*. This publication is a vital tool for staff and can be accessed at www.nncc.us. The standards assist nursing centers to assess growth and development and areas that need improvement. The standards also include quality indicators, population groups, performance targets, and measures. The indicators are grouped into the areas of prevention, utilization, client satisfaction, functional status, symptom severity, and others.

Utilization of the standards and select indicators and associated processes enable a nursing center to document evidence-based practice. References used to develop the standards include the National Committee for Quality Assurance (NCQA) (Gingerich, 2000). An example of evidence-based practice follows; also refer to Table 21-1.

The Philadelphia Nurse-Family Partnership (NFP) serves first-time low-income parents and their children through an intensive public health nurse home visit model. This replication model is based on the most rigorously tested program of its kind

TABLE 21-1 Examples of Quality Health Indicators for Nursing Centers

Indicator	Population	Performance Targets	Measure
Prevention			
Annual influenza vaccine	High-risk groups: Age 65 or those with heart or lung disease and other chronic conditions	<i>Healthy People 2020</i> = 90% age 65+ <i>Healthy People 2020</i> = 60% high-risk ages 18-64 years	Client self-report and/or clinical records/audit
Utilization			
Mammogram within past 2 years	HEDIS: Women age 52-69 years <i>Healthy People 2020</i> : Women 40 years and older	HEDIS 2001 = 81% <i>Healthy People 2020</i> = 70%	Client self-report and/or clinical records/audit
Client Satisfaction			
Client satisfaction, annual	100 consecutive clients per quarter	Performance targets to be determined by individual nursing center and/or health care plan	Surveys
Functional Status			
Quality-of-life indicator	Adults age 18 years and older	Determined by individual nursing center and related to baseline indicators and improvement goals	Screen using Short Form 12 or 36

(www.nursefamilypartnership.org). Philadelphia's NFP was established July 1, 2001. It is the largest countywide site in the Commonwealth of Pennsylvania and was formed to reduce child abuse and neglect in high-risk Philadelphia neighborhoods. Eligible low-income women are enrolled during pregnancy. Each woman receives intensive home visit services until the child reaches age 2 (program graduation). The Philadelphia NFP adheres to the national NFP model of nurse home visitation. NFP goals are to improve pregnancy outcomes, improve children's health and development, and improve families' economic self-sufficiency over time. NFP is based on the primary prevention and early intervention model developed by Dr. David Olds and colleagues (Eckenrode et al, 2010). Advanced practice public health nurses receive extensive education in NFP protocols, maternal-infant-toddler assessment measures, and motivational interviewing strategies. As of 2014, NFP nationally serves over 29,000 women in 43 states, the US Virgin Islands and six tribal communities.

On July 21, 2010, Health and Human Services Secretary Kathleen Sebelius announced the Affordable Care Act Initial Funding for Maternal, Infant, and Early Childhood Home Visiting (MIECHV) State Grants to fund evidence-based home visiting programs that improve the well-being of families with young children. In 2012, Philadelphia NFP and its complementary Mabel Morris Family Home Visit Program received a MIECHV federal expansion grant award and increased enrollment from 400 pregnant adolescent and adult women in any given year to 650. Data released in July 2014 summarize participant demographics and health and employment outcomes from 2001 to 2014 ($N = 4012$). Upon enrollment, the median age of clients was 18 years (range, 10 to 45 years). The median education was eleventh grade. Ninety-three percent of the population was unwed with 72% unemployed and from 2010 to present a decline in median annual incomes to \$7,500. Ninety-two percent of the population was of African American or Hispanic heritage. Cumulative data document the following outcomes: there was a 19% reduction in smoking during pregnancy, a statistically significant (63%) reduction in marijuana use, and a statistically significant (62%) reduction in domestic

violence during pregnancy. Seventy-five percent of mothers initiated breastfeeding with 13.5% breastfeeding at 12 months of infancy. Upon graduation when children turn 2 years, 93% of the toddlers were fully immunized. Of the mothers who entered the program without high school or GED diplomas, 60% were still in school and 40% completed education, with 17% pursuing higher education. Philadelphia NFP mothers during the first year postpartum entered the workforce earlier than national counterparts and remained employed. The Mabel Morris Family Home Visit program complements the NFP model as it uses the Parents As Teachers curriculum and enrolls pregnant and parenting families and follows the youngest child until age 5. This program enables graduating NFP families to continue with home visit services if needed. Nurse home visitors also staff this program and are involved in extensive Parents As Teachers training. This model focuses on positive parenting education emphasizing parents as the child's first teacher and school readiness at age five for each child.

The Philadelphia NFP reflects NFP National Service Office findings across the nation. It is a cost-effective nurse home visit program proven to be of great benefit for low-income, first-time at-risk mothers and their first-borns (NFP, 2014). Dr. Ted Miller of the Pacific Institute for Research and Evaluation prepared a report analyzing to date NFPs costs, outcomes and return from investment. NFP programs in Pennsylvania have an average cost per family of \$8,327 and Miller's model predicts that by a child's 18th birthday the benefits to society of NFP are estimated to be \$59,972, which represents a \$7.20 return on investment for every dollar invested in Nurse-Family Partnership (Maternal and child health program, 2014).

The momentum to support evidence-based home visitation programs will continue beyond this decade. Forty-nine states, the District of Columbia, and five territories were awarded funds to create and support successful home visiting programs, such as Nurse-Family Partnerships and Parents As Teachers Home Visit models (USDHHS, 2010a).

This is an opportune time for APNs interested in public health and prevention initiatives to explore employment options in NLHCs that host nurse-family partnerships and other maternal-child-family health services. Throughout the nation, there is great momentum in the health and economic sectors to create social impact bonds that would sustain early childhood initiatives demonstrating measurable, long-term personal and family outcomes. The cost savings to society are measurable and investors want to make wise investment decisions that have “payouts.” Nurses committed to prevention work in community settings are on the cusp of new careers in early childhood programs.

Quality Improvement

The evidence-based practice application exemplifies what nurses can do to measure outcomes, strive to improve those outcomes given particular standards, and make meaningful contributions to the public’s health. Accurate data collection, measurement methods, summary statistics, and preparation of evidence-based practice reports are fundamental standards in any NLHC.

As the nursing center model continues to grow throughout the nation, the potential to collectively summarize data and outcomes will further strengthen this movement. Through collaboration and the pooling of data, this model will continue to move into the mainstream health care system (Christensen,

Bohmer, & Kenagy, 2000; Naylor & Kurtzman, 2010). However, the staff must be as committed to data as to the provision of quality services. Data will enable the staff to clearly understand what goals are in place, and if areas are to be improved, they can develop action plans to improve services and client outcomes (Campbell, 2000). The concurrent emphasis on service and data can stress staff and the capacity of any nursing center to effectively and efficiently manage services and technology (Bates & Bitton, 2010). The [Quality and Safety in Nursing Education](#) box describes how to use data to improve care.

Technology and Information Systems

Currently, technology and information systems are essential for data collection and analyses. Available technologies need to be used to collect, collate, and analyze data and to support the provision of quality health care services (Shortliffe, 2005; DesRoches, Campbell, & Vogeli, 2010). Technology and information systems will continue to change and adapt to accommodate existing health care legislation, HIPAA, *Healthy People 2020*, public health mandates, and unfolding global and national events. Continual reinforcement about the confidentiality of client records is critical (Callahan & Jennings, 2002). Transfer of information must be carefully monitored, and the use of computers and the entering and retrieval of data by staff will be delineated by role and responsibility and passwords. One resource tool that should be on site for reference is the National

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Quality and Safety Focus

Targeted Competency: Quality Improvement

Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems.

Important aspects of quality improvement include:

- **Knowledge:** Recognize that nursing and other health professions students are parts of systems of care and care processes that affect outcomes for patients and families
- **Skills:** Seek information about outcomes of care for populations served in care setting
- **Attitudes:** Value own and others’ contributions to outcomes of care in local care settings

Quality Improvement Question

Nursing centers are established to address a specific health need in a community. You are a public health nurse who has been invited to help develop a new nursing center whose primary aim is to provide primary care to a newly insured group prevalent in your community: previously uninsured young adults. This population is newly insured because of the Affordable Care Act of 2010. As you begin to research this population, you come to appreciate the importance of this target population. In your research you discover that an important aspect of the success of the Affordable Care Act is the inclusion of young adults (age 19 to 29). According to 2013 statistics collected by The Commonwealth Fund, this population has historically been uninsured at higher rates than any other age group, not because of a lack of desire for health coverage

but because they have lacked access to affordable health coverage—only 64 percent of young adults had health insurance coverage in 2010. Additionally, 41 percent of all young adults and 60 percent of uninsured young adults said they did not receive needed health care because of the cost of care. Half of uninsured young adults also reported medical debt or problems paying medical bills, while 29 percent of insured young adults reported these problems due to the lack of sufficient health care coverage (Collins, Robertson, Garber & Doty, 2013).

The new Nursing Center is funded by a local large university (whose many graduates stay in the community), the local, large regional university hospital, and a large regional charity organization. Consider the following questions in the development of this important community-based resource:

- Knowing that quality improvement is data driven work, what data will you need to track to demonstrate an improvement in providing primary care to your target population?
- How will you gather data about current barriers to access to care for your target population?
- How might you involve your financial stakeholder partners in ensuring that your nursing center is providing more accessible care to your target population?
- Since ongoing monitoring of relevant data is vital to assessing whether a nursing center is meeting its stated goal for its target population, how will you educate the staff of the nursing center about the importance of these data? Develop bullet points for ongoing education/motivation of the nursing center staff.

Collins SR, Robertson R, Garber T, Doty MM: *Insuring the future: current trends in health coverage and the effects of implementing the Affordable Care Act*, New York, 2013, The Commonwealth Fund.

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

Nursing Center Consortium Guide: *Community and Nurse-Managed Health Centers: Getting Them Started and Keeping Them Going* (Torrisi & Hansen-Turton, 2005).

EDUCATION AND RESEARCH

Nursing centers provide many education and research opportunities. Clinical assignments through the nursing center model enable students at all levels to work with skilled clinicians, develop positive community collaboratives, and build their skills to become professionals. These students often develop an interest in working with underserved populations in medically underserved areas of the nation. Students are assets to the nursing center model. Faculty brings skills that enable nursing center staff to develop and implement programs that integrate faculty-student contributions and enable the programs to engage more of the target population.

It is necessary to carefully coordinate, supervise, and evaluate student education in nursing centers. A faculty liaison enables students to have a resource within the educational system as well as a link with the center. Student schedules must also be coordinated with nursing center timelines. A year-round nursing center that provides 24-hour coverage of services must accommodate academic schedules and students moving in and out of clinical assignments. Nursing center staff and faculty must work to maintain ongoing communication with clients and community agencies about student rotations, program assignments, and student projects. Students should be encouraged to share their work with the community because learning is a mutual exchange of goods and services. In addition, in any nursing center model nothing is done in isolation (Shiber & D'Lugoff, 2002).

Research in nursing centers provides the opportunity to gain answers to questions and to share the findings with colleagues and the public (Sherman, 2005). It is important to answer questions about individual and population health status, client outcomes over time, roles and capacities to address health promotion with the existing health system, and the value and affordability of care (Gladwell, 2005). Centers offer many opportunities for educational research.

Each center needs a research or program evaluation agenda. Resource Tool 21.E displays the WHO's priorities for a common nursing research agenda. The research focus includes identification and clarification of client needs, particularly those not engaged in an existing health system; description of nursing interventions and linkages with consumer needs and resources; demonstration of effective interventions that produce appropriate outcomes; and cost analysis and documented cost-effectiveness of services (Hirschfeld, 1998).

Over the past three decades, nursing center research has principally focused on the development and characteristics of nursing centers (Sherman, 2005). Descriptive data have been collected about clients, types of services, the financial supports, and community relationships. However, more than descriptive clinical studies are needed. Research efforts are underway to capture and name the unique features of nursing models of care and link them with health outcomes. For example, the significance of

psychosocial interventions inherent in nursing practice is being examined, such as listening to, supporting, and interpreting information for clients. Client satisfaction studies document the perceived value by those who use nursing centers. Factors associated with access to services are being examined. These include availability, timeliness, acceptability, and affordability of services. Environmental conditions, such as housing, transportation, criminal activities, and welfare-to-work transitions that influence health care access and use patterns are being examined. Resource Tool 21.F presents a template for research in NLHCs.

Program Evaluation

Program evaluation is an essential organizational practice in NLHCs, and research questions emerge from program evaluation. The evaluation process is a systematic approach to improve and account for public health and primary care actions. Evaluation is thoroughly integrated in routine program operations. The process drives community-focused strategies, allows for program improvements, and identifies the need for additional services.

Program evaluation separates what is working from what is not and enables clinicians, faculty, and students to ask difficult questions and handle pressing challenges (Schultz, Krieger, & Galea, 2002). Resources are available to nursing center staff to enhance their understanding and application of program evaluation in their particular setting. Resources include courses offered through the Centers for Disease Control and Prevention (CDC) Public Health Training Network, The Community Toolbox (<http://www.cdc.gov/eval/framework.index.htm>), and other resources updated by the CDC Evaluation Working Group (2010a). These resources enable nursing center staff to implement the six essential program evaluation steps in the context of their model and in their particular community. The essential steps are outlined in Box 21-4.

POSITIONING NURSE-LED HEALTH CENTERS AND ADVANCED PRACTICE NURSES FOR THE FUTURE

The future for nurse-led health centers is promising. The advent of the Affordable Care Act and consumer demand is changing the traditional Western model of health care. NLHCs continue to be strategically positioned to meet these changing demands and needs. Consumers are seeking alternative sources of care such as acupuncture, meditation, and mindfulness training. They are also presenting with health stressors related to the

BOX 21-4 Essential Program Evaluation Steps

- Engaging stakeholders
- Describing the program
- Focusing the evaluation design
- Gathering credible evidence
- Justifying conclusions
- Ensuring use and sharing lessons learned

enduring aftermaths of natural and man-made catastrophes such as hurricanes, droughts, and bioterrorism (Rottman, Shoaf, & Dorian, 2005). NLHCs and their community counterparts must be prepared to meet the daily needs of people as well as any unexpected events that threaten society's future (Fairbrother et al, 2010). In addition, health care providers must appreciate the societal and economic consequences of the "great recession" of 2008 that is predicted to influence American life for a decade or longer (Henig, 2010) as more public dollars will be consumed to support those in need (Lancaster, 2005).

Clinics in retail stores are often staffed by nurse practitioners and offer a convenient point of service. The clinics are typically located in high-volume retail businesses including grocery stores and pharmacies. These clinics have a limited scope of care that includes immunizations, routine school physicals, and common acute problems. The majority of retail clinics are owned by for-profit organizations whose management does not consider the clinics as NLHCs. In fact, there is concern that the retail clinic fragments care and threatens the viability of primary care provider services, including NLHCs (Pollack, Gidengil, & Mehrotra, 2010). In the future, market forces including the public's interest in convenient and affordable care will determine the growth of NLHCs and the demand for retail clinics as alternative sources of care.

Given the complexity of care in the twenty-first century, as well as the positioning of NLHCs to be the provider of choice, all staff should identify and join one or more professional organizations such as the National Nursing Centers Consortium, the American Nurses Association and the American Public Health Association, Public Health Nursing Section. The NNCC website (www.nncc.us) provides an extensive overview of one membership organization service. Services include data warehousing, information systems, public policy development, health care advocacy, and monthly postings of relevant grant opportunities for education, service, and research initiatives.

Much has been noted about the nursing workforce issues that confront our nation and the world in this century. Legislators, health care systems, the nursing profession, and educational institutions as well as the public continue to focus on interrelated factors that contribute to the available pool of advanced practice nurses (Bingham, 2002; Donelan et al, 2008; Buerhaus, Auerbach, & Staiger, 2009). NLHCs and associated community-based initiatives need highly qualified and committed nursing staff to contribute to this work. More professional nurses are choosing public health or community-based practices, reporting their belief that they are making a positive difference in their communities as well as a high level of job satisfaction (University of Michigan Center of Excellence in Public Health Workforce Studies, 2013). The opportunities to make meaningful differences in the lives of people served and to shape an evolving practice model are appealing. Nurses attracted to this model often discover that they can be front-line advocates for people and have more opportunity to do policy development (Drevdahl, 2002).

Nurses involved in NLHCs focus on health disparities and access to care for all. They educate others about the NLHC as a model of public health and primary care services responsive to

personal, family, and community need and interest. An article in the *Harvard Business Review* cited nurse-led centers as a disruptive and innovative approach to the delivery of health care services (Christensen, Bohmer, & Kenagy, 2000). A decade and a half later, NLHCs continue to be disruptive, innovative, and constantly in the forefront, identifying new opportunities to better address the needs and strengths of unique population groups.

There is no better time than the present to be a nurse and to advance the profession (Zysberg & Berry, 2005). Nurses in NLHCs are uniquely positioned to introduce nursing to community members, to speak on behalf of the profession, and to introduce educational opportunities to those seeking a future in health care. They are and will continue to be front-line advocates for social justice and equality for all. Their work is a lasting legacy for those who follow (Figure 21-5).

The authors envision the following advancements within this decade and beyond: (1) a full complement of APNs, population-focused nurses, nurse practitioners, and other nurse experts who are the backbone of primary health care providers throughout the nation, and (2) an exponential expansion of the NLHC model, focusing on wellness and prevention initiatives. The practice application at the conclusion of this chapter exemplifies the potential of nursing contributions to improve the health of one urban community.

FIG 21-5 Preparing for their future as advanced practice nurses in a nurse-managed health clinic. (From Mabel Morris Head Start Program, Philadelphia, PA.)

PRACTICE APPLICATION

Annual summaries of client use patterns and program outcome data document erratic patterns of client access and ongoing use of one nursing center's services. The center, located in a public housing site, offers comprehensive primary health care to clients of all ages, a sliding-fee schedule so no one is turned away, managed care contracts, and a variety of public health and social services provided in home or community settings. The office is open 6 days a week with appointments available during day and early evening hours. The site is readily accessible by public or private transit, and it is less than a 5-minute walk for any public housing resident. A large, attractive sign is in the front of the site for advertising purposes. Monthly outreach is conducted to local businesses, schools, social service agencies, and tertiary care centers. Outreach includes information such as the center's services, hours, and location. Personal contacts, flyers, and posters advertising unique programs such as flu clinics are strategically placed within the housing complex and proximal neighborhoods.

Despite these efforts, data indicate that other strategies are needed. A focus group held with staff, public housing residents, and users of the health center services began. Client users candidly shared their need to have more flexibility in the

appointment schedule. Appointments made months in advance were often not kept because of conflicting schedules (such as work or school), despite the client's best intent. Staff said that too many clients were "no-shows" and their work schedules were "too light." Public housing residents were concerned about keeping their "business private."

Consensus was reached to establish an "open access" appointment model. Clients can schedule appointments or call the day before or day of a needed visit. Nurses would reinforce the open access model and the center's confidentiality standards with clients. All staff would reinforce the option during client visits as well as prepare press releases and community presentations. Staff would review client access and use patterns quarterly. By the next quarter, client access and adherence to appointments increased by 50% and primary care staff reported greater satisfaction in their work responsibilities. Nurses noted that clients in public housing expressed positive comments on how the nursing center had helped them manage their appointment schedules better. Overall, the increased access and use of appropriate primary health care services support the center's goal to promote community well-being.

KEY POINTS

1. NLHCs provide unique opportunities to improve the health status of individuals, families, and communities through direct access to nursing care.
2. Nurse-led center models combine people, place, approach, and strategy in everyday life to develop appropriate health care interventions.
3. A nurse-led center's health and community orientation builds strong connections to the community served.
4. A center is defined by its particular array of services and programs, such as comprehensive primary health care centers and special care centers.
5. The foundations for the nurse-led model include the perspective of the World Health Organization and the *Healthy People 2020* systematic approach to improving individual and community health.
6. Each center develops its philosophy, goals, and activities through a process of community collaboration, assessment, and strategic planning.
7. As the community and the center work together for health, a multilevel approach is used that includes individuals and expands to legislators.
8. Nurse-led center development is rooted in public health nursing history and the evolution of the nursing profession.
9. Most current nursing center models emerged from academic nursing centers in the 1970s.
10. Nurse-led models support the skill development of advanced practice nurses, allied health professionals, and paraprofessionals.
11. Any nurse-led center must have a board of directors or an advisory board to guide program development, fund-raising, community networking, and other work.
12. The nurse-led center requires careful planning and structure to be a successful education, service, and business enterprise.
13. Start-up and sustainability are based on a community-focused feasibility study, a sound business and financial plan, operational support, and resource management.
14. Evidence-based practice in nursing centers is essential and represents the clinical application of particular nursing interventions and documented client outcomes.
15. The Health Insurance Portability and Accountability Act will increase a center's investment in administrative and oversight services.
16. Available technology and systems management must be used to collect, collate, and analyze center data.
17. Education, community service and learning, and research opportunities abound in this model.
18. Program evaluation is an organizational practice in nurse-led centers; research questions are developed from program evaluation.
19. Threats to the viability of nursing centers include the uninsured or underinsured, erratic funding resources, community decline, and disenfranchised high-risk populations.
20. Nurses attracted to the nurse-led model discover professional fulfillment in advocating for people in need and becoming involved in public policy change.
21. Nursing centers represent an innovative approach to the delivery of primary health care services.
22. Nurses involved in the nurse-led model are front-line advocates for social justice and equality for all.

CLINICAL DECISION-MAKING ACTIVITIES

1. Discuss why a nurse-led center should be started or not started in your hometown.
2. What is your state's position on credentialing APNs who work in an NLHC model?
3. What existing public policy might adversely affect the viability of nurse-led centers?
4. Why would APNs be attracted to this model of primary health care?
5. How many elected officials at the local level are familiar with the nurse-led center model and, if the majority is uninformed, what could you do to educate the officials?
6. Where do you envision yourself professionally in 2020?

Case Management

Ann H. Cary, PhD, MPH, RN, FNAP

Dr. Ann H. Cary began practicing public health nursing as a home-health nurse in New Orleans, Louisiana, where she executed case management functions daily. She has served on national workgroups to establish the standards of practice for public health nurses and case managers and created certification examinations for case managers; authored numerous articles on case management issues, taught baccalaureate and graduate-level courses in case management, and directed graduate programs in case management and continuity of care. She is the Dean of the School of Nursing and Health Studies at the University of Missouri, Kansas City, MO. In Kansas City, she also serves on a variety of non-profit and interprofessional foundation and community boards whose missions are to increase access, coordinated care, and quality delivery for clients; and, to prepare health care leaders of the future to assure population health.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Define *continuity of care, care management, case management, care coordination, transitional care, integrated care, social determinants of health, and advocacy.*
2. Describe the scope of practice, roles, and functions of a case manager.
3. Compare and contrast the nursing process with processes of case management and advocacy.
4. Identify methods to manage conflict, as well as the process of achieving collaboration.
5. Define and explain the legal and ethical issues confronting case managers.

Issues in Case Management

Legal Issues
 Ethical Issues

Since the Patient Protection and Affordable Care Act (ACA) was initiated in 2010, the health care industry continues to re-evaluate systems that attempt to integrate financing, management, quality, and service delivery models. Challenges abound for clients and providers as they attempt to coordinate care, transition clients among providers and systems, access and share information and documentation about clients and communities, and navigate the complexity of integrated care to optimize quality and access while managing costs. The new models of health care financing provide incentives to value care outcomes over the volume of care provided. Delivery of care is now organized through a network of providers, such as negotiated contracts with hospitals and other levels of care, physicians, nurse practitioners, pharmacies, ancillary health services, and outpatient centers.

Managing the health of populations served by the integrated systems is essential (Newman et al, 2014). These include **accountable care organizations** (ACOs). Nurse case managers and nurse care managers will play a pivotal role in innovative systems of delivery (Institute of Medicine [IOM], 2011). **Population management** includes wellness and health promotion, illness prevention, acute and subacute care, chronic disease, rehabilitation, end-of-life care, care coordination, and community engagement. Case managers are at the core of population health strategies to improve the community outcomes (Noonan, 2014). Population health management can maintain and improve the physical and psychosocial status of clients through cost-effective and customized solutions, such as coordinating and transitioning of care to reduce gaps and costs; supporting evidence-based practices; selecting quality care that is culturally competent; and providing disease management and self-management educational programming (Case Management Society of America [CMSA], 2009; Noonan, 2014). Examples include planning and health delivery strategies for adolescents in a school system or the chronic disease management of elderly in a rural community (Huber, 2010; McKesson Corporation, 2014).

Like the earlier concept described by the American Hospital Association (AHA, 2003-2004), the ACA endorses the use of

integrated systems to realize the following important consequences on the focus of care:

- Emphasis is on population health management across the continuum, rather than on episodes of illness for an individual.
- Management has shifted from inpatient care as the point of management to primary care providers as points of entry.
- Care management services and programs provide access and accountability for the continuum of health.
- Successful outcomes are measured by systems performance and pay for performance for providers to meet the needs of populations.

The contemporary focus of integrated health systems defines the nature of the client as a population in addition to that as an individual. In these systems, population management involves the following activities:

- Assessing the needs of the client population through health histories (and, in the future, genograms), claims, use-of-service patterns, and risk factors; and communicating through interoperable information systems to ascertain patterns, trends, and responses to health programming in a population
- Creating benefits and network designs to address these needs
- Selecting **dashboard indicators** to measure performance
- Prioritizing actions to produce a desired outcome with available resources
- Selecting evidence-based programs related to wellness, prevention, health promotion, and demand management; patient/client engagement; and educating the population about them
- Instituting evidence-based care management processes that assure transitional and coordinated care across the health continuum for a population aggregate
- Deploying case managers within a variety of delivery and insurance systems to clients and providers
- Evaluating provider patterns of performance and client dashboard indicators for impact

Establishing a relationship between financing, managing, delivering, and coordinating services is critical to reach the goal

of population management—that is, achieving health outcomes at the population level. The *Healthy People 2020* goals are to attain both quality of life and increase years of healthy life, achieve health equity and eliminate health disparities, and create social and physical environments as a **social mandate** for health care. In the second decade of the twenty-first century, case management will be an essential intervention to positively influence the leading health indicators, chronic disease outcomes, and focus areas of *Healthy People 2020* (USDHHS 2010).

Establishing evidence-based strategies for all functions is critical to the success of case management for individuals and populations. Using the current best evidence blended with clinical expertise is a critical skill of the case manager (American Nurses Association [ANA], 2013; Lamb, 2013; CMSA, 2010). In their practice, nurse case managers have the following core values: increasing the span of healthy life, reducing disparities in health among Americans, and promoting access to care and to preventive services. Many of the interventions nurses use with clients and health care systems will further the *Healthy People 2020* objectives. These include case management interventions to minimize fragmented care and promote quality transitions of care; incorporate standardized practice tools and adherence guidelines; improve safety of care; and use interprofessional teams to deliver services.

In the Intervention Wheel model for public health nursing practice, the nursing actions of case management, collaboration, and advocacy comprise 3 of 17 evidence-based interventions for individuals, families, and populations served by public health nurses (Keller et al, 2004; and see Chapter 9). These three concepts and practice arenas for public health nurses are more fully described in this chapter. Case management incorporates many of the *Quad Council Competencies for Public Health Nursing* (Quad Council, 2011) because it involves individual and family care as well as community resources, population health, interprofessional teams, and policy implementation.

HEALTHY PEOPLE 2020

Case management strategies offer opportunities for nurses to help meet the following *Healthy People 2020* objectives for target populations:

Access to Care

- **AHS-2:** Increase the proportion of insured persons with coverage for clinical preventive services
- **AHS-3:** Increase the proportion of persons with a usual primary care provider
- **AHS-6:** Reduce the proportion of individuals who experience difficulties or delays in obtaining necessary medical care, dental care, or prescription medications
- **ECBP-14 and -14.1:** Increase the inclusion of clinical prevention and population content in undergraduate nursing, including counseling training for health promotion and disease prevention
- **SA-9:** Increase the portion of persons who are referred for follow-up for substance abuse problems

AHS, Access to health services; ECBP, educational and community-based programs; SA, substance abuse.

From USDHHS: *Healthy People 2020: A roadmap for health*, Washington, DC, 2010, U.S. Government Printing Office.

DEFINITIONS

Care management is a health care delivery process that helps achieve better health outcomes by anticipating and linking populations with the services they need more quickly (CMSA, 2010). It is an enduring process in which a population manager establishes systems and processes to monitor the health status, resources, and outcomes for a targeted aggregate of the population. The population manager is the tactical architect for a population's health in the delivery system. According to a report by McKesson Corporation (2014), nurse care managers are predicted to hold the primary responsibility for the care management process in health systems. Building blocks that are used by the manager include risk analysis; data mapping; predictive modeling; dashboard indicators; monitoring for health processes, indicators, and unexpected illnesses; epidemiologic investigation of unexpected illnesses; development of multidisciplinary action plans and programs for the population; and identifying case management triggers or events (e.g., when dramatic results are obtained by prevention or early intervention) that indicate the need for early referrals of high-risk clients (ANA, 2013; Stricker, 2014).

Care management strategies were initially developed by health maintenance organizations (HMOs) in the late 1970s to manage the care of different populations. The purpose was to promote quality and ensure appropriate use and costs of services. Typically these involved clients with reduced self-care capacity and whose diseases and treatments were intense (Michaels and Cohen, 2005). Care management strategies include utilization management, critical pathways, case management, disease management, and demand management.

Utilization management attempts to promote optimal use of services to redirect care and monitor the appropriate use of provider care/treatment services for both acute and community/ambulatory services. Providers are offered multiple options for care with different economic implications. Through the use of utilization management, clients who have repetitive readmissions (i.e., they fail to respond to care) are often referred to care management programs.

Critical pathways and maps, which were initiated in the early 2000s, are tools that specify activities providers may use in a timely sequence to achieve desired outcomes for care. The outcomes are measurable, and the pathway tools strive to reduce variation in client care. Today, agencies are more likely to call these clinical paths, evidence-based practice protocols, clinical decision supports or guidelines, or case management plans of care.

Care management services are used for clients with specific diagnoses who may have high-use patterns, noncompliance issues, cost caps (e.g., no more than \$10,000 to \$20,000 can be spent on their case), or threshold expenses.

Disease management constitutes systematic activities to coordinate health care interventions and communications for populations with disease conditions in which client self-care efforts are significant (CMSA, 2010). For example, diabetes, asthma, and depression are typically targeted by providers and insurers. These programs have evolved largely

as initiatives in managed care organizations (Huber, 2010) and will be a focus of accountable care organizations (ACOs).

Demand management seeks to control use by providing clients with correct information and education strategies to make healthy choices, to use healthy and health-seeking behaviors to improve their health status, and to make fewer demands on the health care system (Tufts Managed Care Institute, 2011).

In contrast to care management—which was developed as a population approach to manage care after the aegis of individual case management—*case management* comprises the activities implemented with individual clients/families in the system. In the latest *Standards of Practice for Case Management*, case management is defined as “a collaborative process of assessment, planning, facilitation, care coordination, evaluation, and advocacy for options and services to facilitate an individual’s and family’s comprehensive health needs through communication and available resources to promote quality cost-effective outcomes. Related activities...include care coordination; complex condition management; population health management through wellness, disease and chronic care management; and promoting transitions of care services” (CMSA, 2010, p. 224).

The case manager builds on the basic functions of the traditional nurse’s role and adapts new competencies for managing

transitions among health care facilities, such as wellness and prevention, and interprofessional teams. The complexity of care and the publishing of the ICD-10s bring more in-depth documentation requirements to the scope of the case manager’s activities but the essence remains: accountability, collaboration, advocacy, care coordination, and professionalism (Owen, 2014).

Case management is provided by the disciplines of nursing, social work, and rehabilitation counseling, to name a few. Research by Park and colleagues (2009) found that common knowledge exists for case management providers from the disciplines of nursing, social work, and rehabilitation counseling: case recording and documentation, conflict resolution strategies, negotiation, ethics, relevant legislation, interpersonal communication, and roles and functions required in various settings. Figure 22-1 illustrates the unified knowledge domains for professionals in case management and emphasizes the fluidity of common knowledge used by case managers regardless of discipline.

Treiger (2013) indicates that the challenges of academic preparation for future case managers will be to prepare them in interprofessional case management programs rather than through the lens of a particular clinical practice. In addition, case managers in case management programs are expanding their clinical expertise to embrace the process of disease management, a successful strategy for population outcomes. Specialty case management in advanced nursing practice is a critical

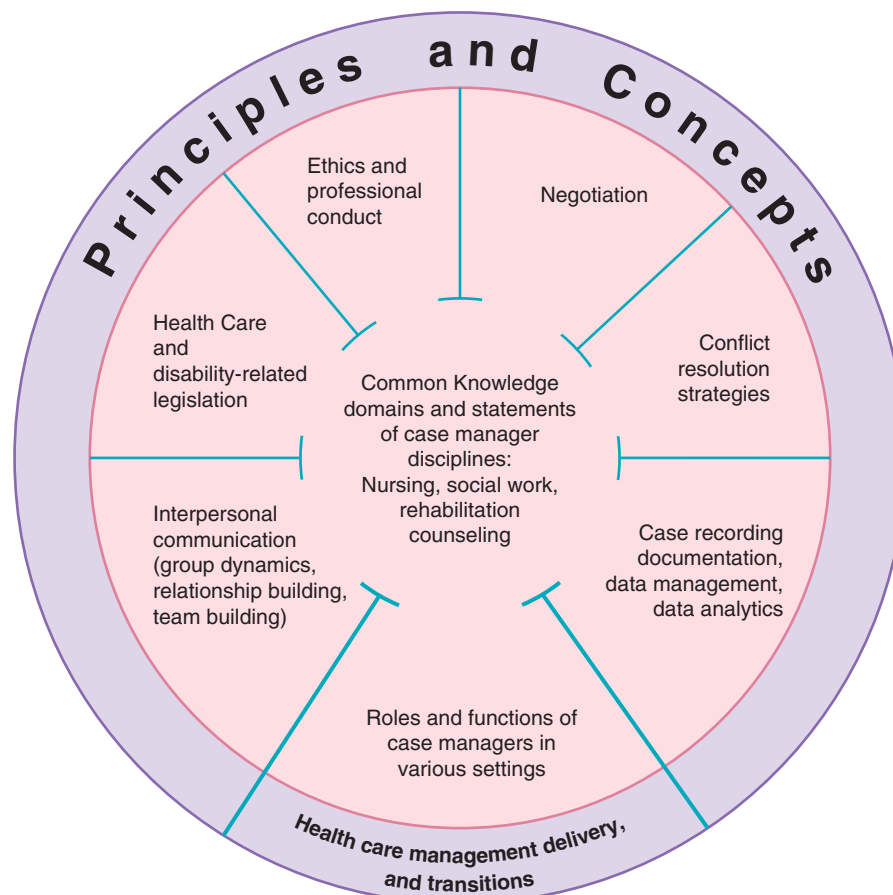

FIG 22-1 Evidence-based knowledge of case managers from disciplines of nursing, social work, and rehabilitation counseling. (Courtesy of Ann H. Cary.)

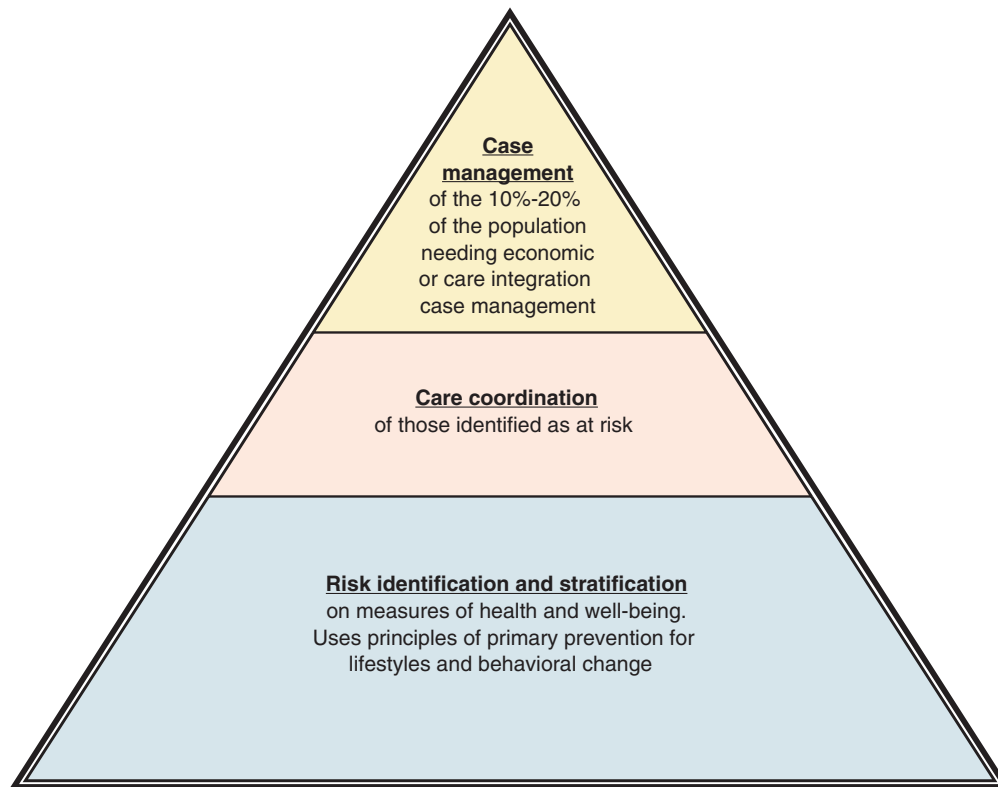

FIG 22-2 Case management model. (From Coggeshall Press: *Case Management Model*. Coralville, IA, 2008, Coggeshall Press; as cited in [Huber, 2010](#).)

role in this field ([Treiger, 2013](#)). In implementing case management, advance practice nurses work with clients or community aggregates as well as systems managing disease and outcomes, whereas nurses with bachelor's degrees more often focus on care at the individual level. [Treiger \(2013\)](#) also observes that there are many individuals working under the title of case manager who fail to perform the full scope of roles and functions, leading to the question of title protection for case managers.

This chapter describes the nature and process of case management for individual and family clients. Case management has a rich tradition in public health nursing as practiced by Lillian Wald and now is frequently found in hospitals, transitional and long-term care, home and hospice care, and health insurance companies. Case management is at the top of the care management pyramid, reserved for a subset of the population. In [Figure 22-2, Coggeshall Press \(2008\)](#) illustrates a case management model pyramid that recognizes the tenets of risk stratification and case finding, coordination, and ultimately case management of a smaller proportion of clients in the population. This model recognizes the interchange of public health and populations at risk for service intensity resulting from economic or care integration needs.

CONCEPTS OF CASE MANAGEMENT

Reviewing multiple or historical definitions of case management helps to demonstrate the complex process and the concept of case management over time. [Weil and Karls, in 1985](#), described

case management as a “set of logical steps and process of interacting within a service network which ensures that a client receives needed services in a supportive, effective, efficient and cost-effective manner” (p. 4). Case management was defined by the [American Hospital Association \(1986\)](#) as the process of planning, organizing, coordinating, and monitoring services and resources needed by clients, while supporting the effective use of health and social services. [Secord \(1987\)](#) defined case management as a systematic process of assessing, planning, and coordinating the service, referrals, and monitoring that meets the multiple needs of clients. [Bower \(1992\)](#) described the continuity, quality, and cost containment aspects of case management as a health care delivery process, the goals of which are to provide quality health care, decrease fragmentation, enhance the client's quality of life, and contain costs.

A focus on collaboration is important in the National Case Management Task Force definition. The definition emphasizes a collaborative process between the case manager, the client, and representatives of other agencies and provider groups. The process includes assessments, plans, implementation, coordination, monitoring, and the evaluation of options and services to meet an individual's health needs. Effective communication is essential to identify available resources to promote quality, cost-effective outcomes ([CMSA, 2010](#); [Mullahy, 2010](#); [Stricker, 2013](#)).

As a competency, case management was defined in the public health nursing literature as the “ability to establish an appropriate plan of care based on assessing the client/family and coordinating the necessary resources and services for the client's

benefit” (Muller and Flarery, 2003, p. 230). Case management has been a term prevalent in the social work literature as well as in public health nursing beginning in the mid-1900s. Knowledge and skills required to achieve this competency include the following:

- Knowledge of community resources and financing mechanisms
- Written and oral communication and technology-enhanced documentation
- Proficient negotiating and conflict-resolving practices
- Critical-thinking processes to identify and prioritize problems from the provider and client viewpoints
- Application of evidence-based practices and outcomes measures

Case management practice is complex as evidenced by the need to **coordinate** activities of multiple providers, payers, and settings throughout a client’s continuum of care. **Care coordination**, one function of case management, is the deliberate organization of client care activities between two or more participants involved in a client’s care to facilitate the appropriate delivery of health care services...and involves the marshaling of personnel and resources to carry out all required patient care activities...managed by the exchange of information among participants for different aspects of care (McDonald et al, 2010). For example, in a contemporary model of primary care practice, the **Medical/Health Home or Patient/Client-Centered Medical Home model** provides accessible, continuous, coordinated, comprehensive care and is managed centrally by a physician/nurse practitioner with the active involvement of nonphysician practice staff. Care provided must be assessed, planned, implemented, adjusted, and evaluated on the basis of goals designed by many disciplines as well as goals of the client, the family, significant others, and community organizations. Although likely employed and located in one setting, the nurse as case manager will be influencing the selection, monitoring, and evaluation of care provided in other settings by formal and informal care providers.

With the increased use of electronic care delivery through telehealth activities, case management activities are now handled via iTablets, phones, e-mail, and fax, and through video visits with the electronic monitoring of physiological status at a client’s residence from a case manager who is located elsewhere. Case managers may also deliver care to a global network of clients located in different countries. A challenging problem is the fragmentation of services and miscommunication handoffs, which can result in overuse, underuse, gaps in care, and miscommunication. These can result in costly client outcomes and quality issues in hand-offs and transitions from provider to provider. Health information technology and electronic health records are benefiting collaborative care team communication, real-time data, and timely adjustments in care.

Case management, including the care coordination function, is part of a wider concept of **transitions of care** illuminated by the **National Transitions of Care Coalition (NTOCC, 2011)**. Transitional care services bridge the gaps among diverse services, providers, and settings through the systematic application of evidence-based interventions that improve communication and transfer of information within and across services, enhancing

post-acute care follow-up, and decreasing gaps in care by the use of a single consistent provider (cited in **ANA, 2013**, p. 19). To advance knowledge on the outcomes of transitions of care, NTOCC has developed a number of tools and resources for case managers to assure effective communication between clients, caregivers, and providers, and published a compendium of transition models in practice that provides evidence of cost savings and lower 30-day hospital readmission rates and emergency room visits. The Transitional Care Bundle includes seven essential interventions: medication management, transition planning, client/family engagement and education, information transfer, follow-up care, provider engagement, and shared accountability across providers (**Lattimer, 2013**). Research indicates that the models employing the “Transitions” concept are currently ensuring higher quality and health care savings (<http://www.ntocc.org/portals/0/Tangiblesavings.pdf>).

Case management differs between urban and rural settings. In the rural setting, where the distance between populations is more expansive, there are fewer organized community-based systems and communication and distance are often a greater challenge. Furthermore, the economics, pace and style of life, values, and social organization all differ. In a study referenced in **Stanton and Dunkin (2009)**, rural residents identified four barriers to access to care that confront case managers in rural areas: lack of proximity to providers, limited services, scarcity of providers, and reduced availability of emergency and acute care services. Transportation, both for nurses and for clients, and lack of health insurance and benefits were documented challenges to rural clients of case managers.

In a study of rural Veterans Affairs (VA) mental health patients who received case management services, **Mohamed, with Neale and Rosenheck (2009)** and **Mohamed, with colleagues Rosenheck and Cuerdon (2010)** found that intensive case management services were characterized as slightly less frequent, less intensive, and less recovery oriented than services delivered to the urban VA population. Travel distances and times were longer for rural case managers. Case management service intensity was related to premature termination of services for the veteran populations. Because case management is part of a transitional care model and coordination of care can reduce readmissions and promote safety, appropriate delivery of case management is essential to support **The Joint Commission’s National Safety Goals (2009)** as well as the National Quality Strategy (**AHRQ, 2013**).

Case Management and the Nursing Process

The nurse views the process of case management through the broader health status of the community. Clients and families receiving service represent the microcosm of health needs within the larger community. Through a nurse’s case management activities, general community deficiencies in quality and quantity of health services are often discovered. For example, the management of a severely disabled child by a nurse case manager may uncover the absence of respite services or parenting support and education resources in a community. While managing the disability and injury claims within a corporation, the nurse may discover that alternative care referrals

Nursing Process	Case Management Process	Activities
Assessment	<ul style="list-style-type: none"> • Case finding • Identification of incentives for target population • Screening, selection and intake • Determination of eligibility • Assessment of challenges, opportunities, and problems 	<ul style="list-style-type: none"> • Develop networks with target population • Disseminate written materials • Seek referrals • Apply screening tools according to program goals and objectives • Use written and on-site screens • Apply comprehensive assessment methods (physical, social, emotional, cognitive, economic, and self-care capacity) • Obtain consent for services if appropriate
Diagnosis	<ul style="list-style-type: none"> • Identification of problem/opportunity and challenges 	<ul style="list-style-type: none"> • Hold interprofessional, team, family, and client conferences • Determine conclusion on basis of assessment • Use interprofessional team
Planning for Outcomes	<ul style="list-style-type: none"> • Problem prioritizing • Planning to address care needs • Identification of resource match 	<ul style="list-style-type: none"> • Validate and prioritize problems with all participants • Select evidence-based interventions • Develop goals, activities, time frames, and options • Create case management plan • Gain client's consent to implement • Have client choose options
Implementation	<ul style="list-style-type: none"> • Advocating for client interests • Frequent monitoring to assess alignment with goals and changing nature of client needs 	<ul style="list-style-type: none"> • Contact providers • Coordinate care activities • Negotiate services and price • Adjust as needed during implementation • Document processes and monitor progress
Evaluation	<ul style="list-style-type: none"> • Measuring attainment of activities and goals of service delivery plan • Continued monitoring and follow-up of client status during service • Reassessment • Bringing closure to care when client needs are achieved or change • Appropriate discharge to ensure effective transitional care and termination of case management processes 	<ul style="list-style-type: none"> • Ensure quality of transitional communication and coordination of service delivery • Monitor for changes in client or service status • Follow up as needed • Examine outcomes against goals • Examine needs against service • Examine costs • Examine satisfaction of client, providers, and case manager • Examine best practices and outcomes for this client

for home-health visits and physical therapy are generally underused by the acute care providers in the community. Through a nurse's case management of brain-injured young adults, the absence of community standards and legislative policy for helmet use by bicyclists and motorcyclists may be revealed, stimulating advocacy efforts for changing community policy. Case management activities with individual clients and families will reveal the broader picture of health services and health status of the community. *Community assessment, policy development, and assurance activities* that frame core functions of public health actions are often the logical next step for a nurse's practice. When observing lack of care or services at the individual and family intervention levels, the nurse can, through case management, intervene at the community level to make changes. Clearly, the core components of case management and the nursing process are complementary (Table 22-1).

Secord's classic illustration of case management (1987) remains an appropriate picture of the process that nurses use. The CMSA model (2010) is a contemporary illustration of the case manager's process in the continuum of care (Figure 22-3) and Table 22-1 also compares the case management process and nursing process.

Characteristics and Roles

Case management can be labor intensive, time consuming, and costly. Because of the rapid growth in the nature of complexity in clients' problems managed by the case manager, the intensity and duration of activities required to support the case management function may soon exceed the demands of direct caregiving. Managers and clinicians in community health are exploring methods to make case management more efficient including the use of providers who can perform to the limit of their licenses, auxiliary case management providers/services, and evidence-based practices. These provider characteristics, which incorporate the four CMSA activities (previously noted in the Concepts of Case Management section), are used today (CMSA, 2010):

1. The technical/intellectual qualifications to understand and evaluate specific diagnoses, generally requiring clinical credentials (and experience), financial resources, health information technology knowledge and analyses, and risk arrangements
2. Capability in language and terminology (able to understand and then to explain to others in simple terms)
3. Assertiveness, diplomacy, and negotiation skills with people at all levels

FIG 22-3 The continuum of care case management model. (From Case Management Society of America [CMSA]: *Standards of Practice for Case Management*. Little Rock, AR, 2010, CMSA, p. 5.)

4. The ability to *assess* situations objectively and to *plan* appropriate case management services
5. Knowledge of available clinical evidence and resources as well as their strengths and weaknesses
6. The ability to act as *advocate* for the client and payer in models relying on third-party payment
7. The ability to act as a counselor or *facilitator* to clients to provide support, understanding, information, and intervention
8. Interprofessional team player

In 1998, Cary described the roles of case managers in the practice setting. These roles are clearly affirmed today by the CMSA (2010) (Box 22-1). The roles demanded of the nurse as case manager are greatly influenced by the forces that support or detract from the role. Figure 22-4 presents factors that demand the attention of both the nurse and the system during the case management process.

Knowledge and Skill Requisites

Nurses, as in other disciplines, are not automatically experts in the role of case manager. First, they develop and refine the knowledge and skills that are essential to implementing the role successfully. Knowledge domains useful for nurses in systems desiring to implement quality case management roles are found in Box 22-2 (Cary, 1998; Stanton and Dunkin, 2009; Treiger, 2013).

When a nurse seeks a case manager position, some of the skills and knowledge will need to be acquired through

academic and continuing education programs, literature reviews, onboarding, orientation, and mentoring experiences. Basic nursing education may need to be updated, and practical experiences in case management may be required. Treiger (2013) recommends that case managers pursue advanced education in case management. In fact, professional development activities for case managers in public health have been demonstrated to contribute to job satisfaction (Schutt et al, 2010). Finally, title protection for case managers is an issue under discussion in the literature in order to ensure credibility of services provided by professional, skilled case managers.

Tools of Case Managers

The six “rights” of case management are right care, right time, right provider, right setting, right price/value, and right outcomes. How does the nurse judge the effectiveness of case management? Three tools are useful for case management practice: case management plans, disease management, and life care planning tools. An underlying principle for the use of each of these tools is the need to use robust evidence as the basis for the selection of activities; technology and health information systems and analytics are now the drivers of these tools.

Technology supports the delivery of processes used by the case manager. The technology sector is refining software in the areas of documentation, decision support, dashboard tools, predictive modeling, workflow automation, reporting capabilities, electronic health records, **patient engagement** strategies and social media, and remote monitoring (Carneal and Pock,

BOX 22-1 Case Manager Roles

- **Broker:** Acts as an agent for provider services that are needed by clients to stay within coverage according to budget and cost limits of health care plan
- **Client advocate:** Acts as advocate, provides information, and supports benefit changes that assist member, family, primary care provider, and capitated systems
- **Consultant:** Works with providers, suppliers, the community, and other case managers to provide case management expertise in programmatic and individual applications
- **Coordinator:** Arranges, regulates, and coordinates needed health care services for clients at all necessary points of services. Effectively participates and leads interprofessional teams
- **Educator:** Educates client, family, and providers about case management process, delivery system, community health resources, and benefit coverage so that informed decisions can be made by all parties
- **Facilitator:** Supports all parties in work toward mutual goals
- **Liaison:** Provides a formal communication link among all parties concerning the plan of care management
- **Mentor:** Counsels and guides the development of the practice of new case managers
- **Monitor/reporter:** Provides information to parties on status of member and situations affecting client safety, care quality, and client outcome, and on factors that alter costs and liability
- **Negotiator:** Negotiates the plan of care, services, and payment arrangements with providers; uses effective collaboration and team strategies
- **Researcher:** Accesses and applies evidence-based practices for programmatic and individual interventions with clients and communities; participates in protection of clients in research studies; initiates/collaborates in research programs and studies; accesses real-time evidence for practice
- **Standardization monitor:** Formulates and monitors specific, time-sequenced critical path and care map plans (see [page 485](#)) as well as disease management protocols that guide the type and timing of care to comply with predicted treatment outcomes for the specific client and conditions; attempts to reduce variation in resource use; targets deviations from standards so adjustments can occur in a timely manner; uses dashboards and predictive modeling to anticipate outcomes
- **Systems allocator:** Distributes limited health care resources according to a plan or rationale

BOX 22-2 Knowledge Domains for Case Management

- Standards of practice for case management
- Evidence-based practice guidelines for specific health and disease conditions and communities
- Knowledge of health care financial environment and the financial dimension of client populations managed by nurses
- Clinical knowledge, skill, and maturity to direct quality timing and sequencing of care activities
- Care resources for clients within institutions and communities: facilitating the development of new resources and systems to meet clients' needs
- Transition planning for ideal timing, sequencing, and levels of care
- Management skills: communication, delegation, persuasion, use of power, consultation, problem solving, conflict management, confrontation, negotiation, management of change, marketing, group development, accountability, authority, advocacy, ethical decision making, and profit management
- Teaching, counseling, and education skills
- Program evaluation and research
- Performance improvement techniques
- Peer and team consultation, collaboration, and evaluation
- Requirements of eligibility and benefit parameters by third-party payers
- Legal and ethical issues
- Information management systems: clinical and administrative
- Health care legislation/policy
- Technical information skills, interoperable information systems, dashboard monitoring, data management and analysis, predictive modeling software, facile use of EHRs
- Outcomes management and applied research

EHRs, Electronic health records.

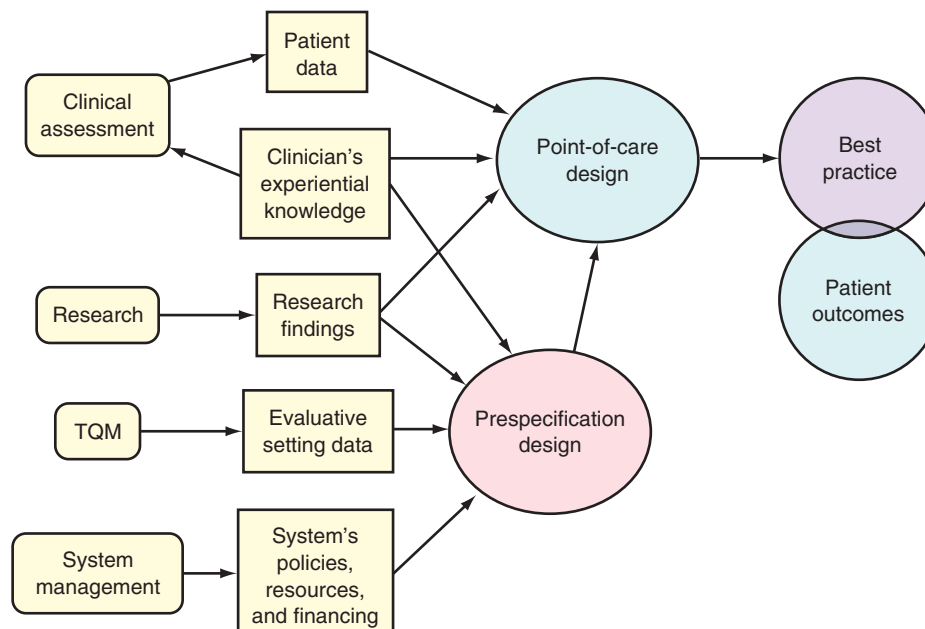

FIG 22-4 Factors that require the attention of the nurse and client in the case management process. *TQM*, total quality management.

2014; Stricker, 2014; Treiger, 2013). For example, health information technology (HIT) allows the case manager to access real-time data to improve timeliness of decisions or program changes for any number of adjustments in care protocols to ensure optimal outcomes. Data analytic software and dashboards allow for rapid decisions for clinical, administrative, and financial outcomes. Dashboard functions typically include (1) manipulation of report data, (2) access to information, (3) observing individual/population trends, and (4) observing trends in large datasets (Stricker, 2014). These data-reporting tools can vary from off-the-shelf, to customized, to simple Excel spreadsheets—each with their own advantages and gaps.

Historically, **case management plans** have evolved through various titles and methods (e.g., critical paths, critical pathways, care maps, multidisciplinary action plans, nursing care plans). Regardless of the title given, standards of client care, standards of nursing practice, and clinical guidelines using evidence-based practices for case management serve as core foundations of case management plans. Likewise, in interprofessional action plans, core professional standards of each discipline guide the development of the standard process.

As early as 1985, the New England Medical Center (Boston, MA) instituted a system of critical path development to guide the case management process in the acute care setting. This method of designing structures and processes of care laid the groundwork for the critical paths, care maps, and clinical decision tools now used in the industry. A *critical path* was described as a case management tool composed of abbreviated versions of discipline-specific processes; it was used to achieve a measurable outcome for a specific client “case” (Zander et al, 1987). The critical path detailed the essential and sequential activities in care, so that the expected progress of the client was known at a point in time. Outcomes from critical paths included satisfaction, client competency, continuity of care, continuity of information, and costs and quality of care. However, one criticism was that critical paths may not be evidence based (Renholm et al, 2002).

At that time the prevailing method of establishing critical paths was by internal, “expert knowledge” from a specific institution, the result being that they could not be applied generally or tested under systematic, scientific methods. In the New England model, key incidents included consults, tests, activities, treatments, medication, diet, discharge planning, and teaching. The paths showed the differences between clients’ progress. However, the paths were generally not revised unless a body of evidence was found to adjust the expected actions.

Care maps became the second generation of critical pathways of care. Rather than give definitions, as early as in 2001 Brown discussed the “various types of evidence that must be accessed, interpreted, and integrated into care design” (p. 3). Brown proposed the best practice health care map (BPHM) as a model for providing quality clinical care within an interprofessional practice. This model discussed all the components of knowledge development and care planning activities that must occur to have positive client outcomes. The author noted that care designed in advance takes the form of “clinical guidelines, care maps, decision algorithms, and clinical proto-

cols for specified populations of clients” (Brown, 2001, p. 3). The “prespecification design” of the BPHM entailed these preplanning courses of care. Brown (2001) stressed the importance of incorporating research findings and clinical experience when developing prespecified plans. Furthermore, the author emphasized that at the point of care, these prespecified plans must be adapted to the individual client or population. The Brown BPHM was (1) client centered, (2) scientifically based, (3) population-outcomes based, (4) refined through quality assessment and compared with other maps, (5) individualized to each client, and (6) compatible with the larger system of health care in the United States.

Such activities today are more likely referred to as case management plans, care maps, and integrated clinical pathways and are the foundation for the methods to establish standardized, evidence-based case management plans. Clinical paths today are defined as structures of care based on interventions translated from evidence for use with clients; include detailed steps in a course of care; are based on pilot applications; and are modified (Kinsman et al, 2010). In the electronic health record (EHR) critical paths become the centerpiece of communication and interprofessional team processes for the case manager (Hyde and Murphy, 2012). Care guidance formats (critical paths, care maps) are integrated into the EHR to be used by the case manager to provide clinical decision support. They may appear as prompts, checklists, references, for example, that will auto-populate a documented service and remind providers as to the array of procedures to be implemented. Case managers need to ensure that any “guidance care plans” embrace the unique needs of the client and care in order to optimize outcomes of care for clients.

Adaptation of any standardized case management plan to each client’s characteristics is a crucial skill for the process and outcome of care. These plans link multiple provider interventions to client responses and offer reasonable predictions to clients about health outcomes. Institutions report that sharing case management plans with clients empowers the clients to assume responsibility for monitoring and adhering to the plan of care. Self-responsibility by clients incorporates autonomy and self-determination as the core of case management. For the nurse employed as a **case manager**, ample opportunity exists to apply and revise critical path/map care guidance prototypes for a target population experiencing acute and chronic health problems.

Disease management is an organized program of coordinated health care interventions that use consensus-driven performance measures and scientifically based evaluations in clinical outcomes for populations with conditions in which client self-care efforts are critical (CMSA, 2010; URAC, 2014). This approach focuses on the natural progression of a disease in high-risk populations. Disease management programs may contain many of the following components (Disease Management Association of America [DMAA], 2008, 2010):

- Selection of high-risk patients, with a focus on a singular disease state (diabetes, asthma, congestive heart failure [CHF])
- Financial and **risk-sharing** arrangements between payers and providers

- Programs for monitoring the use of clinical paths and evidence-based guidelines to assess outcomes and costs
- Protocols for clinical, financial, and administrative processes
- Services to educate clients and promote self-management skills, including the use of motivational interviewing techniques.
- Enhanced quality through evidence-based decision support and other registry technologies
- Support for provider/client relationships and plans of care
- Evaluation of clinical, humanistic, and economic outcomes to address the goal of improving overall health

HOW TO Apply Telehealth Interventions for Clients

To learn more about telehealth interventions for clients, case managers can do the following:

- Make it a point to learn how telehealth works in your community and in the industry.
- Examine the evidence base for telehealth as an option for the types of clients you are servicing when considering available resources.
- Seek continuing education to prepare you on the art and science of telehealth application and client receptivity. Read the literature on e-communication and monitoring impact effectiveness.
- Be aware of the strengths and weaknesses of this delivery and plan to adjust the delivery model to optimize effectiveness for your clients.
- Seek networking opportunities with professional organizations and other case managers about the uses of telehealth.
- Examine the clinical guidelines and practice algorithms for telehealth adoption, application, and use.
- Sharpen your personal interaction and program evaluation skills to better assist in decision making about the use of telehealth services.

From Hagan L, Morin D, Lepine R: *Evaluation of telenursing outcomes: satisfaction, self-care practices, and cost savings*. Public Health Nurs 17:305–313, 2000.

The philosophy of disease management can give clients the tools needed to better manage their lives (Newman et al, 2014; CMSA, 2010). Clients with chronic diseases may benefit from a disease management approach. The goals are to interrupt the continued development of a disease and prevent future disease and complications through secondary and tertiary prevention interventions. Promotion of wellness is necessary for success. For specific client populations that consume a disproportionate share of resources, disease management programs allocate the correct resources in an efficacious manner. Disease management programs may reduce emergency department visits, result in fewer inpatient days and rehospitalizations, greater client satisfaction, and reduced school absences (NTOCC, 2011; Sidorov, 2010). As the science of disease management evolves to predict direct relationships between outcomes and protocols of care, case managers will need to demonstrate cost-effective, optimal clinical care across the continuum—a goal of care management for populations. In fact, disease management is viewed as a top strategy by employers. The Joint Commission (TJC)

certifies and URAC accredits disease management organizations and programs on the basis of their respective standards (see websites www.jointcommission.org and www.urac.org). This may influence the choice of programs a case manager selects to use with clients.

Opponents of the use of disease management programs cite the study by McCall and Cromwell (2011), which described a comparison of eight commercial disease management programs used with Medicare populations and using a nurse call center approach. This comparative evaluation study revealed only modest improvement in quality of care measures with no significant reduction in utilization of acute care services or costs. Some of the possible explanations included that clients had complex comorbidities that required more than a singular disease approach; social determinants and environmental factors may not have been adequately addressed in the plans; and the inclusion of high-risk with low-risk patients could have diluted the significance of the results. Clearly, more research with innovative models that can capture the true nature and intensity of client needs in a disease management program will be necessary to inform the use or discontinuance of this approach in the future.

Life care planning is another tool used in case management. A life care plan assesses the current and future needs of a client for catastrophic or chronic disease over a life span. The life care plan is a customized, medically based document that provides an organized plan to estimate reasonable and necessary current and future medical and nonmedical needs of clients with associated costs and frequencies of goods and services. Typically these needs incorporate medical, financial (income), psychological, vocational, built environment, and social costs during the remaining life of the client (Sambucini, 2013). Life care plans are typically used for clients experiencing catastrophic illness or adverse events resulting from professional malpractice or accidents/injuries or those who have sustained an injury when younger and subsequently have changes in requirements as they age. For example, conditions may include spinal cord injury, traumatic brain injury, chronic pain, amputation, cerebral palsy, and burns. Life care plans are also used to set financial rewards, which can be used to secure resources for care in the future and create a lifetime care plan. A systematic process like the nursing process is used and interprofessional input is required.

The American Association of Nurse Life Care Planners (AANLCP) has published a *Code of Professional Ethics and Conduct for Nurse Life Care Planners with Interpretive Statements* (2012a) as well as the *Nurse Life Care Planners Standards of Practice with Interpretive Statements* (2012b). Nurse life care planners have access to academic course work, continuing education activities, and a published *A Core Curriculum for Nurse Life Care Planning* (Apuna-Grummer and Howland, 2013). There is also a certification examination for nurse life care planners that awards the designation of Certified Nurse Life Care Planner (CNLCP) as a specialty designation (www.cnlcp.org).

The first phase of the plan is crafted to include a thorough assessment of the client, financial/billing agreements, an information release signed by the client, and a targeted date for report completion. Development of the plan is the second

phase. Plans are based on a number of factors: social and cultural situation, leisure activities, educational and employment status, medical history, physical and psychological abilities, current status, assistance required for completing activities of daily living, and regulatory requirements.

HOW TO Ensure High-Quality Care

The following actions can ensure high-quality care for clients and have implications for case managers in their practice:

- Provide access to easily understood information for each client based on his or her needs and health literacy level.
- Remember that the client is the source of control and that patient/family engagement is critical.
- Provide access to appropriate specialists with coordination and communication transparency.
- Ensure continuity of care for those with chronic and disabling conditions (transition care).
- Provide access to emergency services when and where needed.
- Disclose financial incentives that could influence medical decisions and outcomes.
- Prohibit “gag clauses” (which mean that providers cannot inform clients of all possible treatment options).
- Provide antidiscrimination protections.
- Provide internal and external appeal processes to solve grievances of clients.
- Make decisions on the basis of evidence.

McClinton DH: Protecting patients. Contin Care 17:6, 1998; Institute of Medicine (IOM): Crossing the Quality Chasm: A New Health System for the 21st Century. Washington, DC, 2001, National Academies Press.

The following can ensure high-quality care for clients and have implications for case managers in their practice:

- Provide access to easily understood information for each client based on their needs and health literacy level
- The client is the source of control and patient/family engagement is critical.
- Provide access to appropriate specialists with coordination and communication transparency.
- Ensure continuity of care for those with chronic and disabling conditions (transition care).
- Provide access to emergency services when and where needed.
- Disclose financial incentives that could influence medical decisions and outcomes.
- Prohibit “gag clauses” (which mean that providers cannot inform clients of all possible treatment options).
- Provide antidiscrimination protections.
- Provide internal and external appeal processes to solve grievances of clients.
- Decision making is evidence based.
- The plan includes projected costs and resources needed for the frequency and duration of treatments, equipment, supplies, and future evaluations.
- The execution of a life care plan is typically managed by a case manager who will work with the life care planner, especially when re-evaluation of the plan is necessary (AANLCP, 2013).

All of these tools/programs, in coordination, constitute population health management strategies to educate clients and promote self-management, provide nurse coaching support, promote safe care transitions, improve care management and coordination, and enhance quality (DMAA, 2010).

EVIDENCE-BASED EXAMPLES OF CASE MANAGEMENT

Historical Evidence

Carondelet Health at St. Mary's Hospital in Tucson, Arizona, developed a community nursing network in which enrollees are distributed among a number of community health centers. Professional nurse case managers assisted older clients to attain healthier lifestyles and maintain themselves in the community. Nurses were successful in delivering economical services per month for Medicare enrollees. Through nurse case management services, this nursing HMO was reported to have reduced the number of inpatient days per 1000 enrollees by one third, at an average cost of \$900 per day, for a savings of \$300,000 for every 1000 enrollees (ANA, 1993; American Nurses Foundation [ANF], 1993). These strengths have been critical to allow the model to evolve to provide group and telephonic case management and automated standardized care instruments. Future endeavors will capitalize on the advances in information technology to capture clinical and cost data in a timely manner for decision support (Cohen and Cesta, 2005).

Community-based statewide programs in New Jersey used case management methods to promote early identification, selection, evaluation, diagnosis, and treatment of children who are potentially physically compromised. Local case management units provided coordinated and comprehensive care. Collaboration with existing local and regional agencies serving children supported this process. The nurse case manager (1) provided counseling and education to parents and children about identifying problems and increasing their knowledge, (2) developed individual plans incorporating multidisciplinary services (education, social issues, medical development, rehabilitation), (3) obtained appropriate community services, (4) acted as a family resource in crises and service concerns, (5) facilitated communication between child and family, and (6) monitored services for outcomes. Interprofessional teams include nurses and social workers (with master's degrees) for larger caseloads. A recommended caseload was 300 to 350 children per case manager (Bower, 1992).

A national study of 2437 people who tested positive for human immunodeficiency virus (HIV) and who had case managers demonstrated that, regardless of the model, these clients were more likely to use life-prolonging HIV medications and meet the needs for income, health insurance, home care, and supportive emotional counseling than those without case management. Having contact with a case manager was not significantly related to use of outpatient care, hospital admission, or emergency department visits. Case managers in this study included social workers, nurses, and acquired immunodeficiency syndrome (AIDS) service organization staff (Katz et al, 2001).

Liberty Mutual Insurance Company had used case management principles for more than 30 years in workers' compensation cases and expanded services for employees whose conditions were noted as chronic or catastrophic. Case managers coordinated all clients, providers, and services to reduce expenses caused by lack of coordination; failure to use beneficial alternatives; and duplication and fragmentation of services (Bower, 1992).

LINKING CONTENT TO PRACTICE

Important guidance in developing a community-based case management program can be found in the United States. Case management is a key component of federally financed and many state-financed health delivery options. The experiences of states over the past two decades provide testimony to the importance of case management for populations at risk. For older clients, state-derived case management provides objective advice and assistance with care needs. It also provides access to interprofessional providers and services. For payers (federal, state, clients), case management serves as a way to ensure that funds are allocated appropriately to those in greatest need. Case management serves a policy assurance and accountability function for communities. The PACE (Program of All-Inclusive Care for the Elderly) program addresses the needs of chronically ill seniors who wish to remain in their homes rather than be admitted to nursing homes and are enrolled in a managed care model of medical and support services, case management, medications, respite, hospital, and nursing home care when necessary. PACE prevents institutionalization in nursing homes, uses a strong social model of health care delivery, and case manages transitions of clients between delivery systems and providers. Studies (Wieland et al, 2013; Fretwell and Old, 2011) have demonstrated cost savings with PACE programs compared with nursing home costs. The PACE model has been permanently recognized as a provider type under both Medicare and Medicaid and has grown to 104 programs operating in 31 states (National PACE Association, 2014).

Within the states, the types of agencies designated to conduct case management are often district offices of state government, area agencies on aging, county social services departments, and private contractors. States maintain the oversight responsibilities for case management agencies to (1) ensure they are complying with program standards, contracts, reporting, and fiscal controls, (2) identify emerging problems and issues to be resolved by additional state policies, and (3) provide on-site technical assistance and consulting to improve performance. States' payment methods for case management include daily/monthly rates, hourly/quarterly rates, capped rates for services, and capped aggregate rates to cover both case management and provider costs (Health Resources and Services Administration [HRSA], 2004; U.S. Department of Health and Human Services [USDHHS], 2008).

The models of case management vary today as they did in the recent past. In 1999, Taylor described three models by their focus: client, system, and social service. *Client-focused models* are concerned with the relationship between case manager and client to support continuity of care and to access providers of care. *System-focused models*, in contrast, address the structure and processes of using the population-based tools of disease management and case management plans to offer care for client populations. The *social service models* provide services to clients

to assist them in living independently in the community and in maintaining their health by eliminating or reducing the need for hospital admissions or long-term care.

These models offer a solution to unnecessary health care expenses by reducing costs and accessing appropriate health care services. Imagine the impact on health status if these saved expenses were shifted to primary prevention and health promotion activities.

Contemporary Evidence

Reducing the rate of readmission within 30 days of hospital discharge is a quality goal in health care. For psychiatric clients, the risk of rehospitalization is greatest and most costly during this time. Kolbasovsky (2009) replicated a model of intensive case management (ICM) in the United States that had been successful in Europe in reducing 30-day readmission rates (Burns et al, 2001, 2007) and found that ICM significantly reduced readmissions and the associated costs of 305 clients at a cost of \$41.39 per member during the 30-day period. Had these persons been rehospitalized, the hospital psychiatric costs would have been \$1528.14 per member. The nature of the case management activities included transitional and coordination of aftercare, monitoring of symptoms, medication and treatment adherence, education of client and families, motivational interviewing to detect barriers, linkages to community-based resources, treatment refill reminders, alcohol screening, and brief interventions.

In a randomized controlled trial of 450 clients post-cardiac bypass surgery, case management intervention by nurses using telephone-based collaborative care improved the mental and physical health of persons experiencing depression after cardiac bypass in an 8-month case management intervention. Case management activities included education about post-cardiac surgery depression, self-management skills, assessing and monitoring of treatment and medication adherence, interprofessional weekly case conferences, and routine communication with persons and primary care providers to ensure the provision of coordinated, consistent care. The case manager used ongoing telephone support, encouragement of client preferences, self-management workbooks, coaching, and electronic support for care guidelines and protocols. Outcomes included increased mental health scores, improved physical and functional status, and fewer readmissions among males with subsequent cost savings (AHRQ, 2010a).

Using a managed care model of enrollment, the Care One program at the University of New Mexico Health Sciences Center provides intensive case management and care coordination to medically complex, costly clients who lack health insurance. Among the top 1% of high-cost clients, all were offered enrollment in a case management service with an interprofessional team of providers who help persons in this population to navigate the system, access available financial assistance, and use appropriate community resources. Each person meets with the entire team to assess and prioritize needs, goals, and subsequent steps, and to schedule medical appointments. Activities also include securing financial resources; counseling and assistance to complete paperwork; scheduling appointments,

reminders, and follow-ups; behavioral health counseling; medication management; and access to community resources to support health. Case management resulted in 80% fewer hospital admissions, a 60% decline in emergency room visits, and consistently high client satisfaction scores (AHRQ, 2010b).

EVIDENCE-BASED PRACTICE

A successful pilot program led to the execution of a randomized controlled trial—After Discharge Care Management of Low Income Frail Elderly (AD-LIFE)—for community-based elderly. The care management model uses the integration of medical and social care to improve the outcomes of low-income and chronically and functionally impaired elderly after hospital discharge. AD-LIFE uses an interprofessional team, comprehensive geriatric assessment, and care management by a team nurse. Throughout the first year after hospital discharge, the nurse works with the area Agency on Aging social services program, performs a hospital and home assessment, uses a client goal-setting approach, creates a plan for development of self-care skills, and provides care planning for chronic illnesses and geriatric syndromes (e.g., incontinence, depression, nutrition, skin problems, and memory impairment). The interprofessional team can access specialists, and the primary care provider performs frequent evaluations and revises care plans as needed.

Ninety-two percent (92%) of the 118 clients had the need for at least one medical or social intervention. Half were taking 5 to 10 prescription drugs, 40% were living alone, 28% had congestive heart failure, 28% had diabetes, and many were unable to perform some ADLs or experienced geriatric syndrome. About 70% of clients said the care management program improved their health, allowed them to more easily access health care services, and provided them with a greater understanding of their disease(s). Hospital admissions decreased and the care cost savings were \$1000 per client per month.

- As a nurse working in public health, aspects of this program could be built on to design an interprofessional program for community-based clients with Alzheimer's disease, people living with AIDS, chronically ill or disabled children, or clients with unstable psychiatric conditions.

Nurse Use

Postdischarge care management that integrates medical, nursing, and socially and culturally proficient care can improve outcomes of the low-income elderly as well as other groups named above. It is important to identify the interprofessional team members who could be assembled to conduct the program with each client group, to identify measures of success for each of the programs, and to relate the case management process to *Healthy People 2020* objectives that could be addressed for each of these client groups.

From Wright K, Hazelett S, Jarjoura D, Allen K: The AD-LIFE trial. *Home Healthcare Nurse* 25(5):308–314, 2007.

The impact of using a nurse case manager (NCM) and community health worker (CHW) team on diabetic control, emergency room (ER) visits, and hospitalizations among urban African Americans with type 2 diabetes in a randomized controlled clinical trial comparing intensive case management with minimal case management revealed the positive effects of the intensity of case management services on outcomes. Intensive services included mailings and telephone calls about preventive screenings, culturally tailored care provided by the NCM and CHW team, and evidence-based clinical algorithms with feedback to the primary care providers. Those clients receiving intensive case management were 23% less likely to have ER visits, and this effect was strongest for clients who received the

most nurse and community health worker visits for their care (Gary et al, 2009). Culturally tailored interventions are essential to approaching health equity outcomes.

In a 2012 study with 83 clients in an urban setting, most of whom were uninsured, a community-based case management program with clients experiencing one or more chronic diseases yielded impressive results: acute outpatient encounters decreased by 62% and inpatient admissions by 53%. Primary care visits increased by 162% with an overall reduction in aggregate costs of 41%—from \$16,208 preintervention to \$9541 postintervention (Glendenning-Napoli et al, 2012).

ESSENTIAL SKILLS FOR CASE MANAGERS

Three skills are essential to the role performance of the case manager: advocacy, conflict management, and collaboration.

Advocacy

Case managers report that they are first and foremost client advocates (Barefield, 2003; Stanton and Dunkin, 2009; CMSA, 2010). The definition of nursing includes **advocacy**: “Nursing is the protection, promotion and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities and populations” (ANA, 2010, p. 6). For nurses, advocacy involves a number of activities, ranging from exploring self-awareness to lobbying for health policy. Advocacy is essential for practice with clients and their families, communities, organizations, and colleagues on an interprofessional team. The functions of advocacy require scientific knowledge, expert communication, facilitating skills, and problem-solving and affirming techniques.

As the *Guide to the Code of Ethics for Nurses* (ANA, 2008) states, “The nurse, in all professional relationships, practices with compassion and respect...” (p. 4). This means the nurse has the obligation to move beyond his or her own personal feelings of agreement or disagreement to respond compassionately. However, this goal is a contemporary one; the perspective regarding the advocacy function has shifted through history. The nurse advocate has been described in earlier writings as one who acted on behalf of or interceded for the client (Nelson, 1988). An example of the nurse interacting on behalf of the client is the nurse who calls for a well-child appointment for a mother visiting the family planning clinic when the mother is capable of making an appointment on her own.

The advocate role evolved to that of mediator and is described as a response to the complex configuration of social change, reimbursement, and providers in the health care system (Tahan, 2005). Mediating is an activity in which a third party attempts to provide assistance to those who may be experiencing a conflict in obtaining what they desire. The goal of the nurse advocate as mediator is to assist parties to understand each other on many levels so that agreement on an action is possible. In the example of a nurse as case manager for an HMO, mediating activities between an older adult client and the payer (the HMO) could accomplish the following results: the client may understand the options for community-based skilled nursing

care, and the payer may understand the client's desires for a less restrictive environment for care, such as the home. The case manager as mediator does not decide the plan of action but facilitates the decision-making processes between the client and the payee so that the desired care can be reimbursed within the options available.

In contemporary practice, nurse advocates place the client's rights as the highest priority. The goal of promoter for the client's autonomy and self-determination may result in an optimal degree of independence in decision making. For example, when a group of young pregnant women is the collective "client" (the aggregate), the nurse advocate's role may be to inform the group of the benefits and consequences of breastfeeding their infants. However, if the new mothers decide on formula feeding, the nurse advocate should support the group and continue to provide parenting, infant, and well-child services. This example shows a different perspective of the nurse as advocate. It notes that the nurse's role as advocate may demand a variety of functions that are influenced by the client's physical, psychological, social, and environmental abilities. Advocacy can result in clients becoming their own "client expert" in problem solving, decision making, maximization of resources, partnership development with providers, and ultimately appropriate interventions (Burton et al, 2010).

The advocacy role aims to achieve client engagement—a process in which clients are invested in their health and care through programs that provide information and tools to empower them to take control and evaluate their care (ANA, 2013). The nurse adapts the advocacy function to the client's dynamic capabilities as the client moves from one health state to another. Even clients who desire access to more substantial health promotion activities can benefit from a partnership with the nurse advocate. Case managers are called to mediate between client needs and payer requirements/economic constraints without becoming a barrier to quality care. Examples of advocacy in such cases might include promoting a client's (as an aggregate) access to on-site physical fitness programs in the occupational setting, or supporting parents' and students' concerns about the high-fat content of vending machine food in the school system. With the cost of health care exceeding \$2.7 trillion annually and consumers assuming a larger financial portion of the care they choose, the promoter role of advocacy for those clients capable of autonomy is expected to increase.

Process of Advocacy

The goal of advocacy is to promote self-determination in a client. The client may be an individual, family, peer, group, or community. The classic process of advocacy has been historically defined by Kohnke (1982), Mallik and Rafferty (2000), and Smith (2004) to include informing, supporting, and affirming. All three activities are more complex than they may initially seem, and they require self-reflection by the nurse as well as skill development. It is often easier for the nurse to inform, support, and affirm another person's decision when it is consistent with the nurse's values. When clients make decisions within their value systems that are different from the nurse's values, the advocate may feel conflict about contributing to the process of

LINKING CONTENT TO PRACTICE

Advocacy: Text Link to Public Health Nursing

The clinical practice skill of advocacy as an inherent concept in the practice of case management. Of the 16 interventions by public health nurses described in the Wheel of Intervention model (see Chapter 9), both advocacy and case management are described in accordance with best practices and operational definitions of 2 of the 16 interventions. Advocacy can be applied at the community, systems, individual, or family level. In fact, when a public health nurse advocates for clients at any of these levels, the source of conflict and collaboration will likely come from competing values, that is, those of the client and any of these other levels of population values. For example:

- a client may want access to unlimited treatment, financial values may pose a source of conflict as the system attempts to justify the comparative effectiveness or costs.
- Family members may pose conflicting values for the nature of care they wish a family member to receive, even as the client refuses care.
- Communities can divert budget allotments to needs that are in competition for other population services such as community policing, health care access, and environmental services.

The nurse as advocate must listen carefully to his or her client in order to truly represent the interest of the client and encourage "win-win" processes and outcomes for the client. Advocacy occurs in all three of the core functions of public health: assessment, policy development, and assurance.

informing, supporting, and affirming those decisions. Promoting self-determination in others demands that the nurse have a philosophy of free choice once the information necessary for decision making has been discussed.

Informing. Knowledge is essential, but it is not enough to make decisions that affect outcomes. Interpreting knowledge is affected by the client's values and the meanings assigned to the knowledge. Interpreting facts is the result of both objective and subjective processing of information. Subjective processes greatly influence client decisions.

Informing clients about the nature of their choices, the content of those choices, and the consequences to the client is not a one-way activity. The **information exchange process** is composed of interactions that reflect three subprocesses: amplifying, clarifying, and verifying. **Amplifying** occurs between the nurse and the client to assess the needs and demands that will eventually frame the client's decision. Information is exchanged from both viewpoints. Although the exchange may be initiated at the objective, factual level, it is likely to proceed to incorporate the subjective perspectives of both parties.

The tone of the amplifying process can direct the remainder of the information exchange. It is important to relate with clients in a manner that reflects the advocate's endorsement of the client's self-determination. Setting aside the time necessary to listen to clients is critical. Clients will sense they are part of a mutual process if the nurse can engage them during the information exchange with a message that says, "I respect your needs and desires as I share my knowledge with you." Nonverbal behaviors, including using direct eye contact, sitting at the client's level, arriving and concluding at a prescribed time, and using verbal patterns that foster exchange (e.g., open-ended statements, questions, probes, reflections of feelings,

paraphrasing), convey the nurse's desire to promote the client's ability to self-determine. Recent research indicates that clients' race and ethnicity may influence how providers and clients communicate with one another, thus contributing to disparities in health. Active communication among clients and providers has been linked to better treatment compliance and health outcomes (Schraeder and Shelton, 2011).

A client may not desire to exchange information because of lack of self-esteem, fear of the information, or inability to comprehend the content of the communication. In such a case, the focus is to understand the client's desire to be given no information and to express to the client the consequences of such inaction. The nurse may invite the client to ask for the information exchange at a later time, when the client is ready, and can periodically check with the client whether information exchange and amplifying are desired. In these cases, the nurse should document the implemented nursing actions to reflect the guidelines just discussed. This can reduce the basis for lawsuits and misunderstanding by other parties.

Clarifying is a process in which the nurse and client strive to understand meanings in a common way. Clarifying builds on the breadth and depth of the exchange developed during amplifying to determine whether the nurse and client understand each other. During this process, misunderstandings and confusions are examined. The goal of clarifying is to avoid confusion between the nurse and the client. To foster clarifying, nurses can use certain verbal prompts such as the following:

- "What do you understand about...?"
- "Please tell me more about how you..."
- "I don't think I am clear. Let me explain the situation in another way."
- "As an example,..."
- "What other information would be helpful so that we both understand?"

Verifying is the process used by the nurse advocate to establish accuracy and reality in the informing process. Low health literacy is a challenge for 90 million Americans who have difficulty understanding and acting on health information. Peterson and colleagues (2011) report that 40% of whites and 41% of those from Asia and the Pacific Islands living in the United States are proficient in reading English. In contrast, 13% of African American, 5% of Hispanic, and 18% of Native American U.S. students are proficient in reading English. Reading/literacy proficiency varies by ethnicity/race (Baer et al, 2009). In 2014, a *Public Broadcasting Newshour* publication cited the Department of Education as revealing that about 1 in 10 people in the United States has a proficient level of health literacy (Gorman, 2014).

If the nurse discovers that a client is misinformed, the nurse may return to the clarifying or amplifying stage and begin the process again. Verifying produces the chance for the advocate and client to examine "truth" from their points of view, which may include knowledge, intuition, previous experiences, and anticipated consequences.

Promoting a client's self-determination may take the advocate and client through the information exchange process several times, as new dimensions, or obstacles, to an issue

develop. Information exchange is a critical process for advocacy and is applicable to all advocacy clients: individuals, families, groups, and communities (see the [How To Box](#)).

HOW TO Provide for Information Exchange between Nurse and Client

1. Assess the client's present understanding of the situation. Have you considered your client's literacy level? Health literacy level? Cultural and ethnic values? Age and any disabilities that would interfere with learning?
2. Provide correct information.
3. Communicate on the client's literacy level, making the information as understandable as possible. Use interpreters and translators where needed.
4. Use a variety of media sources and teach-back methods to increase the client's comprehension.
5. Discuss other factors that affect the decision, such as financial, legal, and ethical issues.
6. Discuss the possible consequences of a decision.

Supporting. The second major process, **supporting**, involves upholding a client's right to make a choice and to act on it. People who are aware of clients' decisions fall into three general groups: supporters, dissenters, and obstructers. Supporters approve and support clients' actions. Dissenters do not approve and do not support clients. Obstructers cause difficulties when clients try to implement their decisions.

In 1998, Cary noted that the nurse advocate needs to implement several actions to fulfill the supporting role. Important interventions are assuring clients that they have the right and responsibility to make decisions, and reassuring them that they do not have to change their decisions because of others' objections.

Affirming. The third process in the advocacy role is **affirming**. It is based on an advocate's belief that a client's decision is consistent with the client's values and goals. The advocate validates that the client's behavior is purposeful and consistent with the choice that was made. The advocate expresses a dedication to the client's mission, and a purposeful exchange of new information may occur so that the client's choice remains possible. Recognizing that a client's needs may fluctuate with changing resources, the affirming activity must encourage a process of re-evaluation and rededication to promote client self-determination.

The importance of affirming activities cannot be emphasized strongly enough. Many advocacy activities stop with assuring and reassuring, but affirming is often critical in promoting a client's self-determination. [Table 22-2](#) compares the nursing process with the advocacy process.

The advocate's role in the decision-making process is *not* to tell the client that an option is correct or right. The advocate's role is to provide the opportunity for information exchange, and to arm clients with tools that can empower them in making the best decision from their point of view. Enabling clients to make an informed decision is a powerful tool for building self-confidence. It gives clients the responsibility for selecting the options and experiencing the success and consequences of their decisions. Clients are empowered in their decision making when they recognize that although some events are beyond

TABLE 22-2 Comparison of Nursing Process and Advocacy Process

Nursing Process	Advocacy Process
Assessment/ diagnosis	<ul style="list-style-type: none"> • Exchange information • Gather data • Illuminate values
Planning/outcome	<ul style="list-style-type: none"> • Generate alternatives and consequences • Prioritize actions
Implementation	<ul style="list-style-type: none"> • Make decisions • Support the client • Assure • Reassure
Evaluation	<ul style="list-style-type: none"> • Affirm • Evaluate • Reformulate

their control, other events are predictable and can be affected by decisions they can make.

Nurses can promote client decision making by using the information exchange process, promoting the use of the nursing process, incorporating written techniques (e.g., contracts, lists), using reflecting and prioritizing techniques, and using role playing and sculpturing to “try on” and determine the “fit” of different options and consequences for the client. By engaging clients in the information-sharing process and assisting them to recognize the progression of activities they experience as they build their informed decision-making base, the nurse advocate is providing clients the opportunity to empower themselves with skills that can strengthen their autonomy and confidence in the future.

Advocacy is a complex process that maintains a delicate balance between doing for the client and promoting autonomy. The process is influenced by the client’s physical, emotional, and social capabilities. The goal of advocacy is to promote the maximal degree of client self-determination, given the client’s current and potential status; for most clients, this goal can be realized. When clients are comatose, unborn, or legally incompetent, nurse advocates have unique functions. The advocate’s role is usually determined by the legal system; however, in some cases, nurses must decide what roles they will play. These are areas requiring intensive self-exploration, research, and collaboration with professionals, family members, and significant others. We are reminded that every encounter with a client is an opportunity to serve in the advocacy role (Mahlin, 2010).

Skill Development

Skills needed by the nurse advocate are not unique to their profession. Nursing demands scientific, technical, relationship, and problem-solving knowledge and skills. Advocacy applies nursing skills of communication and competency to promote client self-determination.

Knowledge of nursing and other disciplines as well as of human behavior is essential for the advocacy role in establishing authority, promoting authenticity, and developing skills. The capacity to be assertive for personal rights and the rights of others is essential.

Systematic Problem Solving

The nursing process—assessment, diagnosis, planning, implementing, and evaluating—is an example of a method of **problem solving** that can be used in the advocacy role. Advocates can be particularly helpful with clients in identifying values and generating alternatives.

Illuminating Values. People’s values affect their behavior, feelings, and goals. In the process of amplifying, clarifying, and validating, the advocate understands a client’s values. Through the process of self-revelation, an emerging value (such as environment, people, cost, or quality) may become more apparent to a client. This can have an effect in two ways. The client may be able to focus on actions on the basis of the value, or the value may confuse the decision process. The nurse can assist the client in prioritizing action and clarifying the value. Values can also change as new or relevant data are processed. The advocate’s role is to assist clients in discovering their values. This process can be particularly demanding in the information exchange and affirming process.

Generating Alternatives. Clients and advocates may feel limited in their options if they generate solutions before completely analyzing the problems, needs, desires, and consequences. Several techniques can be used to generate alternatives, including brainstorming and a technique known as the problem-purpose-expansion method. In **brainstorming**, the nurse, client, professionals, or significant others generate as many alternatives as possible, without placing a value on them. Brainstorming creates a list that can then be examined for the critical elements the client seeks to preserve (e.g., environmental preferences, degree of control). The list can be analyzed according to the consequences and the effect of the alternatives on self and others.

The classic **problem-purpose-expansion method**, as described by Volkema (1983) and later expanded on by Heslin and Moldoveanu (2002) and Winston and Albright (2012), is a way to broaden limited thinking. It involves restating the problem and expanding the problem statement so that different solutions can be generated. If problem formulation yields to solution generation too early, important dimensions of the problem may go undetected and opportunities are missed. For example, if the problem statement is to convince the insurance company to approve a longer length of service, the nurse and client have narrowed their options. However, if the problem statement is to improve the client’s convalescence and safety, several solutions and options are available, such as the following:

- Obtaining skilled nursing facility placement
- Obtaining home-health skilled services
- Arranging physician home visits
- Paying for custodial care
- Paying for private skilled care
- Obtaining informal caregiving

Impact of Advocacy

Advocacy empowers clients to participate in problem-solving processes and decisions about health care. Clients try to understand changing opportunities in the health care system for access, use, and achieving continuity of care. Nurse advocates

promote client self-determination and management of behavior as it relates to health and the adherence to therapeutic regimens. Clients are part of larger systems: the family, the work environment, and the community. Each system interacts with the client to shape the available options through resources, needs, and desires. Each system also exhibits both confirming and conflicting goals and processes that need to be understood for client self-determination to be successful. For example, the practice of advocacy among minority groups may involve the ability to focus attention on the magnitude of problems caused by diseases affecting minority clients. Whether the client is an individual, family, group, or community, the advocacy function can promote the interest of self-determination, which influences the progress of societies.

Advocacy is not without opposition. Clients and advocates may find barriers to services, vendors, providers, and resources. A community may experience a shortage in nursing home beds or providers, a childcare facility may experience staffing shortages, a family may not have the money to keep a child at home, and a client may find that the school system cannot fund a full-time nurse for its clinic. The reality of scarce resources creates a difficult barrier for advocates. However, events such as these often stimulate a community's self-determination and lead to innovative actions to correct gaps in service (see the [Levels of Prevention](#) box).

LEVELS OF PREVENTION

Case Management

Levels of Prevention	Strategy
Primary	Use information exchange process to increase health literacy in order to use the health care system, adopt health promotion strategies that will maintain health, and engage in health education to create and maintain healthy lifestyles
Secondary	Use case finding and dashboard data to identify existing health problems in your caseload and the population served by your agency. Timely, holistic assessments and interventions can slow disease trajectories and promote healing and health
Tertiary	Monitor and adjust the use of prescription medications and adherence to treatment to reduce the risk of complications. Use models such as the CMSA Case Management Adherence Guidelines at http://www.csma.org to prevent subsequent consequences of issues in medication compliance as part of the treatment plan. Institutionalize this model in your agency

Allocation and Advocacy: Complements or Conundrum?

Whereas advocacy holds a traditional role in the nursing profession, **allocation** is a staple of market competition. Nurses perform allocation roles when they triage clients or perform the gatekeeping and rationing functions. Nurses often reflect that clinical judgments are influenced by their values and ethics as well as organizational demands (ANA, 2008). When working in organizations, nurses experience allocation demands at the

systems level through budgetary decisions and staffing assignments. At the clinical level, demands relate to implementing treatment protocols. When nurses act as client advocates by clarifying a client's desires or needs, they can conflict with systems procedures for allocation of limited resources within these systems. Case managers need to balance efficient use of resources.

Nurses who shoulder both advocacy and allocation responsibilities may benefit from a clear understanding of their personal and professional values. A systematic procedure for mediating conflict between the two competing responsibilities is also helpful (Cary, 1998; Fink-Samnick and Muller, 2010).

Conflict Management

Case managers help clients manage conflicting needs and scarce resources. Techniques for managing conflict include a range of active communication skills. These skills are directed toward learning all parties' needs and desires, detecting their areas of agreement and disagreement, determining their abilities to collaborate, and assisting in discovering alternatives and activities for reaching a goal. Mutual benefit with limited loss is a goal of conflict management.

Conflict and its management vary in intensity and energy in a number of ways. The effort needed to manage a conflict depends on various factors: the existing evidence to support facts and the objective and subjective perceptions of the parties involved.

Negotiating is a strategic process used to move conflicting parties toward an outcome. The outcome can vary from one in which one party gains benefit at the other's expense (**distributive outcomes**) or in which mutual advantages override individual gains (**integrative outcomes**) (Thompson et al, 2010).

The process of negotiating can be characterized in three stages: prenegotiating (preparing and discussing), negotiating (discussing, proposing, bargaining), and aftermath (closing, renegotiating, willingness to negotiate again). Prenegotiating activities are designed to have parties agree to collaborate. Parties must see the possibility of agreeing and the costs of not agreeing (Lee and Lawrence, 2013). Preparations must be made as to time, place, and ground rules concerning participants, procedures, and confidentiality.

The negotiation stage consists of phases in which parties must develop trust, credibility, distance from the issue (to limit the feeling of "one best way"), and the ability to retain personal dignity. Bazarman (2005) and Lee and Lawrence (2013) agree that stages occur in negotiation:

Phase 1: Establishing the issues and agenda. This is accomplished by identifying, clarifying, presenting, and prioritizing the issues.

Phase 2: Advancing demands and uncovering interests. Negotiations center on presenting parties' interests and differentiating parties' demands and positions on the conflict.

Phase 3: Bargaining and discovering new options. Debates include gathering facts, based on reasoning, that will generate understanding and promote relearning. Bargaining reduces differences on issues by giving or removing rewards or desired objects. Creating new solutions or options through

brainstorming, reflective thinking, and problem-purpose-expansion techniques is important in achieving options that provide mutual benefits.

Phase 4: Working out an agreement. This may involve settling on some but not all points. Parties can agree to re-examine the issues later, and steps for implementing and follow-up must be clarified.

The aftermath of negotiation is the period following an agreement in which parties are experiencing the consequences of their decisions and will discern the degree to which they are willing to work together in the future (Thompson et al, 2010). The reality of their decisions may lead to re-evaluating their values. In a conflict situation, parties engage in behaviors that reflect the dimensions of assertiveness and cooperation. **Assertiveness** is the ability to present one's own needs. **Cooperation** is the ability to understand and meet the needs of others. Each person uses a primary and secondary orientation to engage in conflict (Box 22-3).

Clearly, flexibility in conflict management behavior can facilitate an outcome that meets the client's goals. Helping parties navigate the process of attaining a goal requires effective personal relations, knowledge of the situation and alternatives, and a commitment to the process.

Collaboration

In case management, the activities of many disciplines (social workers, nurses, physicians, insurers, physical therapists, etc.) are needed for success. Clients, the family, significant others, payers, and community organizations contribute to achieving the goal. **Collaboration** is achieved through a developmental process. Collaboration is a dynamic, highly interactive, and interdependent process in which people work together, sharing resources and even a vision for a goal (Morales Arroyo, 2003). Androwich and Cary (1989) found that collaboration occurs in a sequence and is reciprocal and can be characterized by seven stages and activities (Figure 22-5).

The goal of communication in the collaborative development process is to amplify, clarify, and verify all team members' points of view. Although communication is essential in

collaboration, it is not sufficient to result in or maintain collaboration. Although the collaboration model recognizes the contributions of joint decision making, one member of the team should be accountable to the system and to the client. This team member should be responsible for monitoring the entire process (see the following QSEN box).

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Teamwork and Collaboration—Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality client interventions and outcomes.

Important aspects of teamwork and collaboration include:

Knowledge: Describe scopes of practice and roles of health care team members

Skills: Clarify roles and accountabilities under conditions of potential overlap in team member functioning

Attitudes: Value the perspectives and expertise of all health team members

Teamwork and Collaboration Question

Observe a typical workday of a nurse in community health or public health nurse, noting the types of activities that are done in coordination and case management and the amount of time spent in these areas. Interview several staff members to determine whether they perceive that the amount of their time spent in case management is changing. To what degree are the staff members involved in care management activities? Ask about colleagues with whom case managers collaborate. Besides primary care physicians, which health care team members are often involved in managing clients' care across time and across settings? What skills are needed by the case management nurse to best facilitate these interdisciplinary teams?

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

BOX 22-3 Categories of Behaviors Used in Conflict Management

Accommodating: Individual neglects personal concerns to satisfy the concerns of another.

Avoiding: Individual pursues neither his or her concerns nor another's concerns.

Collaborating: Individual attempts to work with others toward solutions that satisfy the goals of both parties.

Competing: Individual pursues personal concerns at another's expense.

Compromising: Individual attempts to find a mutually acceptable solution that partially satisfies both parties.

Modified from Volkema RJ, Bergmann TJ: Conflict styles as indicators of behavioral patterns in interpersonal conflicts, *J Social Psychol* 135: 5-15, 2001; CPP: *History and Validity of the Thomas-Kilmann Conflict Mode Instrument (TKI)*. Mountainview, CA, CPP, Inc. Available at <http://www.cpp.com/products/tki/tkiinfo.aspx>. Retrieved June 14, 2010.

Case managers encounter conflict on a daily basis. Competing needs, resources, organizational demands, and professional role boundaries present opportunities and pitfalls for conflict management and collaboration (Box 22-4). Providers report that in the collaborative role of serving as advocates for clients, they encounter competing expectations by other providers in the system—even other case managers (Sands, 2013).

Teamwork and collaboration clearly demand knowledge and skills about clients, health status, resources, treatments, and community providers. The ability to assess clients' and families' complex needs involves knowledge of intrapersonal, interpersonal, medical, nursing, and social dimensions. Demonstrating team member and leadership skills in facilitating a goal-directed group process is essential. It is unlikely that any single professional possesses the expertise required in all dimensions. It is likely, however, that the synergy produced by all can result in successful outcomes.

ISSUES IN CASE MANAGEMENT

Legal Issues

Case managers today face pressure to control costs, to use evidence-based guidelines for practice, and to reduce risks for

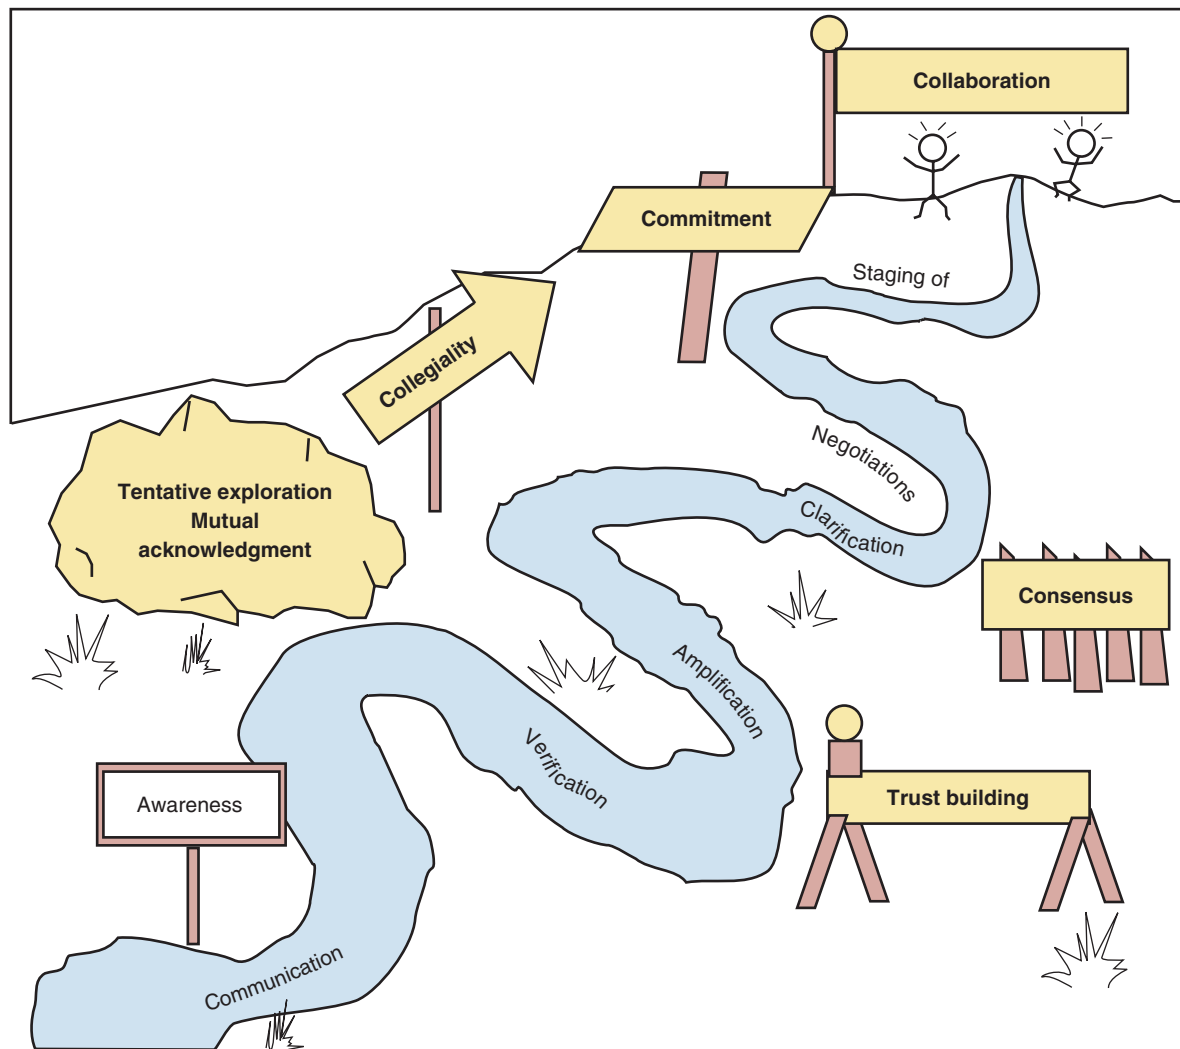

FIG 22-5 Collaboration is a sequential yet reciprocal process. (From Androwich I, Cary AH: *A Collaboration Model: A Synthesis of Literature and a Research Survey*. Paper presented at the Association of Community Health Nurse Educators Spring Institute, Seattle, June 1989.)

BOX 22-4 Stages of Collaboration**1. Awareness**

- Make a conscious entry into a group process; focus on goals of convening together; generate a definition of collaborative process and what it means to team members.

2. Tentative exploration and mutual acknowledgment

- Exploration: Disclose professional skills for the desired process; disclose areas where contributions cannot be made; disclose values reflecting priorities; identify roles and disclose personal values, including time, energy, interest, and resources.
- Mutual acknowledgment: Clarify each member's potential contributions; verify the group's strengths and areas needing consultation; clarify members' work style, organizational supports, and barriers to collaborative efforts.

3. Trust building

- Determine the degree to which reliance on others can be achieved; examine congruence between words and behaviors; set interdependent goals; develop tolerance for ambiguity.

4. Collegiality

- Define the relationships of members with each other; define the responsibilities and tasks of each; define entrance and exit conditions.

5. Consensus

- Determine the issues for which consensus is required; determine the processes used for clarifying and making decisions to reach consensus; determine the process for re-evaluating consensus outcomes.

6. Commitment

- Realize the physical, emotional, and material actions directed toward the goal; clarify procedures for re-evaluating commitments in light of goal demands and group standards for deviance.

7. Collaboration

- Initiate a process of joint decision making reflecting the synergy that results from combining knowledge and skills.

Modified from Cary A, Androwich I: A collaboration model: a synthesis of literature and a research survey, paper presented at the Association of Community Health Nurse Educators Spring Institute, Seattle, June 1989; Mueller WJ, Kell B: Coping with conflict, Englewood Cliffs, NJ, 1972, Prentice Hall.

legal liability. They are vulnerable to legal risks because of inadequate preparation, changing legislation and policy, health systems changes, the advent of new workers and the absence of title protection, insufficient support, and role expectations. Liability concerns of case managers exist when the following three conditions are met: (1) the provider had a duty to provide reasonable care, (2) a breach of contract occurred through an act or an omission to act, and (3) the act or omission caused injury or damage to the client. Case managers must strive to reduce risks, practice wisely within acceptable practice standards, and limit legal defense costs through professional insurance coverage. Areas of risk are adapted from [Hendricks and Cesar \(2003\)](#), [Cunningham \(2007\)](#), [Llewellyn and Leonard \(2009\)](#), and [Sambucini \(2013\)](#):

1. Liability for managing care

- Inappropriate design or implementation of the case management system
- Failure to obtain all pertinent records on which case management actions are based
- Failure to have cases evaluated by appropriately experienced and credentialed clinicians
- Failure to confer directly with the treating provider (physician or nurse practitioner) at the onset and throughout the client's care
- Substituting a case manager's clinical judgment for that of the medical provider
- Requiring the client or his or her provider to accept case management recommendation instead of any other treatment
- Harassment of clinicians, clients, and family in seeking information, and setting unreasonable deadlines for decisions or information
- Claiming orally or in writing that the case management treatment plan is better than the provider's plan

- Restricting access to otherwise necessary or appropriate care because of cost
 - Referring clients to treatment furnished by providers related to the case management agency without proper disclosure
 - Connecting case managers' compensation to reduced use and access of services
 - Inappropriate delegation of care
 - Inappropriate use of clinical practice guidelines
- 2. Negligent referrals**
- Referral to a practitioner known to be incompetent
 - Substituting inadequate treatment for an adequate but more costly option
 - Curtailing treatment inappropriately when treatment was actually needed
 - Referral to a facility or practitioner inappropriate for the client's needs
 - Transfer to another facility that lacks care requirements
 - Communication and transition handoff failures
- 3. Experimental treatment and technology**
- Failure to apply the contractual definition of "experimental" treatment found in the client's insurance policy
 - Failure to review sources of information referenced in the applicable insurance policy (e.g., Food and Drug Administration, or published medical literature)
 - Failure to review the client's complete medical record
 - Failure to make a timely determination of benefits in light of timeliness of treatment
 - Failure to communicate coverage determined to be needed, to the insured client or participant
 - Improper economic considerations determining the coverage
 - Failure to understand and retrieve information from HIT sources.

4. Confidentiality/security
 - a. Failure to deny access to sensitive information that is awarded special protection by federal or state law
 - b. Failure to protect access to computerized medical records
 - c. Failure to adhere to regulatory provisions (e.g., Health Insurance Portability and Accountability Act provisions [<http://hipaa.cms.gov>]; Americans with Disabilities Act)
5. Fraud and abuse
 - a. Making false statements of claims or causing incorrect claims to be filed
 - b. Falsifying the adherence to conditions of participation of Medicare and Medicaid
 - c. Submitting claims for excessive, unnecessary, or poor-quality services
 - d. Engaging in remuneration, bribes, kickbacks, or rebates in exchange for referral
 - e. Upcoding intensity of care or intervention requirements

Legal citations relevant to case management and managed care include negligent referrals, provider liability, payer liability, breach of contract, denial of care, and bad faith. As in any scope of nursing practice and with the potential growth in tort reform, it behooves the nurse to seek preventive education on contemporary practice and legal trends to lower exposure to legal liability.

[Sambucini \(2013\)](#) notes that court cases and federal and state tort reforms influence the legal considerations of case managers generally. When courts find that cost considerations affect medical care decisions, all parties to the decision will be liable for resulting damages. Guidelines to reduce risk exposure include the following:

1. Clear documentation of the extent of client participation in decision making and reasons for decisions
2. Records demonstrating accurate and complete information on interactions and outcomes
3. Use of reasonable care in selecting referral sources, which may include verifying of licensure of providers
4. Written agreements when arrangements are made to modify benefits other than those in the contract
5. Good communication with clients
6. Informing clients of their rights of appeal
7. Applying the ethical guidelines of case management ([Valiant and Jensen, 2012](#))

Ethical Issues

Case managers as nursing professionals are guided in ethical practice by the *Code of Ethics for Nursing* ([ANA, 2008](#); to be revised for publication in 2015) and *Code of Professional Conduct for Case Managers* ([Commission for Case Management Certification \[CCMC\], 2005](#)), by performance indicators for ethics in the *Standards of Practice for Case Management* ([CMSA, 2010](#)), and by the contract expressed in *Nursing's Social Policy Statement* ([ANA, 2010](#)).

By integrating these guidelines and philosophies, nursing practice is ideally suited to preserve the ethical principles of autonomy, beneficence, fidelity, justice, nonmaleficence, and veracity in case management processes. Numerous authors,

notably [Hendricks and Cesar \(2003\)](#), [McCollom \(2004\)](#), [Llewellyn and Leonard \(2009\)](#), [Fink-Samnack and Muller \(2010\)](#), and [Apuna-Grummer and Howland \(2013\)](#), describe how case managers may confront dilemmas in these areas:

- Case management may hamper a client's **autonomy**, or the individual's right to choose a provider, if a particular provider is not approved by the case management system. If a new provider must be found who can be approved for coverage, continuity of care may be disrupted.
- **Beneficence**, or doing good, can be impaired when excessive attention to containing costs supersedes the nurse's duty to improve health or relieve suffering.
- **Fidelity** is defined as faithfulness to the obligation of duty (www.merriam-webster.com/dictionary), in this case to the client by keeping promises and remaining loyal within the nurse-client relationship (www.merriam-webster.com/dictionary. Accessed July 7, 2014). Duty to clients to secure benefits on their behalf and to limit unnecessary expenditures can create dilemmas when the goals are not uniform.
- **Justice** as an ethical principle for case managers considers equal distribution of health care with reasonable quality. Tiers of quality and expertise among provider groups can be created when quality providers refuse to accept reimbursement allowances from the managed system, leaving less experienced or lower quality providers as the caregiver of choice for clients being managed.
- **Nonmaleficence** is defined as doing no harm. When case managers incorporate outcomes measures, evidence-based practice, and monitoring processes in their plans of care, this principle is addressed.
- **Veracity**, or truth telling, is absolutely necessary to the practice of advocacy and building a trusting relationship with clients. Clients particularly complain that in the changing health care system, payers do not seem to be able to provide comprehensive yet inexpensive options for care.

Three of the most common legal dilemmas have been historically classified as conflicts in advocacy, priorities, and duties ([Hendricks and Cesar, 2003](#); [Mahlin, 2010](#)). For example, a case manager may advocate for many perspectives—clients, organizations, and society—that are not harmonious. When considering priorities in values, the case manager will ultimately be considering personal, professional, organizational, and client values. Selecting which values to honor can result in violating the values of the other, and asking the question “Whose best interests can be served?” may create a dilemma. Finally, conflicts in duties can result when placing the best interest of a client first adversely affects the other party.

Standards of practice and care, codes of ethics, licensure laws, credentialing through certification, and organizational policies and procedures (e.g., ethics committees, risk management units) offer the case manager information and support in managing ethical conflicts and dilemmas in the case management system. Maintaining familiarity with ethical issues published in the case management literature can offer specific assistance for practicing case managers ([Tables 22-3 and 22-4](#)).

TABLE 22-3 Credentialing Resources for Case Managers (Individual Certification Options)

Organization	Website	Credentials
American Nurses Credentialing Center	http://www.nursecredentialing.org	Nurses: RN-BC, for Registered Nurse-Board Certified for Case Management
Case Management Administrators	http://www.ptcny.com	CMA-C, for Case Management Administrator-Certified
Certification of Disability Management Specialists Commission	http://www.cdms.org	Interprofessionals: CDMS, for Certified Disability Management Specialist
Commission for Case Manager Certification	http://www.ccmcertification.org	Interprofessionals: CCM, for Certified Case Manager
Certification Board for Certified Nurse Life Care Planners	http://www.ptcny.com	CNLCP, for Certified Nurse Life Care Planner (specialty certification for nurses who are life care planners)
National Academy of Certified Care Managers	http://www.naccm.net	Interprofessionals: CLM, for Certified Long-term Care Manager
Rehabilitation Nursing Certification Board	http://www.rehabnurse.org/certification	CRRN, for Certified Rehabilitation Registered Nurse

TABLE 22-4 Websites for Case Management Resources

Resource	Website	Details
URAC	www.urac.org	Accredits disease management, case management, and health plan programs and other services. Supports efforts for clinical benchmarking, quality of care, chronic care evidence-based models
America's Health Insurance Plans	http://www.ahip.org	Trade association representing health insurance industry
American Nurses Credentialing Center	http://www.nursecredentialing.org	Offers review course materials for nurse case managers
American Medical Association	http://www.ama-assn.org	Includes continuing medical education unit (CEU) programs
Case Management Society of America	http://www.cmsa.org	Specialty organization for case managers
Centers for Medicare and Medicaid Services	http://www.cms.gov	Oversees execution of rules and regulations for clients of state and federally funded services
Center Watch Clinical Trial Listing Service	http://www.centerwatch.com	Global source for clinical trials information
Centers for Disease Control and Prevention	http://www.cdc.gov	Provides education, training, and research for disease, emergency preparedness, environmental health, traveler health, workplace safety and health, population health, and healthy living
The Joint Commission (TJC)	http://www.jointcommission.org	Accredits health care–related delivery organizations and disease-specific care programs
Medscape	http://www.medscape.org	Features clinical updates and education for professionals
National PACE Association	http://www.npaonline.org	Provides information on models and locations of PACE services for the elderly
National Transitions of Care Coalition (NTOCC)	http://www.ntocc.org	Provides information on transitions of care models and outcomes
National Committee for Quality Assurance	http://www.ncqa.org	Publishes HEDIS performance indicators for provider systems and accredits managed care organizations. Provides certification of disease management, utilization management, and credentialing verification organizations. Also ACOs, case management and patient-centered medical homes (among other organizations)
National Library of Medicine	http://www.nlm.nih.gov	Global medical library
<i>NurseWeek</i>	http://www.nurse.com	Provides information links to other sites and nursing professional education course work
Oncology	http://www.oncolink.upenn.edu	Oncology links
<i>Online Journal of Issues in Nursing</i>	http://www.nursingworld.org	Publication on issues in nursing
Commission on Accreditation of Rehabilitation Facilities	http://www.carf.org	Accredits services globally that may be used by case management clients such as adult day care, assisted living, behavioral health, disability rehab, addiction and substance abuse rehabilitation, employment and community services, and medical rehabilitation

ACO, Accountable care organization; HEDIS, Healthcare Effectiveness Data and Information Set.

PRACTICE APPLICATION

During her regularly scheduled visit to a blood pressure clinic in a local apartment cluster, a Hispanic resident, Mrs. B., 45 years old, complained of feeling dizzy and forgetful. She could not remember which of her six medications she had taken during the last few days. Her blood pressure readings on reclining, sitting, and standing revealed gross elevation. The nurse and Mrs. B. discussed the danger of her present status and the need to seek medical attention. Mrs. B. called her physician from her apartment and agreed to be transported to the emergency department.

In the emergency department, Mrs. B. manifested the progressive signs and symptoms of a cerebrovascular accident (a CVA, or stroke). During hospitalization, she lost her capacity for expressive language and demonstrated hemiparesis and loss of bladder control. Her cognitive function became intermittently confused, and she was slow to recognize her physician and neighbors who came to visit. The utilization review/discharge planning nurse at the hospital contacted the case manager from the health department to screen and assess for

the continuum of care needs as early as possible, because Mrs. B. lived alone and family members resided out of town.

It became apparent that family caregiving in the community could only be intermittent because family members lived too far away. Mrs. B. had residual functional and cognitive deficits that would demand longer-term care.

As the case manager contracted by the plan, place the following actions in the correct sequence to construct a case management plan:

- A. Discuss with the family their schedule of availability to offer care in the client's home.
- B. Discuss their cultural values in caring for family members.
- C. Call the client and introduce yourself, as a prelude to working with her.
- D. Obtain information on the scope of services covered by the benefit plan for your client.
- E. Arrange a skilled nursing facility site visit for the client and family.

Answers can be found on the Evolve site.

KEY POINTS

- An important role of the nurse is that of client advocate.
- The goal of advocacy is to promote the client's self-determination.
- When performing in the advocacy role, conflicts may emerge about the full disclosure of information, territoriality, accountability to multiple parties, legal challenges to clients' decisions, and competition for scarce resources.
- The functions of advocacy and allocation can pose dilemmas in practice.
- Amplification, clarification, and verification are three communication skills necessary in the advocacy process.
- Additional skills important to fulfilling the role of client advocate include the helping relationship, assertiveness, and problem solving.
- Problem solving is a systematic approach that includes understanding the values of each party and generating alternative solutions.
- Brainstorming and the problem-purpose-expansion method are two techniques to enhance the effectiveness of problem-solving skills.
- During conflict, negotiations can move conflicting parties toward an outcome.
- Prenegotiation, negotiation, and aftermath are three phases of managing a conflict.
- Each individual has a predominant orientation when engaging in conflict: competing, accommodating, avoiding, collaborating, or compromising.
- Collaboration may result by moving through seven stages: awareness, tentative exploration and mutual acknowledgment, trust building, collegiality, consensus, commitment, and collaboration.
- Case management is a strategic program to maintain the health of a population enrolled in a delivery system.
- Continuity of care is a goal of nursing practice. It requires making linkages with services and information systems to improve the client's health status.
- As the structure of the health care system moves toward delivering more services in the community, the achievement of continuity of care will present a greater challenge.
- Case management is typically an interprofessional process in which the client is the focus of the plan.
- Documentation and use of dashboards for case management activities and outcomes are essential to nursing practice.
- Case management is a systematic process of assessment, planning, service coordination, referral, monitoring, and evaluation that meets the multiple service needs of clients.
- A nurse's scope of practice includes advocacy, allocation, and case management functions.
- Nurses functioning as advocates and case managers need to be aware of the ethical and legal issues confronting these components of their practice.
- Standardization of care for predictable outcomes can be achieved through critical paths, disease management protocols, dashboards, clinical guidelines, interprofessional action plans, and a caring-based practice in which processes of diagnosis and treatment are applied to the human experiences of health and illness.
- Nurses are guided by a philosophy of caring and advocacy.
- Nurses have a high regard for client self-determination, independence, and informed choice in decision making.
- Recognizing that responses to illness and disability may limit independence and self-determination, nurses focus on the rights of individuals, families, and communities to define their own health and evidence-based guidelines for practice.
- Telehealth application provides expansive alternatives within resource delivery options but must be customized for clients.

CLINICAL DECISION-MAKING ACTIVITIES

1. Observe a typical work day of a nurse working with a population, noting the types of activities that are done in coordination, transition care, case management, and documentation as well as the amount of time spent in these areas. Interview several staff members to determine whether they perceive that their time spent in case management is changing. To what degree are the staff members involved in care management activities? What are the top three legal and ethical issues they encounter in their practice? What do the nurses report as their greatest sources of satisfaction and dissatisfaction in their jobs?
2. Initiating, monitoring, and evaluating resources are essential components of nursing practice. Describe a client situation and the case management process that might occur in the following practices:
 - A. A school nurse in an elementary school and one in a high school working with brain-injured students
 - B. An occupational health nurse in a hospital and one in a manufacturing plant
 - C. A nurse working in a well-child clinic
 - D. A case manager employed by a managed care organization
 - E. A care manager employed in a health benefits corporation
3. Explain how the case management processes affected client outcome in each of these situations.
4. The values and beliefs held by a nurse influence the nurse's ability to be an advocate for clients. Analyze your values and beliefs about rationing health care and describe how they may affect your ability to be a client advocate. How did you develop your values and beliefs?
5. Read one of the following and respond to the respective questions: Fink-Samnack E, Muller LS: Case management across the life continuum: ethical obligations versus best practice. *Prof Case Manag* 15:153-156, 2010. Discuss your reactions to the mini case studies and the statement, *Allocation always works within the mixed interests of the individual and other stakeholders*. What values do you hold and how do they frame your reactions?
 - A. What are the mixed values of individuals?
 - B. What are the mixed values of other stakeholders (providers, policy makers, insurers)?
 - C. What are the mixed values of society in the United States? What are the mixed values of society in underdeveloped nations? How are the mixed values different or similar in these three situations (A-C)? How does your answer affect client outcomes?

Or read: Sands JR: Where was care coordination? *CMSA Today* 8:14-17, 201.

 - A. Name three problems the author described as her aunt transitioned between levels of care in the hospital.
 - B. Name three problems the author experienced with the manner in which case management was delivered.
 - C. What changes would you make as the manager of the case management office to the manner in which case management and coordination was delivered in the future? What criteria would you use to judge if the change was effective?
 - D. Which of the categories of legal risks exist based on the story the authors tell?

Public Health Nursing Practice and the Disaster Management Cycle

Sharon A. R. Stanley, PhD, RN, FAAN

Dr. Sharon Stanley was Chief Nurse of the American Red Cross, 2009 – 2013. She has worked in public health for over 30 years and her leadership positions in disaster include National Director of Disaster Health and Mental Health, American Red Cross; Chief of Disaster Planning, Ohio Department of Health; and Director, Ohio Center for Public Health Preparedness, The Ohio State University. Colonel Stanley retired from the U.S. Army Reserve in 2007 with 34 years of service, 12 of them on active duty to include Desert Storm and Operation Iraqi Freedom. She is the recipient of numerous awards, including the Order of Medical Military Merit, the Surgeon General's "A" proficiency designator, the 2013 Florence Nightingale Medal of Honor, induction into the 2013 Ohio Veterans Hall of Fame, and the 2011 Association of State and Territorial Directors of Nursing (ASTDN) Recognition Award.

Sharon L. Farra, PhD, RN

Dr. Sharon Farra has practiced nursing for over 30 years and is experienced in emergency and disaster preparedness, response, and recovery. She is an Assistant Professor at Wright State University, where she is leading evaluation efforts for a national disaster health certificate program. A Regional Nurse Leader with the American Red Cross, Dr. Farra serves on the Clinton County Red Cross Board and volunteers with the Medical Reserve Corps. As a nurse educator she has designed, developed, and launched disaster courses for health care providers, to include nurses and allied health professionals. Her research concentration is in disaster training, including innovative teaching methods integrating virtual reality simulation and interprofessional triage.

Susan B. Hassmiller, PhD, RN, FAAN

Dr. Susan Hassmiller is the Senior Advisor for Nursing at the Robert Wood Johnson Foundation in Princeton, New Jersey, and Director of the Future of Nursing: Campaign for Action. The Foundation provides support to improve the health and health care for all Americans. Dr. Hassmiller has taught public health nursing at the university level and has dedicated her career to the care and prevention of disease in vulnerable populations. She is a former member of the National Board of Governors for the American Red Cross, having served as the Chair of Chapter and Disaster Services. She is Chair of the Central New Jersey Chapter of the American Red Cross. She is a 2002 recipient of both the national American Red Cross Ann Magnussen Award and the regional American Red Cross Clara Barton Award, both recognizing her outstanding leadership in the field of nursing and disaster services. She is the 2009 recipient of the Florence Nightingale Medal of Honor, the highest award in nursing presented by the International Committee of Red Cross in Geneva, Switzerland. She oversees the annual Susan Hassmiller American Red Cross Award, which provides recognition to a Red Cross chapter that has made outstanding contributions in providing disaster health services involving nurses as leaders.

- Answers to Practice Application

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Discuss how disasters, both human-made and natural, affect people and their communities.
2. Differentiate disaster management cycle phases to include prevention (mitigation and protection), preparedness, response, and recovery.
3. Examine the nurse's role in the disaster management cycle.
4. Describe competencies for public health nursing practice in disasters.
5. Explain how the community works together to prevent, prepare for, respond to, and recover from disasters.
6. Identify organizations where nurses can volunteer to work in disasters.

The authors wish to acknowledge the manuscript review and consultation of a review committee, which included Linda MacIntyre, PhD, RN, Chief Nurse, American Red Cross; Barbara J. Polivka, PhD, RN, Shirley B. Powers Endowed Chair & Professor, School of Nursing, University of Louisville; and Janice Springer, DNP, RN, Public Health Nurse Consultant and Division Disaster Health Services Advisor, American Red Cross.

CHAPTER OUTLINE

Defining Disasters
 Disaster Facts
 National Disaster Planning and Response: A Health-Focused Overview
 Healthy People 2020 Objectives

The Disaster Management Cycle and Nursing Role
 Prevention (Mitigation and Protection)
 Preparedness
 Response
 Recovery
 Future of Disaster Management

“Wherever disaster calls there I shall go. I ask not for whom, but only where I am needed.”

From Creed of the Red Cross Nurse, by Lona L. Trott, RN, 1953

Around the world, people are experiencing unprecedented disasters from natural causes, such as hurricanes and earthquakes to human-made disasters such as oil spills and terrorism.

Disasters, whether human-made or natural, are inevitable, but there are ways to help communities prepare for, respond to, and recover from disaster. This chapter describes the disaster management cycle phases of prevention, preparedness, response, and recovery as well as the public health nurse's role.

DEFINING DISASTERS

A disaster is any natural or **human-made incident** that causes disruption, destruction, and/or devastation requiring external

assistance. Although natural incidents such as earthquakes or hurricanes trigger many disasters, predictable and preventable human-made factors can further affect the disaster. On March 11, 2011, northeastern Japan was rocked by a 9.0 magnitude earthquake that was quickly followed by a tsunami (see [Figure 23-1](#)). These dual natural disasters caused an estimated death toll of 20,000, but there was a third, human-made component to complete the incident triad: a nuclear reactor crisis. An independent parliamentary investigation later found the Fukushima nuclear disaster to be the result of a mix of several human-made factors ([Inajima et al, 2012](#)). [Box 23-1](#) lists examples of natural and human-made disasters.

In the disaster response phase, the incident type and timing predict subsequent injuries and illnesses. If there is prior warning (e.g., in hurricanes or slow-rising floods), the impact brings fewer injuries and deaths. Disasters resulting with little or no advance notice such as earthquakes or **bioterrorism** could have more casualties because those affected have little time to make evacuation preparations or to obtain adequate

FIG 23-1 A week after the earthquake struck and tsunami surged through northeast Japan, a Japanese Red Cross volunteer surveys the damage to Ōtsuchi in Iwate Prefecture. (Courtesy of the American Red Cross Disaster Online Newsroom, Washington, DC. From: <http://newsroom.redcross.org>. Retrieved January 2015.)

BOX 23-1 Types of Disasters

Natural

Hurricanes
Tornadoes
Hailstorms
Cyclones
Blizzards
Drought
Floods
Mudslides
Avalanches
Earthquakes
Volcanic eruptions
Pandemics and epidemics
Lightning-induced forest fires
Tsunamis
Thunderstorms and lightning
Extreme heat and cold

Human-Made

Conventional warfare
Unconventional warfare (e.g., nuclear, chemical)
Transportation accidents
Structural collapse
Explosions/bombing
Fires
Hazardous materials incident
Pollution
Civil unrest (e.g., riots)
Terrorism (chemical, biological, radiological, nuclear, explosives)
Cyber attacks
Airplane crash
Radiological incident
Nuclear power plant incident
Critical infrastructure failure
Water supply contamination

From U.S. Department of Health and Human Services: *Healthy People 2020: A Roadmap to Improve all Americans Health*. Washington, DC, 2010, USDHHS.

treatment. Individuals can also be injured attempting to prepare for the disaster or while evacuating. Public health disasters can create needs across a widespread region. In a **pandemic**, pressing and competing health needs occur within a close time frame, producing a **public health surge**. In the disaster recovery phase, the immediate threat shifts to adjusting to a new normal in the affected community or region.

DISASTER FACTS

Disasters can affect one family at a time, as in a house fire, or they can kill thousands and result in economic losses in the

millions, as with floods, earthquakes, tornadoes, hurricanes, tsunamis, and bioterrorism. The **American Red Cross** reports that it responds to a disaster in the United States every 8 minutes, resulting in response to more than 70,000 incidents each year (**American Red Cross, 2014**).

The number of reported natural and human-made disasters continues to rise worldwide, yet the number of lives lost has declined over the past couple of decades. The increase in the number of lives saved in a disaster may be explained by better forecasting and early warning systems (International Federation of Red Cross and Red Crescent Societies [**IFRC**], 2013).

Around the globe in 2012, the reported numbers of people (139 million) affected by disasters were the lowest of the decade after previous peaks in 2003, 2010, and 2011. Flooding, the largest number impacted in China, accounted for the majority of that influence, with droughts in Kenya, Sudan, and Ethiopia and elsewhere affecting 28 million people. Typhoon Bopha affected 6.3 million people in the Philippines and an earthquake in Guatemala affected 1.3 million people (**IFRC, 2013**).

In 2013 alone, there were more than 60 major disaster declarations in the United States with another 5 emergency declarations and more than 25 fire management assistance declarations (**Federal Emergency Management Agency [FEMA], 2014a**). An additional explanation on how a disaster declaration is made is presented later in this chapter, but the point is that disaster incidents are a regular occurrence. Hurricane names such as Katrina (2005) and Sandy (2012) and tornado pathways in Joplin, Missouri (2011) and Norman, Oklahoma (2013) are familiar to all. Yet, the latest report card for our nation's emergency care environment in disaster preparedness grades our overall system with a C– for 2014, dropping from a C+ in 2009 (**American College of Emergency Physicians [ACEP], 2014**). The report states that this is due, in large part, to state variation. For example, although the average number of health professionals registering in the volunteer system (the Emergency System for Advance Registration of Volunteer Health Professionals [ESAR-VHP]) is 279.6 nurses per 1 million people overall, that number is 0 per 1 million in Mississippi and 1069 per 1 million in the District of Columbia (**ACEP, 2014**).

Disaster disproportionately strikes at-risk individuals, whether their day-to-day risk is physical, emotional, or economic. Disasters in less developed communities can also destroy decades of progress in a matter of hours, in a manner that rarely happens in more developed countries. The poor, elderly, ethnic minorities, people with disabilities, and women and children in developing communities are excessively affected and least able to rebound (**World Health Organization, 2011**). Unfortunately, by 2050, the percentages of population areas more vulnerable to disasters will increase. Eighty percent of the world's population will live in developing countries, with 46% living in tornado and earthquake zones, near rivers, and on coastlines (**United Nations Development Programme, 2012; Dilley et al, 2005**).

The monetary cost of disaster recovery efforts also rose sharply. The cost in more developed countries is higher because of the extent of material possessions and complex infrastructures, including technology. In the United States, increases in

TABLE 23-1 Total Amount of Disaster Estimated Damage by Continent, Level of Human Development,* and Year (2003-2012), in Millions of U.S. Dollars (2012 Prices)

	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	Total

Notes: Some totals in Table 23-1 may not correspond, due to rounding.

Damage assessment is frequently unreliable. Even for existing data, methodologies are not standardized and the financial coverage can vary significantly. Depending on where the disaster occurred and who reported it, estimations may vary from zero to billions of U.S. dollars. The total amount of damage reported in 2012 was the fifth lowest of the decade. In the Americas and in Europe, the amount of damages was the second highest of the decade and the fifth highest in Africa. In Asia and Oceania, however, the amount of reported damages was, respectively, the third and fourth lowest of the decade. The Americas accounted for almost 66% of damage and Europe for 15%, higher than their respective 43 and 9% average for the decade.

The contribution of very high human development countries to the total amount of damages climbed to 80%, an amount greater than their 72% average for the decade. Inversely, high human development countries accounted for only 16% of damage (decade average, 22%). The two costliest disasters in 2012 occurred in the United States. Hurricane Sandy cost U.S.\$ 50 billion and a drought in the Southwest and Midwest regions cost U.S.\$ 20 billion. Two earthquakes that hit Italy's Ferrara region cost more than U.S.\$ 15 billion.

population and development in areas vulnerable to natural disasters, especially coastal areas, have led to sharply increased insurance payouts (see Table 23-1).

NATIONAL DISASTER PLANNING AND RESPONSE: A HEALTH-FOCUSED OVERVIEW

There is a concerted national effort to provide guidance to state and local planning regions to assist with the coordinated and successful responses and recovery efforts in all-hazard disasters and catastrophes. Many documents have been written at the national level, some of which are reviewed in this chapter.

The reader may ask: "Isn't this all beyond what an individual nurse should have to know?"

As the single largest profession within the health care network, nurses must understand the national disaster management cycle. Without nursing integration at every phase, communities and clients lose a critical part of the prevention network, and the multidisciplinary response team loses a first-rate partner. Actually, it matters greatly how the nation dials 911, and it matters to individuals as well as communities,

regions, and the country as a whole. It also matters globally, beyond our own borders. Our national response is not just about the United States, but our international ability to assist other nations in their times of need.

The U.S. Department of Homeland Security (DHS) was created through the **Homeland Security Act of 2002** (DHS, 2002), consolidating more than 20 separate agencies.

Presidential Policy Directive 8: National Preparedness (PPD-8) was signed and released by President Barack Obama on March 30, 2011. PPD-8 replaced Homeland Security Presidential Directive 8 from the Bush era, and guides how the nation, from the federal level to private citizens, can "prevent, protect against, mitigate the effects of, respond to, and recover from those threats that pose the greatest risk to the security of the Nation" (DHS, 2011). The **National Preparedness Guidelines** (NPG) (DHS, 2007a) and the National Response Plan (NRP), which provide a national doctrine for preparedness that includes the **National Response Framework** (NRF), was promulgated in January 2008. The second edition of the National Response Framework, updated in 2013, provides context for how the whole community works together and how response

efforts relate to other parts of national preparedness (DHS, 2013). Each of the five frameworks covers one mission area: Prevention, Protection, Mitigation, Response, or Recovery. In that framework there are also 15 emergency support functions. **Emergency Support Function 8: Public Health and Medical** provides coordinated federal assistance to supplement state, local, and tribal resources in response to public health and medical care needs (FEMA, 2013a).

Homeland Security Presidential Directive 5 (HSPD-5) created the **National Incident Management System (NIMS)**, a unified, all-discipline, and all-hazards approach to domestic incident management (Naval Postgraduate School [NPS], 2014; FEMA, 2013c). The NIMS was established to provide a common language and structure enabling all those involved in disaster response to communicate with each other more effectively and efficiently.

Two national preparedness documents specifically guide disaster health preparedness, response, and recovery: **Homeland Security Presidential Directive (HSPD) 21: Public Health and Medical Preparedness** and the **National Health Security Strategy (NHSS)**. HSPD-21 established a national strategy that enables a level of public health and medical preparedness sufficient to address a range of possible disasters. It did so through four critical components of public health and medical preparedness: (1) biosurveillance, (2) countermeasure distribution, (3) mass casualty care, and (4) **community resilience** (NPS, 2014). The NHSS is updated every 4 years and focuses on the national goals for protecting people's health in the case of disaster in any setting. National health security is achieved when "the Nation and its people are prepared for, protected from, respond effectively to, and able to recover from incidents with potentially negative health consequences" (U.S. Department of Health and Human Services [USDHHS], 2013a, p. 2). The NHSS was directed by the 2006 Pandemic and All-Hazards Preparedness Act (PAHPA), an act to improve the nation's ability to detect, prepare for, and respond to a variety of public health emergencies. The PAHPA was re-enacted in 2013 and is now called the **Pandemic and All-Hazards Preparedness Reauthorization Act (PAHPRA)**. The PAHPRA funds public health and hospital preparedness programs, medical countermeasures under the BioShield Project, and enhances the authority of the Food and Drug Administration (FDA) (USDHHS, March 2014).

In discussing community resiliency and impact of health care reform on public health preparedness, Vinter and colleagues (2010) state: "Comprehensive health reform presents a rare opportunity to further strengthen our nation. However, even with health reform, there are still major gaps in our public health preparedness. Addressing these underlying weaknesses in our health system will not be easy or cheap, but failure to address these concerns could prove extremely costly" (p. 340).

Our national system of homeland security includes public health preparedness and response as a core part of its national strategies. Some of the strategy documents introduced in this section are covered in greater detail throughout the chapter. Every aspect of disaster management involves the practice of public health nursing.

HEALTHY PEOPLE 2020 OBJECTIVES

Because disaster affects the health of people in many ways, disaster incidents have an effect on almost every *Healthy People 2020* objective. For example, although Access to Health Services and Public Health Infrastructure comprise two important *Healthy People 2020* topic areas with subsequent objectives, they become even more significant when individual and community needs escalate in disaster (USDHHS, 2010). Disasters also play a direct role in the objectives related to environmental health, food safety, immunization and infectious disease, and mental health and mental disorders. Public health professionals, such as those who work at the Centers for Disease Control and Prevention (CDC), study the effect that disasters have on population health and continuously develop new prevention strategies. Other organizations, such as the American Psychological Association and the American Red Cross, work with communities in the preparedness, response, and recovery phases of a disaster and to revise and align the *Healthy People 2020* objectives related to mental health.

HEALTHY PEOPLE 2020

Objectives Related to Preparedness

- **PREP-1:** Reduce the time necessary to issue official information to the public about a public health emergency.
- **PREP-2:** Reduce the time necessary to activate designated personnel in response to a public health emergency.
- **PREP-3:** Increase the proportion of Laboratory Response Network (LRN) laboratories that meet proficiency standards.
 - **PREP-3.1:** Increase the proportion of LRN biological laboratories that meet proficiency standards for Category A and B threat agents (<http://www.bt.cdc.gov/agent/agentlist-category.asp>).
 - **PREP-3.2:** Increase the proportion of LRN chemical laboratories that meet proficiency standards for chemical threat agents.
- **PREP-4:** Reduce the time for state public health agencies to establish after-action reports and improvement plans following responses to public health emergencies and exercises.

From U.S. Department of Health and Human Services (USDHHS): *Healthy People 2020*. Washington, DC, 2014 (updated 2015), USDHHS. Retrieved January 2015 from <http://www.healthypeople.gov/2020/topicsobjectives2020/objectiveslist.aspx?topicid=34>

THE DISASTER MANAGEMENT CYCLE AND NURSING ROLE

Disaster management includes four stages: prevention (including mitigation and protection), preparedness, response, and recovery. **Figure 23-2** shows the disaster emergency management cycle. Nurses have unique skills for all aspects of disaster including assessment, priority setting, collaboration, and addressing both preventive and acute care needs. In addition, public health nurses have a skill set that serves their community well in disaster, including health education and disease screening, mass clinic expertise, an ability to provide essential public health services, community resource referral and liaison work, population advocacy, **psychological first aid**, **public health**

FIG 23-2 Disaster management cycle. (From Ontario Agency for Health Protection and Promotion (Public Health Ontario). Public health emergency preparedness: an IMS-based workshop. Base scenario. Toronto, ON: Queen's Printer for Ontario; 2015 July. (p. 7))

triage, and **rapid needs assessment**. Nurses have served worldwide in disaster care for more than a century. They continue to provide a significant resource to both the employee and the volunteer disaster management workforce, and their numbers are unmatched by any other profession. In addition, nurses work closely with the **interprofessional** health team, community leaders, and organizations, engaging with and advocating for clients as needed across the disaster management cycle.

The World Association for Disaster and Emergency Medicine (WADEM) includes a nursing section. The Nursing Section of WADEM represents nurses from all countries to strengthen and improve the practice and knowledge of disaster nursing. The Nursing Section purposes are as follows (WADEM, 2013):

- Define nursing issues for public health care and disaster health care.
- Exchange scientific and professional information relevant to the practice of disaster nursing.
- Encourage collaborative efforts enhancing and expanding the field of nursing disaster research.
- Encourage collaboration with other nursing organizations.
- Inform and advise WADEM of matters related to disaster nursing.

The International Council of Nurses (ICN) also hosts a disaster-focused response network and published a framework of disaster nursing competencies in 2009 (ICN, 2013).

Prevention (Mitigation and Protection)

All-hazards mitigation (prevention, protection) is an emergency management term for reducing risks to people and property from natural hazards before they occur. The ability to provide primary prevention through national missions of prevention, mitigation, or protection can include structural measures, such as protecting buildings and infrastructure from the forces of wind and water, and nonstructural measures, such as land development restrictions. These primary prevention

measures implemented at the local government level achieve effectiveness, in an all-hazards approach to threats. Of course, prevention also includes human-made hazards and the ability to deter potential terrorists, detect terrorists before they strike, and take decisive action to eliminate the threat (DHS, 2007b). Prevention activities for terrorism may include heightened inspections; improved surveillance and security operations; public health and agricultural surveillance; and testing, immunizations, isolation, or neutralizing **CBRNE threats (chemical, biological, radiological, nuclear, and explosive)**.

The nurse may be involved in many roles in the primary prevention of disaster. As community advocates, nurses promote environmental health by identifying environmental hazards and serving on the public health team for mitigation purposes. Public health nurses in particular are involved with organizing and participating in mass prophylaxis and vaccination campaigns to prevent, treat, or contain a disease. The nurse should be familiar with the region's local cache of pharmaceuticals and how the **Strategic National Stockpile (SNS)** (described later in this chapter) will be distributed. Once federal and local authorities agree that the SNS is needed, medicine delivery to any state in the United States occurs within 12 hours (CDC, 2012c). State and local emergency planners then ensure **points of dispensing (POD)**, to provide prophylaxis to the entire population within 48 hours.

In terms of human-made disaster prevention, the nurse should be aware of high-risk targets and current vulnerabilities and what can be done to eliminate or mitigate the vulnerability. Targets may include military and civilian government facilities, health care facilities, international airports and other transportation systems, large cities, and high-profile landmarks. Terrorists might also target large public gatherings, water and food supplies, banking and finance, information technology, postal and shipping services, utilities, and corporate centers.

Preparedness

Role of the Public Health Nurse in Personal and Professional Preparedness

Public health nurses play a key role in community preparedness, but they must accomplish the critical elements of personal and professional preparedness first.

Personal Preparedness. Disasters by their nature require nurses to respond quickly. Public health nurses without plans in place to address their own needs, to include family and pets, will be unable to fully participate in their disaster obligations at work or in volunteer efforts (Figure 23-3). In addition, the nurse assisting in disaster relief efforts must be as healthy as possible, both physically and mentally. Disaster workers who do not practice self-health are of little service to their family, clients, and community (see the **How To box entitled Be Red Cross Ready**). Disaster kits should be made for the home, workplace, and car. There are emergency supplies specific to nursing that should be prepared and stored in a sturdy, easy-to-carry container (see the accompanying How To box). Important documents should always be in waterproof containers. Nurses should consider several contingencies for children and older adults with a plan to seek help from neighbors in the event of being

FIG 23-3 Personal preparedness. Public health nurses need to develop their own disaster plan as a part of their community disaster activities. (Courtesy of the Wichita Falls Health District [Wichita Falls, TX]. From: <http://tx-wichitafalls2.civicplus.com/index.aspx?NID=1301>. Retrieved January 2015.)

called to a disaster. Many public shelters do not allow pets inside and other arrangements must be made. At present, local emergency management agencies include pet management in the local disaster plans and so should the pet owner (FEMA, 2014c).

One way a nurse can feel assured about family member protection is by working with them to develop the skills and knowledge necessary for coping in disaster. For example, long-term benefits occur by involving children and adolescents in activities such as writing preparedness plans, exercising the plan, preparing disaster kits, becoming familiar with their school emergency procedures and family reunification sites, and learning about the range of potential hazards in their vicinity to include evacuation routes. This strategy also offers children and adolescents an opportunity to express their feelings.

Professional Preparedness. Every state needs a qualified workforce of public health nurses for solutions for today's public health problems that include natural disasters and the threat of terrorism. Public health nurses, in turn, need "dedicated, resourceful, and visionary leaders" (ASTDN, 2008, p. 4). Chief public health nurse officers at the state level develop and maintain a strong public health nursing workforce and practice, especially when those nurses are scattered throughout state and local systems.

Disaster management in the community is about population health: The core public health functions of *assessment*, *policy development*, and *assurance* hold as true in disaster as in day-to-day operations. Operating in the chaos of disaster surge, however, demands a flexible and proficient practice base in each of public health's 3 core functions and 10 essential services (see <http://www.cdc.gov/nphpsp/essentialservices.html>).

Just as the mission of public health and its core functions and essential services do not change in disaster, neither does the practice of public health nursing. The public health nurse must be prepared to advocate for the community in terms of a

HOW TO Be Red Cross Ready

1. Get a Kit

Consider the following when assembling or restocking your kit to ensure that you and your family are prepared for any disaster:

- Store at least 3 days of food, water, and supplies in your family's easy-to-carry preparedness kit. Keep extra supplies on hand at home in case you cannot leave the affected area.
- Keep your kit where it is easily accessible.
- Remember to check your kit every 6 months and replace expired or outdated items.

2. Make a Plan

When preparing for a disaster, always:

- Talk with your family.
- Plan.
- Learn how and when to turn off utilities and how to use life-saving tools such as fire extinguishers.
- Tell everyone where emergency information and supplies are stored. Provide copies of the family's preparedness plan to each member of the family. Always ensure that information is up to date and practice evacuations, following the routes outlined in your plan. Don't forget to identify alternative routes.
- Include pets in your evacuation plans.

3. Get Informed

There are three key parts to becoming informed:

- **Get Info:** Learn the ways you would get information during a disaster or an emergency.
- **Know Your Region:** Learn about the disasters that may occur in your area.
- **Action Steps:** Learn first aid from your local Red Cross chapter.

Emergency Supplies That Nurses Should Have Ready

- Identification badge and driver's license
- Proof of licensure and certification (e.g., RN, CPR/AED, First Aid)
- Pocket-size reference books (e.g., nursing protocols and intervention standards)
- Blood pressure cuff (adult and child) and stethoscope
- Gloves, mask, other personal protective equipment (PPE) for general care
- First aid kit with mouth-to-mouth cardiopulmonary resuscitation (CPR) barrier
- Radio with batteries and cell phone charger
- Cash, credit card
- Important papers and contact information in hard copy
- Sun protection
- Sturdy shoes with socks
- Medical identification of allergies, blood type
- Medications for self
- Weather-appropriate clothing to include rain gear
- Toiletries
- Watch, cell phone, PDA with pre-entered emergency numbers
- Flashlight, extra batteries
- Record-keeping materials, including pencil/pen
- Map of area

(Courtesy of the American Red Cross. Retrieved January 2015 from <http://www.redcross.org/flash/brr/english-html/default.asp>).

focus on population-based practice. The number of public health nurses available to get the job done is small when compared with those with generic or other specialty nurse preparation. Also, disaster produces conditions that demand an aggregate-care approach, increasing the need for public health

nursing involvement in community service during disaster and catastrophe.

The Public Health Nursing Intervention Wheel ([Chapter 9](#)) is a population-based practice model that encompasses 3 levels of practice (community, systems, and individual/family) and 16 public health interventions. Each intervention and practice level contributes to improving population health, providing a practice foundation. This Wheel holds true to public health nursing interventions whether the nurse is working in day-to-day or in disaster operations.

Interprofessional disaster care teams need nurses with disaster and emergency management training and experience. Although the majority of disaster work is not high tech, the knowledge one needs for CBRNE disasters must be developed to include access to a ready cache of information related to nursing care. The following sites provide useful information:

- CDC: *Emergency Preparedness and Response: A to Z Index* (<http://www.bt.cdc.gov/agent>)
- National Library of Medicine: *Disaster Information Management Research Center* (<http://disaster.nlm.nih.gov/>)
- Unbound Medicine: *Relief Central* (<http://relief.unboundmedicine.com/relief/ub/>)
- National Library of Medicine: *WISER—Wireless Information System for Emergency Responders* (<http://wiser.nlm.nih.gov/>) (see [Box 23-2](#) for further information)

Depending on the job and possible volunteer assignments, it is expected that nurses know how to use **personal protective equipment** (PPE), operate specialized equipment needed to perform specific activities, and safely perform duties in disaster environments.

BOX 23-2 Nurses and Technology

Hazardous Material Information Delivered via Wireless

WISER (Wireless Information System for Emergency Responders) is a system designed to assist emergency responders in hazardous material incidents. Developed by the National Library of Medicine, WISER provides a wide range of information on hazardous substances, including substance identification support, physical characteristics, human health information, and containment and suppression guidance. By inputting a substance's physical properties and entering an individual's symptoms, WISER can help narrow the range of substances that may be involved. It provides detailed information about hazardous substances, health effects, treatment, personal protective equipment, toxicity, the emergency resources available, and the surrounding environmental conditions. In January 2014, WebWISER version 4.5 was released. This new release integrates Chemical Hazards Emergency Medical Management (CHEMM) content and updates the Emergency Response Guidebook (ERG) content to 2012. It also now includes hospital provider and preparedness profiles. WISER is available as a standalone application on Microsoft Windows PCs, Apple's iOS devices (iPhone, iPad, and iPod touch), Google Android devices, BlackBerry devices (Internet connectivity required), Windows Mobile devices, and Palm OS PDAs.

From National Library of Medicine: *About WISER*. Bethesda, MD, 2014, National Library of Medicine. From: <http://wiser.nlm.nih.gov/about.html>. Retrieved January 2015.

Professional preparedness also requires that nurses become aware of and understand emergency and disaster plans at their workplace and in their community. Nurses should review the disaster history of the community, understanding how past disasters have affected the community's health care delivery system. It is important for nurses to understand and gain the competencies needed to respond in times of disasters *before* disaster strikes.

Box 23-3 displays core disaster competencies for those working in public health. Disaster competencies for public health nursing practice have been proposed in a set of 25 competencies categorized into preparedness, response, and recovery ([Polivka et al, 2008](#)). The preparedness competencies focus on personal preparedness and on comprehending disaster preparedness terms, concepts, and roles. The competencies also define the role of the public health nurse in a surge event. Response phase competencies include the ability to provide a rapid needs assessment, outbreak investigation and surveillance, public health triage, risk communication, and technical skills such as mass dispensing. Recovery competencies include after-action participation, disaster plan modifications, and

BOX 23-3 Core Competencies for Disaster Medicine and Public Health

- 1.0:** Demonstrate personal and family preparedness for disasters and public health emergencies.
- 2.0:** Demonstrate knowledge of one's expected role(s) in organizational and community response plans activated during a disaster or public health emergency.
- 3.0:** Demonstrate situational awareness of actual/potential health hazards before, during, and after a disaster or public health emergency.
- 4.0:** Communicate effectively with others in a disaster or public health emergency.
- 5.0:** Demonstrate knowledge of personal safety measures that can be implemented in a disaster or public health emergency.
- 6.0:** Demonstrate knowledge of surge capacity assets, consistent with one's role in organizational, agency, and/or community response plans.
- 7.0:** Demonstrate knowledge of principles and practices for the clinical management of all ages and populations affected by disasters and public health emergencies, in accordance with professional scope of practice.
- 8.0:** Demonstrate knowledge of public health principles and practices for the management of all ages and populations affected by disasters and public health emergencies.
- 9.0:** Demonstrate knowledge of ethical principles to protect the health and safety of all ages, populations, and communities affected by a disaster or public health emergency.
- 10.0:** Demonstrate knowledge of legal principles to protect the health and safety of all ages, populations, and communities affected by a disaster or public health emergency.
- 11.0:** Demonstrate knowledge of short- and long-term considerations for recovery of all ages, populations, and communities affected by a disaster or public health emergency.

coordinating efforts to address the psychosocial and public health impact. See [Box 23-4](#) for education and training opportunities.

Nurses who seek increased participation or who seek a better understanding of disaster management can become involved in any number of community organizations. The [National Disaster Medical System](#) (NDMS) provides nurses the opportunity to work on specialized teams such as the [Disaster Medical Assistance Team](#) (DMAT). The [Medical Reserve Corps](#) (MRC) and the [Community Emergency Response Team](#) (CERT) provide opportunities for nurses to support emergency preparedness and response in their local jurisdictions. The American Red Cross offers training in disaster health services and disaster mental health for both local response and national deployment opportunities. In the Red Cross, nurses and nursing students can join a local disaster action team (DAT); act as a liaison with local hospitals; plan health services support for shelter sites; participate on an interprofessional team for optimal service delivery; address the logistics of health and medical supplies; and teach disaster nursing in the community. A list of opportunities is shown in [Box 23-5](#).

The importance of being adequately trained and properly associated with an official response organization to serve in a disaster cannot be overstated. In a disaster, many untrained and ill-equipped individuals rush in to help. Spontaneous volunteer overload, leading to role conflict, anger, frustration, and helplessness, adds to the burden in an already tense situation. The

BOX 23-6 Trust for America's Health (TFAH): Bioterrorism and Public Health Preparedness

Health emergencies pose some of the greatest threats to our nation, because they can be difficult to prepare for, detect, and contain. Important progress has been made to improve emergency preparedness since September 11, 2001. However, while there has been significant progress toward improving public health preparedness over the past 10 years, particularly in core capabilities, there continue to be persistent gaps in the country's ability to respond to health emergencies, ranging from bioterrorist threats to serious disease outbreaks to extreme weather events.

In the 10th annual *Ready or Not? Protecting the Public from Diseases, Disasters, and Bioterrorism* report, 35 states and Washington, DC, scored a 6 or lower on 10 key indicators of public health preparedness.

Along with its annual report on public health preparedness, TFAH also offers a series of recommendations to further strengthen America's emergency preparedness.

What do you think about the recommendations through a public health nursing lens?

From Trust for America's Health: *TFAH Initiatives—Bioterrorism and Public Health Preparedness*. 2012. From: <http://healthyamericans.org/report/101/>. Retrieved January 2015.

World Trade Center attacks of September 11, 2001, brought many qualified but unassociated responders to the site. "Many well-intentioned local physicians in shirt sleeves and light footwear proceeded to the area and attempted to find victims, risking further injuries to themselves and getting in the way of structured rescue protocols. ... [They were] prohibited from participating in rescue operations within any area designated as a disaster by the Fire Department of New York" ([Crippen, 2002](#)). After the bombing of the Alfred P. Murrah building in Oklahoma City in 1995, a nurse who rushed into the building to rescue people became the only fatality who was not killed or injured in the initial blast and collapse ([Oklahoma City National Memorial & Museum, 2010](#)). See [Box 23-6](#) for more on the importance of national preparedness.

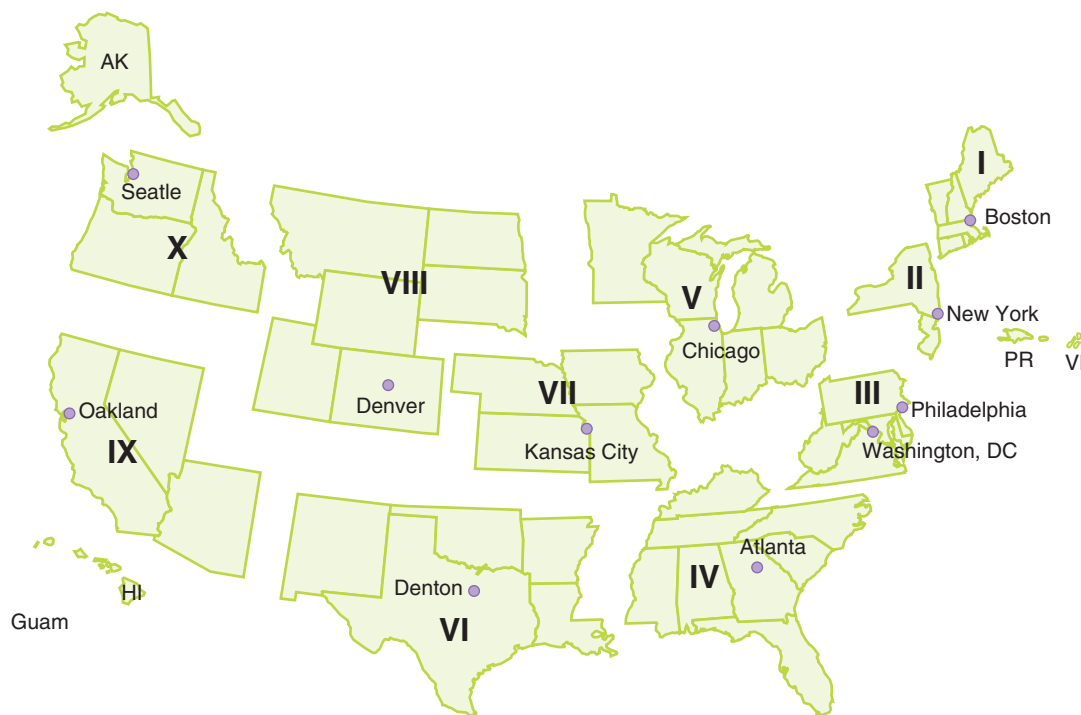

FIG 23-4 The 10 FEMA regions. (Courtesy of the Federal Emergency Management Agency [FEMA]: *Regional Operations*. Washington, DC, 2014, FEMA. From: <http://www.fema.gov/regional-operations>. Retrieved January 2015.)

Community Preparedness

Presidential Policy Directive (PPD)-8 emphasizes that true preparedness is a *whole* community event. PPD-8 urges the strengthening of our nation's security and resilience through an integrated set of guidance, programs, and processes to implement the national preparedness goal, described earlier in this chapter (DHS, 2011).

This planning and implementation require a coordinated response that involves many stakeholders, including first and foremost the general public. Community preparedness also involves all levels of government, public health agencies, hospitals, first responders, emergency management, health care providers within the community, schools and universities, the private sector, and business and nongovernmental organizations (NGOs) such as the Red Cross. Mutual aid agreements and prior planning help to bridge perceived and actual barriers; establish relationships before the incident at the local, regional, state, and national levels; and ensure seamless service. Sometimes barriers involve regulatory authority and jurisdictional boundaries; sometimes the barriers involve organizational control versus the common good.

Emergency management is responsible for developing and coordinating emergency response plans within their defined area, whether local, state, federal, or tribal. The Federal Emergency Management Agency (FEMA) coordinates comprehensive, all-hazard planning at the national level, assuring a menu of exercises and plan templates to address plausible incidents in any given community. Emergency management personnel at the state and local levels work closely with their communities

and response partners, providing opportunities to train, exercise, evaluate, and update disaster plans. Stronger predisaster partnerships, which include all stakeholders, produce a more coordinated response. Figure 23-4 shows FEMA regions across the nation.

Disaster planning involves simplicity and realism with back-up contingencies because (1) the disaster will never be an “exact fit” for the plan, and (2) all plans must be implementation ready, no matter who is present to start them (DHS, 2007a). The following Quality and Safety Education for Nurses box describes safety guidelines for the nurse's family.

Finally, the community must have an adequate warning system and an evacuation plan that includes measures to remove those individuals who hesitate to leave areas of danger. Some people refuse to leave their homes over fear that their possessions will be lost, destroyed, or looted. They also do not want to leave pets behind. Also, some people mistakenly believe that experience with a particular type of disaster is enough preparation for the next one. This faulty belief was demonstrated in New York City during Hurricane Sandy in October 2012, fueled by a false sense of security after Hurricane Irene in August 2011. Sandy killed at least 125 people, including 60 in New York—48 of them in New York City (Huffington Post, 2012). The nurse's visibility in the community can help develop the trust and credibility needed to help in contingency planning for evacuation. In December 2014 nurses were rated the highest on honesty and ethics in a ranking of professions. Their ranking of 80% was compared to medical doctors at 65% and clergy at 4 percent (www.gallup.com/poll/1654/Honesty-Ethics-Professions.aspx).

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES**Targeted Competency: Safety:**

Minimize risk of harm to clients and providers through both system effectiveness and individual performance. Selected knowledge, skills, and attitudes are cited below in order to develop a disaster safety plan:

Knowledge

Examine human factors and other basic safety design principles as well as commonly used unsafe practices (such as workarounds and dangerous abbreviations). Specific steps might be:

1. Learn how you can get information during the disaster or emergency.
 - a. Determine what types of disasters are most likely to happen.
 - b. Learn about warning signals in your community.
 - c. Ask about postdisaster pet care (shelters usually will not accept pets).
 - d. Review the disaster plans at your workplace, school, and other places where your family spends time.
 - e. Determine how to help older adult or disabled family members or neighbors.
 - f. WHAT should you do?

Skills

Demonstrate effective use of strategies to reduce risk of harm to self or others.

1. Create a disaster plan:
 - a. Talk with your family and create two places to meet, including outside your home and outside your neighborhood. Give each member of the family a copy of the plan.
 - b. Discuss the types of disasters that are most likely to happen, and review what to do in each case and make a plan.
 - c. Choose an out-of-state friend to be your family contact; this person will verify the location of each family member. After a disaster, it may be easier to call long distance than to make local calls.
 - d. Review evacuation plans, including care of pets. Have alternative routes for evacuation.
2. Complete this checklist:
 - a. Post emergency phone numbers next to telephones.
 - b. Teach everyone how and when to call 911.

- c. Determine when and how to turn off water, gas, and electricity at the main switches.
- d. Check adequacy of insurance coverage for yourself and your home.
- e. Locate and review the use of fire extinguishers.
- f. Install and maintain smoke detectors.
- g. Conduct a home hazard hunt and fix potential hazards.
- h. Stock emergency supplies and assemble a disaster supplies kit.
 - i. Acquire first aid and cardiopulmonary resuscitation (CPR) certification.
 - j. Locate all escape routes from your home. Find two ways out of each room.
 - k. Find safe spots in your home for each type of disaster.
3. Practice and maintain your plan:
 - a. Review the plan every 6 months.
 - b. Conduct fire and emergency evacuation drills.
 - c. Replace stored water every 3 months and stored food every 6 months.
 - d. Test and recharge fire extinguishers according to manufacturer's instructions.
 - e. Test your smoke detectors monthly and change the batteries at least once a year.
 - f. WHAT more should you do?

Attitudes

Appreciate the cognitive and physical limits of human performance.

1. Monitor your personal reactions to the disaster and seek assistance if the stress of the losses and the potential work to re-establish a new normal seem overwhelming. Monitor also the reactions of your colleagues and the clients you serve and provide or refer to others anyone who needs stress management intervention.

Safety Question

To prepare more effectively for the event of a future disaster, list the steps that you would take to ensure the safety of your family, including any pets you may have.

Nurses should be involved in identifying and educating communities about what effect the disaster might have on them, including helping at-risk populations to address preparedness planning. In addition to identifying high-risk individuals in neighborhoods, locations of congregate concern include schools, college campuses, residential centers, prisons, hospitals, and high-rise buildings. During Hurricane Sandy even the health care facilities did not have consistency in evacuation decisions and risk assessment (Powell et al, 2012). Nurses can greatly assist in community preparedness given their knowledge of the community's diversity such as non-English-speaking groups, the immunocompromised, children, older adults with functional and access needs, and the physically and mentally challenged.

The National Health Security Strategy and Community Resilience

The NHSS, mentioned earlier in this chapter, as part of the nation's national planning has been instrumental in bringing

the concept of community resilience into all preparedness operations. The NHSS is designed to achieve two goals: (1) build community resilience and (2) strengthen and sustain health and emergency response systems (U.S. Department of Health and Human Services (USDHHS), 2013a). Some maintain, though, that the concept of community resilience is not fully defined at our national level and accountability measures to examine resilience pre- and postdisaster are lacking (Uscher-Pines et al, 2013). Community resilience is a policy issue in all levels of planning (federal, state, and local) because limited resources postdisaster demand whole community resilience in order to move back into normalcy. Healthier communities, by default, will have better bounce-back ability.

Community resilience is defined as the sustained ability of a community to withstand and recover from adversity (Chandra et al, 2011). Healthy individuals, families, and communities with access to health care and protective, preventive knowledge that can be used to launch timely action become some of our nation's strongest assets in disaster incidents. A recent Rand publication

dedicated to advancing operational implementation of community resilience developed a list of resilience indicators after carefully researching the existing literature and national disaster policy documents and conducting focus groups with communities recently affected by disasters (Chandra et al, 2011):

- Engagement at the community level, including a sense of cohesiveness and neighborhood involvement or integration
- Partnership among organizations, including integrated pre-event planning, exercises, and agreements
- Sustained local leadership supported by partnership with state and federal government
- Effective and culturally relevant education about risks
- Optimal community health and access to quality health services
- Integration of preparedness and wellness
- Rapid restoration of services and social networks
- Individual-level preparedness and self-sufficiency
- Targeted strategies that empower and engage vulnerable populations
- Financial resiliency of families and businesses, and efficient leveraging of resources for recovery

Disaster and Mass Casualty Exercises

Although practice will not ensure a perfect response to disaster, disaster and mass casualty drills and exercises are extremely valuable components of preparedness. After the exercise, the lessons learned through after-action reports are used to update disaster plans and subsequent operations. Exercise categories include discussion-based simulations or “tabletops” and operations-based events such as drills, functional, and full-scale exercises (FEMA, 2013b). The latter operation types involve escalating scope and scale testing of the disaster preparedness and response network, using a specific plan. In addition, implementation of virtual reality (VR)-based training for disaster preparedness and response, conducted either independently or combined with other training formats, is growing within the exercise community. For example, a virtual reality preparedness research project led through the University of Minnesota Preparedness Emergency Response Research Center focuses on an immersive simulation workshop that is designed especially for health science students in public health, medicine, nursing, pharmacy, veterinary medicine, and dentistry at the university. The researchers propose that engaging interprofessional health students in realistic simulated disaster response scenarios will improve system performance and quality disaster response through the acquisition of knowledge and team-based skills (University of Minnesota School of Public Health, 2014).

National Level Exercise 2009 (NLE09) was the first major exercise conducted by the U.S. government that focused exclusively on terrorism prevention and protection, as opposed to incident response and recovery. NLE09 was designated a Tier I National Level Exercise. These exercises started out as the Top Officials exercise series [TOPOFF]) but now incorporate the whole community, with an understanding that the practice must reach all levels of the public, private, and government sectors to be effective.

The National Exercise Program (NEP) serves to test and validate core capabilities. Participation in exercises, simulations or other activities, including real world incidents, helps organizations validate their capabilities and identify shortfalls, pulling in their partners and stakeholders including citizen participation (FEMA, 2014b). An annual Capstone Exercise, formerly titled the National Level Exercise (NLE), is conducted every 2 years as the final component of each NEP progressive exercise cycle. The Capstone Exercise for 2014 examined the nation’s collective ability to coordinate and conduct risk assessments and implement National Frameworks and associated plans to deliver core capabilities (FEMA, 2014b).

Most exercises conducted in hospitals, communities, colleges, counties, or regions are much smaller in scope and scale than the Capstone Exercises. The **Homeland Security Exercise and Evaluation Program** (HSEEP) was developed to help states and local jurisdictions improve overall preparedness with all natural and human-made disasters. It provides a standardized methodology and terminology for exercise design, development, conduct, evaluation, and improvement planning and assists communities to create exercises that will make a positive difference before a real incident (FEMA, 2013b). HSEEP is the national standard for all exercise development and implementation.

Whether conducted as drills, tabletops, functional, or full-scale scenarios, and whether the scope is local or national in nature, nurses and other health care providers must be included as a part of the exercise’s planning, response, and after-action activities. Nurses, as client and community advocates, are essential players in the exercise and preparedness arena.

HOW TO Conduct a Disaster Exercise

Formidable Footprint: A National Community/Neighborhood Exercise Series

A team of national, regional, state, and local agencies and organizations has undertaken an effort to develop, conduct, and evaluate a recurring series of disaster exercises entitled “Formidable Footprint.”

This series of exercises serves as an opportunity for community and faith-based organizations along with governmental agencies to assess their capability to prepare for, respond to, and recover from a variety of natural disasters that affect communities and neighborhoods across the United States. There is no charge to participate in one or several of the neighborhood exercises, provided by the Disaster Resistant Communities (DRC) Group.

In addition, DRC provides the Disaster Health and Sheltering Course through nursing faculty and to their nursing students through the American Red Cross National Student Nurse Program.

Wherever and whenever you get to practice nursing in disaster response and recovery, you become a better-prepared health team member.

From Disaster Resistant Communities Group: Formidable Footprint—A National Community/Neighborhood Exercise Series, 2014. Retrieved January 2015 from <http://www.drc-group.com/project/footprint.html>.

Response

The first level of disaster response occurs at the local level with the mobilization of a team of responders such as the fire department, law enforcement, public health, and emergency services. If the disaster exceeds local resources, the county or city emergency management agency (EMA) will coordinate activities through an **Emergency Operations Center** (EOC). The EOC provides central functions at a strategic level to oversee the emergency situation. In general, local responders within a county sign a regional or statewide **mutual aid agreement** to allow the sharing of needed personnel, equipment, services, and supplies.

The initial scope of disaster assessment is usually measured in dollars, health risk, injury, and/or lives lost. The more destruction and lives at risk, the greater the degree of attention and resources provided at the local, regional, and state levels. When state resources and capabilities are overwhelmed, governors may, through provisions provided in the **Robert T. Stafford Disaster Relief and Emergency Assistance Act** (FEMA, 2013e), request federal assistance under a presidential disaster or emergency declaration. If the event is considered an incident of national significance (a potential or high-impact disaster), appropriate response personnel and resources are provided.

In a mass casualty incident, the goal is to maximize the number of lives saved and to do the greatest good for the greatest number of individuals. These circumstances could lead to changes in the usual standards of health and medical care in the affected locality or region. Rather than doing everything possible to save every life, **crisis standards of care** enable the health care operations necessary to allocate scarce resources in a different manner to save as many lives as possible (Institute of Medicine [IOM], 2012). Crisis standards need to be explored and discussed with all community stakeholders in the preparedness phase. Community engagement is key to this process.

National Response Framework

As previously discussed, the NRF was written to provide an approach to domestic incidents in a unified, well-coordinated manner, enabling all responding entities the ability to work together more effectively and efficiently. The online component of the NRF Resource Center (<http://www.fema.gov/national-response-framework>) contains supplemental materials including annexes, partner guides, and other supporting documents and learning resources. The framework involves the entire community and is scalable, flexible, and adaptable to the given situation. It is a living document that is revised every 18 months in response to evolving conditions, and real-world applications (DHS, 2013).

The NRF includes the 15 emergency support functions (ESFs) (FEMA, 2014d):

- ESF #1:** Transportation
- ESF #2:** Communications
- ESF #3:** Public Works and Engineering
- ESF #4:** Firefighting
- ESF #5:** Information and Planning

ESF #6: Mass Care, Emergency Assistance, Temporary Housing and Human Services

ESF #7: Logistics

ESF #8: Public Health and Medical Services

ESF #9: Search and Rescue

ESF #10: Oil and Hazardous Materials

ESF #11: Agriculture and Natural Resources

ESF #12: Energy

ESF #13: Public Safety and Security

ESF #14: Long-Term Community Recovery

ESF #15: External Affairs/Standard Operating Procedures.

Each ESF includes a coordinator function, and the primary and support agencies that work together to coordinate and deliver federal capabilities. Specifically, the ESFs provide the structure for coordinating federal interagency support to align with state, regional, and local capabilities. The NRFs also include support annexes, incident specific annexes, and partner guides.

ESF-8, Public Health and Medical Services, provides guidance for medical and mental health personnel, medical equipment and supplies, assessment of the status of the public health infrastructure, and monitoring for potential disease outbreaks (FEMA, 2013a). The ESF-8 primary coordinating agency is the U.S. Department of Health and Human Services; supporting agencies include the DHS, the American Red Cross, the Department of Defense, and the Department of Veterans Affairs. The National Disaster Medical System (NDMS) is part of ESF-8.

National Incident Management System

The National Incident Management System (NIMS) is the national platform for disaster response and it includes universal protocols and language. The NIMS identifies concepts and principles that answer how to manage emergencies from preparedness to recovery regardless of their cause, size, location, or complexity. “NIMS provides a consistent, nationwide approach and vocabulary for multiple agencies or jurisdictions to work together to build, sustain and deliver the core capabilities needed to achieve a secure and resilient nation” (FEMA, 2013c, p. 1).

No matter what type of nursing practice or which agency a nurse chooses, they will come into direct contact with NIMS, which includes the Incident Command System (ICS). **Figure 23-5** displays basic ICS operations. The NIMS includes varying levels of education and training, with many organizations requiring a base level of familiarization to comply with federal funding requirements.

A well-developed training program promotes nationwide NIMS implementation, producing an adequate number of trained and qualified emergency management/response personnel. The Emergency Management Institute (EMI) is the premier emergency management training institution, training more than 2 million students annually. The mission of EMI is to “directly supports the implementation of the National Incident Management System (NIMS), the National Response Framework (NRF), the National Disaster Recovery Framework (NDRF), and the National Preparedness Goal (NPG) by conveying necessary knowledge and skills to improve the nation’s capa-

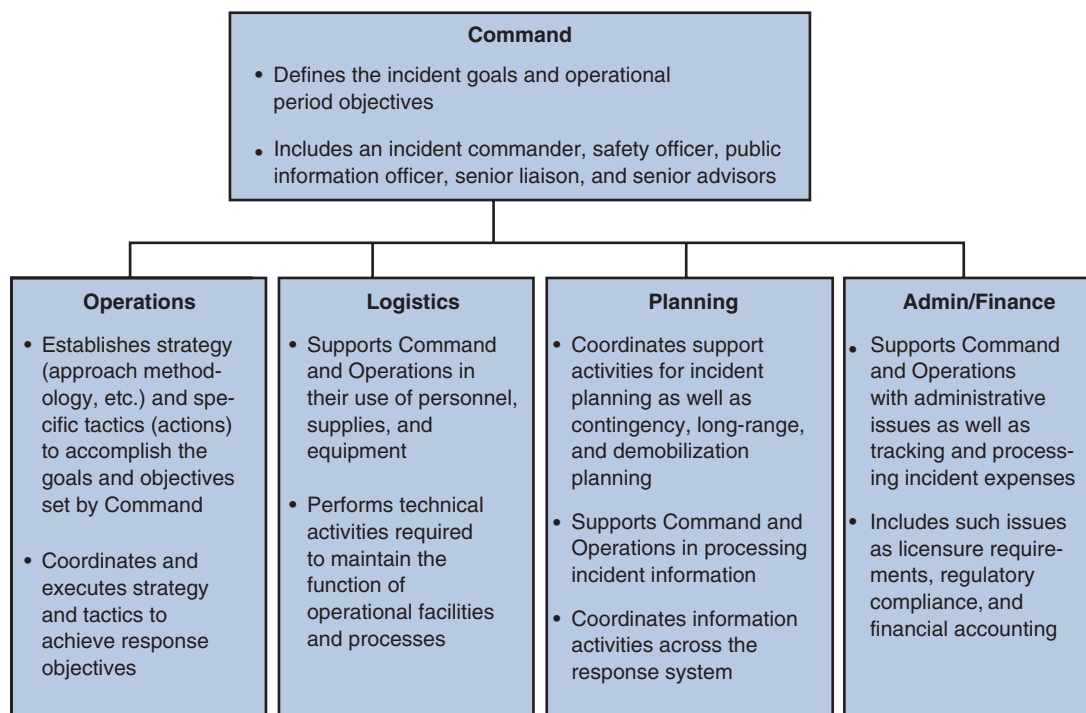

FIG 23-5 Incident Command System (ICS). (Courtesy of U.S. Department of Health and Human Services, Washington, DC. From: <http://www.phe.gov/Preparedness/planning/mscc/handbook/chapter1/Pages/emergencymanagement.aspx>. Retrieved January 2015.)

bility” (FEMA, 2012, paragraph 1). EMI is located at the National Emergency Training Center in Emmitsburg, Maryland, and offers a broad range of both onsite and online courses related to all phases of the disaster cycle. Some of the NIMS-related training offered includes the following online courses (FEMA, 2013c):

- IS-100.HCb: Introduction to the Incident Command System for Healthcare/Hospitals
- IS-200.HCa: Applying ICS to Healthcare Organizations
- IS-700.a: National Incident Management System (NIMS), An Introduction
- IS-701.a: NIMS Multiagency Coordination System
- IS-800.b: National Response Framework, An Introduction

Response to Biological Incidents

Biological agents pose a high risk to public health because only small amounts of the agents are needed to affect thousands of people and some of the agents are easy to conceal, transport, and disseminate. The CDC is an excellent source of biological agent information, including the latest agent fact sheets for health (CDC, 2014a). Important information provided includes the methods of transmission and communicability period. Through the Pandemic and All-Hazards Preparedness Reauthorization Act (PAHPRA), several biodefense programs exist to help public health professionals mount a proactive response to these events (USDHHS, 2013b):

- *BioWatch* is an early warning system for biothreats that uses an environmental sensor system to test the air for biological agents in several major metropolitan areas.

- *BioSense* is a data-sharing program to facilitate surveillance of unusual patterns or clusters of diseases in the United States. It shares data with local and state health departments and is a part of the BioWatch system.
- *Project BioShield* is a program to develop and produce new drugs and vaccines as countermeasures against potential bio-weapons and deadly pathogens.
- *Cities Readiness Initiative* is a program to aid cities in increasing their capacity to deliver medicines and medical supplies during a large-scale public health emergency such as a bioterrorism attack or a nuclear accident.
- *Strategic National Stockpile (SNS)* is a CDC-managed program with the capacity to provide large quantities of medicine and medical supplies to protect the public in a public health emergency to include bioterrorism. The SNS is deployed through a combination of a state-level request and the public health system.

Some of the most important lessons from live biological incidents and exercises involve communication. In an effort to keep the public health community informed, the CDC developed the Public Health Information Network (PHIN). The PHIN provides for the electronic exchange of information among governmental agencies. It focuses on six components that help ensure information access and sharing: early event detection, outbreak management, connecting laboratory systems, countermeasure and response administration, partner communications and alerting, and cross-functional components, and is critical to information exchange (CDC, 2014b).

How Disasters Affect Communities

One Health recognizes that the health of humans is connected to the health of animals and the environment, and the One Health concept integration in disaster preparedness and response requires interprofessional efforts at global, national, and local levels (CDC, 2013). The spread of infectious diseases and the relationships among humans, animals, and the environment are at the core of One Health. For example, animals serve as early warning signs of potential human illness; an example is that birds often die of West Nile virus before humans get sick with West Nile virus fever.

The first goal of any disaster response is to re-establish sanitary barriers as quickly as possible (Veenema, 2012). Water, food, waste removal, vector control, shelter, and safety are basic needs. Difficult weather conditions such as extreme heat or cold can hamper efforts, especially if electricity is affected. Continuous monitoring of the environment proactively addresses potential hazards. Disease prevention is an ongoing goal, especially if there is an interruption in the public health infrastructure. Infectious disease outbreaks can also occur in the recovery phase of disasters, and occasionally disaster workers introduce new organisms into the area.

People in a community will be affected physically and emotionally, depending on the type, cause, and location of the disaster; its magnitude and extent of damage; the duration; and the amount of prewarning provided. Immediate effects may include loss of life and morbidity, but other health effects such as those during and after disaster disease outbreaks may be delayed.

Although the immediate emotional response to a disaster by civilians may be unpredictable, the response is not always a negative one. For example, the terrorist attacks of September 11, 2001, created extreme anger and grief but also led to a marked increase in compassion and patriotism. Thousands of people helped, from donating blood and money to rescuing individuals from the buildings. Four days after the attack, buying an American flag was nearly impossible, as most stores had sold out (Associated Press, 2001). Within 1 month of the attack, an estimated \$757 million in cash contributions and hundreds of truckloads of goods had been donated to help the families of victims and rescue workers (Yates, 2001). This was the worst human-made disaster in American history, killing more than 2500 civilians and 460 emergency responders. Yet, the terrorist attacks of September 11 will also be remembered for how they unified the country (Rand Corporation, 2004).

The psychological effects of September 11 were different from those of more contained, single-event disasters. The attack was unexpected and of great magnitude, with much uncertainty and fear about what might happen next. Not knowing when or if a subsequent attack will occur may sustain fear and anger.

Another U.S. disaster raised similar issues. At 7:10 A.M. EDT on August 29, 2005, Hurricane Katrina made landfall in southern Plaquemines Parish, Louisiana, as a category 3 hurricane. Starting as a natural disaster, its consequences were compounded by a human-made disaster caused by flooding from levee failure. Later joined by Hurricane Rita, Hurricane Katrina affected the Gulf Coast and the nation in ways that will be felt for generations to come. It is the costliest U.S. disaster ever, with

economic estimates of more than \$125 billion (National Oceanic and Atmospheric Administration [NOAA], 2007). The hurricane, floods, and more than 1800 confirmed deaths created traumatic stress that rose to unbearable levels in New Orleans, resulting in a tense and sometimes violent aftermath (Reagan, 2005). New Orleans was typically described as a war zone in the weeks following the disaster, as was the Gulfport-Biloxi coastline in Mississippi, where 90% of the buildings were demolished. Hundreds of thousands of people lost access to their homes and their jobs as a result of Hurricane Katrina. Although the response and recovery efforts eventually superseded any natural recovery efforts in the history of the country, many residents of both Louisiana and Mississippi believed that the help was too little, too late. Despite the enormous efforts of people and the vast amounts of money spent to help the area recover, there is much work to be done and more funds will be needed to restore the area (Institute for Southern Studies [ISS], 2009).

Stress Reactions in Individuals. A traumatic event can cause moderate to severe stress reactions. Individuals react to the same disaster in different ways depending on their age, cultural background, health status, social support structure, and general ability to adapt to crisis. Symptoms that may require assistance are listed in Table 23-2.

People who are affected by a disaster often have an exacerbation of an existing chronic disease. For example, the emotional stress of the disaster may make it difficult for people with diabetes to control their blood glucose levels. Grief results in harmful effects on the immune system. It reduces the function of cells that protect against viral infections and tumors. Hormones produced by the body's flight-or-fight mechanism also play a role in mediating the effects of grief. Those with mental health issues may experience increased symptoms (CDC, 2012a).

Older adults' reactions to disaster depend a great deal on their physical health, strength, mobility, independence, and income (Banks, 2013) (Figure 23-6). They can react deeply to the loss of personal possessions because of the high sentimental value attached to the items and their irreplaceable value. Their need for relocation depends on the extent of damage to their home or their compromised health. They may try and conceal the seriousness of their health conditions or losses if they fear loss of independence. Box 23-7 lists other populations at higher risk for serious disruption postdisaster, many of them the same populations at risk for adverse health effects predisaster as well.

The effect of disasters on young children (Figure 23-7) can be especially disruptive (National Institute of Mental Health [NIMH], 2013). Young children may respond with regressive behaviors such as thumb-sucking, bedwetting, crying, and clinging to parents. Older children tend to re-experience images of the traumatic event or have recurring thoughts or sensations, or they may intentionally avoid reminders, thoughts, and feelings related to disaster events. Children may have heightened sensitivity to sights, sounds, or smells and may experience exaggerated responses or difficulty with usual activities. Children not immediately impacted by a disaster can also be affected by it. The constant bombardment of disaster stories on television

FIG 23-6 Older adults and disaster. Red Cross nurse Jeanne Pollard chats with Ora White Church, 88, while making door-to-door visits with families in flood-damaged neighborhoods in Picayune, Mississippi, after Hurricane Isaac. TABLE 23-2 Common Responses to a Traumatic Event

COGNITIVE	EMOTIONAL	PHYSICAL	BEHAVIORAL
Poor concentration	Shock	Nausea	Suspicion
Confusion	Numbness	Light-headedness	Irritability
Disorientation	Feeling overwhelmed	Dizziness	Arguments with friends and loved ones
Indecisiveness	Depression	Gastrointestinal problems	Withdrawal
Shortened attention span	Feeling lost	Rapid heart rate	Excessive silence
Memory loss	Fear of harm to self and/or loved ones	Tremors	Inappropriate humor
Unwanted memories	Feeling nothing	Headaches	Increased/decreased eating
Difficulty making decisions	Feeling abandoned	Grinding of teeth	Change in sexual desire or functioning
	Uncertainty of feelings	Fatigue	Increased smoking
	Volatile emotions	Poor sleep	Increased substance use or abuse
		Pain	
		Hyperarousal	
		Jumpiness

BOX 23-7 Populations at Greatest Risk for Disruption after Disaster

- Seniors
- Vision and/or hearing impaired
- Women
- Children
- Individuals with chronic disease
- Individuals with chronic mental illness
- Non-English-speaking
- Low income
- Homeless
- Tourists; persons new to an area
- Persons with disabilities
- Single-parent families
- Substance abusers
- Undocumented residents

From National Institutes of Health, National Library of Medicine: *Special Populations: Emergency and Disaster Preparedness*. 2010. Available at <http://sis.nlm.nih.gov/outreach/specialpopulationsanddisasters.html>. Accessed January 25, 2011.

can cause fear in children. Parental reaction to a disaster will greatly influence children (NIMH, 2013).

Public health nurses should help those in the affected community talk about their feelings, including anger, sorrow, guilt, and perceived blame for the disaster or the outcomes of the disaster. Community members should be encouraged to engage in healthy eating, exercise, rest, daily routine maintenance, limited demanding responsibilities, and time with family and friends.

Stress Reactions in the Community. Communities reflect the individuals and families living in them, both during and after a disaster incident. Four community phases as seen in Figure 23-8 are commonly recognized: (1) heroic, (2) honeymoon, (3) disillusionment, and (4) reconstruction (Duane's

FIG 23-8 Phases of disaster: Collective reactions. (Courtesy of U.S. Department of Health and Human Services, Substance Abuse and Mental Health Services Administration [SAMHSA]: *Training Manual for Mental Health and Human Services Workers in Major Disasters*, ed 2. Washington, DC, 2000, SAMHSA. From: <http://store.samhsa.gov/product/Training-Manual-for-Mental-Health-and-Human-Service-Workers-in-Major-Disasters/SMA96-0538>. Retrieved January 2015.)

Dartboard, 2010). The first two phases, the heroic and honeymoon phases, are most often associated with response efforts. The latter two phases, disillusionment and reconstruction, are most often linked with recovery.

During the heroic phase, there is an overwhelming need for people to do whatever they can to help others survive the disaster. First responders, including health and medical personal, will work hours on end with no thought of their own personal or health needs. They may fight needed sleep and refuse rest breaks in their drive to save others. Moreover, deployed responders from outside the disaster area may be unfamiliar with the terrain and inherent dangers. Those with supervisory responsibilities need to take necessary breaks and attend to their health needs. This means back-up plans must be made sooner than later. Exhausted, overworked responders present a danger to themselves and the community served.

In the honeymoon phase, survivors may be rejoicing that their lives and the lives of loved ones have been spared. Survivors will gather to share experiences and stories. The repeated telling to others creates bonds among the survivors. A sense of thankfulness over having survived the disaster is inherent in their stories.

The disillusionment phase occurs as time elapses and people notice that additional help and reinforcement are not coming as quickly as in the initial response. Fatigue and gloom can result and exhaustion starts to take its toll on volunteers, rescuers, and medical personnel. The community begins to realize that a return to the previous normal is unlikely and that they

must make major changes and adjustments. Nurses in response must consider the psychosocial impact and the resulting emotional, cognitive, and spiritual implications. Public health nurses should identify groups/population segments particularly at risk for burnout and exhaustion, to include volunteers involved in response efforts. They may need breaks and reminders for nourishment. In addition, those in shock and those consumed by grief related to loss of loved ones will need compassionate care, with possible referrals to mental health counseling resources.

The last phase, reconstruction, is the longest. Recovery as a disaster cycle phase is addressed later in this chapter. Homes, schools, churches, and other community elements need to be rebuilt and reestablished. The goal is to return to a new state of normalcy. Community needs may still be extensive; the nurse continues to function as a member of the interprofessional team to provide and assure provision of the best possible coordinated care to the population.

Role of the Public Health Nurse in Disaster Response

The role of the public health nurse during a disaster depends a great deal on the nurse's experience, professional role in a community disaster plan, and prior disaster knowledge to include personal readiness. Public health nurses bring leadership, policy, planning, and practice expertise to disaster preparedness and response (Association of Public Health Nurses [APHN], 2014). One thing is certain about disasters: continuing change. Public health nursing roles in disaster are generally consistent with the

TABLE 23-3 The Disaster Cycle Linked to the Nursing Process

Disaster Cycle Phase: RESPONSE	Assessment	Planning	Implementation	Evaluation
Response comprises “the capabilities necessary to save lives, protect property and the environment, and meet basic human needs after an incident has occurred.” (Burkle, 2006, p. 1120)	Use public health, population-based triage to assess communicable disease outbreak impact and needed response (e.g., influenza) Use population-based triage involving surveillance to divide the affected population into susceptible, exposed, infected, removed, and vaccinated for expedient and life-saving treatment	Collaborate with response partners to develop plans for triage algorithms that determine appropriate care and sustenance logistics for populations, based on their symptoms and comorbid conditions (e.g., chronic disease)	Identify and place public health nurses and other support personnel to provide care according to the developed algorithms Assure that logistics are in place to support community care during the crisis period Conduct ongoing rapid needs assessments during the response phase in order to meet population needs	Maintain ongoing response planning during the incident (e.g., the Incident Management System and its Planning “P”) Participate in service planning and provide real-time adjustment on the basis of real-time public health response evaluation Assure needed and necessary public health nursing care

From Association of Public Health Nurses (APHN): *The Role of the Public Health Nurse in Disaster Preparedness Response, and Recovery: A Position Paper*. 2014. From: http://www.phnurse.org/index.php?option=com_content&view=article&id=120&Itemid=547. Retrieved January 2015.

scope of public health nursing practice, but that practice is often provided in chaotic surges. There is ongoing demand for flexibility in disaster, especially during the response phase of the disaster cycle (Stanley et al, 2008). See Table 23-3 to visualize the role of the public health nurses in response, using the nursing process.

Nursing Role in First Response. Although valued for their expertise in community assessment, case finding and referring, prevention, health education, and surveillance, there may be times when the nurse is the first to arrive on the scene. In this situation, it is important to remember that life-threatening problems take priority. Triage should begin immediately. Triage at the individual level is the process of separating casualties and allocating treatment on the basis of the individuals’ potentials for survival. Highest priority is given to those who have life-threatening injuries but, also, who have a high probability of survival once stabilized (Veenema, 2012). A type of triage called public health triage also exists, using a population-based approach for use in an incident undefined by a geographical location. Public health triage involves the sorting or identification of populations for priority interventions (Burkle, 2006).

Nursing Role in Epidemiology and Ongoing Surveillance. Public health remains the first line of defense in disease outbreak. Epidemiology investigation components do not vary from normal operations in disaster; they simply become “field expedient” (Polivka et al, 2008). The need to collect surveillance data is heightened during a disaster. To detect adverse effects on the community, data are collected related to deaths, injuries, and illnesses. This information allows public health to determine impacts of disaster and assess for potential problems related to response and recovery. Surveillance includes disease tracking, injury trends, and vigilance for the potential for disease outbreaks. These data allow decision-makers to plan and allocate resources. Ongoing assessments or surveillance reports are just as important as initial assessments. Surveillance

reports indicate the continuing status of the affected population and the effectiveness of ongoing relief efforts. Surveillance continues into and through the recovery phase of a disaster, a vital part of establishing the new normal.

Nursing Role in Rapid Needs Assessment. The traditional model of community assessment presents the foundation for the rapid community assessment process. The acute needs of populations in disaster turn the community assessment into rapid appraisal of a sector or region’s population, social systems, and geophysical features. Elements of a rapid needs assessment include the following: determining the magnitude of the incident, defining the specific health needs of the affected population, establishing priorities and objectives for action, identifying existing and potential public health problems, evaluating the capacity of the local response including resources and logistics, and determining the external resource needs for priority actions (Stanley et al, 2008). The Community Assessment for Public Health Emergency Response (CASPER) is a toolkit developed to assist public health practitioners and emergency management officials determine the health status and basic needs of the affected community. The CASPER guides in the collection of health and basic need information (CDC, 2012b). Noji (1997) points out that disaster assessment priorities relate to the type of disaster. Sudden-impact disasters such as tornadoes and earthquakes involve ongoing hazards, injuries and deaths, shelter requirements, and clean water. Gradual-onset disasters such as famines produce concerns with mortality rates, nutritional status, immunization status, and environmental health.

Nursing Role in Disaster Communication. Nurses working as members of an assessment team need to return accurate information in the NIMS environment to facilitate situational awareness. A part of that communication is involved with the rapid and ongoing needs assessment just described. A lack of or inaccurate information regarding the scope of the disaster and its initial effects can contribute to mismatched resources and

increased morbidity. After Hurricane Andrew in 1992, a well-meaning public continued to ship thousands of pounds of clothing to South Florida. Much of the clothing eventually was burned because there were inadequate on-site personnel to sort and distribute the clothing, and the piles eventually became a public health nuisance. This effort took resources away from real population-based needs.

Times of crisis or great uncertainty call for great skills in communication. The community needs accurate information transmitted in a timely manner. Health care personnel are the best sources for essential health information that is technical in nature. The NIMS approach uses public affairs spokespersons for formal communication. The Public Information Officer (PIO) is an individual with the authority and responsibility to communicate information to the public at large. Still, nurses are considered trustworthy sources of information and may be approached for an interview. The nurse should refer the media to the PIO representing the agency. If the public approaches the nurse for health information, however, it should be conveyed. Nurses provide health education and information to assist in disaster response and recovery.

Although there are official spokespersons in all major disasters, there may be an occasion for the nurse to serve as a health consultant on the risk communication team. **Risk communication** includes providing critical information to the public. The information should be presented in a calm, brief, and concise manner. As a spokesperson in disaster, it is important to prepare key points in writing before speaking, verify all information is accurate, and never speculate or embellish.

Social media, mobile technology, and their combined use in disaster are quickly changing disaster communication for the community as well as responders (see the example of using social media in Box 23-8). The **Federal Emergency Management Agency (2013d)** National Preparedness Report states that during and immediately after Hurricane Sandy users sent more than 20 million Sandy-related Twitter posts despite the loss of cell phone service during the storm's peak. This trend is expected

to rapidly increase, and relief organizations such as the American Red Cross are devoting separate response cells for the analysis of social media data in real time (**American Red Cross, 2013**). The following Evidence-based Practice box provides an example of communications in public health preparedness.

EVIDENCE-BASED PRACTICE

Savoia and colleagues (2013) performed a systematic review of the literature exploring communications in public health emergencies and preparedness (131 articles). One of the most consistent findings identified by the authors was an association between lower socioeconomic factors and public health emergency preparedness communication and outcomes. Specifically, individuals living in poverty have lower levels of emergency preparedness and are less likely to receive communications regarding public health emergencies and preparedness.

The findings highlight the need for nurses to develop targeted communication interventions toward identified population segments to help them better prepare and respond to emergencies. An example of one strategy is the Red Cross Mobile Applications (<http://www.redcross.org/prepare/mobile-apps>). These applications provide preparedness information, ongoing emergency communication and alerts, and give response information such as shelter locations and other features such as "I am safe" messaging. Nurses can assist in ensuring that at-risk populations with limited resources are assured the tools to be ready in the event of emergencies and disasters.

BOX 23-8 The Resilient Social Network: @OccupySandy #SuperstormSandy

A few hours after Superstorm Sandy made landfall in New Jersey, members of the Occupy Wall Street movement used social media to tap their established network for resources to combat the effects of the massive storm. Overnight, a corps of young, educated, tech-savvy individuals deployed to the region's hardest-hit neighborhoods. The network that came to be known as "Occupy Sandy" emerged as one of the leading humanitarian collectives providing relief to survivors across New York City and New Jersey. At its peak, it mobilized an estimated 60,000 volunteers, most having no prior disaster relief experience. Yet unlike traditional disaster relief organizations, there were no appointed leaders, no regulations to follow, no predefined mission.

Learn more about how social networks are changing the world of disaster response.

From Homeland Security Studies & Analysis Institute: *The Resilient Social Network*. 2014. From: <http://homelandsecurity.org/node/1195>. Retrieved January 2015.

Nursing Role in Disaster Response Ethics. Hurricane Katrina's impact was one of the largest catastrophic natural disasters in the United States. Thousands of health care personnel were stranded in New Orleans hospitals. These workers were faced with limited resources and rapidly deteriorating conditions as they awaited evacuations (**Powell-Young et al, 2013**). In disasters, nurses may work with limited resources. In disaster surge the nurse may no longer be focused on the care of individual clients, but on the entire community. In extreme conditions, traditional ethics of doing the best for every patient may shift to a **utilitarian framework** where nursing's goal becomes to do the "greatest good for the greatest number of individuals" (**American Nurses Association [ANA], 2008**, p. 10). In these circumstances, each patient may not receive all the care that would occur under normal conditions. Instead, the focus is on providing care that maximizes the benefit to the greatest number of people.

In addition to limited resources, nurses may be faced with situations that personally put them in harm's way. The **ANA Code of Ethics (2010a)** states, "the nurse owes the same duties to self as to others." Yet, abandonment of patients may be grounds for disciplinary action in many states. Extreme conditions may cause the nurse to make many difficult decisions, and using an ethical framework will make these decisions easier. As part of disaster preparedness, nurses need to consider their role in their agency's disaster plan. Will they be needed in times of

disasters? What plans have been made for their families if such a response is needed? Written policy should assure protections and make clear the expectations of the registered nurse, the employer, and the government response systems before the disaster occurs (ANA, 2010b).

Nursing Role in Sheltering. General population shelter management is often the responsibility of the local Red Cross chapter within their ESF-6 colead function. In catastrophic disaster, however, governmental authority may establish “mega shelters” housing thousands. ESF-6 provides for both short- and long-term care. This responsibility includes the plan for structure, operations, management, and staffing of mass care sites.

Nurses, because of their comfort with delivering aggregate health promotion, disease prevention, and emotional support, make ideal shelter managers and team members. Nurses in shelter functions are involved in providing assessment and referral, health care needs (e.g., prescription glasses, medications), first aid, and appropriate dietary adjustment; keeping client records; ensuring emergency communications; and providing a safe environment (American Red Cross, 2013). The Red Cross provides training for shelter support and use of appropriate protocols and partners with other agencies such as the Medical Reserve Corps (MRC) and local public health agencies to accomplish this mission.

Common-sense approaches work best when dealing with the shelter community. Basic measures that can be taken by the shelter nurse include the following: listen to shelter residents tell and retell their disaster story and current situation; encourage residents to share their feelings with one another if it seems appropriate to do so, especially those suffering from similar circumstances; help residents make decisions; delegate tasks (e.g., reading, crafts, and playing games with children) to teenagers and others to help combat boredom; provide the basic necessities (e.g., food, clothing, rest); attempt to recover or gain needed items (e.g., prescription glasses or medication); provide basic compassion and dignity (e.g., privacy when appropriate and if possible); and refer to a mental health counselor or other sources of help as the situation warrants.

Emergency managers and shelter planners have the responsibility of planning to ensure that sheltering services and facilities are accessible to everyone. Children and adults with disabilities as well as those who have access and/or are functional should be integrated into general population shelters. According to FEMA (2010), the needs of the whole community should be considered in every aspect of emergency shelter planning and response. To help assist these individuals, **Functional Needs Support Services** (FNSS) are implemented to aid individuals in maintaining their independence with the general population shelter. Required FNSS include reasonable modification to policies, practices, and procedures to accommodate individuals with functional needs as well as access to durable medical equipment within the shelter environment (e.g., walkers, beds, ventilators), consumable medical supplies (e.g., ostomy supplies, dressings). All shelter residents should have access to personal assistance services and other goods and services as needed (FEMA, 2010), and arrangements to make this so must be made in advance.

Alternate care centers may be used to shelter patients with medical needs designated as “Non-ambulatory care/Hospital overflow,” for example, care of nonambulatory patients with less intense medical needs. In addition, Federal Medical Stations (FMSs) are another alternate care area for clients. These units also provide basic care for nonambulatory, hospital overflow, patients with minimal medical needs or to shelter patients with more advanced outpatient needs. Requested by state health or emergency management agencies, FMSs are designed to plug and play in “structures of opportunity” in the community, such as schools or convention centers (IOM, 2012). See the [Linking Content to Practice](#) box for ways to deal with a disaster.

Psychological Stress of Disaster Workers

Disaster relief work can be rewarding because it provides an opportunity to have a profound and positive impact on the lives of those who may be experiencing their greatest time of need. However, the work can also be challenging and stressful. During an assignment, responders may be exposed to chaotic environments, long hours, rapidly changing information and directives, long wait times before getting to work, noisy environments, and living quarters that are less than ideal. According to the [National Institute of Occupational Health and Safety](#) (NIOSH, 2013), responders may not recognize the need for self-care, and to monitor their own emotional and physical health. As recovery efforts span time frames of weeks to months, there is increasing risk of adverse effects to responders.

No one who experiences a disaster either personally or in a professional capacity is untouched by it. Nurses who work with survivors of disasters may be at risk for stress reactions. Self-care is as important as the care that is provided to community members.

Symptoms that may signal a need for stress management assistance include the following: being reluctant or refusing to leave the scene until the work is finished; denying needed rest and recovery time; feelings of overriding stress and fatigue; engaging in unnecessary risk-taking activities; difficulty communicating thoughts, remembering instructions, making decisions, or concentrating; engaging in unnecessary arguments; having a limited attention span; and refusing to follow orders (American Red Cross, 2012). Physical symptoms such as tremors, headaches, nausea, and colds or flulike symptoms can also occur.

The nurse should understand that everyone reacts differently after a disaster assignment. Most reactions are considered normal and are temporary, resolving in days to a few weeks. For some workers, disasters bring forth strong thoughts and emotions, both positive and negative. Other workers may experience mild reactions or hardly any reaction at all. There are some common strategies that will help individuals returning from the incident: rest and recovery time, focusing on accomplishments, using calming strategies such as relaxation techniques or working on hobbies, and concentrating on self-care to include healthy food and drink, exercise, and sleep (American Red Cross, 2012).

LINKING CONTENT TO PRACTICE

About Federal Medical Stations

Twenty-four hours. That is how long it took CDC's Division of Strategic National Stockpile (DSNS) to unpack and set up a 40,000-square-foot federal medical station (FMS) in the Middlesex College gymnasium in Edison, New Jersey, capable of caring for up to 250 people displaced by Hurricane Sandy and in need of nonacute (nonemergency) medical care. Somewhere between a temporary shelter and temporary hospital, a FMS is a nonemergency medical center set up during a natural disaster to care for people with special health needs, including those with chronic health conditions (e.g., respiratory illnesses and diabetes), limited mobility, and common mental health issues. Although FMSs are typically up and running within 48 hours, their length of service is more open ended. FMSs remain operational for as long as they are needed by the state. The Middlesex College FMS opened on November 3 and discharged its last person 11 days later.

Are you ready to work in this type of environment?

Retrieved January 2015 from <http://blogs.cdc.gov/cdcworksforyou24-7/2012/11/up-and-running-in-48-hours-how-federal-medical-stations-help-people-after-natural-disasters-like-hurricane-sandy/>

Recovery

Disaster recovery starts much sooner than most nurses may think. In recovery, the immediate response actions to address initial consequences subside, which could be within hours. Also, there will not be a clean break between response and recovery periods. Rather, the process is a transition. Recovery is about returning to the new normal, a community balance of infrastructure and social welfare that is near the level that it would have had if the event had not occurred (Leonard and Howitt, 2010).

The recovery phase is often the hardest part of a disaster. It involves ongoing work beyond preparedness and the response rush. Recovery is where prior community resilience has the ability to make a real difference. Although the initial disaster response phase provides an onslaught of relief aid and resources, the reality of loss and enormity of the task involved in getting back to normalcy is soon felt (see Figure 23-8). During the

recovery phase for a large-scale incident, the federal government provides assistance with rebuilding property, restoring lifelines, and restoring economic institutions with the assistance of individuals, the private sector, and nongovernmental entities.

An incident that creates a need for a public health surge response is not a transitory event. Recovery involves a shift from short-term aid to long-term support for communities: sustainment of effort. Long-term support should include the disaster-affected population representation in the recovery effort, using local knowledge and skills to prioritize use of resources, personnel, and surviving systems and infrastructure. Assisting relief organizations will integrate and build on the existing community resilience.

Role of the Public Health Nurse in Disaster Recovery

The role of the public health nurse in the recovery phase of a disaster is as varied as in the preparedness and response phases,

but the nurse's connection to the community puts the nurse in an incredible position of knowledge and awareness on the inter-professional recovery team. Flexibility is key to a successful recovery operation. Nurses need awareness of the potential public health challenges specific to the disaster area and should monitor the physical and psychosocial environment. Disruption of the public health infrastructure—water and food supply, sanitation system, vector control programs, and access to primary and mental health care—can lead to increased disease and community dysfunction for weeks and months after the incident.

Nursing Role in Ongoing Community Assessment. The reality of the recovery effort is that the rapid needs assessment continues into an ongoing community needs assessment. To determine effective interventions to ensure the best possible outcomes, it is essential to have ongoing accurate data about the population. Some conditions are manifest only after time elapses. A major advantage of the recovery community assessment efforts is that they can be more in-depth, with greater confidence in the results. Some examples of community data points in the recovery phase include the following: ongoing illness and injuries related to the disaster; diseases related to disruption of environmental or health services; health facility infrastructure in terms of adequate personnel, beds, medical and pharmaceutical supplies; and environmental health assessment to include water quantity and quality, sanitation, shelter, solid waste disposal, and vector populations.

A realistic perspective is most useful to the community recovery effort. It will take months or perhaps years to achieve the new sense of normalcy, which may be significantly different from the normal predisaster state. The health care system and its related resources will continue to be taxed, perhaps beyond its abilities for adequate response.

Nurses should also be aware that postdisaster cleanup creates opportunities for unintentional injury and hazards, including those occurring from falls, contact with live wires, accidents with cutting devices, heart attacks from overexertion and stress, and auto accidents resulting from road conditions and missing traffic controls (e.g., stoplights). Nurses should also educate the public of the hazards related to carbon monoxide poisoning stemming from using lanterns, gas ranges, or generators or from burning charcoal for a heat source in enclosed areas.

The Nursing Role in Community Resilience. The public health nurse understands that a resilient community is interconnected; it has strong horizontal and vertical relationships among its residents. There is evidence that both the sense of community created by these relationships and the individual connections of those relationships help improve disaster preparedness and, by default, disaster recovery (Chandra et al, 2011). The recovery period demands that these relationships be reactivated as soon as possible. The public health nurse will have knowledge of the previously existing relationships, and must work with the population to find creative ways to reinstitute those ties.

After disaster, for example, it may be easier for individuals to get to know their neighbors through the promotion of horizontal social relationships, and local NGOs can host social

events that allow residents to interact (Chandra et al, 2011). Block associations and other local citizen-led efforts provide opportunities to develop social relationships in places that residents will frequent postdisaster (e.g., schools or emergency distribution centers). Also, residents can connect with decision-makers (i.e., vertical relationship) or join a local volunteer group focused on disaster response and recovery (e.g., the Community Emergency Response Team). A key to timely community recovery is in repairing or rebuilding social and community organizations, and this effort should be specifically referenced in response and recovery plans.

The Nursing Role in Psychosocial Support. Acute and chronic illnesses can become worse by the prolonged effects of disaster. The psychological stress of cleanup and/or moving can cause feelings of severe hopelessness, depression, and grief in the disillusionment phase (see Figure 23-8). Recent research, though, underscores the need for a tiered community approach where psychological disruption is viewed as normal in the immediate aftermath of the disaster, with a concurrent belief that community mental health wellness will return in time for most. In fact, leveraging primary prevention (i.e., community resilience education) and secondary prevention (e.g., use of early population-based mental health triage tools) can actually engage existing community resilience to promote population recovery (Stanley et al, 2012). Although the majority of individuals will eventually recover from disasters, especially at risk are the members of high-needs populations who continue to live in chronic adversity.

Shehab and colleagues (2008) describe a community assessment of a Mississippi manufactured-home population conducted 2 years after Katrina. The researchers surveyed the displaced population for health care needs and access to care as well as identified barriers to and gaps in health care services. At the time of the study, there were about 17,800 trailers in 20 Mississippi counties. Manufactured home parks were included in the survey if they contained 10 or more trailers. There were 69 parks sampled, and homes were selected using random sampling methods. Data gathered included demographic data, displacement information, self-reported health status, types of health services needed and accessed during displacement, depression, suicidal ideation and attempts, and reproductive child health.

Key findings from the 610 respondents included the following: 80% of households had at least one adult with a chronic condition, and 58% of households had a child with a chronic condition. Sixty-two percent of respondents indicated their health was fair or poor since displacement. Fifty-seven percent of respondents were clinically depressed, 72% had depressive symptoms, 24% had suicidal ideation, and 5% had attempted suicide. Ninety-four percent noted that health care services were not available in their community, and 75% reported no access to counseling or support services since displacement (Shehab et al, 2008).

Referrals to mental health professionals should continue throughout the recovery phase and as long as the need exists. The role of the nurse in case finding and referral remains critical during this phase. In the end, it is the leveraging its resiliency

that will help the community progress into its new normal. The public health nurse is the community and client advocate that ensures resilience is fostered in partnership with the population. The Levels of Prevention box provides examples of how nurses respond to preparation for and dealing with a disaster.

LEVELS OF PREVENTION

Primary Prevention

Participate in community disaster exercises; assist in development of the disaster management plan for the agency/community; preidentify vulnerable populations.

Secondary Prevention

Assess disaster survivors; conduct rapid needs assessment; use individual and population-based triage for care; provide psychological first aid.

Tertiary Prevention

Ensure that community service linkages are available to individuals and families; conduct community outreach; participate in planning efforts for the community's "new normal."

FUTURE OF DISASTER MANAGEMENT

Uber-disasters such as the terrorist events of September 11, 2001, Hurricane Katrina in 2005, the 2010 H1N1 pandemic and Haiti earthquake, and Japan's 2012 earthquake, tsunami, and nuclear reactor meltdown continued to underscore the need for nursing involvement at every step of the disaster management cycle. To fully participate as a part of the interprofessional team across the disaster cycle, all nurses must continue to plan and train in

an all-hazards environment, regardless of their specialty practice. As the largest national health care provider, nurses will remain leaders in disaster care.

Public health nurses are particularly critical members of the multidisciplinary disaster health team given their population-based nursing focus and specialty knowledge in epidemiology and community assessment skills. Although sophisticated technology and surveillance will continue to advance in response to both human-made and natural disasters, the nature of disasters will retain the element of unpredictability. That unpredictability and the disaster medicine and public health surge requirements make prevention and preparedness activities on the part of individuals and communities even more important. Disaster information changes rapidly because of the learning that occurs during and after each incident, producing progressive best practices. Staying current in disaster training requires the public health nurse's commitment in continuing to develop expertise related to community planning activities for disaster and everyday resilience.

Throughout this chapter, how nurses practice and provide care across the disaster cycle is aligned and applied using standards of public health nursing, various sets of disaster competencies for health professionals, and the Public Health Nursing Intervention Wheel. Other practice applications include discussion about the continuous processes of assessment, planning, implementation, evaluation, collaboration and cooperation in disaster. The role of the nurse in disaster practice and care aligns with standards of nursing practice as well as public health practice. Specifically, in the disaster cycle the nurse must rapidly and continuously assess, and then plan, implement, and evaluate nursing practice while simultaneously providing interprofessional, population-based care.

PRACTICE APPLICATION

You are a nurse working in your middle school when a level 7.4 earthquake strikes with the epicenter 40 miles away. As a single parent, you have two children in grade school at a neighboring school complex, and older parents who live 10 miles out of town, toward the epicenter. The high school building is also connected to your complex.

You are not hurt and the middle school does not appear extensively damaged, but there is structural glass breakage and some visible cracks and damage. Neither cell phone nor landline phones are working. Emergency auxiliary electricity is activated, but the computer system is down. A rapid damage assessment and visual survey within the immediate neighborhood reveals some structural damage, and 12 individuals with injuries have already approached your office for assistance. Two of

the clients' injuries are serious but not life-threatening, with the remainder of the clients experiencing minor injuries and varying stress levels.

An hour passes and there is no word about damage outside of the immediate school area. School workers are very worried and concerned about their homes and family. Two staff members have already left on foot to check on their homes, which are within 3 miles of the school.

What are your priorities in this situation? List them in order and think through your position with another. Discuss the concepts of prevention and preparedness and how they relate to this disaster situation to include home, community, and workplace.

Answers can be found on the Evolve site.

KEY POINTS

- The number of disasters, both human-made and natural, continues to increase, as do the number of people affected by them.
- Professional preparedness involves personal planning as well as an understanding of the disaster plan at work and in the community.

KEY POINTS—cont'd

- *Healthy People 2020* objectives are linked in many ways to the disaster management cycle, because a disaster incident affects the health of a community in many areas.
- For effectiveness in disaster prevention, preparedness, response, and recovery, nurses must get involved in their community's disaster plan: as a community member, through their workplace, or with a partnering community organization.
- Nurses must be adequately trained and properly associated with an official response organization to best serve those affected by a disaster.
- Becoming knowledgeable about available community resources before a disaster incident will ensure a better coordinated response and recovery.
- Flexibility is a key attribute in providing nursing care during disaster.
- The Public Health Nursing Intervention Wheel is appropriate for daily operations as well as during disaster chaos.
- With any disaster it is always best to use the resources, personnel, and infrastructure of the community itself to promote self-reliance and resilience.
- Our nation's planning efforts for disaster continue to develop, test, and evaluate the goal of a unified, well-coordinated public and private national response.
- The public health nursing role in the disaster management cycle includes helping clients maintain a safe environment and advocating for environmental safety measures in the community; risk communication and client education; community assessment to include rapid needs assessment; public health triage; and surveillance and field epidemiology.
- Triage in a disaster setting involves both individual and population-based approaches, and everything possible for one individual is provided while determining how to promote the greatest good for the greatest number of those affected.
- People in a community react differently to a disaster depending on the type, cause, and location of the disaster; its magnitude and extent of damage; its duration; and the amount of warning that was provided.
- Individual variables that cause people to react differently include their age, cultural background, health status, social support structure, and general adaptability to crisis.
- The affected community experiences four stages of stress during disaster: heroic, honeymoon, disillusionment, and reconstruction.
- The recovery phase begins almost immediately after a disaster occurs.
- Community organizations and social networks can foster community resiliency across the disaster cycle.
- The nurse assisting in disaster relief efforts must maintain self-health, both physically and mentally, to be of service to his or her family and clients.
- Ongoing community assessment is just as important as initial rapid needs assessment. Surveillance reports indicate the continuing status of the affected population and the effectiveness of ongoing relief efforts.

CLINICAL DECISION-MAKING ACTIVITIES

1. Select a vulnerable population within your community and determine what needs the group would have in time of disaster. *What community resources are currently available to help this group? Where is the gap in services?*
2. Describe the role of the public health nurse across the disaster management cycle: prevention (mitigation and protection), preparedness, response, and recovery. *How do you practice nursing across these stages? How do you work with other members of the team?*
3. Interview a nurse who has responded to a disaster. *What role did the nurse play? Were his or her interventions provided at the individual, population level or both? Can you describe two specific examples?*
4. Conduct an interview with a leader from the Emergency Management Agency, American Red Cross, Medical Reserve Corps, or other agency involved with disaster management. *What is your community's plan for response to a disaster? What agencies are involved?*
5. Discuss the advantages and disadvantages of serving on a disaster team in your own community. *Are you a good candidate to serve on a disaster team? What about your personal preparedness? Is there a work conflict? How (or does) this differ from day-to-day nursing practice?*
6. Contact your local public health department to determine its role in a local disaster. Describe a specific nurse's role in disaster management. *How does that nurse navigate interprofessional practice?*
7. Determine what the disaster plan is where you work. Get specific details and share them with others who are important to you.

Public Health Surveillance and Outbreak Investigation

Marcia Stanhope, PhD, RN, FAAN

Dr. Marcia Stanhope is currently an Associate of the Tufts and Associates Search Firm, Chicago, Ill. She is also a consultant for the nursing program at Berea College, Kentucky. She has practiced community and home health nursing, has served as an administrator and consultant in home health, and has been involved in the development of two nurse-managed centers. At one time in her career, she held a public policy fellowship and worked in the office of a U.S. Senator. She has taught community health, public health, epidemiology, policy, primary care nursing, and administration courses. Dr. Stanhope formerly directed the Division of Community Health Nursing and Administration and served as Associate Dean of the College of Nursing at the University of Kentucky. She has been responsible for both undergraduate and graduate courses in population-centered nursing. She has also taught at the University of Virginia and the University of Alabama, Birmingham. During her career at the University of Kentucky she appointed to the Good Samaritan Foundation Chair and Professorship in Community Health Nursing, and was honored with the University Provost's Public Scholar award. Her presentations and publications have been in the areas of home health, community health and community-focused nursing practice, as well as primary care nursing.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Define public health surveillance.
2. Analyze types of surveillance systems.
3. Identify steps in planning, analyzing, interviewing, and evaluating surveillance.
4. Recognize sources of data used when investigating a disease/condition outbreak.
5. Relate the role of the nurse in surveillance and outbreak investigation to the national core competencies for public health nurses.

The Investigation

Investigation Objectives
 Patterns of Occurrence
 When to Investigate
 Steps in an Investigation
 Displaying of Data

Disease surveillance has been a part of **public health protection** since the 1200s, during the investigations of the bubonic plague in Europe. During the 1600s John Graunt developed the fundamental principles of public health including surveillance and outbreak investigation, and in the 1700s Rhode Island passed the first public health laws to provide for the protection of health and care of the population of the state. In the eighteenth century, William Farr introduced the modern version of surveillance and, along with the United States, Italy, and Great Britain, began required reporting systems for infectious diseases. In 1901, the United States began the requirement for reporting cases of cholera, smallpox, and tuberculosis. By 1925 the United States began national reporting of morbidity causes. By 1935 the first national health survey had been conducted, and in 1949 the National Office of Vital Statistics published weekly mortality and morbidity statistics in the journal *Public Health Reports*. This activity was later transferred to the Centers for Disease Control and Prevention, who began publishing the *Morbidity and Mortality Weekly Report* in 1961. Laws, regulations, reporting mechanisms, and data collections are all essential to surveillance and disease outbreak investigations (Thacker et al, 2012).

The Constitution of the United States provides for “police powers” necessary to preserve health safety as well as in other events (see [Chapter 8](#)). These powers include public health surveillance. State and local “police powers” also provide for surveillance activities. Health departments usually have legal

authority to investigate unusual **clusters of illness** as well (Gostin, 2010).

Florence Nightingale first demonstrated the nurse’s role in responding to disasters. Public health nurses bring specific skills to events that require emergency responses. They are prepared to focus on the population that is affected in order to develop policies and comprehensive plans for conducting and evaluating disaster response drills, exercises, and trainings. Public health nurses are first responders in emergency situations in the community, they can lead and manage in the field and in the incident command center, and they are able to collaborate with others to sustain the emergency infrastructure ([Association of Public Health Nurses \[APHN\], 2013](#)). It is important for nurses to be prepared to lead and be a team member if an unusual occurrence or event strikes a community (see [Chapters 3 and 46](#) about the public health response to the Ebola virus outbreak in the United States in 2014).

DISEASE SURVEILLANCE

Definitions and Importance

Disease surveillance is the ongoing systematic collection, analysis, interpretation and dissemination of specific health data for use in public health (Lee et al, 2010; *Webster’s New World Medical Dictionary*, 2014). Surveillance provides a means for nurses to monitor disease trends in order to reduce morbidity and mortality and to improve health (Veenema, 2013).

Surveillance is a critical role function for nurses practicing in the community. A comprehensive understanding and knowledge of the surveillance systems and how they work will help nurses improve the quality and the usefulness of the data collected for making decisions about needed community services, community actions, and public health programming (Chapter 23 provides additional information). The surveillance features indicate it:

- Is organized and planned
- Is the principal means by which a population's health status is assessed
- Involves ongoing collection of specific data
- Involves analyzing data on a regular basis
- Requires sharing the results with others
- Requires broad and repeated contact with the public about personal health issues
- Motivates public health action as a result of data analyses to:
 - Reduce morbidity
 - Reduce mortality
 - Improve health

Surveillance is important because it generates knowledge of a disease or **event** outbreak patterns (including timing, geographic distribution, and susceptible populations). The knowledge can be used to intervene to reduce risk or prevent an occurrence at the most appropriate points in time and in the most effective ways. Surveillance is built on understanding of epidemiologic principles of agent, host, and environmental relationships and on the natural history of disease or conditions (see Chapter 12). Surveillance systems make it possible to engage in effective continuous quality improvement activities within organizations and to improve quality of care (Veenema, 2013).

Surveillance focuses on the collection of process and outcome data. **Process data** focus on what is done (i.e., services provided or protocols for health care delivery). **Outcome data** focus on changes in health status. The activities generated by analyses of these data aim to improve public health response systems. An example of process data is collection of data about the proportion of the eligible population vaccinated against influenza in any one year. Outcome data in this case are the incidence rates (new cases) of influenza among the same population in the same year.

Although surveillance was initially devoted to monitoring and reducing the spread of infectious diseases, it is now used to monitor and reduce chronic diseases and injuries, and environmental and occupational exposures (Centers for Disease Control and Prevention [CDC], 2014e; Veenema, 2013) as well as personal health behaviors. Surveillance systems help nurses and other professionals monitor emerging infections and bioterrorist outbreaks (Pryor and Milligan, 2013). Bioterrorism is one example of an event creating a critical public health concern that involves environmental exposures that must be monitored. This event also requires serious planning in order to be able to respond quickly and effectively. **Biological terrorism** is defined as “the deliberate release of viruses, bacteria, or other germs (agents) used to cause illness or death in people, animals, or plants” (<http://www.bt.cdc.gov/bioterrorism>) (CDC, 2014a).

Chemical terrorism is the intentional release of hazardous chemicals into the environment for the purpose of harming or killing (CDC, 2013a). In the event of a bioterrorist attack, imagine how difficult it would be to control the spread of biological agents such as botulism or anthrax or chemical agents such as sarin or ricin if no data were available about these agents, their resulting diseases or symptoms, and their usual incidence (new cases) patterns (new cases) in the community. The United States spent approximately \$60 billion by 2012 to assist states in preparing for bioterrorist incidents. Roughly one half of that money has funded detection systems; dramatically expanded research on bioweapon agents; and the development, procurement, and stockpiling of vaccines and other medical countermeasures against these agents.

Uses of Public Health Surveillance

Public health surveillance can be used to facilitate the following (CDC, 2010a):

- Estimate the magnitude of a problem (disease or event)
- Determine geographic distribution of an illness or symptoms
- Portray the natural history of a disease
- Detect epidemics; define a problem
- Generate hypotheses; stimulate research
- Evaluate control measures
- Monitor changes in infectious agents
- Detect changes in health practices
- Facilitate planning (Koo 2010)

Purposes of Surveillance

The overall purposes of surveillance are as follows:

- Assess public health status
- Define public health priorities
- Evaluate programs
- Stimulate research

Surveillance helps public health departments identify trends and unusual disease patterns, set priorities for using scarce resources, and develop and evaluate programs for commonly occurring and universally occurring diseases or events. Surveillance activities can be related to the core functions of public health: assessment, policy development, and assurance. Disease surveillance helps establish baseline (endemic) rates of disease occurrence and patterns of spread. Surveillance makes it possible to initiate a rapid response to an outbreak of a disease or event that can cause a health problem. For example, surveillance made it possible to respond quickly to the anthrax outbreak that occurred shortly after the September 11, 2001, attack on the World Trade Centers. Surveillance also made it possible to respond early to the H1N1 outbreak that initially began in Mexico in 2009 (CDC, 2012).

Surveillance data are analyzed, and interpretations of these data analyses are used to develop policies that better protect the public from problems such as emerging infections, bioterrorist biological and chemical threats, and injuries from problems such as motor vehicle accidents. In 2006 a great deal of emphasis was placed on developing disaster management policies in health care organizations, industries, and homes so that the U.S.

population could be prepared in the event of an emergency. Surveillance within individual organizations, such as infection control systems in hospitals, can be used to establish policies related to clinical practice that are designed to improve quality of care processes and outcomes. An example is documented by [Ergaz and colleagues \(2010\)](#), where a policy of weekly fecal cultures for vancomycin-resistant enterococci (VRE) was instituted after the investigation of an outbreak of VRE in the neonatal intensive care unit.

Surveillance makes it possible to have ongoing monitoring in place to ensure that disease and event patterns improve rather than deteriorate. They can also make it possible to study whether the clinical protocols and public health policies that are in place can be enhanced, based on current science, so that disease rates actually decline ([World Health Organization \[WHO\], 2014a](#)). For example, the ongoing monitoring of obesity in children in a community may show that new clinical and effective protocols need to be developed to be used in school-based clinics to reduce the prevalence of obesity among the school populations.

Surveillance data are very helpful in determining whether a program is effective. Such data make it possible to determine whether public health interventions are effective in reducing the spread of disease or the incidence of injuries. By determining the change in the number of cases at the beginning of a program (baseline) with the number of cases after program implementation, it is possible to estimate the effectiveness of a program. One could then compare the effectiveness of different approaches to reducing the problem or to improving health. [Johns and colleagues \(2010\)](#) investigated whether prior seasonal influenza vaccination was effective against the pandemic strain of H1N1 (pH1N1) virus among military personnel. Their findings indicated that with the seasonal influenza vaccines of 2004 to 2009, moderate protection against H1N1 was associated with the vaccines of these years. The protection seemed to have a greater association with severe disease rather than a mild case regardless of age of the ill person.

Collaboration among Partners

A quality surveillance system requires collaboration among a number of agencies and individuals: federal agencies, state and local public health agencies, hospitals, health care providers, medical examiners, veterinarians, agriculture, pharmaceutical agencies, emergency management, and law enforcement agencies, as well as 911 systems, ambulance services, urgent care and emergency departments, poison control centers, nurse hotlines, schools, and industry. Such collaboration promotes the development of a comprehensive plan and a directory of emergency responses and contacts for effective communication and information sharing. It is sometimes essential to include collaboration with international agencies as well. The type of information to be shared includes the following:

- How to use [algorithms](#) to identify which events should be investigated (i.e., this means using a precise step-by-step plan outlining a procedure that in a finite number of steps helps to identify the appropriate event)
- How to investigate

- Whom to contact
- How and to whom information is to be disseminated
- Who is responsible for appropriate action

Nurses are often in the forefront of responses to be made in the surveillance process whether working in a small rural agency or a large urban agency; within the health department, school, or urgent care center; or on the telephone performing triage services during a disaster. It is the nurse who sees the event first ([APHN, 2013](#)).

EVIDENCE-BASED PRACTICE

An analysis was conducted to identify uses of spatial analysis in cancer screening interventions. Researchers used a spatial analysis tool called *cluster detection* to identify geographic areas with populations at high risk for colorectal cancer. Specifically, the investigators used the free cluster detection software application SaTScan to map the at-risk population. The researchers sought to identify which spatial analysis method was most successful in identifying at-risk populations. Various methods were used to detect areas in Florida where the population was at high risk. Although no single method emerged as being able to detect all significant clusters, all methods did detect one area as high risk. This area could be seen as a priority area to implement a screening intervention to improve early identification of disease and early treatment.

Nurse Use

Cluster detection is a surveillance tool that public health nurses can use to determine geographic priority areas for health promotion and disease prevention interventions. Being able to focus on a specific area would enable the nurse to use public health resources in an efficient manner and provide outreach to the populations at highest risk for disease.

From [Sherman RL, Henry KA, Tannenbaum SL, et al: Applying spatial analysis tools in public health: an example using SaTScan to detect geographic targets for colorectal cancer screening interventions. *Prev Chronic Dis* 11:130264, 2014. DOI: <http://dx.doi.org/10.5888/pcd11.130264>.](#)

Nurse Competencies

The national core competencies for public health nurses were developed from the Core Competencies for Public Health Professionals ([Council on Linkages between Academia and Public Health Practice, 2014](#)) and by the [Quad Council of Public Health Nursing Organizations \(2011\)](#). These competencies are divided into eight practice domains: analytical assessment skills, policy development/program planning, communication, cultural competency, community dimensions of practice, basic public health sciences, financial planning/management, and leadership and systems thinking.

To be a participant in surveillance and investigation activities, the staff nurse must have the following knowledge related to the core competencies:

1. Analytical assessment skills
 - Defining the problem
 - Determining a cause
 - Identifying relevant data and information sources
 - Partnering with others to give meaning to the data collected
 - Identifying risks

2. Communication
 - Providing effective oral and written reports
 - Soliciting input from others and effectively presenting accurate demographic, statistical, and scientific information to other professionals and the community at large
3. Community dimensions of practice
 - Establishing and maintaining links during the investigation
 - Collaborating with partners
 - Developing, implementing, and evaluating an assessment to define the problem
4. Basic public health science skills
 - Identifying individual and organizational responsibilities
 - Identifying and retrieving current relevant scientific evidence
5. Leadership and systems thinking
 - Identifying internal and external issues that have an effect on the investigation
 - Promoting team and organizational efforts
 - Contributing to developing, implementing, and monitoring of the investigation

While the staff nurse participates in these activities, the nurse clinical specialist should be proficient in applying these competencies. In addition, the nurse applies the nursing process in preparedness as illustrated in [Table 24-1](#).

The Minnesota Model of Public Health Interventions: Applications for Public Health Nursing Practice (2001, pp. 15-16; also see [Chapters 9](#) and [23](#)) suggests that surveillance is one of the interventions related to public health nursing practice. The model gives seven basic steps of surveillance for nurses to follow:

1. Consider whether surveillance as an intervention is appropriate for the situation.
2. Organize the knowledge of the problem, its natural course of history, and its aftermath.
3. Establish clear criteria for what constitutes a case.
4. Collect sufficient data from multiple valid sources.
5. Analyze data.
6. Interpret data and disseminate to decision-makers.
7. Evaluate the impact of the surveillance system.

Data Sources for Surveillance

Clinicians, health care agencies, and laboratories report cases to state health departments. Data also come from death certificates and administrative data such as discharge reports and billing

records ([Pryor and Milligan, 2013](#)). The following are select sources of mortality and morbidity data:

1. Mortality data are often the only source of health-related data available for small geographic areas. Examples include the following:
 - Vital statistics reports (e.g., death certificates, medical examiner reports, birth certificates)
 - Mortality data can be obtained from the National Vital Statistics System. These data are available and one of the few sources of health-related data that are available for a long time period for small geographic areas ([CDC, 2014g](#))
2. Morbidity data include the following:
 - Notifiable disease reports
 - Laboratory reports
 - Hospital discharge reports
 - Billing data
 - Outpatient health care data
 - Specialized disease registries
 - Injury surveillance systems
 - Environmental surveys
 - Sentinel surveillance systems

A good example of a process in place to collect morbidity data is the National Program of Cancer Registries ([CDC, 2014f](#)). This program provides for monitoring of the types of cancers found in a state and the locations of the cancer risks and health problems in the state.

Each of the data sources has the potential for underreporting or incomplete reporting. However, if there is consistency in the use of surveillance methods, the data collected will show trends in events or disease patterns that may indicate a change needed in a program or a needed prevention intervention to reduce morbidity or mortality. Underreporting or incomplete reporting may occur for the following reasons: social stigma attached to a disease (such as human immunodeficiency virus [HIV]/acquired immunodeficiency syndrome [AIDS]); ignorance of required reporting system; lack of knowledge about the [case definition](#), procedural changes in reporting, or changes in a database; limited diagnostic abilities; or low priority given to reporting ([CDC, 2010a](#)).

Mortality data assist in identifying differences in health status among groups, populations, occupations, and communities, and in monitoring preventable deaths; they also help in examining cause-and-effect factors in diseases ([CDC, 2014g](#)). Vital statistics can be used to plan programs and to monitor

TABLE 24-1 Phases of Nursing Process Linked to Preparedness

DEFINITION OF:				
Preparedness	Assessment	Planning	Implementation	Evaluation
Assure capacity to respond effectively to disasters and emergencies	Assess the populations at risk for special needs during a disaster	Develop plans to care for special needs populations during a disaster	Conduct training, drills, and exercises related to care of special needs persons	Evaluate plans for serving populations with special needs

Excerpted from Association of Public Health Nurses (APHN): *The Role of Public Health Nurses in Emergency Preparedness and Response: Position Paper* [Table 1: The Phases of Disaster Linked to the Nursing Process], 2013. Retrieved January 2015 from https://www.resourcenter.net/images/ACHNE/Files/APHNRoleofPHNinDisasterPRR_30May13.pdf

programs to meet *Healthy People 2020* goals (see the *Healthy People 2020* box for objectives related to surveillance).

The National Notifiable Disease Laboratory (NNDSS) as well as local public health laboratories, hospital discharge data, and billing data provide mechanisms for classifying diseases and events and calculating rates of diseases within and across groups, populations, and communities (CDC, 2013).

The **sentinel** surveillance system provides for the monitoring of key health events when information is not otherwise available for vulnerable populations in order to calculate or estimate disease morbidity. Registrations monitor chronic disease in a systematic manner, linking information from a variety of sources (health department, clinics, hospitals) to identify disease control and prevention strategies. Surveys then provide data from individuals about prevalence of health conditions and health risks. Such surveys allow for monitoring changes over time and assessing the individual's knowledge, attitudes, and beliefs (see QSEN box). This information can be used for health education and other planned interventions (Gostin, 2010).

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Safety

Minimizes risk for harm to clients and providers through both system effectiveness and individual performance.

- **Knowledge:** Discuss potential and actual impact of national client safety resources, initiatives, and regulations.
- **Skill:** Use national resources for own development and to focus attention on safety in the community.
- **Attitude:** Value relationships between national safety campaigns and implementation in locales, times and settings.

Safety Question

The Quad Council competency for communication skills indicates that the public health nurse uses a variety of methods to disseminate public health information to populations within a community and provides a presentation of targeted health information to multiple audiences at a local level: groups, professionals, and agency peers.

How would the nurse use the national sentinel surveillance system to identify health conditions and risks in the community? What types of data sources in this system would the nurse collect? After careful analysis of the data sources, what would the nurse include in a presentation to multiple audiences?

NOTIFIABLE DISEASES

Before 1990 state and local health departments used many different criteria for identifying cases of reportable diseases. Using different criteria made the data less useful than it could have been because it could not be compared across health departments or states. For this reason some diseases may have been under-reported and others may have been over-reported. In 1990 the CDC and the Council of State and Territorial Epidemiologists assembled the first list of standard case definitions. This list was revised in 1997, and more information may be

HEALTHY PEOPLE 2020

Surveillance Objectives

- **EH-5:** Reduce waterborne disease outbreaks arising from water intended for drinking among persons served by community water systems.
- **FS-1:** Reduce outbreaks of infections caused by key foodborne bacteria.
- **FS-2:** Reduce infections associated with foodborne outbreaks due to pathogens commonly transmitted through food.
- **GH-1:** Reduce the number of cases of malaria reported in the United States.
- **IID-16:** (Developmental) Increase the scientific knowledge on vaccine safety and adverse events.
- **PHI-2:** Increase the proportion of tribal, state, and local public health agencies that incorporate core competencies for public health professionals into the job.
- **PHI-7:** Increase the proportion of population-based *Healthy People 2020* objectives for which national data are available for all population groups identified for the objective.

From USDHHS Healthy People 2020: A Roadmap to improve all Americans' health. Wash, DC, 2010 US Govt Printing Office

found at the CDC Division of Public Health Surveillance and Informatics website (CDC, 1997). This site contains information about the National Notifiable Disease Surveillance System (CDC-NNDSS, 2013), and the standard case definitions are updated on a case-by-case basis or otherwise remain the same. For example, the definition of anthrax was updated in 2010. New case definitions are added as new diseases are identified.

National Notifiable Diseases

Box 24-1 shows the national notifiable infectious diseases. Reporting of disease data by health care providers, laboratories, and public health workers to state and local health departments is essential if trends are to be accurately monitored. "The data provide the basis for detecting disease outbreaks, for identifying person characteristics, and for calculating incidence, geographic distribution, and temporal trends. They are used to initiate prevention programs, evaluate established prevention and control practices, suggest new intervention strategies, identify areas for research, document the need for disease control funds, and help answer questions from the community" (CDC, 2014b). The CDC and the Council of State and Territorial Epidemiologists have a policy that requires state health departments to report selected diseases to the CDC-NNDSS. The data for nationally notifiable diseases from 50 states, the U.S. territories, New York City, and the District of Columbia are published weekly in the *Morbidity and Mortality Weekly Report* (MMWR). Data collection about these diseases is ongoing and revision of statistics is ongoing. Annual updated final reports are published in the *CDC Summary of Notifiable Diseases—United States* (CDC, 2014b).

State Notifiable Diseases

Requirements for reporting diseases are mandated by law or regulation. Although each state differs in the list of reportable diseases, the usefulness of the data depends on "uniformity,

BOX 24-1 Infectious Diseases Designated as Notifiable at the National Level during 2014*

- Anthrax
- Arboviral diseases, neuroinvasive and non-neuroinvasive
- Babesiosis
- Botulism
- Chancroid
- *Chlamydia trachomatis* infection
- Cholera
- Coccidioidomycosis
- Congenital syphilis
- Cryptosporidiosis
- Cyclosporiasis
- Dengue virus infections
- Diphtheria
- Ehrlichiosis and anaplasmosis
- Giardiasis
- Gonorrhea
- *Haemophilus influenzae*, invasive disease
- Hansen's disease
- Hantavirus pulmonary syndrome
- Hemolytic uremic syndrome, postdiarrheal
- Hepatitis A, acute
- Hepatitis B, acute
- Hepatitis B, chronic
- Hepatitis B, perinatal infection
- Hepatitis C, acute
- Hepatitis C, past or present
- HIV infection (AIDS has been reclassified as HIV stage III)
- Influenza-associated pediatric mortality
- Invasive pneumococcal disease
- Legionellosis
- Leptospirosis
- Listeriosis
- Lyme disease
- Malaria
- Measles
- Meningococcal disease
- Mumps
- Novel influenza A virus infections
- Pertussis
- Plague
- Poliomyelitis, paralytic
- Poliovirus infection, nonparalytic
- Psittacosis
- Q fever
- Rabies, animal
- Rabies, human
- Rubella
- Rubella, congenital syndrome
- Salmonellosis
- Severe acute respiratory syndrome—associated coronavirus disease
- Shiga toxin-producing *Escherichia coli*
- Shigellosis
- Smallpox
- Spotted fever rickettsiosis
- Streptococcal toxic-shock syndrome
- Syphilis
- Tetanus
- Toxic shock syndrome (other than streptococcal)
- Trichinellosis
- Tuberculosis
- Tularemia
- Typhoid fever
- Vancomycin-intermediate *Staphylococcus aureus* and vancomycin-resistant *Staphylococcus aureus*
- Varicella
- Varicella deaths
- Vibriosis
- Viral hemorrhagic fever
- Yellow fever

simplicity, and timeliness.” Because state requirements differ, not all nationally notifiable diseases are legally mandated for reporting in a state. For legally reportable diseases, states compile disease incidence data (new cases) and transmit the data electronically (weekly) to the CDC through the National Electronic Telecommunications System for Surveillance (CDC-NETSS, 2013) (www.cdc.gov/surveillance).

Ongoing analysis of this extensive database has led to better diagnosis and treatment methods, national vaccine schedule recommendations, changes in vaccine formulation, and the recognition of new or resurgent diseases (CDC-NETSS, 2013d). Selected data are also reported in documents such as *Epidemiologic Notes and Reports* located weekly in the CDC MMWR report (www.CDC.gov). Adverse health data for the calendar year are documented on the reportable disease form, entitled EPID, to the local health department or the state department for public health. Local health department surveillance personnel investigate case reports and proceed with recommended

public health measures, requesting assistance from the state's department assigned to monitor the reports when needed. Reports are forwarded by mail or fax or, in urgent circumstances, by telephone 24 hours a day, 7 days a week. When reports are received, they are scrutinized carefully and, when appropriate, additional steps are initiated to assist local health departments in planning interventions.

To determine which of the national notifiable diseases are reportable in your state, go to your state health department website.

CASE DEFINITIONS

Criteria

Criteria for defining cases of different diseases are essential for having a uniform, standardized method of reporting and monitoring diseases. A case definition provides understanding of the data that are being collected and reduces the likelihood that

different criteria will be used for reporting similar cases of a disease. Case definitions may include clinical symptoms, laboratory values, and epidemiologic criteria (e.g., exposure to a known or suspected case). Each disease has its own unique set of criteria based on what is known scientifically about that particular disease. Cases may be classified as *suspected*, *probable*, or *confirmed*, depending on the strength of the evidence supporting the case criteria.

Although some diseases require laboratory confirmation, even though clinical symptoms may be present, other diseases do not have laboratory tests to confirm the diagnosis. Other cases are diagnosed on the basis of epidemiologic data alone, such as exposure to contaminated food. If a case definition has been established by the CDC or another official source, it should be used for reporting purposes. The case definition should not be used as the only criterion for clinical diagnosis, quality assurance, standards for reimbursement, or taking public health action. Action to control a disease should be taken as soon as a problem is identified, although there may not be enough information to meet the case definition. For example, following the September 11, 2001, terrorist attacks and subsequent crises, when white powder substances were found in the offices of Congress and select post offices, the offices were shut down and evacuated for safety until the final determination of the presence or absence of anthrax (Wright et al, 2010).

Case Definition Examples

Many examples of case definitions exist in the literature and in government documents. The case definition for a *confirmed* case of anthrax was given by the CDC (2010b) as “(1) a clinically compatible case of cutaneous, inhalational, or gastrointestinal illness that is laboratory confirmed by isolation of *B. anthracis* from an affected tissue or site, or (2) other laboratory evidence of *B. anthracis* infection based on at least two supportive laboratory tests.” A *suspected* case was defined as “an illness suggestive of one of the known anthrax clinical forms. No definitive, presumptive, or suggestive laboratory evidence of *B. anthracis*, or epidemiologic evidence relating it to anthrax” (<http://www.cdc.gov>).

Kuo and colleagues (2009) reported on the first *Shigella sonnei* outbreak in Austria in July 2008. They provided case definitions for confirmed cases as follows: a cluster of 22 laboratory-confirmed cases of infection with *S. sonnei*, which was restricted to public health district X in the province of Salzburg. All cases had attended a youth group trip to a small village in the province of Tyrol from July 7 to July 9. An outbreak case among the trip participants was a person who (1) attended the trip, and (2) fell ill with diarrhea in the period between July 8 and July 12. Among the 61 trip participants, 42 fit the outbreak case definition, including 31 culture-confirmed cases. A household outbreak case was a person who (1) did not participate in the trip, (2) fell ill with diarrhea not before July 10, and (3) had household contact with an outbreak case between 1 and 3 days before the onset of illness.

Although at this time there are limited data on the clinical presentation, the CDC (2014c) encourages health care providers to be familiar with the case definitions for Middle East

respiratory syndrome coronavirus (MERS-CoV) infections. The case definition of a **person under investigation** (PUI) includes “fever and pneumonia or acute respiratory distress syndrome and either (1) a history of travel from countries in or near the Arabian Peninsula within 14 days before symptom onset, or (2) close contact with a symptomatic traveler who developed fever and acute respiratory illness (not necessarily pneumonia) within 14 days after traveling from countries in or near the Arabian Peninsula, or (3) a member of a cluster of persons with severe acute respiratory illness of unknown etiology in which MERS-CoV is being evaluated” (CDC, 2014c). This case definition relies on clinical presentation of the patient, clinical judgment of the provider, and the geographic location (epidemiologic place) of the person to confirm possible exposure to the disease.

TYPES OF SURVEILLANCE SYSTEMS

Informatics is essential to the mission of protecting the public’s health. Surveillance systems are designed to assist public health professionals in the early detection of disease/event outbreaks in order to intervene and reduce the potential for morbidity or mortality, or to improve the public’s health status (CDC, 2012; Koo, 2010). Surveillance systems in use today are defined as *passive*, *active*, *sentinel*, and *special*.

Passive System

In the passive system, case reports are sent to local health departments by health care providers (e.g., physicians, public health nurses), or laboratory reports of disease occurrence are sent to the local health department. The case reports are summarized and forwarded to the state health department, national government, or organizations responsible for monitoring the problem, such as the CDC or an international organization such as the World Health Organization (WHO).

The **National Notifiable Disease Surveillance System** (NNDSS) is a voluntary system monitored by the CDC and includes a total of 68 infectious diseases or conditions with case definitions that are considered important to the public’s health. In the list of 68 reportable conditions, 10 critical biological agents have potential use in a terrorist attack (CDC, 2014b). Each state determines for itself which of the diseases and conditions are of importance to the state’s health and legally requires the reporting of those diseases to the state health department by health care providers, health care agencies, and laboratories. The passive system may not provide an accurate picture of the problem because of delayed reporting by providers and laboratories and incomplete reporting across providers and laboratories. This system, however, has the ability to provide disease-specific demographic, geographic, and seasonal trends over time for reported events. An example is a cancer registry system in which cases are required to be reported to the state on the basis of the type of cancer, the demographics of the client, and the geographic location. Because the system has limits, a disease outbreak may be occurring before all reports are received by the state health department (Veenema, 2013; CDC-NNDSS, 2013c).

Active System

In the active system, the public health nurse, as an employee of the health department, may begin a search for cases through contacts with local health providers and health care agencies. In this system, the nurse names the disease/event and gathers data about existing cases to try to determine the magnitude of the problem (how widespread it is).

A recent example would be a search for existing cases of severe acute respiratory syndrome (SARS) within a geographic area or a foodborne outbreak of gastroenteritis, or H1N1 at the local school. An ongoing tracking system within an occupational setting to monitor work-related injuries/illnesses and symptoms is a process that includes occupational health and infection control personnel in interviewing workers, collecting laboratory data and demographics of workers, and seeking potential agents of exposure (Utterback and Schnorr, 2010). The active system is costly and requires numerous personnel. Because the nurse is actively looking for a case, this system offers a more complete picture of the number of existing cases. Because of limits, the active system is often used on a limited basis for investigation after a disease outbreak has been recognized (Gordis, 2008; Veenema, 2013).

Sentinel System

In the sentinel system, trends in commonly occurring diseases or key health indicators are monitored (*Healthy People 2020* [U.S. Department of Health and Human Services (USDHHS), 2010]; WHO, 2014a). A disease/event may be the sentinel, or a population may be the sentinel. In this system a sample of health providers or agencies is asked to report the problem. Some of the questions that may be asked include the following: What really happened? What are the consequences? What was different in this event? What was the outcome? Could the occurrence have been prevented? Did providers follow procedures? Did providers know what to do? Has this happened before? If so, how was it fixed? Who reported the event? What might prevent it from happening again? (WHO, 2014b).

For example, certain providers/agencies in a community may be asked to report the number of cases of influenza seen during a given time period in order to make projections about the severity of the “flu season.” Another example would be monitoring the population of children in the local elementary school to determine the rate of obesity among school-age children. Although much may be learned about diseases and conditions using the sentinel system, because the system data are based on a sample of a problem or a specific population, they cannot be used to monitor specific clients, or to initiate prevention and control interventions for individuals. The system is useful because it helps monitor trends in commonly occurring diseases/events.

Special Systems

Special systems are developed for collecting particular types of data and may be a combination of active, passive, and/or sentinel systems. An example of a special system is the **PulseNet** system developed by the CDC, the Association of Public Health

Laboratories, and federal food regulatory agencies to “fingerprint” foodborne bacteria. This system is designed to provide data for early recognition and investigation of foodborne outbreaks in all 50 states. Similarly, **BioNet** is a system developed by the PulseNet Partners and the **Laboratory Response Network** (LRN) to detect and determine links between disease agents during terrorist attacks. As a result of bioterrorism, newer systems called **syndromic surveillance systems** are being developed to monitor illness syndromes or events. For example, data showing increased medication purchases, physician or emergency department visits, or culture orders as well as increased school or work absenteeism may indicate that an epidemic is developing hours or days before disease clusters are recognized or specific diagnoses are made and reported to public health agencies (Goodman et al, 2012). This approach requires the use of automated data systems to report continued (real time) or daily (near real time) disease outbreaks (Tokars et al, 2010) (Box 24-2).

Another example of a special system designed to help assess unusual patterns of diseases or conditions is the CDC’s **Enhanced Surveillance Project** (CDC, 2013c). The ESP monitors emergency department data to detect unusual patterns (or aberrations) so that quick epidemiologic case confirmation and follow-up can be initiated. More information on this system can be found at the WebLinks website. Although useful, these systems are designed to be used for disease case detection, case management, and outbreak management; they require good timing. False alarms occur. The systems provide national data to detect, diagnose, and handle disease and the effects of biological and chemical agents resulting from bioterrorism. The systems are intended to be used with more traditional systems. In epidemics or terrorist attacks, there is a network of links for foodborne (**PulseNet**), chemical (LRN), and biological genetic patterns of disease (BioNet). New systems are being developed and tested to predict epidemics, as in bioterrorism, before they have occurred (CDC, 2013c; Veenema, 2013). The new syndromic systems may also predict naturally occurring epidemics

BOX 24-2 Bioterrorism and Response Networks

Integrating of training and response preparedness can be supported by the following networks:

- Health Alert Network
- Emergency Preparedness Information Exchange (EPIX)
- Emerging Infections program
- Epidemiology and Laboratory Capacity program
- Assessment initiatives
- Hazardous substances
- Emergency events surveillance
- Influenza surveillance
- Local metropolitan medical response systems

From Koo D: *Overview of Public Health Surveillance*, 2010, Epidemiology Program Office, Centers for Disease Control and Prevention. Available at <http://www.cdc.gov/ncepidisssndssphs/overview.htm>. Accessed September 27, 2010.

(see Box 24-2 for a list of special systems available to assess data in the case of a terrorist event).

Although all of the systems are important, the public health nurse is most likely to use the active or passive systems. An example of when one might use a passive system is the use of the state reportable disease system to complete a community assessment or MAPP (Mobilizing for Action through Planning and Partnerships; see Chapters 18 and 25). The active system is used when several school children become ill after eating lunch in the cafeteria or at the local hot dog stand, to investigate the possibility of food poisoning, or following up on contacts of a newly diagnosed tuberculosis or sexually transmitted disease (STD) client at the local homeless shelter (CDC, 2012). The most recent use of the active system occurred in 2012, when a Liberian citizen in Dallas, Texas, was found to be infected with Ebola virus (see Chapter 46).

THE INVESTIGATION

Investigation Objectives

Any unusual increase in disease incidence (new cases) or an unusual event in the community should be investigated. The system used for investigation depends on the intensity of the event, the severity of the disease, the number of people/communities affected, the potential for harm to the community or the spread of disease, and the effectiveness of available interventions (CDC, 2013b). The objectives of an investigation are as follows:

- To control and prevent disease or death
- To identify factors that contribute to the disease outbreak/event occurrence
- To implement measures to prevent occurrences

Defining the Magnitude of a Problem/Event

The following definitions provide a way to describe the level of occurrence of a disease/event for purposes of communicating the magnitude of the problem. A disease/event that is found to be present (occurring) in a population is defined as **endemic** if there is a persistent (usual) presence with low to moderate disease/event cases. The endemic levels of a disease/event in a population provide the baseline for establishing a public health problem. For example, foodborne botulism is endemic to Alaska. One would need to know the baseline to determine the existence of a change or increase in the number of cases from the baseline. If a problem is considered **hyperendemic**, there is a persistently (usually) high number of cases. An example is the high cholera incidence rate among Asians/Pacific Islanders. **Sporadic** problems are those with an irregular pattern, with occasional cases found at irregular intervals. **Holoendemic** implies a highly prevalent problem found in a population and commonly acquired early in life. The prevalence of this problem decreases as age increases (*Mosby's Medical Dictionary*, 2013). **Epidemic** means that the occurrence of a disease within an area is clearly in excess of expected levels (endemic) for a given time period. This is often called the **outbreak**. **Pandemic** refers to the epidemic spread of the problem over several countries or continents (such as the SARS and most recently the H1N1

influenza outbreak). **Outbreak detection**, or identifying an increase in frequency of disease above the usual occurrence of the disease, is the function of the investigator (Tokars et al, 2010).

Patterns of Occurrence

Patterns of occurrence can be identified when investigating a disease or event. These patterns are used to define the boundaries of a problem to help investigate possible causes or sources of the problem. A **common source** outbreak refers to a group exposed to a common noxious influence such as the release of noxious gases (e.g., ricin in the Japanese subway system several years ago and in a water system in the United States) (Sobel and Watson, 2009). A **point source** outbreak involves all persons exposed becoming ill at the same time, during one incubation period. A **mixed outbreak** (which was described by Kuo and colleagues [2009] while investigating a foodborne gastroenteritis caused by a *Shigella sonnei* virus) is a common source followed by secondary exposures related to person-to-person contact, as in the spreading of influenza. **Intermittent or continuous source** cases may be exposed over a period of days or weeks, as in the recent food poisonings at restaurants throughout the United States as a result of the purchase of contaminated sprouts. A **propagated outbreak** does not have a common source and spreads gradually from person to person over more than one incubation period, such as the spread of tuberculosis from one person to another.

Causal Factors from Epidemiologic Triangle

Factors that must be considered as causes of outbreak are categorized as agents, hosts, and environmental factors (see Chapter 12). The belief is that these factors may interact to cause the outbreak and therefore the potential interactions must be examined. The following presents definitions used to classify agents in an attack:

- **Infectivity**: Refers to the capacity of an agent to enter a susceptible host and produce infection or disease
- **Pathogenicity**: Measures the proportion of infected people who develop the disease
- **Virulence**: Refers to the proportion of people with clinical disease who become severely ill or die

Box 24-3 lists the types of agent factors that may be present. The host factors associated with cases may be age, sex, race, socioeconomic status, genetics, and lifestyle choices (e.g., cigarette smoking, sexual practices, contraception, eating habits). The environmental factors that may be related to a case are physical (e.g., weather, temperature, humidity, physical surroundings) or biological (such as insects that transmit the agent). Some of the socioeconomic factors that might affect development of a disease/event are behavior (e.g., terrorist behaviors), personality, cultural characteristics of group, crowding, sanitation, and availability of health services.

When to Investigate

An unusual increase in disease incidence should be investigated. The amount of effort that goes into an investigation depends on the severity or magnitude of the problem, the numbers in

BOX 24-3 Types of Agent Factors

1. Biological
 - Bacteria (e.g., tuberculosis, salmonellosis, streptococcal infections)
 - Viruses (e.g., hepatitis A, herpes)
 - Fungi (e.g., tinea capitis, blastomycosis)
 - Parasites (protozoa causing malaria, giardiasis; helminths [roundworms, pinworms]; arthropods [mosquitoes, ticks, flies, mites])
2. Physical
 - Heat
 - Trauma
3. Chemicals
 - Pollutants
 - Medications/drugs
4. Nutrients
 - Absence
 - Excess
5. Psychological
 - Stress
 - Isolation
 - Social support

the population who are affected, the potential for spreading the disease, and the availability and effectiveness of intervention measures to resolve the problems. Most of the outbreaks of diseases (or increased incidence rates) occur naturally and/or are predictable when compared with the consistent patterns of previous outbreaks of a disease, such as influenza, tuberculosis, or common infectious diseases. When a disease/event outbreak occurs as a result of purposeful introduction of an agent into the population, the predictable patterns may not exist. Clues are provided to be used when trying to determine the existence of bioterrorism. These clues are simplified and appear in the How To box entitled “Recognize the Epidemiologic Clues” (Khan and Pesik, 2011).

Steps in an Investigation

First confirm whether a real disease/condition outbreak exists or if there has been a false alarm. Review the information available about the situation. Determine the nature, location, and severity of the problem. Verify the diagnosis and develop a case definition to estimate the magnitude of the problem; this may change as new information is made available. Compare current incidence (number of new cases) with usual or baseline incidence. Use local data if available and compare them with the literature, or call the state health department. Assess the need for outside consultation. Report the situation to state public health authorities if required. Check the state reportable disease list. Early and continually changing control measures should be used on the basis of the magnitude and nature of the condition (infectious disease, chronic disease, injuries, personal behaviors, environmental exposure). Control measures may include eliminating a contaminated product, modifying procedures, treating carriers, or immunizing those who might contract the infectious disease. A request should be made that laboratory specimens be saved until the investigation is completed (if applicable to the case definition).

HOW TO Recognize the Epidemiologic Clues That May Signal a Covert Bioterrorism Attack

- Large number of ill persons with similar disease or syndrome
- Large number of unexplained disease, syndrome, or deaths
- Unusual illness in a population
- Higher morbidity and mortality than expected with a common disease or syndrome
- Failure of a common disease to respond to usual therapy
- Single case of disease caused by an uncommon agent
- Multiple unusual or unexplained disease entities coexisting in the same person without other explanation
- Disease with an unusual geographic or seasonal distribution
- Multiple atypical presentations of disease agents
- Similar genetic type among agents isolated from temporally or spatially distinct sources
- Unusual, atypical, genetically engineered, or antiquated strain of agent
- Endemic disease with unexplained increase in incidence
- Simultaneous clusters of similar illness in noncontiguous areas, domestic or foreign
- Atypical aerosol, food, or water transmission
- Ill people presenting at about the same time
- Death or illness among animals that precedes or accompanies illness or death in humans
- No illness in people not exposed to common ventilation systems, but illness among those people in proximity to the systems

HOW TO Conduct an Investigation

- Identify investigation team and resources.
- Confirm the existence of an outbreak.
- Verify the diagnosis/define a case.
- Estimate the number of cases.
- Orient the data collected to person, place, and time.
- Develop and evaluate a hypothesis.
- Institute control measures and communicate findings.
- Maintain surveillance (CDC, 2014h).

Centers for Disease Control and Prevention (CDC): Steps to Investigation, 2014h. Retrieved January 2015 from www.CDC.gov

As the investigation continues, seek additional cases and collect critical data and specimens. Encourage immediate reporting of new cases from laboratory reports (e.g., radiology in cases of pneumonia) and physicians/other health care providers, including public health nurses, health care agencies, and others in the community as appropriate. In addition, search for other cases that may have occurred in the past or are now occurring by reviewing laboratory reports, medical records, and client charts and questioning physicians, other health providers and agencies, and others in the community. Use a specific data collection form such as a questionnaire or a data abstract summary form. Characterize the cases by person, place, and time. Evaluate the client characteristics (i.e., age, sex, underlying disease, geographic location) and possible exposure sites. The place where the outbreak occurs provides clues to the population at risk. Did the problem occur in a community, school, or homes? Drawing tables or spot maps helps to visualize the clusters of the disease condition in specific areas of the

TABLE 24-2 Potential Epidemiologic Factors That Call for Increased Investigation or Monitoring

Factors	Reason
Disease located in one geographic area	Might indicate a point source of a disease agent that can be discovered and controlled
Severe symptoms/diagnoses such as encephalitis or death	Indicates disease process that needs rapid investigation because of severity
Rapid rise to very high numbers of illness two to three times normal baseline with steep epidemic curve	Potential for continuing rapid rise in numbers; requires immediate investigation to institute control measures
Outbreak detected and confirmed by multiple data sources	Unlikely to be attributable to error; possibly widespread
Outbreak occurring at an unusual time or place (e.g., respiratory/influenza-like symptoms in summer)	Might indicate targeted population or early signs in a susceptible population (e.g., very young or very old)
Outbreak confined to one age or gender group	Might indicate targeted population or early signs
Number of cases continuing to rise over time	Indicates sustained outbreak that might continue to grow

From Andersson T, Bjelkmar P, Hulth A, et al: Syndromic surveillance for outbreak detection and investigation. *Online J of Public Health Inform* 5:e78, 2013.

community. The exact time period of the outbreak/occurrence is important (be sure to go back to the first case or first indication of outbreak/occurrence activity). Given the diagnosis, describe what appears to be the period of exposure. Record the date of onset of morbidity/mortality cases and draw an epidemic curve. Determine whether the outbreak/condition originates from a common source or is propagated. Table 24-2 suggests factors to monitor and explains the reasons for their use. It provides clues to the use of time, place, and person.

As the investigation continues, develop a tentative hypothesis (the best guess about what is happening). Do a quick evaluation of the outbreak by assessing previous findings. Record, tabulate, and review data collected from the previously described activities to summarize common agent, environment, host factors, and exposures. On the basis of this analysis (and literature review if necessary), develop a hypothesis (best guess) on (1) the likely cause, (2) the source(s), and (3) the mode of transmission of the disease. The hypothesis should explain the majority of cases. Frequently, there will be concurrent cases not explained by the hypothesis that may be related to endemic or sporadic cases, a different disease or condition (similar symptomatology), or a different source or mode of transmission.

Test your hypothesis with other public health team members (e.g., epidemiologists). Many investigations do not reach this stage because of lack of available personnel, lack of severity of the problem, and lack of resources available. Situations that should be studied include disease/events associated with a commercial product, disease/events associated with considerable morbidity and/or mortality, and disease/events associated with environmental exposures (e.g., terrorist attack). Analyze data collected to determine sources of transmission and risk factors associated with disease/condition. Determine how this problem differs in incidence or exposure for other population groups. Refine the hypothesis (best guess) and carry out additional studies if necessary.

Evaluate the effects of control measures. Cases may cease to occur or return to endemic (normal) level. If the control interventions do not produce change, return to the beginning and start the investigation over or reevaluate cases. Use the

FIG 24-1 Hepatitis A cases reported in the United States and U.S. territories in 1 year.

opportunity of an outbreak to review and correct practices related to the current situation that may contribute to an outbreak in the future.

Communicate findings to those who should be notified. Communication of findings may take two forms: an oral briefing for local authorities or a written report. Describe the problem, the data collected, the case definition with verification of the diagnosis, data sources, the hypothesis, and testing of the hypothesis. Present only the facts of the situation, the data analysis, and the conclusions.

Displaying of Data

Reporting of data in an investigation needs to be valid: Does the event reported reflect the true event as it occurs? It must also be reliable: Is the same event reported consistently by different observers? A number of tools can be used to display data according to time, place, or person. The spatial map shows where the event is occurring and allows prevention resources to be targeted. Figure 24-1 provides a map of the location of reported cases of hepatitis A in the United States. From looking at this map, priority prevention target areas appear to be

TABLE 24-3 Example of Ways to Display Data* Number of Clients with Hepatitis A, by Month, for 4 Years

	Year 1	Year 2	Year 3	Year 4
January	12	20	21	16
February	14	19	26	19
March	7	21	8	27
April	12	10	11	13
May	5	0	11	0
June	4	11	1	6
July	5	5	9	8
August	5	9	12	7
September	6	7	13	8
October	15	8	10	70
November	?	8	11	0
December	0	11	20	0
Total	75	129	153	174

*This table shows the number of persons who match a case definition of a select infectious disease over a 4-year period. Note that for Year 4, there were overall more cases, especially in March and October, with a serious outbreak in October. Modified from [Centers for Disease Control and Prevention \(CDC\): Notifiable diseases and mortality tables. MMWR 63\(28\):ND-382-ND-395, July 18, 2014d](http://www.cdc.gov/mmwr/preview/mmwrhtml/mm6328md.htm?s_cid=mm6328md_w). Retrieved January 2015 from http://www.cdc.gov/mmwr/preview/mmwrhtml/mm6328md.htm?s_cid=mm6328md_w

Georgia, the District of Columbia, California, New Mexico, Kansas, and Florida. [Table 24-3](#) shows the number of cases of an infectious disease compared by month and year over 4 years. In this table, cases have increased by year with a serious outbreak in October of Year 4. When cases are reported by person, they are usually reported by a person's characteristics. Data displays are a step in analysis that shows graphically what is happening. It reduces the assumptions made about the event and provides a means for describing the event using quantitative data. Data help in stating your hypothesis or your best guess about what is happening (refer to the CDC website for additional information on outbreak investigations).

LEVELS OF PREVENTION

Surveillance Activities

Primary Prevention

Develop an approach for mass immunizations of citizens to prevent the occurrence of H1N1 in the community.

Secondary Prevention

Investigate an outbreak of flu-like illness in a local school.

Tertiary Prevention

Provide health care and treatment for those infected by H1N1.

LINKING CONTENT TO PRACTICE

Remember that disease and event surveillance systems exist to help improve the health of the public through the systematic and ongoing collection, distribution, and use of health-related data. A nurse can contribute to such systems and best use the data collected through such systems to help manage endemic health problems and those that are emerging, such as evolving infectious diseases and bioterrorist (human-made) health problems. Functions of surveillance and investigation are detecting cases, estimating the impact of disease or injury, showing the national history of a health condition, determining the distribution and spread of illness, generating hypotheses, evaluating prevention and control measures, and facilitating planning ([CDC, 2012](#)). Response to bioterrorism or large-scale infectious disease outbreak may require the use of emergency public health measures such as quarantine, isolation, closing public places, seizing property, mandatory vaccination, travel restrictions, and disposal of the deceased. In 2008 in preparation for a projected H1N1 flu epidemic, information was distributed about the use of several of these interventions, including isolation and closure of public places (see Appendix D-3).

Suggestions for protecting health care providers from exposure include use of standard precautions when coming in contact with broken skin or body fluids, use of disposable nonsterile gowns and gloves followed by adequate hand washing after removal, and use of a face shield ([CDC, 2012](#)).

The Robert Wood Johnson Foundation (RWJF) funded a project initiative focusing on the development of competencies and resources to enhance the ability of nursing professionals to deliver high-quality and safe nursing care. The Quality Safety Education for Nurses (QSEN) collaboration identified and defined six quality and safety competencies for nursing. In addition, the

project allowed for the development of proposed targets for the knowledge, skills, and attitudes of students for each of the six competencies that were identified by the Institute of Medicine as client-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics. The overall goal for the QSEN project is to meet the challenge of preparing future nurses who will have the knowledge, skills, and attitudes (KSAs) necessary to continuously improve the quality and safety of the health care systems within which they work. This chapter focuses on the importance of using informatics to identify, monitor, and intervene in unusual occurrences and events to protect the public and to keep communities safe (see [Chapter 26](#) for further discussion). Informatics in the QSEN project is defined as the use of information and technology to communicate, manage knowledge, mitigate error, and support decision making. The knowledge requirement for the public health nurse and student is to explain why information and technology skills are essential for safety. The skill to be developed is the seeking of education about how information is managed in the setting before providing an intervention. This chapter applies this by looking at trends of occurrences and events before investigating the situation and deciding on an intervention. It is also important to be able to use the databases and the tools of investigation to ensure safe processes of care. The attitude of engaging in continuous learning and the development of new technology skills is essential. In the case of an influenza pandemic and to assist clients in being safe during such an outbreak, the How To box entitled "Plan for Pandemic Flu, Using a Planning Checklist for Individuals and Families" provides steps for assisting individuals and families in preparation for such an occurrence.

HOW TO Plan for Pandemic Flu, Using a Planning Checklist for Individuals and Families

Nurses are responsible for assisting clients by providing them the means for safety. One of the roles of the nurse, to assure safety, is to assist clients in being prepared for an occurrence or an event in emergency and urgent situations that could compromise their health status or health outcomes. Following is a checklist to assist individual and family clients to prepare for a pandemic. Although this presents a process in preparation for pandemic flu, this process may be used in other communicable disease outbreaks that may reach pandemic proportions.

Use this as a guide to educate clients if an epidemic or pandemic is forecast:

Prepare for an influenza pandemic as soon as it is forecast. Prepare clients with the knowledge of both the magnitude of what can happen during a pandemic outbreak and what actions can be taken to help lessen the impact of an influenza pandemic on the client(s). This checklist helps to gather the information and resources needed in case of a flu pandemic.

1. To plan for a pandemic: the client(s) will want to:

- Store a 2-week supply of water and food.
- During a pandemic, if clients cannot get to a store, or if stores are out of supplies, it will be important to have extra supplies on hand.
- This can be useful in other types of emergencies, such as power outages and disasters.
- Periodically check regular prescription drugs to ensure a continuous supply at home.
- Have nonprescription drugs and other health supplies on hand, including pain relievers, stomach remedies, cough and cold medicines, fluids with electrolytes, and vitamins.

2. To limit the spread of germs and prevent infection:

- Teach children to wash hands frequently with soap and water, and suggest that family members model the current behavior.
- Teach children to cover coughs and sneezes with tissues, and be sure to model that behavior in families.

- Teach children to stay away from others as much as possible if they are sick.
 - Encourage family members to stay home from work and school if sick.
3. Items to have on hand for an extended stay at home:
- Examples of food and nonperishables
 - Ready-to-eat canned meats, fish, fruits, vegetables, beans, and soups
 - Protein or fruit bars
 - Dry cereal or granola
 - Peanut butter or nuts
 - Dried fruit
 - Crackers
 - Canned juices
 - Bottled water
 - Canned or jarred baby food and formula
 - Pet food
 - Examples of medical, health, and emergency supplies
 - Prescribed medical supplies such as glucose and blood pressure-monitoring equipment
 - Soap and water, or alcohol-based (60% to 95%) hand wash
 - Medicines for fever, such as acetaminophen or ibuprofen
 - Thermometer
 - Antidiarrheal medication
 - Vitamins
 - Fluids with electrolytes
 - Cleansing agent/soap
 - Flashlight
 - Batteries
 - Portable radio
 - Manual can opener
 - Garbage bags
 - Tissues, toilet paper, disposable diapers

Excerpted and adapted from the U.S. Department of Health and Human Services: Plan for pandemic flu using a planning checklist for individuals and families, 2006. Available at www.flu.gov. Accessed October 28, 2010.

PRACTICE APPLICATION

As a clinical project, the health department asked the public health nursing class at the university to develop a community service message to air on local radio about the potential of a

pandemic flu H1N1 outbreak in 2014. What does the message need to contain to help the community prepare?

Answers can be found on the Evolve site.

KEY POINTS

- Disease surveillance has been a part of public health protection since the 1200s, during the investigations of the bubonic plague in Europe.
- By 1925 the United States began national reporting of morbidity causes.
- Surveillance provides a means for nurses to monitor disease trends in order to reduce morbidity and mortality and to improve health.
- Surveillance is a critical role function for nurses practicing in the community.
- Surveillance is important because it generates knowledge of a disease or event outbreak patterns.
- Surveillance focuses on the collection of process and outcome data.
- Although surveillance was initially devoted to monitoring and reducing the spread of infectious diseases, it is now used to monitor and reduce chronic diseases and injuries, and environmental and occupational exposures.

KEY POINTS—cont'd

- Surveillance activities can be related to the core functions of public health of assessment, policy development, and assurance.
- A quality surveillance system requires collaboration among a number of agencies and individuals.
- *The Minnesota Model of Public Health Interventions: Applications for Public Health Nursing Practice* (2001) suggests that surveillance is one of the interventions related to public health nursing practice.
- Clinicians, health care agencies, and laboratories report cases to state health departments. Data also come from death certificates and administrative data such as discharge reports and billing records.
- Each of the data sources has the potential for under-reporting or incomplete reporting. However, if there is consistency in the use of surveillance methods, the data collected will show trends in events or disease patterns that may indicate a change needed in a program or a needed prevention intervention to reduce morbidity or mortality.
- The National Notifiable Disease Laboratory, hospital discharge data, and billing data provide mechanisms for classifying diseases and events and calculating rates of diseases within and across groups, populations, and communities.
- The sentinel surveillance system provides for the monitoring of key health events when information is not otherwise available or in vulnerable populations to calculate or estimate disease morbidity.
- In 1990 the CDC and the Council of State and Territorial Epidemiologists assembled the first list of standard case definitions.
- Reporting of disease data by health care providers, laboratories, and public health workers to state and local health departments is essential if trends are to be accurately monitored.
- Requirements for reporting diseases are mandated by law or regulation.
- Criteria for defining cases of different diseases are essential for having a uniform, standardized method of reporting and monitoring diseases. A case definition provides understanding of the data that are being collected and reduces the likelihood that different criteria will be used for reporting similar cases of a disease.
- Surveillance systems in use today are defined as *passive*, *active*, *sentinel*, and *special*.
- Any unusual increase in disease incidence (new cases) or an unusual event in the community should be investigated.
- Patterns of occurrence can be identified when investigating a disease or event. These patterns are used to define the boundaries of a problem to help investigate possible causes or sources of the problem.
- Factors that must be considered as causes of outbreak are categorized as agents, hosts, and environmental factors.
- An unusual increase in disease incidence should be investigated.
- Functions of surveillance and investigation are detecting cases, estimating the impact of disease or injury, showing the national history of a health condition, determining the distribution and spread of illness, generating hypotheses, evaluating prevention and control measures, and facilitating planning.

CLINICAL DECISION-MAKING ACTIVITIES

1. Call the local health department and attend an emergency response team planning meeting. How many agencies are involved? Determine the roles of each agency. Does the nurse have a role on the team? Explain.
2. Go to the Health Hazard Evaluation program website (see WebLinks). What is the purpose of this program? How would information from the website be used in a disease investigation?
3. Explain the purpose of applying the sentinel system to improve population health outcomes.

Program Management

Marcia Stanhope, PhD, RN, FAAN

Dr. Marcia Stanhope is currently an Associate of the Tuft and Associates Search Firm, Chicago, Ill. She is also a consultant for the nursing program at Berea College, Kentucky. She has practiced community and home health nursing, has served as an administrator and consultant in home health, and has been involved in the development of two nurse-managed centers. At one time in her career, she held a public policy fellowship and worked in the office of a U.S. Senator. She has taught community health, public health, epidemiology, policy, primary care nursing, and administration courses. Dr. Stanhope formerly directed the Division of Community Health Nursing and Administration and served as Associate Dean of the College of Nursing at the University of Kentucky. She has been responsible for both undergraduate and graduate courses in population-centered nursing. She has also taught at the University of Virginia and the University of Alabama, Birmingham. During her career at the University of Kentucky she appointed to the Good Samaritan Foundation Chair and Professorship in Community Health Nursing, and was honored with the University Provost's Public Scholar award. Her presentations and publications have been in the areas of home health, community health and community-focused nursing practice, as well as primary care nursing.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Compare and contrast the program management process and the nursing process.
2. Analyze the application of the program planning process to nursing.
3. Critique a program planning method to use in nursing practice.
4. Analyze the components of program evaluation methods, techniques, and sources.
5. Compare different types of cost studies applied to program management.

Program Funding

Program management consists of assessing, planning, implementing, and evaluating a program. This chapter focuses primarily on planning and evaluation. Although presented in separate discussions, these factors are related and interdependent processes that work together to bring about a successful program. This chapter does not address implementing programs because other chapters in this text focus on implementation.

The program management process is parallel to the nursing process. One process is applied to a program that addresses the needs of a specific population, whereas the other process is applied to individuals or families. The process of program management, like the nursing process, consists of a rational decision-making system designed to help nurses know when to make a decision to develop a program (through the needs assessment and defining the problem), where they want to be at the end of the program (goal setting), how to decide what encompasses a successful program (planning), how to develop a plan to go forward so they will know where they want to be (implementing), how to know that they are getting there (**formative evaluation**), and what to measure to know that the program has successful outcomes (**summative evaluation**).

Today there is a greater need for the nurse to be accountable for nursing actions and client outcomes. Prospective payment systems, pay for performance, health care reform, and integrated care delivery models have changed the focus of nursing. Planning for nursing services is necessary today if the nurse is to survive in the health care delivery field. Nurses are expected to demonstrate leadership in addressing community-based health problems.

This chapter examines how nurses can act, instead of react, by planning programs that can be evaluated for their effectiveness. The discussion focuses on the historical development of health planning and evaluation, a general program planning and evaluation method, the benefits of planning and evaluation, the elements of planning and evaluation, how cost studies are applied to program evaluation, and how programs may be

funded. Some sections of this chapter can be used by undergraduate students, whereas other sections are more appropriately used by graduate students.

DEFINITIONS AND GOALS

Community health planning is population focused, and it positions the well-being of the public above private interests (American Planning Association, 2013). A **program** is an organized approach to meet the assessed needs of individuals, families, groups, populations, or communities by reducing the effect of or eliminating one or more health problems. Community health programs are planned to meet the needs of designated populations or subpopulations in a community. Many programs exist as specific efforts within the umbrella of large, complex organizations such as state health departments, universities, health systems, and private organizations such as insurance companies. Unlike these complex organizations, smaller programs are endeavors that focus on more specific services and communities or groups. Specific examples in population-focused nursing are home health, immunization and infectious disease programs, health-risk screening for industrial workers, and family planning programs. These are usually conducted under the direction of the total plan of a local health department, a managed care agency, or, in some instances, an insurance company. Examples of more complex broadly based group and community programs are the community school health, occupational health and safety, environmental health, and community programs directed at preventing specific illnesses through special-interest groups (e.g., American Heart Association, American Cancer Society, March of Dimes). Disaster preparedness is a type of program that may be conducted through collaborative efforts of several community organizations or agencies.

Programs are ongoing organized activities that become part of the continuing health services of a community or organization, whereas **projects** are smaller, organized activities with a

limited time frame. A health fair and a blood pressure screening day at the mall are examples of projects that nurses may implement.

Planning is defined as the selecting and carrying out of a series of activities designed to achieve desired improvements (Issel, 2013). The *goal* of planning is to ensure that health care services are acceptable, equal, efficient, and effective. Planning provides a blueprint for coordination of resources to achieve these goals. **Evaluation** is determining whether a service is needed and can be used, whether it is conducted as planned, and whether the service actually helps people in need (Royse, 2010). Evaluation is a process of accountability. Evaluation for the purpose of assessing whether objectives are met or planned activities are completed is referred to as *formative* or *process evaluation*. This type of evaluation begins with an assessment of the need for a program and involves ongoing monitoring of the activities conducted by the program. Evaluation to assess program outcomes or as a follow-up of the results of the program activities is called *summative* or *impact evaluation*.

Program evaluation is an ongoing process from the beginning of the planning phase until the program ends. It is used to make judgments about improving, managing, and continuing programs. The major goals of program evaluation are to determine the relevance, adequacy, progress, efficiency, effectiveness, impact, and sustainability of program activities (USDHHS, 2011).

HISTORICAL OVERVIEW OF HEALTH CARE PLANNING AND EVALUATION

As the health care delivery system has grown during the last century, emphasis on health planning and evaluation has increased. Factors that have intensified interest in planning and evaluation are advances in health care technology and consumer education, escalating health care costs, increased consumer expectations, third-party payers, focus on health care as a business, personnel shortages, unionizing of health care workers, professional conflicts, focus on preventive care, recognition of increasing health disparities, and the threats from terrorism, natural disasters, and emerging infectious diseases. From the 1920s to the 1940s, specific actions were initiated that related to health planning. Table 25-1 outlines the development of health planning.

The post–World War II era brought an interest in evaluating **program effectiveness**. As government and third-party payers began to finance health care services and money became more plentiful, public demand for health services grew. As a result, numbers and kinds of health care agencies increased; laws were passed to increase the scope of and control over health care, and the health care delivery system began to be held accountable for its actions. During this time, legislation was passed to require health care providers and consumers to work together in groups to address issues in health care.

Through the 1970s, laws were passed to provide more comprehensive structure and more power over federal program funds. In 1974 Congress enacted the National Health Planning and Resources Development Act. This legislation had the goal

of reducing the growth of health care costs by ensuring that only needed services and facilities would be added to the health care system. Under this legislation, health care providers were required to obtain a certificate of need (CON) in order to add services or facilities. However, very little authority existed to carry out some of the more critical tasks of improving the health of clients, increasing access and quality of services, restraining costs, and preventing the duplication of unnecessary services. Power over the private health care sector continued to be absent.

As “the new federalism” became the catch phrase of the 1980s and emphasis was placed on shifting costs, reducing costs, and providing more competition within the health care system, President Ronald Reagan proposed eliminating the federal government’s role in health planning. In 1981, with cutbacks in federal spending, states began the takeover or dismantling of their own health planning systems. The national health planning system came to a halt. The federal, state, and consumer partnership for health care was ended.

In 1993, with President Bill Clinton’s emphasis on health care reform, the decision was made that the government would continue to not be involved in health planning. It would use its power to set limits on health insurance costs and limit overall health care spending. In this way, it would influence health planning decisions made by the private health care agencies and providers (Sparer, 2011). Although national health care reform did not occur, many states engaged in reforming their systems.

Today, in the early years of the twenty-first century, the process of health planning is not coordinated but is for the most part in the control of different interests in the health care industry. The health care system has been mainly shaped by decisions of hospitals, physicians, pharmaceutical companies, equipment companies, insurance companies, and managed care organizations, which determine where, how, and for whom health care will be delivered. Although the federal health planning legislation is no longer in effect, some states continue to have health system agencies (HSAs), even though these organizations have much less authority than when they were established in the 1970s. In some states, the HSA must approve the planned expanding of agencies or services, and a CON must be issued by the state before these plans may proceed. The primary purpose of such health planning is to improve the health of local communities by increasing available and accessible services, preventing the duplication of services, and controlling health care costs.

The political party in power often influences the outcome of the national and state health planning efforts. To impact the direction of health care reform, nurses must be involved in all aspects of health planning for the community in which they live. An example of this is the passage of the Affordable Care Act, led by President Obama and the Democratic party in March 2010, which addresses planning at national, state, and local levels (PL 111-148). The **American Nurses Association (March 2010)** reports numerous activities nurses participated in related to the health care reform effort (see <http://www.nursingworld.com/healthcarereform>).

TABLE 25-1 Historical Development of Health Planning and Evaluation

Year	Initiator	Action-Purpose
Late 1800s	Lumber, railroad, mining, and other industry	Contract with providers for health care to maintain health of workers.
1920	Committees on administrative practice and evaluation of American Public Health Association	Called for public health officers to engage in better program planning. Reduced haphazard methods used to develop public health programs.
1920s	Committee on costs of medical care	Studied social and economic aspects of health services. Cited the need for comprehensive health care planning because of rising costs and unequal health care services to target populations.
1921	Congress	Sheppard Towner Act on Maternity and Infancy provided first continuing program of federal grants-in-aid for state health departments to provide direct care. States established maternal-child divisions with the funding.
1930s	Federal government, Congress	Blue Cross Insurance founded for provision of prepayment for hospital services in response to Great Depression and increased cost of health care.
1935	Federal government, Congress	Social Security Act passed. This was an early movement to provide resources for the elderly and impoverished.
1944	American Hospital Association	Established committee on postwar planning.
1946	Federal government, Congress	Passed the Hospital Survey and Construction Act (Hill-Burton Act) to legislate health planning, which resulted in increase in number of hospitals.
1963	Federal government, Congress	Community Mental Health Centers Act (PL 88-464) passed to provide mental health programs in the states; defined the role of consumers in making decisions and of professionals as advisors in the planning process.
1965	U.S. Department of Health and Human Services	Office of Health Planning opened; no direct authority for health planning given.
1965	Federal government, Congress	Passed regional medical program legislation (PL 89-239); upgraded quality of tertiary health care services for the leading causes of death. Coined the term <i>Partnership for Health</i> .
1966	Federal government, Congress	Passed the Comprehensive Health Planning (CHP) and Public Health Services amendments (Public Law 89-749). Developed a national health planning system.
Late 1960s to early 1970s	Individual state legislation	Certificate of Need established as a check against duplication of services. Limited new construction, plant modernization, and major technology.
1973	President Nixon	Government encouragement for health maintenance organizations (HMOs) for prepaid health insurance with emphasis on preventive health efforts.
1974	Federal government, Congress	Passed National Health Planning and Resources Development Act (Public Law 93-641), which provided specific directions for developing the structure, process, and functions of a national health planning system.
1980	U.S. Department of Health and Human Services	Began <i>Healthy People</i> initiative. Support for national level assessment, data collection, analysis, goal setting, and evaluation for the U.S. population.
1982	Congress	Tax Equity and Fiscal Responsibility Act (TEFRA) imposed financial cuts to Medicare and Medicaid and directed the Department of Health and Human Services (DHHS) to instill a prospective payment system for hospitals. Capitation through prospective payment was created with diagnosis-related groups (DRGs).
1993	President Clinton	Introduced Health Security Act to provide for health care reform and planning based on population needs (not passed).
2000	Congress	Home Health Prospective Payment System placed capitation on Medicare home health expenses based on clinical assessment of recipients using the Outcome and Assessment Information Set (OASIS).
2001	Congress	Creation of Department of Homeland Security following the terrorist attacks of September 11, 2001. Consolidated selected government departments into one entity for providing national security.
2004	CDC	Development of guidelines for distribution of flu vaccine to the U.S. population following flu vaccine recall.
2005	Hurricane Katrina	This natural disaster on the Gulf Coast and New Orleans shed light on deficiencies of government for emergency planning at local, state, and national levels.
2010	President Obama	Passage into law of the Patient Protection and Affordable Health Care Act (Public Law 111-148).

In addition to health planning in the external environment, internal health care agency planning is necessary to meet the goals and objectives of providing efficient, effective health care services to clients at a reasonable cost. Health care planning within the community and national health care planning affect health planning within an agency. For example, following the attack on the World Trade Center in 2001, there was much emphasis on developing national and community health plans for emergency preparedness and to prevent terrorism. In a comprehensive reorganization of the federal government, President George W. Bush created the Department of Homeland Security. This reorganization consolidated 22 federal agencies into a single department with the goal of protecting America from terrorism. In addition, states and communities have been given federal monies to develop their own plans. Agencies within communities have been asked to develop emergency preparedness plans and to be a part of community plans.

Public health personnel have a responsibility to participate in internal planning and evaluation to solve the problems of a client population and to ensure the delivery of health services that are accessible, acceptable, and affordable. Emphasizing population health means focusing on the health outcomes of a group of persons, including the health outcome distribution in that group (IHI, 2012).

BENEFITS OF PROGRAM PLANNING

Systematic planning for meeting the health needs of populations in a community has benefits for clients, nurses, employing agencies, and the community. It ensures that available resources are used to address the actual needs of people in the community, and it focuses attention on what the organization and health provider are attempting to do for clients. Planning assists in identifying the resources and activities that are needed to meet the objectives of client services. It also reduces role ambiguity (uncertainty) by giving responsibility to specific providers to meet program objectives (IHI, 2012).

Furthermore, planning reduces uncertainty within the program environment and increases the abilities of the provider and the agency to cope with the external environment. Everyone involved with the program can anticipate what will be needed to implement the program, what will occur during the implementation process, and what the program outcomes will be. Planning helps the provider and the agency anticipate events. Also, planning allows for quality decision making and better control over the actual program results by setting specific goals, examining those goals regularly to determine whether the agency continues with the existing programs or makes changes based on the needs of the population they serve. Today, this type of planning is referred to as **strategic planning**, and it involves the successful matching of client needs with specific provider strengths and competencies and agency resources. Managers of programs engage in *management planning*. This type of planning assists managers to determine whether the resources of the agency are used properly to actually implement the agency programs. The type of planning emphasized in this chapter is the program planning process (Kettner et al, 2012). This planning

process shifts from a focus on the agency as a unit to one aspect of the agency. Program planning reflects the desire to implement a reality-based program that can be readily evaluated and can reduce the number of unexpected events that occur in a defined population. There can be numerous programs within an agency, and each needs to engage in program planning and evaluation. A major national program to assist communities to plan, organize, and develop programs specific to their needs is the Centers for Disease Control and Prevention's program planning model (CDC, 2014).

ASSESSMENT OF NEED

Planning for effective and efficient programs must be based on identifying the needs of populations within a community. Identification of at-risk groups and documentation of the health needs of the targeted population provide the basic justification and rationale for the proposed program plan. Such documentation of need is essential if funding will be required to implement the plan. Funding is always required either from the agency or the community at large unless the program is totally voluntary. An assessment of health needs may be approached as either a community assessment or a population needs assessment.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency-Quality Improvement

Uses data to monitor outcomes of care processes and uses improvement methods to design and test changes to continually improve quality and safety of health care systems

- **Knowledge:** Describe approaches for changing processes of care
- **Skill:** Identify gaps between local and best practice
- **Attitude:** Value measurement and its role in good client care

QI Question

The PHN Quad Council has identified a beginning PNH competency as policy development and program planning skills. The beginning PHN participates in developing organizational plans to implement programs and policies and participates in evaluating programs as a team member. How could the new PHN best contribute to program management? What type of activity might the PHN participate in to determine gaps in existing programs?

Community Assessment

A thorough assessment of a community is necessary to provide a clear understanding of the overall health status of a community, to identify populations at risk, and to document health needs. Public health agencies, health planners, nurses, and agencies wishing to address the true needs of a community benefit from accurate and thorough community assessment data. (CDC, 2014b; NACCHO, 2014)

A **community assessment** is comprehensive. It is a population-focused approach that views the entire community as the client. Community assessment considers all of the people in a community for the purpose of identifying the most vulnerable populations and determining unmet health needs. All of the services of a community are examined to assess their effect on the health of the population, and the environment is assessed for its

impact on the health of the people. For example, some vulnerable groups may lack access to existing services because of lack of transportation, or there may be a high prevalence of asthma because of air pollution from a particular industrial source (see [Chapter 18](#)).

Community assessment begins with the collection of existing data (secondary data). Variables related to the characteristics of the population in the community include demographic data such as age, sex, ethnic group/race, income, occupation, education, and health status. Such data, which for most communities are readily available on the Internet, are derived from census data and morbidity and mortality statistics. Much can be learned about a community through use of secondary data found on the Internet ([UNC, 2014](#)). In addition, data about communities may be found in local libraries, courthouse records, service agencies, newspapers, the phonebook, and other local resources. Public health departments are also good sources of secondary data.

New data about the community may be collected through surveys or interviews with community members and key informants. When community members have a voice in clarifying norms and values of their community, in identifying needs, and in planning programs, community acceptance and use of that program are likely to be increased ([CDC, 2014b](#)).

Variables related to people, resources, and the environment of a community may be determined by using existing models that provide an organizing framework for the collection and analysis of data. (For more information about community assessment and the community-as-partner model, see [Chapter 18](#).)

Population Needs Assessment

Agencies or health care providers are frequently interested in providing a specific service in a community and want to assess

the need for that service in a target population. In this case, an assessment may be focused on determining the needs of a specific population in a community. Population health is the basis for doing the *assessment of need*, which is defined as a systematic appraisal of type, depth, and scope of problems as perceived by clients or health providers, or both ([CDC, 2014](#); [NACCHO, 2014](#)).

A **population needs assessment** focuses on the characteristics of a specific population, its health needs, and the resources available to address those needs. For example, a nurse may want to initiate a health education program for older adults with diabetes, to establish an immunization program for children of a certain age, or to provide health services for migrant workers. In each case, assessment would focus on the characteristics and health status of the target population and the resources available to address the identified need for that group. When assessing a population, the same types of data collected for community assessment are collected and entered for the population, such as demographic data.

It is important to avoid planning services that do not focus on the health needs of the target population and services already provided by other agencies. A needs assessment determines gaps in or duplication of needed services (i.e., their availability), examines the quality of existing resources to meet the identified needs (i.e., their adequacy), and identifies barriers to the use of existing resources (i.e., their acceptability).

A number of needs assessment tools exist to assist the nurse in the needs assessment process. The major sources of information used for needs assessment, summarized in [Table 25-2](#), are census data, key informants, community forums, surveys of existing community agencies with similar programs, surveys of residents of the community to be served (client population), and statistical indicators ([Kettner et al, 2012](#)).

TABLE 25-2 Summary of Needs Assessment Tools

Name	Definition	Advantages	Disadvantages
Community forum	Community, group, organization, open meeting	Low cost Learn perspectives of large number of persons	Limited data Limited expression of views Discourages less powerful Becomes arena to discuss political issues
Focus groups	Open discussion with small representative groups	Low cost Clients participate in identification of need Initiates community support for the program	Time consuming Allows focus on irrelevant or political issues
Key informant	Identify, select, and question knowledgeable leaders	Provides picture of services needed	Bias of leaders Community characteristics may be incorrectly perceived by informants
Indicators approach	Existing data used to determine problem	Excellent data on problems and characteristics of client groups	Growth and change in population may make data outdated
Survey of existing agencies	Estimates of client populations via services used at similar community agencies	Easy method to estimate size of client group Know extent of services offered in existing programs	Records and data may be unreliable All cases of need may not be reported Exaggeration of services may occur
Surveys	Measurement of total or sample client population by interview or questionnaire	Direct and accurate data on client population and their problems	Expensive Technically demanding Need many interviews or observations Interviews may be biased

TABLE 25-3 Basic Planning Process

Basic Planning	Elements
1. Formulating	Client identifies problems.
2. Conceptualizing	Provider group identifies solutions.
3. Detailing	Client and provider analyze available solutions.
4. Evaluating (the plan)	Client, providers, and administrators select best plan.
5. Implementing	Best plan is presented to administrators for funding.

Nurses working in community agencies who identify unmet needs among vulnerable populations can initiate program development and find funding to provide needed services and modify health disparities. For example, staff public health nurses in one community identified a need for schools to have more school health nurses, especially to meet the needs of unserved children in poverty. The nurses held a series of meetings with key informants, surveyed health departments of surrounding counties, and found an unknown source of funds through the state Medicaid program that would reimburse public health nurses for providing school health services. The result was the development of a program to increase the numbers of school health nurses in the community.

PLANNING PROCESS

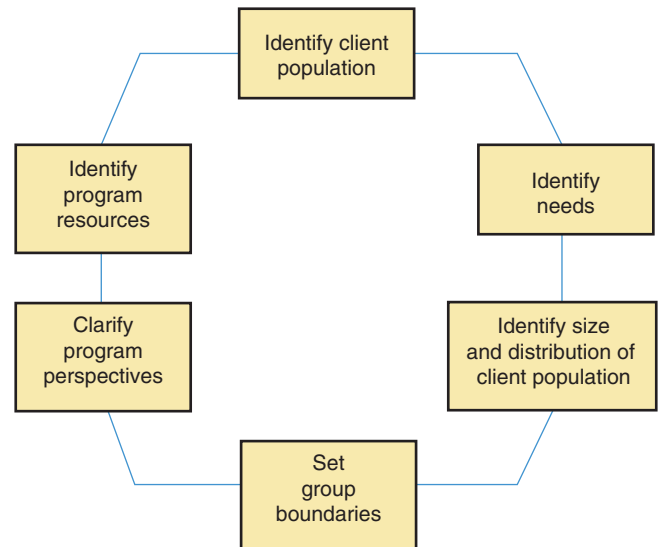

Health program planning is affected by government control over licensure and funding by political forces, and by the culture and belief system of the population in which the program must function. Program planning is required by federal, state, and local governments; by philanthropic organizations; and by the employing agency. Planning programs and planning for the evaluation of programs are two very important activities, whether the program being planned is a national health insurance program such as Medicare, a state health care program such as an early childhood development screening program, or a local program such as vision screening for elementary school children. Regardless of the type of program, the planning process is the same.

Nutt (1984) describes a basic planning process that is reflected in the steps of most planning methods and remains a great influence on strategic planning for population health and health programs today (Issel, 2013). The process includes five planning stages: formulating, conceptualizing, detailing, evaluating, and implementing (Table 25-3).

Basic Program Planning Model Using a Population-Level Example

Formulating

The initial and most critical step in planning a health program is defining the problem and assessing client need. This stage in the planning process can be *proactive*, projecting a future need; *reactive*, defining the problem based on past needs; *inactive*, defining the problem on the basis of the existing health state of the population to be served; or *interactive*, describing the

**FIG 25-1** Steps in the needs assessment process.

problem using past and present data to project future population needs.

Needs assessment is a key component of the planning process in the formulating stage. The target population or client to be served by any program must be identified and involved in every stage of designing the program. To avoid duplication or gaps in services, program planners must verify that a current health problem exists and is being either ignored or unsuccessfully treated in a client group. Data provide the rationale to establish a new program or revise existing programs to meet the needs of the client group. The client population should be defined specifically by its demographic and psychosocial characteristics, by geographic location, and by problems to be addressed (Figure 25-1).

For example, in a community with a large number of preschool children who require immunizations to enter school, the client population may be described as all children between 4 and 6 years of age residing in Central County who have not had up-to-date immunizations. A health education program may be necessary to alert the population to the existing need. In the example of the need for immunizing preschool children, public service announcements on television and radio and in newspapers may be used to alert parents to laws requiring immunizations, to the continuing problems with communicable diseases, and to the outcomes of successful immunizing programs, such as vaccination programs that have been successful in eliminating smallpox worldwide. A good example of the use of media can be found in a press release by the Centers for Disease Control and Prevention highlighting the threat of measles to health security locally and globally (CDC, 2013).

Specifying the size and distribution of a client population for a program involves more than counting the number of persons in the community who may be eligible for the program. It involves determining the number of persons with the problem who are not being served by existing programs and the numbers of eligible persons who have and have not taken advantage of existing services. For example, consider again the community

need for a preschool immunization program. In planning the program, the size of the population of preschool children in the county may be obtained from census data or state vital statistics. The nurse then must determine the number of children unserved and the number of children who have not used services for which they are eligible. Today there are many opportunities to locate the unserved children through early start programs for preschool children.

Boundaries for the client population are primarily established by defining the size and distribution of the client population. The boundaries will stipulate who is included in and who is excluded from the health program. If the fictional immunization program were designed to serve only preschool children of low-income families, all other preschool children would be excluded.

Perspectives on the program, or what people think about the need for a program, might differ between health providers, agency administrators, policy makers, and potential clients. These groups are considered the stakeholders in the program. Collecting data on the opinions and attitudes of all persons, whether directly or indirectly involved with the program, is necessary to determine if the program is feasible, if there is a need to redefine the problems, or if a new program should be developed or an existing program should be expanded or modified. If a new or changed program is to be successful, it must not only be *available*, but also be *accessible* and *acceptable* to the people who will use it. For example, policy makers in the 1970s decided that neighborhood health clinics were the answer to providing services for low-income residents. They discovered that their perspective was not the same as those of most health providers and clients, who did not support development of neighborhood clinics.

The neighborhood health clinics have evolved over time to better reflect clients' perspectives. It is important for policy makers to explore the perspectives of the clients when planning the program. Clients might choose another type of service to offer rather than the one the policy maker or provider thinks best for them. The needs to be met for the client population must be identified by both the client and the health provider if the program is to be accepted by the client population. If the client population does not recognize the need, the program will usually be unsuccessful. Today community health centers have replaced the concept of the neighborhood health centers, and these centers are being supported and increased in number by health care reform (Shin, 2015).

Before implementing a health program, the nurse must also identify available resources. *Program resources* include financing, personnel, facilities, and equipment and supplies. The source and amount of funds must be adequate to support the program. The number and kinds of personnel required and available must be determined. There must be a place for the program to operate, and up-to-date equipment and supplies are essential. If any one of the four categories of resources is unavailable, the program is likely to be inadequate to meet the needs of the client population. If planners consider the problem to be a critical one, funding may be sought by seeking donations or by writing a proposal for grant funds to support the program. A well-done

assessment provides direction and suggests strategies for appropriate interventions (see the [Evidence-Based Practice](#) box).

EVIDENCE-BASED PRACTICE

The prevention of youth violence is a priority community health concern across the nation. A thorough community needs assessment of suburban Cook County (SCC), Illinois, revealed the leading cause of death for people aged 15 to 25 years was homicide, at a rate three times the national rate. Furthermore, significant health disparities existed with African Americans nearly 15 times more likely and Hispanics five times more likely to die of homicide than whites. The Cook County Health Department of Public Health (CCDPH) set a goal to reduce the incidence of violence in communities suffering from disproportionate rates of violent acts.

The CCDPH sought to introduce community stakeholders, including key community leaders, social service workers, and nurses, to the *Blueprints for Violence Prevention* program. *Blueprints* is a web-based program that provides communities with a set of evidence-based youth violence prevention programs and an interactive system for selecting population-specific programs. The focus of this project was to provide the CCDPH Prevention Services Unit and community members with the tools necessary to select evidence-based violence prevention programs. *Blueprints* and current available funding sources were presented through hands-on workshops. A nurse practitioner from the Loyola University Medical Center served as the project director. The 2½-hour educational program sessions provided participants with an overview of the *Blueprints* program, an opportunity to use the interactive program search feature, and reviewed available funding sources for youth violence prevention programs. At the end of the educational program, participants evaluated the program by completing a 5-point Likert survey in which participants evaluated the program content, delivery of the content, and its relevance to the participant and their community. To assess program impact telephone interviews of program participants were also conducted three weeks after the session. These interviews consisted of open-ended questions focused on progress toward adopting a youth violence prevention program. Three themes emerged from the program evaluation: (1) hands-on, interactive sessions were an effective learning strategy; (2) participants voiced a need for collaboration and the formation of partnerships for effective programming within the districts; and (3) for sustainability of the program, community members must have access to "live" experts on the *Blueprints* program.

Nurse Use

Educational workshop programs are an effective strategy for informing the community about available resources. Nurses can teach leaders in the community how to identify and evaluate evidence-based prevention programs. By educating key stakeholders, community mobilization on priority health needs is strengthened.

From Ruffolo DC, Andresen PA, Winn KL: Meeting the needs of a community: teaching evidence-based youth violence prevention initiative to members of strategic communities. *J Trauma Nurs* 20(1):24–30, 2013.

Conceptualizing

The need and demand for a program are determined through the formulating process. The conceptualizing stage of planning creates options for solving the problem and considers several solutions. Each option for program solution is examined for its uncertainties (risks) and consequences, leading to a set of **outcomes**. The outcomes sought are improvements in the health status of the population served by the program.

A first step in the conceptualizing process is a review of the literature to determine what approaches have been used in other places with similar problems, and with what success. Such review can assist nurses to improve the quality, effectiveness, and appropriateness of health programs by synthesizing the evidence and translating it into practice (**evidence-based practice**). Review of the literature should be guided by the following question: What can be learned from the experience of others in similar circumstances?

Some alternative solutions to the problem will have more risks or uncertainties than others. The nurse must decide between a solution that involves more risk and a solution that is free of risk. A “do nothing” decision is always the decision with the least risk to the provider. When choosing a solution, the nurse looks at whether the desired outcome can be achieved. After careful thought about each possible solution to the problem, the nurse rethinks the solutions. The assessment data compiled during the formulation stage should be used to develop alternative solutions.

Decision trees are useful graphic aids that give a picture of the solutions and the risks of each solution. Such a picture graph of the process of identifying a solution helps clients and administrators rank the consequences of a decision (Sanders, 2009). Figure 25-2 shows an example of a decision tree.

As shown in Figure 25-2, the best consequence would be for each low-income child to be given flu immunization by their private physician. One must consider the value of this action to the person, the odds that immunizations will be obtained, the cost to families as opposed to the taxpayer, and the cost to the community. Costs to the community include the possibility of increased incidence of communicable disease or mortality and increased need for more expensive services to treat the diseases if vulnerable people are not immunized. Conversely, if families

self-pay for the immunizations, costs to the taxpayer and to the community are low.

Detailing

In this phase, the provider, with client input, considers the possibilities of solving a problem using one of the solutions identified. The provider details (or is specific about) the costs, resources, and program activities needed to choose one of the solutions from the conceptualizing phase. For each of the three proposed alternatives shown in the immunization scenario in Figure 25-2, the program planner lists the activities that would need to be implemented. Using the proposed solution of encouraging families to see their private physicians for the vaccine (the best consequence), examples of activities include developing a script for a health education program and implementing a television program to encourage parents to see a physician. If an alternative that produced the second, third, fourth, or fifth best consequence was chosen, offering a clinic at the health department or providing a mobile clinic to each daycare center to provide the immunizations would be possible activities.

For each alternative, the nurse lists the resources needed to implement each activity. The resources to be considered include all costs of personnel, supplies, equipment, and facilities, and the potential acceptance by the clients and the administrators of the program. In the example, personnel could include nurses, volunteers, and clerks; supplies might include handouts, Band-Aids, vaccines, records, and consent forms; equipment might include syringes, needles, stethoscopes, and blood pressure cuffs; and facilities might include a television studio for a media blitz on the education program and a room with examination tables, chairs, and emergency carts. The total costs of each solution must be considered. As indicated, clients should review each solution for acceptance.

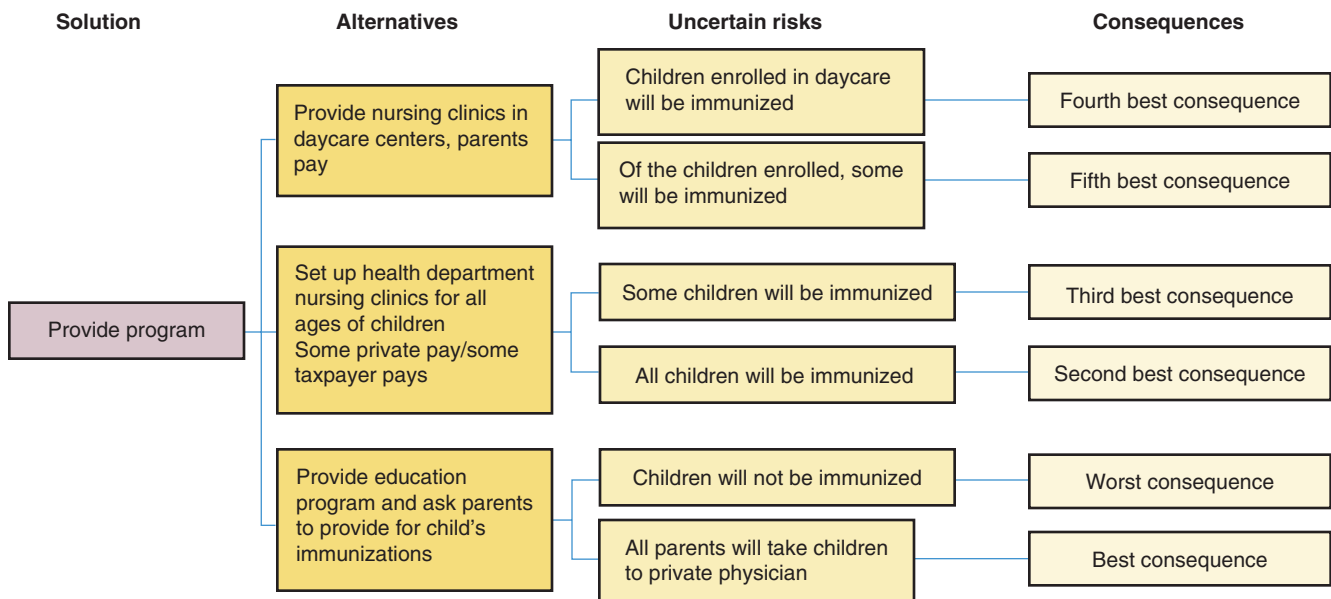

FIG 25-2 Ranking of solutions to a problem: providing a preschool immunization program to low-income children using a decision tree.

Evaluating

In the evaluation phase of the plan, each alternative is weighed to judge the costs, benefits, and acceptance of the idea to the client population, community, and providers. The information outlined in the detailing phase would be used to rank the solutions for choice by the client population and provider on the basis of cost, benefit, and acceptance. Consideration must be given to the solution that will provide the desired outcomes. Review of the literature or interviews might disclose whether someone else had previously tried each of the options in another place, and what costs and outcomes occurred. The experience of others in similar circumstances is helpful in deciding whether a chosen solution would be useful.

Implementing

In the planning process, the clients, providers, and administrators selected the best plan to solve the original problem. Providing reasons why a particular solution was chosen will help the provider get the approval of the agency administration for the plan. Once approved, the plan is implemented.

Implementation requires obtaining and managing the resources required to operationalize the program in a way that is consistent with the plan. Program implementation requires accountability and responsibility (Issel, 2013). Change theory can be useful to help create an environment in which the program is supported.

Community members may participate in implementing the program either as volunteers or as paid staff. Program success will be increased if community residents are included in the work of the program and if they are on advisory boards and participate in program evaluation. The greater the participation of community members in developing a program, the greater the sense of ownership of that program by members of the

target population, and therefore the greater the probability that the program will achieve its objectives and result in positive changes in health (Issel, 2013). The planning process may be compared with the nursing process (Table 25-4).

Objectives Development for Program Planning and Evaluation

The most important step in the planning and evaluation process is the writing of program objectives. The objectives provide direction for conducting the program, and they provide the mechanism for evaluating specific activities and the total program. The following discussion addresses the development of well-written objectives. Development of program objectives begins with the initial phases of program planning.

Specifying Goals and Objectives

A program may begin with a mission statement. This is a broad general statement of the overall conceptual framework or philosophy of the program. The mission statement clarifies the values and overall purpose of the program and provides a framework for the goals and objectives that follow.

A goal is a statement that describes the general direction of logical response to a demonstrated need. One or two goals are often sufficient for a program to state how it will resolve or lessen the problem defined in the need statement. The goals should be consistent with the values and overall intent set forth in the mission statement. Their purpose is to focus on the major reason for the program, to support the mission. The goals are also the basis for writing the objectives for the program and the action steps that reflect the overall goal accomplishment.

- Mission—statement of values
- Goal—overall aim

TABLE 25-4 Comparison of the Nursing Process and Program Planning	
Nursing Process	Basic Planning Process
Assessment Subjective and objective data are systematically collected.	Formulation Assess the client’s need and define the problem.
Nursing Diagnosis Client’s problem is defined by using the assessment data to guide the nurse in looking for similar patterns in the systematically collected subjective and objective data.	Conceptualization Provider group identifies solutions; each solution is examined for its risks, consequences, and expected outcomes.
Nursing Intervention Any direct care treatment or nursing action based on the nursing diagnosis is performed by a nurse and includes rationale that justifies the treatment or nursing action. Treatment or action is evaluated by the nurse for its appropriateness and acceptability to the client before implementation.	Detailing Client and provider analyze solutions proposed in the conceptualizing phase for costs, resources, and program activities.
Implementation Direct care treatment or nursing action established in the intervention is implemented.	Evaluation of the Plan Client, providers, and administrators select best plan based on costs, benefits, and acceptability of the plan to the client and provider.
Evaluation Implementation of the nursing intervention is evaluated.	Implementation Best plan (solution) based on input from the client and provider is presented to administration and implemented.
	Program Evaluation Implemented best plan (solution) is evaluated.

- Objectives—specific measurable outcomes
- Action steps—explicit actions to accomplish objectives

Objectives are concise statements describing in measurable and time-bound terms precisely what specific outcome is to be accomplished. *Measurable* means that the objective contains the specific outcome anticipated that could be documented with collectable data. *Time-bound* means that the objective contains the target date when the specific outcome will be accomplished. Objectives should be realistic and attainable means to meet the program goal (CDC, 2014; UNC, 2014).

Clear, concise, and measurable objectives help with evaluating the program. If the objectives are too general, program evaluation becomes impossible. The objectives must be specific and stated so that anyone reading them could conduct the program without further instruction. The document *Healthy People 2020* (USDHHS, 2010) may be used as a template to guide the development of more specific objectives that are tailored to address the needs of a given community.

Useful program objectives include a statement of the specific behaviors that the program will accomplish, and success criteria, or expected results, for the program. Each program objective requires a *strong, action-oriented verb* to specify the behavior; *a statement of a single purpose; a statement of a single result; and a time frame for achieving the expected result.*

For example, a general program goal may be to reduce the incidence of low-birth-weight babies in Center County by 2020 by improving access to prenatal care. Several specific objectives are required to meet a general program goal. A specific objective for this program may be to open (action verb) a prenatal clinic in each health department within the county by January 2015 (time frame) to serve the population within each census tract of the county (purpose) to improve pregnancy outcomes (result).

As objectives are developed, an *operational indicator* for each objective should be considered so the evaluator knows when and if the objective has been met. For instance, an operational indicator for the previous objective would be a 10% to 25% increase in the use of prenatal care by women in Center County. Such indicators provide a target for persons involved with implementing programs. A review of *Healthy People 2020* health objectives will give the reader examples of objectives that include all the elements just listed.

Action steps are written for each program objective. An action step is defined as a concise statement describing precisely how (by what method), when, and by whom each activity will be accomplished to achieve the objective for which it was written. These activities address resources, such as number of nurses, equipment, supplies, and location. A time frame is planned for each activity. It is assumed that as each specific objective is met, progress is made toward achieving the general program objective (or goal) (Box 25-1).

BOX 25-1 Planning Programs for Elders in the Community

The Jefferson Area Board for Aging (JABA) has created a vision for the one-city, five-county planning district. In concert with 85 public and private organizations and more than 500 individuals, they developed a comprehensive community plan, known as the “2020 Community Plan on Aging.” The plan started with a comprehensive community assessment that addressed the livability for elders in the community. The “2020 Community Plan on Aging” has been an asset for the community in providing guidance for specific programs at JABA and throughout the community. In September 2005 the city of Charlottesville and the surrounding counties were honored when presented with the U.S. Department of Health and Human Services, Administration on Aging (AOA), “Livable Communities for All Ages” award. Seven communities received the award for their model efforts to make their communities more supportive places to live and grow for seniors and all populations. The competition was administered by the Center for Home Care and Policy Research, Visiting Nurse Service of New York, with the participation of the American Planning Association and the International City/County Management Association.

Accessed January 31, 2011.

funding sources. The major benefit of program evaluation is that it shows whether the program is fulfilling its purpose and whether the program addresses merit or quality, worth or value (such as cost effectiveness), and significance or importance (CDC, 2012). It should answer the following questions:

1. Are the needs for which the program was designed being met?
2. Are the problems it was designed to solve being solved?

This is critical information for program managers, funding agencies, top-level decision-makers, program accreditation reviewers, health providers, and the community. Evaluation data are used to make judgments about a program and may be used to justify sustaining the program, making adjustments in the program, expanding or reducing the program, or even discontinuing it.

Process evaluation, also referred to as formative evaluation or the evaluation of implementation, occurs while the program is being implemented. This type of evaluation makes it possible to do mid-program corrections to ensure achievement of program goals. Designing the evaluation during the planning phase of the program allows the evaluation to be guided by the program goals (Issel, 2013). Brownson, Fielding, and Maylahn (2009) describe process evaluation as an ongoing function of examining, documenting, and analyzing the progress of a program. Changes are required when there is an unacceptable difference between what was observed and what was anticipated from the implementation of program activities. Corrective action may then be taken to get the program back on track. This description of process evaluation is consistent with what the USDHHS (2011) refers to as implementation evaluation. Four critical questions are addressed when monitoring a program (USDHHS, 2011): (1) Are the activities taking place, (2) Who is conducting the activities, (3) Who is reached through the activities, and (4) Have sufficient inputs been allocated or mobilized?

PROGRAM EVALUATION

Benefits of Program Evaluation

Program evaluation is a method of ensuring that a program has met its goals (CDC, 2014). It is a means of documenting accountability by the program managers to the clients and the

HOW TO Develop a Program Plan*A. Define the problem**B. Formulate the plan**1. Assess population need*

- a. Who is the program population?*
- b. What is the need to be met?*
- c. How large is the client population to be served?*
- d. Where are they located?*
- e. How does the target population define the need?*
- f. Are there other programs addressing the same need? (Describe.)*
- g. Why is the need not being met?*

2. Establish program boundaries

- a. Who will be included in the program?*
- b. Who will not be included? Why?*
- c. What is the program goal?*

3. Program feasibility

- a. Who agrees that the program is needed (stakeholders: administrators, providers, clients, funders)?*
- b. Who does not agree?*

4. Resources (general)

- a. What personnel are needed? What personnel are available?*
- b. What facilities are needed? What facilities are available?*
- c. What equipment is needed? What equipment is available?*
- d. Is funding available to support the project? Is additional funding needed?*
- e. Are resources being donated (space, printing, paper, medical supplies)?*
 - (1) Type*
 - (2) Amount*

5. Tools used to assess need

- a. Census data*
- b. Key informants*
- c. Focus groups*
- d. Community forums*
- e. Existing program surveys*
- f. Surveys of client population*
- g. Statistical indicators (e.g., demographic and morbidity/mortality data)*

C. Conceptualize the problem

- 1. List the potential solutions to the problem.*
- 2. What are the risks of each solution?*
- 3. What are the consequences?*

*4. What are the outcomes to be gained from the solutions?**5. Draw a decision tree to show the problem-solving process used.**D. Detail the plan*

- 1. What are the objectives for each solution to meet the program goal?*
- 2. What activities will be done to conduct each of the alternative solutions listed under C1 and based on objectives?*
- 3. What are the differences in the resources needed for each of the alternative solutions?*
- 4. Which of the alternative solutions would be chosen if the resources described under B4 were the only resources available?*
- 5. Who would be responsible or accountable for implementing the plan?*

E. Evaluate the plan

- 1. Which of the alternative solutions is most acceptable to the following:*
 - a. The client population*
 - b. The agency administrator*
 - c. You*
 - d. The community*
- 2. Which of the alternative solutions appears to have the most benefits to the following:*
 - a. The client population*
 - b. The agency administrator*
 - c. You*
 - d. The community*
- 3. On the basis of cost, which alternative solution would be chosen by the following:*
 - a. The client population*
 - b. The agency administrator*
 - c. You*
 - d. The community*

F. Implement the program plan

- 1. On the basis of data collected, which of the solutions has been chosen?*
- 2. Why should the agency administrator approve your request? Give a rationale.*
- 3. Will additional funding be sought?*
- 4. When can the program begin? Give date.*

Developed by M. Stanhope and based on the Basic Program Planning Model (Nutt, 1984; Issel, 2013)

**HEALTHY PEOPLE 2020****Example of Healthy People 2020 Goals for Program Planning**

Focus Area	Overall Goal	Objective	Measuring the Objective
IID-23: Immunization and infectious diseases	Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.	IID-11: Increase routine vaccination coverage levels for adolescents.	IID: 11-1: Increase (action verb) to one dose of tetanus-diphtheria-acellular pertussis (Tdap) booster vaccine by 13 to 15 years (purpose) for 80% of this age group (operational indicator) by 2020 (time frame).

USDHHS: *Healthy People 2020: A Roadmap for Health*. Washington, DC, 2010, U.S. Government Printing Office.

Quality assurance programs are prime examples of program evaluation in health care delivery. Evaluation data are used to justify continuing programs in public health. Program evaluation focuses on whether goals were met and the efficiency and effectiveness of program activities. Many methods of program evaluation are described in the literature. One of the primary methods of evaluation used in health care today is **Donabedian's** (1982; updated in 2003) classic evaluative framework, which examines the structure, process, and outcomes of a program. Other models and frameworks have been developed using this approach (McDonald, 2007). The tracer method and case register are examples of other methods applied to program evaluation. (See Chapter 26 for further discussion.)

Program records and a community index serve as the major source of information for program evaluation. Surveys, interviews, observations, and diagnostic tests are ways to assess client and community responses to health programs. **Cost studies** help identify program benefits and objectiveness (Refer to chapter 5) (CDC, 2012).

As financial resources become scarce, nursing and the health care system must be able to justify their existence, prove that their services are responsive to client needs, and show their concern for being accountable. Planning and evaluation will assist in meeting these objectives.

Planning for the Evaluation Process

Planning for the evaluation process is an important part of program planning. When the **planning process** begins, the plan for evaluating the program should also be developed. All persons to be involved in implementing a program should be a part of the plan for program evaluation. Assessment of need is one component of evaluation. The basic questions to be answered, after carefully considering the data collected from a census, key informants, community forums, surveys, or health statistics indicators, are as follows:

1. Will the objectives and resources of this program meet the identified needs of the client population?
2. Is the program relevant?

Once need has been established and the program is designed, the nurse must continue plans for program evaluation. As a part of the planning process, Posavac (2011) described six steps to use for continuing program evaluation (Figure 25-3):

1. Identify the key people for evaluation. Program personnel, program funders, and the clients of the program should be included in planning for evaluation.
2. Arrange preliminary meetings to discuss the question of how the group wants to evaluate the program and where to start. If the program planners and others agree on an evaluation, the resources needed to do the evaluation must be identified. Evaluation is necessary even though some may not be interested in it. Nurses can help others see that without evaluation, money to support programs will not be available, or the need for a new nurse to help with the work cannot be justified. In health care today, there is great emphasis on outcomes of care. The only way to see outcomes is through evaluation.
3. After the key people have met and considered the questions in the previous steps, they are ready to begin the evaluation

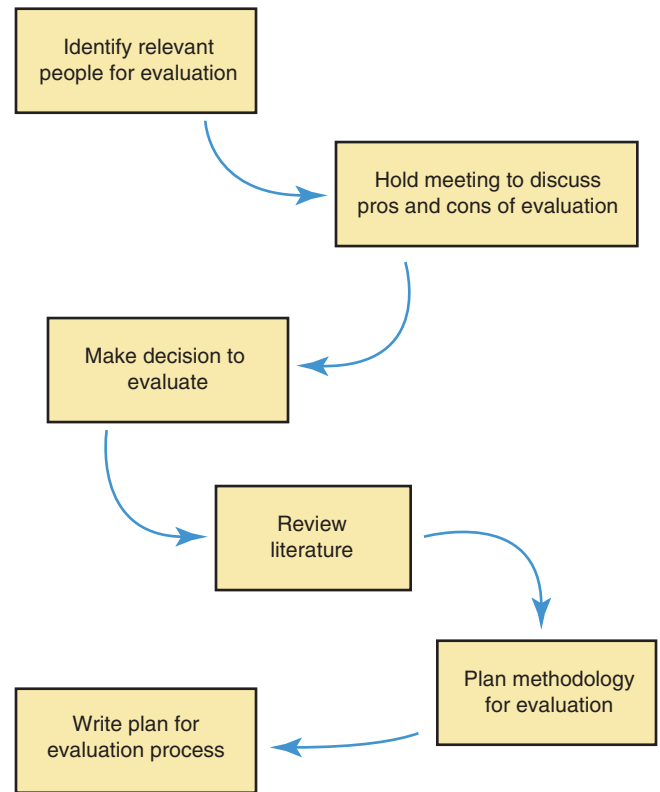

FIG 25-3 Six steps in planning for program evaluation.

process. Even though evaluation may be desired, the decision to conduct the evaluation may be an administrative one, based on available resources and existing circumstances. For example, if a program evaluation were attempted in a situation in which program personnel wanted it but clients chose to be uncooperative, evaluation efforts would be unsuccessful.

4. Examine the literature for suggestions about the appropriate methods and techniques for evaluation and their usefulness in program evaluation. If an agency has chosen to use an external evaluator, this person may make suggestions about the questions to be answered in the evaluation process. These questions are based on the program goals. Nurses who have reviewed the literature and communicated with others affected by the evaluation can determine whether the evaluation suggestions are appropriate for the situation.
5. Plan the method to be used, including decisions about what goals and objectives will be measured, how they will be measured, and for what population.
6. Write a plan that outlines the mission and goals of the overall program, the type of evaluation to be done, the operational measures to be used to evaluate the program goals, the choice of who will do the evaluation (i.e., internal or external personnel), the available resources for conducting the evaluation, and the readiness of the organization, personnel, and clients for program evaluation. Nurses at all levels of education and preparation can participate in program planning and evaluation.

Evaluation Process

A framework for evaluation in public health has been developed by the Centers for Disease Control and Prevention (CDC) to

guide understanding about program evaluation and to facilitate integration of evaluation in the public health system. This framework defines program evaluation as a systematic way to improve and to account for public health actions by using methods that are useful, feasible, ethical, and accurate. Six interdependent steps are identified that must be part of an evaluation process (USDHHS, 2011):

1. *Engage stakeholders*—This includes those who are involved in planning, funding, and implementing the program, those who are affected by the program, and the intended users of its services.
2. *Describe the program*—The program description should address the need for the program and should include the mission and goals. This sets the standard for judging the results of the evaluation.
3. *Focus the evaluation design*—Describe the purpose for the evaluation, the users who will receive the report, how it will be used, the questions and methods to be used, and any necessary agreements.
4. *Gather credible evidence*—Specify the indicators that will be used, sources of data, quality of the data, quantity of information to be gathered, and the logistics of the data gathering phase. Data gathered should provide credible evidence and should convey a well-rounded view of the program.
5. *Justify conclusions*—The conclusions of the evaluation should be validated by linking them to the evidence gathered and then appraising them against the values or standards set by the stakeholders. Approaches for analyzing, synthesizing, and interpreting the evidence should be agreed on before data collection begins to ensure that all needed information will be available.
6. *Ensure use and share lessons learned*—Use and dissemination of findings require deliberate effort so that the lessons learned can be used in making decisions about the program (CDC, 2012).

Sources of Program Evaluation

Both quantitative and qualitative methods may be used to conduct an evaluation; however, the strongest evaluation designs combine both qualitative and quantitative methods. Major sources of information for program evaluation are the program clients, program records, and community indexes.

Qualitative methods such as site visits, structured observations of interventions, or open-ended interviews may be used (Trickett et al, 2011). The program participants, or clients of the service, have a unique and valuable role in program evaluation. Whether the clients, for whom the program was designed, accept the services will determine to a large extent whether the program achieves its goal. Thus, their reactions, feelings, and judgments about the program are very important to the evaluation. For example, to garner feedback from participants in a program, an evaluator may use a written survey in the form of a questionnaire or an attitude scale. Interviews and observations are other ways of obtaining feedback about a program. Attitude scales are probably used most often, and they are usually phrased in terms of whether the program met its objectives. The client satisfaction survey is an example of an attitude

scale often used in the health care delivery system to evaluate the program objectives (Finkelstein et al, 2011). Client input into the development of evaluation tools ensures that the questions and approaches are more acceptable to the clients and that the tools effectively elicit the information needed.

The second major source of information for program evaluation is program records, especially clinical records. Clinical records provide the evaluator with information about the care given to the client and the results of that care. To determine whether a program goal has been met, one might summarize the data from a group of records. For example, if one overall goal were to reduce the incidence of low-birth-weight babies through prenatal care, records would be reviewed to obtain the number of mothers who received prenatal care and the number of low-birth-weight babies born to them. Records would be reviewed from the beginning of the program and at the end of a specific time frame, such as at the end of each year. Care must be taken to ensure that any review and use of clinical records complies with HIPAA regulations. (For details about HIPAA compliance, see <http://aspe.hhs.gov/admsimp/index.shtml>.)

The third major source of evaluation is epidemiologic data. Mortality and morbidity data measuring health and illness are probably cited more frequently than any other single index for program evaluation. These health and illness indicators are useful in evaluating the effects of health care programs on the total community. Incidence and prevalence data are valuable indexes for measuring program effectiveness and impact, and these data are readily available on the Internet. Useful sites for such data include vital statistics available at state department of health sites, the CDC, and the U.S. Census site. Most counties and communities have their own sites, and many of these contain very useful demographic and health data.

An example of a national program based on a needs assessment of the U.S. population is the national health objectives program *Healthy People 2020* (USDHHS, 2010). *Healthy People* documents have been published every 10 years since 1980. The data gathered from each 10-year period have been used to evaluate the population needs met and the assessment of needs for the next *Healthy People* document.

The Healthy Communities Program (USDHHS, 2010) and named community health status indicators project suggests activities to evaluate national health objectives related to communities. The example shown in the *Healthy People 2020* box on p. 559 highlights injury and violence prevention. This box shows that objectives include an action verb, a result, an operational indicator, and a time frame for implementing the objective (10 years, begun in 2010).

The Levels of Prevention box provides examples of applying levels of prevention to program planning and evaluation.

Aspects of Evaluation

The aspects of program evaluation include the following (USDHHS, 2011):

1. *Relevance*—Need for the program
2. *Adequacy*—Program addresses the extent of the need
3. *Progress*—Tracking of program activities to meet program objectives

HEALTHY PEOPLE 2020

Objectives Focus Areas

1. Access to Health Services
2. Adolescent Health
3. Arthritis, Osteoporosis, and Chronic Back Conditions
4. Blood Disorders and Blood Safety
5. Cancer
6. Chronic Kidney Diseases
7. Dementias, including Alzheimer's
8. Diabetes
9. Disability and Health
10. Early and Middle Childhood
11. Educational and Community-Based Programs
12. Environmental Health
13. Family Planning
14. Food Safety
15. Genomics
16. Global Health
17. Healthcare-Associated Infections
18. Health Communication and Health IT
20. Hearing and Other Sensory or Communication Disorders (Ear, Nose, Throat—Voice, Speech, and Language)
21. Heart Disease and Stroke
22. HIV
23. Immunization and Infectious Diseases
24. Injury and Violence Prevention
26. Maternal, Infant, and Child Health
27. Medical Product Safety
28. Mental Health and Mental Disorders
29. Nutrition and Weight Status
30. Occupational Safety and Health
31. Older Adults
32. Oral Health
33. Physical Activity and Fitness
34. Preparedness
35. Public Health Infrastructure
36. Respiratory Diseases
37. Sexually Transmitted Diseases
38. Sleep Health
40. Substance Abuse
41. Tobacco Use
42. Vision

Three other objectives are under development: numbers 19, 25, 39. USDHHS: *Healthy People 2020: A Roadmap for Health*. Washington, DC, 2010, U.S. Government Printing Office.

HEALTHY PEOPLE 2020

Example of a Measurable National Health Objective

In the *Healthy People* focus area of injury and violence prevention, one objective is:

- IPV-5: Increase (action verb) the number of States and the District of Columbia where 90% of deaths of children aged 17 years and under (operational indicator) due to external causes are reviewed by a child fatality review team (purpose), by 2020 (time frame).

USDHHS: *Healthy People 2020: A Roadmap for Health*. Washington, DC, 2010, U.S. Government Printing Office.

LEVELS OF PREVENTION

Program Planning and Evaluation**Primary Prevention**

Plan a community-wide program with the local school system and health department to serve healthy meals and snacks in all schools to promote good childhood nutrition.

Secondary Prevention

Develop screening programs for all school children to determine the incidence/prevalence of childhood obesity before implementing the program.

Tertiary Prevention

Evaluate the incidence/prevalence of obesity among school children after the implementation of the program and provide programs to reduce complications from the condition.

4. *Efficiency*—Relationship between program outcomes and the resources spent
 5. *Effectiveness*—Ability to meet program objectives and the results of program efforts
 6. *Impact*—Long-term changes in the client population
 7. *Sustainability*—Enough resources to continue the program
- The How To box suggests questions that may be asked about program evaluation using this process.

The following paragraphs provide an explanation of each step in program evaluation.

Relevance. Evaluation of relevance is an important component of the initial planning phase. As money, providers, facilities, and supplies for delivering health care services are more closely monitored, the needs assessment done by the nurse will determine whether the program is needed.

Adequacy. Evaluation of adequacy looks at the extent to which the program addresses the entire problem defined in the needs assessment. The magnitude of the problem is determined by vital statistics, incidence, prevalence, and expert opinion.

Progress. The monitoring of program activities, such as hours of services, number of providers used, number of referrals made, and amount of money spent to meet program objectives, provides an evaluation of the progress of the program. This type of evaluation is an example of formative or process evaluation, which occurs on an ongoing basis while the program exists. This provides an opportunity to make effective day-to-day management decisions about the operations of the program. Progress evaluation occurs primarily while implementing the program. The nurse who completes a daily or weekly log of clinical activities (e.g., number of clients seen in clinic or visited at home, number of phone contacts, number of referrals made, number of community health promotion activities) is contributing to progress evaluation of the nursing service.

Efficiency. If the reason for evaluation is to examine the efficiency of a program, it may occur on an ongoing basis as formative evaluation or at the end of the program as a summative evaluation. The evaluator may be able to determine whether the program provides better benefits at a lower cost than a similar program, or whether the benefits to the clients, or number of clients served, justify the costs of the program.

HOW TO Do a Program Evaluation

To do a program evaluation, first choose the type of evaluation you wish to conduct. Second, identify the goal and objectives for the evaluation. Third, decide who will be involved in the evaluation. Fourth, answer the questions related to the type of evaluation as follows:

A. Program relevance: needs assessment (formative)

1. Use answers to all questions listed in section B of How To Develop a Program Plan.
2. On the basis of the needs assessment, was the program necessary?

B. Adequacy

1. Is the program large enough to make a positive difference in the problem/need?
2. Are the boundaries of the services defined so that the problem/need can be addressed for the target population?

C. Program progress (formative)

1. Monitor activities (circle which this reflects: daily, weekly, monthly, annually).
 - a. Name the activities provided.
 - b. How many hours of service were provided?
 - c. How many clients have been served?
 - d. How many providers are there?
 - e. What types of clients have been served?
 - f. What types of providers were needed?
 - g. Where have services been offered (e.g., home, clinic, organization)?
 - h. How many referrals have been made to community sources?
 - i. Which sources have been used to provide support services?
2. Budget
 - a. How much money has been spent to carry out activities?
 - b. Will more/less money be needed to conduct activities as outlined?
 - c. Will changes to objectives and activities be needed to sustain the program?
 - d. What changes do you recommend and why?

D. Program efficiency (formative and summative)

1. Costs
 - a. How do costs of the program compare with those of a similar program to meet the same goal?
 - b. Do the activities outlined in C1 compare with the activities in a similar program?

- c. Although this program costs more/less than expected, is it needed? Why?

2. Productivity (may use national or state averages for comparison)

- a. How many clients does each type of staff see per day (e.g., registered nurses, clinical nurse specialists, nurse practitioners)?
- b. How does this compare with similar programs?
- c. Although the productivity level of this program is low/high, is the program needed? Why?

3. Benefits

- a. What are the benefits of the program to the clients served?
- b. What are the benefits to the community?
- c. Are the benefits important enough to continue the program? Why? (Look at cost, productivity, and outcomes of care.)

E. Program effectiveness (summative)**1. Satisfaction**

- a. Is the client satisfied with the program as designed?
- b. Are the providers satisfied with the program outcomes?
- c. Is the community satisfied with the program outcomes?

2. Goals

- a. Did the program meet its stated goal?
- b. Are the client needs being met?
- c. Was the problem solved for which the program was designed?

F. Impact (summative)**1. Long-term changes in health status (1 year or more)**

- a. Have there been changes in the community's health?
- b. What are the changes seen (e.g., in morbidity or mortality rates, teen pregnancy rates, pregnancy outcomes)?
- c. Have there been changes in individuals' health status?
- d. What are the changes seen?
- e. Has the initial problem been solved or has it returned?
- f. Is new or revised programming needed? Why?
- g. Should the program be discontinued? Why?

G. Sustainability**1. Was the program funded as a demonstration or by an external agency?****2. Can money and resources be found to continue the program after the initial funding is gone?**

Depending on the answers to the questions, the program can be found to be successful or unsuccessful.

Effectiveness and impact. An evaluation of program effectiveness may help the nurse evaluator determine both client and provider satisfaction with the program activities, as well as whether the program met its stated objectives. However, if evaluation of impact is the goal, long-term effects such as changes in morbidity and mortality must be investigated. Both effectiveness and impact evaluations are usually summative evaluation functions primarily performed as end-of-program activities.

Sustainability. A program can be continued only if there are resources for the program. Ongoing evaluation of sustainability is important!

ADVANCED PLANNING METHODS AND EVALUATION MODELS

After a need and a client demand for a program have been determined through the needs assessment process, the next step

in the development of the program is to choose a procedural method that will assist the nurse in planning the program to be offered. The following is offered for students who are more advanced in their career and need to consider several methods of program planning plus more extensive evaluation models for program management.

Five planning methods are discussed in this section:

1. Program planning method (PPM)
2. Multi-attribute utility technique (MAUT)
3. Planning Approach to Community Health (PATCH)
4. Assessment Protocol for Excellence in Public Health (APEXPH)
5. Mobilizing for Action through Planning and Partnership (MAPP)

PPM is a more general approach to program planning, whereas MAUT offers guidelines for identifying and tracking specific program activities essential to program success. PATCH,

APEXPH, and MAPP are PPMs that were designed by the CDC and the National Association of County Health Officials with input from local and state health departments. All of these approaches establish the basis for program evaluation.

Program Planning Method

PPM is a technique using the nominal group technique described by [Delbecq and Van de Ven in 1971](#). The nurse can use this method to involve clients more directly in the planning process. PPM is a five-stage process to identify program needs. It focuses on three levels of planning groups composed of clients, providers, and administrators. The client or consumer group relays a list of problems to the provider group, who in turn aids the client group by presenting the solutions to the problems to the administrative group ([Issel, 2013](#)).

The stages of PPM are compared with MAUT's planning process in [Table 25-5](#). The five stages are as follows:

1. *Problem diagnosis.* Each client in the group works with all other members of the group to develop a written problem list, one problem at a time. After all problems have been shared and recorded, they are discussed by the total client group. After the discussion, clients select the problems with the highest priority by voting on the ranking of each problem.
2. *Expert provider group identifies solutions for each of the problems identified by the clients.*
3. *Client and provider groups present their problems and suggested solutions* to the administrative group to determine the possibilities of developing a program to resolve one or more of the problems using one or more of the solutions. In this phase, clients and providers are seeking acceptance from the administrators who control the program resources.
4. *Alternative solutions to the problem are identified,* and the pros and cons of each are analyzed.
5. *Clients, providers, and administrators select the best plan* for program implementation. In this phase, the link between

the planned solutions and the problem is evaluated, pointing out strengths and limitations of the proposed program plan.

A nurse might use this technique for developing school health services within the total community or in one school. A nurse working with a senior citizens group might use this method to identify the priority needs for nursing clinic services at the health department. It is important to note that this method is used to obtain consensus among all persons involved in the program: clients, providers, and administrators. Consensus is most helpful in having a successful program. The process may also be used in a community decision-making activity in which community representatives come together to decide health care service needs for the entire community.

Multi-Attribute Utility Technique

MAUT is a planning method based on decision theory ([Saaty and Vargas, 2013](#)). This method can be adapted for making decisions about the care of a single client or about national health care programs. Recently it has been used to evaluate nursing practice. The purpose of MAUT is to separate all elements of a decision and to evaluate each element separately for its effects on the overall decision, considering available options.

If money is no object, then the option with the highest use value is the best decision. However, if this option exceeds the budget, the next best option may be the alternative to choose. The steps of MAUT (listed in [Box 25-2](#)) relate closely to the basic planning process described by [Nutt \(1984\)](#) as shown in [Table 25-5](#).

Steps 1 and 2 of MAUT relate to problem formulating. Step 3 involves conceptualizing the program alternatives, and steps 4 through 9 focus on detailing and the implications of each option. Step 10 involves the evaluating phase of planning or the choice of the best solution as identified in steps 4 through 9. Placing quantitative values on solutions to meet program needs is most helpful in the implementing phase of planning

TABLE 25-5 Planning Methods Compared with Basic Planning Process

Basic Planning	PPM	PATCH	APEXPH	MAUT	MAPP
Formulating	Problems identified by client.	Community members identify health priorities.	Assess community capacity to address health problems.	Identify target populations and program objectives.	Assess community themes and strengths, health status, and strategic issues.
Conceptualizing	Provider group identifies solution.	Stakeholders use data to develop program activities.	Assess with community the strengths and health problems.	Identify alternative problem solutions.	Formulate goals and strategies.
Detailing	Analyze available solutions.	Design comprehensive program to meet identified health priorities.	Choose plan based on community capacity resources.	Identify criteria for choice; rank and weight; calculate value.	Develop plan for action; engage in visioning.
Evaluating	Clients, providers, and administrators select best plan.	Use process evaluation to improve program.	Support recommendations for program change.	Choose best alternatives.	Evaluate the plan.
Implementing	Best plan presented to administrators for funding.		Partners implement the plan.		Assess community ability to change and implement the plan.

BOX 25-2 Ten Basic Steps of the Multi-Attribute Utility Technique Method

1. Identify the person or aggregate for whom a problem is to be solved. Who is the client for whom the program is being planned?
2. Identify the issue(s) or decision(s) that is (are) relevant. This step involves the identification of the program objectives.
3. Identify the options to be evaluated. The program planner identifies the available options or action alternatives to accomplish the program goals.
4. Identify the relevant criteria related to the value of each option. The program planner places a value on competing options or alternatives or identifies criteria to be considered in making a choice between them.
5. Rank the criteria in order of importance. The program planner decides which of the criteria are most important and which are least important for meeting program goals.
6. Rate criteria in importance. In this step the program planner assigns an arbitrary rating of 10 to the least important criterion. In considering the next least important criterion, the planner decides how many times more important it is than the least important criterion. If it is considered twice as important, the dimension will be assigned a 20. If it is only considered half as important, it will be assigned a 15. If it is considered four times as important, it will be assigned a 40. The process is continued until all criteria have been rated.
7. Add the importance rate, divide each by the sum, and multiply by 100. This process is called *normalizing* the weights. It is recommended that the number of criteria be kept between 6 and 15. Therefore, in this initial process, the planner can be concerned with only general criteria for choosing action alternatives.
8. Measure the location of the option being evaluated by each criterion. The planner may ask a colleague or expert to estimate on a scale of 0 to 100 the probability that a given option from step 3 will maximize the value of the criterion from step 4.
9. Calculate the use of options. The program planner will obtain the usefulness of each identified action alternative by multiplying the weight for each criterion (step 7) by the rating of an option for each criterion (step 8) and adding the products. The sum of the products for each action is termed the *aggregate utility*.
10. Decide on the best alternative to meet the program objective. The action alternative with the highest aggregate use is considered the best decision for meeting the program objectives.

Kabassi K, Vroom M: MAUT and adaptive techniques for web based educational software. *Instruct Sci* 34(2):313–358, 2006.

(e.g., convincing administrators of the need for such a program). However, caution must be taken in using all planning methods, because the best solution reflects the bias of the planner.

Planning Approach to Community Health (PATCH)

The PATCH model, which has not been emphasized as much in recent years, was developed in the 1980s by the CDC with input from state and local health departments. The model was developed using as a framework the PRECEDE model developed by Laurence Green in the 1970s. The PRECEDE model was used originally for planning health education programs (Glanz and Bishop, 2010).

Although this model was originally developed to strengthen health promotion activities, the PATCH model is used by communities and agencies to plan, develop, implement, and

evaluate both health promotion and disease prevention programs. Application of PATCH emphasizes community participation and ownership by all who are involved. The PATCH process includes the following:

- Mobilizing the community
- Collecting and analyzing data to support local health issues
- Choosing health priorities
- Setting objectives and standards to denote progress and success
- Developing and implementing multiple intervention strategies to meet objectives
- Evaluating the process to detect the need for change
- Securing support of the public health infrastructure within the target community

These elements are essential to the success of any community-based program:

- Participation in the planning process by community members (stakeholders)
- Use of data to help stakeholders select health priorities and develop and evaluate program activities
- Development by stakeholders of a comprehensive approach to design the program to meet the identified health needs
- Use of process (formative) evaluation to improve the program and provide feedback to the stakeholders
- Increase in the capacity of the community to address a variety of health priorities by improving the health program planning skills of the stakeholders

The PATCH model has been useful in developing programs to address *Healthy People 2020* goals (<http://www.cdc.gov>). PATCH materials are available online at the CDC.

Assessment Protocol for Excellence in Public Health (APEXPH)

Following the development of the PATCH model in 1987, the CDC, partnering with the National Association of City and County Health Officers (NACCHO) and other organizations, developed its APEXPH model. The model was introduced for use in 1999.

The APEXPH model incorporates the three core functions of public health in assessment, assurance, and policy development. Although the model was developed for use by local health departments, it can be adapted to fit other situations and resources. The model framework includes the following:

- Process for assessing agency organization and management
- Process for working with communities to assess the health of a community as well as a community's strengths and health problems
- Process for integrating plans for resolving health problems based on the capacity, resources, and community members partnering to implement the plan

This model uses the strategic planning process of Nutt (1984) and has three elements:

1. Assessing internal organization capacity to address the community's health problems
2. Assessing and priority setting for the community's health problems
3. Implementing the plan to address these problems

Application of the APEXPH process is useful for the following:

- Supporting recommendations for change in programs/services
- Highlighting the need for improvements in program functions

If APEXPH is applied along with the project budget process, key stakeholders may unite to discuss health and program priorities and options for providing services as well as to make plans for the year (<http://www.cdc.gov>). Workbooks and other resources are available through NACCHO at their website (<http://www.naccho.org>).

Mobilizing for Action through Planning and Partnership (MAPP)

The strategic planning model MAPP can be applied at the community level to improve the community's health. Application of this model helps to identify public health issues and priorities and to identify resources to address the priorities.

As with PATCH and APEXPH, it is important that the community feels ownership of the process. The community's strengths, needs, and wishes are integral to the process.

Two figures (Figures 25-4 and 25-5) show the MAPP process and the community roadmap to a healthier community. The phases of the MAPP process are as follows:

- Organize for success/partnership development.
 - Organize agencies.
 - Recruit partners.
 - Prepare to implement MAPP.
- Visioning.
 - Work toward long-range goals through a shared vision and common values.

- Engage in four assessment processes.
 - Identify issues.
 - Identify interest to community.
 - Explore quality of life perceptions.
 - Identify community assets.

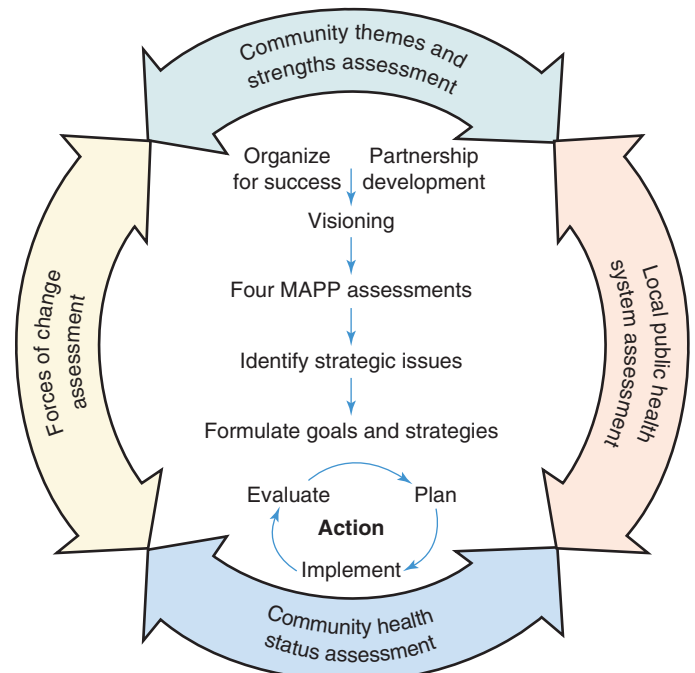

FIG 25-4 MAPP process.

FIG 25-5 MAPP roadmap to community's health.

2. Assess local public health system.
 - a. Identify all agencies and other partners who contribute to the public's health.
 - b. Measure each partner's capacity to participate; what can each partner contribute?
 - c. Measure the performance of each partner; how have they addressed issues in the past?
3. Assess the health status of the community.
 - a. Assess available data.
 - b. Assess quality of life.
 - c. Assess community risk factors.
4. Assess ability of community to change.
 - a. Identify forces for change.
 - b. Identify forces against change.
- D. Identify strategic issues.
 1. What are the health issues that need to be addressed?
 2. Which are the most important?
 3. Where should the community begin?
- E. Formulate goals and strategies.
 1. Which goals will be met?
 2. Which strategies will be used to meet the goals?
- F. Act.
 1. Participants develop plan for action.
 2. Implement the plan.
 3. Evaluate the implementation.

Two products are available to assist in implementing the MAPP process (Figure 25-4): the NACCHO website (see the WebLinks on this book's Evolve site) and the MAPP toolbox (<http://www.naccho.org>).

The five models of program planning presented here may be adapted to use with a single program or with a community.

Evaluation Models and Techniques

Structure-Process-Outcome Evaluation

The method for evaluation of programs by Donabedian (1982) was initially directed primarily toward medical care but is applicable to the broader area of health care. He describes three approaches to assessment of health care: structure, process, and outcome.

- **Structure** refers to settings in which care occurs. It includes materials, equipment, qualification of the staff, and organizational structure (Donabedian, 1982). This approach to evaluation is based on the assumption that, given a proper setting with good equipment, good care will follow. However, this assumption is not strongly supported.
- **Process** refers to whether the care that was given was "good" (Donabedian, 1982), competent, or preferred. Use of process in program evaluation may consist of observing practice but more likely consists of reviewing records. The review could focus on whether documentation of preventive teaching was on the clinical record. Audits using specific criteria are examples of the use of process.
- **Outcome** refers to results of client care and restoration of function and survival (Donabedian, 1982), but is also used in the sense of changes in health status or changes in health-related knowledge, attitude, and behavior. Thus program outcomes may be expressed in terms of mortality, morbidity, and disability for given populations, such as infants, but they

could be expressed in a broader sense through health promotion behaviors such as weight control, exercise, and abstinence from tobacco and alcohol.

Donabedian's model of evaluating program quality is a popular model and is widely used for evaluation in the health care field. It can be useful in evaluating program effectiveness. The Center for Medicare and Medicaid Services and other third-party payers are currently placing more emphasis on outcome evaluation. It is essential that nurses begin to develop outcome criteria for client interventions.

Tracer Method

The Board of Medicine of the National Academy of Sciences developed a program to evaluate health service delivery called the tracer method (Papanicolas and Smith, 2013). The tracer method of evaluation of programs is based on the premise that health status and care can be evaluated by viewing specific health problems called **tracers**. Just as radioactive tracers are used to study the thyroid gland, specific health problems are selected to evaluate the delivery of health and nursing services. Examples of conditions selected as tracers are cardiovascular disease, diabetes, obesity, smoking patterns, and breast and cervical cancer. This approach can be used to compare the following:

- Health status among different population groups and in different geographic locations
- Health status in relation to social status, economic level, medical care, nursing care, and behavioral variables
- Various arrangements for health care delivery

The tracer method is a useful technique for looking at the efficiency, effectiveness, and effect of a program.

Case Register

Systematic registration of a contagious disease has been a practice for many years. Denmark began a national register of tuberculosis in 1921 (Friis and Sellers, 2010). Its contribution to the reduction in the incidence of contagious diseases has been widely recognized. **Case registers** (Issel, 2013) are also used for acute and chronic diseases (e.g., cancer and myocardial infarction).

Registers collect information from defined groups, and the information may be used for evaluating and planning services, preventing disease, providing care, and monitoring changes in patterns and care. The method is described here because of its use in evaluation of services. The answers to the questions listed in Box 25-3, asked before and after implementing a program, give information about the effects of the program. A tuberculosis register indicates the degree to which infection is being controlled. Cancer registers make state, regional, national, and international comparisons possible, and they provide clues to causes of disease. They are also used to direct the development of programs specific to population needs.

PROGRAM FUNDING

Providing adequate funding for programs to meet the needs of populations can be a challenge to nurse managers in communities. When money is not available to support endeavors that

BOX 25-3 Examples of Questions Asked About Cases for Case Register

1. What is the incidence of disease? What is the prevalence? What differences in incidence and prevalence are there between one community and another?
2. What percentage of clients recover? What percentage die?
3. Where does death occur?
4. How long do clients wait before contacting a health care provider?
5. How long is it before they are seen by a health care provider?
6. How many cases are associated with other major risk factors?
7. How many cases are associated with environmental factors such as water hardness or air pollution?
8. What happens after clients leave the hospital and when they return to work? Are there rehabilitation programs?
9. How many clients had been seen by a health care provider shortly before the problem occurred?
10. What prevention measures are taken for persons considered susceptible?

serve the public good, nonprofit organizations may seek funding from outside the organization. Such funding may be in the form of gifts, contracts, or grants.

Gifts are philanthropic contributions from individuals, foundations, businesses, religious or civic organizations, or voluntary associations. Many organizations engage in extensive development efforts to solicit monetary gifts that support the agency's goals. Contracts are awarded for the performance of a specific task or service, usually to meet guidelines specified by the organization making the award. Contracts are frequently used by the government to purchase services of others to perform certain services. Grants are awards to nonprofit organizations to allow recipients to implement activities of their own design that address the interests of the funding agency. Grants are given by the government, foundations, and corporations.

Nurse leaders working in nonprofit agencies may write grants to fund community programs that meet the needs of at-risk populations. Development of a proposal is guided by concepts and principles of program planning and evaluation that have been discussed in this chapter. Successful **grant writing** meshes the plan for the envisioned program of the applying organization with the criteria set forth by the funding agency. A grant proposal is a means of recording plans for establishing, managing, and evaluating a program into a written document. Funding agencies provide guidelines for grant applications, and it is essential to follow those specific guidelines if grant funding is to be acquired. In general, however, most grant proposals include certain essential components.

First, it is important to identify the target population and define the problem(s) that the project intends to address. Specific data, conditions, or circumstances that illustrate the problem and that document the need (e.g., environmental characteristics, economic conditions, population characteristics, and health status indicators) should be included and discussed. Health services should be discussed in relationship to availability, accessibility, and acceptability to the target population

within both the public and private sectors. Identification of duplication or gaps in services that result in unmet needs should be addressed.

The second component is the description of the program that is being proposed. The program description should provide details about what is planned, how it will be done, where it will be done, and by whom. This section should present the reviewer with a clear understanding of the details of the program structure and function. It should be apparent that the program is realistic and can be accomplished. This section includes goals, objectives, action steps, and anticipated outcomes that describe how, when, and by whom each activity will be accomplished to achieve the outcome of the objective for which it was written.

Plans for evaluation address the method that will be used to ensure ongoing and timely review of the specific action steps and objectives involved in achieving the stated goal (formative) and to assess program outcomes (summative).

Applicants for grant funds should develop a realistic operating budget that is appropriate to the requirements of the project. The budget represents the plan for how the program will be implemented and reflects the project's proposed spending plan.

LINKING CONTENT TO PRACTICE

Program planning skills and knowledge are essential for public health nurses. In *Public Health Nursing: Scope and Standards of Practice* (ANA, 2013), the first standard is that of assessment. This addresses the issue of conducting needs assessments and having the ability to collect multiple sources of data, analyze population characteristics, problem solve, and set priorities based on the data collected. Standard 2 speaks to using the assessment data to diagnosis health problems with input from the client population. Standards 3 through 5 address the nurses' roles in identifying health status outcomes, planning and implementing processes to address the health problem, and directing strategies to meet the outcomes. Standard 6 discusses the nurses' role in evaluation including participating in process and outcome evaluation by monitoring activities in programs.

The four professional organizations dedicated to public health nursing—the Association of State and Territorial Directors of Nursing (now APHN), The Association of Community Health Nursing Educators, The Public Health Nursing section of the APHA, and the American Nurses Association—have banded together to form an organization called the Quad Council. This council developed a document identifying the domains of practice for public health nurses. One of the domains is Policy Development and Program Planning Skills. The competencies the nurse needs for this domain of practice related to program management are:

- Manages public health programs consistent with public health laws and regulations.
- Develops a plan to implement policy and programs.
- Develops mechanisms to monitor and evaluate programs for their effectiveness and quality (Quad Council, 2011).

New baccalaureate nurses will want to be knowledgeable and be able to participate in program management; graduate nurses will want to be able to direct programs. Appendix B describes a Program Planning and Design process to use for practicing the content from this chapter. Try out this process on the development of a small program of interest to you and the client population you want to serve and the community level health problem of interest to you.

PRACTICE APPLICATION

The following is a real-life example of the application of the program management process by an undergraduate nursing student. This activity resulted in the development and implementation of a nurse-managed clinic for the homeless. This example shows how students as well as providers can make a difference in health care delivery. It also illustrates that no mystery surrounds the program management process.

Eva was listening to the radio one Sunday afternoon and heard an announcement about the opening of a soup kitchen within the community for the growing homeless population. She was beginning her public health nursing course and wanted to find a creative clinical experience that would benefit herself as well as others. The announcement gave her an idea. Although it mentioned food, clothing, shelter, and social services, nothing was said about health care.

Eva was interested in finding a way to provide nursing and health care services at the soup kitchen. Which of the following should she do?

- A. Talk with key leaders to determine their interest in her idea.
- B. Review the literature to find out the magnitude of the problem.
- C. Survey the community to determine if others are providing services.
- D. Discuss the idea with members of the homeless population.
- E. Consider potential solutions to the health care problems.
- F. Consider where she would get the resources to open a clinic.
- G. Talk with church leaders and nursing faculty members to seek acceptance for her idea.

Answers can be found on the Evolve site.

KEY POINTS

- Planning and evaluation are essential elements of program management and vital to the survival of the nursing discipline in health care delivery.
- The program management process is population focused and is parallel to the nursing process. Both are rational decision-making processes.
- The health care delivery system has grown in the past century, making health planning and evaluation very important.
- Comprehensive health planning grew out of a need to control costs.
- A program is an organized approach to meet the assessed needs of individuals, families, groups, populations, or communities by reducing or eliminating one or more health problems and addressing health disparities.
- Planning is defined as selecting and carrying out a series of actions to achieve a stated goal.
- Evaluation is defined as the methods used to determine if a service is needed and will be used, whether a program to meet that need is carried out as planned, and whether the service actually helps the people it intended to help.
- To develop quality programs, planning should include four essential elements: assessment of need and problem diagnosis, identification of problem solutions, analysis and comparison of alternative methods, and selection of the best plan and planning methods.
- The initial and most critical step in planning a health program is assessment of need. Assessment focuses on the needs of the population who will use the services planned.
- Some of the major tools used in needs assessment are census data, community forums, surveys of existing community agencies, surveys of community residents, and statistical indicators about demographics, morbidity, and mortality of the population.
- The major benefit of program evaluation is to determine whether a program is fulfilling its stated goals. Quality assurance programs are prime examples of program evaluation.
- Plans for implementing and evaluating programs should be developed at the same time.
- Program records and community indexes and health data serve as major sources of information for program evaluation.
- Planning programs and planning for their evaluation are two of the most important ways in which nurses can ensure successful program implementation.
- Cost studies help identify program benefits, effectiveness, and efficiency.
- Program planning helps nurses and agencies focus attention on services that clients need.
- Planning helps everyone involved understand their role in providing services to clients.
- The assessment of need process provides an evaluation of the relevance that a new service may have to clients.
- A decision tree is a useful tool to choose the best alternative for solving a problem.
- Setting goals and writing objectives to meet the goals are necessary to evaluate program outcomes.
- *Healthy People 2020* is an example of a national program based on needs assessment that has stated goals and objectives on which the program can be evaluated.
- Program planning models include PPM, MAUT, PATCH, APEXPH, and MAPP.
- Program evaluation includes assessing structure, process, and outcomes of care.
- Grant writing is a tool used by nurse managers to provide resources for needed services.
- Grant proposals are documents that incorporate principles of program planning and evaluation.

CLINICAL DECISION-MAKING ACTIVITIES

- Choose the definitions that best describe your concepts of a program, planning, and evaluation. Explain how each of these definitions can help you in accomplishing planning and evaluation.
- Apply the program planning process to an identified clinical problem for a client group with whom you are working in the community. Give specific examples.
 - Assess the client needs and existing resources.
 - Choose tools appropriate to the assessment of unmet needs.
 - Analyze the overall planning process of arriving at decisions about implementing a program.
 - Summarize the benefits for program planning that apply to your situation.
- Given the situation just described, choose three or four of your classmates to work with you on the following projects:
 - Plan for evaluation of the program in activity 2.
 - Apply the evaluation process to the situation.
 - Identify the measures you will use to gather data for evaluating your program.
 - Identify the sources you will tap to gain information for program evaluation.
 - Analyze the benefits of program evaluation that apply to your situation.
 - Talk with a nurse or an administrator working in the community about the application of program planning and evaluation processes at the local agency. Compare their answers to your research. What are some of the difficulties that your group and the agency had in evaluating a program?

Quality Management

Marcia Stanhope, PhD, RN, FAAN

Dr. Marcia Stanhope is currently an Associate of the Tufts and Associates Search Firm, Chicago, Ill. She is also a consultant for the nursing program at Berea College, Kentucky. She has practiced community and home health nursing, has served as an administrator and consultant in home health, and has been involved in the development of two nurse-managed centers. At one time in her career, she held a public policy fellowship and worked in the office of a U.S. Senator. She has taught community health, public health, epidemiology, policy, primary care nursing, and administration courses. Dr. Stanhope formerly directed the Division of Community Health Nursing and Administration and served as Associate Dean of the College of Nursing at the University of Kentucky. She has been responsible for both undergraduate and graduate courses in population-centered nursing. She has also taught at the University of Virginia and the University of Alabama, Birmingham. During her career at the University of Kentucky she appointed to the Good Samaritan Foundation Chair and Professorship in Community Health Nursing, and was honored with the University Provost's Public Scholar award. Her presentations and publications have been in the areas of home health, community health and community-focused nursing practice, as well as primary care nursing.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Explain differences in total quality management/continuous quality improvement (TQM/CQI).
2. Evaluate the role of QA/QI in CQI.
3. Analyze the historical development of the quality process in nursing and describe the changes developing under managed care.
4. Evaluate approaches and techniques for implementing CQI and the method of documentation.
5. Plan a model QA/QI program.
6. Identify the purposes for the types of records kept in community and public health agencies.

KEY TERMS

accountability, p. 572
 accreditation, p. 574
 audit process, p. 580
 certification, p. 575
 charter, p. 575
 client-centered care, p. 588

Community and Public Health Agency Records

Although the concept of quality assurance has been a part of the health care arena for a number of years, it is only in the last few years that major movement to improve health care quality has begun in the United States. The [Institute of Medicine \(IOM, 2001\)](#), not confident of the health care systems' ability to deliver the quality of care expected, set forth a series of recommendations to transform systems to meet Americans' expectations. Very little is known about quality of care in this country for two reasons: (1) a variety of definitions of *quality* are used, and (2) it is difficult to obtain comparable data from all providers and health care agencies.

However, in the Healthcare Research and Quality Act of 1999 (PL 106-129), Congress mandated that the Agency for Healthcare Research and Quality (AHRQ) produce an annual report on health care quality in the United States beginning in fiscal year 2003. This National Healthcare Quality Report (NHQR) is a collaborative effort among the agencies of the U.S. Department of Health and Human Services (USDHHS) and includes a broad set of performance measures that will be used to monitor the nation's progress toward improved health care quality. The NHQR represents the broadest examination of quality of health care, in terms of number of measures and number of dimensions of care, ever undertaken in the United States. The report represents progress toward improving quality as well as recommendations for how to improve quality outcomes ([USDHHS, 2014](#)).

The NHQR is intended to serve a number of purposes, such as demonstrating the validity (or lack) of concerns about quality; documenting whether health care quality is stable, improving, or declining over time; and providing national benchmarks against which specific states, health plans, and providers can compare their performance ([AHRQ, 2014b](#); [NCQA, 2013a](#)).

In a changing health care market, the demand for quality has become a rallying point for health care consumers. All

consumers, including private citizens, insurance companies, industry, and the federal government, are concerned with the highest quality outcomes at the lowest cost ([Clancy and Lloyd, 2011](#)). In addition to the demand for higher quality and lower cost, the public wants health care delivered with greater access, and health care that is accountable, efficient, and effective. Moreover, consumers want information about quality. Information is empowering to the consumer. With the expanded use of the Internet, access to information about quality in health care is readily available, ranging from talking to consumers about quality health care (<http://www.talkingquality.gov>) to clinical practice guidelines that promise to improve care for all (<http://www.guideline.gov>). **Total quality management** (TQM) is a management philosophy that includes a focus on client, **continuous quality improvement** (CQI), and teamwork ([Kelly, 2011](#)). Although relatively new in public health care, the concepts of TQM/CQI have been tried and proven in industry at large. The terms *total quality management*, *continuous quality improvement*, *total quality*, and *organization-wide quality improvement* are often used interchangeably. However, they have different meanings. As indicated, TQM refers to a management philosophy that focuses on the statistical processes by which to assess work done with the goal of organization-wide quality effectiveness. TQM is often referred to as TQ, and both acronyms have the same meaning. CQI, while different from the other three terms, can be implemented not only to address system problems, but also to maintain and enhance good performance through the use of differing techniques. Everyone in the public health or community-based organization is involved in CQI—the leaders, the staff, and the client. By obtaining facts about work processes (e.g., all the steps in certifying a child for the women, infants, and children nutritional program [WIC]), it is possible to discover which steps are unnecessary (i.e., non-value adding) and to eliminate those steps to produce better health outcomes for individuals and communities ([Oakland,](#)

BOX 26-1 Commonly Used Abbreviations

AACN	American Association of Colleges of Nursing
ACHNE	Association of Community Health Nursing Educators
AHRQ	Agency for Healthcare Research and Quality (formerly AHCPR)
ANA	American Nurses Association
APHA	American Public Health Association
CCNE	Commission on Collegiate Nursing Education
CHAP	Community Health Accreditation Program
CMS	Centers for Medicare and Medicaid Services (formerly HCFA)
CQI	Continuous Quality Improvement
HEDIS	Health Plan Employer Data and Information Set
IOM	Institute of Medicine
JCAHO	Joint Commission on Accreditation of Healthcare Organizations
MCO	Managed Care Organization
NCQA	National Committee for Quality Assurance
NHQR	National Healthcare Quality Report
NLN	National League for Nursing
NPHPS	National Public Health Performance Standards Program
OCQI	Outcomes-Based Quality Improvement
QA	Quality Assurance
QI	Quality Improvement
QIO	Quality Improvement Organization
TQI	Total Quality Improvement
TQM	Total Quality Management

2014). Box 26-1 presents several abbreviations that are commonly used in health care and quality management.

Both consumers and providers have a vested interest in the quality of the health care system to do the following:

1. Improve safety of care to save lives
2. Reduce costs by using effective interventions
3. Increase client confidence in health care delivery regardless of setting (NQF, 2010)

Kovner and Jonas state that in health care there is a direct link between doing a good job and individual and professional survival. Health care providers pride themselves on individual achievement and responsibility for good client outcomes (Kovner and Knickman, 2011). Health care organizations are natural extensions of health care providers and thus can demonstrate their responsibility for optimal outcomes through a rigorous **quality improvement** process. The application of quality improvement strategies through the following six areas of performance could affect both process and outcomes of health care:

1. Consistently providing appropriate and effective care
2. Reducing unjustified geographic variation in care
3. Eliminating avoidable mistakes
4. Lowering access barriers
5. Improving responsiveness to clients
6. Eliminating racial/ethnic, gender, socioeconomic, and other disparities and inequalities in access and treatment (USDHHS, 2011a)

In the 1990s the United States entered a new era of population-centered, community-controlled delivery of care in which **managed care organizations (MCOs)** played an integral role. MCOs are agencies such as health maintenance organizations (HMOs) and preferred provider organizations (PPOs)

designed to monitor and deliver health care services within a specific budget. Currently providers, clients, payers, and policy makers all have input into the quality measurement process. The Health Plan Employer Data and Information Set (HEDIS), a data collection arm of the National Committee for Quality Assurance (NCQA), provides performance information, or report cards, for 90 percent of America's health plans. In 2012, 538 health insurance plans, including HMOs and PPOs, reported audited HEDIS data to show the level of quality performance (NCQA, 2013b). In the ACA (KHN, 2014) accountable care organizations (ACO) are being promoted. The ACO may involve a network of physicians.

Although introduced in the 1990s, **report cards** for public health agencies are currently being developed and promoted to measure quality health care in communities. The term *community health report card* refers to different types of reports, community health profiles, needs assessments, scorecards, quality of life indicators, health status reports, and progress reports. All of these reports are critical components of community-based approaches to improving the health and quality of life of communities (UK, 2014).

An example at the national level is the Community Health Status Indicator (CHSI) Project, which is a collaborative effort between the Health Resources and Services Administration (HRSA), the Association of State and Territorial Health Officials (ASTHO), the National Association of County and City Health Officials (NACCHO), and the Public Health Foundation. In 2000, the project published and disseminated community health status reports for all U.S. counties. These reports provided county-level data, including peer county and national comparisons, for every county in the country. The goal of CHSI is to provide an overview of key health indicators for local communities and to encourage dialogue about actions that can be taken to improve a community's health. The CHSI report was designed not only for public health professionals, but also for members of the community who are interested in the health of their community. They are designed to support health planning by local health departments, local health planners, community residents, and others interested in community health improvement. The CHSI report contains over 200 measures for each of the 3141 U.S. counties. Although CHSI presents indicators like deaths resulting from heart disease and cancer, it is imperative to understand that behavioral factors such as tobacco use, diet, physical activity, alcohol and drug use, and sexual behavior substantially contribute to these deaths (NICHSR, 2012).

These community health improvement initiatives have grown out of three major trends: (1) an increasing recognition of the importance of local community action to solve local problems, (2) an increasing emphasis on outcomes and accountability, and (3) the Healthy Cities/Healthy Communities movement (see Chapter 20). The Healthy Cities/Healthy Communities movement views community health and its determinants broadly, and they use a set of indicators (to track their progress) that reflects this broad definition. These indicators might include the following:

- Physical and mental health status
- Educational achievement
- Economic prosperity

- Public safety
- Adequate housing and transportation
- A clean and safe physical environment
- Recreational and cultural opportunities (Braunstein and Lavizzo-Mourey, 2011)

Community health report cards can be a useful tool in efforts to help identify areas where change is needed, to set priorities for action, and to track changes in population health over time. The report card may be used to track leading causes of morbidity and mortality in a community, looking at trends over time to see if public health interventions have improved health care outcomes. The card may also be used to assess a specific chronic disease, like diabetes, to determine the health status of the community for this particular disease (CDC, 2010). The report card may be used as an internal measure of public health program outcomes and CQI measures within the agency (Gunzenhauser et al, 2010).

In 2014, HEDIS measures of care included several that address public health issues, including BMI reduction and maintenance, smoking or tobacco use quit rates, and physical activity levels (NCQA, 2014).

As a part of a movement to provide quality health care in communities, health departments are increasingly examining their place in promoting quality (CDC, 2014). Sollecito and Johnson (2013) state that public health and CQI are connected because of the use of systems approaches that public health takes in identifying problems and developing interventions. Aspects of planning, implementing, and evaluating by TQM fall under each of the core public health functions of assessment, assurance, and policy development. However, it is with the assurance core function, related to ensuring available access to the health care services essential to sustain and improve the health of the population, that TQM programs must be undertaken. Public health cannot ensure services that improve health if those services lack quality. Public health will want to maintain quality in its workforce and continually evaluate the effectiveness of its services whether service is delivered to the individual, the community, or the population.

At least four documents provide report cards on how well the United States is performing on improving safety of health care delivery, quality of and access to care across population groups, progress and opportunities for improving health care quality, and the state of health care quality. These reports are published regularly by the Agency for Health Care Research and Quality, the National Quality Forum, and the National Committee for Quality Assurance.

Nurses are in a perfect position to implement strategies to improve population-centered health care. Community assessments, identification of high-risk individuals, use of targeted interventions, case management, and management of illnesses across a continuum of care are strategies suggested as part of the focus in improving the health of communities (Quad Council of Public Health Nursing Organizations, 2011). These strategies have long been used by nurses.

The growth of the **managed care** industry has changed the face of health care in the United States, both in how health care is delivered and in how it is received by consumers. Consumers are forming **partnerships** in communities to counteract the

power of MCOs by holding them accountable for health outcomes in relation to costs. The ACA's (KHN 2014) emphasis on ACOs is promoting the managed care approach to health care delivery with quality indicators. Partnerships are using data-based community assessments to improve health and to ensure that communities receive quality services. Projects are being funded to meet this goal (Kresge Foundation, 2014).

Because of managed care agencies and consumer demands for quality nursing, objective and systematic evaluation of nursing care is a priority for the nursing profession. Since organized nursing is committed to direct individual accountability, is evolving as a scientific discipline, and is concerned about how costs of health services limit access, it demands delivery and evaluation of quality service aimed at superior client outcomes (ANA, 2009). In the public health arena, the **Quad Council of Public Health Nursing Organizations** (2011), which includes four nursing organizations—the ANA, the Association of Community Health Nursing Educators, the APHA public health nurses, and the Association of Public Health Nurses—has identified competencies for public health nursing based on the Council on Linkages Between Academia and Public Health Practice document of 2008 with the most recent update on these competencies occurring in 2014 (Council on Linkages). Other states have developed models to document outcomes attributable to nursing interventions and are adding methods for evaluating total quality (Minnesota Department of Health, 2001; Keller et al, 2004a, 2004b; Sakamoto and Avila, 2004; Smith and Bazini-Barakat, 2004; University of Wisconsin-Madison, 2010). **Box 26-2** is a list of the areas of nursing interventions that nurses will want to be able to use. (See **Chapter 9** for the most recent updates on the Keller et al model of the Intervention Wheel.)

BOX 26-2 The Areas of Public Health Nursing Interventions for Quality Population-Centered Health Care

Interventions	Chapter
Advocacy	5, 6, 10, 16, 22, 30, 32, 34, 37, 46

Survey	18, 24

From Minnesota Department of Health, Division of Community Health Services: Public health interventions: applications for public health nursing practice, St Paul, MN, March 2001, p 1, Public Health Nursing Section.

The competencies for public health leadership developed by the Council on [Linkages \(2001, updated 2014\)](#) are crucial to ensure the quality and performance of the public health workforce. See Resource Tool 46.A on the Evolve website for a list of the competencies.

Records are maintained on all health care system clients to provide complete information about the client and to show the quality of care being given to the client within the system. Records are a necessary part of a CQI process, as are the tools and methods for evaluating quality. Electronic health records are becoming more common and are aiding in decreasing errors, increasing quality, and monitoring interventions ([Keyser et al, 2009](#)).

DEFINITIONS AND GOALS

The IOM definition of quality is “the degree to which health services for individuals and populations increase the likelihood of desired health outcomes and are consistent with current professional knowledge” (2001, p. 1000; 2011). The AHRQ defines quality health care as doing the right thing, for the right client, and having the best possible results (2014a). Quality in public health is defined as “the degree to which policies, programs, services, and research for the population increase desired health outcomes and conditions in which the population can be healthy” ([IOM, 2013](#), p. 3).

However, a definition of quality rests largely on the perception of the client, the provider, the care manager, the purchaser, the payer, or the public health official. Whereas the physician views quality in a more technical sense, the client may look at the personal outcome; the manager, purchaser, or payer may consider the cost-effectiveness; and the public health official will look at the appropriate use of health care resources to improve population health ([AHRQ, 2012](#)).

According to the [AHRQ \(2012\)](#), problems with quality of care were divided into five groups: variation of service, underuse of service, overuse of service, misuse of service, and disparities in quality. Variation in service refers to the lack of standards of practice continuity. This variation is often seen between regional, state, and local health care services and stems from lack of evolutionary health care practice and not keeping abreast of the constant changes taking place in health care (evidence-based practice) ([NCQA, 2013b](#); [IOM, 2011](#)). Underuse of service refers to conservative treatment practices. As an example, there is a lack of immunizations for pneumonia given to Asians 65 years or older as a preventive measure as compared with immunization levels of whites ([AHRQ, 2014b](#)). Overuse of service refers to the over-ordering of unnecessary tests, surgeries, and treatments. This overuse drives up the cost of already expensive health care. Misuse of service refers to client safety issues and how disability and mortality can be reduced. With diligent care by health care providers, client injury and death can be avoided ([IOM, 2011](#)). Disparities in quality refer to racial, ethnic, and socioeconomic disparities in accessibility and affordability of health care ([AHRQ, 2014b](#)).

The term *health services* applies to a wide range of health delivery institutions. Of particular interest to public health is

the question of access to appropriate and needed services, a well-prepared workforce, and improvement in the status of the population's health. Client satisfaction and well-being and the processes of client-provider interaction should be considered as well.

TQM is a process-driven, customer-oriented management philosophy that includes leadership, teamwork, employee empowerment, individual responsibility, and continuous improvement of system processes to yield improved outcomes ([Oakland, 2014](#)). Under TQM, quality is defined as customer satisfaction. **Quality assurance/quality improvement (QA/QI)** is the promise or guarantee that certain standards of excellence are being met in the delivery of care. [Van den Heuvel, Niemeijer, and Does \(2013\)](#) discuss what is called the *Juran trilogy*. This consists of quality planning, quality control, and quality improvement. This trilogy combines components of QA as well as CQI to improve client outcomes in health care delivery.

QI is defined as “systematic and continuous actions that lead to measureable improvement in health care services and the health status of targeted patient groups” ([USDHHS, 2011b](#)). QI in public health is the use of a deliberate and defined improvement process, such as plan-do-check-act (PDCA), which is focused on activities that are responsive to community needs and improving population health. It refers to a continuous and ongoing effort to achieve measurable improvements in the efficiency, effectiveness, performance, accountability, outcomes, and other indicators of quality in services or processes that achieve equity and improve the health of the community ([Bialek et al, 2010](#)).

QA is concerned with the accountability of the provider and is only one tool in achieving the best client outcomes. **Accountability** means being responsible for care and answerable to the client ([Sollecito and Johnson, 2013](#)). Under QA/QI, quality may have a variety of definitions. According to [Kaplan and colleagues \(2010\)](#), QA should consist of peer review leading to QI to improve health care delivery. Client standards of care and safety issues are the core of QA.

The AHRQ has indicated that the assurance of quality is organized around four dimensions (effectiveness, client safety, timeliness, and client centeredness) and is assessed using four stages of care [staying healthy (primary prevention), getting better (secondary prevention), living with illness or disability, and coping with end of life (tertiary prevention)] ([AHRQ, 2014b, 2014c](#)).

Quality traditionally has been an important issue in the delivery of health care. QA programs historically have ensured this accountability. The goals of QA and QI are on a continuum of quality, and in public health they are (1) to continuously improve the timeliness, effectiveness, safety, and responsiveness of programs, and (2) to optimize internal resources to improve the health of the community ([Riley et al, 2010](#)).

Under a CQI philosophy, QA and QI are but two of the many approaches used to ensure that the health care agency fulfills what the client thinks are the requirements for the service. QA focuses on finding what providers have done wrong in the past (e.g., deviations from a standard of care found through a chart audit). CQI operates at a higher level on the quality continuum

but requires the commitment of more organization resources to move in a positive direction. CQI focuses on the sources of differences in the ongoing process of health care delivery and seeks to improve the process (Kelly, 2011; Sullivan, 2013).

The process of health care includes two major components: technical interventions (e.g., how well procedures are accomplished, accurate assessments, and effective interventions) and interpersonal relationships between public health practitioner and client. Both contribute to quality care, and both can be evaluated. Several approaches and techniques are used in quality programs. *Approaches* are methods used to ensure quality, and *techniques* are tools for measuring differences in quality (Kovner and Knickman, 2011).

Traditional approaches to quality focus on assessing or measuring performance, ensuring that performance conforms to standards, and providing remedial work to providers if those standards are not met. Such a definition of quality is too narrow in health care systems that try to meet the needs of many clients, both internal and external to the agency. CQI requires constant attention and should involve surveillance of all records while there is still the opportunity to intervene in both the client's care and the practitioner's actions. Comprehensive data analysis is necessary to detect process failure. Many agencies use some of the TQM/CQI concepts, such as client satisfaction questionnaires, but have not adopted the entire management philosophy. However, because QA/QI methods have traditionally been used and are still in use in many agencies, the QA/QI concepts will be covered.

HEALTHY PEOPLE 2020

Goal of Improving Access to Comprehensive, High-Quality Health Care, and Examples of Objectives to Eliminate Health Disparities

- AHS-1: Increase the proportion of persons with health insurance.
- AHS-5: Increase the proportion of persons who have a specific source of ongoing care.
- AHS-7: Increase the proportion of persons who receive evidence-based clinical preventive services.

From U.S. Department of Health and Human Services: Healthy People 2020, Washington, DC, 2010, U.S. Government Printing Office.

HISTORICAL DEVELOPMENT

Improving the quality of care has been a part of nursing since the days of Florence Nightingale. In 1860 Nightingale called for the development of a uniform method to collect and present hospital statistics to improve hospital treatment. Nightingale was a pioneer in setting standards for nursing care. The movement to establish nursing schools in the United States came in the late 1800s from a desire to set standards that would upgrade nursing care. In the early 1900s efforts were begun to set similar standards for all nursing schools. From 1912 to 1930 interest in quality nursing education led to the development of nursing organizations involved in accrediting nursing programs. Licensure has been a major issue in nursing since 1892. By 1923 all states had permissive or mandatory laws directing nursing practice.

After World War II, the attention of the emerging nursing profession focused on establishing a scientific method of practice. The nursing process was the chosen method and included evaluation of how nursing activities helped clients (Maibusch, 1984). QA/QI was the evaluative step in the nursing process.

The 1950s brought the development of QA measurement tools. One of the first tools was Phaneuf's nursing audit method (1965), which has been used extensively in population-centered nursing practice.

In 1966, the American Nurses Association (ANA) created the Divisions on Practice. As a result, in 1972, the Congress for Nursing Practice was charged with developing standards to institute QA programs. The Standards for Community Health Nursing Practice were distributed to ANA Community Health Nursing Division members in 1973. In 1986, 1999, and in 2005, with updates in 2007 and 2013, the scope and standards were again revised with a change in focus from community health nursing to public health nursing.

In 1972, the Joint Commission on Accreditation of Hospitals (JCAH) clearly stated the responsibilities of nursing in its description of standards for nursing services. The JCAH called on the nursing industry to clearly plan, document, and evaluate nursing care provided. In the mid-1980s, the JCAH became the Joint Commission on Accreditation of Healthcare Organizations (JCAHO) and began developing quality control standards for hospital and home health nursing. JCAHO is now known as The Joint Commission (TJC) and presently incorporates CQI principles in its standards.

Also in 1972, the Social Security Act (PL 92-603) was amended to establish the Professional Standards Review Organization (PSRO) and to mandate the process review of the delivery of health care to clients of Medicare, Medicaid, and maternal and child health programs. The PSRO program later became the Peer Review Organization (PRO) under the 1983 Social Security amendments. The purpose of the PROs was to monitor the implementation of the prospective reimbursement system for Medicare clients (the diagnosis-related groups [DRGs]). Although PSROs were intended for physicians, PROs made QI a primary issue for all health care professionals. The PRO was renamed the QIO, or the quality improvement organization (QIO), and is mandated to improve the quality and efficiency of Medicare funded services (CMS, 2014a).

In response to increasing charges of malpractice, the government passed the National Health Quality Improvement Act of 1986. Although it was not funded until 1989, its two major goals were to encourage consumers to become informed about their practitioner's practice record and to create a national clearinghouse of information on the malpractice records of providers. The emphasis of this act continued to be on the structure of care rather than the process or outcomes of care (NAHQ, 1993; Zale and Selvan, 2009). (See Chapter 25 for discussion of structure, process, and outcome.)

Efforts to strengthen nursing practice in the community have been carried out by several nursing organizations, including the ANA, the Public Health Nursing Section of the American Public Health Association (APHA), the Association of State and Territorial Directors of Nursing (now APHN), and

the Association of Community Health Nursing Educators (ACHNE). The quality of nursing education is a major concern of the ACHNE, which was established in 1978. In 1993, 2000, 2003, and 2007, five reports published by this organization identified the curriculum content required to prepare nursing students for practice in the community (ACHNE, 1993, 2000a/2009, 2000b, 2003, 2007). In 2005, and again in 2007, the Quad Council reviewed scopes and standards of population-focused (public health) and community-based nursing practice and developed new standards to guide the profession in obtaining the best health outcomes for the populations they serve. These standards were updated again in 2013. QA/QI programs remain the enforcers of standards of care for many agencies that have not elected to engage in a program of CQI. These activities are called *assurance activities* because they make certain that those policies and procedures are followed so that appropriate quality services are delivered.

The Council on Linkages between Academia and Public Health Practice (the Council) is a coalition of representatives from 17 national public health organizations. Since 1992, the Council has worked to further academic/practice collaboration to ensure a well-trained, competent workforce and a strong, evidence-based public health infrastructure. The Council is funded by the CDC and staffed by the Public Health Foundation. The most recent core competencies were updated in 2014. These competencies are used in QA/QI as performance measurements of providers to ensure quality of services (Council on Linkages, 2014).

APPROACHES TO QUALITY IMPROVEMENT

Two basic approaches exist in QI: *general* and *specific*. The general approach involves a large governing or official body's evaluation of a person's or agency's ability to meet criteria or standards. Specific approaches to QI are methods used to manage a specific health care delivery system in an attempt to deliver care with outcomes that are acceptable to the consumer. QA/QI programs that evaluate provider and client interaction through compliance with standards historically have been used alone to monitor quality care. In a TQM approach, CQI with QA/QI methods are an integral, but not the only, tool for ensuring quality or customer satisfaction.

General Approaches

General approaches to protect the public by ensuring a level of competency among health care professionals are *credentialing*, *licensure*, *accreditation*, *certification*, *charter*, *recognition*, and *academic degrees*. Although there has been a long history of public oversight of quality in the United States, this public oversight increasingly involves the private sector. Public oversight for quality emerged when the private market failed to focus on health care quality. Previously mentioned reports about quality are indicators of public sector involvement in public oversight of quality.

Credentialing is generally defined as the formal recognition of a person as a professional with technical competence, or of an agency that has met minimum standards of performance.

These mechanisms are used to evaluate the agency structure through which care is provided and the outcomes of care given by the provider. Credentialing can be mandatory or voluntary. Mandatory credentialing requires laws. State nurse practice acts are examples of mandatory credentialing. Voluntary credentialing is performed by an agency or an institution. The certification examinations offered by the ANA through the American Nurses Credentialing Center are examples of voluntary credentialing. Licensing, certification, and accreditation are all examples of credentialing (ANCC, 2014).

Licensure is one of the oldest general QA approaches in the United States and Canada. Individual licensure is a contract between the profession and the state. Under this contract, the profession is granted control over entry into, and exit from, the profession and over quality of professional practice (NCSBN, 2014a).

The licensing process requires that written regulations define the scope and limits of the professional's practice. Job descriptions based on these regulations set minimum and maximum limits on the functions and responsibilities of the practitioner. Licensure of nurses has been mandated by law since 1903. Today all 50 states have mandatory nurse licensure, which requires all individuals who practice nursing, whether it be for money or as a volunteer, to be licensed. A new approach to interstate practice requires a pact between states so that nurses can practice across state borders (NCSBN, 2014b). Although reciprocity (which means nurses can have their license accepted through an application process if there is agreement between the states requiring application) exists among states for nursing licensure, interstate practice without approval is an issue for state boards of nursing. The states' compact agreements were to reduce the barriers for interstate practice. The mutual recognition model of nurse licensure allows a nurse to have one license (in his or her state of residency) and to practice in other states (both physically and electronically when giving advice through programs like "ask a nurse"), subject to each state's practice law and regulation. Under mutual recognition, a nurse may practice across state lines unless otherwise restricted. This is referred to as a multi-state nurse licensure model, specifically referred to as the Nurse Licensure Compact (NLC). All states that currently belong to the NLC also operate the single-state licensure model for those nurses who do not reside legally in an NLC state or do not qualify for multistate licensure. To achieve mutual recognition, each state must enact legislation or regulation authorizing the NLC. States entering the compact also adopt administrative rules and regulations for implementation of the compact.

Once the compact is enacted, each compact state designates a Nurse Licensure Compact Administrator to facilitate the exchange of information between the states relating to compact nurse licensure and regulation. On January 10, 2000, the **Nurse Licensure Compact Administrators (NLCA)** were organized to protect the public's health and safety by promoting compliance with the laws governing the practice of nursing in each party state through the mutual recognition of party state licenses (NCSBN, 2014b).

Accreditation, a voluntary approach to QI, is used for institutions. Since 1954 the National League for Nursing (NLN), a

voluntary organization, has had established standards for inspecting nursing education programs. In 1997 the NLN board established an accrediting body as an independent organization: the NLN Accrediting Commission (NLNAC). The name of this organization is now the Accreditation Commission for Nursing Education (ACEN) (NLN, 2014). In 1997 the American Association of Colleges of Nursing (AACN), also a voluntary organization supporting baccalaureate and higher degree programs, established an affiliate—the Commission on Collegiate Nursing Education (CCNE)—to accredit baccalaureate and higher degree nursing programs (CCNE, 2014). In 1966 community health/home health program standards were established by the NLN for the purpose of accrediting these programs through their Community Health Accreditation Program, now an independent organization (CHAP, 2014). In addition, state boards of nursing accredit basic nursing programs so that their graduates are eligible for the licensing examination. In some states, state boards of nursing accredit graduate programs.

The accreditation function is quasi-voluntary. Although accreditation appears to be a voluntary program, it is often linked to government regulation that encourages programs to participate in the accrediting process. Examples include the federal Medicare regulations restricting payments only to accredited public health and home health care agencies (CMS, 2014b).

Accreditation, whether voluntary or required, provides a means for effective peer review and an opportunity for in-depth review of program strengths and limitations. Accreditation applies external pressure and places demands on institutions to improve quality of care. In the past, the accreditation process primarily evaluated an agency's physical structure, organizational structure, and personnel qualifications. However, beginning in 1990, more emphasis was placed on evaluation of the outcomes of care and on the educational qualifications of the person providing the care.

In the past there has not been a mechanism for accrediting public health agencies. In 2007 the Public Health Accreditation Board (PHAB) was incorporated, after public health leaders explored the feasibility of a national accreditation program. The field saw the need for, and value of, public health accreditation, and advocated for the implementation of a national voluntary program. The PHAB was developed in accordance with the recommendations generated by the Exploring Accreditation Steering Committee. The Steering Committee was comprised primarily of state and local public health officials, including boards of health. The committee called on the expertise from other specialty areas engaged in accreditation. The PHAB is a nonprofit organization and is developing and testing national standards and processes that will be used to assess the strengths and areas for improvement in public health (PHAB, 2014).

The PHAB mission is to promote and protect the health of the public by advancing the quality and performance of *all* public health departments in the United States. The PHAB works toward creating a high-performing public health system that will make the United States the healthiest nation. The CDC and the Robert Wood Johnson Foundation are funders, and

partners, of PHAB. The goal is for the accreditation program and the accrediting process, which began in 2011, to be self sustaining.

Certification, another general approach to quality, combines features of licensure and accreditation. Certification is usually a voluntary process within professions. Educational achievements, experience, and performance on an examination determine a person's qualifications for functioning in an identified specialty area. The American Nurses Credentialing Center provides certification in several areas of nursing (ANCC, 2014). Many other professional nursing specialty credentialing organizations also provide for individual certification.

Although usually a voluntary process, certification can also be a quasi-voluntary process. For example, to function as a nurse practitioner in all but three states, one must show proof of educational credentials and take an examination to be certified to practice within the boundaries of the state (Fitzgerald, 2013).

Major concerns exist about certification as a QA mechanism. Data are lacking about the clinical competence of the practitioner at the time of certification because clinical competency is usually not measured by a written test. Although better data exist about the quality of the practitioner's work after the certification process, the American Nurses Credentialing Center conducted a research program to look at how certification is related to the work of the certified nurse (Blegen, 2012; Boltz et al, 2013; Kendall-Gallagher et al, 2011; Martinez, 2011). Except for occupational health nurses and nurse anesthetists, certification has not been universally recognized by employers as an achievement beyond basic preparation, so financial rewards have been few (Keefe, 2010).

Although the nursing profession has accepted the certification process as a mechanism for recognizing competence and excellence, certifying bodies must help nurses communicate the importance of certified nurses to the public.

Charter, recognition, and academic degrees are other general approaches to QA. **Charter** is the mechanism by which a state government agency, under state laws, grants corporate status to institutions with or without rights to award degrees (e.g., university-based nursing programs).

Recognition is a process whereby one agency accepts the credentialing status of and the credentials conferred by another. For example, most state boards of nursing accept nurse practitioner credentials that are awarded by the American Nurses Credentialing Center or by one of the specialty credentialing agencies. Academic degrees are titles awarded to individuals recognized by degree-granting institutions as having completed a predetermined plan of study in a branch of learning. There are four academic degrees awarded in nursing, with some variety at each degree level: Associate of Arts/Sciences; Bachelor of Science in Nursing; master's degrees, such as Master of Science in Nursing and Master of Nursing; and doctoral degrees, such as Doctor of Philosophy and Doctor of Nursing Practice.

Although these general quality management methods are important and should continue, newer and better approaches must be devised. If performance in the area of quality health

care is to advance, better diagnosis of performance problems and corrective strategies that are effective will be necessary (USDHHS, 2011a). The National Network of Public Health Institutes (2010) a toolkit designed to improve quality performance in public health, developed a toolkit.

An approach to recognition is the Magnet nursing services recognition status given by the American Nurses Credentialing Center to agency nursing services that, after an extensive review, are considered excellent. This program began with recognition of excellent hospital nursing services. The Magnet program has expanded to include nursing home and home health agencies. Reapplication for Magnet status must occur every 4 years to ensure that Magnet organizations stay at the top of their games (ANCC, 2014).

Specific Approaches

Historically, QA programs conducted by health care agencies have measured or assessed the performance of individuals and how they conformed to standards set forth by accrediting agencies. TQM as a management philosophy uses CQI methods that incorporate many tools, including QA, to increase customer satisfaction with quality care. According to the AHRQ, quality health care means doing the right thing, at the right time, in the right way, for the right people—and having the best possible results (AHRQ, 2012, 2014b). To the Institute of Medicine (IOM, 2001, p. 3), quality health care is care that is as follows:

- *Effective*—Providing services based on scientific knowledge to all who could benefit and refraining from providing services to those not likely to benefit
- *Safe*—Avoiding injuries to clients from the care that is intended to help them
- *Timely*—Reducing waits and sometimes harmful delays for both those who receive and those who give care
- *Client-centered*—Providing care that is respectful of and responsive to individual client preferences, needs, and values and ensuring that client values guide all clinical decisions
- *Equitable*—Providing care that does not vary in quality because of personal characteristics such as gender, ethnicity, geographic location, and socioeconomic status
- *Efficient*—Avoiding waste, including waste of equipment, supplies, ideas, and energy

QA seeks to eliminate errors before negative outcomes can occur rather than waiting until after the fact to correct individual performance.

Health care agencies have only recently paid heed to the tenets of TQM. This management philosophy has been used in Japanese industry since the post–World War II era when W. Edwards Deming was invited to Japan to help rebuild its broken economy. In addition to Deming, people associated with the total quality concept are Walter Stewart (who first published on the subject), Joseph M. Juran, Armand F. Feigenbaum, Phillip B. Crosby, Genichi Taguchi, and Kaoru Ishikawa. Unlike traditional QA programs, the focus of CQI is the *process* of delivering health care. This focus on process avoids placing personal blame for less-than-perfect outcomes. Applying TQM in health care allows management to look at the contribution of all systems to outcomes of the organization.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Quality Improvement

Use data to monitor the outcomes of intervention processes, and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems.

Important aspects of quality improvement include:

- **Knowledge:** Recognize that nursing and other health professions students are parts of systems and intervention processes that affect outcomes for clients and families
- **Skills:** Identify gaps between local practices and best practice
- **Attitudes:** Value own and others' contributions to outcomes in local community settings

Quality Improvement Question

You are working as a home care nurse and are discovering a trend of frequent readmissions to the hospital of many of your clients with heart failure. Using the quality assurance approach, consider the following questions:

- What is being done now?
- Why is it being done?
- Is it being done well?
- Can it be done better?
- Should it be done at all?
- Are there improved ways to deliver service?
- How much is it costing?
- Should certain activities be abandoned or replaced?

To which aspects of your clients' quality of life and care transitions will you apply these questions?

Answer

It would be helpful to look at a group of clients discharged from the hospital. Are they receiving adequate education and preparation to return home? You could also gather data about how clients are being managed by the community. How often are they following up with their primary care clinician? Are clients adequately educated to monitor their own fluid status, weight, and dietary restrictions? Are there community-based cardiovascular care programs that can help clients maintain optimum health and avoid exacerbations?

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

Deming's (1986, p. 23) guidelines are summarized by his 15-point program:

1. Create, publish, and give to all employees a statement of the aims and purposes of the company or other organization. The management must demonstrate constantly their commitment to this statement.
2. Learn the new philosophy, top management, and everybody.
3. Understand the purpose of inspection, for improvement of processes and reduction of costs.
4. End the practice of awarding business on the basis of price tag alone.
5. Improve constantly and forever the system of production and service.
6. Institute training.
7. Teach and institute leadership.
8. Drive out fear. Create trust. Create a climate for innovation.
9. Optimize toward the aims and purposes of the company the efforts of teams, groups, and staff areas.

10. Eliminate exhortations for the workforce.
11. Eliminate numerical quotes for production. Instead, learn and institute methods for improvement.
12. Eliminate management by objective. Instead, learn the capabilities of processes and how to improve them.
13. Remove barriers that rob people of pride of workmanship.
14. Encourage education and self-improvement for everyone.
15. Take action to accomplish the transformation.

Deming's first point emphasizes that an organization must have purpose and values. Health care providers have a clear idea of their values and have been committed to quality in the past, as demonstrated by codes of ethics and standards of care. However, successful TQM and CQI processes rely on a cultural change within an organization and the full support of management. With respect to providing quality health care, a paradigm shift from individual provider responsibility to team responsibility must occur (Sollecito and Johnson, 2013). A guiding principle is a customer orientation focused on positive health outcomes and perceived satisfaction. Customer (client) satisfaction surveys must be done for both internal and external users of services.

Personnel policies that are motivating as well as continuous training/learning opportunities are crucial to any CQI program. Deming's eighth point addresses driving out fear. Fear in this context means the fear of being fired for being innovative or taking risks. In the CQI process, individuals are not blamed for failures in the system and therefore are motivated through the group to continually look for problems and improve system performance.

TQM works best in a flat organizational structure. This means there are very few supervisors between the staff and the director. This organization operates with an interprofessional team approach and a separate but parallel management quality council that monitors strategy and implementation. Teams are empowered to solve problems and locate opportunities for system improvement. Shewhart's plan-do-check-act cycle serves as a guideline for the team approach to problem solving. This approach is also known as the Demming wheel. Steps include the following (Deming, 1986, p. 88; Deming Institute, 2014):

1. PLAN: Ask questions, such as: What could be the most important accomplishments of this team? What changes might be desirable? What data are available? Are new observations needed? If yes, plan a change or implement a test. Decide how to use the observations.
2. DO: Carry out the change or test decided upon.
3. CHECK: Observe the effects of the change. Study the results. What did we learn? What can we predict?
4. ACT: Repeat the cycle, if the changes worked, or implement a different strategy if the first plan was flawed, or revise the initial strategy based on the changes needed.

A suggested way to start the problem-solving process with a team in step 1 is brainstorming (Simon, n.d.). Brainstorming is getting everyone's input about a possible process situation with no team member criticizing the suggestion. Because TQI organizations are data driven, moving to step 2 requires that ongoing statistics be collected. Differences from the mean (average) or norm are detected through consistent use of tools, such as the

flow chart, the Pareto chart (used to compare the importance of differences between groups of data), cause-and-effect diagrams, check sheets (see p. 583 for a client satisfaction check sheet), histograms, control charts, regression, and other statistical analyses (e.g., QA data and techniques, risk management data, risk-adjusted outcome measures, and cost-effectiveness analysis) (Sollecito and Johnson, 2013). Steps 3, 4, and 5 are self-explanatory.

Joseph Juran built on Deming's initial quality work and became a supporter of building quality into all processes. The *Juran trilogy* provides an effective way to compare the tasks of quality planning, QA, and QI. Quality planning involves determining who the clients are, the needs of those clients, the service that fulfills the needs, and the process to produce that service. QA evaluates the performance of that service, compares it with the service goals, and then makes corrections if necessary. QI makes sure the infrastructure exists to enable individuals to identify improvement projects. Management of QI establishes project teams and provides those teams with the resources needed to carry out improvement projects (Van den Heuvel et al, 2013).

TQM/CQI IN COMMUNITY AND PUBLIC HEALTH SETTINGS

Guidelines provided by the 1991 APHA *Model Standards* linked standards to meeting the health goals for the nation in the year 2000 (Sollecito and Johnson, 2013). *Healthy People 2000* and APHA *Model Standards* (APHA, 1991) provided not only lists of priority health objectives for the nation and a way for public health to implement TQM/CQI, but also the most current statistics and scientific knowledge about health promotion and disease prevention. *Healthy People in Healthy Communities* (USDHHS, 2001) provided the objectives with their stated targets, measurement tools, and reflected intended performance expectations.

Healthy People 2010 built on *Healthy People 2000* and contained modified and additional objectives for promoting health and preventing disease (USDHHS, 2000). An important part of the framework of *Healthy People 2010* was eliminating health disparities and ensuring access to quality health care for all. After extensive review of the *Healthy People 2010* objectives, new goals and objectives were developed for *Healthy People 2020* (USDHHS, 2010). The goals for *Healthy People 2020* are as follows:

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death.
- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health for all.
- Promote quality of life, healthy development, and healthy behaviors across all life stages.

Although all of the goals speak to quality of life and health, goal two specifically addresses issues related to quality of health care delivery.

In addition, the *Planned Approach to Community Health* (PATCH) (CDC, 1995 with update in 2010); the Assessment Protocol for Excellence in Public Health (APEXPH), APEXPH

in Practice (NACCHO, 1995, 2014); and most recently the *Mobilizing for Action through Planning and Partnerships* (MAPP) process (NACCHO, 2014) provide methods of assessing community needs to see how well health departments are operating to meet existing standards (see Chapter 25).

As health care reform continues, especially with the implementation of the Affordable Care Act, public health agencies face competition and are trying to reform themselves. A promising outcome of reform is how private health care and public health can come together in a community-level effort to monitor performance and improve health (see Chapter 3).

Recognizing the many factors that cause health problems and the fragmenting that continues to exist in the health care system, the public-private collaborative framework supported by the *Healthy People* documents involves many stakeholders, including public health, in monitoring the health of entire communities. Performance monitoring is defined as “a continuing community-based process of selecting indicators that can be used to measure the process and outcomes of an intervention strategy for health improvement (making the results available to the community as a whole) to inform assessments of an effective intervention and the contributions of accountable agencies to this” (*Healthy People*, 2020, 2011). These indicators would measure processes or states that contribute to health, and thus the processes are potentially alterable. As previously noted, there are four documents that monitor the quality and safety of health care, including the contributions of public health. Box 26-3 provides highlights from each of these reports.

Home health care agencies have increasingly adopted QI programs because of the competition that exists. Congruent with the TQM philosophy, meeting customer expectations is essential for home health care agencies. Models for QA/QI in home health care have been developed to improve the quality of care in TQM frameworks emphasizing processes, empowerment, collaboration, consumers, data and measurement, and standards and outcomes (Oakland, 2014). Datasets of clinical information, such as those developed through the Omaha System (see Chapter 40) and the OASIS toolkit from the National Association of Home Care and Hospice (NAHC, 2010), are useful in measuring quality of care. In 2003 the Home Health Care Quality Initiative (HHQI) was developed by the USDHHS to provide consumers with data on the quality of home health services. *Home Health Compare*, posted on the Medicare website, is a home health report card available to consumers nationwide (USDHHS, 2014).

Finally, in the area of standards and guidelines, Honoré and Scott (2010) address six priority areas of performance that need improvement. One of these areas is consistently providing appropriate and effective care. This area is applicable to all health care practitioners, including nurses. Evidence-based practice guidelines are one way to deliver consistent, up-to-date care and to improve outcomes for individuals, communities, and populations. Every year the American Cancer Society (ACS) provides a summary of current cancer screening guidelines for health care professionals and updates the guidelines at least every five years, or sooner if new evidence warrants an

BOX 26-3 National Quality and Safety Reports

Name of Report	Most Recent Results
The National Health Care Quality Report, Agency for Healthcare Research and Quality, began publication in 2003 and has published for ten years	Assesses four dimensions of quality: effectiveness, client safety, timeliness, and client centeredness. Between 2003-2013: <ul style="list-style-type: none"> • Health care quality is getting better. • Large variation in quality across states. • 70% of recommended care actually received. • Access is fair and getting worse. • There has been no change in the disparities in health care over time and it is poor.
The State of Health Care Quality, 2013; The National Committee for Quality Assurance	Has been published annually for 18 years. Assesses HEDIS to determine quality improvement across third-party payers. <ul style="list-style-type: none"> • Reports after more than a decade of progress in quality of care • There is stagnant or declining performance in appropriate use of antibiotics. • Childhood obesity measures improving. • Childhood immunization results mixed. • Sustained decline in initiation of alcohol and drug treatment. • Better care in Medicaid HMOs.
National Healthcare Disparities Report, 2013; The Agency for Healthcare Research and Quality	Published since 2000 for 13 years. Assesses 11 dimensions of quality including safety: <ul style="list-style-type: none"> • Findings indicate disparities in quality and access remain common, with blacks, Hispanics, and Asians receiving worse care than whites. • Poor people receive worse care than high income persons. • For some quality measures, persons with limited activity receive poorer care.
Safe Practices for Better Healthcare, 2010; The National Quality Forum	Published first in 2003, then in 2006 and 2009. The 2010 update report presents 34 safe practices with descriptions of their safety impact. <ul style="list-style-type: none"> • Adverse health care events continue to be a leading cause of death and injury. • Evidence indicates that the 34 safe practices identified are effective in improving safety. • Although many of the 34 practices can be adapted to public health, two can be specifically applied in public health: a quality workforce and influenza prevention.

update (Smith et al, 2014). The use of guidelines helps in gathering data on the effectiveness and outcomes of nurse interventions (Matthew-Maich et al, 2013). The AHRQ, formerly the Agency for Healthcare Policy and Research (AHCPR), has played a major role in developing clinical practice guidelines.

Guidelines are protocols or statements of recommended practice developed by governmental and health care agencies, and by professional organizations; they are based on the distilling of scientific evidence and expert opinion that guide a clinician in decision making. Guidelines provide research-based evidence for interventions and promote improved health outcomes. Using research findings as guidelines or frames of reference can improve nurses' awareness of new or better ways to practice, allow for documentation of nurse interventions, and improve outcomes at all levels of public health nursing practice (Matthew-Maich et al, 2013) (see Chapter 9). Keystones of evidence-based practice guidelines arise from client concerns, clinical experience, best practices, and clinical data and research (Malloch and Porter-O'Grady, 2010). Clinical practice guidelines are systematically developed statements to assist practitioner and client decisions about appropriate health care for specific clinical circumstances (as discussed in Chapter 15). An example of criteria for clinical practice guidelines are those set forth by the AHRQ and available on the Internet at the National Guideline Clearinghouse (NGC) website (<http://www.guideline.gov/>) (NGC, 2010).

- The practice guideline contains systematically developed statements that include recommendations, strategies, or information that assists health care practitioners and clients make decisions about appropriate health care for specific health care circumstances.
- The practice guideline was produced under the auspices of specialty associations; relevant professional societies, public or private organizations, government agencies at the federal, state, or local level; or health care organizations or plans. A practice guideline developed and issued by an individual not officially sponsored or supported by one of the above types of organizations does not meet the inclusion criteria for the NGC.
- Corroborating documentation can be produced and verified that a systematic literature search and review of existing scientific evidence published in peer reviewed journals was performed during the guideline development. A guideline is not excluded from the NGC if corroborating documentation can be produced and verified detailing specific gaps in scientific evidence for some of the guideline's recommendations.
- The full text guideline is available upon request in print or electronic format (for free or for a fee) in English. The guideline is current and the most recent version produced. Documented evidence can be produced or verified that the guideline was developed, reviewed, or revised within the last 5 years (<http://www.guideline.gov/contact/coninclusion.aspx>).

One of the quality reports published by the clearinghouse each year is the *National Healthcare Disparities Report*, the most recent being 2013. The most recent guideline development and updates are related to cancer control.

Primary care practice guidelines are available in the *Guide to Clinical Preventive Services* (USPSTF, 2014) and the population-based *Guide to Community Preventive Services* available on the CDC website. This guide is an ongoing process of the Taskforce on Community Preventive Services that offers information on changing risk behaviors; reducing specific diseases, injuries and impairments, and environmental concerns; and state-of-the-art public health activities. Nurses need guidelines to reduce differences in care practices, to improve outcomes on the basis of the best research available, and to deliver effective care to individuals, communities, and populations.

Using QA/QI in CQI

QA/QI methods and tools help agencies conform to standards required by external accrediting agencies. QA/QI provides a way to identify examples of substandard care and to improve that care when standards are not met. QA is focused on problem detection, whereas CQI is focused on problem prevention and continuous improvement. In QA, little attention is paid to preventing errors or problems and finding out who owns the quality issues. Furthermore, the QA process may stop unless another problem is found. Sollecito and Johnson (2013) point out differences in traditional management models that use performance standards versus those that use TQM (Table 26-1). The most important difference is in the emphasis on QA, or simply identifying the problem in the traditional management model versus the emphasis on CQI in the total quality management model. In TQM the problem is identified and measures are implemented to correct the problem. The TQM model is required in health care delivery because of the standards set by the national accrediting agencies such as TJC. Public health, through the public health accrediting process begun in 2011, is required to emphasize TQM.

Positive steps of a known QA program can be integrated into a CQI approach. Strengths of QA include a history of expertise in developing evaluation of structure, identifying high-priority problems, and developing knowledge in QA and information systems (de Jonge et al, 2011). These strengths can be used advantageously in a CQI effort.

Traditional Quality Assurance

Traditional QA programs can fit well with the CQI process. The overall goal of specific QA approaches is to monitor the process and outcomes of client care. The goals of CQI are as follows:

TABLE 26-1 Traditional Management Model Compared with Total Quality Management (TQM) Model

Traditional Model	TQM Model
Legal or professional authority	Collective or managerial responsibility
Specialized accountability	Process accountability
Administrative authority	Participation
Meeting standards	Meeting process and performance expectations
Longer planning horizon	Shorter planning horizon
Quality assurance	Continuous improvement

1. To identify problems between provider and client through QA methods
2. To intervene in problem cases
3. To provide feedback regarding interactions between client and provider
4. To provide documentation of interactions between client and provider

Specific approaches are often implemented voluntarily by agencies and provider groups interested in the quality of interactions in their setting. However, state and federal governments require mandatory programs within public health agencies. For example, periodic utilization review, peer reviews (audits), and other QA measures are required in public health agencies that receive funds from state taxes, Medicaid, Medicare, and other public funding sources. Examples of specific approaches to QA are agency staff review committees for peer review (Banner Health, 2012), utilization review committees for Medicare and Medicaid, research studies, quality improvement organization (QIO) monitoring, client satisfaction surveys, risk management, and malpractice lawsuits.

Staff Review Committee

Staff review committees are the most common specific approach to QA in the United States. Staff review committees are designed to monitor client-specific aspects of certain levels of care. The audit is the major tool used to evaluate quality of care.

The **audit process** (Figure 26-1) consists of six steps:

1. Select a topic for study.
2. Select explicit criteria for quality care.
3. Review records to determine whether criteria are met.
4. Do a peer review for all cases that do not meet criteria.
5. Make specific recommendations to correct problems.
6. Follow-up to determine whether problems have been eliminated.

Two types of audits are used in nursing peer review: concurrent and retrospective. The **concurrent audit** is a process audit that evaluates the quality of ongoing care by looking at the nursing process. Concurrent audit is used by Medicare and Medicaid to evaluate care being received by public health/home health clients. The audit data look at the group, population, or community served. The advantages of this method are as follows:

- Identification of problems at the time care is given
- Provision of a mechanism for identifying and meeting client needs during the intervention
- Implementation of measures to fulfill professional responsibilities
- Provision of a mechanism for communicating on behalf of the client

The disadvantages of the concurrent audit are as follows:

- It is time consuming
- It is more costly to implement than the retrospective audit
- Because the intervention is ongoing, it does not present the total picture of the outcomes of the intervention that the client ultimately will receive

The **retrospective audit**, or outcome audit, evaluates quality of care through evaluation of the nursing process at the end of

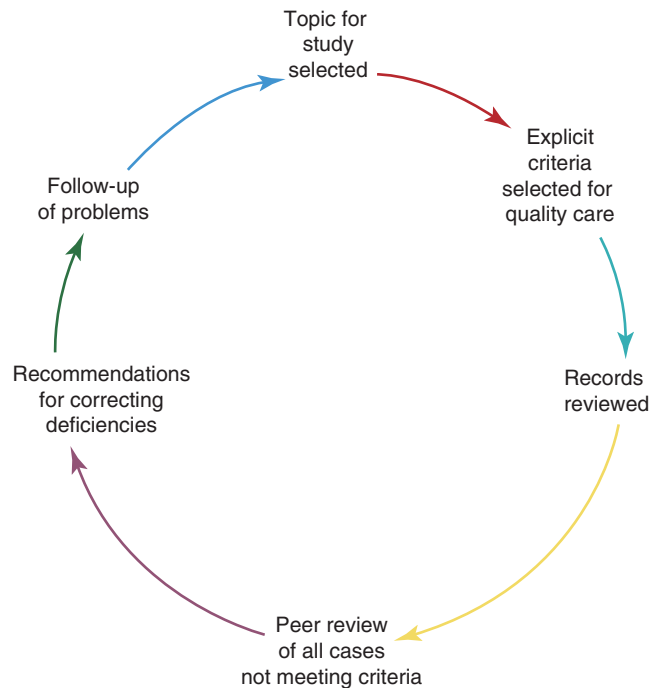

FIG 26-1 The audit process.

a program or as an audit of the long-term impact of a program within the health care system. The advantages of the retrospective audit are that it provides the following:

- Comparison of actual practice to standards of care
- Analysis of actual practice findings
- A total picture of care given to a population or group of clients
- More accurate data for planning corrective action

Disadvantages of the retrospective audit method are as follows:

- The focus of evaluation is directed away from ongoing care.
- Client problems (group or population or community) are identified after care is offered through the program; thus corrective action can be used only to improve the care of future clients.

Currently in public health, program record audits are done to determine the processes and outcomes of care, such as family planning audits, WIC audits, breast and cervical cancer screening audits, billing coding (to audit costs) and registration audits. Programs regarding physical activity, nutrition, obesity, arthritis, smoking cessation, and others are all designed to address the major causes of morbidity and mortality locally, statewide, and nationwide. The audits assist in determining the progress being made in reducing morbidity and mortality.

Utilization Review

The purpose of **utilization review** is to ensure that care is needed and that the cost is appropriate. Utilization review is more likely used in HMOs, other MCOs, and ACOs including Medicaid or Medicare state-level managed care programs. There are three types of utilization review:

1. **Prospective:** An assessment of the necessity of care before giving service

2. *Concurrent*: A review of the necessity of services while care is being given
3. *Retrospective*: An analysis of the necessity of the services received by the client after the care has been given

Each of these reviews assesses the appropriate cost of care. Prospectively, care can be denied and money saved. Concurrently, services can be cut if they are not found to be essential. Retrospectively, payment can be denied to the provider if the care was not necessary.

Utilization review began in the middle part of the twentieth century out of concern for increasing health care costs. The first committees were developed by insurance companies and professional groups. Utilization review committees became mandatory under the 1965 Medicare law as a way to control hospital costs.

The utilization review process includes development of explicit criteria regarding the need for services and the length of service. Utilization review has been used primarily in hospitals to establish the need for client admission and to determine the length of hospital stay. In community and public health, especially home health care, utilization review establishes criteria for admission to agency service, the number of visits a client may receive, the eligibility for client services (e.g., a nursing aide or physical therapist), and discharge.

Utilization review has several advantages:

- It helps clients avoid unnecessary care.
- It may encourage clients to consider alternative care options, such as home health care rather than hospital care.
- It can provide guidelines for staff and program development.
- It provides for agency accountability to the consumer.

The major disadvantage of utilization review is that not all clients fit the classic picture presented by the explicit criteria used to determine approval or denial of care. For example, an older adult client was admitted to a home health care agency for management after hospital discharge. The client was paraplegic as a result of a cerebrovascular accident. After several weeks of physical and speech therapy, the client showed little sign of progress. The utilization review committee considered the client's condition to be stable and did not recognize the continued need for management to prevent future complications; therefore, Medicare payment was denied.

Appeal mechanisms have been built into the utilization review process used by Medicare and Medicaid. The appeal allows providers and clients to present additional data that may help to reverse the original decision to deny payment.

Risk Management

Risk management committees are often a part of the CQI program of a community agency. Risk management seeks to reduce the agency's liability because of grievances brought against them. The risk management committee reviews all risks to which an agency is exposed. It reviews client and personnel safety policies and procedures and determines whether personnel are following the rules. Examples of problems reviewed by a risk management committee in public health clinics include administering incorrect vaccination dosage, pediatric client injury caused by a fall from an examination table, or injury to the nurse from a needlestick in the sexually transmitted diseases

EVIDENCE-BASED PRACTICE

This mixed-methods study sought to identify factors that support or hinder the development of a quality improvement culture in public health agencies. The researchers conducted case studies of ten agencies that participated in early quality improvement efforts. Agency staff who participated in National Association of County and City Health Officials (NACCHO)-sponsored quality improvement trainings were invited to complete a survey. Health directors and quality improvement teams from these agencies were also interviewed. The investigators found that agencies that were successful in creating a positive quality improvement culture had the following characteristics: had leadership support; had participated in national quality improvement initiatives; had a greater number of staff trained in quality improvement; had quality improvement teams that met regularly with decision-making authority; reported that accreditation was a major driver to quality improvement work; and had a history of evidence-based decision making and use of quality improvement to address emerging issues. The investigators reported that the role of accreditation preparation as a driving force in quality improvement appears to diminish as an agency develops a quality improvement culture. The researchers noted that common barriers to creating a quality improvement culture included lack of time and resources and relevance of quality improvement to daily work. However, they also reported that staff used quality improvement to overcome these barriers.

Nurse Use

Leadership and teamwork within an organization plays a key role in creating a positive quality improvement environment. Community health nurses are in a prime position to be leaders in their organizations in developing a quality improvement environment.

From Davis MV, Mahanna E, Joly B, et al: Creating quality improvement culture in public health agencies. *Am J Public Health* 104(1):e98–e104, 2014.

clinic at the health department or as a result of an accident while making a home visit. Incident reports are reviewed by the risk management committee for appropriate, accurate, and thorough documentation of any problem that occurs relating to clients or personnel. In addition, patterns are identified from looking at program data that may require changes in policy or staff development to correct the problem. As a part of risk management, grievance procedures are established for both clients and personnel.

Professional Review Organizations/ Quality Improvement Organizations

The **Professional Standards Review Organization (PSRO)** was established in 1972 in an amendment to the Social Security Act (PL 92-603) as a publicly mandated utilization and peer review program. This law provided that medical, hospital, and nursing home care under Medicare, Medicaid, and Title V Maternal and Child Health Programs would be reviewed for appropriateness and necessary care to be reimbursed.

In 1983 Congress passed the Peer Review Improvement Act (PL 97-248), creating **professional review organizations (PROs)**. PROs replaced PSROs and are directed by the federal government to reduce hospital admissions for procedures that can be performed safely and effectively in an ambulatory surgical setting on an outpatient basis. The goal was to reduce inappropriate or unnecessary admissions or invasive procedures by

specific practitioners or hospitals. Quality measures include reducing unnecessary admissions caused by previous substandard care, avoidable complications and deaths, and unnecessary surgery or invasive procedures (Chassin and Loeb, 2011). The PRO is now known as the Quality Improvement Organization.

Institutions contracting with QIOs for quality reviews are usually state organizations that establish criteria for care on the basis of local patterns of practice, and they are private contractors to CMS and mostly not-for-profit organizations. They may have on their board health care providers who are independent from the QIO and the board must have at least one consumer. QIOs must define their operational objectives, monitor access to care, cost of care, and quality concerns, and protect the Medicare Trust. Professionals working under the regulation of QIOs should develop accurate and complete documenting procedures to ensure compliance with the criteria of the QIO (CMS, 2014a).

Debate has occurred over the limits and benefits of the federally mandated quality review process. Limits include jeopardizing professional autonomy because decision making regarding care includes professionals, consumers, and government representatives. Another limitation of this process is the development of a costly control mechanism whereby client care activities may be determined by cost rather than by professional criteria. The benefit of the QIO system has been the development of standards and the peer review mechanisms to increase accountability for care provided.

TQM provides direction for managing a system of care, whereas CQI using QA/QI focuses on the care a client receives within the system.

Evaluative Studies

Evaluative studies for quality health care increased during the twentieth century. Studies demonstrate the effect of nursing and health care interventions on client populations. Three key models have been used to evaluate quality: Donabedian's structure-process-outcome model, the tracer method, and the sentinel method.

Donabedian's model (1981, 1985, 2003) introduced three major methods for evaluating quality care:

1. **Structure:** Evaluating the setting and instruments used to provide care; examples of structure are facilities, equipment, characteristics of the administrative organization, client mix, and the qualifications of health providers
2. **Process:** Evaluating activities as they relate to standards and expectations of health providers in the management of client care
3. **Outcome:** The net change or result that occurs as a result of health care

The three methods may be used separately to evaluate a part of care. However, to get an overall picture of quality of care, they should be used together.

The **tracer** method described by Kessner and Kalk (1973) is a measure of both process and outcome of care and is used today. This method is more effective in evaluating health care of groups than of individual clients. It is also more effective in evaluating care delivered by an institution than care delivered by an individual provider. The following are essential

characteristics for implementing the tracer method (Papanicolaos and Smith, 2013; Kelly, 2011):

1. A tracer, or a problem, that has a definite impact on the client's level of functioning
2. Well-defined and easily diagnosed characteristics
3. Population prevalence high enough to permit adequate data collection
4. A known variation resulting from use of effective health care
5. Well-defined management techniques in prevention, diagnosis, treatment, or rehabilitation
6. Understood (documented) effects of nonmedical factors on the tracer

Client groups selected for tracer outcome studies in nursing would have the following:

1. A shared health problem
2. Receiving a similar intervention
3. Sharing similar needs
4. Located in the same community
5. Having a similar lifestyle
6. Being at the same illness stage

The tracer method provides nurses with data to show the differences in outcomes as a result of nursing care standards.

The **sentinel** method of quality evaluation is based on epidemiologic principles. This method is an outcome measure for examining specific instances of client care (Kelly, 2011). Changes in the sentinel indicate potential problems for others. For example, increases in encephalitis in certain communities may result from increases in mosquito populations. Data may be collected at the health department through a state or local required disease reporting system. The health department would be notified and an immediate mosquito control strategy would be put into place. Such an intervention would include, for example, nurses notifying the population to remove standing water around the outside of homes, such as animal water bowls, rain barrels, and gutter downspout water collection pools. Flyers may be sent home with school children or given to clients visiting the public health clinics, and media announcements may be used. In addition, the environmental office at the health department may inspect local swimming pools and may also implement a nighttime mosquito spraying program throughout the community.

HOW TO Conduct a Sentinel Evaluation

- Identify cases of unnecessary disease, disability, and complications (for example, tuberculosis).
- Count the deaths from these causes.
- Examine the circumstances surrounding the unnecessary event (or sentinel), in detail.
- Review morbidity and mortality rates as an index for comparison; determine the critical increase in the untimely event, which may reflect changes in quality of care. Example: Compare the incidence and prevalence of TB cases before the increased population occurred.
- Explore health status indicators, such as changes in social, economic, political, and environmental factors that may have an effect on health outcomes. Example: Overcrowding in the shelter where migrant workers stay (environmental) and the inability to follow-up on testing because of the transient nature of the population (social).

CLIENT SATISFACTION

Client satisfaction is another approach to measuring quality of care. Client satisfaction can be assessed using in-person or telephone interviews and mailed questionnaires. Satisfaction surveys are used to assess care received during an admission to a specific agency, to assess a client's personal nursing care, or to assess the total care that the client received from all services.

Satisfaction surveys may measure the interventions used for client care, attitudes about the care received and the providers of care, and perceptions of the situation (environment) in

which the care was received. Clients are often more critical of interpersonal and situational components of care than of the interventions of care.

Satisfaction surveys are an essential aspect of QA. Survey data provide clues to reasons for client compliance or noncompliance with plans of care. Although consumers may not view quality in the same light as the health professional, surveys provide data about health-seeking behaviors, the probability of malpractice litigation, and the likelihood of continuing client-provider-agency relationships—always an important measure for community-based and public health agencies (Oakland, 2014) (Figure 26-2).

Please mark the following questions using the scale.

Domain	Example	Strongly Agree	Somewhat Agree	Agree	Somewhat Disagree	Strongly Disagree
Affective support	1. The visiting nurse was understanding of my health concerns.					
	2. The nurse gave me encouragement in regard to my health problems.					
Health information	3. I got my questions answered in an individual way.					
	4. The information I received from the nurse helped me to take care of myself at home.					
Decision control	5. I was included in decision making.					
	6. I was included in the planning of my care.					
Technical competencies	7. The care I received was of high quality.					
	8. Decisions regarding my health care were of high quality.					
Accessibility	9. The nurse was available when I needed help.					
	10. The nurse was on time.					
Overall satisfaction	11. Overall, I was satisfied with my health care.					
	12. The care I received was of high quality.					

FIG 26-2 Client satisfaction tool domains and examples.

Malpractice Litigation

Malpractice litigation (i.e., a lawsuit) is a specific approach to QA imposed on the health care delivery system by the legal system. Malpractice litigation typically results from client dissatisfaction with the provider and with the content of the care received. Nursing is not immune from malpractice litigation. Nursing must continue to have a sound QA program that ensures quality care. This will reduce the risk of quality control measures being imposed by an external source, such as the legal system. As a true example, a public health nurse was individually sued by a new family to the community because the nurse repeated an immunization the child had already received prior to moving to the community. The result was Guillain-Barré syndrome. The nurse was found at fault even though the parents did not provide the physician's record of immunizations to the nurse. It was the nurse's responsibility to follow standard guidelines and to obtain the essential records prior to providing the immunization. The public health department was dismissed from the lawsuit because of immunity granted to state agencies.

MODEL CQI PROGRAM

The primary purpose of a QA/QI program is to ensure that the results of an organized activity are consistent with the expectations. All personnel affected by a QI program should be involved in its development and implementation. Although administration and management are responsible for the quality of services, the key to that quality is in the personnel who deliver the service: their knowledge, skills, and attitudes.

Figure 26-3 shows a model that identifies the basic components of a QI program. QI programs answer the following questions about health care services and nursing care:

1. What is being done now?
2. Why is it being done?
3. Is it being done well?
4. Can it be done better?
5. Should it be done at all?
6. Are there improved ways to deliver the service?
7. How much does it cost?
8. Should certain activities be abandoned or replaced?

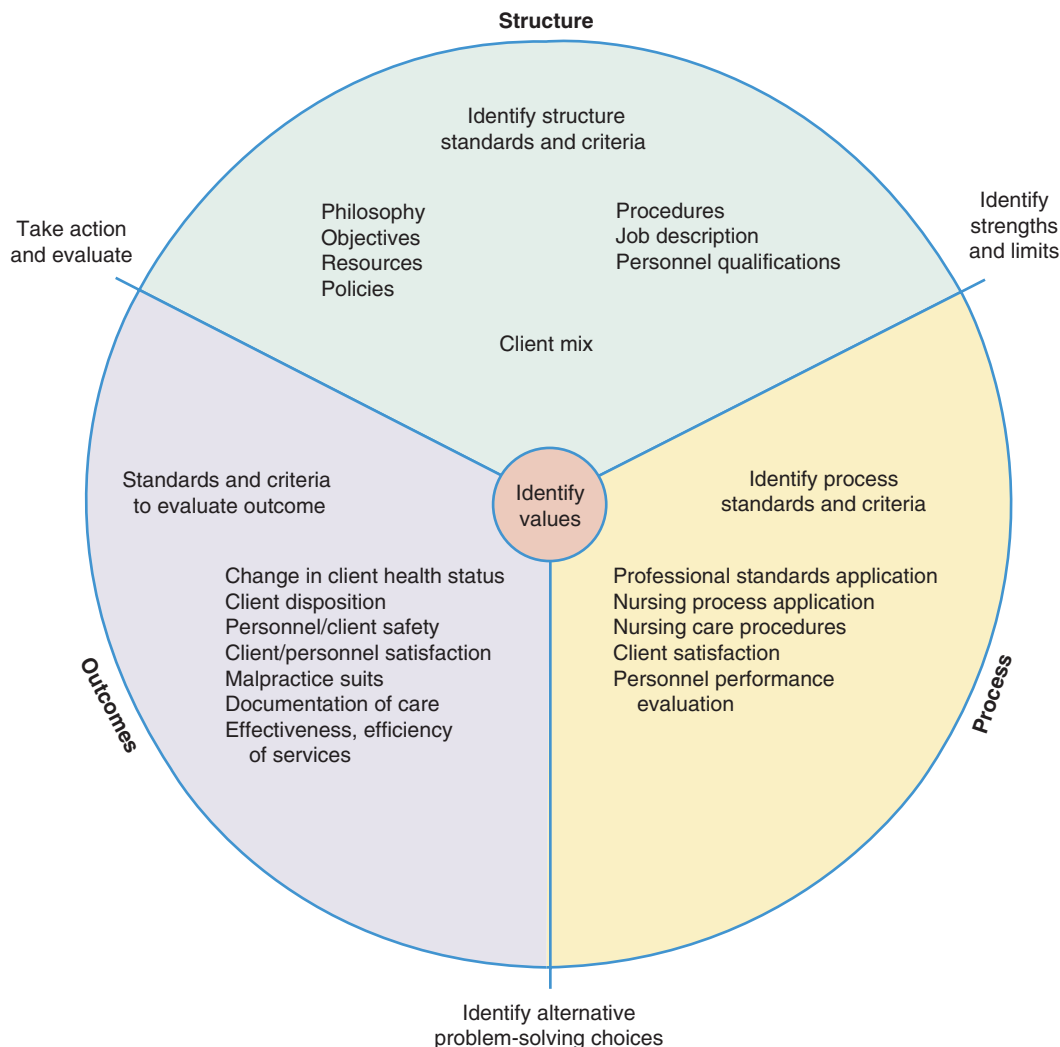

FIG 26-3 Model quality improvement programs.

FIG 26-4 The plan-do-check-act (PDCA) model of continuous quality improvement. The concept of the PDCA cycle was originally developed by Walter Shewhart, the pioneering statistician who developed statistical process control in the Bell Laboratories in the United States during the 1930s. It is often referred to as the “Shewhart Cycle.” It was adopted in the 1950s by W. Edwards Deming, and is often referred to as the “Deming Wheel.”

As a part of answering the questions and determining changes that can improve services, public health can use the PDCA model. The steps of the model are shown in [Figure 26-4](#).

The PDCA is a model for continuous improvement and can be used after an audit of a program, for example to begin a new improvement project or when developing a new or improved

design of a process, product, or program. It can also be used to define a repetitive work process or for planning data collection and analysis to verify and prioritize problems or root causes, which are actually the system problems that lead to the problem. It is also used to implement change.

The PDCA procedure involves the following steps:

1. **Plan.** Recognize an opportunity and plan a change.
2. **Do.** Test the change. Carry out a small-scale study.
3. **Check.** Review the data, analyze the results, and identify what has been learned.
4. **Act.** Take action based on what was learned in the check/study step: If the change did not work, go through the cycle again with a different plan. If successful, incorporate what you learned from the test into wider changes. Use what was learned to plan new improvements, and begin the cycle again. Beginning the cycle again defines the continuous program of CQI. This is also referred to as a rapid cycle improvement process in health care.

Donabedian’s framework for evaluating health care programs using the components of structure, process, and outcome can be used in developing a QI program. *Outcome* is the most important ingredient of a program because it is the key to evaluating providers and agencies by accrediting bodies, by insurance companies, and by Medicare and Medicaid through QIOs, report cards, and other accrediting agencies.

LINKING CONTENT TO PRACTICE

The PDCA model is being used in public health to promote CQI. A brief example of how to apply this model is given below.

This approach was designed to improve new mother and baby outcomes by improving nurse/client communication processes. This model for improvement includes four components recommended by the Institute of Healthcare Improvement: (1) aims and goals, (2) performance measures, (3) strategies and ideas for changes, and (4) the use of PDCA cycles.

1. The goal of the project is to improve health outcomes for at-risk new mothers and babies involved in the nurse home visiting program by offering a daily telephone consultation to answer questions and provide support up to 3 months after the baby’s birth.
2. The performance measures include:
 - A. An assessment of the numbers of nurses on the home visiting team who could successfully answer the questions of the mothers who received the daily consultation.
 - B. The second measure is a retrospective record audit at 6 months to assess the progress of the mothers who had access to the daily call as compared with mothers who were involved in the program prior to the daily phone consult.
3. The strategies include:
 - A. A work session of the nurses to review their knowledge about parenting and caring for a new baby up to 3 months using a simple pretest.
 - B. An update on what new mothers need to know to bond with their babies and to provide for the new babies’ needs followed by a post-test of the nurses’ knowledge.
 - C. The development of the process for the daily phone consultation including a checklist of assessment questions the nurse might ask and time built in to respond to parent’s questions.

Plan: Plan a mock “daily consult” call to a public health nurse (or a fellow student) with her first baby. Develop different scenarios for the public health nurse to respond to in order to assess each home visiting nurse’s ability to

respond to the mother’s questions, such as feeding techniques, bathing, crying, and holding the baby.

Do: Engage each of the home visiting nurses in participating in the mock calls.

Check: Assess the abilities of each of the nurses to respond to the questions from the new mother by having the public health nurse use a simple yes/no checklist of prepared questions.

Assess how efficient the nurse is in completing the consultation. Can answers to the questions be noted immediately, or does help need to be sought from others prior to answering the mother’s question? Use a checklist to identify the time on the call, and ability to independently answer the questions.

Act: If the nurses were able to provide the consultation efficiently and without assistance, implement the process with new mothers and babies, use PDCA for the implementation to identify any problems with the process.

If the nurses were unable to efficiently provide the consult, provide additional education and tools to increase their efficiency. Use the PDCA process until the nurses are able to efficiently provide the consult.

The PDCA cycle is continuously repeated until the administration, the nurses, and the clients are satisfied that the process is working.

Data from these small tests will provide realistic estimates of the percentage of the nurses who can successfully engage in consultation via phone. The purpose in the initial assessment and education of the nurses is to ensure faster consults so more mothers and babies can be contacted in a short period without adding to the nurses’ workload, while potentially reducing the amount of time for the home visit because the mother may be better prepared to care for the baby’s needs with this support. The improvement process may enlist the support of all nursing staff and administration and create a change in the work environment through the development of a planned phone consultation process for all clients who may receive home visits.

As students develop questions, they also develop a PDCA approach to answering those questions.

Structure

The vision, values, philosophy, and objectives of an agency serve to define the structural standards of the agency. Evaluation of structure is a specific approach to looking at quality. In evaluating the structure of an organization, the evaluator determines whether the agency is adhering to the stated philosophy and objectives and to its vision and stated values. Is the agency providing services to populations across the life span? Are primary, secondary, and/or tertiary preventive services offered? Standards of structure are defined by the licensing or accrediting agency (e.g., the Community Health Accreditation Program's [CHAP's] standards for accrediting home health agencies).

Identifying values, the first step in a QA program, serves to define the beliefs of the agency about humanity, nursing, the community, and health. The beliefs of the community, the population to be served, and the providers of care are equally important to the agency, and all need to be considered to provide quality service.

Identifying standards and criteria for QA begins with writing the philosophy and objectives of the organization. Program objectives define the intended results of nursing care, descriptions of client behaviors, and/or change in health status to be demonstrated on discharge.

Once objectives are formulated, the resources needed to accomplish the objectives should be identified. The personnel, supplies and equipment, facilities, and financial resources that are needed should be described. Once resources are determined, policies, procedures, and job descriptions should be formed to serve as behavioral guides to the employees of the agency. These documents should reflect the essential nursing and other health provider qualifications needed to implement the services of the agency.

Standards of structure are evaluated internally by a committee composed of administrative, management, and staff members for the purpose of doing a self-study. Standards of structure are also evaluated by a utilization review committee, often composed of an external advisory group with community representatives for all services offered through an agency, such as a nurse, a public health physician, an environmental engineer, a sanitation engineer, a health educator, a board member, and an administrator from a similar agency. The data from these committees identify the strengths and weaknesses of the agency structure.

Process

The evaluation of process standards is a specific look at the quality of care being given by agency providers, such as nurses. Agencies use a variety of methods to determine criteria for evaluating provider activities: conceptual models; the standards of care of the provider's professional organization, such as the ANA's *Scope and Standards of Public Health Nursing Practice* (ANA, 2013) (see [Chapter 1](#)); or the nursing process. The activities of the nurse are evaluated to see whether they are the same as the nursing care procedures defined by the public health agency.

The primary approaches used for process evaluation include the peer review committee and the client (often community) satisfaction survey. The techniques used for process evaluation are direct observation, focus groups, questionnaire, interview,

written audit, and video or digital recordings of client and provider encounters.

Once data are collected to evaluate nursing process standards, the peer review committee reviews the data to identify strengths and weaknesses in the quality of care delivered. The peer review committee is usually an internal committee composed of representatives of the nursing staff who are trained to administer audit instruments and conduct client interviews.

Outcome

The evaluation of outcome standards, or the result of nursing care, is one of the more difficult tasks facing nursing today. Identifying changes in the client's health status that result from nursing care provides nursing data that demonstrate the contribution of nursing to the health care delivery system. Research studies using the tracer or sentinel method to identify client outcomes and client satisfaction surveys can be used to measure outcome standards. Measures of outcome standards include client data about the changes in the community in low-birth-weight babies as a result of improved prenatal care and client compliance with care through the WIC program.

From these data, strengths and weaknesses in nursing care delivery can be determined. The most common measurement methods are direct physical observations and interviews. Instruments have also been developed to measure general health status indicators in home health. The Omaha Visiting Nurse Association problem classification system includes nursing diagnosis, protocols of care, and a problem rating scale to measure nursing care outcomes. In addition, the ANA has developed 10 areas for data collection of outcome criteria in community-based, non-acute care settings, including pain management, consistency of communication, staff mix, client satisfaction, prevention of tobacco use, cardiovascular disease prevention, caregiver activity, identification of primary caregiver, activities of daily living, and psychosocial interactions (Rowell, 2001). Nursing has been involved primarily in evaluating program outcomes to justify program expenses rather than in evaluating client outcomes.

Outcome evaluation assumes that health care has a positive effect on client status. The major problem with outcome evaluation is determining which nursing care activities are primarily responsible for causing changes in client status. Recently, studies have been conducted on nurse-sensitive indicators, such as failure to rescue, that show the importance of nurse staffing in adverse client outcomes (Doran, 2011; McCormack et al, 2010). In nursing, many uncontrolled factors in the field, such as environment, community services, and family relationships, have an effect on client status. Often it is difficult to determine whether these factors are the cause of changes in client status or whether nursing interventions have the most effect.

Types of problems studied in a QA program include reasons for the following:

- Client death (population mortality)
- Client injury (population morbidity)
- Personnel and client safety
- Agency liability
- Increased costs

TABLE 26-2 Quality Assurance Measures

Structure	Process	Outcome
Internal agency	Peer review committees	Internal agency committees
Self-study	Prospective audit	Evaluative studies
Review agency	Concurrent audit	Survey health status
documents	Retrospective audit	
External agency	Client	Client
Regulatory audit	Satisfaction survey	Malpractice suits
	Utilization review	Satisfaction survey

- Denied reimbursement by third-party payers (decreased program funding by government)
- Client complaints
- Inefficient service
- Staff noncompliance with standards of structure
- Lack of resources
- Unnecessary staff work and overtime
- Documenting of care
- Client health status (population health status)

Table 26-2 summarizes QA measures.

Evaluation, Interpretation, and Action

Interpreting the findings of a quality care evaluation is an important part of the process. It allows differences between the quality care standards of the agency and the actual practice of the nurse or other health providers to be identified. These patterns reflect the total agency's functioning over time and generate information for decisions to be made about the strengths and limits of the agency. Regular intervals for evaluation should be established within the agency, and periodic reports should be written so that the combined results of structure, process, and outcome efforts can be analyzed and health care delivery patterns and problems can be identified. These reports should be used to establish an ongoing picture of changes that occur within an agency to justify nursing services.

Identifying choices of possible courses of action to correct the weaknesses within the agency should involve both the administration and the staff. The courses of action chosen should be based on their importance, cost, and timeliness. For example, if there is a nursing problem in the recording of client health education, the agency administration and staff may analyze the problem to see why it is occurring. Reasons for lack of record-keeping given by the nurses include a lack of time to do paperwork properly, workloads that reduce the amount of time spent with clients, and lack of available resources for health education. If such reasons are given, it would not be appropriate for management to deal with the problem by providing a staff development program on the importance of doing and recording health education; it would be more important to assess how to provide the time and resources necessary for the nurses to offer health education to the clients. Economically, it may be more beneficial to provide personal data assistants or laptop computers and clerical assistance so that nurses can make notes at the point of implementation, thereby providing more client contact time, or it may be more beneficial economically to employ an additional nurse and reduce workloads.

Taking action is the final step in the QA/QI model. Once the alternative courses of action are chosen to correct problems, actions must be implemented for change to occur in the overall operation of the agency. Follow-up and evaluation of actions taken must occur to improve quality of care. Although health provider evaluation will continue to be included in a QI effort, the focus of a CQI effort emphasizes the process and not the person. The assumption here is that health care professionals and other employees customarily want to do the best job possible for the client, and problems or differences in a process should not be automatically attributed to their behavior. Although frequent feedback should be given to all employees, the hallmark of QI is continuous learning. Staff development must be ongoing for all employees. (The [Levels of Prevention box](#) shows prevention levels related to quality management.)

LEVELS OF PREVENTION

Quality Management

Primary Prevention

The nurse participates in a parent education program to improve the immunization level of children in the local elementary school and develops a strategy for follow-up.

Secondary Prevention

Agency evaluation, using a retrospective audit of records of the immunization program, determines that the vaccine-preventable infectious disease rates have declined in the elementary school after the implementation of the parent education program.

Tertiary Prevention

A review of the public health report card indicated that community incidence of complications from vaccine-preventable diseases have declined over a 2-year period after the implementation of the parent education program.

Documentation is essential to evaluating quality care in any organization. The following section focuses on the kinds of documentation that normally occur in a community agency.

RECORDS

Records are an important part of the communication structure of the health care organization. Accurate and complete records are required by law and must be kept by all government and nongovernment agencies. In most states, the state departments of health stipulate the kinds of records to be kept and their content requirements for community agencies.

Records provide complete information about the client (whether a family, group, population or community), indicate the extent and quality of services being given, resolve legal issues in malpractice suits, and provide information for education and research.

Community and Public Health Agency Records

Within the community or public health agency, many types of records are kept and used to predict population trends in a community, to identify health needs and problems, to prepare and justify budgets, and to make administrative decisions. The kinds

of records kept by the agency may include reports of accidents, births, census, chronic disease, communicable disease, mortality rates, life expectancy, morbidity rates, child and spouse abuse, occupational illness and injury, and environmental health.

Other types of records kept within the agency are those used to maintain administrative contact and control of the organization. Three types of records make up this category: clinical, provider service, and financial. The *clinical record* is the client health record. The *provider service records* include information about the number of clinic clients seen daily, the immunizations given, home visits made daily, transportation and mileage, the provider's time spent with the client, and the amount and kinds of supplies used. The service record is completed on a daily basis by each provider and is summarized monthly and annually to indicate trends in health care activities and costs related to personnel time, transportation, maintenance, and supplies. The provider service records are used to compare with the agency's *financial records* of salaries, overhead, and transportation costs, and they serve as the basis for the cost accounting system. These records are basic to peer review and audit.

Three additional kinds of service records seen in the community agency are the central index system, the annual implementation plan, and the annual summary of agency activities. The *central index system* is a data filing system that indicates the services requested, services offered, active and inactive clients of the agency, and a profile of the agency's clients.

The *annual implementation plan* (often referred to as the strategic plan or tactical plan) is developed at the beginning

of each fiscal year to define the short- and long-term goals of the agency. The annual implementation plan serves as the basis for the agency's annual summary. The *annual summary* reflects the success of the agency in meeting the annual objectives, the changes in population trends and health status during the year, the actual versus the projected budget requirements, the number of services offered, the number of clients served, and the plans and changes recommended for the future. This plan serves as the basis for the evaluation of agency structure.

As an outgrowth of QA efforts in the health care system, comprehensive methods are being designed to document and measure client progress and client outcome from agency admission through discharge. An example of such a method is the client classification system developed at the Visiting Nurses Association of Omaha, Nebraska (Martin, 2005; The Omaha System, 2014). This comprehensive method for evaluating client care has several components: a classification system for assessing and categorizing client problems, a database, a nursing problem list, and anticipated outcome criteria for the classified problem. Such schemes are viewed as having the potential to improve the delivery of nursing care, documentation of care, and the descriptions of client care. Briefly, implementing a comprehensive documentation method improves nursing assessment, planning, implementation, and evaluation of client care; it also allows the organization of important client information for more effective and efficient nurse productivity and communication (see Figure 26-2).

▶▶ LINKING CONTENT TO PRACTICE

The Robert Wood Johnson Foundation (RWJF) funded a project initiative focusing on the development of competencies and resources to enhance the ability of nursing professionals to deliver high-quality and safe nursing care. The Quality Safety Education for Nurses collaboration identified and defined six quality and safety competencies for nursing. In addition, the project allowed for the development of proposed targets for the knowledge, skills, and attitudes of students for each of the six competencies identified by the Institute of Medicine as: client-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics. The overall goal for the Quality and Safety Education for Nurses (QSEN) project is to meet the challenge of preparing future nurses who will have the knowledge, skills, and attitudes (KSAs) necessary to continuously improve the quality and safety of the health care systems within which they work. The following are the definitions for each of the six competencies and examples of the chapters in the text where content can be found and related to the competency:

Client-centered care: Recognize the client or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for client's preferences, values, and needs. (Chapters 4, 6, 7, 9, 12, 14, 15, 19)

Teamwork and Collaboration: Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality client care. (Chapters 5, 6, 8, 10, 16, 18, 20-22, 26-28, 30, 32-35, 37, 39, 41, 45, 46)

Evidence-Based Practice (EBP): Integrate best current evidence with clinical expertise and client/family preferences

and values for delivery of optimal health care. (All chapters, with emphasis in Chapters 15 and 26)

Quality Improvement (QI): Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems. (Chapters 3, 8, 10, 12, 14, 18, 20, 24, 25, 26)

Safety: Minimizes risk of harm to clients and providers through both system effectiveness and individual performance. (Chapters 12, 13, 14, 23, 24, 28, 39-46)

Informatics: Use information and technology to communicate, manage knowledge, mitigate error, and support decision making. (Chapters 23-26)

All of these competencies are addressed in this text as the competencies relate to public health nursing practice. The knowledge, skills, and attitudes related to QI are addressed in this chapter and one area of the QI competency appears in the following table.

Knowledge	Skills	Attitudes
Describe approaches for changing processes of care	Design a small test of change in daily work (using an experiential learning method such as PDCA) Practice aligning the aims, measures, and changes involved in improving care Use measures to evaluate the effect of change	Value local change (in individual practice or team practice on a unit) and its role in creating joy in work Appreciate the value of what individuals and teams can do to improve care

PRACTICE APPLICATION

Oscar, a nursing student, has been working in the migrant farmworker clinic and has noted that each practitioner uses a different educational method for teaching good nutrition practices to newly diagnosed diabetic clients. The clinic has seen a substantial increase in the number of new diabetic clients in the Hispanic farmworker population. Oscar knows that practice guidelines for teaching nutrition practices exist in his clinical facility and that charts have an area to note nutrition education information. He also knows that for nurses to be most effective and ensure quality client outcomes, research-based practice guidelines should be used by all nurses in the health department.

As part of his course, Oscar must prepare a teaching plan and conduct a class on a health care problem. He obtains permission from his instructor and the director of the clinic to conduct an in-service program. The purpose of Oscar's in-service program is to instruct the nursing staff how to teach newly diagnosed diabetic clients good nutrition practices. He obtains and studies the guidelines about teaching good

nutrition practices from the National Guideline Clearinghouse titled Diabetes Type 1 and 2 Evidence-based Nutrition Practice Guideline for Adults (2010), and he researches the methodological background for development of the guidelines. Oscar's native language is Spanish, so this will help him in determining whether brochures for newly diagnosed diabetic clients regarding good nutrition convey the appropriate message.

As part of his in-service program, Oscar keeps demographic records on attendees and conducts before-and-after tests of knowledge, adding questions about the present use of the guidelines. He plans to follow up with the nurses in 6 months with a further test and questions about use of the guidelines. The director will help him determine an outcome measure that can be used with the client population to show effective use of the guidelines.

A. What outcome measure would be useful in this project?

B. How will this help in the overall assessment of quality in the nursing service?

Answers can be found on the Evolve site.

KEY POINTS

- The health care delivery system is the largest employing industry in the United States; society is demanding increased efficiency and effectiveness from the system.
- The actual quality and safety of care in the United States is being assessed regularly and reported in four reports.
- Because of varying definitions, logistics, and data collection methods, quality is difficult to assess accurately.
- Responding to the quality of care question, the federal government has instituted several quality improvement programs. Among these are the National Healthcare Quality Report (NHQR) that is used to monitor the nation's progress toward improved health care quality; the Center for Medicare and Medicaid Services (CMS) Outcomes Based Quality Improvement (OBQI) for home health; and the National Committee for Quality Assurance (NCQA), which provides performance information, or report cards, for health care agencies.
- Quality improvement is the tool used to ensure effective and efficient care.
- The managed care industry is changing the face of the American health care delivery system and how quality is defined and measured.
- Objective and systematic evaluation of nursing care has become a priority within the profession for several reasons, including the effects of cost on health care access, consumer demands for better quality care, and increasing involvement of nurses in formulating public and health agency policy.
- Total quality management is a management philosophy new to the public health care arena. It is prevention oriented and process focused. Its primary focus is to deliver quality health care. One measure of quality is customer satisfaction.
- Public and private sectors are forming partnerships to monitor the performance of all players in health care delivery to improve the health of communities. The different players in the health care system have different perceptions of quality.
- Quality assurance/quality improvement (QA/QI) is the monitoring of client care activities to determine the degree of excellence attained in implementing activities.
- Quality assurance has been a concern of the profession since the 1860s, when Florence Nightingale called for a uniform format to gather and disseminate hospital statistics.
- Licensure has been a major issue in nursing since 1892.
- Two major categories of approaches exist in QA/QI today: general and specific.
- Accreditation is an approach to quality control used for institutions, whereas licensure is used primarily for individuals.
- Certification combines features of both licensing and accreditation.
- Three major models have been used to evaluate quality: Donabedian's structure-process-outcome model, the sentinel model, and the tracer model.
- A fourth model to evaluate quality—the PDCA model—has been adopted by the public health system.
- Seven basic components of a quality improvement program are (1) identifying values, (2) identifying structure, process, and outcome standards and criteria, (3) selecting measurement techniques, (4) interpreting the strengths and weaknesses of the care given, (5) identifying alternative courses of action, (6) choosing specific courses of action, and (7) taking action.

KEY POINTS—cont'd

- Records are an integral part of the communication structure of a health care organization. Accurate and complete records are by law required of all agencies, whether governmental or nongovernmental.
- QA/QI mechanisms in health care delivery are the mechanisms for controlling the system and requesting accountability from individual providers within the system. Records help establish a total picture of the contribution of the agency to the client community.
- Delivering quality care to individuals, communities, and populations falls under the 10 essential services of public health.
- Evidence-based practice guidelines can help population-centered nurses document the outcomes and effectiveness of their interventions.

CLINICAL DECISION-MAKING ACTIVITIES

- Write your own definition of TQM; compare your definition with the one given in the text. Are they the same or different? Give justification for your answer.
- How does traditional QA/QI fit with the CQI effort? Explain the relative importance of a continuing QA/QI effort.
- Interview a nurse who is a coordinator of or is responsible for QA/QI in a local health agency. Ask the following questions and add your own. Do the answers to the questions relate to what you have learned about QA/QI? Explain.
 - Does the agency subscribe to the TQM approach to management?
 - If not, is the agency incorporating elements of the TQM process as outlined by Deming (1986) in his 15 points?
 - Is a traditional method of management used to ensure quality?
 - Describe the components of the QA/QI program.
 - How are records used in your QA/QI effort?
 - Discuss the approaches and techniques that are used to implement the QA/QI program.
 - How has the QA/QI program changed in the health agency over the past 20 years?
 - What influence has the QA/QI program had on decreasing problems attributable to process? To provider accountability?
 - List and describe the types of records usually kept in a community health agency. Explain the purpose of each type of record.
- Identify partnerships necessary to ensure quality health outcomes for your community from data gathered in a community assessment. Explain why these partners are necessary.
- Find the *Guide to Community Preventive Services* on the CDC website, and look for the segments on smoking cessation or tuberculosis control. How could you use this information in your practice in health?
- Explain the nurse's responsibilities and role in the CQI program.

Health Promotion with Target Populations Across the Life Span

The family is a major influence on the individual's concept of health and illness. It is within the family that a person's sense of self-esteem and personal competence is developed. The action taken by or for the person with a health problem depends on this sense of self-worth and the family's definitions of health and illness. Environmental, social, cultural, and economic factors, as well as the resources of the community to meet health needs, influence the family's health risks and reaction to health. The goals of the nation for the year 2020 focus on changing the overall health of the nation, with emphasis on the specific health and health care issues of populations. Through family support the individual may develop the responsibility to participate in activities that will lead to a healthier lifestyle.

Major health problems of individuals can be identified and related to their developmental phase. This factor becomes evident when age-specific morbidity data are reviewed. Nurses can influence the actions and reactions to health of all individuals in the community from birth through senescence. The nurse can influence the health of children by introducing healthy parenting behaviors, risk factor appraisal, and age-appropriate interventions.

Women and men are faced with many life changes and challenges, some of which are gender specific. Previous lifestyles and increases in stress from social, environmental, and economic constraints often result in risk for major health problems during adulthood.

The nurse's primary function with persons of all ages should be to promote quality as well as a long and healthy life. As the elderly segment of the population continues to grow, the health care delivery system and nurses must address and plan strategies to cope with increasing longevity and chronic health problems.

Attention is also focused on the needs of compromised populations. *Healthy People 2020* has a specific goal to promote the health and well-being of compromised populations. Over 15% of the United States population has some type of long-lasting condition. Nursing interventions must be refined to assist this group in meeting their health care needs. As the nurse studies and gathers evidence about the health issues of populations such as children, women, men, and the elderly, he/she can better understand how to assess and plan for care of individuals who are members of these compromised populations. Community-oriented nurses assess the risk of age-related issues in populations, promote the development of programs and policies that will promote initiatives to enhance population health status, and ensure that such programs are available to address the health risks of these target populations.

Working with Families in the Community for Healthy Outcomes

Joanna Rowe Kaakinen, PhD, RN

Dr. Joanna Rowe Kaakinen has been a family nurse scholar for the last 25 years. She has written extensively about family nursing. She is a reviewer for the *Journal of Family Nursing*, the *Journal of Family Relations*, a member of the International Association of Family Nurses, and a member of the National Council of Family Relations. She has presented nationally and internationally on family nursing. Dr. Kaakinen is a Professor in the School of Nursing at the Linfield College School of Nursing in Portland, Oregon.

Jackie F. Webb, FNP-BC, MS, RN

Jackie Webb has been a practicing family nurse practitioner for over 25 years, working primarily with underserved populations. She was also director for student health services for a small New England college for almost 10 years, serving young adults. She has taught nursing students both at the undergraduate and graduate levels for the past 15 years. Currently she is a professor at Linfield College School of Nursing in Portland, Oregon. She is currently a doctoral student at Oregon Health Sciences University in Portland, Oregon. Her research focus is looking at innovations in health care delivery.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Explain the multiple ways public health nurses work with families and communities.
2. Identify challenges to working with families in the community.
3. Describe family function and structure.
4. Describe family demographic trends and demographic changes that affect the health of families.
5. Compare and contrast three social science theoretical frameworks nurses use when working with the family in the community.
6. Work with families using a strength-based approach to assess, develop, and evaluate family action plans.

Social and Family Policy Challenges

The health of communities is directly related to the health of its families (ANA, 2007; APHA, 2010; Eddy, Bailey, and Doutrich, 2015). The importance of establishing collaborative relationships with families for providing care has been well documented in public health nursing literature (Wald, 1915; Paavilainen and Astedt-Kurki, 1997; Jonsdottir, Litchfield, and Pharris, 2003; Porr, Drummond, and Olson, 2012). Public health nurses must have skills to move competently between working with individual families, bridge relationships between families and the community, advocate for family and community legislation, and influence policies that promote and protect the health of populations. Therefore, public health nurses must integrate knowledge and practice of family nursing and community health nursing (APHA, 2014) in meeting the needs of families.

Family nursing is a philosophy and a science that is based on the following assumptions: health and illness are family events; what affects one family member affects the whole family; and health care practices, decisions, and behaviors are made within the context of the family (Kaakinen and Hanson, 2015a).

Public health nursing practice has a secondary focus: the “synthesis of nursing theory and public health theory applied to promoting, preserving and maintaining the health of populations through the delivery of personal health care services to individuals, families, and groups. The focus of practice is the health of individuals, families and groups and the effect of their health status on the health of the community as a whole” (p. 596) Refer to the inside cover of this text for a table about distinctions in practice.

Nurses practicing in the community use the core competencies for public health professionals (PHF, 2011) and the core public health functions of assessment, assurance, and policy development to promote the interconnectedness of individual health with the health of families and communities (Eddy et al, 2015). The *Linking Content to Practice* box shows the applications of public health nursing practice from a family perspective. The *Healthy People 2020* box highlights four new objectives that have been identified as leading health issues that address ways to improve the health of families and the nation. Nurses who practice with a family nursing philosophy and theory base

will improve the health of families, their members, and the community.

LINKING CONTENT TO PRACTICE

In this chapter the public health core functions with the essential services below are applied to family nursing.

Assessment

- Monitor health status of families to identify community health problems.
- Diagnose and investigate health problems and health hazards in the community that affect families.
- Evaluate effectiveness, accessibility, and quality of personal and population-based health services.

Policy Development

- Develop policies and plans that support family and community health efforts.
- Enforce laws and regulations that protect health and ensure safety of families in the community.
- Research for new insights and innovative solutions to health problems.

Assurance

- Link people to needed personal health services and assure the provision of health care when otherwise unavailable.
- Assure a competent public health and personal health care workforce.
- Mobilize community partnerships to identify and solve health problems.

HEALTHY PEOPLE 2020

New objectives specific to families and family nursing that relate to a leading health issue.

- AHS 1: Increase the proportion of persons with health insurance
- AH-5-1: Increase the proportion of students who graduate with a regular diploma 4 years after starting the 9th grade
- D-5: Improve glycemic control among persons with diabetes, especially those with A1C greater than 9%
- NWS-9 & 10: Reduce the proportion of adults and children who are obese

From: US Department of Health and Human Services: *Healthy People 2020*, Washington DC, 2010, US Government Printing Office.

CHALLENGES FOR NURSES WORKING WITH FAMILIES IN THE COMMUNITY

Numerous challenges exist that affect the practice of family nursing in a community setting. Many of the following challenges have been recognized in the family nursing literature for a long time, yet they persist in the current health care system. One role for the nurse would be to advocate that the following challenges be addressed in federal and state health care policies and programs.

Definition of Family

Now more than ever, the traditional definition of **family** is being challenged with the legalization of same-sex marriages. There is still no universally agreed on definition of family (Kaakinen and Hanson, 2015a).

Public health nurses and family nurses struggle on a daily basis with the conflict between the narrow traditional legal

definition of family used in the health care system and by social policy makers and the broader term used by the family. Family, as defined and implemented in the health care system, continues to be based on the legal notions of relationships such as biological/genetic blood ties and contractual relationships such as adoption, guardianship, or marriage. However, the family system and family nurses use the following broader definition of family: “Family refers to two or more individuals who depend on one another for emotional, physical, and/or financial support. The members of the family are self-defined” (Hanson, 2005).

Given the current social and political climate, nurses need to adopt the open definition described above because the families they work with have a wide variety of family structures. Nurses who work with the people in the individual’s everyday world have a higher likelihood of helping them to achieve better health outcomes.

Transitions of Care

Nurses have a pivotal role relative to communication of information in **transitions of care** between agencies that frequently result in hospital admission or readmission. Nationally, the number of home health care clients who were admitted to the hospital between 2002 and 2006 was 28.3% (AHCRCQ, 2008). The majority of these hospital admissions in home health care clients occurred within 7 days of admission to the home health agency (Vasquez, 2008). It is estimated that about 20% of individuals discharged from a hospital in the United States are readmitted within 30 days (Cloonan, Wood, and Riley, 2013). Of the estimated \$17.5 billion in Medicare spending on readmissions, approximately \$12 billion is potentially preventable (Centers for Medicare and Medicaid Services, 2013). Individuals most at risk for readmissions are males over 75 years of age, African American, hospitalized with a medical diagnosis, and without insurance other than Medicare (Cloonan et al, 2013).

There are communication issues between health care providers within the community agencies, such as incomplete or missing documentation, that result from rushed assessments. Rushed procedures and failure to follow the plan of action and standards of care are known causes of hospital readmissions (Vasquez, 2008). Persons at high risk for readmission rates parallel those of the population with low health literacy rates (Cloonan et al, 2013; Berkman et al, 2011). Approximately 35% of adults in the United States have limited literacy skills, with an additional 30 million adults who have below basic literacy skills (Berkman et al, 2011). A systematic review of the literature indicated that low health literacy was associated with increased health care use, inappropriate drug use, low use of preventive services, and overall poorer health (Berkman et al, 2011).

It is crucial that home health care staff have current updates on evidence-based practice, standards of care, and interventions to ensure quality health outcomes. Nurses practicing in the community have a significant role in working with multiple health care systems to improve communication and evidence-based design protocols to improve the quality of care and the health of the home health population (Ventura et al, 2010).

Nurses must develop and hone excellent negotiation skills because they spend a significant amount of time arranging for limited services for their **under-insured** and uninsured clients and families. In working with families, communication and teaching will be more effective if hours of service match the times of day when family members, specifically the family care provider, can attend appointments. Bringing a companion to office visits benefits communication (Wolff et al, 2009; Wolff and Roter, 2008), especially for those with low health literacy (Rosland et al, 2011); enhances shared decision making (Clayman et al, 2005); and improves the sharing of information (Eggle et al, 2006). Involving family in the care of the client improves self-management of health care, results in fewer medication errors (Kinnersley et al, 2007; Wolff et al, 2009), and improves health outcomes (Weinberg et al, 2007). Based on this information about companion participation, it is crucial that nurses involve family as much as possible in their interactions and decisions with clients.

Uninsured, Underinsured, and Limited Services

Nursing practice in the community presents various challenges such as knowing how to access health care resources for clients and understanding how recent health care reforms are transforming the landscape of our current health care system. **Uninsured** clients are those who do not have health insurance for any family member. **Underserved** are individuals who have minimal insurance coverage and usually have a high deductible. Individuals with **limited services** are people who may have trouble accessing health care and/or experience barriers to health care. For example, a family with insurance coverage may live in a rural area that does not have a primary health care provider or services near them. The main goals of the Affordable Care Act (ACA) of 2010 were to provide U.S. citizens with patient protection and affordable health care, and decrease the overall cost of health care (see Chapter 3 for more discussion). The ACA is designed to offer premium subsidies to help eligible individuals and their families purchase insurance coverage when affordable employer sponsored insurance is not available. Questions remain about how this affordability protection will be applied in situations where self-only coverage offered by an employer is affordable but family coverage is not.

The U.S. Supreme Court ruled that the ACA Medicaid expansion is a voluntary program for states. As a result, not all states have expanded Medicaid coverage. What this means for persons living in states that have expanded Medicaid coverage is that they qualify for either Medicaid or reduced costs on a private insurance plan if they earn up to \$16,104 a year for one person or \$32,913 for a family of four (CMS, 2013). For persons living in states that have not expanded Medicaid coverage it means if their income is more than 100% of the federal poverty level (about \$11,490 a year as a single person or about \$23,550 for a family of four) they qualify to buy a private health insurance plan in the Marketplace and may get lower costs based on their household size and income (CMS, 2013).

The ACA is estimated to insure at least half of the United States population that is currently uninsured (USDHHS, 2012). The individuals that make up the uninsured are predominantly

undocumented immigrants, citizens who choose not to enroll in Medicaid, residents of states that opt out of the Medicaid expansion provision, and citizens whose cost of health care is 8% or more of their total income (USDHHS, 2012). Undocumented immigrants, who are prohibited from enrolling in Medicaid and purchasing coverage through the new health insurance exchanges, are projected to constitute 25% of the uninsured after the major provisions of the ACA are fully implemented (USDHHS, 2012). Providing health care to the uninsured is already a challenge and will continue to require creative solutions even after the ACA is fully implemented.

Nurses must be adept at working among health care systems to find resources and services for the large population of uninsured clients and families. The number of uninsured Americans in 2010 was 49 million or roughly 16.3% of the total population (DHHS, 2011). A 2014 survey by the Commonwealth Fund suggests that the number of uninsured has dropped significantly since the beginning of the enrollment period in 2013 (Commonwealth Fund, 2014). The percentage of children under the age of 18 without health insurance in 2010 was 9.8%, which significantly decreased from 12% in 1999 due to the expansion of coverage to the Children's Health Insurance Program (CHIP). Since the enactment of the 2010 Affordable Care Act, children can now remain on their parents' insurance plans until the age of 26.

Employer-sponsored insurance continues to be the largest source of health insurance coverage, with 55.3% of the U.S. population covered. However, it is important to note the differences in insurance coverage among minority populations. Hispanics have the highest uninsured rates at 30.7% and blacks are at 20.8%; only 11.7% of non-Hispanic whites are uninsured (USDHHS, 2011).

The demand for primary care will be driven over the next decade and a half not only by the ACA mandates, but also by an aging population and an overall growth in the size of the U.S. population. This growth in demand also accompanies a shift from acute care services to more chronic care management as the nation's disease patterns change as the population ages (Dower & O'Neil, 2011). Various studies projecting current or imminent shortages in primary care providers are shifting attention away from the traditional physician model of care to nurse practitioners, who now account for about 19% of the U.S. primary care workforce, and physician assistants, who account for 7% of the U.S. workforce (Green, Savin & Lu, 2013). Nurse practitioners and physician assistants not only provide effective care but they can also meet the growing demands for primary care providers (Green et al, 2013).

The lack of insurance makes finding adequate services for clients and families difficult. In some areas federal and state funding for care in health clinics is free or available for a minimal fee. However, because the number of primary health care clinics is limited, care is often provided based on the number of volunteer health care providers working that day in the clinic. Many clinics are program based, such as family planning clinics, sexually transmitted disease (STD) clinics, and immunizations clinics. Thus, it is difficult to meet the needs of the uninsured or underinsured populations.

Nurses need to understand the effects of the ACA reforms and how they are being implemented in their states. Nurses help clients and families negotiate and maneuver through the health care system. They must work closely with the family to remove barriers and provide services and resources that enhance the families' abilities to provide quality care to family members. To successfully address these challenges, the community health nurses must integrate principles of family nursing with those of community/public health (see [Evidence-Based Practice](#) and [Levels of Prevention](#) boxes).

EVIDENCE-BASED PRACTICE

Reducing obesity in the United States is a *Healthy People 2020* objective. A study by the [Center for Disease Control \(2013b\)](#) shows that there was a 43% drop in obesity rates among children ages 2 to 5 years of age over the last 10 years. Part of this decline is directly related to the change in the social policy of improvements in the food packages available to these parents through the Woman's Infant and Children (WIC) Program. The improvements include adding health items like fruits and vegetables and whole grain foods while reducing the amount of fruit juice and whole milk. This change, coupled with nutrition education for families with infants and young children led to parents selecting healthier food choices and improved access to healthy foods for at risk families.

Nurse Use

Nurses have a significant role by advocating for social policies that improve the health of families and educating parents of young children to make healthy food choices. Public health nurses should be actively involved in helping to decrease childhood obesity. Refer to the [Levels of Prevention](#) box for reducing childhood obesity.

From: Center for Disease Control: *Vital signs: obesity among low income, preschool aged children-United States, 2008–2011, 2013b*. Available at <http://www.cdc.gov/mmwr/preview/mmwrhtml/mm6231a4.htm>. Accessed March 22, 2014.

LEVELS OF PREVENTION

Reduce the proportion of children and adolescents aged 2–19 years who are considered obese (*Healthy People 2020* objective NWS 10.4)

Primary Prevention

- Educating parents about healthy nutritional choices for young children and the risks associated with obesity
- Provide counseling and weight management for overweight children and teens
- Help mothers who qualify for Women's Infant and Childhood Program complete the extensive paperwork

Secondary Prevention

- Screen teens for obesity with body mass index (BMI) greater than or equal to 30
- Analyze children's height and weight growth as part of annual health assessments

Tertiary Prevention

- Work with schools to improve quality of food offered in school lunch
- Help communities establish local farm to school networks, create school gardens, and ensure that more local foods are used in the school setting.

FAMILY FUNCTIONS AND STRUCTURES

Knowledge of [family functions](#) and structures is essential for understanding how families influence health, illness, and well-being. Nurses who understand family functions and structures can use this knowledge to empower families through evidence-based interventions.

Family functions are the ways in which families meet the needs of (1) each family member, (2) the family as a whole, and (3) their relationship to society. Throughout history, the following functions have been performed by families ([Kaakinen and Hanson, 2015a](#)):

1. *Economic function:* Family income is a substantial part of family economics, but it is also related to family consumerism, money management, housing decisions, insurance choices, retirement, and savings. Family economics affect and reflect the nation's economy.
2. *Reproductive function:* The survival of a society is linked to patterns and rates of reproduction. The family has been the traditional structure in which reproduction was organized. Today, the reproductive function of family has become more separated from traditional family structure as more children are born outside of marriage and into nontraditional family structures.
3. *Socialization function:* A major expectation of families is that they are responsible for raising their children to fit into society and take their place in the adult world. In addition, families disseminate their culture, including religious faith and spirituality.
4. *Affective function:* Families provide boundaries and structure that provide a sense of belonging and identity of who the family members are individually and to their family. The purpose of the affective function is to learn about intimate reciprocal caring relationships, to learn about dependency and how to nurture future generations.
5. *Health care function:* It is in the family that one learns the concepts of health, health promotion, health maintenance, disease prevention, and illness management. Family members provide informal caregiving to ill family members and are primary sources of support.

[Family structure](#) refers to the characteristics and demographics (e.g., sex, age, number) of individual members who make up family units. More specifically, the structure of a family defines the roles and the positions of family members ([Box 27-1](#)).

Family structures have changed over time to meet the needs of the family and society. The great speed at which changes in family structure, values, and relationships are occurring makes working with families at the beginning of the twenty-first century exciting and challenging. According to [Kaakinen and Hanson \(2015a\)](#), the following aspects need to be addressed when determining the family structure:

1. The individuals that compose the family
2. The relationships between them
3. The interactions between the family members
4. The interactions with other social systems

As social norms have become more tolerant of a range of choices in relation to managing one's life, there is no longer a

general consensus that the traditional nuclear family model, consisting of father, mother, and children, is the “best” model. There is no “typical” family model or family structure. For example, the single-mother household may be represented by the unmarried teenage mother with an infant (unplanned pregnancy), the divorced mother with one or more children or the

career-oriented woman in her late 30s who elects to have a baby and remain single.

The family structure changes and modifies over time. An individual may participate in a number of family life experiences over a lifetime (Figure 27-1). For example, a child may spend the early, formative years in the family of origin (mother, father, siblings); experience some years in a single-parent family because of divorce; and participate in a stepfamily relationship when the single parent who has custody remarries.

This same child as an adult may experience several additional family types: cohabitation while completing a desired education, and then a commuter marriage while developing a career. As an adult, the individual may divorce and become a custodial parent. The adult may eventually cohabit with another partner and finally marry a different partner who also has children. As couples age, they have to address issues of the aging family, and subsequently the woman may become an older single widow. Thus, nurses work with various families representing different structures and living arrangements.

Prospects for families in the twenty-first century are numerous. New family structures that are currently experimental will emerge as everyday “natural” families (e.g., families in which the members are not related by blood or marriage, but who provide the services, caring, love, intimacy, and interaction needed by all persons to experience a quality life).

At times it is helpful to understand families through a narrow framework of family function and structure. However, a family is a system within itself as well as the basic unit of a society. Some would argue that the traditional concept of family is disintegrating based on how the structure and functions of the family have changed over time. On the other side of that debate, families change in response to the societal changes and are ever evolving and thriving as they seek different ways of interconnectedness (Kaakinen and Hanson, 2015a).

BOX 27-1 Family and Household Structures

Married Family

- Traditional nuclear family
- Dual-career family
- Spouses reside in same household
- Commuter marriage
- Husband/father away from family
- Stepfamily
- Stepmother family
- Stepfather family
- Adoptive family
- Foster family
- Voluntary childlessness

Single-Parent Family

- Never married
- Voluntary singlehood (with children, biological or adopted)
- Involuntary singlehood (with children)
- Formerly married
- Widowed (with children)
- Divorced (with children)
- Custodial parent
- Joint custody of children
- Binuclear family

Multi-Adult Household (With or Without Children)

- Cohabiting couple
- Communes
- Affiliated family
- Extended family
- Newly extended family
- Home-sharing individuals
- Same-sex partners

FAMILY DEMOGRAPHICS

Historically, **family demographics** can be analyzed by looking at data about the families and household structures and the

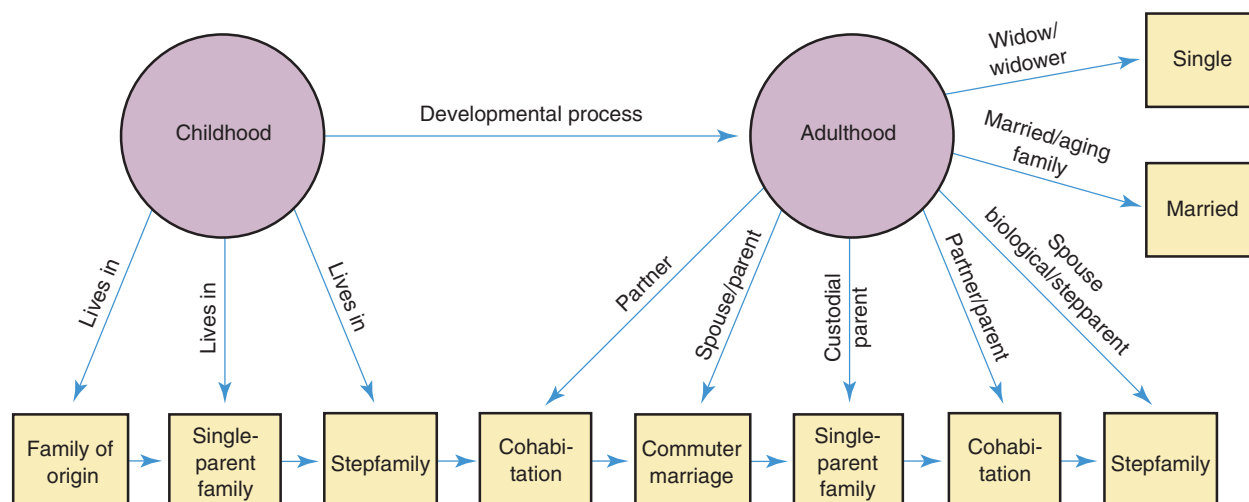

FIG 27-1 An individual's family life structure over time.

events that alter these structures. Recent trends in family demographics show that there has been a quieting of the rapid changes that were found in family structure and living arrangements in the twenty-first century. Nurses draw on family demographic data to forecast and predict family community needs, such as family developmental changes, stresses, and ethnic issues affecting family health, as they formulate possible solutions to identified family community problems. In this chapter, major family demographic trends valuable to nurses practicing in the community are presented.

Living Arrangements

The number of households in the United States has tripled from 35 million households in 1940 to 117 million households in 2010 (Jacobsen, Mather, and Dupuis, 2012). Of these 117 million households, 67% were considered family households and the remaining 33% being nonfamily households (U.S. Census Bureau, 2012a). Family households include a householder and at least one other member related by birth, marriage, or adoption, whereas a nonfamily household is either a person Kreider and living alone or a householder who shares the house only with nonrelatives, such as boarders or roommates (Kreider and Elliot, 2007).

The fastest growth was among persons living alone, with much of this growth occurring during the 1960s and 1970s. The proportion of households with just one person more than doubled from 13% to 27% between 1960 and 2012 (Casper, Florian, and Brandon, 2015).

Family demographic trends have continued in the direction of fewer married couples with children households: 20 million in 2010 compared with 23 million in 2009 and 30 million in 1980 (Jacobsen et al, 2012).

Americans are living longer. By 2009, life expectancy at birth was nearly 79 years for Americans (Arias, 2008). An American woman who reached age 60 in 2009 could expect to live an additional 25 years, on average, and a 60-year-old American man would live another 22 years. The proportion of elderly adults living alone has increased dramatically. Just 15% of widows aged 65 or older lived alone in 1900, whereas 66% lived alone in 2011 (U.S. Census Bureau, 2011a). In 2011, 44% of the population aged 65 and older lived alone (U.S. Census Bureau, 2011b). Elderly women (37%) are twice as likely as elderly men (19%) to live alone (Casper et al, 2015).

Living alone can mean delays in getting attention for illness or injury and can complicate arrangements for informal care or transportation to formal care when needed. What this means is that elderly individuals are more likely to access and need community-based services. In addition, with the geographic mobility of American society, many of these elderly do not live close to family; therefore they do not have as many family members to care for them. Despite the trend toward independent living among older Americans, many of them are not able to live alone without assistance.

Marriage, Divorce, and Cohabitation

Marriage, although still a popular American ideal, has assumed a forerunner: cohabitation. Cohabitation is a couple living

together who are having a sexual relationship without being married. The number of divorces has leveled off and remained constant.

Most Americans do marry. In 2011, 90% of women aged 50 to 54 had been married at least once (U.S. Census Bureau, 2011c). However, the age at marriage continues to be delayed, with the age for first marriage being 26 years for women and 28 years for men (Kreider and Ellis, 2011b). This delay in marriage has implications for the delay in child birthing.

The rapidly escalating divorce rate of families found in the 1970s and 1980s has leveled off and remained relatively constant since 1990, with about 43% and 46% of marriages ending in divorce (Schoen and Canudas-Romo, 2006). However, the divorce rates among married people 50 years or older doubled between 1990 and 2010 with 1 in 4 divorces in 2010 being people over 50 years of age (Brown and Lin, 2013). As cohabitation has become more acceptable, fewer divorced people are getting remarried and the remarriage rate has dropped 40% in the last 20 years (Jayson, 2013). In 1990 there were 50 per 1000 divorced people remarried; in 2011 that number declined to 29 out of 1000 (Jayson, 2013).

One of the most significant household changes in the second half of the twentieth century in North America was the increase in men and women living together without marrying. Approximately 9% of the households in 2011, representing 7.6 million family groups, are unmarried partner opposite-sex family groups and about 40% of these households included children (U.S. Census Bureau, 2011d). The number of same-sex couples in the United States grew approximately by 80% from 358,390 in 2000 to 646,464 in 2010 (Lofquist, Lugaila, O'Connell, and Feliz, 2012).

Casper et al (2010) suggest that people cohabitate for three reasons: some cohabitants would marry but do not for economic reasons; others seek a more egalitarian relationship; and others use cohabitation as a trial period to negotiate and assess whether to marry. Younger cohabitants are more likely to view their relationship as a prelude to marriage (King and Scott, 2005). This view is common, with a 65% chance of cohabitation transitioning to marriage within the first 5 years (Goodwin, Mosher, and Chandra, 2010). Phillips and Sweeney (2005) suggest that there is an ethnic factor in the meaning of cohabitation, with whites viewing cohabitation as a trial marriage and African Americans and Hispanic Americans viewing cohabitation as a substitute for marriage. In 2005 King and Scott found that older adults enjoyed relationships of higher quality and perceived stability despite having fewer plans to marry and were more likely than younger cohabitants to view their relationship as an alternative to marriage.

Different factors were associated with duration of marriage and cohabitation. Duration of marriage was associated with two factors: age of first marriage and timing of first child. Marriage at a younger age had a lower probability of the marriage lasting 10 years. Women who gave birth 8 months or more after the marriage began compared with women who had no first birth during the marriage had a 79% chance versus a 34% chance of the marriage lasting 10 years. Education was a factor in both men's and women's duration of cohabitation, with lower

education being associated with longer cohabitation (Goodwin et al, 2010).

As cohabitation increases, ensuring sexually transmitted disease (STD) reduction and family planning services becomes essential. The most frequently reported infectious disease in the United States is chlamydia (CDC, 2010). In 2008 more than 1.2 million cases of chlamydia were reported. Women between the ages of 15 and 19 years of age and minority women are at the highest risk (CDC, 2010). Untreated chlamydia can cause severe and costly reproductive health problems. A model collaborative program is the [Region X Infertility Prevention Project \(2000\)](#), which aims to control chlamydia through collaborative efforts of STD and family planning providers and public health laboratories. A comprehensive approach to STD prevention that includes screening, treatment of infected partners, and behavioral interventions with a focus on reducing racial disparities is an important aspect of providing community health (CDC, 2010).

Effects of Cohabitation on Children

Cohabiting couples in the United States live together for shorter periods of time than cohabiting couples in other countries (Cherlin, 2010). Parental separation is five times greater for children born to cohabiting parents than to married parents (Brown, 2010). The unstable living arrangements for children born outside of marriage remains an important question relative to the well-being of these children. The number of transitions is associated with negative child well-being (Osborne and McLanahan, 2007). Many of these children experience about three transition relationships from birth to 3 years of age (Osborne and McLanahan, 2007). The research shows that children in cohabiting relationships have more behavioral and cognitive problems (Ray, 2013).

DeLeire and Kalil (2005) found relatively high rates of poverty in cohabiting families with children compared with the national average (18.2% to 22.4%, compared with 12.1% overall and 5.3% among married couples). They also found that cohabiting-parent families spend a greater share of their budgets on alcohol and tobacco than do married, divorced, and never-married single-parent families (DeLeire and Kalil, 2005). Nurses must ensure that these families have access to health insurance such as the Medicaid S-CHIP program. Teaching cohabiting families with children about the implications of secondhand smoke becomes a priority because these children are at risk for health problems such as increased lower respiratory tract infections and asthma. Because poverty rates are higher, assisting these families in gaining access to resources such as food stamps and budget management skills is the work of nurses in the community.

Births

Replacement-level fertility refers to the required number of children each woman in the population would have to bear on average to replace herself and her partner, and it is conventionally set at 2.1 children per woman for countries with low mortality rates (Casper et al, 2015). The fertility rate in the United States has been in continual decline over the last

century, with occasional boosts, such as the baby boom after World War II in the late 1940s and early 1950s. In 2010 the fertility rate in the United States was 1.93, which is just below replacement factor (Martin et al, 2012). In response to this lower fertility rate, the United States typically responds by opening immigration into the country, as immigrant women tend to have higher fertility rates than native-born American women. In 2010, native-born women had on average 1.8 children, whereas foreign-born women had 2.2 children (U.S. Census Bureau, 2010a).

Fertility rates differ by race and ethnicity. Hispanic women have the highest fertility rates at 2.3, followed by African American women at 2.0, and Asian women have the lowest fertility rate at 1.8 (U.S. Census Bureau, 2010b). Not all cultures value limiting the number of children in a family, and nurses may be challenged to understand these values and provide services where the woman assumes the value of limiting the number of children while the husband does not. For example, a Hispanic woman comes to the public health clinic for family planning services. It is not uncommon for the husband to come in at the end of the week to pay for those services. If the wife is on birth control, such as Depo, but does not want her husband to know, itemizing services on the receipt would present a problem. The nurse needs to understand these changing values and facilitate the family planning services requested by the woman without violating her confidentiality.

One of the major changes in the births in the United States is the increase in the rise of children born to women outside of marriage. In 2010, 41% of all births in the United States were to unmarried women (Martin et al, 2012). As women are delaying marriage, so too are they older at the birth of their first child. In 2010, the average age at first birth was 25.4 (Martin et al, 2012). This means that nurses will likely have older mothers who are at risk of having more complications with pregnancy and birth. The birth rate for teenagers has decreased substantially, but the United States still has one of the highest rates of teenage pregnancies in the industrialized world. The U.S. teenage birth rate for women ages 15 to 19 was 34.3 births per 1,000 women in 2010, down from 52.2 in 1981 (Martin et al, 2012).

Parenting

Even with the increase in divorce and cohabitation, postponement of marriage, and decline in childbearing, most North American adults have children, and most children live with two parents. In 2011, 64% of families with children were two-parent, married families and an additional 5% were two-parent, unmarried families (U.S. Census Bureau, 2011e, 2011f; Casper et al, 2015). Blended family households are when two people marry and at least one of these individuals brings a child with them into the marriage. In 2009, 13.3% of households with children under 18 were blended family households, numbering 5.3 million (Kreider and Ellis, 2011a). Therefore, almost 16% of U.S. children (11.7 million) lived in blended families in 2009 (Kreider & Ellis, 2011a). Because the blended family comprises a significant proportion of families with children, nurses are likely to interact with parents and children whose roles and

responsibilities are not well defined. Obtaining legal authorization can be challenging when legal obligations are unclear; therefore it is important that nurses identify which parent(s) have legal responsibility for medical decision making. It is also important for nurses to be aware that they may also need to notify nonresidential parents when their children require medical attention because these parents may share the legal right to make medical decisions.

Single mothers, never married, are particularly disadvantaged; they are younger, less well educated, and less often employed than are divorced single mothers and married mothers (Casper et al, 2015). Mothers who never married (25%) are much less likely to get child support from the father than are mothers who are divorced or separated (43%) (Casper et al, 2015). Divorced mothers are substantially better educated and more often employed than are mothers who are separated or who never married. However, the average income of families headed by divorced mothers is less than half that of two-parent families (Casper et al, 2015). Approximately 12% of single mothers and their children live in the homes of their grandparents and 5.2% have a grandparent living with them (U.S. Census Bureau, 2011f).

Despite the fact that the majority of American single mothers are not poor, they are much more likely to be poorer than other parents. For example, a single mother with two children with an annual income of less than \$18,123 in 2011 was below the federal poverty level (Casper et al, 2015). Overall, 20% of U.S. children lived in poverty in 2009 (Kreider and Ellis, 2011b). Children in two-parent families had the lowest rate of poverty at 13.3%, followed by children living in father-only families at 19.9%. Children in mother-only families had the highest poverty rate at 38.1% (Kreider & Ellis, 2011b).

The slow but steady increase in the number of single-father households is one changing aspect of family life in America. Between 1950 and 2011 the number of households with children that were maintained by an unmarried father increased from 229,000 to 2.2 million (U.S. Census Bureau, 2011g). Fathers who are divorced are more likely to share child custody than in the past; however, that does not mean that there are fewer obstacles in such complicated family arrangements (Carlson and McLanahan, 2010). In general, fathers are spending more time with their children than in the past (Casper et al, 2015).

Many children are raised by or receive regular care from their grandparents. These grandparents may or may not have legal responsibility for their grandchildren, but may seek medical care for them. In 2011, about 7.7 million children lived in a home with a grandparent (Desilver, 2013). Of these children 80% had at least one parent also living in the same household. However, 3 million of these children had their grandparent as their primary caregiver and provider (Desilver, 2013). Although there are many rewards for both the grandparent and grandchild, taking care of children at such an “off family” time creates stress and can be very difficult.

Immigration

In 2010 the U.S. Census Bureau estimated that there were 40 million U.S. residents born outside the country, which is nearly

13% of the total population (Grieco et al, 2012). Because immigrants tend to arrive in the United States early in their working careers, they are younger, on average, than the overall U.S. population and account for a larger share of young families (Casper et al, 2015). In 2010, for example, 20% of all births in the United States were to mothers born outside the country (U.S. Census Bureau, 2010b). This means that nurses need a solid understanding of culture and health beliefs because they are essential components of practice with families. Half of adults 18 to 40 years old who speak Spanish at home reported that they could not speak English well (Shin and Kominski, 2010). In addition to a language issue, many of these immigrants are in the United States illegally and do not qualify for federal public benefits or health care.

Family Caregivers

In 2010, 30% of adults were family caregivers with 55% of the caregivers being women and 45% being men (PEW, 2012). Most family caregivers (7 out of 10) provide care to someone 50 years of age or older, 14% take care of an adult age 18 to 49, while 14% take care of a child under the age of 18 (National Alliance for Family Caregiving, 2009). The most prevalent reasons for providing care are due to an aging family member who needs assistance with activities of daily living and some type of dementia (National Alliance for Family Caregiving, 2009). The 2012 National Health Survey states that about 40 million people (12% of the population) are limited in their activities of daily living due to one or more chronic health conditions. About 10 million people require the help of another person with their instrumental activities of daily living.

The majority (31%) of the family caregivers are over the age of 50 and 12% of them are over the age of 65 (Pew, 2012). On average the family caregivers reported providing 24 hours of assistance each week for an adult family member and parents reported providing care for 30 hours a week for a child with special health needs (National Alliance for Family Caregiving, 2009). Of these caregivers, 24% reported that they themselves have a disability (Pew, 2012). Of these caregivers, 47% work full time, 13% work part time, 14% are retired, and 18% do not work for pay (Pew, 2012).

An invisible trend that needs attention is the number of children under 19 years of age who are providing care for a family member. In the United States there are 1.3 to 1.4 million children, ranging in age from 10 to 20 years who provide care for sick or disabled relatives, with about a third caring for a grandparent (National Alliance for Family Caregiving, 2005). Three in ten child caregivers are ages 8 to 11 (31%), 38% are ages 12 to 15, and the remaining 31% are ages 16 to 18. Child caregivers are evenly balanced by gender (male 49%, female 51%). Caregivers tend to live in households with lower incomes than do noncaregivers, and they are less likely than noncaregivers to have two-parent households (76% vs. 85%) (National Alliance for Family Caregiving, 2005, p. 5). In a large study conducted by Siskowski (2006) of 12,681 public school children in Palm Beach County, Florida, more than 1 in 2 middle and high school children (6,210) were providing care for a family member. Of these young caregivers 67% missed school or after

school activities, did not complete their homework or were interrupted in their studying to provide care for a family member. Approximately 22% of high school dropouts leave school to provide care for a family member (Bridgeland, Dilulio and Morrison, 2006).

As family caregivers are the primary care providers, it is crucial that they be supported in all ways possible. Nurses can work with families who are providing care to their family member in the following ways (National Alliance for Family Caregiving, 2009):

1. Identify and help caregivers who are most at risk for deteriorating health, financial security, and quality of life so that they can continue to provide care while maintaining their own well-being.
2. Identify and advocate for programs that make a real difference in caregivers' well-being and in their ability to continue providing care.
3. Identify and promote the use of technologies that can facilitate caregiving.
4. Extend the reach of caregiver programs to all caregivers regardless of the age of their care recipient.
5. Encourage families to plan proactively for aging and potential health/disability issues.

FAMILY HEALTH

The meaning of family health is not precise and lacks consensus, despite the increased focus on family health within the nursing profession. The term **family health** is often used interchangeably with the concepts of family functioning, healthy families, and familial health. Hanson (2005, p. 7) defines family health as “a dynamic changing relative state of well-being which includes the biological, psychological, spiritual, sociological, and cultural factors of the family system.” This holistic approach refers to individual members as well as the family unit as a whole entity and in turn the family within the community context. An individual's health (the wellness and illness continuum) affects the functioning of the entire family, and in turn, the family's functioning affects the health of individuals. Thus assessment of family health involves simultaneous assessment of individual family members, the family system as a whole, and the community in which the family is embedded.

Health professionals have tended to classify clients and their families into two groups: healthy families and nonhealthy families, or those in need of psychosocial evaluation and intervention. The term *family health* implies mental health rather than physical health. A popular term for *nonhealthy families* is **dysfunctional families**, also called noncompliant, resistant, or unmotivated—phrases that label families who are not functioning well with each other or in their communities.

Families are neither all good nor all bad; rather, all families have both strengths and difficulties. All families have seeds of resilience and strengths upon which the nurse should work with the family to build interventions and design plans of action.

Families with strengths, functional families, and **balanced families** are terms often used to refer to *healthy families* that are doing well. Studies have identified traits of healthy families as

BOX 27-2 Characteristics of Healthy Families

1. The family tends to communicate well and listen to all members.
2. The family affirms and supports all of its members.
3. Teaching respect for others is valued by the family.
4. The family members have a sense of trust.
5. The family plays together, and humor is present.
6. All members interact with each other, and a balance in the interactions is noted among the members.
7. The family shares leisure time together.
8. The family has a shared sense of responsibility.
9. The family has traditions and rituals.
10. The family shares a religious core.
11. Privacy of members is honored by the family.
12. The family opens its boundaries to admit and seek help with problems.

well as family stressors that are useful for nurses to include in their assessment (Kaakinen and Hanson, 2015a; Driver et al, 2003; Olson and Gorall, 2003). Box 27-2 shows characteristics of families who are healthy and functioning well in society.

The most recent concept described in the family literature pertains to ways families function across the family life cycle. Balanced families are those that have the ability to adapt to situations; therefore, they demonstrate **family flexibility** in leadership, relationships, rules, control, discipline, negotiation, and role sharing (Kaakinen and Hanson, 2015a; Olson and Gorall, 2003). Balanced families have the ability to allow family members to be independent from the family yet remain connected to the family as a whole, which is termed **family cohesion** (Olson and Gorall, 2003).

FOUR APPROACHES TO FAMILY NURSING

Central to the practice of family nursing is conceptualizing and approaching the family from four perspectives. All have legitimate implications for family nursing assessment and intervention (Figures 27-2 and 27-3). The approaches that nurses use are determined by many factors, including the issues for which the individuals or families as a whole are seeking help, the environment in which they coexist with other family members and the community, the interaction among all of these factors, and of course the nursing resources available to deal with all of these factors (Hanson, 2005).

Family As Context

The family has a traditional focus that places the individual first and the family second. The **family as context** serves as either a strength or a stressor to individual health and illness issues. The nurse is most interested in the individual and realizes that the family influences the health of the individual. A nurse using this focus might ask an individual client the following questions: “Is your family available to help you get to your doctor appointments?” “Can your wife help you with your insulin injections?”

FIG 27-3 Four views of the family.

or “Perhaps your son could help you go up and down the stairs since your mother is so much smaller than you and your dad.”

Family As Client

When the nurse views the **family as client** the family is the primary focus and individual family members are secondary. The family is seen as the sum of individual family members. The focus is concentrated on how the family as a whole is reacting to the event when a family member experiences a health issue. In addition, the nurse looks to see how each family member is affected by the health event. From this perspective, a nurse might say the following to a family member who has recently become ill: “How is the family reacting to your mother’s recent diagnosis of liver cancer?” “How have you experienced your mother’s recent diagnosis of liver cancer?” “How has your diagnosis of insulin-dependent diabetes affected your family?” “Will your need for medication at night be a problem for your family?”

Family As a System

The focus is on the family as client, and the family is viewed as an interactional system in which the whole is more than the sum of its parts. This approach focuses on individual members and the family as a whole at the same time. The interactions among family members become the target for nursing interventions (e.g., the interactions among both parents and children, and between the parental dyad). The systems approach to families always implies that when something happens to one family member, the other members of the family system also are affected, and vice versa. Questions nurses ask when approaching the **family as a system** are the following: “What has changed between you and your spouse since your child’s head injury?” “How do you feel about the fact that your son’s long-term rehabilitation will affect the ways members of your family are functioning and interact with one another?”

Family As a Component of Society

The **family as a component of society** is seen as one of many institutions in society, along with health, education, and religious and financial institutions. The family is a basic or primary

FIG 27-4 Theory-based family nursing. (Modified from Hanson SMH, Kaakinen JR: Theoretical foundations for family nursing. In Hanson SMH, Gedaly-Duff V, Kaakinen JR, editors: *Family Health Care Nursing: Theory, Practice and Research*, Philadelphia, 2005, FA Davis.)

unit of society, as are all the other units, and they are all a part of the larger system of society. The family as a whole interacts with other institutions to receive, exchange, or give services. Nurses who work with families have derived many of their tenets of practice from this component of society, because they focus on the interface between families and community agencies. Nurses using this approach see families as a population. Questions the nurse might ask using this lens are, “How do we meet the needs of adolescent pregnant women?” or “What plan should we develop to increase the H1N1 immunization rates in the families living in the lower-income housing developments?” This is the approach used by public health nurses as they implement population-centered strategies to improve the health of the overall community.

THEORIES FOR WORKING WITH FAMILIES IN THE COMMUNITY

There is no single theory or conceptual framework that fully describes the relationships and dynamics and can be used to understand and intervene with families. Thus, an integrated theoretical approach is necessary because one theoretical perspective does not provide nurses with enough knowledge to work effectively with families. Public health nurses must also blend family nursing theories with public health theories and frameworks to work both with individual families and populations of families.

Family nursing theory is an evolving synthesis of the scholarship from three different traditions: family social science, family therapy, and nursing (Figure 27-4). Of the three categories of theory, the family social science theories are the most well-developed and informative with respect to how families function, the environment–family interchange, interactions within the family, how the family changes over time, and the family’s reaction to health and illness. Therefore, in this chapter, three family social science theories that blend well with public health nursing are reviewed. These social science theories are

the **family systems theory**, **family developmental and life cycle theory**, and the **bioecological systems theory**.

Family Systems Theory

Families are social systems and much can be learned from the systems approach. A system is composed of a set of organized, complex, interacting elements. Nurses use family systems theory to understand how a family is an organized whole as well as composed of individuals (Kaakinen and Hanson, 2015b). The purpose of the family system is to maintain stability through adaptation to internal and external stresses that are created by change (Kaakinen and Hanson, 2015b; White and Klein, 2008). Assumptions of family systems theory include the following:

- Family systems are greater than and different from the sum of their parts.
- There are many hierarchies within family systems and logical relationships between subsystems (e.g., mother–child, family–community).
- Boundaries in the family system can be open, closed, or random.
- Family systems increase in complexity over time, evolving to allow greater adaptability, tolerance to change, and growth by differentiation.
- Family systems change constantly in response to stresses and strains from within and from outside environments.
- Change in one part of a family system affects the total system.
- Family systems are an organized whole; therefore, individuals within the family are interdependent.
- Family systems have homeostatic features to maintain stable patterns that can be adaptive or maladaptive.

An excellent way to understand family systems theory is to visualize a mobile that consists of different members of a family suspended from each arm of the mobile; this represents the family as a whole. The parts of the mobile move about in response to changes in the balance. The amount of movement and length of time it takes to achieve a calm, balanced state depends on the severity of the imbalance. The family is a system similar to that of the mobile. When one member is affected by a health event, the whole family and each member of the family is affected differently by this change in balance. Imagine what would happen to the mobile if one of the parts was cut off as in the death of a family member, an additional part was added as in the birth or adoption of an infant, an arm of the mobile was extended such as a child moving out of the family home, or one part is yanked really hard and held down for an extended period of time and then suddenly released such as when a family member experiences a life-limiting illness and recovers or proceeds to a chronic illness.

The family systems theory encourages nurses to view the individual clients as participating members of a whole family. The goal is for nurses to help families maintain balance and stability in the family system so that the family can maximize their ability to function and adapt (Kaakinen and Hanson, 2015a). Nurses using this theory determine the effects of illness or injury on the entire family system. Emphasis is on the whole rather than on individuals. Nursing assessment of family systems includes assessment of individual members,

subsystems, boundaries, openness, inputs and outputs, family interactions, family processing, and adapting or changing abilities. Examples of assessment questions nurses could ask a family based on a family systems theory would include the following:

- Who are the members of your family?
- How has one member's illness affected the family?
- Who in the family is or will be affected the most?
- What has helped your family in the past when you have had a similar experience?
- Who outside of your family do you see as being able to help?
- How would your family react to having someone from outside the family come to help?
- How do you think the children, spouse, or parents are meeting their needs?
- What will help the family cope with the changes?

Interventions need to build on the strengths of the family to improve or support the functioning of the individual members and the whole family. Some nursing strategies based on a family systems theory include establishing a mechanism for providing families with information about their family members on a regular basis, helping the family maintain routines and rituals, and discussing ways to provide for everyday functioning when a family member becomes ill.

The major strength of the systems framework is that it views families from both a subsystem and a suprasystem approach. That is, it views the interactions within and between family subsystems as well as the interaction between families and the larger supersystems, such as the community and the world. The major weakness of the systems framework is that the focus is on the interaction of the family with other systems rather than on the individual, which is sometimes more important.

Family Developmental and Life Cycle Theory

Family developmental and life cycle theory provides a framework for understanding normal predicted stresses that families experience as they change and transition over time. In the original theory of family development by Duvall and Miller (1985) they applied the principles of individual development to the family as a unit. The stages of family development are based on the age of the eldest child. Overall family tasks are identified that need to be accomplished for each stage of family development. Table 27-1 shows the stages of the family life cycle and some of the family developmental tasks. One developmental concept of this theory is that families as a system move to a different level of functioning, thus implying progress in a single direction. Family disequilibrium and conflicts occur during these expected transition periods from one stage of family development to another. The family begins as a married couple. Then the family becomes more complex with the addition of each new child until it becomes simpler and less complex as the younger generation begins to leave the home. Finally, the family comes full circle to the original husband–wife pair. Recognizing that families of today are different in structure, function, and processes, Carter and McGoldrick (2005) expanded the work of Duvall and Miller (1985) to have the family developmental and life cycle theory include different family structures such as divorced families and blended families.

TABLE 27-1 Traditional Family Life Cycle Stages and Family Developmental Tasks

Stages of Family Life Cycle	Family Developmental Tasks
Married couple	Establish relationship as a family unit, role development Determine family routines and rituals
Childbearing families with infants	Adjust to pregnancy and then birth of infant Learn new roles as mother and father Maintain couple time, intimacy, and relationship as a unit
Families with preschool children	Understand growth and development, including discipline Cope with energy depletion Arrange for individual time, family time, and couple time
Families with school-aged children	Learn to open family boundaries as child increases amount of time spent with others outside of the family Manage time demands in supporting child's interest and needs outside of the home Establish rules, new disciplinary actions Maintain couple time
Families with adolescents	Adapt to changes in family communication, power structure, and decision making as teen increases autonomy Help teen develop as individual and as a family member
Families launching young adults	As young adult moves in and out of the home allocate space, power, communication, roles Maintain couple time, intimacy, and relationship
Middle-aged parents	Refocus on couple time, intimacy, and relationship Maintain kinship ties Focus on retirement and the future
Aging parents	Adjust to retirement, death of spouse, and living alone Adjust to new roles (i.e., widow, single, grandparent) Adjust to new living situations, changes in health

Traditional Family Life Cycle Stages and Family Developmental Tasks

Family developmental and life cycle theory explains and predicts the changes that occur to families and its members over time. Achievement of family developmental tasks helps individual family members to accomplish their tasks. Two of the major assumptions of this theory are as follows:

- Families change and develop over time based on the age of the family members and the social norms of the society. Families have predictable stressors and changes based on changes in the family development and family structure. For example, when a family has their first child, there are predictable stresses and goals to accomplish. Also, families who experience a divorce have some predictable stresses based on when in the life cycle of the family the divorce occurs.
- Families experience disequilibrium when they transition from one stage to another stage. These transitions are

considered “on time” or “off time.” For example, a couple in their late 20s having their first child would be considered “on time,” whereas a teenager having a child or a 30-year-old wife and mother dying from breast cancer would be considered “off-time” transitions.

This theory assists nurses in anticipating stresses families may experience based on the stage of the family life cycle and if the family is experiencing these changes “on time” or “off time.” Nurses can also use these predictable stresses to identify family strengths in adaptation to the changes. In conducting an assessment of families, the following are examples of the types of questions nurses can ask based on the family developmental and life cycle theory.

- How has time that the family spends together been affected?
- How has communication among and between the family members been altered?
- Has physical space in the home been changed to meet the needs of the evolving family?
- In what ways have the informal roles of the family been changed?
- What changes are being experienced in family meals, recreation, spirituality, or sleep habits?
- How are the family finances affected as the family members age?
- Who should be included in the family decision making?

Nursing intervention strategies that derive from the family developmental and life cycle theory help individuals and families understand the growth and development stages and manage the normal transition periods between developmental periods (e.g., tasks of the school-age family member versus tasks of the adolescent family member) with the least amount of stress possible. Family nurses must recognize that in every family there are both individual and family developmental tasks that need to be accomplished for every stage of the individual or family life cycle that are unique to that particular family.

The major strength of this approach is that it provides a basis for forecasting normative stresses and issues that families will experience at any stage in the family life cycle. The major weakness of the model is that it was developed at a time when the traditional nuclear family was emphasized and that some theory development has been conducted on how family life cycles or stages are affected in divorced families, step-parent families, and domestic-partner relationships (Carter and McGoldrick, 2005).

Bioecological Systems Theory

The bioecological systems theory was developed by Urie Bronfenbrenner (1972, 1979, 1997) to describe how environments and systems outside of the family influence the development of a child over time. Even though this theory was designed around how both nature and nurture shape the development of a child, the same underlying principles can be applied when the client is the family. This theory is very useful for public health nurses since it helps identify the stresses and potential resources that can affect family adaptation. Figure 27-5 depicts the four systems in this theory at different levels of engagement that can affect family development and adaptation. The family as the client is at the center of the concentric circles. Each of the levels

FIG 27-5 Bioecological family systems model: levels of systems.

contains roles, norms, and rules that influence the current situation of the family.

Microsystems are composed of the systems and individuals that the family directly interacts with on a daily basis. These systems vary for each family, but could include their home, neighborhood, place of work, school systems, extended family, health care system, community/public health system, or close friends.

Mesosystems are the systems that the family interacts with frequently but not on a daily basis. These systems vary based on the situation in which the public health nurse is working with a family. Some ideas for systems at this level could be a home health aide who comes to the home twice a week, a hospice nurse who comes to the home once a week, a social worker, church members who come to deliver food to the family, the transportation system, the school system, specialty physicians, pharmacy, or extended family.

Exosystems are external environments that have an indirect influence on the family. For example, some of these systems could be the economic system, local and state political systems, religious system, the school board, community/health and welfare services, the social security office, or protective services.

Macrosystems are broad overarching social ideological and cultural values, attitudes, and beliefs that indirectly influence the family. Examples include a Jewish religious ethic, a cultural value of autonomy in decision making, or ethnicity.

Chronosystems refer to time-related contexts in which changes that have occurred over time may influence any or all of the other levels/systems. Examples include the death of a young parent, a divorce and remarriage, war, or natural disasters.

One assumption of this model is that what happens outside of the family is equally as important as what happens inside the family. The interaction between the family and the systems in which it interacts is bidirectional in that the family is affected by the outside systems and the family affects these systems. The

strength of this model is that it provides a holistic view of interactions between the family and society. In working with the family, a critical intervention strategy is drawing a family ecomap that shows the systems with which the family interacts, including the flow of energy from that system into the family or out of the family. The family ecomap is explained in more detail later in the chapter. The weakness of this model is that it does not address how families cope or adapt to the interaction with these systems.

WORKING WITH FAMILIES FOR HEALTHY OUTCOMES

Family nurses should transcend the traditional nursing approach as a service model and change their practice to a **capacity building model** (Kim-Godwin and Bomar, 2015; Bomar, 2004). In a capacity building model nurses assume the family has the most knowledge about how their health issues affect the family, supports family decision making, empowers the family to act, and facilitates actions for and with the family. The goal of family nursing is to focus care, interventions, and services to optimize the self-care capabilities of families and to achieve the best possible outcomes.

Nurses work with all types of family structures in a variety of settings. Each family is unique in how it responds to the stresses that evolve when a family member experiences a health event. Public health nurses are in a unique position to help families by providing direct care, removing barriers to needed services, and improving the capacity of the family to take care of its members (Kaakinen and Tabacco, 2015).

Pre-encounter Data Collection

Using excellent communication skills, nurses help families determine the priority of issues they are confronting, identify their needs, and develop a plan of action. Family members are experts in their own health. They know the family health history, their health status, and their health-related concerns (Smith, 2009).

Nurses gather information about the family from a myriad of sources as well as directly from the family. Data collection begins when an actual or potential problem is identified by a source, which may be the family, the health care provider, a school nurse, or a caseworker. Several examples follow:

1. A family is referred to the home health agency because of the birth of the newest family member. In that district, all births are automatically followed up with a home visit.
2. A family calls hospice to request assistance in providing care to a family member with a terminal illness.
3. A school nurse is asked to conduct a family assessment by a teacher who noticed that the student has frequent absences and has demonstrated significant behavior changes in the classroom.
4. A nurse practitioner requests a family assessment for a child who has failure to thrive.
5. An individual seeks health care in a primary care county clinic or a program-specific clinic such as family planning or an STD clinic.

The assessment process and data collection begin as soon as the referral occurs or the appointment is made. Sources of pre-encounter data the nurse gathers include the following:

- *Referral source.* The information collected from the referral source includes data that led to the identification of a problem for this family. Demographic information and subjective and objective information may be obtained from the referral source.
- *Family.* A family may identify a health care concern and seek help. During the initial intake or screening procedure, valuable information can be collected from the family. Information is collected during phone interaction with the family member, even when calling to set up the initial appointment. This information might include family members' views of the problem, surprise that the referral was made, reluctance to set up the meeting, avoidance in setting up the interview, or recognition that a referral was made or that a probable health care concern exists.
- *Previous records.* Previous records may be available for review before the first meeting between the nurse and the family. Often, a record release for information is necessary to obtain family or individual records. However, one challenge may be that many of the electronic health records are premade templates that ignore family information.

Determine Where to Meet the Family

Before contacting the family to arrange for the initial appointment, the nurse decides the best place to meet with the family, which might be in the home, clinic, or office. The [How To Plan for Family Assessment](#) box identifies reflection questions nurses need to address before meeting the family. Often the decision about the place of the family meeting will be determined by the type of agency with which the nurse works (e.g., home health is conducted in the home, and mental health agencies meet the family in the clinic).

HOW TO Plan for Family Assessment

Assessment of families requires an organized plan before you see the family. This plan is developed through the following questions:

1. Why are you seeing the family?
2. Are there any specific family concerns that have been identified by other sources?
3. Is there a need for an interpreter?
4. Who will be present during the interview?
5. Where will you see the family and how will the space be arranged?
6. What are you going to be assessing?
7. How are you going to collect the data?
8. What services do you anticipate the family will need?
9. What are the insurance sources for the family?
10. What cultural factors need to be considered in working with this family?

One major advantage to meeting in the family home is seeing the everyday family environment. Family members are likely to feel more relaxed in their home, thereby demonstrating typical family interactions. Meeting with a family in their home

emphasizes that the whole family and not one family member is the client. This approach allows the whole family to participate in the identification and resolution of the health problem. Conducting the interview in the home may increase the probability of having more family members present. There are two important disadvantages of meeting in the family home: (1) the family home may be the only sanctuary or safe place for the family or its members to be away from the scrutiny of others, and (2) meeting with a family on their ground requires the nurse to be highly skilled in communication by setting limits and guiding the interaction.

Conducting the family appointment in the office or clinic allows easier access to other health care providers for consultation. An advantage of using the clinic may be that the family situation is so intense that a more formal, less personal setting may be necessary for the family to begin discussion of emotionally charged issues. A disadvantage of not seeing the everyday family environment is that it may reinforce a possible culture gap between the family and the nurse.

Making an Appointment with the Family

After the decision is made regarding where to meet the family, the nurse contacts the family. It is important to remember that the family gathers information about the nurse from this initial phone call to arrange a meeting, so the nurse should be confident and organized. After the introduction, the nurse concisely states the reason for requesting the family visit and encourages all family members to attend the meeting. The [How To Make an Appointment with the Family](#) box reviews steps for making an appointment with the family. Determine if you need an interpreter with you or if you need to arrange to have one available by phone during the visit. Several possible times for the appointment can be offered, including late afternoon or evening, which allows the family to select the most convenient time for all members to be present. It is important to remember that families ultimately retain control of the situation and they do not have to let the nurse enter their home (Smith, 2009).

HOW TO Make an Appointment with the Family

Data collection starts immediately upon referral to the nurse. The following are suggestions that will make the process of arranging a meeting with the family easier:

1. Remember that the assessment is reciprocal and the family will be making judgments about you when you call to make the appointment.
2. Introduce yourself and the purpose for the contact.
3. Do not apologize for contacting the family. Be clear, direct, and specific about the need for an appointment.
4. Arrange a time that is convenient for all parties and allows the most family members to be present.
5. If appropriate, ask if an interpreter will be needed during the meeting.
6. Confirm place, time, date, and directions.

Planning for Your Own Safety

It is critical to plan for your own safety when you make a home visit. Learn about the neighborhood you will be visiting,

anticipate needs you may have, and determine if it is safe for you to make the home visit alone or if you need to arrange to have a security person with you during the visit. Always have your cell phone fully charged and readily available. In addition, the following strategies will help to ensure your own safety when you visit families in their homes (Smith, 2009, p. 316):

1. Leave a schedule at your office.
2. Plan the visit during safe times of day.
3. Dress appropriately, bringing little jewelry or money.
4. Avoid secluded places if you are by yourself.
5. Obtain an escort; take a coworker or neighborhood volunteer.
6. Sit between the client and the exit.
7. If you feel unsafe, do not visit or leave immediately.
8. Check in with your work at the end of the day.

Interviewing the Family: Defining the Problem

One of the underlying central tenets of family nursing is to build a trusting family–nurse relationship. Working with families requires nurses to use therapeutic communication efficiently and skillfully by moving between informal conversation and skilled interviewing strategies. Prepare your family questions before your interview based on the best family theory given what is known about the family situation.

Although it seems commonplace, it is important for nurses to introduce themselves to the family and to initiate conversation with each member present. Spending some initial time on informal conversation helps put the family at ease, allows them time to assess the person/nurse, and disperses some of the tension surrounding the visit (Tabacco, 2010). Involving each family member in the conversation, including children, elderly, or any disabled family member, demonstrates respect and caring and sends the message that the purpose of the visit is to help the whole family and not just the individual family member. Too much disclosure during the early contacts between the family and nurse may scare the family away. Slow down the process and take time to build trust.

Shifting the conversation into a more formal interview can be accomplished by asking the family to share their story about the current situation. If the nurse focuses only on the medical aspect or illness story, much valuable information and the priority issue confronting the family may be missed in the data collection. The purpose of the interview is to gather information and help the family focus on their problem and determine solutions. The following specific therapeutic questions have been found to provide important family information (Leahey and Svavarsdottir, 2009, p. 449):

- What is the greatest challenge facing your family now?
- Who in the family do you think the illness has the most impact on?
- Who is suffering the most?
- What has been most and least helpful to you in similar situations?
- If there is one question you could have answered now, what would that be?
- How can we best help you and your family?
- What are your needs/wishes for assistance now?

BOX 27-3 Family Interview Questions

- What do you believe is the most important or pressing issue right now?
- What have you done to improve the situation?
- Share with me your primary goal in the immediate situation.
- What are the main problems you are having related to ____?
- What is causing you the most stress?
- How has this stress affected you and the members of your family?
- How are the everyday needs of the family getting done (e.g., cooking, shopping, cleaning, laundry, transportation, sleeping)?
- How well is your family managing this stress?
- What results or outcomes do you hope for?
- What do you feel you need to help solve this situation?
- What can your family do for you?
- Who do we need to involve in this situation?
- What information do you need to know?
- Walk me through a typical 24-hour day in your home.
- During times of need, where can you go for support and resources?
- What do you think would help me better understand what you are experiencing?
- How does your family anticipate caring for ____?
- How does this situation affect you financially?
- Where, how, and from whom do you receive your support, inspiration, and energy to maintain the responsibilities required of you?
- What has been the biggest surprise to you about all of this?
- How do you think your family roles and routines are going to change in this situation?
- How have you and your family prepared to provide care for ____?
- What are your family plans for when you have to return to work?
- What does your family do to feel relief or take a break?
- What are some specific changes that you and your family members have had to make?
- What do you fear the most about ____?

Box 27-3 lists a variety of additional interview questions that will help uncover the family story. Encourage several members of the family to provide input into the discussion. One strategy is to ask the same question of several different family members. It is critical for the nurse to not take sides in the family discussion and to focus on guiding them in their decision making. In addition to the family story, the nurse will likely need to ask specific assessment questions about the family member who is in need of services.

Family Assessment Instruments

One quick way for nurses to gather information from a family is to use reliable and valid short assessment instruments that are specifically focused on the relevant family situation. Well over 1000 different family assessment instruments exist (Touliatos, Perlmutter, and Straus, 2001); therefore, it is critical that the following criteria be used to help determine the most appropriate assessment instrument (Kaakinen and Tabacco, 2015):

- Written in uncomplicated language at a fifth-grade level
 - Only takes 10 to 15 minutes to complete
 - Relatively easy and quick to score
 - Offers valid data on which to base decisions
 - Sensitive to gender, race, social class, and ethnic background
- Families should always be asked their permission to use an assessment instrument and be informed of how the

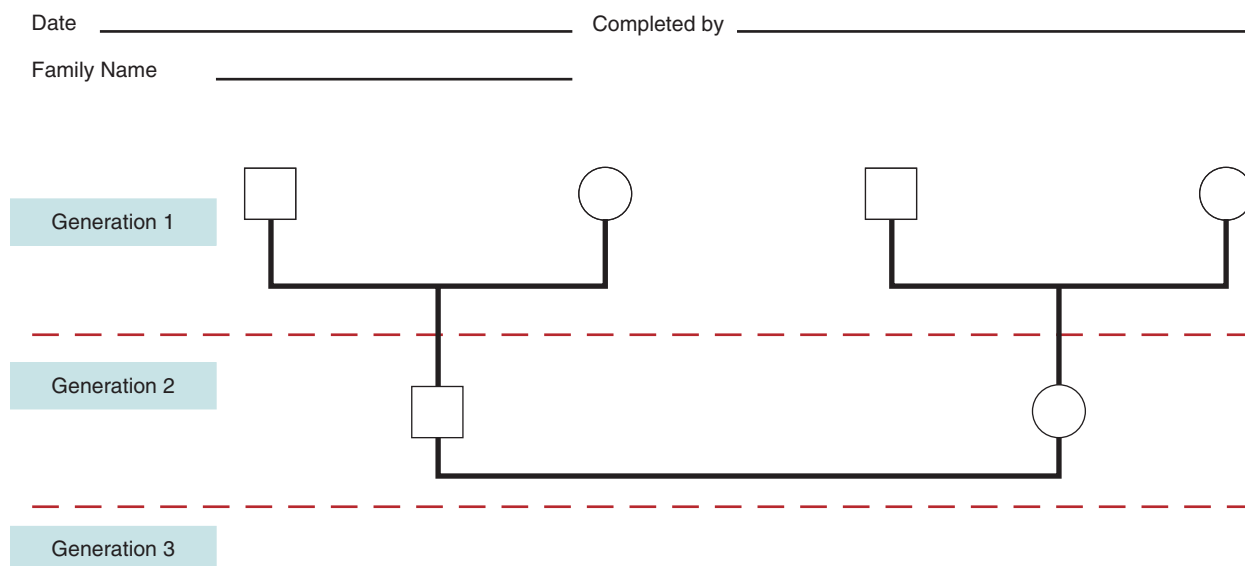

FIG 27-6 Genogram form. (Modified from McGoldrick M, Gerson R, Schellenburger S: *Genograms: Assessment and Intervention*, ed 2, New York, 1999, Norton.)

information will be used by the nurse in helping to plan their care. Nurses should review the results or interpretation of the information with the family.

Genograms and ecomaps are both assessment instruments that actively engage the family in their care. In addition, they both provide visual diagrams of the current family story and offer ideas about the plan of action, solutions, and resources (Kaakinen and Tabacco, 2015; Harrison and Neufeld, 2009). The genogram and ecomap are essential components of any family assessment, and they should be used concurrently with any other specific assessment instruments used in the interview.

Genogram

The **genogram** displays pertinent family information in a family tree format that shows family members and their relationships over at least three generations (McGoldrick, Gerson, and Petry, 2008). The genogram shows family history and patterns of health-related information, which is a rich source of information for planning interventions. The identified client and his or her family are highlighted on the genogram. Genograms enhance nurses' abilities to make clinical judgments and connect them to family structure and history.

Nurses have various resources available to them to assist families with the collection of family history. In 2002, the Office of Public Health Genomics (OPHG) through the Centers for Disease and Prevention (CDC) started the Family History Public Health Initiative to increase awareness of family history as an important risk factor for common chronic diseases such as cancer, heart disease, and diabetes, and to promote its use in programs aimed at reducing the burden of these diseases in the U.S. population (CDC, 2013a). The initiative has four main activities (For more information check out their website: <http://www.cdc.gov/genomics/famhistory/famhist.htm>):

- Conducting research to define, measure, and assess family history in populations and individuals

BOX 27-4 Outline For a Genogram Interview

For each person on the genogram, the nurse should determine which of the following pieces of information to include on the genogram. The information should be relevant to the issues the family is facing.

- First name
- Age
- Date of birth
- Occupation
- Health problems
- Cause of death
- Dates of marriages, divorces, separations, commitments, cohabitations, and remarriages
- Education level
- Ethnic or religious background

Modified from: McGoldrick M, Gerson R, Petry SS: *Genograms: assessment and interventions*, ed 3, New York, 2008, W.W. Norton.

- Developing and evaluating tools for collecting family history
- Evaluating whether family history-based strategies work
- Promoting evidence-based applications of family history to health professionals and the public

The diagramming of the genogram must adhere to a specific format to ensure that all parties understand the information. A form that can be used for developing genograms is depicted in Figure 27-6, and the symbols most often used in a genogram are shown in Figure 27-7.

An outline for gathering information during the genogram interview is presented in Box 27-4, and genogram interpretive categories are found in Box 27-5. The health history for all family members (morbidity, mortality, onset of illness) is important information for family nurses and can be the focus of analysis of the family genogram. The more information that

Symbols to describe basic family membership and structure.

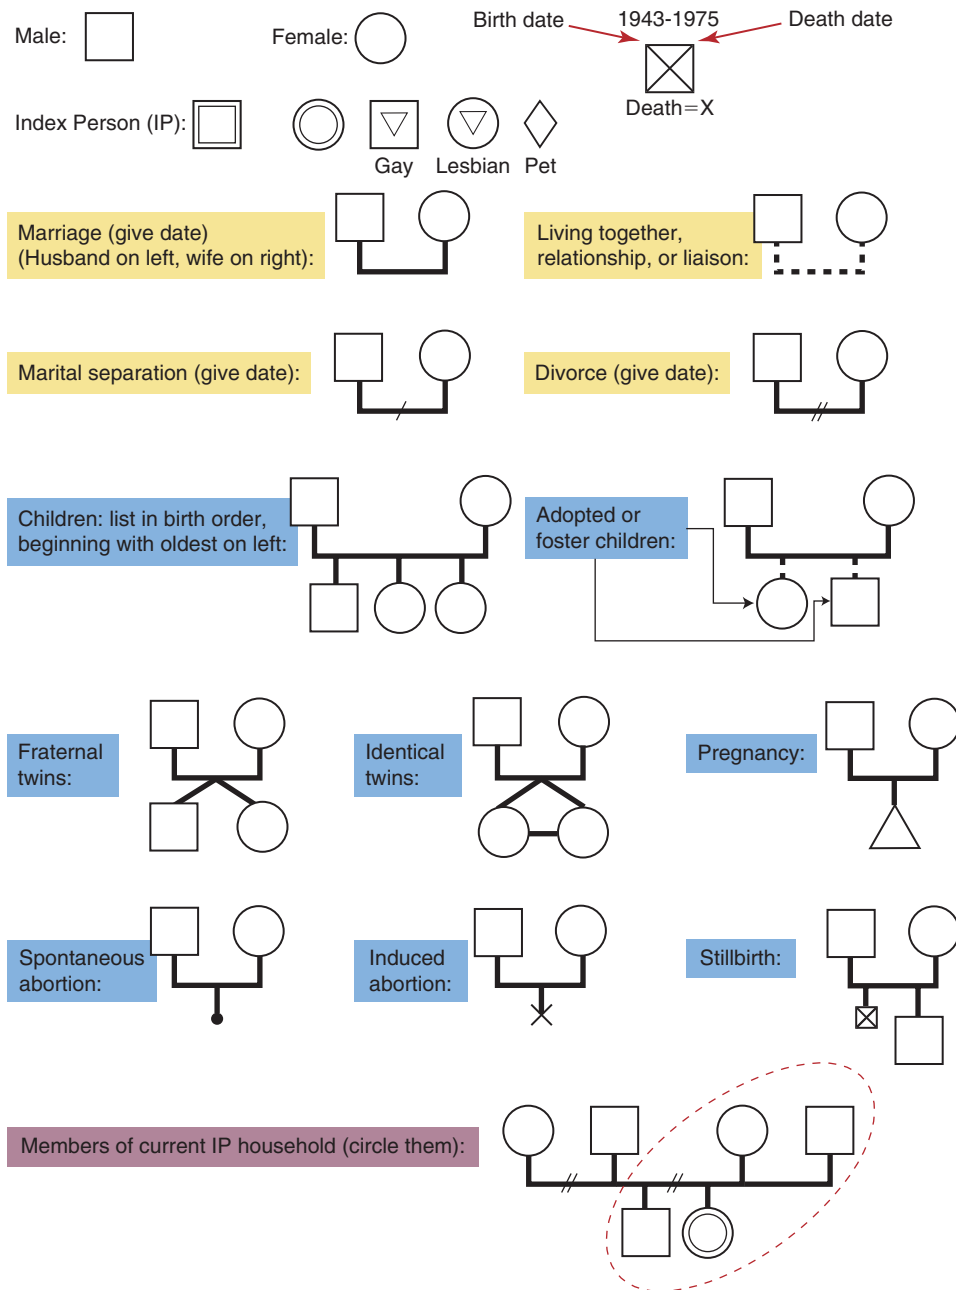

FIG 27-7 Genogram symbols. (Modified from McGoldrick M, Shellenberger S, Petry SS: *Genograms: Assessment and Intervention*, ed 3, New York, 2008, Norton.)

BOX 27-5 Genogram Interpretive Categories

The following areas are important to note in the family genogram:

- Family structure: nuclear, blended, single-parent household, gay/lesbian relationship, cohabitation, divorces, and separations
- Sibling subsystem group: birth order, sex, distance between ages of children
- Patterns of repetition: patterns across the generations related to family structure, behaviors, health problems, relationships, violence, abuse, poverty
- Life events: repeated similar events across generations, such as transitions, traumas

can be added to the family genogram, the more the family and nurse understand the family situation. Most families are cooperative and interested in completing the genogram, which does not have to be completed in one sitting. The genogram becomes a part of the ongoing health care record.

Ecomap

The **ecomap** is a visual diagram of the family unit in relation to other units or subsystems in the community. The ecomap serves as a tool to organize and present factual information and thus allows the nurse to have a more holistic and integrated perception of the family situation. The ecomap shows the nature of the relationships among family members, and between family members and the community; it is an overview of the family, picturing both the important nurturing and the important stress-producing connections between the family and its environment. The nurse starts with a blank ecomap, which consists of a large circle with smaller circles around it (Figure 27-8). The identified client and his or her family are placed in the center of the large circle. The outer smaller circles around the family unit represent significant people, agencies, or organizations in the family's environment that interact with the family members (Kaakinen and Tabacco, 2015). The nature and quality of the relationships and the direction of energy flow

between the family members and the subsystems are shown by different connecting lines.

The ecomap serves as a tool to organize and present information, allowing the nurse and family to have a more holistic and integrated perception of the current situation. Not only does it portray the present situation, but it can also be used to set goals for the future by encouraging connection and exchange with individuals and agencies in the community. A more detailed discussion of ecomapping can be found in Kaakinen and Tabacco (2015) and McGoldrick et al (2008).

Family Health Literacy

Family health literacy is necessary for the family or its members to be actively involved in their care. Family health literacy includes the ability to understand information in order to make appropriate health care decisions, accurately carry out plans of action, and successfully advocate for the family in the complex health care systems in which they receive care (Kaakinen and Tabacco, 2015). Those with poor health literacy skills have been strongly associated with lower health outcomes (Berkman et al, 2011; Wolff et al, 2009).

Functional health literacy includes the ability to read and understand numbers in order to use this health information to make informed decisions (DeWalt, Boone, and Pignone, 2007) and to understand the consequences when instructions or plans of action are not followed (Speros, 2005).

Nurses can assess for health literacy in conversations and when completing genograms and ecomaps. Rather than spend time determining the extent of the health literacy in a family, it is most important that nurses use the following techniques when writing out plans of care, listing directions, discussing medication management, or writing telephone numbers (Kaakinen and Tabacco, 2015; Peters et al, 2007).

- Use black ink on white paper
- Use short sentences
- Use bullets no longer than seven items
- Information should be written at the fifth-grade level
- Remove all extra words
- Print in upper- and lower-case letters
- If using a computer, use 14-point font with high contrasting Arial or sans serif print
- Have plenty of white space

Families retain more information when nurses use a variety of communication methods (Bass, 2005), including both visual materials and visual language (Peters et al, 2007). Families need direct, clear information to assist in their decision making and carrying out the plans of action (Salmond, 2008).

Designing Family Interventions

Nurses will be challenged to help families identify the primary problem confronting them and to step aside and accept the family priority as they work in partnership with the family to keep their interventions simple, specific, timely, and realistic. It is essential that the family participate in determining the primary need and in designing interventions.

It is important to view the family with an open approach, since the central issue identified by the referral source may not

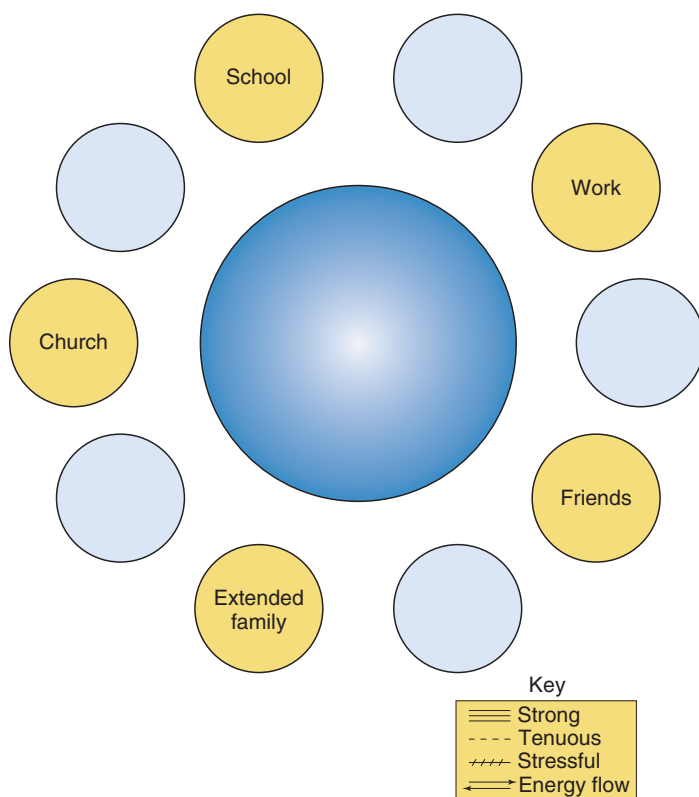

FIG 27-8 Ecomap form. (Modified from Kaakinen JR, Hanson SMH: Family nursing assessment and intervention. In Hanson SMH, Gedaly-Duff V, Kaakinen JR, editors: *Family Health Care Nursing: Theory, Practice and Research*, ed 3, Philadelphia, 2005, FA Davis.)

be the actual problem the family is experiencing. See the following case study:

The Raggs family is referred to the home health clinic by a physician for medication management. Sam, the 73-year-old husband, has been a Type 2 diabetic for 13 years and now requires insulin to manage his condition. He is being discharged from the hospital. The potential area of concern that prompted the referral was the administration of insulin. After the initial meeting with the family, the primary problem the family uncovers is really not the administration of the medication, but managing his nutrition. The inference of the referral source was that the family knew how to manage the dietary aspects of diabetes because Sam had Type 2 diabetes for 13 years.

If the primary family issue is not accurately identified, the family and the nurse will collect data, design interventions, and implement plans of care that do not meet the most pressing family needs. The importance of identifying the family issue of concern and accurately making the family nursing diagnosis is demonstrated by comparing the following two scenarios:

Scenario #1: The hypothesized central issue for the Raggs family was identified by the referral source: Is insulin being administered correctly? Based on this question from the referral source, the nurse asked only for information pertaining to this specific problem. The nurse asked questions that elicited information about (1) concerns of giving injections, (2) difficulty drawing up the accurate amount of insulin, and (3) the storage of insulin. The nurse focused the interventions on (1) the psychomotor skills of family members necessary to give the insulin injection, (2) the correct amount of insulin to give according to blood glucose level, and (3) the correct storage and handling of the medication and the equipment. By not looking at the whole family, the care was based on the nurse's perception of the problem confronting the family.

Scenario #2: The central question asked by a nurse who knows how to integrate family theory into practice was, "What is the best way to ensure that the Raggs family understands how to manage his Type 2 diabetes?" By asking the family to share their story of the situation together, they determined that the primary issue was not medication administration but rather a lack of family knowledge related to health care management of a family member who now requires the addition of insulin to his management plan.

Asking broader-based questions uncovers the whole picture of the family dealing with this specific health concern and directs a more comprehensive holistic data-collection process. More evidence was collected in this case scenario because more options for possible interventions were considered concurrently. Areas of data collection based on the whole family story were (1) administration of medication, (2) nutritional management, (3) blood glucose monitoring, (4) activity/exercise, (5) coping with a changed management plan, and (6) knowledge of pathophysiology of diabetes. Out of all these issues,

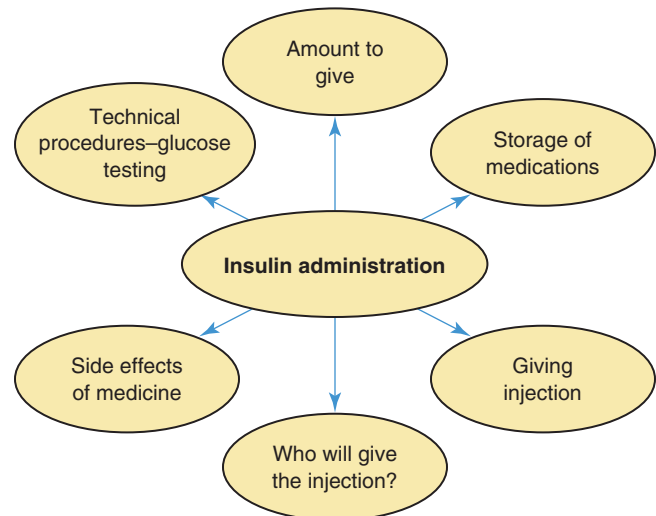

FIG 27-9 Scenario 1: Nurse-led linear problem-solving identification process.

the nurse worked with the family to help them identify that their major concern centered on nutritional management of hypoglycemia, which ultimately affects the administration of medication.

The major difference between the two scenarios presented here was the way in which the nurse framed questions while listening to the family story. In the first scenario the nurse asked questions that allowed for consideration of only one aspect of family health. This type of step-by-step nurse-lead linear problem-solving process is tedious and time consuming, and will likely cause errors in the identification of the most pressing family concern (Figure 27-9). In the second scenario, the nurse asked questions that allowed for critical thinking about the family view of their challenges (Figure 27-10). The nurse gathered information from the referral source, conducted an assessment of the impact of the new management plan on the whole family, and collaboratively the nurse and family identified the critical family issue that had a more far-reaching effect on the health of the whole family.

The nurse works with the family to help them design realistic steps or a plan of action based on their ability to successfully adapt to the health issue given the strengths of the family. Working with the family, the following action plan approach helps focus the family on things they can immediately do to help address the problem:

1. We need the following type of help.
2. We need the following information.
3. We need the following supplies.
4. We need to involve or tell the following people.
5. To make our family action plan happen we need to ... (list 5 things in the order they need to have happen).

Using knowledge and evidence-based practice, the nurse guides the family in outlining ways to prevent a potential problem, minimize the problem, stabilize the problem, or help the family recognize it as a deteriorating problem. The following scenario shows how nurses work with families to

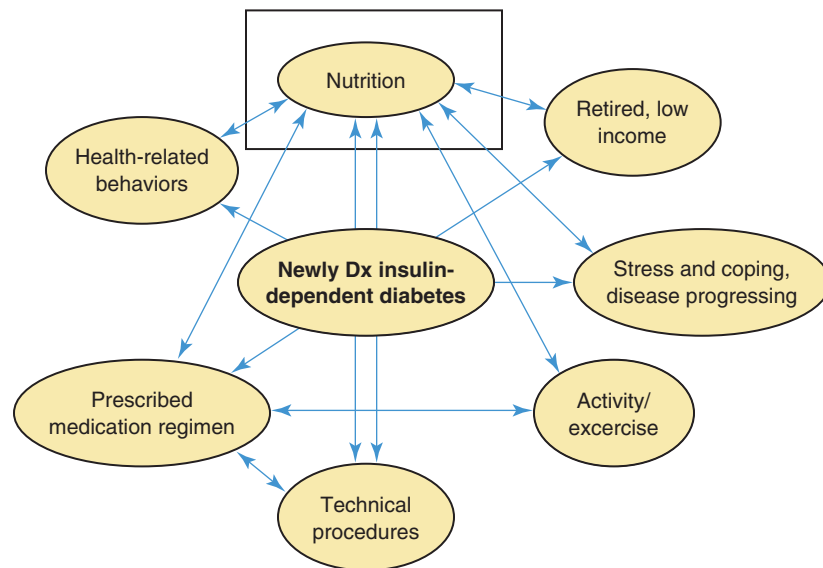

FIG 27-10 Scenario 2: An example of complex relationships between issues affecting the whole family because of the new diagnosis.

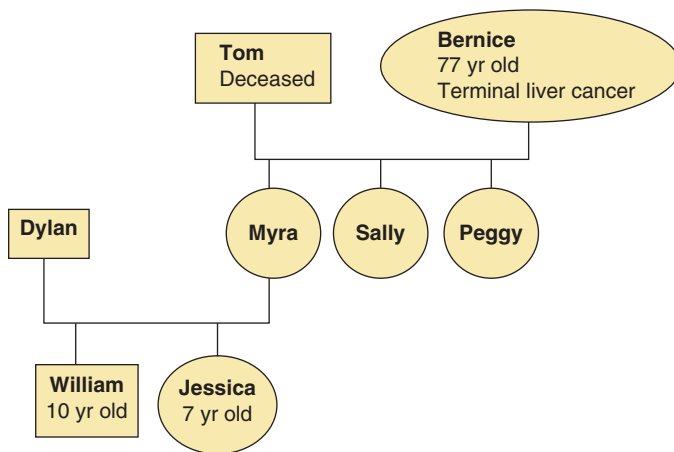

FIG 27-11 The Brush family genogram.

determine their strengths, identify the problem, and design interventions.

Scenario #3: The home hospice nurse has been working with the Brush family for 3 weeks. The Brush family consists of the members outlined in Figure 27-11.

Family story: Beatrice was diagnosed with terminal liver cancer 4 weeks ago. The Brush family—Bernice, Dylan, Myra, William and Jessica—agreed that Bernice should live with them and be cared for until her death in their home. Bernice has other children who live in the same city. The hospice nurse in collaboration with the Brush family identified that the primary problem is that Myra is experiencing role stress, strain, and overload in her new role as the family caregiver. Myra showed her role conflict by stating, “Sometimes I do not know who I am—daughter, nurse, mother, or wife.” As Myra took a family leave from

her job to stay home to care for her mother, some members of the family were surprised by her statement as they did not realize she was so overwhelmed. The family worked with the nurse to find ways to minimize her role strain by spreading the caregiver role among the extended family members.

By understanding the family systems theory, the nurse knows that what affects one member of the family affects all members of the family. One of the strengths this family has is the shared belief that caring for the dying grandmother in their home is the “right” ethical choice for them. The nurse brings knowledge and evidence into this situation because he or she knows that the disruption to the family and their expected roles will be short term because the grandmother will probably not live for more than 4 months. However, experience with families also supports this nurse’s knowledge that Myra’s role conflict may likely increase as her caregiver role becomes more intense as her mother’s health declines. By conducting a family genogram, another strength of this family is uncovered: it has a strong internal and external support system. The family determines that the extended family is willing to be involved in the care of Bernice. The intervention is aimed at mobilizing resources to minimize Myra’s role conflict. Using the simple action plan outlined previously, the family determined the following:

1. We need the following type of help:

- Other family members to come every day to relieve Myra
- Every other weekend, one of Bernice’s other daughters will provide care through the night to relieve Myra
- Jobs in the family will be shared to relieve Myra. Dylan will do the shopping, William will clear the table and put dishes in the dishwasher, and Jessica will help fold the clothes and put them away. William and Jessica agreed to help by spending some time each evening with Bernice, such as reading to her or watching TV with her.

2. We need the following information:
 - How to call the hospice nurse when Bernice gets worse or they need immediate help
 - A list of who to call when an emergency occurs
 - A list and numbers of Bernice's health care team
3. We need the following supplies: None at this time
4. We need to involve or tell the following people: Sally and Peggy
5. To make our family action plan happen we need to ... (list 5 things in the order they need to happen):
 - Invite Sally and Peggy over for a family meeting, and include the home hospice nurse.
 - Make a list of what weekends Sally and Peggy will help with Bernice.
 - Make a calendar with whose turn it is to spend time with Bernice every evening, which will relieve Myra of the care.

Based on the family story just described, as viewed through the frame of family systems theory, the following interventions were implemented: (1) assisting the family in the role negotiation of tasks and who performs them, (2) educating family members so they can safely care for Bernice now and when she enters the stage of active dying, and (3) determining what additional resources the family needs. After a plan is put into place, it needs to be evaluated periodically.

Evaluation of the Plan

In evaluating the outcome, nurses engage in critical thinking to determine if the plan is working, if it is working fast enough to address the problem, if it is addressing only part of the problem, or if the plan needs to be revised based on changes. When the plan is not working, the nurse and the family work together to determine the barriers interfering with the plan or figure out if something changed in the family story. Family apathy and indecision are known to be barriers in family nursing (Friedman, Bowden, and Jones, 2003). Friedman et al (2003) also identified the following nurse-related barriers that can affect achievement of the outcome: (1) nurse-imposed ideas, (2) negative labeling, (3) overlooking family strengths, and (4) neglecting cultural or gender implications. Family apathy may occur because of value differences between the nurse and the family, because the family is overcome with a sense of hopelessness, because the family views the problems as too overwhelming, or because family members have a fear of failure. Additional factors to be considered are that the family may be indecisive because they cannot determine which course of action is better (because they have an unexpressed fear or concern) or because they have a pattern of making decisions only when faced with a crisis.

An important part of the evaluation step in working with families is the decision to terminate the relationship between the nurse and the family. Termination is phasing out the nurse from family involvement. When termination is built into the interventions the family benefits from a smooth transition process. The family is given credit for the outcomes of the interventions that they helped design. Strategies often used in the termination component are decreasing contact with the

nurse, extending invitations to the family for follow-up, and making referrals when appropriate. The termination should include a summative evaluation meeting, in which the nurse and family put a formal closure to their relationship.

When termination with a family occurs suddenly, it is important for the nurse to determine the forces bringing about the closure. The family may be initiating the termination prematurely, which requires a renegotiating process. The insurance or agency requirements may be placing a financial constraint on the amount of time the nurse can work with a family. Regardless of how termination comes about, it is important to recognize the transition from depending on the family nurse on some level to having no dependence. Strategies that help with the termination are to (1) increase time between the nurse's visits, (2) develop a plan for the transition, (3) assess the family support systems, (4) make referrals to other resources, and (5) provide a written summary to the family.

SOCIAL AND FAMILY POLICY CHALLENGES

National, state, and local **social and family policies** provide various challenges to nurses' practices. As professionals, public health nurses are accountable for participating in the three core public health functions: assessment, policy development, and assurance.

National **family policy** is government actions that have a direct or indirect effect on families. The range of social policy decisions that affect families is vast, such as health care access and coverage, low-income housing, social security, welfare, food stamps, pension plans, affirmative action, and education. Although all government policies affect families in both negative and positive ways, the United States has little overall explicit family policy (Gebbie and Gebbie, 2005). Most government policy indirectly affects families. The Family Medical Leave legislation passed in 1993 by the U.S. Congress is an example of a type of family policy that has been positive for families. A family member may take a defined amount of leave for family events (e.g., births, deaths) without fear of losing his or her job. The Affordable Health Care Act (ACA) of 2010 is an example of a national policy that has effects on family policy.

Nurses must become familiar with some of the key features of the ACA reforms affecting individuals and their families, which include the following (check out: www.HHS.gov/healthcare):

- Health plans can no longer limit or deny benefits to children under the age of 19 due to a pre-existing condition.
- Young adults under the age of 26 may be eligible to be covered under their parent's health plan.
- Insurance companies can no longer arbitrarily cancel a person's health insurance coverage.
- An individual's right to appeal is guaranteed.
- Health plans are prohibited from putting a lifetime dollar limit on most benefits individuals receive.
- Insurance companies must now publicly justify any unreasonable rate hikes.
- Requires insurance companies to spend premium dollars primarily on health care. It does this by enforcing a policy

called the “80/20 rule” to hold insurance companies accountable.

- Insurance companies are required to cover certain preventive services at no cost to the individual. There are specific covered preventive services for adults, women, and children.
- Ensures that individuals can seek emergency care at a hospital outside their plan’s network without prior approval from their health plan.

The Congressional Budget Office (2010) estimates that by 2016, some 24 million people will get insurance through the insurance exchanges set up by states, while another 12 million will continue to get individual coverage outside of them.

Many programs that do exist for families, such as Social Security and Temporary Assistance to Needy Families, are not available to all families. State assistance for families varies by state.

The challenges of social policy for families are numerous. Given the ongoing debate as to what constitutes a family, social policies may specify a definition that is not consistent with the family’s own definition. Examples include same-sex partnerships and/or marriage, legal definition of parents, reproductive and fertility issues (e.g., a surrogate mother decides she wants to keep the baby), or issues involving care of older adults (e.g., a niece wants to institutionalize an older aunt with dementia because her children are not available). Besides how families define themselves, governments define health care services that affect families.

Teen pregnancy prevention is a monitored health status throughout the United States and a good example of the challenges of family health policy. In some states, any child who is sexually active may have access to reproductive health services. This is a family policy to which some families object, yet the sexually active teenager is protected by a number of laws, both state and federal. The teenager who requests confidential services is protected by Title X and HIPAA federal regulations given the state law allowing access to services. Providers can encourage the teen to talk with his or her parents, but ultimately it is the teen’s decision. Nurses need to be knowledgeable about these policies since they participate in carrying out family policy and have a responsibility to inform state policy regarding the services they provide.

Nurses participate in enforcing laws and regulations that affect the family such as state immunization laws. Most states have some school immunization laws that exclude children from school who are not vaccinated. If the child does not have that state’s particular set of immunizations and the parents do not want the child vaccinated, two sets of laws are in conflict: the immunization laws and the school attendance laws. The state could provide a mechanism for a waiver, or the child could be excluded from school, thus making home schooling the only option.

Health care insurance is a social and family policy issue. Medicare and Medicaid, enacted in 1965, provide some health care for the elderly and low-income families. Today Medicare covers nearly 42 million beneficiaries, or one in seven U.S. citizens (National Bureau of Economic Research, 2013). Insuring

the elderly has proven to be beneficial, yet is fraught with numerous problems. Both living wills and durable power of attorney for health care, legal contracts that designate a person to make health care decisions when the individual is incapacitated, are more commonplace today than in the past. However, without these legal instruments, families are faced with making end-of-life decisions for their loved ones. Although Medicare and Medicaid provide health care to many, a significant population is still uninsured. Emergency departments continue to be the only access to health care for the uninsured and a convenient and accessible source of health care for many without access to a health care provider (Marco et al, 2012)

The H1N1 pandemic was an excellent example of mobilizing community partnerships to solve health problems. In one county health department, space for storing vaccines was insufficient in the county health clinics, so arrangements were made with the law enforcement departments to store vaccines in their secure evidence refrigerators. Other examples of partnering included collaboration with Health and Human Services departments and homeless programs to get at-risk populations and the homeless vaccinated. County health departments and pediatricians worked together to get members of families who had infants under 6 months of age vaccinated, since these infants were too young to receive the H1N1 vaccine.

These are only a few examples of social and family policy in which nurses are involved. Population-focused nurses need to be involved in making policy at the local, state, and national level that affects families. Using the core public health functions as a framework allows the population-focused nurse to view the broad spectrum of activities that improve the lives of communities, families, and the individuals within those families.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Client-Centered Care

Recognize the client or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for client’s preferences, values, and needs.

Important aspects of client-centered care include:

- **Knowledge:** Describe strategies to empower clients or families in all aspects of the health care process
- **Skills:** Assess level of client’s decisional conflict and provide access to resources
- **Attitudes:** Value active partnership with clients or designated surrogates in planning, implementation, and evaluation of care

Client-Centered Care Question

Describe how a family assessment is different from an individual client assessment. Beyond immediate family members, who might be included in a client’s “family”? Think about the difference between being an advocate for an individual (the client) and an advocate for a family. What different skills are needed?

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

PRACTICE APPLICATION

One of the most notable changes in the twenty-first century is women and mothers working outside of the home. The difference can be seen in the following statistic: In 1960 only 19% of married mothers with children under 6 years of age worked outside the home (U.S. Census Bureau, 2008) compared with 64.8% in 2012 (Bureau of Labor Statistics, 2013).

KEY POINTS

- Families are the context within which health care decisions are made.
- Nurses are responsible for assisting families in meeting health care needs.
- Family nursing is practiced in all settings.
- Family nursing is a specialty area that has a strong theoretical base and is more than just common sense.
- Community health nurses must integrate both family theory and public health theory in their practice.
- There are a variety of family definitions, such as a group of two or more, a unique social group, and two or more persons joined together by emotional bonds.
- The five functions performed by families are economic, reproduction, socialization, affective, and health care.
- Family structure refers to the characteristics, sex, age, and number of the individual members who make up the family unit.
- Family demographics is the study of structures of families and households as well as events that alter the family, such as marriage, divorce, births, and cohabitation. Demographic trends affect the family.
- Family health is difficult to define, but it includes the biological, psychological, sociological, cultural, and spiritual factors of the family system.
- There are four approaches to viewing families: family as context, family as client, family as a system, and family as a component of society.
- Systems theory describes families as a unit of the whole composed of members whose interactional patterns are the

- A. In what ways does this influence family socialization and affective functions?
- B. In what ways does this situation affect the family health care function?
- C. How does this impact family nursing?

Answers can be found on the Evolve site.

focus of attention, in that what affects one member affects all members.

- Family developmental and life cycle theory emphasizes how families change over time and focuses on interactions and relationships among family members.
- Bioecological family theory helps community/public health nurses identify the stressors and potential resources that can affect family adaptation.
- One of the underlying central tenets of family nursing is to build a trusting family–nurse relationship.
- Working with families requires nurses to use therapeutic communication efficiently and skillfully by moving between informal conversation and skilled interviewing strategies.
- Nurses should ask clients whom they consider to be their family and then include those members in the health care plan. Genograms and ecomaps are essential components of any family assessment.
- Families want to be involved in identifying their major problem and designing solutions that are family focused.
- It is important for the nurse to recognize that the family has the right to make its own health decisions.
- The goal of family nursing is to focus care, interventions, and services to optimize the self-care capabilities of families and to achieve the best possible outcomes.
- Nurses working with families must understand the effects of health care reforms at the local, state, and federal levels as all government actions affect the family.

CLINICAL DECISION MAKING ACTIVITIES

1. Select six or more health professionals and ask them to define family. Analyze the responses for common points and differences. Write your own definition of family.
2. Characterize the different family structures and household arrangements represented in your community. This information may be available from various sources, such as the health department, schools, other social and welfare agencies, and census data. Be specific.
3. Draw your own family genogram and ecomap. Discuss how they are used in family nursing.
4. Discuss the role of nursing related to family policy. Be specific about issues related to family culture.
5. Break into small groups and have students discuss the Brush family presented in the chapter in terms of the three family social science theories. What questions would they ask the

family from the different theoretical perspectives? Examine different situations when one theory might be more appropriate to use than another.

6. How might you go about obtaining services for a Hispanic woman who tests positive for diabetes who is uninsured or underinsured?
7. Break into small groups to discuss how you have found judging or reacting to family structure situations that are different from those you personally bring to practice. What helps you try to reframe this situation in order to practice family nursing?
8. You are working with a lesbian family with three children. What barriers or problems do you anticipate with social policies while trying to access resources?

Family Health Risks

Debra Gay Anderson, PhD, PHCNS-BC

Dr. Debra Gay Anderson is a faculty member at the University of Kentucky's College of Nursing. She is certified as a clinical specialist in public/community health nursing and has provided health care for the homeless and other vulnerable populations. Dr. Anderson has taught public health, epidemiology, leadership, and research courses at both the graduate and undergraduate levels. The focus of her program of research, publications, and presentations is vulnerable populations, primarily women who have experienced homelessness, domestic violence or workplace violence. Dr. Anderson completed her doctoral studies and a family nursing postdoctoral fellowship at Oregon Health Sciences University in Portland, Oregon. Dr. Anderson is an active member of the American Public Health Association (APHA) and has served in various leadership capacities, including Chair of the Public Health Nursing Section of APHA.

Hartley Feld, RN, MSN, PHCNS-BC

Hartley Feld received her Masters of Science in Nursing, Community and Public Health nursing specialty, in 2006 from the University of Kentucky. She is board certified as a Public Health Clinical Nurse Specialist. Ms. Feld is a lecturer and clinical instructor in Community and Public Health Nursing. Her clinical interests include global health, health care economics, determinants of health, and vulnerable populations.

Mollie Aleshire, DNP, FNP-BC, PPCNP-BC

Dr. Mollie E. Aleshire is a faculty member at the University of Kentucky College of Nursing and is certified as a family nurse practitioner and pediatric primary care nurse practitioner. Dr. Aleshire has taught interprofessional health systems, health promotion, and primary care prevention in both undergraduate and graduate courses. She received a Master of Science in Nursing and a Doctor of Nursing Practice from the University of Kentucky. Dr. Aleshire's clinical and scholarship interests include prevention strategies in primary care settings and health issues of young women and female adolescents.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Evaluate the various approaches to defining and conceptualizing family health.
2. Analyze the major risks to family health.
3. Analyze the interrelationships among individual health, family health, and community health.
4. Explain the relevance of knowledge about family structures, roles, and functions for family-focused nursing in the community.
5. Discuss the implications of policy and policy decisions, at all governmental levels, on families.
6. Explain the application of the nursing process (assessment, planning, implementation, evaluation) to reducing family health risks and promoting family health.

 Vulnerable Populations: LGBTQ Families at Risk

What is a “family?” Is there one definition that fits all families? Is there a new normal? Was there ever a true “normal” family? In 2011, Lisa Belkin wrote an opinion piece for *The New York Times*, “A ‘Normal’ Family.” In her article, she discussed seven trends identified by the Pew Research Center. The trends were “more unmarried couples raising children; more gay and lesbian couples raising children; more single women having children without a male partner to help raise them; more people living together without getting married; more mothers of young children working outside the home; more people of different races marrying each other; and more women not ever having children” (Belkin, 2011).

Although Belkin is referring to current family incarnations, history demonstrates that the makeup of families is in constant flux, depending on the current socioeconomic pragmatism. We are reminded of Abraham Lincoln’s father leaving his two children following the death of their mother for the purpose of bringing back a new mother. Was that a “normal” family? Sarah Bush Johnston Lincoln, with three children, married Thomas Lincoln, following the deaths of both of their spouses and, in addition to their combined five children, raised a cousin of Nancy Hank Lincoln. Today, we might call that a “blended” family. We refer to Lincoln’s family simply to demonstrate that the “traditional” family was never the “normal” family. As family

makeup transitions, those families are often the ones that are the most vulnerable because they do not conform to traditional societal expectations.

Regardless of makeup, the family as a client unit is basic to the practice of population-centered nursing, and nurses are responsible for promoting healthy families in society. As such, families are described as a unique population in public health. The purpose of this chapter is to make the reader aware of influences, both individual and societal, that place families at risk for poor health outcomes, and to discuss how positive outcomes for diverse families can be accomplished through appropriate nursing interventions.

The expanding definition of the family unit presents today’s nurse with an array of challenges and opportunities to address the health needs of families. First, it is essential to place the family in the context of the twenty-first century. Many Americans tend to idealize *family* and wish for a return to family values of the past and a golden time for families. However, historical demographic statistics reveal that this prevalence of the idealized family that has often been portrayed in the media never actually existed. Rather than arguing for a return to the “traditional family” (male breadwinner and woman at home), serious discussions are needed about how to help today’s diverse families succeed. A focus on all family structures is a moral and

ethical imperative in the promotion of the health of individuals as well as the health of the community (Nightingale et al, 1978; Wright and Leahey, 2013).

The varying family structures of today need to be recognized and examined to better understand both the strengths and weaknesses associated with each. Only by doing this will we be able to help all families live healthy and productive lives. Nurses can play an active role in leading and facilitating this learning process. This facilitation can enable better-informed health care policy decisions that have a positive effect on single-parent families, remarried and stepfamilies, gay and lesbian families, grandparent-headed families, and ethnically diverse families, as well as “traditional” families.

A nation’s family health care **policy** is a primary determinant of **family health**. Family policy means anything that is done by the government that directly or indirectly affects families. Family health policy and its relative effectiveness demonstrates a government’s understanding of families and its role in promoting their health, with an important desired outcome being that families derive a sense of empowerment and are able to take responsibility for their own health (Chinn, 2012). The responsibility for family health programs is shared by the federal government with state and local governments. Each state, as well as regions within states, has programs and laws related to family services. The United States is one of the richest and most technologically advanced countries in the world today and yet, despite the profusion of technological advances and the continually growing proportion of the national budget spent on health care, the disparities in health status between different populations of families has continued to grow (FAMILIES USA, 2014). These disparities have resulted, at least in part, from previous attempts to develop and implement “family policies” that either directly or indirectly affect specific issues related to family health but which have failed to take a comprehensive system-wide approach.

Although many disparities and inequities continue in the United States, the health care disparities related to insurance coverage should begin to change as the **Affordable Care Act** (ACA) expands. At the 2014 Health Action Conference, FAMILIES USA, Vice President Joe Biden spoke of the importance of the Affordable Care Act (discussed throughout this text) and the importance of the ACA for families in the United States. The specific benefits he highlighted were the coverage of pre-existing conditions, mental health coverage, the disparity in the cost of insurance for women and men, the more than three million young adults on their parents’ insurance policies, and not receiving medical care simply because one does not have insurance (Biden, 2014). Nursing has a rich history in social activism and social justice which should be continued, emphasizing advocacy and policy work to help families and communities become healthier for all populations.

Evidence to date suggests that the United States could benefit from a cohesive family policy designed to enhance the well-being of all families. Such a policy would go a long way toward preventing future crises in vulnerable family populations, such as those in or on the verge of poverty or families overwhelmed with abuse and neglect, by providing a structural safety net to

help families to maintain their health in times of disaster, economic downturns, unemployment, health crises, and other situations. An effective family health policy may consider as its foundational element an infrastructure of programs designed to provide access to primary and preventive health care. The building of this foundation requires a multiprofessional process in which nurses can be actively involved. Nurses are educated in community assessment, planning, development, and evaluation activities that emphasize and address issues crucial to promoting and sustaining primary family health. Nurses looking to positively influence family health will want to be aware of and actively participate in the ongoing national debate and dialogue on family health policy that embraces their role as principal constituents in building healthy families.

In establishing health objectives for the nation, an emphasis has been placed on both health promotion and risk reduction. Reducing the risks to segments of the population is a direct way to improve the health of the general population. Specific objectives have been identified related to specific health risks for families. The family is an important environmental factor that affects the health of individuals as well as a social unit whose health is basic to that of the community and the larger population. It is within the family that health values, health habits, and health risk perceptions are developed, organized, and carried out. Individuals’ health behaviors are affected by and acted out within the family environment, the larger community, and society.

Family health habits are developed in the same manner in the context of community norms and values, and on the basis of availability and accessibility. For example, in a television commercial for an over-the-counter stimulant, a man is featured who is able to coach his child’s basketball team, work at a rehabilitation center, and work as a borough inspector for the city, all while pursuing a college degree at night. The commercial credits the drug for providing the man with the energy needed to be successful in all of these areas. The message is clear: you can, and must, do it all, and taking drugs to succeed is a viable option. The health risks to individual and family health are affected by the societal norms—in this example, the norm is increasing productivity through drugs.

To intervene effectively and appropriately with families to reduce their health risk and thereby promote their health, nurses need to understand not only family structure and functioning, but also family theory, nursing theory, and models of health risk (see **Chapters 9, 17, and 27**). In addition, the effective nurse needs to look beyond the individual and the family in order to understand the complex environment in which the family exists. Increasing evidence of the effects of social, biological, economic, and life events on health requires a broader approach to addressing health risks for families. Nurses and the communities they serve have a vital interest in exploring new and appropriate options for structuring nursing interventions with families to decrease health risks and to promote health and well-being for all families. It is important for the nurse to focus on families who share similar health risks as a population. Working and planning interventions to reduce health risks in family populations provides a mechanism for

shared communication and support among families as well as efficient and effective health care interventions that will not only make the families, but the community as a whole, healthier.

EARLY APPROACHES TO FAMILY HEALTH RISKS

Health of Families

Historically, the study of the family relative to health and illness focused on three major areas: (1) the effect of illness on families, (2) the role of the family in the cause of disease, and (3) the role of the family in its use of services. In his classic review of the family as an important unit, Litman (1974) pointed out the important role that the family (as a primary unit of health care) plays in health and illness and emphasized that the relationship between health, health behavior, and family “is a highly dynamic one in which each may have a dramatic effect on the other” (p. 495). At about this same time, Mauksch (1974) proposed the idea of distinguishing between family health and individual health. Pratt’s (1976) examination of the role of the family in health and illness included the role of family health in the promotion of healthy or unhealthy behavior. Pratt proposed and described the *energized family* as being an ideal family type that was most effective in meeting health needs. The energized family is characterized as promoting freedom and change, active contact with a variety of other groups and organizations, flexible role relationships, equal power structure, and a high degree of autonomy in family members. Doherty and McCubbin (1985) proposed a family health and illness cycle consisting of six phases, beginning with family health promotion and risk reduction and continuing through the family’s vulnerability to illness, their illness response, their interaction with the health care system, and finally their ways of adapting to illness.

Health of the Nation

In recent years, increased attention has been given to improving the health of everyone in the United States. As a result of major public health and scientific advances, the leading causes of morbidity and mortality have shifted from infectious diseases to chronic diseases, accidents, and violence, all of which have strong lifestyle and environmental components. A classic population-focused study in Alameda County, California (Belloc and Breslow, 1972) demonstrated the relationships between seven lifestyle habits and decreased morbidity and mortality. These habits were (1) sleeping 7 to 8 hours daily, (2) eating breakfast almost every day, (3) never or rarely eating between meals, (4) being at or near recommended height-adjusted weight, (5) never smoking cigarettes, (6) moderate or no use of alcohol, and (7) regular physical activity. These same lifestyle health habits are still important for improved health in the twenty-first century.

The Alameda study has been supported by Dan Buettner’s (2009) work with The National Geographic Society and their examination of communities around the world who have not only longevity, but quality of life. Public health nurses will want

to read *The Blue Zones: 9 Lessons for Living Longer* for in-depth case studies. The nine lessons include the following:

1. Move naturally: Be active without thinking about it;
2. Hara Hachi Bu: Painlessly cut calories by 20 percent;
3. Plant slant: Avoid meat and processed foods;
4. Grapes of life: Drink red wine in moderation;
5. Purpose now: Take time to see the big picture;
6. Downshift: Take time to relieve stress;
7. Belong: Participate in a spiritual community;
8. Loved ones first: Make family a priority; and
9. Right tribe: Be surrounded by those who share Blue Zone values.

A growing body of literature supports the notion that life-style and the environment interact with heredity to cause disease. In response to these findings and to the limited effect of medical interventions on the growing incidence and prevalence of injuries and chronic disease, the government launched a major effort to address the health status of the population. Part of this effort was a report by the Division of Health Promotion and Disease Prevention of the Institute of Medicine that examined the critical components of the physical, socioeconomic, and family environments related to decreasing risk and promoting health (Nightingale et al, 1978). *The Surgeon General’s Report on Health Promotion and Disease Prevention* (Cali-fano, 1979) described the risks to good health in the United States at that time. As a result of these reports, health objectives for the nation were established and then evaluated and restated for the year 2000 and again for 2010 (USDHHS, 2000). The *Healthy People 2020* objectives extend the work of the three past documents. An innovative part of this latest *Healthy People* (USDHHS, 2010) update has been a move to become more creative and inclusive. The focus challenges health care providers with a national goal of improving health and will provide the necessary background for future policy initiatives to reduce risk in all populations. Of the four goals, three are particularly important to families:

- Achieve health equity, eliminate disparities, and improve the health of all groups.
- Create social and physical environments that promote good health for all.
- Promote quality of life, healthy development, and healthy behaviors across all life stages.

With the notion of **risk**, any factor resulting in a predisposition toward or an increased likelihood of ill health takes on increased importance. Specific attention is being paid to those environmental and behavioral factors that lead to ill health with or without the influence of heredity. Reducing health risks is a major step toward improving the health of the nation. Although the family is considered an important environment related to achieving important health objectives, limited attention and research have been directed at family health risks and the role of society in promoting healthy families.

CONCEPTS IN FAMILY HEALTH RISK

Pender’s *Health Promotion Model* (2010), described in the latest edition of her textbook, continues to be useful in research

HEALTHY PEOPLE 2020

Objectives Related to Family and Home Health

- EH-18: Decrease the number of U.S. homes that are found to have lead-based paint or related hazards.
- MICH-11: Increase abstinence from alcohol, cigarettes, and illicit drugs among pregnant women.
- NWS-12: Eliminate very low food security among children in U.S. households.
- TU-14: Increase the proportion of smoke-free homes.

From U.S. Department of Health and Human Services: *Healthy People 2020*, Washington, DC, 2010, U.S. Government Printing Office.

that is done with families. This health promotion model states there are two factors that motivate individuals to participate in positive health behaviors. One is a desire to promote one's own health, using behaviors that have been determined to increase the individual, family, community, and society's well-being, and in the process, actually moving toward not only individual self-actualization, but a society actualization as well. The second factor is a desire to protect health, using those same behaviors in an effort to decrease the probability of ill health and provide active protection against illness and dysfunction in families (Pender, 2010). Understanding family health risk requires an examination of several related concepts: family health, family health risk, risk appraisal, risk reduction, life events, lifestyle, and family crisis. These concepts will be defined and discussed here. It is important to remember that *health* can be defined in a number of ways, and it is defined by individuals and families within their own culture and value system.

Family Health

Family theorists refer to healthy families but generally do not define family health (White and Klein, 2009). Based on the variety of perspectives on family (see Chapters 9, 17, and 27), definitions of healthy families can be derived within the guidelines of the framework associated with that perspective. For example, within the perspective of the developmental framework, family health can be defined as possessing the abilities and resources to accomplish family developmental tasks. Thus, the accomplishment of stage-specific tasks is one indicator of family health.

Because the family unit is a part of many societal systems, the systems perspective will be discussed in more detail. Using the *Neuman Systems Model* (Nursing Theory Network, 2005; Neumann University, 2010), family health is defined in terms of system stability as characterized by five interacting sets of factors: physiological, psychological, sociocultural, developmental, and spiritual. The client family is seen as a whole system with the five interacting factors. The Neuman Systems Model is a wellness-oriented model in which the nurse uses the strengths and resources of the family to keep the system stable while adjusting to stress reactions that lead to health change and wellness. In other words, this model focuses on family wellness in the face of change. Because change is inevitable in every family,

the Neuman Systems Model proposes that families have a flexible external line of defense, a normal line of defense, and an internal line of resistance. When a life event is big enough to contract the flexible line of defense (a protective mechanism) and breaks through the normal line of defense, the family feels stress. The degree of wellness is determined by the amount of energy it takes for the system to become and remain stable. When more energy is available than is being used, the system remains stable.

Examples of energy-building characteristics in this system are social support, resources, and prevention (or avoidance) of stressors. Nurses can use preventive health care both to reduce the possibility that a family encounters a stressor and to help strengthen the family's flexible line of defense. The following clinical example applies the Neuman Systems Model to one family's situation:

The Harris family consists of Ms. Harris (Gloria), 12-year-old Kevin, 8-year-old Leisha, and Ms. Harris's mother, 75-year-old Betty. Kevin was recently diagnosed with insulin-dependent diabetes mellitus, and the family was referred by the endocrinology clinic to the nursing service at the local health department to work with the family in adjusting to the diagnosis.

The focus of the Neuman Systems Model would be to assess the family's ability to adapt to this stressful change and then focus on their strengths in the stabilizing process. The *five interacting variables* would compose an important component of the assessment:

- *Physiological:* Is the Harris family physically able to deal with Kevin's illness? Is everyone else in the family currently healthy? Are there current health stressors?
- *Psychological:* How well will the family be able to deal with the illness psychologically? Are their relationships stable and healthy? Are there any memories of other family members with diabetes?
- *Sociocultural:* How will the sociocultural variable come into play in Kevin's illness? Does the family have social support? Are the treatment and diagnosis culturally sensitive? Can family members support each other?
- *Developmental:* How will Kevin's development as a preadolescent be affected by diabetes? How will the family's development change? How will Kevin's diagnosis affect Leisha?
- *Spiritual:* How will the family's spiritual beliefs be affected by the diagnosis? What effect will they have on his treatment and willingness to adhere to therapy?

Health Risk

Several factors contribute to the development of healthy or unhealthy outcomes. Clearly, not everyone exposed to the same event will have the same outcome. The factors that determine or influence whether disease or other unhealthy results occur are called **health risks**. Control of health risks is done through disease prevention and health promotion efforts. Health risks can be classified into three general categories: (1) inherited biological risks (including age-related risks), (2) environmental risks (comprised of both social, such as economic, and physical

aspects), and (3) behavioral risks (USDHHS, 2000). These three categories of risk are discussed later in terms of family health risk, under Major Family Health Risks and Nursing Interventions (USDHHS, 2010).

Although single risk factors can influence outcomes, the combined effect of accumulated risks is often greater than the sum of the individual effects. For example, a family history of cardiovascular disease is a single biological risk factor that is exacerbated by smoking (a behavioral risk that is more likely to occur if other family members also smoke). This risk factor can also be affected either positively or negatively by diet and exercise. Diet and exercise are influenced both by family and society's norms. Although the demographics may be changing, residents of the Northwest and West have historically been more likely to eat heart-healthy diets and to exercise compared with people who live in the Midwest and South; thus, communities in the Northwest and West are often more supportive of exercise programs, bicycle paths, and diets lower in fat than communities in other parts of the United States. This illustrative example of how the combined effect of a family history, family behavioral risks, and society's influences is more than just the sum of the three individual behavioral risk factors (smoking, diet, and exercise) and demonstrates how a nurse working with populations of families and intervening within a community is more likely to reduce the effects of the health risks overall and produce a healthier community as well as a healthier family unit.

Health Risk Appraisal

Health risk appraisal refers to the process of assessing for the presence of specific factors in each of the categories that have been identified as being associated with an increased likelihood of an illness, such as cancer, or an unhealthy event, such as an automobile accident. Several techniques have been developed to accomplish health risk appraisal, including computer software programs and paper-and-pencil instruments. One technique is the Youth Behavioral Health Risk Appraisal instrument of the [Centers for Disease Control and Prevention \(CDC, 2014\)](#). The general approach is to determine whether and to what degree a risk factor is present. On the basis of scientific evidence, each factor is weighted, and a total score is derived. This appraisal method provides an individual score that can be examined as a whole within the family being assessed, thus appraising the health risks that are likely to be experienced by other members of the family. Additional research is needed to determine if the individual appraisals can be used to determine family risk.

Health Risk Reduction

Health risk reduction is based on the assumption that decreasing the number of risks or the magnitude of risk will result in a lower probability of an undesired event occurring. For example, to decrease the likelihood of adolescent substance abuse, family behaviors such as parents not drinking, alcohol not available in the home, and family contracts related to alcohol and drug use may be useful. Health risks can be reduced through a variety of approaches, such as those just described. It is important to note the specific risk and the family's tolerance

of it. [Pender \(2010\)](#) provides examples of different kinds of risks:

- Voluntarily assumed risks are better tolerated than those imposed by others.
- Risks over which scientists debate and as a result have some level of uncertainty as to their magnitude are more feared than risks on which scientists agree.
- Risks of natural origin are often considered less threatening than those created by humans.
- Thus, risk reduction is a complex process that requires knowledge of the specific risk and the family's perceptions of the nature of the risk.

Family Crisis

A **family crisis** occurs when the family is not able to cope with an event or multiple events and becomes disorganized or dysfunctional. When the demands of the situation exceed the resources of the family, a family crisis exists. When families experience a crisis or a crisis-producing event, they attempt to gather their resources to deal with the demands created by the situation. [Price, Price, and McKenry \(2010\)](#) differentiate between family resources and family coping strategies. The former are the resources, such as money and extended family, that a family has available to them. The latter are the family's efforts to manage, adapt, or deal with the stressful event in order to achieve balance in the family system ([Price, Price, and McKenry, 2010](#)). Thus, if a family were to experience an unexpected illness of the primary wage earner, family resources might include financial assistance from relatives or emotional support. Family coping strategies, in contrast, would include whether the family was able to ask a relative to loan them emergency funds or was able to talk with relatives about the worries they were experiencing. On the basis of the existing literature, [Friedman et al \(2003\)](#) developed a system of coping strategies ([Table 28-1](#)).

It is important to note that the amount of support available to families in times of crisis from government and nongovernment agencies varies in different regions, states, and locales. In addition, the rules and conditions of support often differ and may inhibit families from seeking support, particularly if the conditions are demeaning. Nurses must be aware and sensitive to these differences in assessing the accessibility of support resources to families.

MAJOR FAMILY HEALTH RISKS AND NURSING INTERVENTIONS

As mentioned earlier, risks to a family's health arise in three major areas: biological, environmental, and behavioral. In most instances, a risk in one of these areas may not be enough to threaten family health, but a combination of risks from two or more categories could threaten health. For example, a family history of cardiovascular disease by itself may not indicate an increased risk, but the health risk is often increased by an unhealthy lifestyle. An understanding of each of these categories provides the basis for a comprehensive perspective on family health risk assessment and intervention.

TABLE 28-1 Framework of Coping Strategies

Internal Strategies (From Within Family)		Processes for Coping
1. Cognitive	2. Relationships	1. Be accepting of the situation and others.
		2. Gain useful knowledge. Use of Internet helpful.
		3. Collaborate in problem solving (reframe the situation).
2. Communication	3. Spiritual	4. Increase cohesion (togetherness).
		5. Increase flexibility.
		6. Share feelings and thoughts.
3. Social support	4. Community links	7. Increase family structure.
		8. Be open and honest.
		9. Listen to one another.
4. External Strategies	5. Spiritual	10. Be sensitive to nonverbal communication.
		11. Use humor when appropriate.
		12. Maintain links in organizations.
5. Social support	6. Community links	13. Be more involved in religious activities.
		14. Increase faith or seek help from God.
		15. Seek help and support from others.

From Friedman M, Bowden V, Jones E: *Family nursing: research, theory & practice*, ed 5, Upper Saddle River, NJ, 2003, Prentice Hall.

Healthy People 2020 targets areas in health promotion, health protection, preventive services, and surveillance and data systems to describe age-related objectives (USDHHS, 2010). Included in the area of health promotion are physical activity and fitness, nutrition, tobacco use, use of alcohol and other drugs, family planning, mental health and mental disorders, and violent and abusive behavior. Health protection activities include issues related to unintentional injuries, occupational safety and health, environmental health, food and drug safety, and oral health. Preventive services, designed to reduce risks of illness, include maternal and infant health, heart disease and stroke, cancer, diabetes and other chronic disabling conditions, human immunodeficiency virus (HIV) infection, sexually transmitted diseases, immunization for infectious diseases, and clinical preventive services. The interrelationships among the various groups of risk are clear when the objectives for the nation are considered. Most of the national health objectives are based on risk factors of groups or populations in a variety of categories like age, gender, and health problems. However, it is important to recognize that some of these factors also relate to and have potential effects on the individuals' families, work, school, and communities.

Family Health Risk Appraisal

Assessment of family health risk requires many approaches. As in any assessment, the first and most important task is to get to know the family, their strengths, and their needs (see Chapter 27). This section focuses on appraisal of family health risks in the areas of biological and age-related risk, social and physical

BOX 28-1 Definitions Related to Family Health

Determinants of health: An individual's biological makeup influences health through interaction with social and physical environments as well as behavior.

Behaviors: These may be learned from other family members.

Social environment: This includes the family, and it is where culture, language, and personal and spiritual beliefs are learned.

Physical environment: Hazards in the home may affect health negatively, and a clean and safe home has a positive influence on health.

environmental risk, and behavioral risk. Box 28-1 provides some definitions related to family health.

Biological and Age-Related Risk

The family plays an important role in both the development and the management of a disease or condition. Several illnesses have a family component that can be accounted for by either genetics or lifestyle patterns. These factors contribute to the **biological risk** for certain conditions. Patterns of cardiovascular disease, for example, can often be traced through several generations of a family. Such families are said to be at risk for cardiovascular disease. How or whether cardiovascular disease is found in a family is often influenced by the lifestyle of the family. Research evidence consistently supports the positive effects of diet, exercise, and stress management on preventing or delaying cardiovascular disease. The development of hypertension can be managed by following a low-sodium diet, maintaining a normal weight, exercising regularly, and using effective stress management techniques, such as meditation (Brill, 2011). Diabetes mellitus is another disease with a strong genetic pattern, and the family plays a major role in the management of the condition. Family patterns of obesity increase the risk in individuals for a number of conditions, including heart disease, hypertension, diabetes, some types of cancer, and gallbladder disease (USDHHS, 2010). The role of genetics is becoming increasingly important in health care and is discussed in Chapter 11. It is often difficult to separate biological risks from individual lifestyle factors.

Transitions (movement from one stage or condition to another) are times of potential risk for families. Age-related or **life-event risks** often occur during transitions from one developmental stage to another. Transitions present new situations and demands for families. These experiences often require that families change behaviors, schedules, and patterns of communication; make new decisions; reallocate family roles; learn new skills; and identify and learn to use new resources. The demands that transitions place on families have implications for the health of the family unit and individual family members and can be considered as life-event risks. How well prepared families are to deal with a transition depends on the nature of the event. If the event is normative, or anticipated, then it is possible for families to identify needed resources, make plans, learn new skills, or otherwise prepare for the event and its consequences. This kind of anticipatory preparation can increase the family's coping ability and lessen stress and negative outcomes. If, on the other hand, the event is non-normative, or unexpected,

TABLE 28-2 Eight Major Stages and Eight Family Development Tasks in the Family Life Cycle

Stages of the Family Life Cycle	Positions in the Family	Family Developmental Tasks
Stage 1. The married couple	Wife/Husband	Establishing a mutually satisfying marriage. Adjusting to pregnancy Fitting into the kin network
Stage 2. Childbearing	Wife/mother Husband/father Infant(s)	Having and adjusting to an infant Establishing a satisfying home for parents
Stage 3. Preschool-aged children	Wife/mother Husband/father Daughter/sister Son/brother	Adapting to the needs of preschool children Coping with energy depletion and lack of privacy as parents
Stage 4. School-aged children	Wife/mother Husband/father Daughter/sister Son/brother	Fitting into the community Encouraging children's educational achievements
Stage 5. Teenage children	Wife/mother Husband/father Daughter/sister Son/brother	Balancing freedom with responsibility Establishing post-parental interests
Stage 6. Launching the children	Wife/mother/ grandmother Husband/father/grandfather	Launching youth into adulthood Maintaining a supportive home base
Stage 7. Middle-aged parents	Wife/mother/ grandmother Husband/father/grandfather	Refocusing on the marriage relationship Maintaining kin ties with older and younger generations
Stage 8. Aging family members	Widow/widower Wife/mother/ grandmother Husband/father/grandfather	Coping with death and living alone Selling the family home Adjusting to retirement

From: DeFraen J: *Getting Connected, Staying Connected: Loving One Another, Day by Day*, (June 20, 2012), iUniverse, Board of Regents of the University of Nebraska. (Table 2-1)

families have little or no time to prepare and the outcome can be increased stress, crisis, or even dysfunction. Table 28-2 lists family stages and the developmental tasks associated with each stage (Friedman et al, 2003).

Several normative events have been identified for families. The developmental model organizes these events into stages and identifies important transition points. It provides a useful framework for identifying normative events and preparing families to cope successfully with related demands. The developmental tasks associated with each stage identify the types of skills families need. The kinds of normative events families experience are usually related to the addition or loss of a family member, such as the birth or adoption of a child, the death of a grandparent, a child moving out of the home to go to school or take a job, or the marriage of a child. There are health-related responsibilities associated with each of these tasks. For example, the birth or adoption of a child requires that families learn about human growth and development, parenting, immunizations, management of childhood illnesses, normal childhood nutrition, and safety issues.

Non-normative events present different kinds of issues for families. Unexpected events can be either positive or negative. Getting a job promotion or inheriting a substantial sum of money may be unexpected but are usually positive events. More often, non-normative events are unpleasant, such as a major illness, divorce, death of a child, or loss of the main family income.

Both normative and non-normative life events pose potential risks to the health of families. Even events that are generally viewed as being positive require changes and can place stress on a family. The normative event of the birth of a child, for example, requires considerable changes in family structures and roles. Furthermore, family functions are expanded from previous levels, requiring families to add new skills and establish additional resources. These changes can in turn result in strain and, if adequate resources are not available, stress. Therefore, to adequately assess life risks, both normative and non-normative events occurring in the family need to be considered. Regardless of whether a life event is normative or non-normative, it is often a source of stress for families. Several theoretical frameworks have been developed to examine the processes of family stress and coping. Perhaps the most widely used is the ABC-X model. The model was originally developed by Hill (1949) and was based on work with families separated by war. In the model, crisis (X) was proposed to be a product of the nature of the event (A), the family's definition of the event (B), and the resources available to the family (C). Doherty and McCubbin (1985) extended the model to the Double ABC-X model to encompass the period after the initial crisis and introduced the idea of a pile-up of stressors. Adaptation or maladaptation by the family is proposed to be determined by the pile-up of stressors (Aa), the family's perception of the crisis (Bb), and new resources and coping strategies (Cc).

Lorenz, Wickrama, and Conger (2004) challenged this step-by-step view of families and stress and coping. They advocated a more systems-oriented concept of family stress. They pointed out that families develop a series of processes to manage or transform inputs to the system (e.g., energy, time) to outputs (e.g., cohesion, growth, love) known as *rules of transformation*. Over time, families develop these patterns in enough quantity and variety to handle most changes and challenges; this is referred to as *requisite variety of rules of transformation*. However, when families do not have an adequate variety of rules to allow them to respond to an event, the event becomes stressful. Rather than being able to deal with the situation, they fall into a pattern of trying to figure out what it is they need to do, and the usual tasks of the family are not adequately addressed. Rules that were implicit in the family are now reconsidered and redefined.

Furthermore, the family stress theory of Lorenz et al (2004) proposed three levels of stress: level I is change “in the fairly specific patterns of behavior and transforming processes” (e.g., change in who does which household chores); level II is change “in processes that are at a higher level of abstraction” (e.g., change in what are defined as family chores); and level III is change in highly abstract processes (e.g., family values) (Lorenz et al, 2004). Coping strategies can be identified to address each level of stress that families go through in sequence, if necessary (see the Evidence-Based Practice box). The work of Lorenz and

his colleagues is extensive and continues to be used in research and practice (The Family Transitions Project, 2012).

Biological Health Risk Assessment

One of the most effective techniques for assessing the patterns of health and illness in families is the genogram (see Chapter 27 for further discussion and an example). Briefly, a genogram is a drawing that shows the family unit of immediate interest and includes several generations using a series of circles, squares, and connecting lines. Basic information about the family, relationships in the family, and patterns of health and illness can be obtained by completing the genogram with the family. Dates of birth, marriage, death, and other important events can be indicated where appropriate. Major illness or conditions can be listed for each family member. Patterns can be quickly assessed and provide a guide for the health interviewer about health areas that need further exploring.

A more intensive and quantitative assessment of a family’s biological risk can be achieved through the use of a standard family risk assessment. Because such assessments involve other areas in addition to biological risk, one will be described later, after the description of assessment of other types of risk.

Community-level support groups (e.g., Families Anonymous, Bereaved Parents, Parents and Friends of Lesbian and Gay Persons, Single Parents) have been successful in assisting

EVIDENCE-BASED PRACTICE

Building the evidence-based case for the effectiveness of a nursing intervention program is not a goal that can be accomplished quickly. Rather, such a case requires many years of testing and refining interventions, as well as the ongoing and arduous task of obtaining funding from federal and state entities. It is also dependent on the intense advocacy involved in influencing legislators to achieve health and social policy reform necessary to enable lasting change. The Nurse Family Partnership (NFP) is one such program that was begun in the late 1970s by a social and behavioral sciences major who focused on psychology, specifically with early infant attachment (Goodman, 2006). Dr. David Olds would later complete his doctoral studies under the mentoring of Dr. Urie Bronfenbrenner, a professor at Cornell University, and continued his research with the goal of improving the lives of children. Using nurses only for the intervention study, Olds set out to study the impact that home visitation to new mothers by nurses would have on social and health outcomes of both mother and baby. The home visitation began during pregnancy. Olds conducted randomized control studies in diverse locations and diverse populations. He also completed a study that compared the use of nurses with the use of paraprofessionals and determined that the use of nurses had more positive outcomes than did the use of paraprofessionals.

Outcomes of these studies have demonstrated that new mothers receiving nurse home visits, beginning during pregnancy and continuing for 2 years, exhibit improvements to maternal health, decrease in childhood injuries, lower rates of child abuse, and greater spacing of subsequent pregnancies when compared with new mothers not receiving nurse home visits. The results have also shown that these mothers are more likely to enter the workforce, and longitudinal data have demonstrated that the nurse-visited families are more economically self-sufficient and that criminal behavior has been less in both mothers and children. The Olds model in 2004 became the Nurse Family Partnership (NFP), a nonprofit organization, in an effort to make it more accessible as well as to ensure quality control, educate nurses, and monitor existing programs. NFP is currently operating in 32 states. Criteria have been established to keep the program true to Olds’

fundamental principles outlined here to ensure consistent quality and positive outcomes.

Of his model, Olds says, “It reduces injuries to children. It helps families plan future pregnancies and create better spacing between the birth of the first and second children. It helps women find employment. It helps improve prenatal health. It improves children’s school readiness.”

Nurse Use

The NFP developed by Dr. Olds and his team provides the ultimate example of the effects of nursing on the individual, family, and community. From care of the pregnant woman, to the care of her newborn and family, to the policy implications that provide for healthier families and healthier communities, the NFP makes a difference in outcomes. The NFP is nursing at its very best—it provides evidence-based early nursing interventions that result in the positive outcomes listed above rather than the poor societal outcomes often described with teen pregnancies and single parenting. The evidence-based NFP model should continue to be tested in other populations and environments, such as in foster and adoptive homes early in the foster or adoption process, thus allowing the benefits of the program to have an even broader reach.

families in dealing with a variety of stressful situations and crises that arise from both life events and age-related events. Nurses have been instrumental in developing and moderating such groups. These are examples of intervening with families as a specific population.

Environmental Risk

The importance of **social risks** to family health is gaining increased recognition (see [Chapters 7 and 18](#)). Living in high-crime neighborhoods, in communities without adequate recreation or health resources, in communities that have major noise pollution or chemical pollution, or in other high-stress environments increases a family's health risk. One social stress is discrimination, whether racial, cultural, or other. The psychological burden resulting from discrimination is itself a stressor, and it adds to the effects of other stressors. The implication of these examples of risky social situations is that they contribute to the stressors experienced by the families. If adequate resources and coping processes are not available, breakdowns in health can occur.

The poor are at greater risk for health problems (see [Chapter 33](#)). **Economic risk**, which is related to social risk, is determined by the relationship between family financial resources and the demands on those resources. Having adequate financial resources means that a family is able to purchase the necessary commodities related to health. These include adequate housing, clothing, food, education, and health or illness care. The amount of money that a family has available is relative to situational, cultural, and social factors. A family may have an income well above the poverty level, but because of a devastating illness in a family member, they may not be able to meet financial demands. Likewise, families from ethnic populations or families with same-sex parents frequently experience discrimination in finding housing. Even if they find housing, they may not be welcome and may be harassed, resulting in increased stress.

Unfortunately, not all families have access to health care insurance. For families at the poverty level, programs such as Medicaid are available to pay for health and illness care. Families in the upper-income brackets usually have health insurance through an employer, or they can afford to either purchase health insurance or pay for health care out of pocket. An increasing number of middle-income families have major wage earners in jobs that do not have health benefits. These people often do not have enough income to purchase health care but earn too much money to qualify for public assistance programs. Consequently, many families have financial resources that allow them to maintain a subsistence level but that limit the quality of their purchasing power. Illness care may be available, but preventive care may not; food high in fat and calories may be affordable, whereas fresh fruit and vegetables are not. Nutritious diets are important in preventing illness and promoting health. [Devaney \(2007\)](#) presents an analysis of the first 35 years of the Women, Infants, and Children (WIC) program and the relationship of participation in WIC to Medicaid costs and use of health care services and found that children who participated in WIC were more linked to the health care system than children who were not. Children in WIC were more likely to receive

both preventive and curative care more often than children not participating in WIC ([Devaney, 2007](#)). WIC continues to be touted as one of the most effective federally funded nutrition programs in the United States ([USDA, 2013](#)).

Environmental Risk Assessment

Assessment of environmental health risk is less well-defined and developed. While the genogram portrays the family relationships, details on the relationships that the family has with others (e.g., relatives and neighbors), their connections with other social units (e.g., church, school, work, clubs, and organizations), and the flow of energy (positive or negative) can be assessed through the use of an ecomap ([Holtzlander, Solar, and Smith, 2014](#)). An ecomap represents the family's interactions with other groups and organizations, accomplished using a series of circles and lines. The family of interest (the Graham family in [Figure 28-1](#)) is represented by a circle in the middle of the page; other groups and organizations are then indicated by other circles. Lines, representing the flow of energy, are drawn between the family circle and the circles representing other groups and organizations. An arrowhead at the end of each line indicates the direction of the flow of energy (into or out of the family), and the darkness of the line indicates the intensity of the energy. The Graham family ecomap indicates that much of the family energy goes into work (also a source of stress for the parents). Major sources of energy for the Grahams are their immediate and extended families and friends. (See [Chapter 27](#) for additional discussion of the ecomap.)

In addition to the support network shown by the ecomap, other aspects of social risk include characteristics of the neighborhood and community where the family lives. A nurse who has worked in the general geographic area may already have performed a community assessment (see [Chapter 18](#)) and have a working knowledge of the neighborhood and community. It is important, however, for the nurse to obtain information from the family to understand their perceptions of the community.

Information about the origins of the family is useful to understand other social resources and stressors. Information about how long the family has lived in their current location and the immigration patterns of the family and their ancestors provides insight into the pressures they experience.

Economic risk is one of the foremost predictors of health. Families often consider financial information private, and both the nurse and the family may be uncomfortable when discussing finances. It is not necessary to know actual family income except in certain instances when it is necessary to determine whether families are eligible for programs or benefits. It is useful to know whether the family's resources are adequate to meet their needs, and it is important to understand that the family may be quite comfortable with their finances and standard of living, which may be different from those of the health care provider. The provider should not try to push financial values onto the family. In terms of health risk, it is important to understand the resources that families have to obtain health/illness care; adequate shelter, clothing, and food; and access to recreation. Families with limited resources may qualify for programs such as Medicaid, WIC, or Maternal Support Systems/Infant

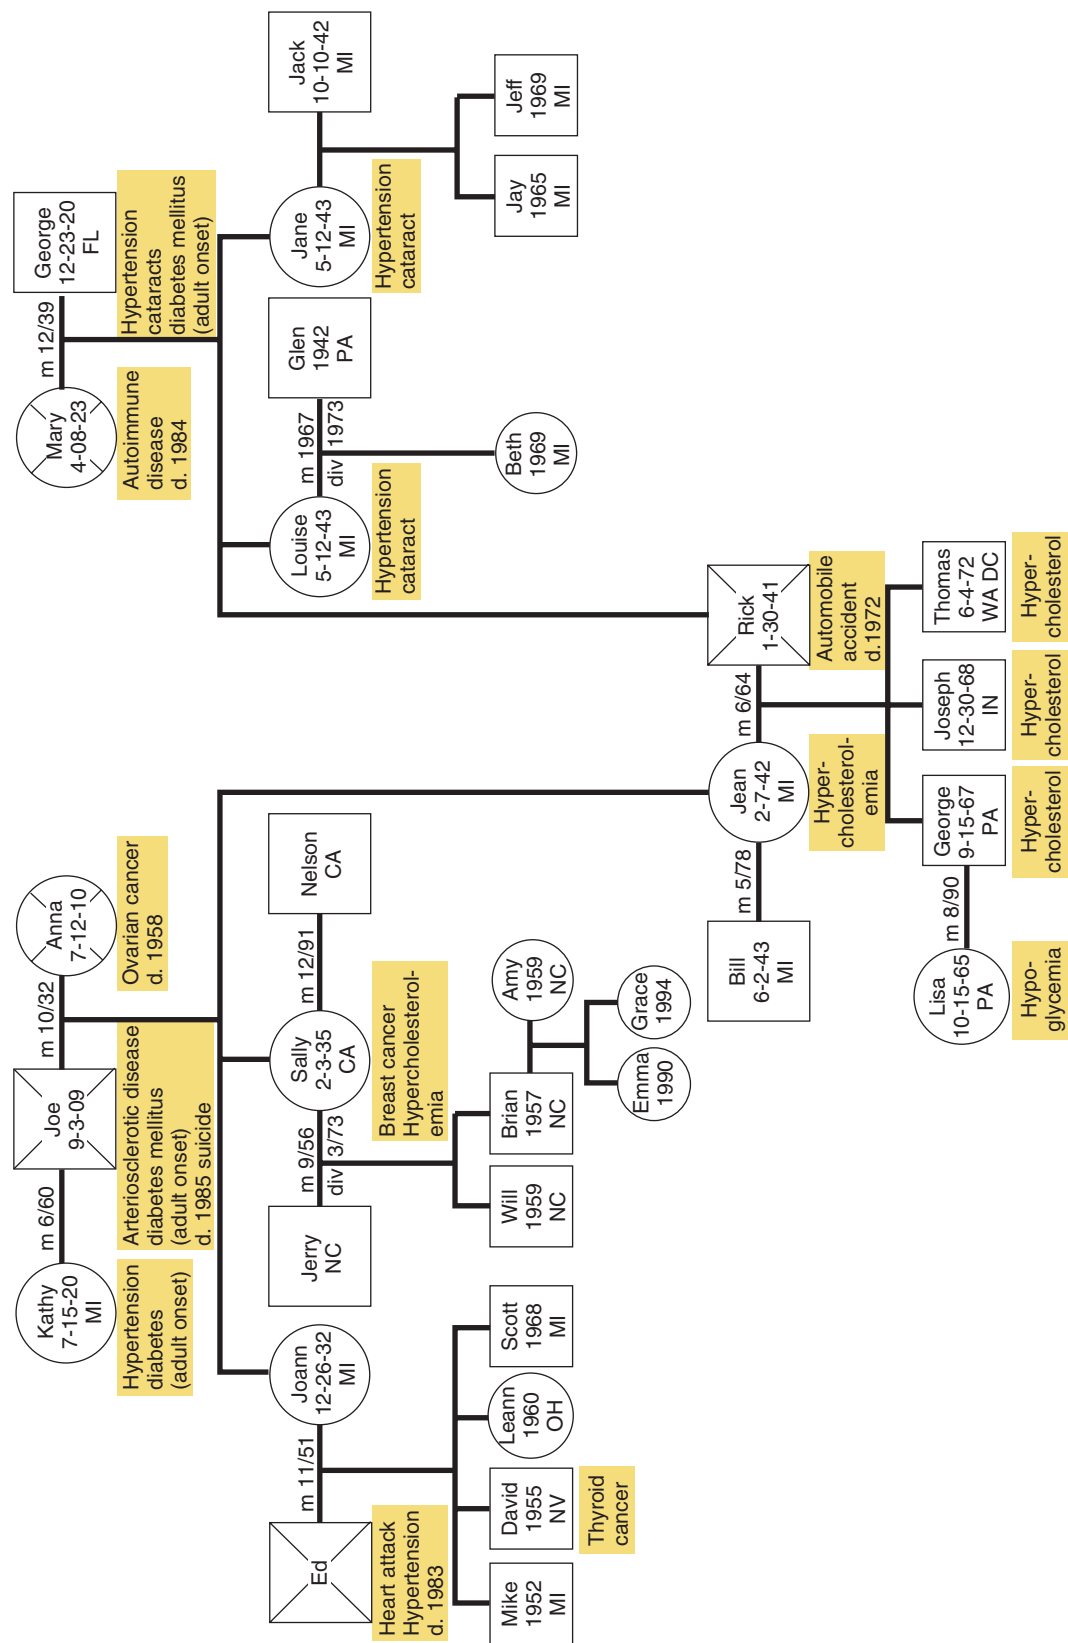

FIG 28-1 Family genogram of the Graham family. (Developed by Carol Loveland-Cherry for the fifth edition of this book).

Support Systems. Families with wage earners with medical benefits and those with enough income are usually able to afford adequate health care. Unfortunately, in a growing number of families, the main wage earner is employed but receives no medical benefits and the salary is not sufficient for health promotion or illness care. This is a policy issue for which nurses are very capable of drafting legislation and providing testimony related to the stories of families in their caseloads. (See [Chapter 8](#) for a discussion of policy involvement by nurses.)

Behavioral (Lifestyle) Risk

Personal health habits continue to contribute to the major causes of morbidity and mortality in the United States (see [Chapter 17](#)). The pattern of personal health habits and **behavioral risk** defines individual and family lifestyle risk. The family is the basic unit within which health behavior—including health values, health habits, and health risk perceptions—is developed, organized, and performed. Families maintain major responsibility for determining what food is purchased and prepared, setting sleep patterns, planning family activities, setting and monitoring norms about health and health risk behaviors, determining when a family member is ill, determining when health care should be obtained, and carrying out treatment regimens. In 2010 more than half of all deaths in the United States were attributed to heart disease or cancer, both of which identify diet as a causative factor ([Minino & Murphy, 2012](#); [NCHS, 2010](#)). General guidelines from the U.S. Department of Health and Human Services and the U.S. Department of Agriculture include eating a variety of foods; maintaining healthy weight; choosing a diet low in fat and cholesterol, including plenty of vegetables, fruits, and grain products; limiting use of sugars, salt, and sodium; and consuming alcohol only in moderation ([USDA, 2013](#)).

Multiple health benefits of regular physical activity have been identified; regular physical exercise is effective in promoting and maintaining health and preventing disease. Physical activity can help to prevent obesity, diabetes, heart disease, cancer, osteoporosis, and depression ([Mayo Clinic, 2010](#)).

Among the benefits of regular physical activity are increased muscle strength, endurance, and flexibility; management of weight; prevention of colon cancer, stroke, and back injury; and prevention and management of coronary heart disease, hypertension, diabetes, osteoporosis, and depression ([USDHHS, 2010](#)). Families can structure time and activities for family members. It is helpful when the community in which they live promotes exercise by having accessible parks and walking or biking paths that help families select activities that provide moderate, regular physical exercise, rather than sedentary activities in the home setting.

Substance use and abuse, such as the use of drugs, alcohol, or tobacco, is a major contributor to morbidity and mortality in the United States. Drug use is a major social and health problem. Drug use is associated with transmission of human immunodeficiency virus (HIV), fetal alcohol syndrome, liver disease, unwanted pregnancy, delinquency, school failure, violence, and crime ([NIDA, 2014](#)). Drunk driving is also a public health hazard. It is well known that tobacco use increases

morbidity and mortality. When caring for families with a smoking member, nurses can consider not only smoking cessation, but also education regarding second-hand smoke. Passive smoking has been associated with several types of cancer, heart disease, chronic obstructive pulmonary disease, low birth weight, premature births, and sudden infant death syndrome ([USDHHS, 2010](#)).

Although violence and abusive behavior are well known health risks for individuals, the extent of their prevalence within families is not well understood. The amount of intrafamilial violence is thought to be underestimated. It is difficult to collect data and obtain accurate statistics on family violence because the issue is so sensitive for families. There is evidence, however, to support the intergenerational nature of violence and abuse—that is, abusers were often abused as children ([USDHHS, 2013](#)).

Behavioral (Lifestyle) Health Risk Assessment

Families are the major source of factors that can promote or inhibit positive lifestyles. They regulate time and energy and the boundaries of the system. A number of tools exist for assessing individuals' lifestyle risks, but few are available for assessing family lifestyle patterns. Although assessment of individual lifestyle contributes to determining the lifestyle risk of a family, it is important to look at risks for the family as a unit. One approach is to identify family patterns for each of the lifestyle components included in *Healthy People 2020*. In the areas of health promotion, health protection, and preventive services, lifestyle can be assessed in several dimensions. From the literature on health behavior research ([Healthy People 2020, 2010](#)), the critical dimensions include the following: value placed on the behavior; knowledge of the behavior and its consequences; effect of the behavior on the family; effect of the behavior on the individual; barriers to performing the behavior; and benefits of the behavior.

It is important to assess the frequency, intensity, and regularity of specific behaviors. It also is important to evaluate the resources available to the family for implementing the behaviors. Thus, items for assessment of physical activity include the value that a family places on physical activity, the hours that a family spends in exercise, the kinds of exercise in which the family participates, and resources available for exercise.

NURSING APPROACHES TO FAMILY HEALTH RISK REDUCTION

Home Visits

Home visits have been effective and have been used since the early days of nursing. Most notable are the [Visiting Nurse Services of New York \(VNSNY, 2014\)](#), founded by Lillian Wald in the late 1800s and the [Frontier Nursing Service \(FNS, 2014\)](#) of Kentucky, founded by Mary Breckinridge in 1925. Both visiting nurse services were developed to work with extremely vulnerable populations, particularly pregnant women and young children. Today's home visitation programs often build on the values of the VNSNY and the FNS, working with young families to help the families learn principles of parenting as well as develop life skills, including resources for employment,

education, and housing. Although nurses work with families in a variety of settings, including clinics, schools, support groups, and offices, the home setting remains an important aspect of the nurse's role in reducing health risks and promoting the health of populations.

Purpose

Home visits, as compared with clinical visits, give a more accurate assessment of the family structure, the natural or home environment, and behavior in that environment. Home visits also provide opportunities to identify both barriers and supports for reaching family health promotion goals. The nurse can work with the client directly to adapt interventions to match resources. Visiting the family in their home may also contribute to the family's sense of control and active participation in meeting their health needs. The majority of historical studies evaluating home visits have focused on the maternal-child population (Fraser et al, 2000; Hammond-Ratzlaff and Fulton, 2001; Wagner et al, 2004). Studies of home visits are often conducted for maternal-child health (Nurse Family Partnership, 2010; Olds et al, 2007). The Health Access Nurturing Development Services (HANDS) program is a voluntary home visitation program offered to new parents in the Commonwealth of Kentucky (KCHFS, 2014). The purpose of HANDS is to provide a positive beginning for families, building on the family's strengths, and improving the well-being of the family.

Home visiting programs have been receiving increased attention and provide a broad range of services to achieve a variety of health-related goals. Long-term effects of home visits are positive and are shown to be cost effective for society. As a result, several states have reinstituted home visits for high-risk families. If the home visit is to be a valuable and effective intervention, careful and systematic planning must occur (Pew Center, 2010).

Advantages and Disadvantages

The effectiveness of health promotion services in the home has been critically reexamined by agencies such as health departments and visiting nurses associations. Advantages include client convenience, client control of the setting, availability of an option for those clients unwilling or unable to travel, the ability to individualize services, and a natural, relaxed environment for the discussion of concerns and needs. Costs are a major disadvantage; the cost of pre-visit preparation, travel to and from the home, time spent with one client, and post-visit preparation is high. Many agencies have actively explored alternative modes of providing service to families, particularly group interventions. The important issue is determining which families would benefit the most and how home visits can most effectively be structured and scheduled. With increasing demands for home health care, the home visit is again becoming a prominent mode for delivery of nursing services. When looking at cost versus effectiveness, it is not always the least costly service that is the most effective (Sewell & Marczak, 2014), rather the social value produced may be more compelling. An example is that of home visits. Although more costly in the short term, some services are more effective in family

TABLE 28-3 Phases and Activities of a Home Visit

Phase	Activity
I. Initiation phase	Clarify source of referral for visit. Clarify purpose for home visit. Share information on reason and purpose of home visit with family.
II. Pre-visit phase	Initiate contact with family. Establish shared perceptions of purpose with family. Determine family's willingness for home visit. Schedule home visit. Review referral and/or family record.
III. In-home phase	Introduce self and professional identity. Interact socially to establish rapport. Establish nurse-client relationship. Implement nursing process.
IV. Termination phase	Review visit with family. Plan for future visits.
V. Post-visit phase	Record visit. Plan for next visit.

From Whitley DM, Kelley SJ, Sipe TA: Grandmothers raising grandchildren: are they at increased risk of health problems? *Health Soc Work* 26:105-114, 2001.

health outcomes using home visitation rather than visits to the health department or clinic.

Process

The components of a home visit are summarized in Table 28-3. The phases include the initiation phase, the pre-visit phase, the in-home phase, the termination phase, and the post-visit phase. Building a trusting relationship with the family client is the cornerstone of successful home visits. Five skills are fundamental to effective home visits: observing, listening, questioning, probing, and prompting. The need for these skills is evident in all phases of the home visit process. Cultural competency cannot be over-stressed when discussing home visits. The PHN is a visitor in the client (or community) setting and every effort should be made to understand our clients' cultures in order to provide the best and most effective interventions for each one. Fadiman's (1997) book, *The Spirit Catches You and You Fall Down*, offers incredible insight into the negative impacts that occur when health care providers and systems do not make the effort to understand a culture other than their own. It is recommended (required) that this book be read by all public health and research students to demonstrate the outcomes based on lack of communication and understanding by health care providers, even those with "good intentions."

Initiation Phase. Usually, a home visit is initiated as the result of a referral from a health or social agency. However, a family may request services, or the nurse may initiate the home visit as a result of case-finding activities. The **initiation phase** is the first contact between the nurse and the family. It provides the foundation for an effective therapeutic relationship. Subsequent home visits should be based on need and

mutual agreement between the nurse and the family. Frequently, nurses are not sure of the reason for the visit. This carries with it the potential for the visit to be compromised and to progress aimlessly or abruptly come to a premature halt. Regardless of the reason for making a home visit, it is necessary that the nurse be clear about the purpose for the visit and that this purpose or understanding be shared with the family.

Pre-visit Phase. The **pre-visit phase** has several components. For the most part, these are best accomplished in order, as presented in the How To box.

HOW TO Prepare for the Home Visit: Pre-Visit Phase

- First, if at all possible, the nurse should contact the family by telephone before the home visit to introduce self, to identify the reason for the contact, and to schedule the home visit. A first telephone contact should be brief, a maximum of 15 minutes. The nurse should give name and professional identity. For example, the nurse might say, "This is Karen Smith. I'm a community health nurse from the Fayette County Health Department." If the client has a first language other than English, it is important to include an interpreter during this first contact, as well as with their continuing care, as this will set the tone for the phone call and the following phases of home visits. The National Standards for Culturally and Linguistically Appropriate Services in Health and Health Care (The National CLAS Standards) should be used to provide respectful and quality care to clients with limited English proficiency (Office of Minority Health, 2014). The purpose of the CLAS Standards is to improve health care quality and equity in increasingly diverse U.S. neighborhoods.
- The family should be informed of how they came to the attention of the nurse—for example, as the result of a referral, or a contact from observations, or records in the school setting. If a referral has been received, it is important and useful to ascertain whether the family is aware of the referral.
- A brief summary of the nurse's knowledge about the family's situation will allow the family to clarify their needs. For example, the nurse might say, "I understand that your baby was discharged from the hospital yesterday and that you requested some assistance with learning more about how to care for your baby at home."
- A visit should be scheduled as soon as possible. Letting the family know agency hours available for visits, the approximate length of the visit, and the purpose of the visit are helpful to the family in determining when to set the visit. Although the length of the visit may vary, depending on circumstances, approximately 30 to 60 minutes is usual.
- If possible, the visit should be arranged when as many family members as possible will be available for the entire visit. It is also important for the nurse to tell the client about any fee for the visit and subsequent visits and possible methods for payment.
- The telephone call can terminate with a review by the nurse of the time, place, and purpose for the visit and a means for the family to contact the nurse in case they need to verify or change the time for the visit or to ask questions. If the family does not have a telephone, another method for setting up the visit can be used. A note can be dropped off at the family home or sent by mail informing the family of when and why the home visit will occur and providing a way for the family to contact the nurse if necessary.

The possibility exists that the family may refuse a home visit. Less-experienced nurses or students may mistakenly interpret this as a personal rejection. Families make decisions about when and which outsiders are allowed entry into their homes. The nurse needs to explore the reasons for the refusal; there may be a misunderstanding about the reason for a visit, or there may be a lack of information about services. The contact may be terminated as requested if the nurse determines either that the situation has been resolved or that services have been obtained from another source, and if the family understands that services are available and how to contact the agency if desired. There are instances when the nurse will be mandated to persist in requesting a home visit because of legal obligations, such as follow-up of certain communicable diseases. This has become more obvious in this era of increasing contagious and infectious diseases in our highly mobile society.

Before visiting a family, the nurse should review the referral or, if this is not the first visit, the family record. If there is a time lapse between the contact and the visit, a brief telephone call to confirm the time often prevents the nurse from finding no one at home.

Personal safety is an issue that may arise either while approaching the family home or when the family has opened the door to the nurse. Nurses need to evaluate personal fears and objective threats to determine if safety is indeed an issue. Certain precautions can be taken in known high-risk situations. Agencies may provide escorts for nurses or have them visit in pairs; readily identifiable uniforms may be required; or a sign-out process indicating timing and location of home visits may be used routinely. Home visits are generally very safe; however, as with all worksites, the possibility of violence exists. Therefore, the nurse needs to use caution. If a reasonable question exists about the safety of making a visit, the visit should not be made. (See Chapter 27 for additional information about personal safety).

The nurse should be aware that families may feel that they are being scrutinized, that they are seen as being inadequate or dysfunctional, or that their privacy is being intruded upon. Nursing services, especially those from health departments, have been perceived by the public as being "public services" for needy families or those with inadequate funds to pay for care. These potential areas of concern underlie the need for sensitivity on the part of the nurse, the need for clarity in information regarding the reason for visits, and the need to establish collaborative, trusting relationships with the family.

Another factor that may affect the nature of the home visit is whether the visit is viewed as voluntary or required. A *voluntary* home visit (visit requested by the client) is characterized by easier entry for the nurse, client-controlled interaction, an informal tone, and mutual discussion of frequency of future visits. An example of a voluntary visit is a new mother who has requested the nurse come to the home and assist her with learning how to care for the infant. In contrast, the client may feel little need for *required* home visits that often may be legally mandated. In these instances, entry may be difficult for the nurse; the interaction may be nurse controlled; there may be a more formal, investigatory tone to the visit with distorted

nurse–client communication; and there may be no mutual discussion of scheduling or frequency of future visits. Two examples of a required home visit are (1) when a family member has been diagnosed with tuberculosis and the nurse needs to make certain that the client is taking medications regularly, and (2) when there is known child abuse and a new baby has arrived. The nurse may need to visit the home to observe the interaction between the parents and the child.

The changing nature of the American family can make it difficult to schedule visits during what have been traditional agency hours. The number of working single-parent or dual-income, two-parent families is increasing, which means that families have more demands on their time. Even if one parent is at home during the usual workday, the ideal is to work with the entire family unit. This often is not possible because of conflict between agency hours and school or work schedules. It may be possible to schedule a visit at the beginning or end of a day to meet with working or school-age members. In some parts of the country, agencies have reconsidered the traditional hours and Monday through Friday visits and include evening and weekend work hours. These issues are important to assess and address during the pre-visit phase so the nurse and the family will be better prepared for the visit.

Culture influences a person's interpretation of and response to health care (Shi and Singh, 2015). It is impossible, given the diversity of the United States and the diversity within cultural groups, to cover every group extensively. Instead, practitioners need to take the responsibility to learn about their client's culture as they prepare for visits with families or communities. Again, refer to the Office of Minority Health's website for additional information regarding culture and diversity.

In-Home Phase. The actual visit to the home constitutes the **in-home phase** and affords the nurse the opportunity to assess the family's neighborhood and community resources, as well as the home and family interactions. The actual home visit includes several components. Once at the family home, the nurse provides personal and professional identification and tells the client the location of the agency. Then, a brief social period allows the client to assess the nurse and establish rapport. The next step is a description by the nurse of his or her role, responsibilities, and limitations. Another important component of the home visit is to determine the client's expectations.

The major portion of the home visit is concerned with establishing the relationship and implementing the nursing process. Assessment, intervention, and evaluation are ongoing. What then occurs in the home visit is determined by the reason for the visit. Keller et al (2004a,b) recommend using the Intervention Wheel to guide nursing practice during home visits. The Intervention Wheel provides appropriate guidelines for the purpose of the home visit. Some reasons for visits are listed in Box 28-2.

A nurse must be flexible and anticipate that families may or may not be able to control interruptions during the visit. Telephones ring, pets join in the visit, people come and go, and televisions may be left on. The nurse can ask that televisions be turned off for a limited time or that other disruptive activities be limited. Families may be so accustomed to the background

BOX 28-2 Reasons For the Home Visit

Nursing interventions may include some or all of the 17 resources identified by the Minnesota Department of Health, Section of Public Health Nursing:

- Advocacy
- Case management
- Coalition building
- Collaboration
- Community organizing
- Consultation
- Counseling
- Delegated medical treatment and observations
- Disease and other health investigation
- Health teaching
- Outreach
- Policy development and enforcement
- Case finding
- Referral and follow-up
- Screening
- Social marketing
- Surveillance

Keller LO, Strohschein S, Lia-Hoagberg B, et al: Population-based public health interventions: practice-based and evidence-supported, Part I. *Public Health Nurs* 21:453-468, 2004.

noises and routine activities that they do not recognize them as being potentially disruptive.

It is important that the nurse be realistic about what can be accomplished in a home visit. In some situations, one visit may be all that is possible or appropriate. In this instance, needs and the resources available to meet them are explored with the family, and it is determined whether further services are desired or indicated. If further services are indicated and the nurse's agency is not appropriate, the nurse can assist the family in identifying other services available in the community and can help in initiating referrals. Although it is not unusual to have only one home visit with a family, multiple visits are often made. The frequency and intensity of home visits vary not only with the needs of the family, but also with the eligibility of the family for services as defined by agency policies and priorities. It is realistic to expect an initial assessment and at least the beginning of building a relationship to occur on a first visit.

Termination Phase. When the purpose of the visit has been accomplished, the nurse reviews with the family what has occurred and what has been accomplished. This is the major focus of the **termination phase**, and provides a basis for planning further home visits. Ideally, termination of the visit and, ultimately, termination of service begin at the first contact with the establishment of a goal or purpose. If communication has been clear to this point, the family and nurse can now plan for future visits, specifically the next visit. Planning for future visits is part of another issue: setting goals and planning service. Contracting is a constructive approach to working with clients to specify and achieve agreed-on goals and is receiving increasing attention by health professionals (Duiveman and Bonner, 2012). The purpose and components of contracting with clients are discussed in more detail later.

Post-visit Phase. Even after the nurse has concluded the home visit and left the client's home, responsibility for the visit is not complete until the interaction has been recorded. A major task of the **post-visit phase** is documenting the visit and services provided. Agencies may organize their records by families. That is, the basic record may be a "family" folder with all members included. However, this often does not occur, although it is useful for the family history and background. More often, each family member has a separate record, and other family members' records are cross-referenced. This is because the focus often shifts from the family to the individual. Consequently, nursing diagnoses, goals, and interventions are directed toward individual family members rather than the family unit. This approach has its shortcomings and it is important for the nurse to recognize these. **Chapter 41** provides an approach for offering nursing diagnoses, stating goals, and identifying interventions for the individual. It is important for the nurse to focus on the continuing assessment of the individual behaviors, responses, or health status and the impact on the family. Interventions at the family level may become necessary, such as educating all family members on hygiene and cleanliness or on the appropriate disposal of supplies of the tuberculosis client in the home.

Record systems and formats vary from agency to agency. The nurse needs to become familiar with the particular system used in the agency. All systems should include a database; a nursing diagnosis and problem list; a plan, including specific goals; actual actions and interventions; and evaluation. These are the basic elements needed for legal and clinical purposes. The format may consist of narratives; flow sheets; problem-oriented medical records (POMRs); subjective, objective, assessment plans (SOAP); or a combination of formats. It is important that recording be current, dated, and signed.

The nurse should be sure to use theoretical frameworks that are appropriate to the family-centered nursing process. For example, a nursing diagnosis of *ineffective mothering skill*, related to lack of knowledge of normal growth and development, is an individual-focused nursing diagnosis. The *inability for family to accomplish stage-appropriate tasks of providing a safe environment for a preschooler* related to lack of knowledge and resources is a family-focused nursing diagnosis based on knowledge of the developmental approach to families. At times, it may be necessary to present information for a specific family member. However, the emphasis should be on the individual as a member of, and within the structure of, the family.

Contracting with Families

Increasingly, health professionals are looking at working with clients in an interactive, collaborative style. This approach is consistent with a more knowledgeable public and the recent self-care movement in the United States. However, it may not be consistent with other cultures that look to health care providers for more direct guidance; therefore, it is important to determine the family's value system before assuming that contracting will work.

Contracting is a strategy aimed at formally involving the family in the nursing process and jointly defining the roles of

both the family members and the health professional. Contracting involves making an agreement between two or more parties and seeks to create a shift in responsibility and control toward a shared effort by client and professional as opposed to an effort by the professional alone. This active involvement of the client is reflected in several nursing models, such as that of **Orem (1995)**. The motivational premise of contracting is family control. It is assumed that when the family has legitimate control, their ability to make healthful choices is increased.

Purposes

The nursing contract is a working agreement that is continuously renegotiable and may or may not be written. It may be either a contingency or a noncontingency contract. A *contingency contract* states a specific reward for the client after completion of the client's portion of the contract; a *noncontingency contract* does not specify rewards. The implied rewards are the positive consequences of reaching the goals specified in the contract.

For family health risk reduction, it is essential that the contract be made with all responsible and appropriate members of the family. Involving only one individual is not sufficient if the goal is family health risk reduction, which requires a total family system effort and change. Scheduling a visit with all family members present may require extra effort. If meeting with the entire family is not possible, each family member can review a contract, give input, and sign it. This allows active participation by all family members without the necessity of finding a time when everyone involved can be present.

Process of Contracting

Contracting is a learned skill on the part of both the nurse and the family (**Duiveman and Bonner, 2012**). All persons involved need to know the purpose and process of contracting. There are three general phases: beginning, working, and termination. The three phases can be further divided into eight sets of activities, as summarized in **Table 28-4**.

The first activity is collection and analysis of data and it involves both the family and the nurse. An important aspect of this step is obtaining the family's view of the situation and its needs and problems. The nurse can present his or her observations, validate them with the family, and obtain the family's view.

TABLE 28-4 Phases and Activities in Contracting

Phase	Activity
I. Beginning phase	Mutual data collection and exploration of needs and problems Mutual establishment of goals Mutual development of a plan
II. Working phase	Mutual division of responsibilities Mutual setting of time limits Mutual implementation of plan Mutual evaluation and renegotiation
III. Termination phase	Mutual termination of contract

It is important that goals be mutually set and be realistic. A pitfall for nurses and clients who are new to contracting is to set overly ambitious goals. The nurse should recognize that there may be discrepancies between their professional priorities and those of the client and determine whether negotiating is required. Because contracting is a process characterized by renegotiation, the goals are not static.

Throughout the process, the nurse and family continually learn and recognize what each can contribute to meeting health needs. The exploring of resources allows both parties to become aware of their own and one another's strengths and requires a review of the nurse's skills and knowledge, the family support systems, and community resources.

Developing a plan to meet the goals involves specifying activities, prioritizing goals, and selecting a starting point. Next, the nurse and the family need to decide who will be responsible for which activities. Setting time limits involves determining the frequency of contacts for evaluating progress toward accomplishing goals and deciding on a deadline for accomplishing the goal. At the agreed-on time or times, the nurse and family together evaluate progress both in terms of process and outcome. The contract can be modified, renegotiated, or terminated on the basis of the evaluation.

Advantages and Disadvantages of Contracting

Contracting takes time and effort and may require the family and nurse to reorient their roles (Duiveman and Bonner, 2012). Increased control on the part of the family also means increased responsibility. Some nurses may have difficulty relinquishing the role of the controlling expert professional. Contracts are not always successful, and contracting is neither appropriate nor possible in some cases. Some clients do not want to have this kind of involvement; they prefer to defer to the "authority" of the professional. Included in this group are individuals with minimal cognitive skills, those who are involved in an emergency situation, those who are unwilling to be more active in their care, and those who do not see control or authority for health concerns as being within their domain. Some of these clients may learn to contract; others never will.

The nursing process does not necessarily provide an active role for the family as a client; the assumption that a need exists is based on professional judgment only, and it is also assumed that changes can and should be made within the family unit. Contracting is one alternative approach that depends on the value of input from both nurse and family, on the competency of the family, on the family's ability to be responsible, and on the dynamic nature of the process. This not only allows for but requires continual renegotiating. Although it may not be appropriate in all situations or with all families, contracting can give direction and structure to health risk reduction and health promotion in families.

Empowering Families

Approaches for helping individuals and families assume that an active role in promoting their health care should be characterized by **empowerment** rather than enabling or providing help (Chinn, 2012). Interventions in which help is given do not

always have positive outcomes for clients. If families do not perceive a situation as a problem or need, offers of help may cause resentment. Providing help also may have negative consequences if there is not a match between what is expected and what is offered. A nurse's failure to recognize a family's competencies and to define an active role for them can lead to the family's dependency and lack of growth. This can be frustrating for both the nurse and the family. For families to become active participants, they need to feel a sense of personal competence and a desire for and willingness to take action. Definitions of empowerment reflect three characteristics of the empowered family seeking help: access and control over needed resources; decision-making and problem-solving abilities; and, the ability to communicate and to obtain needed resources.

The last characteristic refers to the fact that families may need to learn how to identify sources of help, how to contact agencies, how to ask critical questions, and how to negotiate with agencies to meet family needs. These characteristics generally reflect a process by which people (individuals, families, organizations, or communities) take control of their own lives. The outcomes of empowerment are positive self-esteem, the ability to set and reach goals, a sense of control over life and change processes, and a sense of hope for the future (Koelen and Linstrom, 2005). The Levels of Prevention box shows prevention strategies applied to families.

LEVELS OF PREVENTION

Strategies Applied to Families

Primary Prevention

Completing a family genogram and assessing health risks with the family to contract for family health activities to prevent diseases from developing.

Secondary Prevention

Using a behavioral health risk survey and identifying the factors leading to obesity in the family.

Tertiary Prevention

Developing a contract with the family to change nutritional patterns to reduce further complications from obesity.

Empowerment requires a viewpoint that often conflicts with the views of many helping professions, including nursing. Empowerment's underlying assumption is one of a partnership between the professional and the client as opposed to one in which the professional is dominant. Families are assumed to be either competent or capable of becoming competent. This implies that the professional is not an unchallenged authority who is in control. Empowerment promotes an environment that creates opportunities for competencies to be used. Finally, families need to identify that their actions result in behavior change. A nursing intervention that incorporates the principles of empowerment is directed toward the building of nurse-family partnerships that emphasize health risk reduction and health promotion. The nurse's approach to the family should be positive and focused on competencies rather than on problems or deficits. The interventions need to be consistent with

family cultural norms and the family's perception of the problem. Rather than making decisions for the family, the nurse supports the family in primary decision making and bolsters their self-esteem by recognizing and using family strengths and support networks. Interventions that promote desired family behaviors increase family competency and decrease the need for outside help, resulting in families viewing themselves as being actively responsible for bringing about desired changes. The goal of an empowering approach is to create a partnership between the nurse and the family characterized by cooperation and shared responsibility.

COMMUNITY RESOURCES

Families have varied and complex needs and problems. The nurse is often involved in mobilizing several resources to effectively and appropriately meet family health promotion needs. Although the specific resources vary from community to community, general types can be identified. Government resources such as Medicare, Medicaid, Aid to Families with Dependent Children, Supplementary Security Income, Food Stamps, and WIC are available in most communities. These programs primarily provide support for basic needs (e.g., illness/health care, nutritional needs, funds for housing and clothing), and funds are based on meeting eligibility criteria ([Families USA 2012 and 2013](#)).

In addition to government agencies providing health-related services to families, most communities have voluntary (non-governmental) programs. Local chapters of such organizations as the American Cancer Society, the American Heart Association, the American Lung Association, and the Muscular Dystrophy Association provide education, support services, and some direct services to individuals and families. These agencies provide primary prevention and health promotion services, as well as screening programs and assistance after the disease or condition is diagnosed. Local social service agencies, such as Catholic Social Services, provide direct services such as counseling to families. Other voluntary organizations provide direct service (e.g., shelters for homeless or battered individuals, substance abuse counseling and treatment, Meals on Wheels, transportation, clothing, food, furniture).

Health resources in the community may be proprietary, voluntary, or public. In addition to private health care providers, nurses should be aware of voluntary and public clinics, screening programs, and health promotion programs.

Identifying resources in a community requires time and effort. One valuable source is the telephone book. Often community service organizations, such as the local chamber of commerce and health department, publish community resource listings. These resources may be listed on the organizations' websites. Regardless of how the resource is identified, the nurse must be familiar with the types of services offered and any requirements or costs involved. If this information is not available, the nurse can contact the resource.

Locating and using these systems often requires skills and patience that many families lack. Nurses work with families to identify community resources, and as client advocates they help families learn to use resources. This may involve sharing

information with families, rehearsing with families what questions to ask, preparing required materials, making the initial contact, and arranging transportation. The appropriateness and effectiveness of resources should be evaluated with families afterward. Navigating the maze of resources is often difficult, even for the nurse. It is important to remember that if a family is in crisis or does not have a phone or a home base from which to call or receive return calls, this process is even more difficult, and their sense of helplessness may be increased. Therefore, the nurse's assistance, while promoting the family's sense of empowerment, is both necessary and often complex.

Telehomecare

Telehomecare (also referred to as telehealth or telemedicine) is an emerging practice that allows clients to communicate with and transfer health information to providers from home. Researchers have found that telehomecare can improve certain health outcomes, such as reducing the duration of hospitalization, increasing access to care, improving patient satisfaction, and improving patient education and self-care ([Bowles et al, 2011](#); [Shea and Chamoff, 2012](#)). Telehomecare monitoring requires less time per client interaction, so it allows nurses to feasibly care for more clients per day. Nurses may increasingly rely on this technology to assist with home visits to families.

Telehomecare can be a particularly useful option in situations where ongoing and frequent monitoring of a family member's condition is necessary; however, it should be recognized that it is not a substitute for the in-home trust and relationship building and assessment of both family and community resources that can only be accomplished by an attentive and engaged nurse spending time with the family in their home environment. Telehomecare is currently used at Maine General Health in Augusta, Maine. It is used to manage chronic conditions such as heart failure, diabetes, and respiratory illnesses, connecting patients to their HomeCare nurse and/or doctor, while allowing the patient to stay at home ([Maine General Health, 2013](#)).

Family Policy

This chapter ends where it began, with a discussion of the nurse's role in policy development and implementation. Florence Nightingale, Lillian Wald, and Mary Breckenridge were all strongly committed and involved nurses who advocated for families and influenced policy to improve the health of families and consequently the health of communities. Building on the gains made possible by these influential women is essential. Families are affected by the rules and values of their surrounding society in general. If families—all families—are valued, the community will be strong and connected. If any family is neglected and not supported, the community will be weak and disconnected.

Family Medical Leave Act

One current national policy passed to strengthen and support the family is the Family Medical Leave Act (FMLA). On February 5, 1993, President Clinton signed the FMLA (PL 103-3) ([Waldfoegel 2001](#)). This act allows covered employees to take up to 12 weeks of leave each year for certain family and medical

reasons (U.S. DOL, 2012). Under the FMLA, employees may take a leave of absence for many reasons: for their own serious illness; for the illness of their child, parent, or spouse; and for the birth or adoption of a child (PL 103-3). While on leave, employees still receive their medical benefits and are guaranteed that their position or one similar to it will be available to them upon returning to work.

The FMLA was needed to help Americans meet the needs of their families while maintaining employment. Women in particular were experiencing hardship in keeping a job while having a family. The Affordable Care Act and family policies such as the FMLA reflect a growing recognition and valuing of the healthy family unit as a key factor and contributor to the health of not only individuals, but our communities and society at large (USDHHS, n.d.). Nurses are positioned to improve the health of families thus leading to healthier communities, as well as improve the health of communities thus leading to healthier families.

Affordable Care Act

Many of the family health risks discussed in this chapter involve how family stressors can negatively affect health outcomes and suggest strategies and interventions to cope with rectifying these issues. Health policy can also be part of a solution to mitigate the financial and emotional effects of family stress by increasing access and affordability of health care. The Patient Protection and Affordable Care Act of 2010 (ACA) helps women, children, and families by increasing access to health care, improving health care quality, lowering health care costs, and instituting new consumer protections (“The Affordable Care Act,” n.d.). Improving access and control over resources such as health care can (as mentioned on page 624) lead to greater empowerment of families. See Chapters 3 and 27 for additional information.

Vulnerable Populations: LGBTQ Families at Risk

Lesbian, gay, bisexual, transgendered, and queer/questioning (LGBTQ) families are another vulnerable group (the Q stands for someone questioning their sexual orientation. Q may also refer to “queer” as some LGBTs have reclaimed that term for political reasons) (Stanley, 2014). Over the past decade, there has been an explosion of visibility for this population. Debates and legal battles centering on LGBTQ rights have taken place nationally and in states all across the country. Notable examples include same-sex marriage, adoption, and antidiscrimination laws. As of May 2014, 19 states and the District of Columbia had legalized gay marriage, including California, Connecticut, Delaware, Hawaii, Illinois, Iowa, Maine, Maryland, Massachusetts, Minnesota, New Hampshire, New Jersey, New Mexico, New York, Oregon, Pennsylvania, Rhode Island, Vermont, and Washington. Pennsylvania was the most recent state, as of this writing, to allow gay marriage; the U.S. District Court judge struck down the state’s 1996 law that banned gay marriage, calling it unconstitutional, as have several other judges in other states (Worden & Couloumbis, 2014). And, in October 2014, the Supreme Court of the United States refused to intervene in states’ decisions.

LINKING CONTENT TO PRACTICE

Vulnerable Populations: Teenage Parent Families at Risk

Although endless hours have been spent researching ways to help parents of teenagers, it is also important to remember the teenagers who *are* parents. This family structure faces multiple health-related and social challenges, the most prominent being affordable and accessible health care. A closely related challenge is the recruitment and development of mentors to help teen parents acquire this health care, as it is uncharted water for nearly all teenagers. The humiliation teens experience when visiting doctors and agencies is a pain analyzed and discussed incessantly, and yet little has been done for the teenage parents.

The most common issue raised by teenage parents is their uncertainty and low self-confidence in handling adult responsibilities *other* than actual parenting. There is a great need for more teenage-instructional literature on family health policy information and health care service accessibility written from the perspective of teenagers. Single teenage parents need to be able to understand welfare and how to apply, as well as how to find support communities. Teenage parents who decide not to be involved in a child’s life must be able to understand child support, adoption, and legal visitation and involvement issues.

The rising numbers of teenagers giving birth must be met with stronger and more extensive plans for families led by teens. Education, vocational opportunity, and social acceptance are “luxuries” often missed by adolescent parents. While the last of these issues can only be solved by eventual cultural assimilation, schooling and careers should be made possible.

Although it is not advisable to simply hand out opportunities to teenagers with children, it is definitely necessary to offer assistance, not only so that they may have a second chance at a successful life, but for their children as well. It is recognized that the children of teenage parents often make the same mistakes as their parents, due to factors of poor living conditions, low socioeconomic status, and a rough childhood. Without adequate family care, there will be no end to the cycle of child parents. Today, many people are advocating for sex education and prevention, but it is also time *now* for postpregnancy programs, which accept that there is a child born to two teenagers; although they may have made a poor choice, these teenagers now have *no* choice but to accept parental responsibility and be shown the tools to do so.

As noted in the introduction to this chapter, nurses have an ethical obligation to provide culturally competent care to LGBTQ families. To begin, nurses should provide a safe environment for clients to discuss their sexual orientation. Some nurses may feel a degree of discomfort discussing sexual orientation with their clients. However, it is important to overcome this barrier to care for LGBTQ families.

Nurses should assess LGBTQ family dynamics. Just as there is great variation among heterosexual families, all LGBTQ families are not the same. In addition, same-sex couples have historically had special barriers within the health care system. Some problems may stem from the lack of legal recognition for LGBTQ relationships in most areas of the country. Same-sex marriage laws vary widely from state to state. Certain states (e.g., Massachusetts) have legalized same-sex marriage, whereas others have constitutional amendments defining marriage as a union between one man and one woman. Similarly, there is great variation in LGBTQ adoption rights across the nation.

These legal barriers present challenges for LGBTQ families in the health care system. For example, it may be difficult for

LGBTQ couples living in states without same-sex marriage to make medical decisions or visit their partners in the hospital. There are similar barriers for same-sex households with children. Consider this case example:

Sarah and Maria have been in a long-term relationship for 10 years. Five years ago, the couple decided to have a baby. Sarah is the child's biological mother, but the couple has raised Mark together since he was born. The couple lives in a state that does not recognize same-sex marriage or adoption. One day, Sarah and Mark were in a serious car accident. When Maria arrived at the hospital, she learned she was unable to make decisions or access medical information for her partner and child.

On April 15, 2010, President Obama signed a directive instructing hospitals that accept Medicaid and Medicare to allow adult clients the right to designate specific individuals who can visit them in the hospital or make medical decisions on their behalf. This will help alleviate some issues that LGBTQ partners face when interacting with the health care system. (See <http://www.whitehouse.gov/the-press-office/presidential-memorandum-hospital-visitation> for more information.)

Nurses are in an optimal position to fulfill a vital role in helping LGBTQ families achieve equitable access to health care. Nurses can assist with assessing the implementation of President Obama's directive. In addition, nurses can help to advocate for more policies designed to reduce barriers within the health care system for LGBTQ families.

Another type of family at risk is the more “traditional” family with a nonheterosexual member. After a family member declares his or her sexual preferences, families may need initial support to process the information. Nurses may be in a position to provide support during this time. Nurses may also refer families to community resources, such as Parents and Friends of Lesbians and Gays (www.pflag.org). Check within your local community for other appropriate resources.

In addition to providing support for the family unit as a whole, nurses may also be in a position to assess LGBTQ individuals. As in all family units, the health of individual members of a family affects the entire family unit. Sexual minorities face a higher risk for depression, anxiety, substance abuse, thoughts of suicide, and suicide. Addressing mental health issues in this population may help reduce the mental health disparities the LGBTQ population faces.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency

Evidence-based practice integrates the best current clinical evidence with client and family preferences and values to provide optimal care.

- **Knowledge:** Describe how the strength and relevance of available evidence influences the choice of interventions in providing client-centered care.
- **Skill:** Question rationale for routine approaches to care that result in less than desired outcomes or adverse events.
- **Attitude:** Value the need for continuous improvement in clinical practice based on new knowledge.

EBP Question

The PHN Quad Council identified the core competency of policy development and program planning, and suggests the beginning PHN will identify policy issues relevant to the health of individuals, families, groups, and within a community.

In this chapter several family policy issues are discussed. Choose one policy that has been passed legislatively to explore. Policy is one level of evidence used in practice. Before a policy becomes law, the strength and relevance of scientific and other data sources are explored to support the argument for developing the policy. Determine what evidence was used to support the policy. How strong and relevant was the evidence? What reasons were given for the policy becoming law or standard practice? Will the policy improve practice? Is it currently being implemented to improve family health care?

PRACTICE APPLICATION

The initial contact between a nursing service and a family provides limited information, and the situation that develops may be much more complex than originally anticipated. The following example, based on an actual case, illustrates the issues and approaches outlined in this chapter.

The Local County Health Department was notified that Amy C., age 16, had been referred by the school counselor at the local high school for prenatal supervision. Amy was 4 months pregnant, apparently in good health, and in the tenth grade. She lived at home with her mother, stepfather, and younger sister. The family lived in a rural area outside of a small farming

community. The father of the baby also lived in the community and continued to see Amy on a regular basis. The referral information provided the nurse with a beginning, but limited, assessment of the family situation.

- What would you do first as the nurse assigned to this family?
- How would you help this family empower themselves to take responsibility for this situation?
- After the initial contact, how would you extend the assessment to the entire family system?
- Would you contract with this family? How? On what terms?

Answers can be found on the Evolve site.

KEY POINTS

- The importance of the family as a major client system for nurses in reducing health risks and promoting the health of individuals and populations is well documented.
- The family system is a basic unit within which health behavior, including health values, health habits, and health risk perceptions, is developed, organized, and performed.

KEY POINTS—cont'd

- Knowledge of family structure and functioning, family theory, nursing theory, and models of health behavior is fundamental to implementing the nursing process with families in the community.
- Nurses need to go beyond the individual and family, and to understand the complex environment in which the family functions, to be effective in reducing family health risks. Categories of risk factors that are important to family health are biological risk, environmental risk (including economic factors), and behavioral risk.
- Several factors contribute to the experience of healthy/unhealthy outcomes. Not everyone exposed to the same event will have the same outcome. The factors that influence whether disease or other unhealthy results occur are called health risks. The accumulated risks are synergistic; their combined effect is more than the sum of the individual effects.
- An important aspect of nursing's role in reducing health risk and promoting the health of populations has been the tradition of providing services to individual families in their homes.
- Home visits afford the opportunity to gain a more accurate assessment of the family structure and behavior in the natural environment. Home visits also provide opportunities to make observations of the home environment and to identify both barriers and supports to reducing health risks and reaching family health goals.
- Health professionals increasingly have come to look toward working with clients in a more interactive, collaborative style.
- Contracting, which is making an agreement between two or more parties, involves a shift in responsibility and control, from the professional alone to a shared effort by client and professional.
- Families have varied and complex needs and problems. The nurse often mobilizes several resources to effectively and appropriately meet family health needs.
- Policy development and implementation is an important skill that the nurse uses to improve the health of families and thus improve the health and livability of communities.

CLINICAL DECISION-MAKING ACTIVITIES

1. Select one of the *Healthy People 2020* objectives and identify how biological risk (including age-related risk), environmental risk (including economic risk), and behavioral risk contribute to family health risks for that objective. Give examples.
2. Select three to four families (hypothetically or from actual situations) that represent different ethnic and socioeconomic backgrounds. Complete a family genogram and ecomap for each family, and identify and compare major health risks. Summarize your findings.
3. Select one or more agencies in which nurses work, and examine the agency and nursing philosophies and objectives with emphasis on individual care, family care, illness care, risk reduction, and health promotion. If you were to accept a position with this agency, what approach to family risk reduction would you be required to use? Is there a better way?
4. Identify three public health problems in your community, and discuss the implications of these problems for the health of families. How did you arrive at your conclusions?
5. Identify three health problems common to families in your community, and discuss the implications of the problems for the health and/or health care resources of the community. What strategies might you use to address the health problems?

Child and Adolescent Health

Cynthia Rubenstein, PhD, RN, CPNP-PC

Cynthia Rubenstein is currently the Associate Dean for the Undergraduate Program and an associate professor in the Georgia Baptist College of Nursing at Mercer University. She has over 20 years of experience in pediatric nursing, from NICU to ED to home health. She has been a practicing pediatric nurse practitioner for 16 years and has collaborated on childhood obesity prevention educational programs for Virginia.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Describe significant physical and psychosocial developmental factors characteristic of the child and adolescent population.
2. Examine the role of the nurse and discuss appropriate nursing interventions that promote and maintain the health of children and adolescents as individuals, as members of their family, and as members of the community.
3. Discuss the built environment and how it relates to major health issues of children and adolescents.
4. Explain the current status of children and their physical, emotional, behavioral, and environmental health issues.
5. Differentiate between the models for delivery of health care to the pediatric populations in the community and other settings.

Motivational Interviewing

Role of the Population-Focused Nurse in Child and Adolescent Health

Walt Disney identified the greatest natural resource of any nation as the minds of its children. The future of the world depends on how well it cares for its youth. If this population is to thrive, it must be nurtured in an appropriate environment. Focusing on the health needs and health promotion of children increases the chances that they will become adults who value and practice healthy lifestyles. Population-focused nurses have two major roles in the area of child and adolescent health:

1. The nurse provides direct services to children and their families: assessing, managing care, educating, and counseling.
2. Nurses are involved in the assessment of the community and the establishment of programs to ensure a healthy environment for this population.

The population-focused nurse has the opportunity to teach healthy lifestyles to children and caregivers and to provide family-centered care in the community setting. This chapter provides information on the assessment of children and adolescents as well as activities to promote their health. The content

includes basic principles of childhood growth and development and major health problems seen in this population. The concept of evaluating child health and implementing health education and models of health behavioral change will be explored within the context of the child's built environment. The family-centered medical home and motivational interviewing are discussed in this chapter as strategies to promote improved health behaviors within families. *Healthy People 2020* objectives (USDHHS, 2010) are used as a framework for focusing on needs of children in the community.

STATUS OF CHILDREN**Poverty Status**

There were 73.7 million children through age 17 in the United States in 2012, representing 22% of the population. Approximately 45% of them lived in low-income families, with one out of every five children living below poverty levels and 8% of America's children living in extreme poverty with a family

FIG 29-1 Percentage of children living in poverty and low income by ethnicity in 2011. (From *National Center for Children in Poverty: Basic facts about low income children, 2013*. Available at www.nccp.org. Accessed February 19, 2015.)

income of half of the federal poverty level (*Federal Interagency Forum on Child and Family Statistics, 2013; Jiang et al, 2014*). About 30% of children born to immigrant parents live below the federal poverty level compared with 19% of children of native-born parents (*AAP, 2013*). The federal poverty level for 2012 was defined as a family income of less than \$23,364 for a family of four whereas low income (the amount of income necessary to provide for the family's basic needs) is two times the federal poverty level, or \$46,728.

Minority children, most notably black and Hispanic children, have higher proportions of living at poverty or low-income levels (*Figure 29-1*). Characteristics that put children at risk for living in low-income families are parents without a high school degree, having a lack of parental employment, and living in a single-parent household. Children's ability to learn in school and reach their full cognitive ability is affected by low-income status. Children living in poverty experience a higher incidence of behavioral, social, and emotional problems (*Jiang et al, 2014*).

In addition, U.S. children face other challenges. More than 10% of American households with children experience **low food security** (*Wight & Thampi, 2010*). Low food security, a lack of available food and access to food on a regular basis, affects children's physical health, development, and school performance. Homelessness is increasing for American children and is highly correlated to poverty status and the lack of affordable housing. It is estimated that over 200,000 children have no place to live on any given day with 1.6 million U.S. children experiencing homelessness each year (*National Center on Family Homelessness, 2011*).

Immigrant Children

Children of immigrant families represent the largest growing portion of the U.S. population with approximately 18 million

immigrant children (1 in every 4 U.S. children). Of those, 89% are born in the U.S. and have citizenship (*Child Trends Data Base, 2012*). "Immigrant children" are defined as those who were born in a foreign country or children born in the U.S. who live with a parent(s) who was born in a foreign country. When compared to nonimmigrant children, immigrant children are more likely to have poor to fair health.

Immigrant children face many challenges to good health, including lack of health insurance, poverty, language barriers, and substandard housing. These families often experience or fear discrimination related to anti-immigration sentiment and this impacts access to health care and child health outcomes. Nurses should advocate for culturally and linguistically effective comprehensive health care, provide preventive screenings and referrals as appropriate, and encourage early education services for the support of optimal development in immigrant children (*AAP, 2013*).

Access to Care

Access to quality health services is one of the focus areas of *Healthy People 2020* (*USDHHS, 2010*). Children with health care coverage are more likely to have a regular and accessible source of health care. In 2012, 8.9% of all children had no health insurance. For children living in poverty, the uninsured rate for children was 13% (*U.S. Census Bureau, 2013*). With the implementation of the **Affordable Care Act** (ACA), the number of children covered by government health insurance programs has been increasing.

The **Medicaid** program, established by the Social Security Act in 1965, is a state-administered health insurance program financed jointly by the federal and state governments. Children under 18 years of age living in a household with an income level at or below 133% of the federal poverty level or children meeting disability requirements qualify for this program. The program provides health services at no cost to participants and includes outpatient visits, hospitalization, laboratory testing, immunizations, well care/preventive services, and dental care (*CMMS, 2014a*).

The **Children's Health Insurance Plan** (CHIP) was the result of federally mandated legislation passed in 1997 to expand health insurance to the nation's uninsured children. The Children's Health Insurance Program Reauthorization Act of 2009 has continued to provide insurance to over 5 million American children. CHIP is a federal and state partnership directed toward uninsured children and pregnant women in families with incomes too high to qualify for state Medicaid programs but usually too low to afford private coverage. Following federal guidelines, each state determines the model of its particular CHIP program, which includes the eligibility parameters, benefit package, payment levels for coverage, and administrative process. The program is jointly financed by the federal and state governments, and administered by the states (*CMMS, 2014b*). CHIP enrollment eligibility requirements are:

- Family income too high for Medicaid qualification (up to \$44,100 for family of 4)
- Uninsured children under 19 years of age in the home

CHIP coverage includes:

- Primary care provider/specialist visits
- Immunizations
- Hospitalizations and ED visits

Under the ACA, 21 states are mandated to expand their Medicaid coverage to fully provide comprehensive coverage to children of families at 133% of the federal poverty level. This eliminates the “stairstep” eligibility rules that were previously in place in these states and limited enrollment of children in Medicaid. Currently, Medicaid and CHIP combined provide health coverage to over 43 million children (Kaiser Family Foundation, 2013). This remains an area of outreach opportunity for nurses to identify potential families eligible for Medicaid and CHIP and provide appropriate referrals to state agencies. It is expected that as the ACA is fully implemented, health insurance coverage for children will continue to increase, improving access and health outcomes for this population.

Infant Mortality

Promotion of healthy pregnancies is a focus of *Healthy People 2020*. The *Healthy People 2020* target goal for the U.S. infant mortality rate is 4.5 infant deaths per 1000 live births. The U.S. infant mortality rate dropped to a record low of 6.15 infant deaths per 1,000 live births in 2010 (down 3.8% from 2009), although the infant mortality rate for the black population was 2.2 times greater when compared to the white population (Murphy et al, 2013). Although infant death rates have decreased, the United States has a higher infant mortality rate than 50 other nations (Central Intelligence Agency, 2014) and its position in a global ranking has consistently fallen over past years.

Infant mortality rates are critical indicators of a country’s overall health. Infant mortality rates are associated with a variety of factors such as maternal health, socioeconomic circumstances, quality and access to medical care, and community health practices.

Risk-Taking Behaviors

Risk behaviors are any behaviors that place early and middle adolescents at risk for physical, emotional, or psychological harm. Much progress has been made through health promotion and education to decrease risk factors in adolescents. The Youth Risk Behavior Surveillance System (YRBSS) indicates that many teens continue to engage in risk behaviors with smoking tobacco (15.7%), using marijuana (23.4%), and drinking alcohol (34.5%). Increasingly, drugs of abuse are inhalants. Nationally, 8.9% of high school students have breathed the contents of aerosol spray cans, sniffed glue, or inhaled any paints or sprays to get high one or more times (Kann et al, 2014). In regards to motor vehicle safety, 7.6% of adolescents reported never wearing a seat belt while 21.9% rode in the car with an intoxicated driver. Nationwide, 41.4% of teens shared that they texted or e-mailed while driving, an increase of 7% from 2011. The overall prevalence of risk behaviors indicates the continued emphasis on primary and secondary prevention and education with the adolescent population.

Despite extensive education campaigns, adolescents continue to engage in sexual activity (34%) with only 59.1% using

condoms during intercourse and 15% of teens reporting that they had sexual intercourse with four or more partners (Kann et al, 2014). These risk behaviors increase the risk for unintended pregnancies and sexually transmitted infections. Yet the birth rate for teenagers (15-19 years) did drop 6% to an all-time low rate of 29.4 per 1000 in 2010 (USDHHS, 2013a). This number remains a significant concern for public health nurses because teen pregnancy creates a significant socioeconomic burden on society and the family.

Nurses should be aware of the factors associated with increased adolescent risk-taking behaviors: poor academic performance, poor parental role models, low self-esteem, lack of a supportive social environment, and poverty. Individual assessment of an adolescent’s risk-taking behavior can provide the direction to focus education and interventions. Providing after-school extracurricular activities, identifying a positive adult role model, and engaging teens in support systems to build self-esteem can reduce risk-taking behaviors in at-risk adolescents.

The misuse and abuse of prescription stimulant medication to treat attention-deficit hyperactivity disorder (ADHD) has risen in past years. Misuse of these drugs occurs in 2% to 8% of children and adolescents. Misuse ranges from selling or trading the prescription stimulant, taking a prescription stimulant with no ADHD symptoms, taking more than the recommended dose, or taking it by a route other than the prescribed route (i.e., inhaling an oral medication) (Lakhan & Kirchgessner, 2012). It is vital to promote community and family awareness of this problem and educate children and adolescents on the dangers of taking others’ prescription medications.

CHILD DEVELOPMENT

Growth and Development

Growth is the measurable aspect of the individual’s size and follows a predictable pace that is evaluated at regular intervals to determine if a child is growing based on standard parameters. **Development** involves the observable changes in the individual and relates to physical, psychosocial, and cognitive achievements. Growth and development in children is an ongoing, dynamic process that results in physical, cognitive, and emotional changes (Figure 29-2). Health visits or well-child checkups are scheduled at key ages to monitor these processes and provide anticipatory guidance to families. Nursing assessments include growth and health status, developmental level, and the quality of the parent–child relationship. (See Tables 29-2, 29-3, 29-4, and 29-5 for considerations and issues to address at each stage.) The recommendations for preventive pediatric health care (see Resource Tool 5.A on the Evolve site) list components of well-child assessments. Further tools and specific interventions are included in Appendixes D and E.

Developmental Theories

Many developmental theories provide perspectives on children’s growth and development. The work of Erik Erikson on **psychosocial development** emphasizes that personality development culminates in the achievement of ego identity, which involves accepting oneself and having the skills for healthy

FIG 29-2 Conflict between parents and teenagers is normal as teenagers experience physical and emotional growth processes.

functioning in society. According to Erickson, development is a continual process that occurs in distinct stages with a developmental crisis needing resolution at each stage and some degree of mastery being achieved before proceeding successfully to the next stage. All new development is rooted in prior experiences, and difficulty resolving the crisis will cause problems progressing through the subsequent stages.

The work of Jean Piaget is widely used to understand the process of **cognitive development**. According to Piaget, learning results from actively manipulating objects and information followed by a mental processing of the event. As the child interacts with the environment, new objects and problems are discovered. The child creates mental schemes or thought patterns to understand the encounter. This permits the child to receive information from the world, make sense of it, and predict future events. Development occurs as the schemes increase in scope and complexity. Piaget identified four stages of cognitive development that represent increasing problem-solving ability. As one will remember from pediatric courses, these stages are sensorimotor, preoperational, concrete, and formal operations (Shaffer & Kipp, 2013).

Bronfenbrenner's **human ecology theory** emphasizes the complex relationship between the growing child and his/her immediate environment. Children are greatly influenced by the environments in which they spend time and one of the most important environments in affecting growth is the family environment. Educational programs, communities, and other environmental factors also influence the child's development. Children learn to accommodate to their environment and alter

TABLE 29-1 Developmental Screening Tools

Tool	Purpose
Denver II	Domain specific development (gross and fine motor, social, language)
Ages and Stages Questionnaire	Social and emotional development
Parents' Evaluation of Developmental Status (PEDS)	General developmental and behavioral screening
Modified Checklist for Autism in Toddlers (M-CHAT)	Autism spectrum disorder
Pediatric Symptom Checklist	Coping and mental health concerns

themselves based on environmental interactions. This theory explains that individuals do not develop in isolation but in relation to their home and family, school, community, and society (Shaffer & Kipp, 2013).

Developmental Screening

Developmental screening is a process designed to identify children who should receive more intensive assessment or diagnosis of potential developmental delays. These delays may be in any of the developmental domains—gross motor, fine motor, language, or social skills. Developmental screening promotes early detection of delays and improves child health and well-being for identified children. In the United States, 15% of children have a developmental disability such as autism, attention-deficit disorder, hearing loss or a language delay (AAP, 2011a). Nurses are critical to early screening and identification of developmental delays in young children and appropriately initiating referrals to maximize school readiness and maximum achievement. Multiple screening tools are available and are selected based on the nurse's role in the community (Table 29-1).

Children with delayed skills or other disabilities may qualify for special services that provide individualized education programs in public schools that are free of charge to families. Nurses can be effective health advocates for these children within educational settings. The passage of the updated version of the Individuals with Disabilities Education Act 2004 (IDEA) promotes a collaborative focus on meeting the needs of children with disabilities (Department of Education, 2006). Parents, educators, administrators, nurses, and other team members collaboratively develop a plan—the individualized education plan (IEP)—to help children succeed in school. The IEP explains the goals the team sets for a child during the school year as well as any special support needed to help achieve these goals.

IMMUNIZATIONS

Increasing **immunization** coverage for children remains a significant focus of the *Healthy People 2020* objectives. Currently, 92% of the nation's 19- to 35-month-old children have received all of the polio vaccinations as well as 87% of hepatitis B vaccinations in the recommended series but only 53% have received the complete hepatitis A series (CDC, 2013a). For adolescents, vaccination rates continue to rise steadily for this

age group. For those aged 13 to 17 years, 84% received the recommended tetanus-diphtheria-acellular pertussis vaccine (Tdap) and 74% received the meningococcal conjugate vaccine (MCV4). Lowest immunization rates are noted for the human papillomavirus vaccine (HPV4) series, with 53% of girls receiving one dose and only 34% receiving the full three-dose series by 17 years of age (CDC, 2013b). Routine immunization of children is very successful in the prevention of selected diseases. The ultimate challenge is making sure that children receive immunizations.

Barriers

There are several barriers to successful immunizations. These include vaccine cost, vaccine refusal by parents, vaccine shortages, and changes in vaccine scheduling and recommendations. Health disparities in vaccinations continue to exist. Children living in poverty have lower immunization rates than their peers, and African American adolescents have lower immunization rates compared with white adolescents (Burns et al, 2010). It is important to educate parents to obtain immunizations for their children and to focus on the issue at every encounter with families.

Parental fears about vaccines prevent children from getting immunized. Parents readily access the Internet for information about vaccines, and disreputable sites provide parents with incorrect vaccine information. It is critical for nurses to educate families on the safety and efficacy of vaccinations. Scientific studies have not found a relationship between immunizations and autism, sudden infant death syndrome, diabetes, neurologic disabilities, deafness, or cancer. Parents question the need to vaccinate because the incidence of vaccine-preventable diseases is low. However, Japan, Great Britain, and Sweden stopped the use of the pertussis vaccine, and within 5 years there were epidemic levels of the disease and rising death rates (CDC, 2011a). When a parent chooses not to vaccinate their child, this puts the child and others at risk.

Shortages of vaccines have periodically occurred as a result of manufacturing problems, and the U.S. Department of Health and Human Services (USDHHS) has focused on maintaining adequate manufactured supplies of vaccines. When a shortage does occur, the CDC provides priority administration guidelines for highest-risk clients. When the immunization schedule is revised, there can be delays in practitioners implementing the new recommended vaccination schedules. Nurses must continually review the CDC recommendations for any changes to implement within the public health and community settings.

Vaccines and vaccine administration costs are high and those families without health insurance often find following the vaccination recommendations financially prohibitive. A federal program established in 1995, Vaccines for Children (VFC), provides free vaccines to eligible children, including those without health insurance coverage, children enrolled in Medicaid, American Indians and Alaskan Natives, and children whose health insurance does not cover vaccines. Identifying children who qualify for VFC is a primary prevention strategy of population-focused nurses.

Immunization Theory

The goal of immunization is to protect by using immunizing agents to stimulate antibody formation (see Chapter 13 for types of immunity). Immunizing agents for active immunity are in the form of toxoids and vaccines. A toxoid is a bacterial toxin (e.g., from the bacteria that cause tetanus and diphtheria) that has been heated or chemically treated to decrease virulence but not antibody-producing ability. Vaccines are suspensions of attenuated (live) or inactivated (killed) microorganisms. Examples include pertussis (inactivated bacteria); measles, mumps, and rubella (live attenuated viruses); and hepatitis B (inactivated virus) (see Chapter 13) (CDC, 2012a).

The neonate receives placental transfer of maternal antibodies. This natural passive immunity lasts for about 2 months. Protection is temporary and is only to diseases to which the mother has adequate antibodies. The immune system of both term and preterm infants is capable of adequate antibody response to immunizations by 2 months of age. Generally, this is the recommended age to start immunizations; the exception is the hepatitis B series which begins at birth (CDC, 2012a).

The interval between immunizations is important to the immune response. After the first injection, antibodies are produced slowly and in small concentrations (the primary response). When subsequent injections of the same antigen are given, the body recognizes the antigen and antibodies are produced much faster and in higher concentration (the secondary response). Because of this secondary response, once an initial immunization series has been started, it does not need to be restarted if interrupted, regardless of the length of time elapsed. Once the initial series is completed, boosters are required at appropriate intervals to maintain an adequate concentration of antibodies. (Further information about immunizing agents is available on the Evolve website).

Recommendations

Immunization recommendations rapidly change as new information and products are available. The recommended immunization schedule guidelines for children from birth through 18 years and the catch-up immunization schedule have been approved by the U.S. Public Health Services Advisory Committee on Immunization Practices (ACIP), the American Academy of Pediatrics (AAP), the American Academy of Family Physicians (AAFP), and the American College of Obstetricians and Gynecologists (ACOG) (CDC, 2014a). Current recommendations for children and adolescents can be found on the Evolve website. The main goal of the guidelines is to provide flexibility to ensure that the largest number of children will be immunized. All health care providers are urged to assess immunization status at every encounter with children and to update immunizations whenever possible.

Contraindications

There are relatively few contraindications to giving immunizations. Minor acute illness is not a contraindication. Immunizations should be deferred with moderate or acute febrile illnesses because the reactions may mask the symptoms of the illness.

The side effects of the immunization may be accentuated by the illness (CDC, 2012a).

People with the following conditions are not routinely immunized and require medical consultation: pregnancy, generalized malignancy, immunosuppressive therapy or immunodeficiency disease, sensitivity to components of the agent, or recent administration of immune serum globulin, plasma or blood (CDC, 2012a).

Legislation

The National Childhood Vaccine Injury Act became effective in 1988. It requires providers to counsel parents and clients about the risks and benefits of the immunizing agent as well as possible side effects. Informed consent is recommended. Vaccine information statements (VIS) are used for this purpose. The VIS is an information sheet produced by the CDC that explains both the benefits and risks of a vaccine. Federal law requires that a VIS be given to parents or legal guardians before each vaccine dose is given (CDC, 2012a).

The Vaccine Adverse Event Reporting System (VAERS) is a national safety surveillance program. It requires providers and vaccine manufacturers to report any adverse effects following the administration of routinely recommended vaccinations. The program has been effective in tracking and identifying adverse effects associated with vaccinations. In 1999, VAERS detected reports of intussusception above what would be expected to occur by chance alone after the administration of the RotaShield rotavirus vaccine. Subsequently, this vaccine was pulled from manufacturing and the vaccine formulation was redeveloped (CDC, 2012a).

FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency

Teamwork and collaboration: Refers to the ability to function effectively with nursing and interprofessional teams and to foster open communication, mutual respect, and shared decision making to provide quality client care

- **Knowledge:** Recognize the contributions of other individuals and groups in helping clients achieve health goals
- **Skill:** Integrate contributions of others who play a role in helping clients achieve health goals
- **Attitude:** Respect the unique attributes and contributions of others

Question

Teamwork and Collaboration Question: The PHN Quad Council defines one competency for PHNs as analytic and assessment skills. The PHN uses available data and resources related to social determinants of health when planning care for clients. From this chapter you know that the built environment includes the physical environment where the child client lives, plays, goes to school, shops, and seeks safety. This environment assists the child in managing health risks. Many persons and groups assist the child in this endeavor. To determine the potential or real health risks of a child client, what information would you gather and from whom? How would you use the data from your assessment? Name a health risk and discuss the interventions you might plan and the health education you would offer to promote the child's health. What would you see as the role of other individuals and groups in the community to assist you or to take the lead in assisting the child and family? Be specific.

THE BUILT ENVIRONMENT

A **built environment** is simply defined as the person's human-made or modified surroundings in which they live, work, and partake in recreation (Renalds et al, 2010). This is the actual physical environment in which children live and includes neighborhood access to recreation opportunities, grocery stores, the home environment, and the consideration of general safety for children in their physical environments. A child's built environment is influential in the managing of risk factors for obesity, amount and type of physical activity, risk for injuries, and exposure to environmental toxins. Therefore, as nurses, assessing a child's built environment provides a foundation for identifying interventions and education to promote health and prevent injuries and diseases. (See **Evidence-Based Practice box**.)

EVIDENCE-BASED PRACTICE

California has a large Hmong population. Despite having health insurance, community providers noted that the Hmong children consistently had lower than national and state levels for immunizations. The authors conducted a study to determine the primary barriers for this cultural group related to immunizing their children. The study identified two primary barriers to immunization: lower socioeconomic status and greater use of traditional Hmong health care (shamans and herbalists) (Baker et al, 2010).

Nurse Use

We often make assumptions about the barriers to positive health decisions or behaviors. This study demonstrates that cultural differences can be influential in making health care decisions. By targeting the specific population of concern, nurses can identify the specific barriers that prevent parents from obtaining preventive health care. Public health nurses can then develop interventions and education to address those specific barriers and improve pediatric health.

Baker D, Dang M, Diaz R: Perception of barriers to immunization among parents of Hmong origin in California. *AJPH* 100:839–845, 2010.

Obesity

Obesity rates in American children have risen to epidemic levels over the past few decades. These increases are noted for all children aged 2 to 18 years regardless of gender or ethnicity. The CDC defines **overweight** as a body mass index (BMI) at or above the 85th percentile and lower than the 95th percentile, and **obesity** is defined as a BMI at or above the 95th percentile for children of the same age and sex when plotted on the CDC growth charts (Table 29-2) (CDC, 2012b). Recently, it has been recommended to monitor the World Health Organization (WHO) growth standards for children younger than 2 years. Those infants and toddlers who measure above the 97.7th percentile of WHO weight for recumbent length growth standards are considered high risk for obesity (Ogden et al, 2014).

The 2011-2012 prevalence of the overweight and the obese combined is 23% in children ages 2 to 5 years, 35% for children ages 6 to 11 years, and 35% for adolescents 12 to 19 years. The prevalence of obesity in children is approximately 8% for ages 2 to 5 years, 18% for ages 6 to 11 years, and 21% for ages 12 to

TABLE 29-2 Centers for Disease Control and Prevention Classification of Body Mass Index (BMI) for Children Age 2 Years and Above

Plotted Percentile for Age and Gender	BMI Interpretation
<5th percentile	Underweight
5th-85th percentile	Normal
85th-95th percentile	Overweight
>95th percentile	Obese

FIG 29-3 Obesity prevalence for 2 to 19 years. (Data from Fryer C, Carroll M, et al: *Health E-Stat: Prevalence of obesity among children and adolescents: United States, trends 1963-1965 through 2011-2012*, 2013. Centers for Disease Control and Prevention, National Center of Health Statistics. Available at www.cdc.gov. Accessed March 15, 2015.)

19 years (Ogden et al, 2014) (Figure 29-3). Comparing these 2012 National Health and Nutrition Examination Survey (NHANES) findings with 2004 NHANES results demonstrates that prevalence rates for obesity have remained stable with a decrease (5.5%) for the 2 to 5 year age range (Ogden et al, 2014). In addition, 8.1% of infants and toddlers had high weight for recumbent length, indicating a substantial risk for obesity in childhood.

The physiological consequences of childhood obesity are extensive and significantly impact the health status of American children. Research has clearly identified strong relationships between being obese as a child and increased disease risk and disease burden in the cardiovascular, metabolic, musculoskeletal, respiratory, and renal systems (May et al, 2012; Papan-dreou et al, 2012; Papoutsakis et al, 2013; Paulis et al, 2014; Morandi & Maffei, 2013). Another critical consequence for children is the negative psychological and social impact of obesity with decreased self-esteem; higher incidence of depression, sadness, and anxiety; problems with social relationships; and higher reports of being the victim of bullying (Puhl et al, 2012; Ting et al, 2012; Griffiths et al, 2010).

Multiple factors contribute to the likelihood that a child will become overweight or obese. Genetics and genetic susceptibility are certainly contributing components, although the genetic composition of the population has been stable over time, thereby failing to account for a sudden rise in obesity in recent years (Garver et al, 2013). Within the literature, three modifiable risk factors for the development of childhood obesity have been identified. These risk factors are screen time (including television, computer/tablet, phone, and video games), physical activity engagement, and dietary intake/eating behaviors (Hoel-scher et al, 2013; Vollmer & Mobley, 2013; Fakhouri et al, 2013).

A rising comorbidity for childhood obesity is type 2 diabetes mellitus (T2DM). Currently, about 151,000 U.S. children and adolescents have T2DM (CDC, 2013c). Children and adolescents diagnosed with type 2 diabetes are usually between 10 and 19 years old, are obese with a strong family history for T2DM, and have insulin resistance (Springer et al, 2013). Most children and adolescents with T2DM have poor glycemic control with hemoglobin A1C levels between 10% and 12%. T2DM affects all ethnic groups but occurs more frequently in non-white groups with the highest prevalence in American Indian youth (CDC, 2013c).

Screening for T2DM is recommended for children with a BMI of 85th to 95th percentile with two risk factors of family history of diabetes, belonging to a racial minority group, or with signs of insulin resistance; all children with a BMI above the 95th percentile; and at age 10 years or onset of puberty. In addition, these children should be screened for hypercholesterolemia and hypertension, which are also associated with childhood obesity (Springer et al, 2013). Nurses can be instrumental in the management of T2DM in children by educating and counseling.

Built Food Environments

A discussion on the risk factors for childhood obesity should be considered within the context of a child's environment. The emerging research on the relationship of built environments and obesity evaluates the factors within an individual's environment that may contribute on a macro- or micro-level to the development of obesity. The current literature focuses on the role of the built environment in increasing energy consumption while decreasing energy expenditure and looks at the interaction of the individual with his or her environment that influences health (Gose et al, 2013).

For children, the built environment as it relates to nutrition includes both macro- and micro-level considerations. On the community, or macro level, the factors of the built environment that influence nutrition and risk factors for obesity include a greater reliance on convenience foods and fast foods, increasing portion sizes, and the **food landscape** (He et al, 2012). The food landscape evaluates the accessibility and availability of healthy foods, and it is clear that low-income neighborhoods have limited access to stores offering fruits and vegetables (Dutko et al, 2012).

Close proximity to fast food restaurants and convenience stores are negatively correlated with daily fruit and vegetable consumption for school age children (He et al, 2012). Many

urban and rural Americans live in areas termed as **food deserts**, which are defined as having limited access to affordable and nutritious foods. The inability to easily obtain nutritious foods has been identified as a contributing factor to the development of obesity and obesity-related diseases. More than 23.5 million American households live in low-income areas more than 1 mile from a supermarket (Dutko et al, 2012).

The factors on the macro level interact closely with those factors on the micro level. For children, the micro-level factors of the built environment that influence nutrition include the home food environment. The home food environment factors include home availability and accessibility of fruits and vegetables, parent role modeling, child feeding practices, and general parenting style (Osei-Assibey et al, 2012).

Obesity Prevention

A united national movement is underway to reduce risk factors for developing obesity in children. The current White House administration is promoting the “Let’s Move!” campaign as a comprehensive and coordinated initiative to prevent childhood obesity. The initiative emphasizes four primary components: healthy schools, access to affordable and healthy food, raising children’s physical activity levels, and empowering families to make healthy choices (White House, 2014).

HEALTHY PEOPLE 2020

The *Healthy People 2020* priority focus areas of prevention include a direct focus on achieving the goals of reducing the proportion of children who are overweight or obese, increasing the proportion of daily servings of fruits for children, and increasing the proportion of daily servings of vegetables for children.

From: US Department of Health and Human Services: Healthy People 2020, Wash DC, 2010, US Government Printing Office.

Promoting good nutrition and dietary habits is a key to maintaining child health. The first six years are the most important for developing sound lifetime eating habits. Parents as primary caregivers are most influential in teaching children specific eating behaviors through their own child feeding practices. **Child feeding practices** are a primary factor in the development of eating behaviors for children and include the level of control the parent or caregiver exerts over the type and amount of food the child eats, the role modeling of eating behaviors, the feeding cues given to the child, and the actual

mealtime environment and routine. The resulting learned eating behaviors then follow an individual through adolescence and into adulthood (Anzman et al, 2010).

Collaboration between agencies is critical to implementing community based interventions to reduce childhood obesity. Shape NC is an innovative partnership that provides grant funding and training resources to improve obesity risk factors for young children. The resources extend to 100 North Carolina counties and improve policies, practices and outdoor environments in child care centers and communities so that more children are entering kindergarten at a healthy weight. Within 18 months of implementation, Shape NC has shown an increase from 49% to 65% of daycares meeting best practices for obesity prevention. The program is well on its way to reaching the goal of 75% of all daycares meeting best practices and supporting young children in maintaining a healthy weight (National Institute for Health Care Management, 2012).

Nutrition Assessment

Physical growth serves as an excellent measure of adequacy of the diet. Measurements of height and weight, plotted on appropriate growth curves at regular intervals, allow assessment of growth patterns. Head circumference is followed until age 3. For children less than 2 years, the weight for recumbent length is assessed at regular intervals. Those infants and toddlers who measure above the 97.7th percentile of WHO growth standards are considered high risk for obesity. For children 2 years and older, the **body mass index (BMI)** should be calculated (kilograms/[meters]²) based on the weight and height measurements. BMI for age and gender is plotted on the standardized BMI-for-age charts available through the CDC. Children falling outside the expected growth patterns can then be identified and interventions implemented (ADA, 2008).

A 24-hour diet recall by the parent is a helpful screening tool to assess the amount and variety of food intake. If the recall is fairly typical for the child or adolescent, the nurse can compare the intake with basic recommendations for the child’s or adolescent’s age. It is important to ask about parent’s concerns regarding diet. It is also helpful to look at the family’s meal patterns. Other important parts of the nutrition assessment include amount of physical activity and any behavior problems that occur during meals. Table 29-3 offers guidelines to daily requirements for all ages.

TABLE 29-3 Daily Dietary Recommendations: Childhood and Adolescence

Food Group*	2-3 Years	4-8 Years	9-13 Years	14-18 Years
Milk: Try to select low-fat sources of milk, cheese, yogurt	2 cups	2-2½ cups	3 cups	3 cups
Meat and Beans: Lean meats, beans, eggs, seafood	2 oz	4 oz	5 oz	5-6½ oz
Vegetables: Fresh vegetables best choice	1 cup	1-1½ cups	2-2½ cups	2½-3 cups
Fruits: Limit fruit juices	1 cup	1-1½ cups	1½ cups	2 cups
Grains: Half of grains should be whole grains	3 oz	5 oz	5-6 oz	6-8 oz
Cooked pasta or rice, bread, cereals				

*Recommendations are per day for each group.

Physical Activity

Physical activity levels contribute significantly to the overall health of children, particularly related to their risk for obesity. Fewer children are meeting the recommended physical activities levels today compared with previous generations. There are several contributing factors including the physical built environment, changes in school practices for physical education, and increased screen time.

Some children are at higher risk for not getting enough physical activity, particularly those children living in poverty in urban neighborhoods that are unsafe for outdoor playtime and with limited access to playgrounds and parks (CDC, 2010a). Even in suburban areas, parents are wary of allowing their children to play unsupervised outdoors. Few families live in locations where they can regularly walk or bike to school or for errands. As a society, Americans have become increasingly sedentary, which contributes greatly to obesity and the development of many chronic diseases.

The CDC recommends that every child and adolescent gets 60 minutes of physical activity daily. This should primarily consist of moderate-intensity aerobic activity and it is recommended that vigorous-intensity aerobic, muscle strengthening, and bone strengthening activities be incorporated at least three times a week (CDC, 2011b). This can be accumulated throughout the day with smaller increments of activity, those obtained during school, at home, and while engaged in leisure or sports activities. It is important to encourage families to be active

together since this promotes greater physical activity levels in children. It also provides family time for promoting family engagement, connection, and communication. Table 29-4 shows developmental guidelines for physical activity promotion.

According to the most recent NHANES data, all age groups are failing to meet recommended daily activity levels. For children 6 to 11 years of age, 41.8% get 60 minutes of moderate activity daily; this drops to 7.6% for 12- to 15-year-olds and just 7.7% for 16- to 19-year-old adolescents (Tudor-Locke et al, 2012). Of significant note, girls are much more sedentary than boys, with the disparity increasing with age.

Schools

Children and adolescents spend much of each weekday in school. Based on the results of a recent study, there is strong evidence that physical activity improves academic achievement with grades and standardized tests (CDC, 2010b). Currently, 48% of high school students attend physical education classes one or more days a week with only 29.4% attending physical education classes five days per week (Kann et al, 2014). In addition, 54% of adolescents in the United States play on at least one sports team, with more males participating in sports than females.

Schools have a vital ability to influence student health and academic achievement through federal and state school policies. Quality physical education requires adequate time (at least 150 minutes for elementary schools and 225 minutes for secondary

TABLE 29-4 Physical Activity Recommendations by Age Group

Age Group	Recommendations
Infants and toddlers (0-2 years)	Safe, minimally structured play environment Promote outdoor activities and exploration under supervision of a responsible adult No television viewing Organized exercise classes are not recommended
Preschoolers (2-6 years)	Encourage free play and exploration under proper supervision Provide unorganized play with opportunity for running, swimming, tumbling, throwing, catching with supervision Take short walks with family member; limit use of strollers for transportation Limit television viewing to <2 hours/day
Elementary school age (6-9 years)	Encourage free play with emphasis on basic skills acquisition Promote walking, dancing, jumping rope Organized sports (soccer, baseball) can be started but should be flexible with rules, allowing free time in practice Take walks, short bike rides together as a family Limit television viewing, video games to <2 hours/day
Middle school age (10-12 years)	Encourage physical activities enjoyed with families and friends Emphasize skills acquisition with increased focus on strategies Participation in complex sports (football, basketball) is appropriate Weight training can begin with good supervision and small weights Limit television viewing, video games to <2 hours/day
Adolescents	Encourage physical activities that are enjoyed with friends and considered fun to the teen Promote personal fitness—running, yoga, dance, swimming Encourage active transportation—biking and walking Weight training is safe for this age Limit television viewing, video games to <2 hours/day

Data from American Academy of Pediatrics: Policy statement: active healthy living: prevention of childhood obesity through increased physical activity. *Pediatrics* 117(5):1834–1842, 2006. Reaffirmed by the American Academy of Pediatrics, as a continuing policy May 2009.

schools per week), teacher preparation and professional support, and adequate facilities and class size. Recommendations to meet high levels of physical activity in schools include strategies that integrate physical activity into structured classroom activities, encouraging more unstructured play, expanding extracurricular activities promoting physical activity, and guiding adolescents in developing their own personal fitness goals and plans (CDC, 2013d).

The *Healthy People 2020* objectives include a focus on increasing the proportion of adolescents and children who engage in moderate to vigorous activity on a daily basis, increasing the proportion of adolescents who spend at least 50% of school physical education class time being physically active, and increasing the proportion of adolescents who participate in daily school physical education. Nurses will want to be active in educating school administrators and school boards on the benefits of physical activity in improving children's and adolescents' physical health, cognitive performance, and behavior. Nurses should be engaged in policy revisions in the school systems to restore compulsory, quality, daily physical education classes; retain school recess; and expand extracurricular activities that promote physical activity before and after schools.

Media

The concept of “media” has changed significantly over the past decade. In addition to television and movies, **media** now includes the Internet, video games, computers/tablets, and cell or smartphones. Social media is another avenue in which Americans interact with peers, family, and friends. With the extensive incorporation of media and social media into our society, its impact on children and adolescents is significant. Children and adolescents now spend more time engaged with media than any other activity except for sleeping; on average over 7 hours each day. Currently, 20.8% of 6- to 11-year-olds and 26.1% of teens have excessive screen time (Wethington et al, 2013). With video viewing alone, adolescents spend an average of 5 hours online, 8 hours on a mobile device, and 99 hours per month watching videos of some type (Office of Adolescent Health, 2013).

Research has strongly correlated increased use of media with an increased sedentary lifestyle, obesity, hypercholesterolemia, and hypertension. In addition to the negative physiological effects, exposure to such extensive media has been correlated to desensitization to violence and increased aggression, greater sexual content exposure and increased sexual activity, and lower academic performance if the child or adolescent has a television in the bedroom (AAP, 2009a).

Interventions need to be based on the goal of lifestyle changes for the entire family. The AAP recommends that children and adolescents over the age of 2 years be limited to 2 hours per day of media screen time and that children under 2 years do not have any screen time (Strasburger et al, 2010). Televisions, video game systems, tablets, phones, and computers should be kept out of the child's or adolescent's bedroom and in open spaces in the home (Wethington et al, 2013). Parents should engage in media and social media viewing with their children to discuss

appropriate content, avoid exposing young children to PG-13 or R-rated movies, and role model limited media usage.

Nurses are uniquely positioned within the community to effect change in the childhood obesity rates. With the knowledge and skills to identify children as at risk or obese, nurses can develop interventions for healthy change for these families and refer to providers appropriately. Education on healthy eating, child feeding practices, and physical activity levels are necessary for individuals, families, and groups within the community. Nurses have the abilities and knowledge to develop creative programs to provide families with the skills to grow their own gardens and cook healthy meals. Advocating for exercise trails and physical activity programs within the community will improve the health of families living in the vicinity. It is clear from obesity research that a community-based approach is most effective at reducing obesity rates and improving health. The following list highlights some guidelines on nutrition education for families:

- Breastfeeding is the recommended exclusive feeding choice for infants from birth to 6 months and should be continued until 1 year of age. Breastfeeding is associated with a lower risk for developing childhood obesity.
- Parents' responsibilities are to provide healthy meals and snacks for their children. It is their child's responsibility to decide how much to eat.
- Limit 100% fruit juices and avoid all other sugary beverages. These are empty calories and fill children up so they are not hungry at meals. Appropriate beverages are milk and water.
- For toddlers and preschoolers, it sometimes takes 10 to 15 tastes of a new food before they learn to like that food. Be persistent!
- Parents should role model good eating behaviors—lots of fruits and vegetables, no sugary beverages, and little to no “junk” food or “fast” food.
- Family meals are important for teaching manners, listening to hunger cues, and having quality family time together.
- Encourage children to help with food selection and preparation as appropriate to developmental skills. Allow them to select new foods to try in the produce section of the grocery store.
- Avoid using food as a punishment or reward. Do not expect your child to “clean their plate.” These feeding techniques have been associated with increased risk for obesity.
- Turn off the television during meals and do not let your child eat in front of the television. Children do not listen to their cues of satiety when distracted.
- Cook meals at home. Broil, bake, stir-fry, or poach foods rather than frying.
- Modify family eating habits to include low-fat food choices. Serve calorically dense foods that incorporate the food guide pyramid: whole grains, fruits, vegetables, lean protein foods, and low-fat dairy products.
- Encourage family members to stop eating when they are satisfied. Encourage recognizing hunger and satiation cues.
- Schedule regular times for meals and snacks. Include breakfast and do not skip meals.

- Have low-calorie, nutritious snacks ready and available. Avoid having empty-calorie junk foods in the home. Plan for healthy snacks when eating “on the run,” such as granola, fruits, and nuts.
- Decrease salt, sugar, and fat. Increase complex carbohydrates—whole grains.
- Maintain regular activity (e.g., exercise, sports) and limit television viewing.
- Select family activities and vacations that include or focus on physical activity (hiking, bicycling, swimming).

Injuries and Accidents

Unintentional injuries are the leading cause of morbidity and mortality in the United States for young people ages 1 to 19 years. Unintentional injuries are any injuries sustained by accident such as falls, drowning or motor vehicle accidents. It is one of the most under-recognized public health problems facing the United States today, with more than 9,000 children dying from a preventable injury in 2009. Reducing injuries from unintentional causes, as well as from violence and abuse, is a goal of *Healthy People 2020*. More than 8.4 million children were seen in emergency departments in 2009 for treatment from an unintentional injury (MMWR, 2012).

Motor vehicle crashes remain the leading cause of death for unintentional injuries in children and teens. One research study found that 72% of almost 3500 observed car and booster seats were mishandled in a way that could possibly increase a child’s risk of injury during a crash. It is recommended by the National Highway Traffic Safety Administration for children to remain in booster seats until they are at least 8 years of age or 4 feet, 9 inches tall (Figure 29-4). A study found that booster seats reduced injury risk by 59% compared with seat belts alone for children ages 4 to 7 years. National standards recommend that all children ages 12 years and younger ride in the back seat because they are at significant risk of injury from airbag deployment, and the back seat is known as the safest part of the vehicle if a crash occurs. Even for adolescents to age 16 years, sitting in the back seat is associated with a 40% decrease in the risk of serious injury (Borse et al, 2008; CDC 2014b).

Drowning, poisonings, and burns account for most of the other deaths. For infants, the leading cause of death

is suffocation (Table 29-5). From 2000 to 2009, the rates of unintentional infant suffocation deaths increased by 54% leading to an overall increase in newborn and infant death rates (MMWR, 2012). To effectively implement prevention strategies, nurses need to understand the developmental factors that place this population at risk.

Developmental Considerations

Infants. Infants have the second highest injury rate of all groups of children; their small size contributes to some types of injury. The small airway may be easily occluded. The small body fits through places where the head may be entrapped. In motor vehicle crashes, small size is a great disadvantage and increases the risk for crushing or being propelled into surfaces.

The second half of infancy brings major accomplishments in gross motor activities. Rolling, sitting, pulling up, and walking bring safety concerns. Their developing motor skills remain immature, which limits their ability to escape from injury and places them at risk for drowning, suffocating, and burns (CDC, 2012c).

Toddlers and Preschoolers. This population experiences a large number of nonfatal falls and being struck by or against an

FIG 29-4 Children should always be restrained while riding in a vehicle.

TABLE 29-5 Leading Causes of Unintentional Injury Death Among U.S. Children 0 to 19 Years, 2000-2009

Rank	0-1 Years	1-4 Years	5-9 Years	10-14 Years	15-19 Years
1	Suffocation (77%)	Drowning (31%)	MVT-related* (49%)	MVT-related* (68%)	MVT-related* (67%)
2	MVT-related* (8%)	MVT related* (25%)	Drowning (15%)	Transportation Other (15%)	Poisoning (9%)
3	Drowning (4%)	Fire burns (12%)	Burns/fire (11%)	Drowning (10%)	Drowning (6%)
4	Fire burns (2%)	Transportation Other (10%)	Transportation Other (9%)	Burns/fire (6%)	Transportation Other (4%)
5	Poisoning (2%)	Suffocation (9%)	Suffocation (3%)	Suffocation (5%)	Falls (1%)

*MVT-related: Motor vehicle traffic-related includes motor vehicle injuries, pedestrian injuries.

Centers for Disease Control and Prevention, National Center for Injury Prevention and Control: National Action Plan for Child Injury Prevention, Atlanta (GA), 2012C, CDC, NCIPC.

object. They are active and lack an understanding of cause and effect, and their increasing motor skills make supervision difficult (CDC, 2012c). They are inquisitive and have relatively immature logic abilities.

School-Age Children. The school-age group has the lowest injury death rate. At this age, it is difficult to judge speed and distance, placing them at risk for pedestrian and bicycle accidents. Boys are twice as likely as girls to sustain a nonfatal bicycle injury, and the highest injury rate is at 10 to 14 years of age. Universal use of bicycle helmets would prevent most deaths. Peer pressure and lack of parental role modeling often inhibits the use of protective devices such as helmets and limb pads (CDC, 2012c).

Adolescents. Motor vehicle-related injuries and violence are the leading causes of morbidity and mortality for adolescents. Risk-taking becomes more conscious at this time, especially among boys. The injury death rates for boys are twice as high as those for girls. Adolescents are at the highest risk of any age group for motor vehicle deaths and fatal poisonings. Use of weapons and drug and alcohol abuse play an important role in injuries in this age group. Homicides are the second leading cause of death for U.S. adolescents (Borse et al, 2008; CDC, 2012c).

In a survey of adolescents, 24.7% reported being in a physical fight at least one time in the previous 12 months, and 7.1% reported missing school at least one day in the previous month because they felt unsafe at school or on their way to school. Suicide is the third leading cause of death among youths between the ages of 15 and 24 years. Poor social adjustment, psychiatric problems, and family disorganization increase the risk for suicide (Kann et al, 2014; Federal Interagency Forum on Child & Family Statistics, 2013).

For all ages, families should be given anticipatory guidance in the high-risk areas for each age group to promote safety and injury prevention. Nurses can use community centers, schools, workplaces, and health centers to provide teaching to families on how to prevent injuries in their children.

Sports Injuries

Encouraging participation in team sports and individual sports and active leisure activities can increase the physical activity of children and adolescents. Children who are active in sports should have annual sports physicals, and guidelines for sports safety should be discussed as follows:

- Children should be grouped according to weight, size, maturation, and skill level.
- Qualified and competent persons should be available for supervision during games and practices.
- Adequate and appropriate-size equipment should be available.
- Goals should be developmentally and physically appropriate for the child.

Approximately 2.6 million children a year are seen in the emergency department for sports and recreational injuries (CDC, 2012c).

To protect children and adolescents during sports, families require education on selecting age and physically appropriate

FIG 29-5 Involvement in developmentally appropriate sports promotes physical activity and skills acquisition.

activities, using the correct safety gear, maintaining the safety gear in good condition, and practicing good body mechanics (Figure 29-5). Management of acute injuries sustained during sports should be monitored closely by coaches and primary care providers. The incidence of concussions, or brain injuries, is 3.8 million per year in the United States (USDHHS, 2013b).

The state of Washington passed the first law on concussion in sports in 2009, the Zackery Lystedt Law. Between 2009 and 2012, 43 states (as well as the District of Columbia) passed laws on concussions in sports for youth and/or high school athletes. Many of these laws are known as “Return to Play” laws. The CDC’s *Heads Up* program provides recommendations and educational materials to health professionals, coaches, and parents to increase knowledge related to sports-related concussions in youth. Recognition of concussions and proper treatment is critical to prevent repeat concussions, which can cause long-term problems (USDHHS, 2013b) (Table 29-6).

Child Maltreatment

In 2011, 3.7 million children were reported abused or neglected with about 681,000 cases confirmed by Child Protective Services. For the same year, about 1750 U.S. children (2.1 deaths per 100,000 children) died as a result of maltreatment (CDC, 2013e). In 2011, 35% of victims of child maltreatment

FIG 29-6 U.S. child deaths from maltreatment, 2013. Estimated 1,217 deaths in 2013. (U.S. Department of Health and Human Services, Administration for Children and Families, Administration on Children, Youth and Families, Children’s Bureau: Child Maltreatment 2138, 2013. Available from http://www.acf.hhs.gov/programs/cb/stats_research/index.htm#can.)

were less than 3 years of age and infants less than 1 year of age had the highest incidence of abuse.

Child maltreatment is defined as any act or series of acts of commission or omission by an adult that results in harm, potential for harm, or threat of harm to a child. Acts of commission (abuse) include physical abuse, sexual abuse, and psychological abuse; acts of omission (neglect) include failure to provide (physical neglect, emotional neglect, medical/dental neglect, educational neglect) and failure to supervise (inadequate supervision, exposure to violent environments) (Figure 29-6) (Leeb et al, 2008).

Child maltreatment occurs in all socioeconomic, racial, and ethnic groups. Yet African American, American Indian/Native American, and multiracial children experienced higher rates of victimization. Children under the age of 4 years and those children with special needs are at highest risk. Children are most likely to be maltreated by their parents, and common parental characteristics include a poor understanding of child development and children’s needs, history of abuse in the family of origin, substance abuse in the household, and nonbiological transient caregivers in the home (e.g., mother’s boyfriend). Families at highest risk for maltreatment are those families experiencing social isolation, family violence, parenting stress, and poor parent–child relationships (Zimmerman & Mercy, 2010).

The consequences of child maltreatment are often devastating. Children experience long-term physical consequences as well as negative psychological and behavioral consequences. **Abusive head trauma (AHT)**, also known as shaken baby syndrome, results from violent shaking or shaking and impacting of the head of an infant or young child. Intracranial injury, subdural bleeding, retinal hemorrhages, and skull fractures can result, leading to death or survival with associated motor impairments, visual deficits, and cognitive deficits (AAP, 2012a).

Preventive strategies are necessary to reduce the incidence of child maltreatment. Parental education should be started prenatally to prevent AHT. Nurses can use home visiting programs, peer mentoring programs, preschool and Head Start programs, and public health centers to identify at-risk families and provide support and education to prevent child maltreatment. Nurses can provide education to those individuals in the community who work with children on recognizing signs of abuse and how to report suspected maltreatment. Increased awareness within the community and early intervention can prevent maltreatment from occurring and rescue children from violent and unsafe abuse situations.

Injury Prevention

Health care provider offices, schools, community centers, public health centers, and daycare/preschool facilities provide opportunities to teach children, adolescents, and their families about prevention of injuries. Safety and health promotion can be incorporated into required health education courses within the school systems. Community-sponsored car seat and seat belt safety checks and safety fairs are another way to educate families (CDC, 2012c). Early home visitation programs to high-risk families resulted in a reduction of 48% in child abuse. Injury prevention is a topic that should be addressed at all health visits (Zimmerman & Mercy, 2010).

Reducing Gun Violence. Although rates have fallen, deaths of children and adolescents from firearm-related injuries were 11.4 per 100,000 in 2009. The NYRBSS survey of adolescents found that 5.1% had carried a gun on at least one day during the previous month. Witnessing gun violence or knowing the victims affects children indirectly (AAP, 2012b).

A recent study compared firearm-related mortality rates in urban and rural settings. The study found no significant

differences in the death rates between the settings but noted a difference in the firearm intent that resulted in deaths for children and adolescents. The urban victims died from high rates of firearm homicide while the rural victims experienced high rates of firearm suicide and unintentional firearm-related accidental deaths. This study provides evidence that to reduce firearm mortality effectively, prevention strategies should be geared for the specific type of firearm injury issue within the community of interest (Nance et al, 2010).

Characteristics associated with gun violence include history of aggressive behaviors, poverty, school problems, substance abuse, and cultural acceptance of violent behavior. Young children are inquisitive and often imitate in play what they see in the media and on television. A significant number of accidental firearm injuries and deaths in children occur in the homes of friends and family members (AAP, 2012b). Interventions must begin early and address each of these factors.

The *Healthy People 2020* objectives seek to reduce the number of high school students who carry weapons. Nurses can actively participate in efforts to reduce gun violence among young people in the following ways (AAP, 2012c):

- Urge legislators to support gun control legislation, assault weapons bans, and eliminate gun show loopholes.
- Collaborate with schools to develop programs to discourage violence among children.
- Encourage families to remove guns from their homes. If unable to do this, educate families to:
 - Store all firearms unloaded and uncocked in a securely locked container. Only the parents should know where the container is located.
 - Store the guns and ammunition in separate locked locations.
 - When handling or cleaning a gun, never leave it unattended, even for a moment; it should be in the parent's view at all times.
- Initiate community programs focusing on gun storage and safety at school.
- Educate parents on communicating with the homeowners of the homes their children visit regarding gun access and safety.
- Children and adolescents learning to hunt in rural areas should take gun safety courses.
- Identify populations at risk for violence and target aggression or anger management.
- Discourage mixing alcohol or drugs with guns.
- Encourage families to avoid gun violence in media sources at home.

Promoting Safe Playgrounds and Recreation Areas. Schools, daycare centers, families, and community groups often need guidance toward developing safe places for children to play. Each year, more than 200,000 children are treated in emergency departments for injuries sustained on playgrounds and play sets. Approximately 45% of playground-related injuries are severe injuries and include fractures, internal injuries, concussions, dislocations, and amputations. Between 1990 and 2000, 147 children under the age of 14 died from playground-related injuries. These deaths were attributable to

strangulation (56%) and falls (20%) to the playground surface, with most of these deaths (70%) occurring on home playgrounds (CDC, 2012d).

The U.S. Consumer Product Safety Commission has published guidelines for public and home playground safety. Guidelines cover structure, materials, surfaces, and maintenance of equipment:

- Playgrounds should be surrounded by a barrier to protect children from traffic.
- Activity centers should be distributed to avoid crowding in one area.
- Surfaces should be finished with substances that meet Consumer Product Safety Commission (CPSC) regulations for lead.
- Durable materials should be used.
- Sand, gravel, wood chips, and wood mulch (not CCA treated) are acceptable surfaces for limiting the shock of falls.
- Equipment should be inspected regularly for protrusions that could puncture skin or entangle clothes.
- Inspect equipment for openings/angles that allow for possible head entrapment.
- Multiple-occupancy swings, animal swings, rope swings, and trampolines are not recommended.

The developmental skills of specific ages are incorporated, as well as recommendations for physically challenged children. Nurses can use these guidelines to help the community establish standards for play areas (Figure 29-7).

Nurses share responsibility in the prevention of intentional and unintentional injuries in the pediatric population. Assessment of the characteristics of the child, family, and environment identifies risk factors. Interventions include anticipatory guidance, modification of the environment, and safety education. Education focuses on age-appropriate interventions based on knowledge of leading causes of death and risk factors. Topics to consider are listed in Box 29-1.

FIG 29-7 Playground injuries are frequent among young children.

BOX 29-1 Injury Prevention Topics

- Car restraints, seat belts, air-bag safety
- Preventing fires, burns
- Poison prevention
- Preventing falls
- Preventing drowning, water safety
- Bicycle safety
- Safe driving practices
- Sports safety
- Pedestrian safety
- Gun control
- Decreasing gang activities
- Substance abuse prevention

(See also the Evolve website)

HEALTH PROBLEMS OF CHILDHOOD**Acute Illnesses**

Acute illnesses are those illnesses with an abrupt onset and are usually of a short duration. For children, it is common for viruses to spread easily through daycares, preschools, and school systems. Nurses use developmental factors at each age to plan assessment and intervention strategies to prevent the spread of illnesses between children. Community-focused interventions, education, and programs can prevent many childhood illnesses.

Hand washing is a simple and reliable strategy to reduce the incidence of acute illnesses in children. The **How To** box below provides guidelines for the nurse to teach families about hand washing. Infants and young children are particularly at risk for contracting viral and bacterial illnesses spread by contact because their immune systems are not yet fully developed. Focusing community education on preschools, daycare centers, and other programs that serve the families of infants and young children can reduce the occurrence of acute illnesses (Aronson & Shope, 2013).

Several strategies can be used to reduce the occurrence of acute illnesses as follows: sanitizing objects such as toys that are handled by multiple children each day to prevent the spread of diseases; practicing good hand hygiene and diaper disposal techniques in daycares to prevent the spread of illnesses; and educating parents, daycares, and schools on when to keep children home to prevent putting others at risk for illness (Aronson & Shope, 2013).

Influenza is a common viral illness that affects children and adolescents primarily during the winter months. It is a highly contagious acute febrile illness of the nose, throat, and lungs that leads to missed school days and can result in complications including pneumonia and infrequently death. The best prevention strategy is vaccinations for all children ages 6 months and above. It is important to educate families about the need for vaccination and home management of symptoms (Aronson & Shope, 2013).

Nurses can focus on preventive measures and promote high vaccination rates, good hand washing hygiene and early identification to prevent the spread of illness. If a child or adolescent

HOW TO Teach Families About Hand Washing

Use the guidelines below when counseling families about hand washing.

Always wash your hands before:

- Preparing foods
- Eating
- Touching someone who is sick
- Inserting or removing contact lenses

Always wash your hands after:

- Preparing foods, particularly raw meats or poultry
- Using the toilet
- Changing a diaper
- Touching animals, animal toys, leashes, or animal waste
- Blowing your nose, coughing, or sneezing into your hands
- Touching someone who is sick

Or anytime you feel that your hands need washing!

How to wash your hands:

- Wet your hands with warm running water
- Apply soap (liquid, bar, or powder)
- Lather your hands well
- Rub your hands vigorously for at least 20 seconds (sing the "Happy Birthday" song)—scrub all surfaces including between your fingers, under your nails, backs of your hands, and your wrist
- Rinse your hands well
- Dry your hands with a clean towel, disposable towel, or air dryer
- Use your towel to turn off the faucet if possible

is diagnosed with influenza, parents can be instructed to keep children at home until symptoms have improved and fever has been gone for 24 hours. Nurses can be actively involved in developing community-based policies in the event of a pandemic, and this may include plans for mass immunizations, specific flu clinics, and protocols for school closures (Aronson & Shope, 2013).

SIDS/SUIDS

Sudden infant death syndrome (SIDS) is defined as the sudden death of an infant under 1 year of age that remains unexplained after a thorough case investigation, including performance of a complete autopsy, examination of the death scene, and review of the clinical history (AAP, 2011b). **Sudden unexpected infant death (SUID)** is a term that describes any sudden and unexpected death that occurs in infancy; this includes both explained (i.e., suffocation, infection, trauma) and unexplained cases (SIDS). The peak age for SIDS deaths occurs between 2 and 3 months of age, although SIDS may occur up to 1 year of age. There are specific independent risk factors for SIDS (AAP, 2011b):

- Prone or side-lying sleep position
- Sleeping on a soft surface
- Maternal smoking during pregnancy
- Overheating
- Late or no prenatal care
- Young maternal age
- Preterm birth and/or low birth weight
- Male gender
- Lack of immunizations

There are consistently higher rates of SIDS in non-Hispanic black and American Indian/Alaska Native infants—two to three times the national average. The incidence has decreased more than 50% since the “Back to Sleep” campaign was promoted in 1994. There is no test to identify infants who may die, making this a frustrating clinical problem. Nurses should teach the preventive measures that follow:

- Supine position only for infants—no side lying or prone
- No smoking during pregnancy or in home after birth
- Use a firm sleep surface—no soft bedding, no pillows, no stuffed animals, no sleeping on chairs or sofas, no sleeping with adults or in a waterbed
- Offer a pacifier at naptime and bedtime—reduces risk
- Avoid overheating and overbundling—room temperature should be between 68° and 72° F
- Continue “Back to Sleep” campaign (AAP, 2011b)

When an infant dies from SIDS, the family requires tremendous support. The nurse provides empathetic support and assists the family as they progress through the grief process and provides guidance for siblings and other family members. Referral to support groups may be helpful.

Oral Health

Oral health is recognized as an integral component of overall health for children and adolescents. Dental caries in early childhood has been identified by the CDC as one of the most prevalent infectious diseases and the incidence is more common in children living in poverty or low socioeconomic status. Access to pediatric dental care is a barrier to meeting the oral health care needs of children in the United States (Hallas & Shelley, 2009).

Nurses are well positioned to provide oral health screenings and to educate families on preventive oral health topics. Children should be referred to a qualified dentist by 1 year of age. Families should receive anticipatory guidance on optimal use of fluorides, proper nutrition and dietary practices, prevention of poor oral health habits and tooth decay, age-appropriate dental injury prevention, and proper care of teeth and gingival tissue (AAP, 2008).

Chronic Health Conditions

Improved medical technology has increased the number of children surviving with chronic health problems. In addition, environmental factors are leading to an increase in certain chronic health conditions. At present, it is estimated that about 26% of American children have a chronic health condition (Van Cleave et al, 2010). Some examples of common chronic conditions in children are Down syndrome, spina bifida, cerebral palsy, asthma, ADHD, diabetes, congenital heart disease, cancer, hemophilia, bronchopulmonary dysplasia, and AIDS.

Despite the differences in the specific diagnoses, all of these families have complex needs and face similar problems. Several variables exist to assess for each child and family:

- What is the actual health status? Is the condition stable or life threatening?
- What is the degree of impairment to the child’s ability to develop?

- What types of treatments and therapy are required and with what frequency?
- How often are health care visits and hospitalizations required?
- To what degree are the family routines disrupted?

The common issues nurses will want to evaluate for these families include the following:

- All children and adolescents with chronic health problems need routine health care. The same issues of pediatric health promotion and acute health care need to be addressed with this group. The use of the medical home (discussed later in the chapter) is very important for this population.
- Ongoing medical care specific to the health problem needs to be provided. Examples include monitoring for complications of the health problem, medications management, dietary adjustments, and coordination of therapies. Evaluation of the effectiveness of the treatment plan is critical.
- Care is often provided by multiple specialists. There is a need for coordinating the scheduling of visits, tests or procedures and the treatment regimen.
- Skilled care procedures are often required and may include suctioning, positioning, medications, feeding techniques, breathing treatments, physical therapy, and use of appliances.
- Equipment needs are often complex and may include monitors, oxygen, ventilators, positioning or ambulation devices, infusion pumps, and suction machines.
- Educational needs are often complex. Communication between the family, the team of health care providers, school administrators, and teachers is essential to meet the child’s health and educational needs.
- Safe transportation to health care services and school must be available. Several barriers may exist, including family resources, location, and the burden of supportive equipment.
- Financial resources may not be adequate to meet the needs.
- Behavioral issues include the effect of the condition on the child’s behavior as well as on other family members.

The ultimate goal is for children with chronic health conditions to achieve optimal health and functioning. Identifying barriers for individual families and overall community barriers is a focus for nurses. Developing support groups, advocating for improved community access to resources, and educating those working with these children on their conditions and needs will promote the family’s functioning. The **How To** box below details a community nursing approach to supporting a child with ADHD.

Mental Health

Psychosocial stressors have increased over the years for children and mental health issues are a priority health concern for children and adolescents. There are many underlying causes for mental health problems in children, ranging from lead poisoning to exposure to violence in the home. Approximately 1 in 5 children and adolescents in the United States has a diagnosable mental health disorder. Children who live in poverty, live with

HOW TO Implement a Community Nursing Approach to a Chronic Illness: ADHD

The following describes the steps the nurse in the community will follow to support a child with ADHD:

- **Assessment:** Obtaining history, physical, parent/family assessment, environmental assessment, learning, and psycho-educational evaluations
- **Behavioral modifications:** (home and school) Teaching families techniques to support clear expectations, consistent routines, positive reinforcement for appropriate behavior, and consequences for negative behaviors
- **Classroom modifications:** Consulting with family and teachers to meet individual needs for remediation or alternative instruction methods if necessary; structuring activities to respond to the child's needs
- **Support:** Referring family to family therapy/counseling, support groups, or mental health services to assist development of positive coping behaviors
- **Medications:** Consulting with physician to monitor and evaluate therapeutic and adverse effects
- **Follow-up:** Assessing at 3- to 6-month intervals when stable; dynamic process affected by relationships with others; behaviors will change with age; problem may persist through adulthood

a single parent, or are exposed to violence are at higher risk for developing a mental health condition. Only 21% of children with a mental health or substance abuse problem are currently receiving treatment (AACAP, 2009).

Some of the common mental health problems diagnosed in children and adolescents are anxiety disorders, autism spectrum disorders, depression, bipolar disorder, conduct disorder, oppositional defiant disorder, and substance abuse (AACAP, 2009). Each of these mental health diagnoses has a specific set of criteria for diagnosis found in the DSM-V. Early recognition and coordinated management of pediatric mental health issues is critical to a child's functioning in school, home, and the community.

More than 2 million U.S. children during the past 10 years have experienced the stress and emotions associated with being separated from a parent deployed for active duty. These children experience symptoms of depression (25%), excess worry (50%), and sleep problems (50%). By understanding the stressors of military deployment, nurses can identify and provide the support (and referrals) needed to help these children (Siegle & Davis, 2013).

Many families can be at a loss for the behaviors or symptoms they observe in their child. A sense of embarrassment may prohibit parents from seeking help. Nurses can be instrumental in promoting community awareness about common mental health problems in children and identifying resources for families. The use of the medical home to coordinate management of mental health problems is important in the ability to provide oversight of subspecialties, medications, and therapies. A challenge for treating pediatric mental health disorders is an inadequate number of practitioners specializing in pediatric mental health, which may leave some families without adequate support and resources (AAP, 2009b).

Bullying

Bullying has always been an issue for children and adolescents. With the extensive use of texting, e-mails, social networking, and other means of electronic communication among tweens and adolescents, cyber bullying has become a significant problem within communities. Girls are more likely to be victims of cyber bullying, and victims report thinking about self-harm and/or suicide as a result of bullying. Cyber bullying includes sending hurtful messages, starting rumors and uploading and sharing unflattering or altered photographs of the victims via an electronic means. Many cyber bullies use avatars or other ways of disguising their true identity, which makes it difficult for the victim to know who the bully is. The victims often do not report cyber bullying for fear of retaliation from the bully and experience emotional and behavioral symptoms along with school-related problems (Suzuki et al, 2012).

Environmental Health

The built environment that children and adolescents live in directly affects their health. Growth, size, and behaviors place the pediatric population at greater risk for damage from various toxins. Lead poisoning is one of the most common environmental health hazards. Pesticides, mercury exposure, plasticizers, and poor air quality also pose serious risks (National Institute of Environmental Health Science, 2014). Common toxins and sources of pediatric exposure are listed in Table 29-7.

Growing tissues absorb toxins readily. Developing organ systems are more susceptible to damage. Smaller size means increased concentration of toxins per pound of body weight. The fact that children are short exposes them to lower air spaces, where heavy chemicals tend to concentrate. Outdoor play, especially during summer months, increases the opportunity for exposure to air pollutants. Chewing and mouthing behaviors offer contact to toxins such as lead. Playing on the floor increases exposure to chemicals in rugs and flooring. Rolling and playing in grass can result in pesticide exposure and playground materials that are treated with chemicals put children at risk. Exposure risks for adolescents are similar to those for adults and are primarily through work, school, and hobbies (NIEHS, 2014).

It is critical to assess for these environmental health hazards during health care visits. Referral for treatment may be necessary. Counseling families on risk reduction is important to children's health. Population-focused nurses identify environmental problems within the community and target at-risk populations with community interventions (see Table 29-8 for examples). Bringing screening programs into neighborhoods at risk may facilitate early identification and prevent complications. Lobbying efforts and education can effect public policy changes to make the environment healthier. The following case presentation gives an example of how a school environment can lead to health problems.

A child's built environment includes exposure to media and the resulting influence on behavior and choices. Food and beverage corporations spend over \$1.6 billion each year on advertising that specifically targets children. Much of this advertising uses licensed cartoon characters to promote food products, and

TABLE 29-7 Common Environmental Agents Hazardous to Children

Toxins	Sources
Arsenic	Food, water
Asbestos	Building materials: insulation, ceilings, floor tiles
Carbon monoxide	Space heaters, woodstoves, fireplaces, engine exhaust, tobacco smoke
Dioxins	Contaminated foods, water, and soil
Lead	Paint, dust, soil, water, occupational exposure (e.g., battery plant), hobbies (e.g., stained glass)
Mercury	Water contamination, fish, thermometer/sphygmomanometer breakage
Molds	Food, ubiquitous to moist outdoor and indoor environment
Nitrites, nitrates	Water, food
Nicotine, benzene, tars	Environmental tobacco smoke
Particulate matter-nanomaterials	Outdoor air pollution, dust mites, animal dander, roach parts
Pesticides	Food, soil, plants, water, air, topical application for lice treatment, home and school insect management
Phthalates and bisphenol (BPA)	Linings of canned foods, children's toys, vinyl flooring, hard plastics made of polycarbonate (many sports water bottles and baby bottles)
Radon	Soil and rock, the air, ground water, surface water
Solvents/volatile organic compounds	Furniture, carpet, building materials, solvents and degreasers, cleaning products, acetone, formaldehyde
Styrene	vapors from building materials, photocopiers, tobacco smoke
Ultraviolet light	Outdoor sun exposure, tanning beds

From: [National Institutes of Environmental Health: Your Environment your health, 2015](http://www.niehs.nih.gov), Triangle Park, North Carolina, Accessed at [www.NIEHS.Nih.gov](http://www.niehs.nih.gov). March 24, 2015.

TABLE 29-8 Prevention Strategies Applied to Environmental Hazards

Prevention Strategies	Examples
Primary	
Identification of at-risk populations	Substandard housing communities Pregnant women Children with asthma
Health education about environmental risks	Poison prevention Responses to poor air quality alerts Discontinue use of plasticizers
Formation of public health policies	Air/water quality standards Safety inspections: playgrounds, schools, daycare centers Standards for lead levels in imported products intended for children
Research to assess impact of environmental hazards on the pediatric population	Developing reference ranges/biological markers to assess toxic levels in children Identify long-term physiological and cognitive consequences of exposure to environmental toxins
Secondary	
Early detection, treatment, and referral for management of environmental toxins	Removal of at-risk persons when lead hazards are detected Assessment of lead levels of populations of at-risk children with treatment of individuals as indicated
Tertiary	
Restoration of environment and occupants to healthier state	Asbestos/lead abatement of buildings Radon remediation of homes Replacement of heating, ventilation, air conditioning, systems contaminated with mold Chelating agents for individuals with lead toxic levels

Modified from Burns C, Dunn A, Sattler B: Resources for environmental health problems. *J Pediatr Health Care* 16:3, 2002.

the majority of those products are of poor nutritional value. The heart of the question is whether this advertising is effective in influencing children's food choices. A study by [Roberto et al \(2010\)](#) looked at the preferences of preschool children for food packaged with a licensed cartoon character. The study found that preschoolers rated the taste of the foods packaged with the licensed character over the identical food without the character packaging. The children also selected the high-density character-packaged foods more often. Nurses in the community can use

this information to provide guidance to parents to limit exposure to television and media, make healthy food choices for their children, and avoid unhealthy foods packaged with licensed cartoon characters. Nurses can also advocate for stricter advertising laws for those unhealthy foods targeted to children.

Lead Poisoning

Lead is a heavy metal that is absorbed into the body primarily through ingestion. Lead poisoning is defined as a serum lead

BOX 29-2 Steps to Minimize Lead Exposure in Contaminated Toys and Products

- Read recall notices from the CPSC (www.cpsc.gov) and do not buy recalled toys.
- Check old toys at home to make sure they have not been recalled.
- Avoid purchasing toys secondhand from yard sales and flea markets.
- Check labels and recommended ages on all toy labels and follow recommendations.
- Do not purchase children's costume jewelry or allow children to play with adult costume jewelry.

level above 10 µg/dL and it causes significant neurologic, cardiovascular, and renal disease. A *Healthy People 2020* goal is to eliminate elevated blood lead levels in all children. More than 310,000 children younger than 5 years have elevated lead levels, and the most common exposure is through lead-based paints and lead-contaminated soil and dust in houses built before 1987 (Warniment et al, 2010).

Another exposure risk is through imported toys and costume jewelry that are painted with a lead-based paint. Young children are exposed through their mouthing behaviors. If a piece of contaminated costume jewelry is accidentally swallowed, the high lead concentration can result in death. In 2007, the U.S. Consumer Products Safety Commission (CPSC) issued numerous recalls for these toys and passed the Consumer Product Safety Improvement Act in 2008 which requires third-party testing and certification of all imported toys and products marketed to children (Galvez et al, 2009).

Universal screening for lead poisoning of all children at ages 1 and 2 years is recommended. This screening is recommended when children receive well-child or EPSDT screening at regular intervals. In addition, families should be assessed for environmental risk factors to determine the need for screening at other ages. Specific guidelines for minimizing lead exposure through contaminated toys are included in Box 29-2.

Mercury

Mercury is another heavy metal that is highly toxic. The most common exposure for humans is the ingestion of contaminated fish. Mercury poisoning is determined with a blood mercury level of 5.8 µg/L or above. Mercury poisoning can result in significant developmental deficits with the fetuses of pregnant women at particular risk. Screening for dietary intake and other possible exposures is critical to identification of risk factors (Bose-O'Reilly et al, 2010). The nurses' responsibility is to educate families on how to minimize mercury exposure risks. It is recommended that families eat commercially caught fish that are low in mercury (tilapia, Alaskan salmon, herring). For pregnant women, women of child-bearing age, breastfeeding mothers, and young children, these steps are recommended:

- Avoid ingesting shark, tilefish, and king mackerel because of the high mercury levels
- Limit intake of tuna to 4 to 6 ounces each week and all other fishes to 12 ounces each week

Plasticizers

Phthalates and bisphenol (BPA) are chemicals that are commonly added to plastics to create flexibility and durability. Exposure to these products has caused significant adverse health effects in animal studies. Human studies have noted a link between BPA and cardiovascular and liver disease. The possible exposures for children are many and include the linings of canned foods (ready-to-feed formulas), children's toys, and hard plastics made of polycarbonate (many sports water bottles and baby bottles). Increased exposure occurs when these products are exposed to high heat, which occurs with the sterilization of baby bottles. The half-life of these plasticizers is very short, which makes it difficult to thoroughly screen for exposure (Galvez et al, 2009).

The Consumer Products Safety Improvement Act of 2008 provided guidelines for eliminating these plasticizers nationally from children's products. Continued education of families is needed until all of these plasticizers are no longer available for purchase; recommendations on avoiding second-hand children's products should be promoted (Consumer Product Safety Commission, 2013).

LEVELS OF PREVENTION

Lead Poisoning

Primary Prevention

Community education about lead exposure, lead sources in the community, and the adverse health consequences for children.

Secondary Prevention

Implement universal screening for all children ages 1 and 2 years that present to the community health centers and primary care practices.

Tertiary Prevention

Provide families with guidance and resources for lead abatement and to eliminate lead exposure for children with blood lead levels >10 µg/dL.

Obesity

Primary Prevention

Offer healthy cooking classes for families in the community.

Secondary Prevention

Conduct child body mass index screenings in community daycares and preschools.

Tertiary Prevention

Develop individualized weight loss plans and counsel children identified as obese on lifestyle changes.

Environmental Tobacco Smoke

Environmental tobacco smoke (ETS) is exhaled smoke, smoke from burning tobacco or smoke from the mouthpiece or filter end of a cigarette, cigar or pipe. Cigarettes have many known poisons, and both cigarettes and ETS were classified as Class A known human carcinogens in 1992 by the Environmental Protection Agency (EPA). Parents often do not understand or believe the effects of smoking on children. Children, particularly those under age 5 years and those living in poverty, have higher levels of exposure to ETS. The recent introduction of electronic cigarettes is also considered to be a risk for ETS. An initial study found cancer-causing substances in all of the e-cigarette samples that were tested (Goniewicz et al, 2013).

Children exposed to ETS experience increased episodes of middle ear infections, asthma, upper respiratory tract infections, and more missed school days. Prenatal exposure to ETS is linked to preterm births, low birth weight, and increased risk

for several childhood cancers. Prenatal exposure is also linked to the fetal brain becoming sensitized to nicotine, leading to greater addiction when exposed at an older age. Children living in smoking households with a parent role modeling smoking are more likely to start smoking (AAP, 2009c).

Interventions to discourage smoking focus on the parent, the child or adolescent, and public policy. Nurses in public health should offer educational programs for parents dealing with the negative effects of smoking on children, specific interventions to stop smoking, and ways to create a smoke-free environment. Anti-smoking programs directed toward children and teenagers are more successful if the focus is on short-term effects rather than on long-term effects. Developmentally, children and teenagers cannot visualize the future to imagine the consequences of smoking. Teaching social skills to resist peer pressure is critical (CDC, 2014c).

Nurses should become politically active in the area of smoking. Policies to ban tobacco advertising, enforce restrictions of sale to minors, increase funds for anti-smoking education, and restriction of public smoking may reduce the incidence of smoking. Community-based interventions to reduce smoking and ETS exposure are included here.

- Collaborate with schools to provide tobacco-free environments (for all school facilities, vehicles, and events).
- Work with schools to provide prevention curricula in elementary, middle, and high schools.
- Develop or identify smoking cessation programs and provide information to health care providers and workplaces in the community.
- Provide education to families on the dangers of ETS exposure for children and adolescents.
- Partnership with community merchants to enforce minors' access laws
- Advocate for local policy change to limit smoking in public and private enterprises (CDC, 2014c).

MODELS FOR HEALTH CARE DELIVERY TO CHILDREN AND ADOLESCENTS

Nurses are in a position to work with specific populations through programs targeting the health care needs of children and particularly those at risk. In the following section, strategies for promoting the health care of children and adolescents are described.

Family-Centered Medical Home

A **family-centered medical home** is a partnership between a child or adolescent, the child or adolescent's family, and the pediatric team who oversees the child or adolescent's health and well-being within a community-based system that provides uninterrupted care to promote optimal health outcomes. The **medical home** incorporates preventive, acute, and chronic care from birth through transition to adulthood. The medical home emphasizes an integrated health system with collaboration of care from an interprofessional team of primary care physicians, specialists and subspecialists, other health professionals, hospitals and health care facilities, public health, and the community working with children and families (Malouin, 2013).

Approximately 58% of all children have a medical home compared with 47% of children with special health care needs. It is imperative to increase the use of medical homes for all children, particularly children with special health care needs (Homer et al, 2008). A child with Down syndrome will greatly benefit from collaborative care from the primary care provider, subspecialty physicians, school system, community therapists, family support groups, and other community resources to achieve optimal health.

A successful medical home relies on the multitude of supports that are brought to the service delivery system that surrounds the family and community. Families can trust that there is a place where their child or adolescent is provided holistic care that addresses all aspects of physical, mental, and emotional health. The medical home is not a specific building, but it is a system of care that is accessible, continuous, comprehensive, coordinated, compassionate, and culturally effective. Nurses in the community play an active role as a team member of the medical home by identifying resources for families, referring families to a medical home, and participating in the health care of children in medical homes.

Motivational Interviewing

Motivational interviewing is a focused communication strategy in which the parents are encouraged to set goals, identify personal barriers, and identify potential mechanisms to overcome the barriers to make safety and health promotion changes for their child. This can be an effective intervention to promote healthy changes within the family environment (Barnes, 2012). It can be easily implemented by nurses in primary care settings and public health clinics under limited time constraints and is readily incorporated into the medical home model.

Motivational interviewing emphasizes a collaborative approach to behavior change instead of a prescriptive approach (Figure 29-8). Nurses use open-ended questioning and reflection to encourage the parent or adolescent to share their identified barriers to change. When individuals demonstrate positive comments toward change, the nurse expands upon those

FIG 29-8 Motivational interviewing is an effective way for nurses to intervene with families and promote positive behavioral change in the home.

comments and provides further support for that change. This strategy is very effective with positive health behavior changes such as smoking cessation, healthy eating, and safety behaviors. (See [Appendix F.1](#) in the back of the book.)

ROLE OF THE POPULATION-FOCUSED NURSE IN CHILD AND ADOLESCENT HEALTH

Population-focused nurses have the opportunity to work with families to achieve growth toward many of the *Healthy People 2020* objectives. They practice in a variety of settings, including community health centers, school-based clinics, and home health programs. They provide care through well-child clinics, immunization programs, federally mandated programs (such as the nutrition program Women, Infants, and Children [WIC]) or specific state-funded programs, such as Head Start.

With passage of the ACA, strategies to implement improved access include expanding the role of nurses and the settings for practice. The nursing process and a knowledge base of the factors unique to the pediatric population provide a framework of care. Nursing, through developing and coordinating community services and through formation of public policies, promotes the well-being of children and families within the community. Assessments are made to identify the needs and target populations at risk. Programs based on the needs of specific at-risk populations are developed for the delivery of health care.

The nursing plan of care includes three major components. The first is the management of actual or potential health problems. The second involves both education and anticipatory guidance. This enables families to understand what to expect in the areas of growth and development as well as social,

emotional, and cognitive changes. Nurses offer information to promote healthy lifestyles and to prevent acute and chronic health problems as well as unintentional injuries. A third role is case management or coordination of care. For example, the nurse coordinates referrals to community agencies, other health care services or providers or assistance programs. [Box 29-3](#) lists community resources.

BOX 29-3 Community Resources for Pediatric Health Care

- Children's service clinics
- Well-child clinics
- Immunization clinics
- Infectious disease clinics
- Children's specialty services
- Family violence/child abuse centers
- Homeless shelters
- School health programs
- Head Start
- Parents Anonymous
- Crisis hotlines
- Community education classes
- Early intervention/developmental services
- Childbirth education classes
- Breastfeeding support groups
- Parent support groups
- Family planning clinics
- Women, Infants, and Children (WIC) programs
- Medicaid and CHIP
- Youth employment/training programs

LINKING CONTENT TO PRACTICE

In this chapter, emphasis is placed on the community health needs of children and adolescents within the context of the family. The public health core functions of disease prevention, health promotion, and the three levels of health services are directly related to the pediatric population and their specific population needs. To meet the core public health competencies, nurses must learn how to assess children and adolescents using developmental principles to determine safety risks for injury and environmental health exposures. Policy and program development for the pediatric population is geared toward improving the built environment in which a child grows and providing parents with education on health promotion strategies like smoking cessation to improve their child's

health. Nurses develop competencies in communication strategies with children of varying developmental levels and recognize the various locations in the community that need education on promoting the health of children (e.g., daycare centers, schools). Basic health services such as well-child care and immunizations are critical to the health of the pediatric population, and the nurse is poised as a leader within the medical home model of health care delivery for children and adolescents. This chapter prepares the community health nurse to provide comprehensive, developmentally appropriate education to families; deliver basic health care services in a holistic approach; and develop community programming to improve safety and environmental wellness for children and adolescents.

HEALTHY PEOPLE 2020

Objectives Focused on Children and Adolescents

Education and Community-Based Programs

- ECB-4: Increase the proportion of elementary, middle, and senior high schools that provide school health education to promote personal health and wellness in the following areas: hand washing or hand hygiene; oral health; growth and development; sun safety and skin cancer prevention; benefits of rest and sleep; ways to prevent vision and hearing loss; and the importance of health screenings and checkups.
- ECB-7: Increase the proportion of middle, junior high, and senior high schools that provide comprehensive school health education to prevent health problems in the following areas: unintentional injury; violence; suicide; tobacco use and addiction; alcohol or other drug use; unintended pregnancy; HIV/AIDS and STD infection; unhealthy dietary patterns; inadequate physical activity; and environmental health.

Environmental Health

- EH-8: Eliminate elevated blood lead levels in children.

Immunizations and Infectious Disease

- IID-7: Achieve and maintain effective vaccination coverage levels for universally recommended vaccines among young children.

Injury/Violence Prevention

- IVP-16: Increase use of age appropriate child restraints in cars.

Nutrition and Weight Status

- NWS-10: Reduce the proportion of children and adolescents who are overweight or obese.

Physical Activity and Fitness

- PA-4: Increase the proportion of the nation's public and private schools that require daily physical education for all students.

Tobacco Use

- TU-15: Tobacco-free environments in schools, including all school facilities, property, vehicles, and school events.

From: US Department of Health and Human Services: Healthy People 2020, Wash DC, 2010, US Government Printing Office.

PRACTICE APPLICATION

Sam is a 4-year-old boy brought to the clinic by his mother for his 4-year well-child check and immunizations. Sam will be attending the local Head Start program in the fall. He is the oldest of three children and his siblings are 9 months and 35 months. His mother is a single parent who works at a local restaurant as a waitress. Sam and his siblings are insured by Medicaid. Sam's mother is 24 years old and the family lives with the maternal grandparents. Sam's mother is in good health and does not smoke or abuse drugs. Sam has been watched by his grandmother since birth and is exposed to cigarette smoke in the home by both grandparents.

On the developmental exam, Sam is very cooperative, eager to please, and speaks clearly. His development is significant for failure to identify three colors, count to 5, or recognize any letters. His gross motor skills are appropriate but he only scribbles when given a crayon. Sam reports watching television shows with his family for fun. On physical examination, Sam has a >95th percentile BMI for age/gender but no other abnormal exam findings are noted. Hearing and vision are within normal limits for age.

Based on the previous scenario, answer the following questions:

- What additional history and assessment information should you collect based on the child's home environment?
- What immunizations and lab tests are indicated based on his age and risk factors?
- What education should you give this mother on changes in the home to promote development? To reduce ETS exposure? To ensure safety?
- Based on the BMI percentile, what additional nutrition and dietary practices information should you obtain?
- What interventions and education should you provide to this mother regarding Sam's obesity and associated risk factors?
- In an analysis of the Medicaid child population in Sam's medical home, the population-focused nurse found that a number of children had similar risk factors. Is there a population-level intervention the nurse may want to use to reduce the risk in the future child population?

Answers can be found on the Evolve site.

KEY POINTS

- Physical growth and development is an ongoing process resulting in physical, cognitive, and emotional changes that affect health status.
- Good nutrition is essential for healthy growth and development, and it influences disease prevention in later life.
- Childhood obesity is increasing in prevalence. Modifiable risk factors include dietary intake, physical activity, and screen viewing time.
- Immunizations are successful in prevention of selected diseases. Barriers to immunizing children are parental concerns,

KEY POINTS—cont'd

- cost, vaccine shortages, and changes in recommended vaccine scheduling.
- The built environment is influential on a child's physical, emotional, and psychosocial health. Nurses can design interventions for families and communities to improve a child's environment if improvement is indicated.
- The family is critical to the growth and development of the child. Social support has a powerful influence on successful parenting.
- Unintentional injuries are the major cause of morbidity and mortality in the child and adolescent population. Most are preventable. Nurses have a major role in anticipatory guidance and prevention.
- Population-focused nurses have a strong role in the prevention of, identification of, and education about child maltreatment. Child advocacy is critical to reduce the incidence of abuse and neglect in childhood.
- Minimizing complications of the major health risks to the pediatric and adolescent population follows the goals of *Healthy People 2020* initiatives.
- The pediatric population is vulnerable to environmental hazards. Decreasing exposure and identifying problems early are important areas for interventions by population-focused nurses.
- Nurses are involved in strategies to meet the needs of the pediatric population and their families in the community.
- The family-centered medical home is a successful system for coordinating health care for children and for facilitating continuous family support and health management.
- Children who are low income or live in poverty are at increased risk for violence, injuries, and environmental hazards.
- The use of motivational interviewing can facilitate positive health behavior changes for families with children.

CLINICAL DECISION-MAKING ACTIVITIES

- Develop a plan of immunization for a 5½-year-old who has had one DTaP, Hib, and IPV. Be specific about due dates for immunizations.
 - Develop a screening program for children and adolescents who live in a low-income older neighborhood with a large percentage of Hispanic residents. What risk factors would you consider in the process? Have you examined the thoughts of others in the community that might affect the success of the screening program? Be specific.
 - Plan a survey of a school district to determine its “friendliness” to children with chronic health problems. How would you implement changes?
 - Develop a community program for smoking cessation. Identify how you will target parents and caregivers of children.
- Discuss how you will incorporate the concept of ETS exposure in your program.
- Develop nutrition education programs for (1) mothers who are breastfeeding their infants, (2) a group of 5-year-olds in a kindergarten class, and (3) a group of high school sophomores. What factors do these programs have in common? How do they differ?
 - Administer a safety survey (e.g., the Injury Prevention Program [TIPP] from the American Academy of Pediatrics, or develop your own) to assess the home environment of a 6-month-old and a 5-year-old. Develop a plan of education and anticipatory guidance for the family. How would you apply this information to a larger population?

Major Health Issues and Chronic Disease Management of Adults Across the Life Span

Monty Gross, PhD, RN, CNE, CNL

Dr. Monty Gross is Clinical Nurse Educator for the Veterans Health Administration in Las Vegas, Nevada. He received his BS in Communications from Clarion University of Pennsylvania and his BSN and MSN from the University of Virginia. In 2006 he completed his PhD from Virginia Tech. He has practiced nursing in acute care, critical care, and underserved communities in Latin America. He has taught nursing as an Associate Professor at the undergraduate and graduate levels. Staying engaged in academia, he teaches as an adjunct faculty.

Linda Hulton, PhD, RN

Dr. Linda Hulton is Professor of Nursing at James Madison University (JMU) and Coordinator of the Doctor of Nursing Practice (DNP) program. She received her BSN in nursing from Roberts Wesleyan College and her Masters and PhD in nursing from the University of Virginia. Her areas of research interest and practice are adolescent health promotion, unintended pregnancy, and health care for the homeless. In 2012, she received the James Madison University CISAT Distinguished Teaching Award. She has had her scholarly work published in *Issues in Comprehensive Pediatric Nursing*, *Sigma Theta Tau's Online Journal of Knowledge Synthesis in Nursing*, the *Journal of Gynecological and Neonatal Nursing*, *The Journal of School Nursing*, and the *Journal for Specialists in Pediatric Nursing*. At JMU, she teaches graduate courses in research, community health, and analytic methods.

Sharon Strang, RN, DNP, APRN, FNP-BC

Dr. Sharon Strang is an Associate Professor of Nursing and faculty in the Graduate School at James Madison University. She is a Board Certified Family Nurse Practitioner who practices at a free clinic. She received her BSN from Duquesne University in Pittsburgh, PA, and her Masters of Science in Nursing from the University of Pennsylvania at Edinboro. Sharon completed a Post Masters Nurse Practitioner Certificate Program at Old Dominion University and received her DNP from the University of Virginia. The focus of her doctoral studies and grant writing is chronic disease. She has presented at national nursing and education conferences and published in nursing education and nurse practitioner journals. In 2005 she received the Virginia Council of Nurse Practitioner's nurse practitioner in education award and in 2011 she received the Virginia Council of Nurse Practitioner's Distinguished Nurse Practitioner award. She is licensed as a Chronic Disease and Diabetes Self-Management Master Trainer by Stanford University.

OBJECTIVES

After reading this chapter, the student should be able to:

1. Define terms commonly used in the care of adults.
2. Describe historical and current perspectives of adult health and health policy.
3. Discuss sources of population-based public health data and health status indicators about adults to be used to align community resources to support adults with chronic illnesses.

OBJECTIVES — cont'd

4. Use appropriate assessment tools and development strategies to care for adults across the life span.
5. Discuss the concepts of self-management and the implementation of the Chronic Care Model to support adults with chronic illness.
6. Explain the dynamic forces that contribute to shared and gender specific diseases, health disparities, cultural diversity, and the role of social and behavioral factors that contribute to culturally competent care of adults in their communities.

Community-Based Models for Care of Adults

Nursing Roles

Community Care Settings

This chapter provides an overview of major health issues of adults that occur at various stages of life. Nurses struggle with these numerous and complex topics. Changes in population demographics signal challenges of limited resources and increased prevalence of persons living with multiple chronic conditions. Unhealthy lifestyles, environmental pollution, and politics are a sample of factors a nurse will need to consider in population-centered health care. Descriptive statistics are frequently provided to help illustrate the significance of a disease or condition. Despite many pressing issues and political debates, there are abundant opportunities to improve the health of the population. There is strong evidence that community interventions, such as those designed for disadvantaged populations to improve diabetes care, can improve **health** through political involvement and strategies such as implementing well-planned programs (Brownson et al, 2009). Significant changes are rapidly occurring in health care and in the communities through policy changes and research. Nurses will be better prepared to practice by having a better understanding of these major health issues.

HISTORICAL PERSPECTIVES ON ADULT MEN AND WOMEN'S HEALTH

Men and women have always faced a wide array of health issues that transition over time to impact their lives and the community. Gender is a major social determinant of health. Gender equity positively impacts a variety of factors, such as decision making, income allocation, and application and observance of norms, which affect health. Gender inequalities span throughout time and all societies, damaging the health of both genders, but in the majority of societies throughout the world women lose out to men (Fernández-Sáez et al, 2013). Social and political climates influence research and funding agendas that ultimately affect how health care is delivered in the community. A gender gap has existed where the emphasis on health issues and community focus has given priority to one gender over the other through research, policies, and funding. This has resulted in the focus of prevention and treatment being on one or the other gender, depending on social and political time period.

Historically men have dominated the medical and research professions because of cultural and societal norms. At the

beginning of the twentieth century, discussions of **women's health** focused primarily on reproduction and women's roles as mothers. In the 1920s, with the birth control movement in its initial stages, women's health expanded to address family planning and reproductive health. Women began to be empowered by the suffragette movement, winning the right to vote in 1920. As the women's rights movement gained momentum, women's health issues and the research of those issues displaced many issues of men. In the 1980s recommendations were made by the U.S. Public Health Services Task Force on Women's Health Issues to increase gender equity in biomedical research and the establishment of guidelines for including women in federally sponsored studies (Alexander et al, 2007; Public Health Reports, 1985). In 1990 the Society for Women's Research was founded. Through political action of the National Institute of Health (NIH), legislation once again included women and other minorities in research studies (NIH Revitalization Act of 1993).

During the nineteenth and twentieth centuries, illness and death rates from infectious diseases decreased and those of **chronic diseases** increased for men and women in western countries. Due to refinement and understanding of germ theory and the use of medical and public health strategies such as immunizations, pasteurization, and antibiotics, primary infections declined (Egger, 2012). Health policies and programs were implemented to reduce the spread of infections and increase life span. These activities began the shift in focus to chronic illnesses, such as cardiovascular disease and cancers.

HEALTH POLICY AND LEGISLATION

Health policy is action taken by public and private agencies to promote health. It is a reflection of the values held in society and can greatly influence the health of the citizens overall. Legislation consists of laws that regulate health care and promote health. Nursing practice and the care provided is impacted by policy and legislation. Nurses can serve as change agents to improve health care through engaging in health policy. To be fully engaged in improving health care from the bedside to the community level, nurses must understand how policy and legislation, along with other system factors such as social, cultural, and economic forces, can be incorporated into

planning care for clients and use their skills as collaborators and communicators to improve health policy (Ressler and Glazer, 2010).

The following are five examples of important federal legislation that has influenced the health of adults and their lives in communities: The Older Americans Act of 1965, the Americans with Disabilities Act of 1990, the Family and Medical Leave Act of 1993, the Personal Responsibility and Work Opportunity Reconciliation Act of 1996, and the Patient Protection and Affordable Care Act of 2010.

The **Older Americans Act (OAA)**, originally passed in 1965, established the Administration on Aging (AOA) and state agencies to provide for the social service needs of older people. The mission of the AOA is to help older adults maintain dignity and live independently in their communities through a comprehensive and coordinated network across the United States (AOA, 2010). In 2008, of the \$1.9 billion funding allotted to the AOA, two thirds supported state and community grants for multiple social and nutritional service programs. Title III of the OAA authorizes funding for nonprofit area agencies on aging to coordinate social services that provide supportive and nutritional services, family caregiver support, and disease prevention and health promotion activities. The services are available to all people age 60 or over, specifically targeted to those with the greatest economic or social need.

In 1990, the **Americans with Disabilities Act (ADA)** was passed, providing protection against discrimination to millions of Americans with disabilities. A disability is generally defined by the ADA as a physical or mental impairment that substantially limits one or more major life activities, a person who has a history or record of such an impairment, or a person who is perceived by others as having such an impairment (Americans with Disabilities Act of 1990, as amended with ADA Act of 2008, n.d.). The ADA legislation requires government and businesses to provide disabled individuals with equal opportunities for jobs, education, access to transportation and public buildings, and other accommodations for both physical and mental limitations.

The **Family and Medical Leave Act (FMLA)**, initially passed in 1993, provides job protection and continuous health benefits where applicable for eligible employees who need extended leave for their own illness or to care for a family member. Gender equality was expanded with FMLA to offer women the ability to better manage both a career and a family (Guy, 2013). However, FMLA is limited. It only permits eligible employees to take 12 weeks of unpaid leave during a 12-month period for limited situations such as birth, adoption, or care for a serious illness of self or family members. It also only applies to employees who worked for at least 12 months in companies that have 50 or more employees (U.S. Department of Labor Wage and Hour Division [WHD] The Family and Medical Leave Act of 1993). Frequently caregivers provide unpaid care for their family members, including aging parents, children, grandchildren, and partners. Often adults find themselves struggling to balance work and caring for a family member. More families find themselves in this struggle as more women enter the workforce and work full time. Caregivers' multiple roles and

responsibilities are frequently coupled with financial strain, which can lead them to experience **caregiver burden**.

In 1996 Congress passed the **Personal Responsibility and Work Opportunity Reconciliation Act**, commonly known as "welfare reform." This law targeted women who received public assistance and changed the previous Aid to Families with Dependent Children (AFDC) to **Temporary Assistance for Needy Families (TANF)**—a work program that mandates that women heads-of-household find employment to retain their benefits. The Administration for Children and Families (ACF), within the Department of Health and Human Services (USDHHS) is responsible for federal programs such as TANF that promote the economic and social well-being of families, children, individuals, and communities (ACF, n.d.).

The Patient Protection and Affordable Care Act (2010), also known as the Affordable Care Act (ACA) was passed by Congress and signed into law by President Obama in March 2010. The ACA has been considered the most significant reform law passed since Medicare and Medicaid were enacted in 1965. Some of the key features of the ACA include an end to health plans limiting or denying benefits to children under 19 years of age due to a pre-existing condition. Children under the age of 26 can be covered under their parent's health plan, lifetime coverage limits were stopped, no copayment is needed for preventive care, and access to insurance is provided for uninsured individuals (Kominski, 2014). The law is complex and expensive. As such, ACA is a continuing source of debate.

The nurse serves in a unique position for advocacy and support of health legislation and policy that supports the physical, mental, and social well-being of adults. Advocacy can be accomplished in a variety of ways such as lobbying, public speaking, participating in grassroots activities, and staying abreast of proposed legislation that influences the health of men and women, their families, and communities.

Ethical and Legal Issues and Legislation for Older Adults

Ethical issues regarding the care and treatment of older adults arise regularly. As the population continues to age and technological advances continue to be developed, complex ethical and legal questions will continue to increase. The most common of these issues involve decision making—assessment of the ability of the client to make decisions, the appropriate surrogate decision-maker, disclosure of information to make informed decisions, level of care needed on the basis of function, and termination of treatment at the end of life. One often-overlooked concern of older persons is **abuse**. The National Center on Elder Abuse (NCEA), within the Administration on Aging, notes that abuse encompasses physical, emotional, and sexual abuse, as well as exploitation, neglect, and abandonment. Identification of abuse consists of recognizing the following: (a) The willful infliction of physical pain or injury, (b) infliction of debilitating mental anguish and fear, (c) theft or mismanagement of money or resources, and (d) unreasonable confinement or the depriving of services.

It is estimated that every year one out of 10 older adults experiences abuse or neglect by a **caregiver**, with only a fraction

of cases being reported (Hoover and Polson, 2014). Although legal definitions vary from state to state, the NCEA defines **neglect** as “the refusal or failure to fulfill any part of a person’s obligations or duties to an elder. Neglect may also occur if the person who has fiduciary responsibilities fails to pay for items or necessary home care services or, on the part of the in-home service provider, to provide the necessary care (NCEA, n.d., p. 2). Older persons can make independent choices with which others may disagree. Their right to self-determination can be taken from them if they are declared incompetent. According to the Older Americans Act, **financial exploitation** is the “illegal or improper act or process of an individual, including a caregiver, using the resources of an older individual for monetary or personal benefit, profit or gain” (Administration on Aging, n.d., p. 1).

During the assessment process, nurses will want to be aware of contradictions between injuries and the explanation of their cause, codependency issues between client and caregiver, and substance abuse by the caregiver. Hoover and Polson (2014) suggest asking open-ended questions to patients presenting with signs of injuries or abuse, such as, “Can you tell me what happened?” and “What do you remember about how this injury occurred?” The local social services agency or area agency on aging can help with information on reporting requirements. Nurses can play a key role in reducing elder abuse.

The **Patient Self-Determination Act** of 1991 requires those providers receiving Medicare and Medicaid funds to give clients written information regarding their legal options for treatment choices if they become incapacitated. A routine discussion of **advanced medical directives** can help ease the difficult discussions faced by health care professionals, families, and clients. The nurse can help an individual complete a values history instrument. These instruments ask questions about specific wishes regarding different medical situations. “Your Life Your Choices: Planning for Future Medical Decisions: How to Prepare a Personalized Living Will” (Pearlman et al, 2010) is a valuable resource to help people by using scenarios and information to guide people through the process of developing advanced medical directives. There are two parts to the advanced directives. The **living will** allows the client to express wishes regarding the use of medical treatments in the event of a terminal illness. A **durable medical power of attorney** is the legal way for the client to designate someone else to make health care decisions when he or she is unable to do so. A **do-not-resuscitate order** (DNR) is a specific order from a physician not to use cardiopulmonary resuscitation. Physician Orders for Life-Sustaining Treatment (POLST) are becoming common to specify end-of-life care or resuscitation orders for patients not in cardiopulmonary arrest. The POLST document is brightly colored and signed by the physician and the patient, depending on the state, and specifies medical orders to be carried out by health care workers when the patient is unable to speak. The difference between a POLST form and an advance directive is that the POLST is usable throughout the community (Buck and Fahlberg, 2014). State laws vary widely regarding the implementation of these tools, so it is important to consult a knowledgeable source for information. It is also important to involve the family,

and especially the designated decision-maker or agent, in these discussions so that everyone is clear about the client’s choices.

Environmental Impact

The impact of an unhealthy environment adds significantly to the burden of disease for men and women. Men and women are often exposed to different environmental factors because of upbringing, employment, cultural, or tradition variations.

It is important to understand that the hosts (men and women) may respond differently to environmental factors. For example, Clougherty (2010) reports that women and girls are affected more than men and boys by air pollution. Both gender (a social construct) and sex (a biological construct) are factors that make identification of the impact of environmental hazards on men and women more complex. Social and environmental factors influence adults’ choices of health behaviors. Understanding how these factors impact health outcomes will require additional research and policy analysis (USDHHS, 2010). Conducting gender analysis as part of research would help clarify influences of environment on social and biological differences between men and women.

Governmental programs are in place to improve environmental health. The Centers for Disease Control and Prevention (CDC) Environmental Hazards and Effects Program (EHEP) is designed to prevent and control disease or death and to promote health and quality of life that result from interactions between people and their environments. The program uses indicators to assess and monitor progress on goals to improve the environmental health (CDC, National Center for Environmental Health, 2009). It is incumbent on community health nurses to decrease the burden of disease resulting from an unhealthy environment.

HEALTH STATUS INDICATORS

Health status indicators are the quantitative or qualitative measures used to describe the level of well-being or illness present in a defined population or to describe related attributes or risk factors. They can be represented in the form of rates, such as mortality and morbidity, or proportions, such as percentages of a given population that receive immunizations (Community Health Status Indicators, 2009). Data on local communities are available through the Community Health Status Indicators Reports. This report is a collection of nationally available data for localities, including vital statistics, census, infectious disease, environmental health, health care indicators, employment indicators, and many of the vulnerable populations estimates (Community Health Status Indicators Working Group, 2009).

While health status indicators in the United States show persistent health disparities among ethnic and racial groups, the awareness of these disparities remains low among the general public (Benz et al, 2011). Persons with low socioeconomic status are more likely to be affected by chronic illness such as diabetes, hypertension, and human immunodeficiency virus (HIV). They are also less likely to be screened for colorectal cancer or vaccinated against influenza (Meyer et al, 2013).

Over the past decade, efforts to reduce chronic disease risk factors in adults have resulted in less-than-expected improvements. The CDC developed the *Futures Initiative* (2005) as part of a major strategic planning process and developed a set of Health Protection Goals to track measures of mortality and morbidity by life stages (CDC, 2005). The goals were categorized by four themes, each with an overarching goal: Healthy People in Every Stage of Life, Healthy People in Healthy Places, People Prepared for Emerging Health Threats, and Healthy People in a Healthy World. Improvements were noted among all life stages with the exception of adults. Adults reported continued declining trends in perceived health status and dramatic declines in healthy weight indicators (Roy et al, 2009).

EVIDENCE-BASED PRACTICE

Health assessment and early detection are foundations for health promotion. Finding essential health indicators for older adults can better reflect the health status of the older adult population and efficiently detect their health problems in a timely and economical manner. This study aimed to explore the pertinent health indicators and to form a model of health for older adults. This study had two phases. Phase I began with sending evaluation surveys to a panel of ten professional experts to generate health indicators for older adults. Phase II was a preliminary determination of the extent of health predictions using these indicators by conducting a descriptive study involving a stratified random sample of 55 community-dwelling older adults. Results demonstrated three domains (physical health, psychological health, and social-economic health) and four constructs (activities of daily living, physical status, emotional health, and social engagement).

Nurse Use

Results of this study can be used for making health policy and/or setting goals for interventions. In addition, nurses who care for older adults may use the health indicators to plan and control the given quality of care.

From Chen K, Hung H, Lin H, et al: Development of the model of health for older adults. *Journal of Advanced Nursing* 67(9):2015–2025, 2011. Doi: 10.1111/j.1365-2648.2011.05643.x

Mortality

Life expectancy is a measure that is often used to gauge the overall health of a population. Although the United States spends more money per capita on health than any other country, other developed countries have a longer life expectancy for both genders. As illustrated in Figure 30-1, in the United States, life expectancy ranked 25th out of 37 countries and territories for men (75.2 years) and 23rd for women (80.4 years) (MMWR, 2008). However, these ranking methods did not reflect changes in health outcomes over time. A recent study (Kindig and Cheng, 2013) found that female mortality rates increased in 42.8% of U.S. counties, while male mortality rates increased in only 3.4%. Several factors were associated with lower mortality rates, including higher educational levels, not living in the South or West, and low smoking rates.

A comparative study of U.S. population health used data from the massive Global Burden of Disease (GBD) effort (U.S. Burden of Disease Collaborators, 2013). Significant improvements in U.S. health included an increase in overall life

expectancy from age 75.2 to 78.2. Age-standardized years of life lost (YLL) rates increased for Alzheimer disease, drug use disorders, chronic kidney disease, and falls. Ischemic heart disease, lung cancer, stroke, chronic obstructive pulmonary disease, and road injury were diseases and injuries with the largest number of YLLs in 2010 (U.S. Burden of Disease Collaborators, 2013).

Life expectancy and mortality rates also vary among ethnic/racial groups in the United States. Health disparities are strikingly apparent in life expectancy, death rates, and other measures of health status (CDC Health Disparities and Inequalities Report, 2013). For instance, African Americans in 2009 had the highest death rates from heart disease and stroke compared with other racial and ethnic populations. They also had the highest death rates from homicide, with rates among African American males highest across all age groups (CDC Health Disparities and Inequalities Report, 2013). The gap in life expectancy between white adults and African American adults persists but has narrowed since 1990 (National Center for Health Statistics, 2009). The age-adjusted death rate was 1.3 times greater, infant mortality rate 2.4 times greater, and maternal mortality rate 3.4 times greater for the African American population than for the white population. Life expectancy for the white population exceeded that for the African American population by 5.0 years (Heron et al, 2009).

Morbidity

When healthy years of life are increased, longer life spans are generally considered desirable. However, increasing prevalence of chronic diseases and other conditions associated with aging can increase functional limitations and affect quality of life. Moreover, being male or female leads to different socialization, expectations, and lifestyles that affect and interact with health in complex ways. Of particular concern is the high prevalence of adults with risk factors such as tobacco use, high cholesterol, obesity, and insufficient exercise habits, which are associated with chronic disease. Cholesterol levels have been dropping, in particular for the older adults, because of a large increase of drug therapies (NCHS, 2009). The leading risk factors related to disability-adjusted life-years (DALYs) in the United States are dietary risks, tobacco smoking, high body mass index, hypertension, high fasting plasma glucose, physical inactivity, and alcohol use (U.S. Burden of Disease Collaborators, 2013).

The prevalence of diabetes, serious heart conditions, and hypertension among adults 45 to 64 years of age is strongly associated with poverty status. In lower-income populations, modifiable risk factors for these diseases are more common. The number of poor adults 45 to 64 with hypertension was similar to the percentage of higher-income persons who were 65 to 74 years of age (NCHS, 2009).

Although women live longer than men, by about 5 years, they do not necessarily live those extra years in good physical and mental health. Women are more likely to use health services and report greater rates of disability. For instance, men have higher blood pressure levels than women through middle age. However, after menopause, women may be more affected by increased blood pressure. Women also present with different risk factors and symptoms for cardiac-related conditions.

FIG 30-1 Life expectancy at birth for men and women in selected countries.

Women often report more jaw/neck pain, dyspnea, back pain, fatigue, paroxysmal nocturnal dyspnea, and palpitations. Men and women were equally likely to report midsternal chest pain or pressure (Shin et al, 2009).

ADULT HEALTH CONCERNS

Chronic Disease

In 1988 the CDC created the National Center for Chronic Disease Prevention and Health Promotion (NCCDPHP). Chronic illness has become a public health problem of great proportions. The most common and costly chronic diseases are heart disease, diabetes, stroke, cancer, and arthritis. Eighty-four

percent of all health care spending in 2006 was for the 50% of the population who have one or more chronic medical conditions (Robert Wood Johnson Foundation, 2010). Chronic disease is the leading cause of preventable deaths, disability, and decreased quality of life. The CDC has identified four modifiable health risk behaviors for the prevention of chronic disease. These are lack of physical activity, poor nutrition, tobacco use, and excessive alcohol use (NCCDPHP, 2014). Many models have been developed to guide the delivery of care to people with chronic illness. A complex health care system and community model was developed with the funding of the Robert Wood Johnson Foundation. This model is Wagner's **Chronic Care Model** (CCM).

HEALTHY PEOPLE 2020

Selected Objectives Relevant to Major Health Issues and Chronic Disease of Adults

Arthritis, Osteoporosis, and Chronic Back Conditions

- AOCBC-7: Increase the proportion of adults with doctor-diagnosed arthritis who receive health care provider counseling.
- AOCBC-10: Reduce the proportion of adults with osteoporosis.

Cancer

- C-1: Reduce the overall cancer death rate.

Diabetes

- D-3: Reduce the diabetes death rate.

Educational and Community-Based Programs

- ECBP-9: (Developmental) Increase the proportion of employees who participate in employer-sponsored health promotion activities.

Environmental Health

- EH-3: Reduce air toxic emissions to decrease the risk of adverse health effects caused by airborne toxics.

Genomics

- G-1: Increase the proportion of women with a family history of breast and/or ovarian cancer who receive genetic counseling.
- G-2: (Developmental) Increase the proportion of persons with newly diagnosed colorectal cancer who receive genetic testing to identify Lynch syndrome (or familial colorectal cancer syndromes).

Heart Disease and Stroke

- HDS-2: Reduce coronary heart disease deaths.
- HDS-3: Reduce stroke deaths.

Older Adults

- OA-1: Increase the proportion of older adults who are up to date on a core set of clinical preventive services.

Physical Activity and Fitness

- PAF-2: Increase the proportion of adults that meet current Federal physical activity guidelines for aerobic physical activity and for muscle strength training.

U.S. Department of Health and Human Services: *Healthy People 2020*, 2010. Retrieved from <http://www.healthypeople.gov/2020/default.aspx> 9/11/2014

The CCM identifies the essential elements of a health care system that encourages high-quality chronic disease care. These elements are the community, the health system, self-management support, delivery system design, decision support, and clinical information systems. Evidence-based change concepts under each element, in combination, foster productive interactions between informed clients who take an active part in their care and providers with resources and expertise (*Model Elements*, 2014). The CCM continues to be implemented and evaluated today. Using electronic health records, provider reminders for key evidence-based care components, interprofessional teams communicating regularly, and community health classes to educate people with chronic diseases are ways the CCM is being

implemented. A modification of the CCM to include health literacy was suggested by Koh et al (2013).

Chronic disease **self-management** (CDSMP) is one intervention that has shown positive outcomes for people with chronic diseases. The U.S. Administration on Aging initiated CDSMP in 2009. Within two years 9305 workshops were offered to more than 100,000 middle-aged and older adults (Ory et al, 2013). Studies have shown improvement in health behaviors, health outcomes, and reduced health care utilization. A recent study showed significant reductions in emergency room visits and hospitalizations. Potential savings of \$364 per participant and a national savings of \$3.3 billion could result if only 5% of the U.S. population participated (Ahn et al, 2013). Opportunities exist for additional studies to identify effective models and strategies. Nurses should consider using models and strategies that have shown improvements in health behaviors or outcomes when planning community interventions.

Family remains an important source of support for people with chronic disease. A recent review of programs to increase effective family support showed that programs that train families in supportive communication techniques have improved both health behaviors and client symptom management (Rosland and Piette, 2010).

Cardiovascular Disease

About 83.6 million American adults have one or more types of **cardiovascular disease** (CVD). The leading cause of death for African Americans, American Indians or Alaska Natives, Hispanics, and whites in the United States is **heart disease**. It is the leading cause of death for both men and women. Heart disease was responsible for 31.9% of deaths in 2010 (Go et al, 2014). The annual cost of heart disease for 2010 to the United States was estimated to be \$315.4 billion. In response to the high incidence and mortality rates of heart disease, the American Heart Association (AHA) has the following goal: "By 2020, to improve the cardiovascular health of all Americans by 20 percent while reducing deaths from cardiovascular diseases and stroke by 20 percent" (American Heart Association, 2010). Progress is being made in this area as from 2000 to 2010 death rates attributable to CVD declined by 31% (Go et al, 2014). However, with the increased rates of obesity and diabetes in children, future prevalence may increase.

Approximately 23 of the *Healthy People 2020* objectives focus on cardiovascular disease. Reaching these objectives means intervening with all ethnicities in the United States. However, there continue to be gaps in knowledge and awareness for heart disease, particularly in women. In a 2009 survey of 2300 women age 25 or older, 60% of white women were aware that heart disease was the leading cause of death for women. However, only 43% of African American women, 44% of Hispanic women, and 34% of Asian women knew the major cause of death for their gender. Knowledge of heart attack signs and symptoms has not increased since 1997 among all women surveyed, and only 53% of the women surveyed said they would call 911 if they thought they were having a heart attack (Mosca et al, 2010). Improvement in this area has also been noted. Mosca et al (2013) found that "Between 1997 and 2012, the rate

of awareness of CVD as the leading cause of death nearly doubled (56% versus 30%; $P < 0.001$). The rate of awareness among black and Hispanic women in 2012 (36% and 34%, respectively) was similar to that of white women in 1997 (33%). In 1997, women were more likely to cite cancer than CVD as the leading killer (35% versus 30%), but in 2012, the trend reversed (24% versus 56%).” The trend of the data is encouraging but the overall knowledge of women and minority women remains low.

Hypertension

High blood pressure, or **hypertension**, is estimated to occur in one in three, or approximately 78 million Americans. Uncontrolled hypertension leads to heart attack, stroke, kidney damage, and a host of other complications. Only 82% of people with hypertension are aware that they have the disease. Hypertension is controlled in 53% of people with the disease, 75% are under current treatment, and 47% do not have it controlled (AHA, 2014). Although these numbers are not optimal, blood pressure control has improved significantly over time; however, racial, ethnic, and socioeconomic differences have not shown significant improvement. There is no significant difference in prevalence between men and women, but there are racial and ethnic differences in hypertension rates among both men and women. Forty-four percent of African Americans have hypertension; this is the highest ethnic prevalence (AHA, 2007). A recent discovery is the connection between obstructive sleep apnea and hypertension. [Konecny et al \(2014\)](#) examined the evidence on sleep apnea and hypertension and noted that sleep apnea is a modifiable and highly prevalent factor in the development of hypertension. Once hypertension is present, CPAP averages only a modest 2 mm Hg drop in blood pressure (p. 208).

Stroke

Strokes have decreased in the United States since the 1950s. The actual number of stroke deaths declined by 22.8% from 2000 to 2010 ([Go, 2014](#)). However, the estimated prevalence of stroke in 2010 was 6.8 million for people equal to or greater than 20 years of age. Approximately 795,000 people each year experience a new or recurrent stroke. The lifetime risk for stroke is higher in women (≈ 1 in 5) than in men (≈ 1 in 6), and since women live longer than men and strokes increase with age, more women than men are likely to die from stroke. African Americans have almost twice the risk of first-time strokes as whites. Mexican Americans also have an increased incidence of stroke over non-Hispanic whites. The prevalence of strokes is projected to increase 21.9% by 2030 ([Go, 2014](#)).

One *Healthy People 2020* objective is to reduce stroke deaths to 48 in 100,000. Community-based programs and policies regarding stroke care from initial signs and symptoms to after-treatment have been developed by the AHA and other organizations. The CDC’s Division for Heart Disease and Stroke Prevention (DHDSP) is promoting the use of community health workers (CHWs) to support healthy living strategies that would reduce the prevalence of stroke as well as other chronic conditions ([Brownstein et al, \(2013\)](#)). Collaboration between

health care institutions, community leaders, emergency medical services, CHWs, and support groups within the community is needed for programs to be effective. Nurses can direct efforts toward smoking reduction, since the incidence of ischemic stroke is twice as high in smokers as in adults who do not smoke (AHA, 2010).

Diabetes

Diabetes is a serious public health challenge for the United States. Between 1980 and 1990 the number of new cases remained stable, but from 1990 to 2010 the annual number of new cases almost tripled. Increases in obesity, decreases in leisure-time **physical activity**, and the aging population are associated with this dramatic increase in the incidence of type 2 diabetes (CDC, 2012a). An estimated 19.7 million Americans were diagnosed with diabetes mellitus in 2010 ([Go, 2014](#)). Diabetes is an epidemic, with 1 in 12 to 13 adults reportedly having diabetes, costing the nation approximately \$174 billion each year. It is also estimated that for every three people who have diabetes, there is another who does not know he or she has it. Age-adjusted diabetes was diagnosed in 16.1% of American Indian and Alaska Natives, 8.4% of Asian Americans, 11.8% of Hispanics, 12.6% of non-Hispanic African Americans, and 7.1% of non-Hispanic whites. The many complications associated with diabetes include heart disease, stroke, hypertension, retinopathy, kidney disease, neuropathies, amputations, and dental disease (CDC, 2012a).

At least 18 of the goals of *Healthy People 2020* are related to diabetes. There is a tremendous need in the community to strive to limit the toll this disease takes on the person and the community. Social and economic factors related to health and well-being need to be addressed.

Primary prevention includes educating adults about nutrition and the risks of obesity, smoking, and physical inactivity. Community interventions addressing healthy eating, exercise, and weight reduction can also benefit adults at risk for diabetes. Secondary prevention includes screening for diabetes with finger-stick blood glucose tests or glucose tolerance tests. Screening is also accomplished by thorough history and physical examination. Tertiary prevention targets activities aimed at reducing the complications of the disease (see [Levels of Prevention](#) box).

Mental Health

Mental disorders are a common cause of disability. According to the 2012 National Survey on Drug Use and Health: Mental Health Findings, there were an estimated 43.7 million (18.6%) adults in the United States with any mental illness in the prior year and 9.6 million (4.1%) of those were categorized as serious mental illness (U.S. Department of Health and Human Services, 2013). As described previously, gender makes a difference regarding environmental impact on health. Similarly, gender influences how a person responds to stress, presents with symptoms, experiences the course of illness, and accesses and uses **mental health** services ([Forchuk et al, 2009](#)). Although both men and women suffer from the burden of mental illness, women experience certain conditions such as anxiety and

LEVELS OF PREVENTION

Cardiovascular Disease in Women and Prevention of HIV in Men

Primary Prevention

Collaborating with a variety of organizations such as the American Heart Association to design and implement interventions aimed at reducing women's risk for cardiovascular disease.

The nurse advises men who have sex with other men to use a new latex condom during oral or anal sex. In group and individual counseling about HIV, the nurse indicates to clients that they should not share needles, syringes, razors, or toothbrushes.

Secondary Prevention

Establishing screening clinics in community settings for cholesterol and hypertension.

The nurse advises an infected man to swallow all of his highly active anti-retroviral therapy (HAART) medication on schedule. The nurse advises a man who had unprotected sex to be tested with a standard enzyme-linked immunosorbent assay (ELISA), followed by a confirmatory Western blot test.

Tertiary Prevention

Developing a community-based exercise program for a group of women who have cardiovascular disease.

The nurse teaches men newly diagnosed with HIV to exercise regularly, eat a balanced nutritious diet, sleep at least 8 hours a day, and stop or limit alcohol. The nurse advises clients not to donate blood, plasma, or organs.

depression more often than men, yet men have a higher suicide rate (Riska, 2009). It is important to consider sex and gender when generating meaningful knowledge and interventions to promote the health of both men and women.

Researchers are exploring how biological factors, including genetics and sex hormones, affect women's increased risk for depression. Other scientists are focusing on how psychosocial factors such as life stress, trauma, and interpersonal relationships contribute to women's depression (Danielsson et al, 2009). Although the roles men and women traditionally fulfill in society continue to be the framework of much mental health research, additional focus is addressing cultural or other factors to explain differences (Riska, 2009).

Mental illness is generally viewed by society in a negative manner (Bos et al, 2009). This social stigma leads to guilt, low self-esteem, social isolation, and ultimately to poorer health (Stuenkel and Wong, 2009). Community education programs will want to focus on speakers who address audiences to educate them and dispel the stereotypes and fears often applied by society to individuals with mental illness. Local and mass media outlets can be incorporated to broadcast positive aspects of those living with mental disabilities and functioning as a productive part of society.

Cancer

Cancers of all types are a serious public health concern (Table 30-1). Cancer is the second leading cause of death in the United States, surpassed only by heart disease. As of January 1, 2012, approximately 13.7 million Americans with a history of cancer

TABLE 30-1 Deaths Caused by Cancers*

Population	Men	Women
White	218.7	153.4
African American	278.8	176.9
Hispanic	145.4	101.4
Native American	137.0	108.9
Asian/Pacific Islander	128.2	93.3

*Rates are per 100,000.

From Centers for Disease Control and Prevention: Rates for new cancer cases and deaths by race/ethnicity and sex, n.d. Available at www.cdc.gov.

were alive, some of whom were cancer free. The American Cancer Society's (ACS) 2014 Cancer Facts and Figures reports an estimated 585,720 cancer deaths in 2014, 176,000 of which resulted from tobacco use. In the same year, about 1,665,540 new cancer cases are projected to be diagnosed. The report also gave estimates by the National Institutes of Health that place the overall costs of cancer in 2009 at \$216.6 billion. Of this total, \$86.6 billion is for direct medical costs and \$130 billion for indirect costs or those resulting from lost productivity related to illness or premature death. These costs could be reduced by removing barriers to care such as lack of health insurance and improving the health literacy of Americans.

Early screening and detection, promotion of healthy lifestyles, expansion of access to services, and improvement in cancer treatments will help reduce the burden of cancer and disparities. For example, the declining death rates from colorectal cancer are largely attributed to screening and risk factor reduction (Edwards et al, 2009). Finding cancer lesions in a precancerous state, such as those found in cervical, colorectal, and breast cancer, allows for treatment while in a highly treatable stage. Obesity, physical inactivity, smoking, heavy alcohol consumption, a diet high in red or processed meats, and insufficient intake of fruits and vegetables are risk factors for colorectal cancer. Reducing these risk factors will reduce the incidence of the disease.

Public health agencies, health care providers, and communities must work together to reduce the burden of cancer on society. The *Healthy People 2020* goal is to reduce the number of overall cancer cases as well as the illness, disability, and death caused by cancer. Education on the hazards of tobacco use and second-hand smoke, eating a healthy diet and limiting daily consumption of alcohol, and exposure to ultraviolet rays are examples of topics for education programs that will reduce the burden of cancer on society.

STDs/HIV/AIDS

Sexually transmitted diseases (STDs) refer to more than 25 infectious organisms, such as viruses, bacteria, or parasites, transmitted primarily through sexual activity. Some other means of transmission include lice, mother-to-child transmission during pregnancy or breastfeeding, or contaminated needles used in drug use or surgery. The term **sexually transmitted infections** (STIs) is also used synonymously, although

there are distinctions. Shuford (2008) explained that *STI* is a broader term meaning that the body has had an invasion and multiplication of microorganisms, whereas *STD* signifies that pathology or damage has occurred with or without symptoms. STDs continue to be a major burden to society and have tremendous health and economic consequences in the United States despite their relatively preventable nature. The costs to the U.S. health care system related to STDs are as much as \$15.3 billion annually (CDC, 2008).

The CDC (2008) estimates there are approximately 19 million new STD infections each year, with almost half occurring in people from 15 to 24 years of age. Many cases go undiagnosed, so the true burden is not fully known. In 2008, more than 1.5 million cases of chlamydia and gonorrhea occurred, making them the two most reported infectious diseases. Females are at greater risk for STDs as a result of biological differences and other factors. Syphilis, once close to elimination, has reemerged, primarily related to men who have sex with men (MSM), but not in all cases (CDC, 2008). People with an STD are more susceptible to and two to five times more likely to acquire an HIV infection (CDC, 2013).

In the United States approximately 1.1 million people were diagnosed or undiagnosed with HIV infection (CDC, 2013). The HIV incidence is about 50,000 new infections per year, which appears stable. Seventy-eight percent of new HIV infections and 63% of all of these new infections occurred in MSMs. African Americans accounted for 44% of the HIV/AIDS cases whereas Hispanics/Latinos accounted for 21% of new cases in 2010.

The *Healthy People 2020* goal is to promote responsible sexual behaviors, strengthen community capacity, and increase access to quality services to prevent STDs and their complications (USDHHS, 2010b). Nurses have a role in this goal and can serve as advocates by focusing on the high-risk behaviors of men and women, as well as on the factors in their communities that lead to STDs. High-risk populations should be considered when assessing for clients' risk for STDs, including pregnant women, adolescents, MSM, women who have sex with women (WSW), and older clients (Waski and Kachlic, 2009). Interventions to improve education, employment opportunities, and adequate housing—as well as those to decrease drug use, isolation, and poverty—can have a critical impact on this epidemic. The CDC/HRSA Advisory Committee on HIV/AIDS and STD Prevention (CHAC) recommend the following: (1) early detection and treatment of curable STDs should become a major, explicit component of comprehensive HIV prevention programs at national, state, and local levels; (2) in areas where STDs that facilitate HIV transmission are prevalent, screening and treatment programs should be expanded; (3) HIV testing should always be recommended for individuals who are diagnosed with or suspected to have an STD; and (4) HIV and STD prevention programs in the United States, together with private and public sector partners, should take joint responsibility for implementing these strategies (see [How To](#) box).

Weight Control

Americans spend a great deal of time, energy, and money in the never-ending pursuit of the beautiful body. One study indicated

HOW TO

To reduce the prevalence of STDs, the CDC/HRSA Advisory Committee on HIV/AIDS and STD Prevention (CHAC) recommend the following:

- Early detection and treatment of curable STDs should be a major, explicit component of comprehensive HIV prevention programs at national, state, and local levels.
- In areas where STDs that facilitate HIV transmission are prevalent, screening and treatment programs should be expanded.
- HIV testing should always be recommended for individuals who are diagnosed with or suspected to have an STD.
- HIV and STD prevention programs in the U.S., together with private and public sector partners, should take joint responsibility for implementing these strategies.
- Social, behavioral, and biomedical interventions should also be included in a comprehensive HIV prevention program.

Centers for Disease Control and Prevention: *CDC fact sheet: the role of STD prevention and treatment in HIV prevention*, 2010. Available at <http://www.cdc.gov/std/hiv/stds-and-hiv-fact-sheet-press.pdf>.

Accessed April 15, 2014.

that spending on overweight and obesity could be as much as 10%, or \$147 billion, of U.S. health care costs (Finkelstein et al, 2009). In 1998 the National Institutes of Health (NIH) began using the calculation of **body mass index** (BMI) to define overweight and obesity in individuals. BMI is the relationship of body weight and height. A BMI of 25 to 29.9 is defined as overweight, whereas a BMI of 30 and above is considered obese (WIN, 2008) (Table 30-2).

Overweight and obesity are topics addressed numerous times in *Healthy People 2020*. According to the AHA (2009), 145 million Americans age 20 and older are overweight or obese (BMI ≥ 25.0 kg/m²). This number is composed of 76.9 million men and 68.1 million women. Of the total 145 million, 74.1 million are obese (BMI ≥ 30.0).

Obesity has many effects on health and is linked to a number of major health problems. Nurses can provide education regarding obesity's risks to health. The educational offerings can be fashioned after a community health model using the levels of prevention to establish effective interventions for adults at risk for **weight control** issues. For example, only about one third of all adults meet the 2008 Physical Activity Guidelines (CDC, 2008). Therefore, a community prevention project aimed at

TABLE 30-2 BMI Determination and Interpretation

BMI*	Category
≤18.5-24.9	Normal weight
25.0-29.9	Overweight
30.0-39.9	Obesity
≥40	Extreme obesity

*Body mass index is a method used to determine optimal weight for height and is an indicator for obesity or malnutrition.

From National Institutes of Health: Do you know the health risks of being overweight? Rockville, MD, 2004, USDHHS.

increasing activity levels would help in prevention of obesity and subsequent illnesses of diabetes and heart disease.

In addition to obesity, other eating disorders have increased among U.S. women. Common eating disorders seen in women include anorexia nervosa and bulimia. **Anorexia** is defined as a fear of gaining weight coupled with disturbances in perceptions of the body. Excessive weight loss is the most noticeable clue to this disorder. Individuals with anorexia rarely complain of weight loss because they view themselves as normal or overweight. Many of these women also struggle with psychological problems, including depression, obsessive symptoms, and social phobias. **Bulimia** is characterized by a persistent concern with the shape of the body along with body weight, recurrent episodes of binge eating, a loss of control during these binges, and use of extreme methods to prevent weight gain, such as purging, strict dieting, fasting, use of laxatives or diuretics, or vigorous exercise (NIMH, 2014).

Through comprehensive physical and psychosocial assessments, as well as histories of dietary practice, nurses identify women with eating disorders and provide appropriate referrals. Weight control strategies include promoting healthy eating habits and regular physical activity. At a population level, nurses advocate against advertising that promotes exceptionally thin bodies for women. They also promote community-wide exercise and healthy eating programs.

WOMEN'S HEALTH CONCERNS

It is preferable to emphasize prevention in adult health care. Screening, immunizations, and a healthy lifestyle are important for women of all ages. The **Office on Women's Health** (USDHHS, 2014) works through policy, education, and model programs to improve the health of women and girls. This agency has guidelines that include screening tests and disease-specific information for women. The Agency for Research and Health Quality (ARHQ) was mandated by Congress to provide annual reports on health care quality and disparities. Women are one of the populations addressed in this report.

Reproductive Health

Women often use health care services for **reproductive health** concerns. A number of *Healthy People 2020* objectives address areas related to women's reproductive health (see the Maternal Infant and Child Health section of the *Healthy People 2020*).

Nurses are in a unique position to advocate for policies that increase women's access to services for reproductive health. In addition, many nurses discuss contraception with women of child-bearing age. Contraceptive counseling requires accurate knowledge of current contraceptive choices and a nonjudgmental approach. The goal of contraceptive counseling is to ensure that women have appropriate instruction to make informed choices about reproduction. The choice of contraceptive method depends on many factors, including the woman's health, frequency of sexual activity, number of partners, and plans to have future children. Except for abstinence, no method provides a 100% guarantee against **unintended pregnancy** or disease (USDHHS, 2014).

Preconception counseling addresses risks before conception and includes education, assessment, diagnosis, and intervention. The purpose is to reduce and/or eliminate health risks for women and infants. One major health problem that could be significantly impacted by preconception counseling is the problem of neural tube defects. More than 300,000 babies annually are born with neural tube defects (anencephaly and spina bifida). In the United States, it is estimated that the annual health care costs for people with spina bifida exceed \$200 million. The United States is part of a global initiative to reduce these numbers. Research has shown that intake of folic acid can significantly reduce the occurrence of these very serious and often fatal neural tube defects by 50% to 70%. The goal of one *Healthy People 2020* objective is to increase the proportion of pregnancies begun with the recommended folic acid level; a recommendation was made that women capable of or planning a pregnancy take 400 mcg of folic acid daily (CDC, 2012b). Supplementation of cereal and masa flour, surveillance, and detection of levels are part of the initiatives currently being conducted with worldwide partners (NCBDDD, 2014).

Another concern critical to preconception awareness is exposure to substances such as alcohol. A major preventable cause of birth defects, mental retardation, and neurodevelopmental disorders is fetal exposure to alcohol during pregnancy. Although fetal alcohol syndrome disorders (FASD) are declining in the United States, they remain a preventable public health problem. According to the Substance Abuse and Mental Health Services Administration (SAMSHA) in 2010, FASD affects 40,000 babies born in the United States each year. The rate is higher (15 to 25 per 10,000) among some Native American tribes (SAMSHA, 2009). The CDC and the American Academy of Pediatrics recommend no alcohol during pregnancy. Cannon et al (2012) sought to prevent FAS by studying the characteristics of birth mothers. They discovered that predictors were older age, American Indian/Alaska Native or African American ethnicity, unmarried, unemployed, and without prenatal care. In addition they were more likely to be smokers, Medicaid recipients, have a history of treatment for alcohol abuse or confirmed alcoholism, and to have used marijuana or cocaine during their pregnancy. Community interventions have been shown to help decrease the consumption of alcohol during pregnancy. Studies are needed with interventions that target this risk group for children with FAS.

Nurses will want to be involved in community-based interventions for women. They can conduct motivational classes and participate in campaigns that print and broadcast advertisements informing women of child-bearing age that drinking during pregnancy can cause birth defects. Nurses can serve as advocates not only to encourage their clients to use prenatal care services, but also to work toward the establishment of services that are accessible, affordable, and available to all pregnant women.

Gestational Diabetes

Gestational diabetes mellitus (GDM) is a condition characterized by carbohydrate intolerance that is first identified or develops during pregnancy. The incidence of gestational diabetes is

increasing in the United States. Gestational diabetes has a higher incidence among African Americans, American Indians, and Hispanic/Latino Americans. According to the CDC (2011), after the pregnancy ends 5% to 10% of women will continue with diabetes or have a 35% to 60% chance of developing diabetes within the next 10 to 20 years.

Clearly, interventions are needed to prevent gestational diabetes and its consequences for both mother and baby. A meta-analysis of studies regarding physical activity and gestational diabetes was conducted by Tobias et al (2011). Higher levels of physical activity were significantly associated with a lower risk of developing gestational diabetes mellitus. This association occurred with physical activity that occurred before pregnancy or in early pregnancy (p. 223). Nursing interventions related to activity levels are imperative in reproductive women and their unborn children.

Menopause

During **menopause** the levels of the hormones estrogen and progesterone change in a woman's body. This change leads to the cessation of menstruation. Decline in these hormone levels can affect the vaginal and urinary tract, cardiovascular system, bone density, libido, sleep patterns, memory, and emotions (NIA, 2014).

Women's attitudes toward menopause vary greatly and are influenced by culture, age, support, and the recounted experiences of other women. For decades, however, the prevailing medical view of menopause was a state of deficiency that required hormone replacement to reduce heart disease and osteoporosis. A more positive outlook on menopause encourages women to view it as a transitional and natural stage in the life of a woman.

For decades, many U.S. women used hormone replacement therapy (HRT), although HRT remained untested by rigorous scientific study. A clinical trial launched in 1991, the Women's Health Initiative, set out to test specific effects HRT had on women's health, especially its effects on heart disease and osteoporosis. Researchers concluded that HRT did not prevent heart disease and that to prevent heart disease women should avoid smoking, reduce fat and cholesterol intake, limit salt and alcohol intake, maintain a healthy weight, and be physically active. Scientists also concluded that HRT should be used to prevent osteoporosis only among women who are unable to take non-estrogen medications (NOF, 2014).

Complementary and Alternative Therapies

The change in the recommendations regarding HRT led many women to seek alternative approaches for the management of menopausal symptoms. Women experiencing menopause frequently report symptoms including hot flashes, vaginal dryness, and irregular menses. Examples of alternative therapies are those actions that are taken by women instead of HRT. Complementary therapies are those taken to augment (or as a complement to) HRT. The listing of alternative/complementary therapies for menopausal symptoms can be an endless task, but Box 30-1 provides common examples. The National Center for Complementary and Alternative Medicine at the National

BOX 30-1 Examples of Alternative/Complementary Therapies for Menopausal Symptoms

- Acupuncture
- Acupressure
- Massage therapy
- Healing touch
- Aromatherapy
- Guided imagery
- Chiropractic healing
- Yoga
- Tai Chi
- Qi gong
- St. John's wort
- Black cohosh
- Soy and isoflavones
- Ginseng
- Kava
- Red clover
- Dong quai

Institutes of Health (2012) notes that alternative therapies may or may not be helpful in reducing menopausal symptoms and that more research should be done to determine the scientific benefits and risks of these therapies. A systematic review of the literature on mind-body therapies for menopausal symptoms was conducted by Innes et al in 2010. They noted that yoga-based and certain other mind-body therapies may be beneficial, but recommended further study.

Breast Cancer

In 2014 an estimated 232,670 U.S. women will be diagnosed with breast cancer. Of that number, an estimated 40,000 women will die. The breast cancer death rate in the United States has been declining since 1989-1990. The death rate has been declining an average of 1.9% per year over the last 10 years. In 2010, there were an estimated 2,829,041 women living with breast cancer (ACS, 2014b). Although the incidence of breast cancer is higher in white women than in African American women, the death rate for African American women is higher. Secondary prevention that includes screening activities, such as mammography and clinical breast examination, makes a difference in death rates. Early detection can promote a cure whereas late detection typically ensures a poor prognosis (NCI, 2014b).

Osteoporosis

Osteoporosis, or *porous bone*, is a disease "marked by reduced bone strength leading to an increased risk of fractures, or broken bones" (NIAMSD, 2014). This is the most common bone disease, affecting 40 million people in the United States, and is most common in white and Asian women. Among women more than 50 years of age, approximately one out of every two women will have an osteoporosis-related fracture—that is 2 million fractures annually that are attributed to osteoporosis. Hip fractures have the most impact on quality of life and one in 5 people who suffer hip fractures over the age of 50 will die in the year following their fracture (NIAMSD, 2014). According to the National Osteoporosis Foundation's Clinician's Guide to Prevention and Treatment (2014, Version 1), the cost of care for hip fractures is projected to be \$25.3 billion by 2025.

Prevention includes diets rich in calcium and vitamin D and avoiding medications that cause bone loss. Exercise also

improves bone density, especially weight-bearing activities such as walking, running, stair climbing, and weight lifting. Limiting alcohol consumption and avoiding smoking are also important. Home assessment and correction of risk factors for falls, bone density testing, and annual height measurements help with fracture prevention. Finally, several medications are approved for the prevention of osteoporosis in the United States (NOF, 2014).

MEN'S HEALTH CONCERNS

The health status of one gender impacts the health status of the other gender, the children, and ultimately society. For example, when a male is ill and cannot work, the family and society are impacted economically and work productivity is reduced. The family can suffer from lack of income. If the male dies, the widow generally experiences the loss of companionship and assumes the responsibilities of the lost spouse. Resources to promote and sustain health outcomes of both genders must be balanced for the overall health of the community. However, although a vital aspect of community health, **men's health** is often overlooked and factors exist that prevent men from reaching their full health potential. Factors such as "socioeconomic status, access to health care, male acculturation to health issues, harmful perceptions about masculinity, and lack of understanding of male health behaviors contribute to poor health outcomes for men" (Giorgianni et al 2013, p. 343). There are a wide range of poorer overall health status and health outcomes for men in the United States that result in an approximately 5-year shorter life span for men than women. Giorgianni et al (2013) provide examples of these different outcomes; for example, more men than women smoke (21.5% versus 17.3%), more men are overweight (72.3% versus 64.1), and men are less likely to receive routine care or seek out care early in the disease process than women. Changing these health behaviors could significantly improve the health outcomes of men.

Although health policies, campaigns, and community health organizations offer services for men, there are disparities that emphasize women's health and other barriers that negatively impact men's health (Broom and Tovey, 2009). Several barriers to men reaching their full health potential have been identified. Men do not participate in health care to the same level as women, apparently because of the traditional masculine gender role learned through socialization (Giorgianni et al, 2013). Only 57% of U.S. men see a doctor, nurse practitioner, or physician assistant compared with 74% of women (AHRQ, 2010). Even fewer Hispanic (35.5%) and African American (43.5%) men compared with white (63%) men made appointments for routine medical care. Men are socialized to ignore pain, be self-reliant, and be achievement oriented. Large numbers of men do not receive the **health screenings** intended to prevent and identify disease. Men are more often employed in dangerous jobs and incur more work-related injuries than women (Berdahl and Zodet, 2010). Not only do these behaviors limit the opportunity to prevent disease through screening, health education, and counseling, but also once they are diagnosed, management and treatment will be more difficult.

Disparities and barriers such as these provide opportunities and challenges for nurses. By being aware of disparities and barriers in the health care system and recognizing that something should be done, nurses can help reduce the bias and remove barriers to health for both genders. Nurses will want to develop strategies to get men involved in lifestyle changes that prevent illness. All health care providers can do a better job at reaching out to men and offer the guidance and knowledge to improve men's health. Nurses can take an active role in public policy development and implementation. The role also includes encouraging men to identify primary care providers and obtain a physical examination and the appropriate recommended screening tests.

Men who can establish a working relationship with their health care provider and participate in the recommended screening tests may live healthier, happier, and longer lives. Refer to [Box 30-2](#) for a variety of screening tests with suggested frequencies. Health screenings as well as other prevention strategies for adults are regularly updated by AHRQ. Some health screenings are clearly beneficial while health care providers and researchers debate the benefit of other screening procedures. As

BOX 30-2 Prevention Strategies for Adults

Dental Health

- Regular dental examinations
- Floss; brush with fluoride toothpaste

Health Screening

- Blood pressure
- Height and weight
- Nutritional screening (obesity)
- Lipid disorders (men 35 and older; women 45 and older)
- Papanicolaou (Pap) test (all women sexually active with a cervix)
- Colorectal cancer (adults 50 and older)
- Mammogram (women 40 and older)
- Osteoporosis (postmenopausal women 60 and older)
- Problem drinking
- Depression screening
- Tobacco use/tobacco-causing diseases
- Rubella serology or vaccination (women of child-bearing age)
- Chlamydia (sexually active women age 25 and younger; women older than 25 with new/multiple sexual partners)
- Testicular cancer (symptomatic males)
- Coronary heart disease screening (ECG; exercise treadmill)
- Syphilis screening (for at-risk population only)
- Diabetes mellitus (adults with hypertension or hyperlipidemia)

Chemoprophylaxis

- Multivitamin/folic acid (women planning or capable of pregnancy)
- Aspirin prevention (CAD at-risk adults)

Immunizations

- Tetanus-diphtheria (TD) boosters
- Rubella (women of child-bearing age)
- Pneumococcal vaccine (adults 65 and older)
- Influenza vaccine (adults 65 and older/at risk/annually)

From: [Agency for health care quality and research](#), US preventive services taskforce: The guide to clinical preventive services, 2009, Rockville Md, AHRQ

a health care professional, it is important to keep up to date on current research and literature to identify the appropriate screenings for the specific population served.

Nurses can assume many roles to fulfill responsibilities to improve the health of men in the community. As an educator, the nurse provides the knowledge and skill for replacing unhealthy behaviors with a healthy lifestyle. As a client advocate, the nurse supports and interacts with those agencies to obtain the needed resources. The nurse acts as a change agent to assess needs and system influences, identify and set priorities, plan and implement programs for men, and evaluate results. Working within groups and communities, nurses can identify needs and priorities and develop interventions to reduce health risks and improve the health status not only of men, but also of their wives, mothers, daughters, and sisters and the communities in which they live.

Cancers Unique to Men

Prostate Cancer

In 2011, 209,292 men in the United States were diagnosed with **prostate cancer** and 27,970 died from the disease (U.S. Cancer Statistics Working Group, 2014). According to the National Cancer Institute (NCI, 2014a), approximately 15% of men will be diagnosed with prostate cancer in their lifetime. The NCI estimates that 233,000 new cases will be diagnosed in 2014. It is the most common non-skin cancer and the second leading cause of cancer deaths in the United States (NCI, 2014a). African American men have higher rates (223.9/100,000) of prostate cancer compared to all races (147.8/100,000). Prostate cancer is linked to changes in the DNA of a prostate cancer cell and high levels of male hormones, but the exact cause of prostate cancer is unknown (ACS, 2014a).

The ACS recommends men be informed about risks and possible benefits of prostate cancer screening. The information should be provided at age 50 for men of average risk for prostate cancer and age 45 for men at high risk, such as African American men and men who have had a father, brother, or son diagnosed with prostate cancer before age 65. Men who have had several of these family members diagnosed with prostate cancer at an early age should be informed about prostate screening at age 40 (ACS, 2014a).

Two screening tests include the prostate-specific antigen (PSA) and the digital rectal examination (DRE). The PSA test is not accurate in terms of sensitivity or specificity. This blood test produces many false-positive results because many factors can elevate the PSA, such as infections, ejaculation, exercise such as bike riding, and benign prostatic hyperplasia (BPH). The DRE is a procedure where the physician inserts a well-lubricated, gloved index finger into the rectum to palpate the prostate gland and examine the rectum for masses. The examiner is unable to palpate the anterior aspects of the prostate, reducing the accuracy of this examination. Men find this examination unpleasant and another reason for avoiding health care (ACS, 2014a).

Testicular Cancer

Testicular cancer is the most common solid tumor diagnosed in males between the ages of 15 and 40 years, with the peak

incidence between the ages of 18 and 40 years. The ACS predicted 8480 new cases of testicular cancer and 350 deaths in 2010 (ACS, 2013). Age-adjusted incidence showed 6.4 of 100,000 white men and 1.2 of 100,000 African American men were diagnosed with testicular cancer, with a mortality rate of 0.3 of 100,000 and 0.2 of 100,000, respectively. Unfortunately, the cause of testicular cancer is unknown. The only established relationship to testicular cancer is cryptorchidism. The good news is that testicular cancer is rare, and the 5-year survival rate by race was reported as 95.7% for white men and 88.4% for African American men.

The American Cancer Society (ACS) recommends a testicular exam by a doctor as part of a routine cancer-related check-up (ACS, 2013). Because painless testicular enlargement is commonly the first sign of testicular cancer, the testicular self-examination has traditionally been recommended for men. Some testicular cancers might not cause symptoms until they have grown and/or metastasized. However, in 2004 the U.S. Preventive Services Task Force (USPSTF) updated previously published guidelines that significantly altered that tradition for asymptomatic adolescent and adult males (USPSTF, 2004). The new guidelines state:

The USPSTF found no new evidence that screening with clinical examination or testicular self-examination was effective in reducing mortality from testicular cancer. Even in the absence of screening, the current treatment interventions provided very favorable health outcomes. Given the low prevalence of testicular cancer, limited accuracy of screening tests, and no evidence for the incremental benefits of screening, the USPSTF concluded that the harms of screening exceeded any potential benefits.

Depression

More women than men are classified as having depression (6.6% and 4.4%, respectively) for all ages (Pratt and Brody, 2010). Wilhelm (2009) reported that the rates of depression vary between genders based on the type of depression. Of particular concern for men is that higher rates of depression can be found in the unemployed, socially disadvantaged, those who abuse substances, and those with more than one medical condition. There are reasons to believe that men with depression often go unrecognized and underreported. Men tend to be stoic and do not verbalize how they feel and are reluctant to talk about health issues, and men often do not have positive relationships with their health care provider.

The suicide rate is four times greater for men, although women are diagnosed twice as often with major depression. It has been suggested that this difference is due to gender bias in the criteria used to diagnose depression and suggests that men may have more difficulty recognizing or acknowledging depression “because of socially reinforced masculinity norms, including self-reliance, restrictions of emotions and toughness” (Rochlen et al, 2010, p167). Much of how gender is manifested in individuals is learned through socialization. How men manifest signs and symptoms of depression may result in low numbers of men diagnosed with depression because men are

socialized to hide their feelings. Ultimately, men are seen with more incidences of avoidance behavior, anger, violence, and finally suicide. Nurses should recognize how men can manifest depression and be aware of the importance of developing a therapeutic relationship. Through the therapeutic relationship the experience of depression can be normalized, the biological and social factors in depression can be explained, and the positive outcome of depression treatment can be communicated.

Erectile Dysfunction

Erectile dysfunction (ED), also known as impotence, is the consistent inability to achieve or maintain an erection sufficient for satisfactory sexual performance. Up to 52% of men between the ages of 40 and 70 are affected by ED and it is associated with decreased quality of life. ED can lead to withdrawal from intimacy, emotional stress, lower self-esteem, and avoidance of physical contact. The incidence of ED significantly increases with age, and 55% to 70% of men aged 77 to 79 years are sexually active (McMahon, 2014). It can occur in association with cardiovascular disease, diabetes, hypertension, hypercholesterolemia, smoking, spinal cord injury, prostate cancer, genitourinary surgery, psychiatric disorders, and the use of alcohol and drugs (Douglass and Lin, 2010).

It is now known that ED is an independent marker for increased cardiovascular disease with vascular disease of the penile arteries (Jackson and Kirby, 2014). Men with ED and no cardiac symptoms should have a thorough cardiac assessment. Lifestyle changes to reduce weight, manage hypertension and diabetes, stop smoking, reduce alcohol consumption and stress, and start exercising regularly will reduce risk.

Although ED may be discussed more openly with health care providers since the increased publicity generated from the marketing of the medications for ED, many men will still be embarrassed and reluctant to discuss the subject. A variety of treatments are available and can be discussed with the health care provider. Men who respond positively to treatment for ED report significantly better quality of life. With this evidence of positive response, health care providers should be proactive in discussing ED with men.

In summary, regardless of the prevalence differences in the health problems described in this section between men and women, appropriate health care services must be provided. Men and women need to be encouraged equally to take advantage of these services.

HEALTH DISPARITIES AMONG SPECIAL GROUPS OF ADULTS

Health disparities present political implications and influence government actions, including the commitment of resources to address them. In the United States, the government describes health disparities as a continuing and persistent gap in health status between genders, ethnicities, economic statuses, and those who represent the majority populations (NPA, 2010). The causes are complex, but there are two major factors including inadequate access to care and substandard quality of care (NPA, 2010).

Certain groups have been recognized as experiencing health disparities and have become a priority for policy efforts. Many factors contribute to disparities in health and health care for special groups of adult men and women, including education, insurance status, segregation, immigration status, health behaviors and lifestyle choices, health care provider behavior, employment, and the nature and operation of the health system in communities (Kosoko-Lasaki et al, 2009). In particular, poverty is a strong underlying current throughout all of the special groups.

Adults of Color

In 2000, about 33% of the U.S. population identified themselves as members of racial or ethnic minority groups. By 2050, these groups are projected to account for almost half of the U.S. population (NHDR, 2008). Improvements in preventive care, chronic care, and access to care have led to improvements to the health of some populations in areas such as mammograms and smoking cessation counseling. However, the complete picture of disparities is different for each population. For instance, non-Asian racial/ethnic minorities continue to experience higher rates of HIV diagnoses than whites. When compared with whites, a lower percentage of blacks diagnosed with HIV were prescribed antiretroviral therapy and a lower percentage of both blacks and Hispanics had suppressed viral loads (CDC Health Disparities & Inequalities Report, 2013). Diabetes prevalence is highest among non-Hispanic blacks, Hispanics, and those of mixed races (CDC Health Disparities & Inequalities Report, 2013). Although addressing these disparities appears daunting, the intent is to close the gap with regard to the health disparities in adults of color while at the same time preserving and respecting the richness and unique influences of various cultures. Population-focused nurses are positioned to advocate for culturally sensitive and gender-sensitive programs necessary in communities where adults of color may reside.

Incarcerated Adults

Since 2000 the U.S. prison population grew at the slowest rate (0.8%) in 2008, reaching 1,610,446 sentenced prisoners (U.S. Department of Justice, Bureau of Justice Statistics, 2009). However, while this appears to be positive, it does create a challenge to nurses who will be caring for this special population in other community settings. An increase in the number of prison releases has led to offenders being released to the community without supervision. African American males were incarcerated at a rate six and one half times higher than white males. The proportion of prisoners under state or federal jurisdiction was 93% men and 7% women (Sabot et al, 2009). Women are more likely to be serving time for property and drug offenses rather than violent crimes.

Inmates have been shown to have more chronic diseases such as hypertension, diabetes, asthma, chronic liver disease, and HIV than the general population (Kulkarni et al, 2010). Upon release from correctional institutions, ex-offenders face interruptions in their medical care stemming from limited resources, limited ability to access health care, and a lack of adequate discharge planning (Wang et al, 2008; Kulkarni et al, 2010).

Over the past 40 years, legal, social, and political factors have led to the current epidemic of psychiatric disorders in the U.S. prison system. Incarcerated populations with major psychiatric disorders (major depressive disorder, bipolar disorders, schizophrenia, and non-schizophrenic psychotic disorders) have a substantially increased risk of multiple incarcerations. The greatest increase may be among inmates with bipolar disorders (Baillargeon et al, 2009). Nurses can support and deliver beneficial continuity of care reentry programs to help those who are mentally ill connect with community-based mental health programs at the time of release from prison to decrease recidivism rates (Baillargeon et al, 2009).

Lesbian/Gay/Bisexual Adults

Lesbian/gay/bisexual (LGB) adults represent a sometimes hidden special population, in part because of the social stigma associated with homosexuality coupled with the fear of discrimination. Several studies have documented health disparities by sexual orientation in population-based data and have revealed differences in health between LGB adults and their heterosexual counterparts, including higher risks of poor mental health, smoking, higher risk of disability, and excessive drinking (Dilley et al, 2010; Conron et al, 2010; Fredriksen-Goldsen et al, 2013). To improve the health of lesbian/gay/bisexual adults, services that address their unique needs are warranted. Safe places where this special population can voice their concerns and receive effective health promotion, disease prevention, and treatment are critical. Clarification of ways in which sexual orientation is associated with health outcomes will be critical to developing appropriate health interventions (Bostwick et al, 2010).

Adults with Physical and Mental Disabilities

Many issues confront adults with disabilities. Concerns associated with health, aging, civil rights, abuse, and independent living are but a few examples of the types of problems facing this population. In 2007, 69 million adults 18 years of age and over had either basic actions difficulty (including movement or emotional difficulty or trouble seeing or hearing) or complex activity limitation (such as work or self-care limitations). This was an increase by 8 million over the past 10 years. One quarter of adults 18 to 64 years of age had at least one basic actions difficulty or complex activity limitation in 2007, compared with 62% of adults 65 years of age and over (NCHS, 2009).

Adults with lifelong disabilities are more likely to have chronic conditions and multiple comorbidities than adults with no limitations (Dixon-Ibarra and Horner-Johnson, 2014). For instance, adults with developmental disabilities may be at a high risk for obesity and its sequelae (Bazzano et al, 2009). This may be due to individual and community factors including physical challenges, cognitive limitations, medications, lack of accessible adaptive fitness facilities, and segregation from the community in general. A community-based health intervention program called “The Healthy Lifestyle Change Program” targeted adults with developmental disabilities. This program used a twice-weekly education and exercise program to increase knowledge, skills, and self-efficacy regarding health, nutrition, and fitness

with peer mentors serving as participatory leaders and motivators. Outcomes were improved lifestyles, weight loss success, and increased life satisfaction (Bazzano et al, 2009).

Nurses can develop an awareness of the many health-related issues facing adults with disabilities. In particular, care should be taken to recognize the physical barriers that prevent disabled adults from accessing health care, such as structures that are not accessible despite the ADA recommendations. Developing health promotion programs targeted at this vulnerable, high-risk group can assist in overall well-being.

Impoverished and Uninsured Adults

According to the Stanford Center on Poverty and Inequity’s *National Report Card*, the official poverty rate increased from 12.5 in 2007 to 15.0 percent in 2012 and the child poverty rate increased from 18.0 percent in 2007 to 21.8 percent in 2012 (Danziger and Wimer, 2014). Poverty affects acute and chronic conditions, accumulates over the life course, and is transmitted across generations. It limits education and employment opportunities, leaving individuals susceptible to weaker social integration, low control, depressive symptoms, and often a fatalistic outlook (Sanders et al, 2008). Often the stress of poverty may lead to poor dietary habits, tobacco use, and inconsistent personal hygiene. Health disparities, including chronic illness and health care services, are consistently associated with socioeconomic differences. The vulnerable homeless, **impoverished** rural, migrant, and public housing communities suffer from an increased burden of disease and greater morbidity and mortality than the general population (Custodio et al, 2009).

Adults who are insured will access health care services more often, including obtaining recommended screening and care for chronic conditions, thus reducing the overall costs of potential catastrophic illness (Wilper et al, 2009). Although President Obama signed the Patient Protection and Affordable Care Act along with the Health Care and Education Reconciliation Act in March 2010 (United States Congress, Public Law 111-148, 2010), many changes such as health insurance mandates did not begin until 2014. The Rand Corporation reported that by March 2014:

Overall, we estimate that 9.3 million more people had health care coverage in March 2014, lowering the uninsured rate from 20.5 percent to 15.8 percent. This increase in coverage is driven not only by enrollment in health insurance marketplace plans, but also by gains in employer-sponsored insurance and Medicaid. Enrollment in employer-sponsored insurance plans increased by 8.2 million and Medicaid enrollment increased by 5.9 million, although some individuals did lose coverage during this period. The authors also found that 3.9 million people are now covered through the state and federal marketplaces and less than 1 million people who previously had individual-market insurance became uninsured during the period in question. While the survey cannot tell if this latter group lost their insurance due to cancellation or because they simply felt the cost was too high, the overall number is very small, representing less than 1 percent of people between the ages of 18 and 64 (Carman and Eibner, 2014).

Under the Affordable Care Act (ACA), states can extend Medicaid eligibility to nearly all adults with income no more than 138% of the federal poverty level. However, compared with adults who were already enrolled in Medicaid prior to the ACA, a substantial proportion of uninsured adults with chronic conditions do not have good disease control and may require intensive medical care following Medicare enrollment (Decker et al, 2013).

Nurses can be uniquely involved in community assessments to document pockets of poverty within their communities. For example, housing is a fundamental determinant of health and provides shelter and privacy. Exposure to cracks in ceilings and walls, inadequate heat, mold, poor ventilation, pesticide residue, excessive moisture, leaky pipes, and lead paint are all health hazards that can be addressed by nurses. Recent research has also found that health resilience to poverty was supported by protective factors in built and social environments. (See Chapter 29 for discussion of the built environment.) When poverty itself cannot be eliminated, improving the quality of the built and social environments can foster resilience to the harmful effects of poverty (Sanders et al, 2008).

Frail Elderly

In the past decade, the United States experienced a 15% increase in the population 65 years of age and older. By 2020, this group is expected to increase another 36% (A Profile of Older Americans, 2009). In addition, the population of those 85 years and older is projected to increase another 15% by 2020. Most older persons have at least one chronic condition and many have multiple conditions, putting them at risk of experiencing frailty while living in a community setting.

Frailty is a geriatric syndrome that places older adults at risk for adverse health outcomes, including falls, worsening disability, institutionalization, and death (Espinoza and Hazuda, 2008). It is a complex state of impairment that signifies loss in areas of physical functioning, physiological resiliency, metabolism, and immune response (Hackstaff, 2009).

The prevalence of **frail elderly** in the population poses a major public health dilemma since the majority of this group will reside in a community setting, placing new demands on health care systems, family caregivers, and community resources. To improve the health of frail elderly, community-based nursing programs will need to address racial/ethnic and socioeconomic disparities.

The elder-friendly community model identifies four domains needed by the elderly, including having basic needs met, social and civic engagement, physical and mental health and well-being, and independence for the frail and disabled (Feldman and Oberlink, 2003). This model identifies independence for the frail elderly as the ability to “age in place” with specific indicators that focus on activities of daily living, transportation, and caregivers’ ability to complement formal services. Community-level characteristics, including security issues, accessible shopping, and adequate transportation services are important community resources (Weierbach and Glick, 2009). Nurses can use this model to incorporate both individual and

community factors that are necessary for elderly to live and thrive in community settings.

COMMUNITY-BASED MODELS FOR CARE OF ADULTS

Nursing Roles

Communities are where people live, work, and socialize. Community health settings include public health departments, nurse-managed health centers, ambulatory care clinics, and home health agencies. Nurses are involved in direct care, providing self-care information, contributing to the supervision of paraprofessionals, or collaborating with other disciplines to provide the most appropriate, high-quality, cost-effective care at the most appropriate level and location.

Knowledge of community resources is a fundamental part of caring for the adult with special needs in any community. The nurse assesses the need for and helps develop the resources. Every community has an area agency on aging that coordinates planning and delivery of needed services, and it can be a good resource for the nurse. Most communities have information and referral systems as well as a public directory of services available.

The complex nature of chronic illness with care focused primarily on maximizing functional status and well-being is particularly suited to nursing’s holistic focus (Lupari et al, 2011). The Doctor of Nursing Practice (DNP) role brings specific competencies and nursing backgrounds to the role of primary care provider. A recent **community-based model** to provide care for frail elders highlights three areas of expertise that advanced practice nurses in the DNP role can provide: management of complex chronic illness, illness and **injury** prevention, and promotion of quality of life (Auer and Nirenberg, 2008).

Community Care Settings

Patient-Centered Medical Homes

A traditional part of community care for adults with chronic illness is the use of primary care practices. Health care systems with a primary care focus have better outcomes, including better quality, lower costs, less inequality in health care and health, and better population health when compared with systems based on other approaches to health care. The **patient-centered medical home** (PCMH) moves beyond primary care to include new approaches to organizing practice to enhance its responsiveness to individual patient needs (Stange et al, 2010). The following are established basic tenets for the concept of PCMH:

1. A relationship between the patient and medical provider
2. A provider who takes charge of total patient care, including arrangements for specialty care
3. Open access to health care
4. Ongoing care managed by the same provider to assure coordination and collaboration
5. Quality and safety as key aspects of the system
6. Transparent and fair payment (Rittenhouse and Shortell, 2009)

For patients with chronic illnesses, one approach to PCMH is to include physician assistants (PAs) and nurse practitioners (NPs) on primary care teams. This approach has demonstrated positive outcomes in the measure of quality of diabetes care and use of health care services (Everett et al, 2013).

Senior Centers

Senior centers were developed in the early 1940s to provide social and recreational activities. Now many centers are multipurpose, offering recreation, education, counseling, therapies, hot meals, and case management, as well as health screening and education. Some even offer primary care services. Nurses have a unique opportunity to provide services to a group of older persons who wish to remain independent in the community (Weierbach and Glick, 2009; Truncali et al, 2010).

Adult Day Health

Adult day health is for individuals whose mental or physical function requires them to obtain more health care and supervision. It serves as more of a medical model than the senior center, and often individuals return home to their caregivers at night. Some settings offer **respite care** for short-term overnight relief for caregivers. This provides caregivers the opportunity to work or have personal time during the day. Support groups for caregivers may be offered by nurses.

Home Health, Palliative Care, and Hospice

Home health can be provided by multidisciplinary teams. Nurses provide individual and environmental assessments, direct skilled care and treatment, and provide short-term guidance and instruction. Nurses often function independently in the home and must rely on their own resources and knowledge to improvise and adapt care to meet the client's unique physical and social circumstances. They work closely with the family and other caregivers to provide necessary communication and continuity of care. (See Chapter 41 for more details.)

Palliative care is the broad term used to describe the care provided by an interdisciplinary team consisting of physicians, nurses, social workers, chaplains, and other health care professionals. Coyle (2010) describes the distinctive features of palliative care nursing as “a whole person” philosophy of care. This care is provided across a continuum of different settings, including the life span, the illness trajectory, the patient's death, and the family's bereavement. Often, the terms *hospice* and *palliative care* are used interchangeably. Palliative care is a broader concept and includes the entire continuum of care. Hospice care is always palliative care, but not all palliative care is hospice care (Coyle, 2010).

Hospice represents a philosophy of caring for and supporting life to its fullest until death occurs. The hospice team encourages the client and family to jointly make decisions to meet physical, emotional, spiritual, and comfort needs (see palliative care in the Content Resources section of the Evolve website).

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Client-Centered Care

Recognize the client or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for the client's preferences, values, and needs.

Important aspects of client-centered care include the following:

- **Knowledge:** Describe strategies to assist clients and their families in all aspects of the health care process.
- **Skills:** Communicate client values, preferences, and expressed needs to other members of the health care team.
- **Attitudes:** Willingly support client-centered care for individuals and groups whose values differ from your values.

Client-Centered Care Question

You are making a home visit to the Jones family—Mr. and Mrs. Jones and their children, John (10 years), Sally (6 years), and Tommy (3 years). Mr. and Mrs. Jones are considered obese using the body weight index measures of the American Heart Association. John is considered overweight by this same measure, and you note that both Sally and Tommy are at the upper range for weight for their age. You observe during the visit that the family appears to eat a lot of processed food, including lunch meats, chips, and carbonated drinks with sugar. What steps would you take to help this family (1) understand the importance of maintaining an average weight, (2) learn about the different ways in which foods can be prepared, and (3) learn about the relationship among calorie consumption, physical activity, and weight?

Answer: First, you would need to assess their knowledge about weight management. Next, you would need to determine if they have the skill to purchase and prepare lower calorie, nutritious food and if they are capable of engaging in physical activities. You would also need to evaluate their attitude toward body size and image. Their willingness to change their behavior will be influenced by whether they view themselves as needing to change. If there is a willingness to make weight management behavior change, you can refer them to a nutrition expert for a consultation or to attend a class(es). You can find out how they spend their leisure time and what options they can identify that would include the entire family in a physical activity such as a walk, a game, or a trip to the park.

Assisted Living

Assisted living covers a wide variety of choices, from a single shared room to opulent independent living accommodations in a full-service, life-care community. The differences are related to the type and extent of the amenities provided and the contract signed for them. The role of the nurse varies depending on the philosophy and leadership of the management of the facility. The nurse generally provides assessment and interventions, medication review, education, and advocacy (Counsell et al, 2006; Auer and Nirenberg, 2008).

Long-Term Care and Rehabilitation

Nursing homes, or **long-term care** facilities, house only about 5% of the older population at a given time; however, 25% of those adults older than 65 will spend some time in a nursing home. Nursing homes provide a safe environment, special diets and activities, routine personal care, and the treatment and management of health care needs for those needing rehabilitation, as well as for those needing a permanent supportive residence. Rehabilitation is a combination of physical,

occupational, psychological, and speech therapy to help debilitated persons maintain or recover their physical capacities. **Rehabilitation** is typically needed for older adults after a hip fracture, stroke, or prolonged illness that results in serious deconditioning (Olsson et al, 2009).

Like hospitals, nursing homes are paid using the prospective payment model based on the nursing assessment. A recent new model developed by nurse practitioners used collaborative practice techniques to change care management for frail and elderly nursing home residents, which reduced hospitalizations by 45%, reduced emergency room visits by 50%, and effectively reduced the incidence of acute episodes in the nursing home setting (Kappas-Larson, 2008).

LINKING CONTENT TO PRACTICE

The information in this chapter focuses on the health issues of adult and older adult men and women from a population perspective as opposed to the individual or family. In practice, the knowledge, skills, and attitudes, such as those identified by the Quad Council for Public Health Nursing, transcend other public health disciplines. Therefore, nurses practicing in community health need to foster the ability to work effectively with interprofessional teams across a variety of organizations to accomplish goals to improve community health. Working in interprofessional teams is a core competency identified by the Institute of Medicine (IOM) and involves essential features such as “sections related to self, team, team communication and conflict resolution, effect of team on safety and quality, and the impact of systems on team functioning” (Cronenwett et al, 2007, p. 123).

PRACTICE APPLICATION

During her community clinical time in nursing education, Laura had the opportunity to accompany Marie, her preceptor, on an initial home visit to a young woman named Josie. Josie was a 20-year-old single woman who had come to the public health center last week for a gynecological examination because she thought she might have some sort of infection. During the visit, Josie mentioned to the clinic nurse that she did not have any food in her house. After the examination the clinic nurse made a referral to the women’s resource service center for a home visit and for inclusion of Josie into their case management program.

When Marie and Laura arrived at Josie’s apartment, they immediately noted that the living areas were devoid of furniture; however, there was a soiled mattress on the floor of the living room. Dirty clothing was on the floor; empty take-out food sacks and trash littered the area. The kitchen area was also dirty, with evidence of cockroach infestation.

Marie and Laura noticed that Josie appeared to be uncomfortable and had difficulty interacting with either of them. Marie explained that they were there because the nurse at the clinic had asked them to stop by and see if there was any way that they might help Josie with her health care needs and living situation. Immediately Josie began to cry. She had been with her abusive boyfriend until about 3 weeks ago when she asked him to leave. Marie and Laura learned that since that time, Josie had been prostituting as a way to survive. She was frightened and thought that her boyfriend was going to return and harm her. She also feared that she was pregnant.

Based on this situation, what would be potential actions that Laura and her preceptor Marie might take?

- A.** Make an appointment for Josie to return to the women’s clinic for pregnancy testing.

- B.** Suggest to Josie that she focus on cleaning up her apartment, reminding her of the hazards of spoiled food.
C. Refer Josie to a safe-house shelter as a victim of domestic violence.
D. Make a referral for food delivery from a local church.

Answers are in the back of the book.

The nurse in a local public health department talks with the director of the department, who needs to determine what major public health issues exist in the community and prioritize them to better allocate resources. The director formed a committee to assist in this process. The director asks the nurse to participate on the committee because of the nurse’s interest in men’s health. The director asks the nurse to identify up to 10 major health issues in the community, prioritize them, and recommend strategies to improve men’s health in the community. The director wants a report supporting conclusions and strategies that the department could implement.

Based on the previous scenario, answer the following questions:

- A.** What information do you want to collect?
B. How would you identify priorities in your area?
C. What positive and negative factors may be influencing these issues?
D. How would you select strategies to improve health issues?
 1. What interventions, if any, are currently being used, and are they effective?
 2. Who are the key participants that would need to be involved in improving the issues?
 3. Have these issues been addressed effectively in other communities? If they have, what have they done?

Answers can be found on the Evolve site.

KEY POINTS

- The health of adults is embedded in their communities.
- Societal factors influence the distribution of health and disease.
- Women’s health advocates have widened the framework of women’s health by focusing on social, psychological, cultural, political, and economic as well as biological factors.

KEY POINTS—cont'd

- The complexities of women's lives—their educational levels, income, culture, ethnicity/race, and a host of other identities and experiences—shape their health.
- The Office on Women's Health (OWH) works to address inequities in research, health services, and education that have traditionally placed women at risk for health problems.
- The problem of unintended pregnancy exists among adolescents as well as adult women.
- Women's attitudes toward menopause vary greatly and are influenced by culture, age, support, and the shared experiences of other women.
- Cardiovascular disease (CVD) is the leading cause of death among U.S. adults.
- Diabetes has increased dramatically in the United States during the last decade.
- Women in the United States experience depression at higher rates than do men.
- Overall, white women have a higher incidence rate for all cancers while African American women have higher mortality rates.
- Most U.S. women contract HIV/AIDS by heterosexual transmission.
- The Bureau of Justice reports a dramatic rise in the number of women in state and federal prisons.
- Research findings indicate that lesbians and bisexual women have higher prevalence rates of several risk factors than their heterosexual counterparts with regard to smoking, alcohol use, and lack of preventative cancer screening.
- Poverty among female heads of household reflects the disparities that exist in the United States among various ethnic/racial groups because female-headed African American and Hispanic families suffer disproportionately higher rates of poverty than do other families.
- Research shows that older women, especially women of color from lower socioeconomic groups, experience higher rates of chronic illness and disability than their white and more affluent counterparts.
- One out of every two American women more than 50 years of age will experience an osteoporosis-related fracture in her lifetime.
- Men are reluctant to seek health care and are not well connected to the health care system.
- Large numbers of men do not receive the health screenings intended to prevent and identify disease.
- To improve health outcomes for men, chronic disease prevention and control programs should combine individual and population-based strategies developed in collaboration with community members and developing infrastructure to address environmental and policy change.
- Although adverse working conditions and numerous pathological conditions clearly are detrimental to men's health, there is a great need to focus on the mental health of men.
- The nurse acts as a change agent to assess needs and system influences, identify and set priorities, plan and implement programs, and evaluate results.

CLINICAL DECISION-MAKING ACTIVITIES

1. Interview three women, each from a different culture, about their experiences accessing health care. Are there differences in their stories about how they meet their health care needs? Do variances in ethnicity and culture present barriers to accessing health care?
2. Review current legislation that deals with women's health. Note patterns or trends in the issues that are being considered by the Senate or the House of Representatives. Are there obvious gaps in legislation that adversely affect women's health?
3. Considering breast cancer, apply the levels of prevention to women in underserved areas. Describe approaches to meeting their health care, social needs, and psychological needs. What barriers might prevent an effective program addressing breast cancer?
4. Contact your local public health office to determine what services are available for women. Identify community resources and agencies targeted for women. How do these organizations communicate their services to women in the community?
5. Propose a community-based intervention for women with HIV. Describe various program components such as goals and objectives, evaluation methods, and program outcomes.
6. Identify a men's health issue in your community. Contact local health agencies in your area to determine what strategies are currently in place to address the issue.
7. Based on the issue identified in question 6, search the Internet for evidence-based practices related to the issue.
8. Think about television, movie, or magazine portrayals of men and identify both positive and negative influences the media may have on men's health.
9. Locate several websites focusing on men's health topics. Using criteria for credible websites from Health on the Net Foundation (www.hon.ch), evaluate those sites for credible health information.

Disability Health Care Across the Life Span

Lynn Wasserbauer, RN, FNP, PhD*

Lynn Wasserbauer earned an undergraduate degree in Zoology from The State University of New York, Oswego, the BS and MS in nursing from the University of Rochester, and the PhD and FNP certificate from the University of Virginia. She is a nurse practitioner at The University of Rochester Medical Center. Her current practice is in psychiatric nursing.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Define terms related to disability.
2. Discuss implications of developmental disability, physical disability, or chronic illness.
3. Identify the conditions that may contribute to disability.
4. Discuss the effects of being disabled on the individual, the family, and the community.
5. Describe the implications of being disabled for selected (low-income) populations.
6. Discuss selected issues for those who are disabled (abuse, health promotion).
7. Discuss the objectives of *Healthy People 2020* as they relate to disability.
8. Examine the nurse's role in caring for people who are disabled.

KEY TERMS

Americans with Disabilities Act, p. 695

burden of chronic disease, p. 698

children with special health care needs (CSHCN), p. 697

chronic disease, p. 697

disability, p. 695

developmental disability, p. 697

dual diagnosis, p. 699

functional limitations, p. 696

medical model of disability, p. 695

social model of disability, p. 695

—See Glossary for definitions

*Special thanks to Susan Kennel, PhD, RN, CPNP and Carol Lynn Maxwell-Thompson, MSN, RN, FNP-C, who authored this chapter in the seventh edition of the text.

CHAPTER OUTLINE

Understanding Disabilities

- Models of Disability
- Disability Defined
- Census Determination of Disability
- Social Security Disability
- Americans with Disabilities Act
- Functional Disability
- Additional Definitions

Scope of the Problem

- Number of Disabled Americans
- Number of Disabled Worldwide
- Burden of Chronic Disease
- Additional Causes of Disability
- Childhood Disability
- Mental Illness

The Effects of Disabilities

- Effects on the Individual
- Effects on the Family
- Effects on the Community

Special Populations

- Low-Income Populations

Selected Issues

- Abuse and Neglect
- Health Promotion
- Healthy People 2020* Objectives

Role of the Nurse**Legislation**

- Basic Rights Under IDEA

Foundational to the American system of government is the belief that all citizens are entitled to protection of individual civil rights. Unfortunately, individuals with disabilities were among the last groups in the United States to receive civil rights protection. Until the late twentieth century, widespread discrimination against the disabled made it difficult for them to feel fully integrated into society. As a result of this discrimination, the disabled often were literally shut in and shut out of much of American society. The **Americans with Disabilities Act** (ADA) of 1990 was the first comprehensive civil rights legislation for individuals with disabilities. One effect of this legislation is a greater emphasis on community care for the disabled, rather than institutionalization, and there is a growing emphasis on providing that care in as “home-like” an environment as possible.

One of the many challenges for the disabled is access to appropriate health care. Although not all care can be delivered at home, public health nurses are uniquely positioned to serve as care providers and managers for community-dwelling disabled individuals. Having an understanding of disabilities, disability rights, and the legislation specifically enacted to decrease discrimination will assist nurses in intervening and advocating for the disabled.

This chapter provides an overview of disabilities, defines key terms, and reviews the effects of disabilities on individuals, families and communities. The relationships between disabling conditions and *Healthy People 2020* are discussed. Also reviewed is the nurse’s role in planning and providing or securing appropriate interventions for individuals, families, and communities to manage or prevent these health problems.

UNDERSTANDING DISABILITIES**Models of Disability**

There is no single accepted definition for disability. The definition of disability varies depending on common use of the word

or the specific agency defining the term. With regard to health care, the **medical model of disability** is generally used to conceptualize disability. In this model, disability is considered to be a function of physical characteristics or conditions that place an individual at a disadvantage compared with those who do not have the characteristic or condition. This model places emphasis on the disabled person and the need to modify the course of illness, or as much as possible to give the disabled person a “normal” life. The Social Security Administration uses this model for determination of disability. In the **social model of disability**, emphasis is placed on systemic barriers as well as societal attitudes and stigmas that contribute to the perception that those with limitations or physical illnesses are disabled. In this model the focus is on the need to change society and not the individual with a disability. This model has led to a focus on civil rights for the disabled and the need for legislation addressing discrimination (Scullion, 2010).

Disability Defined

Disability is defined by Webster’s as “A condition (such as an illness or injury) that damages or limits a person’s physical or mental abilities; the condition of being disabled; limitation in the ability to pursue an occupation because of a physical or mental impairment; a program providing financial support to one affected by a disability; lack of legal qualification to do something or a disqualification, restriction, or disadvantage” (Merriam-Webster, 2014).

Census Determination of Disability

The last time that disability data were collected using the standard long-form for the decennial census was in 2000 and the population was assessed to determine and define disability based on functional limitations. The Census Bureau collected data on the number of individuals with disabilities. Six specific subpopulations of disability were identified and included employment disability, sensory disability, mental disability,

physical disability, self-care disability, and go-outside-the-home disability ([American Community Survey, 2012](#)).

Beginning with the 2010 Census, disability data were obtained using the American Community Survey (ACS), a yearly supplement to the decennial census, and the Survey of Income and Program Participation (SIPP), a continuous survey of a national panel of households with each panel lasting approximately four years. The definition of disability was also changed in an attempt to improve the response rate and gather more reliable information. For the ACS the current definition of disability includes the following: hearing difficulty/vision difficulty, cognitive difficulty, ambulatory difficulty, self-care difficulty, and independent living difficulty data ([ACS, 2012](#)).

The SIPP survey categorizes types of disabilities into communicative (difficulty seeing, hearing, or having their speech understood); physical (used an assistive device, had difficulty with a specific task such as climbing a flight of stairs, or had a specific illness such as arthritis); and mental (had a cognitive disability or had a mental or emotional problem that interfered with everyday activities) domains. These changes may appear subtle; however, by reclassifying disabilities it became easier to obtain more detailed disability data ([Brault, 2012](#)).

Box 31-1 lists the top ten causes of disability in the United States.

Social Security Disability

The Social Security Administration (SSA), who ultimately determines the individual's status for disability benefits, defines disability as the inability "to engage in any substantial gainful activity (SGA) because of a medically-determinable physical or mental impairment(s): That is expected to result in death, or That has lasted or is expected to last for a continuous period of at least 12 months" ([SSA, 2014](#), p. 5). An individual's inability to perform any SGA is the criteria used by the Social Security Administration to determine disability. A gainful work activity is: "Work performed for pay or profit; or Work of a nature generally performed for pay or profit; or Work intended for profit, whether or not a profit is realized" ([SSA, 2014](#), p. 5).

The Social Security Administration and Workman's Compensation Systems determine the patient's disability based on

clinical evidence. The health care provider should consult the office of Disability Determination Services in the Social Security Administration or the Workman's Compensation Department for guidelines from individual states since requirements may vary.

Americans with Disabilities Act

According to the ADA, the term *disability* means, with respect to an individual, (1) a physical or mental impairment that substantially limits one or more of the major life activities of such an individual, (2) a record of such an impairment, or (3) being regarded as having such an impairment ([ADA, 1990](#), Section 3 [2]).

Thus, individuals who are clearly diagnosed with an illness that limits functioning in one or more major life activities are covered. According to ADA guidelines disability status is based on a person's ability to complete major life activities independently. Major life activities refer to self-care, receptive and expressive language, learning, mobility, self-direction, capacity for independent living, and financial sufficiency.

Also covered by the ADA are individuals who have a history of an illness, those who have been considered (possibly erroneously) to have had an illness, or those who have been treated as if they had a disabling illness. The intent of the ADA is to reduce "discrimination based not only on simple prejudice, but also on stereotypical attitudes and ignorance about individuals with disabilities" ([Jones, 1991](#), p. 34). This means that individuals may have been misdiagnosed or inappropriately treated as if they had an illness or disability. Because of this, these individuals may not have had the same opportunities as do nondisabled individuals. An example of this is intelligence testing or assessment of cognitive ability. If there was an underestimate of intelligence or functioning, an individual may not have been allowed full access in education. This then may have limited his or her ability to be prepared for higher education.

Functional Disability

In 2001 the World Health Organization (WHO) redefined The International Classification of Impairments, Disabilities and Handicaps from 1980. This new classification, called the International Classification of Functioning, Disability and Health (ICF), provides standardized language for measuring, classifying, and defining disability. The new definition of disability considers not only medical problems, but also physical, social, attitudinal, and personal factors ([WHO, 2014](#)). In the new classification, functioning and disability are determined by the complex interaction between the health condition of the individual and environmental and personal factors. It recognizes that external factors beyond body structures and functions contribute to the disability. The emphasis is on function rather than the condition or the disease. It is relevant across cultures, age groups, and genders and is a useful way to measure health outcomes ([WHO, 2014](#)).

Functional limitations occur when individuals experience difficulty performing basic activities of daily living because of their disability. Examples of functional limitations include difficulty standing, walking, climbing, grasping, and reading.

Emphasis is placed on the level of function rather than on the purpose of the activity, so that functional limitation can be associated with the disability. For example, impairment in the strength or range of motion of the arm could lead to functional limitations in grasping or reaching. Affected individuals may have difficulty performing basic self-care activities such as bathing and dressing.

Additional Definitions

The term **children with special health care needs (CSHCN)** is defined by the Maternal and Child Health Bureau (MCHB) of the U.S. Department of Health and Human Services as “those who have or are at increased risk for a chronic, physical, developmental, behavioral or emotional condition and who also require health and related service of a type or amount beyond that required by children generally” (MCHB, 2013, p. 1). This definition is broad and includes children with many conditions and risk factors. The prevalence of special health care needs increases with age and varies with race and ethnicity. The children with the highest prevalence of special health care needs are Native American/Alaska Native children, multiracial children, and non-Hispanic white children. The lowest rates are in Hispanic children and non-Hispanic Asian children (MCHB, 2013).

The term **developmental disability**, as defined by the National Center on Birth Defects and Developmental Disabilities of the Centers for Disease Control and Prevention (CDC), is a chronic impairment that occurs during development and up to age 22 and lasts throughout the person’s lifetime. The disability limits the functioning of an individual in at least three of the following areas: self-help, language, learning, mobility, self-direction, independent living, and economic self-sufficiency (CDC, 2014b).

Chronic disease, or illness, refers to any long-lasting condition or illness. Disease processes (e.g., diabetes mellitus, cancer, heart disease) and congenital or acquired conditions (e.g., Down syndrome, severe burns, amputation of a limb) are examples of chronic diseases. Therefore, concepts related to disabilities and functional limitations may apply to individuals with a chronic disease or other conditions. For nurses working with these clients, the onset, course, outcome, and degree of limitation are important factors to consider when determining the meaning of the disease to individuals and the families.

Persons with disabilities have often been defined by their illness or disability. Defining someone by their disease or disability is devaluing and disrespectful. It can also place artificial limitations on an individual’s potential and value. Language is powerful. The word *handicapped* symbolized the person with a disability begging with a “cap in his hand.” The term *disabled* is often used to describe cars that are disabled, indicating they are broken, not functioning, or defective. Whereas we may refer to *things* that are broken or defective, people with disabilities are not broken. Rather than saying a baby has a birth defect, a better term would be to say a child has a congenital disability. The Person First Movement was initiated in an effort to promote acceptable language for people with disabilities. The Person First Movement advocates for political correctness in defining

persons with disabilities. In other words, refer to a “woman who is blind” rather than a “blind woman” or a “person with diabetes” rather than a “diabetic” (Disability is Natural, 2014).

Definitions of disability need to take into account the degree of disability, the limitations it imposes, and the degree of dependence that occurs as a result of the disability. These definitions can range from minor to severe. Situational factors also affect the disability experience and influence the individual’s ability to cope and function in society. Nurses and the interdisciplinary team need to be included, informed, and involved in the science of disability and rehabilitation to be influential in the decision making related to practice, policy, training, research, and funding.

LINKING CONTENT TO PRACTICE

Within public health nursing, there has been a commitment to caring for people in their communities and working to build the health of communities. The **Council on Linkages (2012)** has identified several core competencies for public health professionals, including public health nurses.

Tier 1 Core Competencies apply to public health professionals, including nurses, who are not in management. Responsibilities of these public health professionals may include basic data collection and analysis, fieldwork, program planning, outreach activities, programmatic support, and other organizational tasks.

Tier 2 Core Competencies apply to individuals with program management and/or supervisory responsibilities. Responsibilities may include program development, program implementation, program evaluation, establishing and maintaining community relations, managing timelines and work plans, presenting arguments, and recommendations on policy issues.

Tier 3 Core Competencies apply to individuals at a senior/management level and leaders of public health organizations. In general, an individual who is responsible for the major programs or functions of an organization, setting a strategy and vision for the organization, and/or building the organization’s culture can be considered to be a Tier 3 public health professional.

Public health nurses working in any tier are needed to ensure that disabled individuals are properly cared for in the community. This may involve providing or directing care, or understanding disability legislation and programs for which individual/families are eligible. Public health nurses may also be involved in developing and implementing programs for the disabled or being the chief executive officer of an agency that advocates for the disabled.

SCOPE OF THE PROBLEM

Number of Disabled Americans

According to the most recent data from the Survey of Income and Program Participation collected in 2010, approximately 18.7%, or 56.7 million civilian, noninstitutionalized men, women, and children in the United States reported a disability. Prevalence rates by type of disability are as follows: vision 3.3%; hearing 3.1%; lower body limitations 12.6%; upper body limitations 8.2%; difficulty with at least one ADL 2.1%; difficulty with one or more IADL 6.4%; and cognitive, mental, or emotional 6.3% (Brault, 2012).

Number of Disabled Worldwide

According to data obtained from the World Health Survey, approximately 785 million (15%) of the world’s population 15

years of age and older have some type of disability and 110 million people (2.2%) have significant difficulty functioning. This number is increasing annually in part because of the increase in chronic diseases, injuries, automobile crashes, violence, an aging population, and improvements in the methodologies used to measure disability. Minorities, including women, and the poor are disproportionately affected by being disabled. Worldwide, most of the people with disabilities have limited access to basic public health services and rehabilitation (WHO, 2011).

Burden of Chronic Disease

Another way to consider disability data is to look at the **burden of chronic disease**. According to 2010 worldwide data obtained from The Global Burden of Disease Study, the prevalence of chronic diseases such as depression and diabetes is increasing faster than public health concerns such as malnutrition and infectious disease (Currie, 2013).

Although not all individuals with chronic diseases are disabled, the following data from the CDC provide convincing evidence that chronic diseases contribute significantly to the development of disability. Chronic diseases such as heart disease, stroke, cancer, diabetes, and arthritis are some of the most common, costly, and preventable of all health problems in the United States. Approximately 7 out of 10 deaths among

Americans each year are from chronic diseases. Heart disease, cancer, and stroke account for more than 50% of all deaths each year. In 2005 nearly 50% of the adult population, or almost 133 million Americans, had at least one chronic illness (CDC, 2010a).

Additional Causes of Disability

Disabilities among the chronically ill are common, and the CDC reports that about one fourth of people with chronic conditions have one or more daily activity limitations. For example, arthritis is the most common cause of disability, with nearly 19 million Americans reporting activity limitations. Diabetes continues to be the leading cause of kidney failure, non-traumatic lower-extremity amputations, and blindness among adults ages 20 to 74 (CDC, 2010a).

There is an obesity epidemic in the United States and according to the CDC (2014c), more than one third of adults, or 72 million Americans, are obese. People who are obese are more likely to develop chronic medical problems and have higher medical costs than people of normal weight. Moreover, older adults who are obese are more likely to have disabilities related to functional impairment.

Several other conditions and inherited problems can cause disability as seen in (Figure 31-1). These include genetic disorders, acute and chronic illnesses, violence, tobacco use, lack of access to health care, as well as failure to eat correctly, exercise

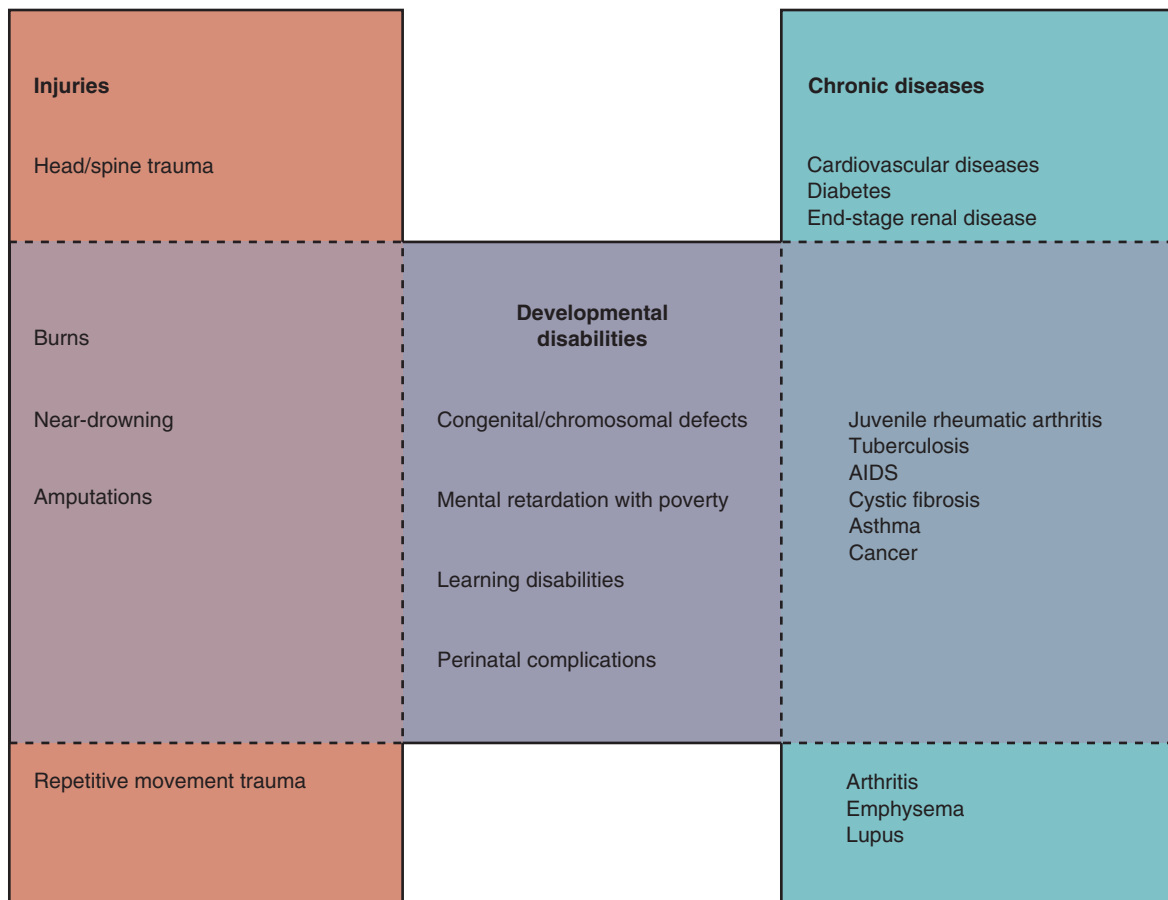

FIG 31-1 Examples of conditions related to being physically compromised.

regularly, or manage stress effectively. In addition, substance abuse, environmental problems, and unsanitary living conditions can cause disability. The people reporting these causes identified difficulty with functional limitations, difficulty with activities of daily living (ADLs)/instrumental activities of daily living (IADLs), or inability to do housework, or to work at a job or business (CDC, 2014a).

Falls among the elderly, especially the frail elderly, are common and one third of adults over the age of 65 fall every year. Of these falls approximately 20% to 30% result in moderate to severe injury and can cause temporary or permanent disability. This places the elderly at greater risk for loss of independence and physical mobility that can in turn cause additional medical problems. This loss of independence places additional burdens on family members and caregivers to provide assistance with ADLs and IADLs (CDC, 2013). A thorough nursing assessment can identify factors placing a community-dwelling elder at risk for falls. The assessment should include functional impairments, medications, and environmental factors that increase fall risk. Early assessment and intervention can prevent a fall and decrease development of additional medical problems and disability.

Childhood Disability

An estimated 15.1% of children in the United States have special needs, which may be developmental, behavioral, or emotional in nature. Moreover, 23.0% of households with children have at least one child with a special health need. Children with special health care needs require such things as prescription medication (86%), specialty medical care (48%), vision care (35%), mental health care (28%), specialized therapies (27%), and medical equipment (11%). Many families with children with special needs have difficulty obtaining services due to waiting lists and difficulty getting to appointments (17.8%), child not eligible for the service (10.8%), trouble getting the needed information (9.0%), the cost of the service (14.9%), and the service not being available in the area (11.2%) (MCHB, 2013).

Of the children with special health care needs, 20.8% are under the age of 5; 38.7% are between the ages of 6 and 11; and 40.5% are age 12 through 17. Moreover, children with special health care needs are more likely to be boys (59.3%) than girls (40.7%) (MCHB, 2013). Childhood disability may be developmental or acquired and may be a result of prenatal damage, perinatal factors, acquired neonatal factors, or early childhood factors. These may include genetic factors, prematurity, infections, traumatic or toxic exposure, or nutritional factors. Although the etiology of many childhood disabilities remains unknown, preventive screening for genetic disorders including developmental disabilities is critical for early detection and medical intervention. Newborn screening, immunization programs, and genetic counseling prevent disabilities. Neonatal screening for phenylketonuria (PKU), hypothyroidism, thalassemias, and other disorders has greatly reduced childhood disabilities.

Mental Illness

Often an overlooked source of disability is that related to mental disorders. According to the WHO (2013), mental health

problems, including depression, are among the 20 leading causes of disability worldwide. In the United States, the National Institute of Mental Health (2010) estimates that each year approximately 57.5 million Americans over the age of 18 (26.2%) have a diagnosable mental disorder. Major depressive disorder is the leading cause of disability in the United States for individuals ages 15 to 44. For individuals with one diagnosable mental illness, almost 45% meet criteria for a second or third mental illness. Multiple diagnoses, including individuals with a **dual diagnosis**, increase the severity of disability and functional impairment.

THE EFFECTS OF DISABILITIES

The costs of chronic disability to the injured persons, family, employers, and society are significant. In 2010 the SIPP estimated that of the noninstitutionalized population ages 21 to 64 who had any type of disability, only 41.1% were employed as compared to the nondisabled population (79.1%). Moreover, employment rates varied by type of disability: 73.4% of individuals with a disability related to communication were employed, while 40.8% of those with physical disabilities and 51.9% of people with mental disabilities were employed (Brault, 2012).

Disability status also affects annual household income, as can be seen in a 2010 survey of the median monthly household income among households with or without a disabled individual age 21 to 64. The monthly household income for households with a disabled member was \$1,961 whereas the monthly income for households without a disabled member was \$2,724. Perhaps of more significance are the number of individuals with disabilities who live in poverty. Moreover, the number of individuals living in poverty increases with the severity of disability. Twenty-eight percent of people with severe disability, 17.9% of people with nonsevere disability, and 14.3% of people with no disability live in poverty (Brault, 2012).

Nurses provide care for persons who are disabled, for their families, for the populations and subpopulations they comprise, and for the communities in which they live. Remember that some clients prefer to be regarded as being physically or mentally challenged or compromised, whereas others may think such terms minimize the importance of the needs and problems of people who are disabled. The extent to which the disabled person may need extra support, care, and services from the family unit and the community is shown in Box 31-2. These relationships are best understood by looking at the stress placed on the individual.

Effects on the Individual

According to the U.S. Department of Health and Human Services, disabilities are characteristics of the body, mind, or senses that affect a person's ability to engage independently in some or all aspects of day-to-day life. Many types of disabilities exist, and they affect people in various ways. People may be born with a disability, develop a disability from being sick or injured, or acquire a disability with the aging process. Most men, women, and children of all ages, races, and ethnicities will

BOX 31-2 Potential Effects of Being Physically Compromised

Individuals, Families, and Communities

Individuals

- Related health problems (e.g., nutrition, oral health, hygiene, limited activity/stamina)
- Self-concept/self-esteem
- Life expectancy and risk for infection and secondary injury
- Developmental tasks; change in role expectations

Families

- Stress on family unit
- Need for use of external resources to help family meet role expectations
- Options limited in use of any discretionary income
- Social stigma

Communities

- Need/demand to reallocate resources
- Discomfort or fear from lack of knowledge of disability
- Need to comply with legislation
- Services provided by health department, health care providers
- Need for other services beyond medical diagnosis (e.g., transportation)

experience disability at some time during their lives ([Erickson et al, 2012](#)).

As the population ages, the likelihood of developing a disability increases. For example, 10.1% of individuals 18 to 64 years old have a disability, 25.0% of those 65 to 74 have a disability, and 75% of those over 75 have a disability. Disability is not a sickness, and most people with disabilities are healthy and without a documented chronic illness. However, persons with disabilities may be at greater risk for developing illnesses as a result of their condition. For example, someone with decreased mobility can suffer from the problems of immobility such as obesity, skin breakdown, osteoporosis, pneumonia, malnutrition, or loneliness. Most persons with disabilities can and do work, play, learn, and enjoy healthy lives ([Erickson et al, 2012](#)).

Many disabled people try to discourage the image that they are helpless and pitiful. For example, *Murderball* is a documentary film about several quadriplegic rugby players who play competitive rugby in wheelchairs. Their motto is “Smashing stereotypes one hit at a time!” These individuals promote the idea of living and working independently ([U.S. Quad Rugby Association, 2010](#)).

Children: Infancy Through Adolescence

Children who live with a disability are affected in many ways. In an effort to decrease childhood obesity, greater emphasis has been placed on increasing children’s physical activity. In spite of this goal, children with any type of disability continue to be less physically active and at greater risk of obesity than their healthy peers. This is in part due to the relative lack of available opportunities for disabled children to participate in organized and spontaneous play. Moreover, nondisabled children and parents have also had negative attitudes about interacting or playing with disabled children ([Obrusnikova et al, 2010](#); [Reinehr et al, 2010](#)).

Children and adolescents with special health care needs are also at higher risk to experience psychological maladjustment compared with their healthy peers. The risk of psychological problems such as depression and anxiety is correlated with the degree of physical impairment, not with the level of disease activity. For some, the inability to participate in certain physical activities affects their feelings of belonging and self-worth ([Wilson and Clayton, 2010](#); [WHO, 2012](#)).

A particular problem for children with cognitive disabilities is difficulty with accurately interpreting social cues. These children are less likely to understand a social interaction that differs from usual and predictable interactions. As a result of misinterpreting social cues, children with cognitive disabilities are at a disadvantage in developing age-appropriate friendships. This can contribute to increased social isolation for many disabled children ([Leffert et al, 2010](#)).

For other children, managing the effects of their disability may cause embarrassment and they may choose to isolate themselves from others. For example, students who have spina bifida or renal disease might need to leave classrooms or other school settings quickly to use the bathroom. Having to explain this need to their classmates could call unwanted attention to these children and their diseases. However, disabled children can overcome some of these obstacles if they have families who are able to provide the support necessary for the development of more positive self-images and a feeling of inclusiveness. The use of assistive technology such as computers can enhance learning and decrease obstacles related to inadequate education ([Heywood, 2010](#); [Murchland and Parkyn, 2010](#); [WHO, 2012](#)).

The unique issues and challenges experienced by adolescents with disabilities have not been studied as well as those that affect younger children and adults. This population is often overlooked by advocacy groups for the disabled and by most of the new initiatives developed for disabled persons. However, the years between 10 and 18 are difficult ones for most adolescents, and the needs of those who are disabled are similar to those of their healthy peers (i.e., education, peer relationships, recreation, and planning for the future). In addition to the expected challenges experienced by adolescents, those who are disabled must also deal with prejudice, discrimination, and social isolation because of their disability ([Redmon, 2010](#); [WHO, 2012](#)).

Disabled adolescents are often viewed as asexual by their healthy peers. However, they are as sexually active as healthy adolescents. They view themselves as “normal” even though they realize that others perceive them differently. Moreover, disabled adolescents are just as likely as their nondisabled peers to engage in risky sexual activity. This places them at risk for unplanned pregnancy and sexually transmitted diseases. Therefore, they should receive the same amount of sexual education as their unaffected peers ([Maart, Jelsma, 2010](#); [WHO, 2012](#)).

Adults

According to The [Center for an Accessible Society \(CAS\)](#) (2014), more than 3 million people in the United States require help from another person to live independently. Many adults receive some, but not enough, help to meet their needs. With inadequate community support, an individual may experience

EVIDENCE-BASED PRACTICE

Researchers studied the effect of psychosocial education given to mothers who had an intellectually disabled child. The researchers wanted to know if providing education to mothers would decrease the mothers' risk of depression, as well as increase their perception of how well their family functioned. The study was a randomized controlled study of 75 women with intellectually disabled children; 40 in the intervention group and 35 in the control group. The intervention group received once weekly educational sessions over four weeks. At the conclusion of the study the researchers found there was a statistically significant difference between the two groups. The mothers who received education were less likely to be depressed and they perceived that their family functioned better.

Nurse Use

This study provides additional evidence that psychosocial education can contribute to the overall health and wellness of mothers with a disabled child. Nurses are often in a position to develop educational programs after assessing what information is needed. It's important for nurses working with families of children with disabilities to have psychosocial educational material available. Moreover, public health nurses should also maintain a database of community services and supports to make appropriate referrals for additional education and support.

Yildirim A, Hacıhasanoğlu R, Karakurt P: Effects of a nursing intervention program on the depression and perception of family functioning of mothers with intellectually disabled children. *J Clin Nurs* 22(1-2):251–261, 2013.

hunger, injuries, falls, or other problems that contribute to the development of secondary health problems, disabilities, and possibly early death. Becoming disabled increases the risk of placement in a nursing home or other long-term care facility, contributing to both decreased community participation and limited social integration for the disabled.

It is estimated that those persons who live by themselves receive only 56% of the help they need, while those living with family members or friends receive 80% of what they need. Informal supports such as family members and friends frequently have multiple work, family, and community responsibilities. This makes it difficult for them to consistently meet the needs of the disabled. Those without informal supports must rely on formal supports, which are increasingly limited in difficult financial times (CAS, 2014).

In addition, millions of Americans depend on Medicaid to finance their long-term services (CAS, 2014). For example, 80% of all Medicaid long-term care funds go to nursing homes or other institutional service providers, even though many of these people could receive services in their own homes. A personal assistant could make it possible for a disabled person to live at home instead of in an institution. Many Americans think that nursing homes are the only alternative for long-term care. However, the elderly often prefer the freedom and control of living at home. Many states offer community-based services such as home health care services and senior services. In home supportive services (IHSS) provide home health services to the aged, blind, or disabled. In addition, adult protective services exist to receive reports of abuse of elders or dependent adults.

Computer technology and use of the Internet can increase the independence of people with disabilities. Homebound persons

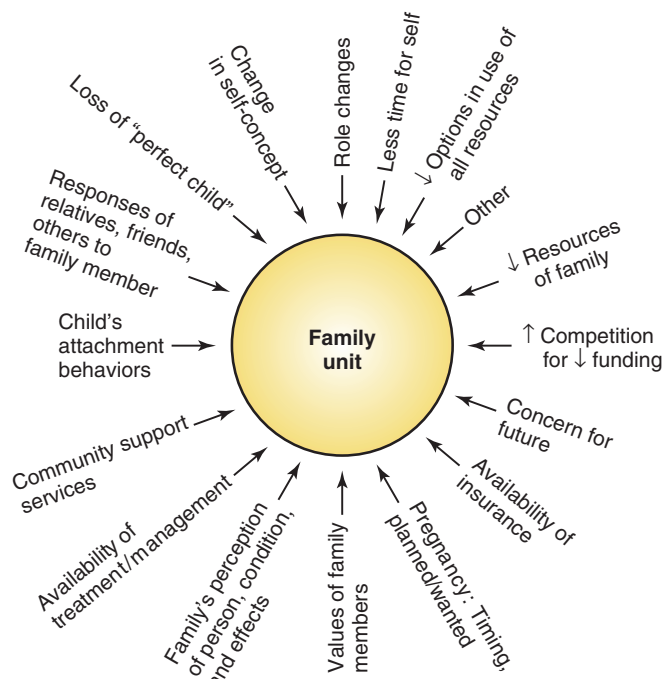

FIG 31-2 Factors influencing a family unit when a member is physically compromised.

can access a computer and order groceries, shop for needed items, research issues, participate in online discussions, and communicate with friends and family. With newer technologies, blind persons can access the computer as well as sighted persons. Even persons who cannot hold a pen or who lack fine-motor skills can use speech recognition and other technologies to write letters, pay bills, and perform other tasks using the computer and Internet (CAS, 2014). However, only one fourth of persons with disabilities own computers, and only one tenth use the Internet. The elderly and African Americans with disabilities, especially low-income or low-education-level elders, rarely take advantage of these new technologies. Fortunately, computers and associated equipment for the disabled has become less expensive. Moreover, there are organizations that provide low-cost or free computer equipment for qualified disabled individuals (CAS, 2014).

Effects on the Family

Most people who are physically disabled are cared for at home by one or more family members. Figure 31-2 lists some of the issues and concerns that occur when a family member is disabled and shows the effect of the disability on the family unit. As this figure shows, the entire family system is affected when one member is disabled.

A report conducted by AARP found that the number of individuals providing care to family members is increasing and the care provided is more complex. Family members provide a wide range of services including coordinating care, transportation to medical care, providing direct medical care, and using medical equipment. This caregiver burden can result in stress, depression, financial problems, as well as physical and social isolation (Diamant, 2011; WHO, 2011).

Children: Infancy Through Adolescence

A child's disability may have long-term effects on the family, primary caregiver, and the marital relationship. Providing care for these children places additional demands on the family, particularly the mother. Mothers of children with special health care needs report higher levels of stress, anxiety, depression, and feelings of isolation compared with mothers of unaffected children. In addition, employment is difficult and sometimes impossible to secure for the parents of children who require extensive care. This is especially true for mothers, single parents, and low-income families who may be unable to afford child care for their disabled children. In addition to the day-to-day physical care these children require, the caregiver must also access and coordinate physical, occupational, and speech therapy as well as specialty care and additional educational services (Bilgin and Gozum, 2009; Wei and Yu, 2012).

The cost of caring for a child with a disability often affects the family's financial well-being. Children with special health care needs are more likely than the general population of children to have health insurance. However, one third of the children with disabilities who have insurance have inadequate coverage to meet their needs. Moreover, 21.6% of CSHCN have conditions that create financial problems for their families. This is due to high out-of-pocket expenses, the services required not being covered, or the child not having access to appropriate providers (Laskar et al, 2010; MCHB, 2013).

Although children with special health care needs are more likely to have health insurance through Medicaid, children from low-income families who lack medical insurance are at a particular disadvantage because their families may be unable to afford the care they need. Siblings of children with special health care needs are at higher risk for developing emotional and psychological problems compared with their unaffected peers. For example, they tend to express more psychosomatic illnesses, anxiety disorders, and aggressive behaviors compared with siblings of nondisabled children (O'Brien et al, 2009; Daut et al, 2010).

Conversely, these siblings are often found to be more mature, altruistic, responsible, and independent when compared with siblings of nondisabled children. Whether a child suffers or benefits from having a disabled brother or sister depends on the attitude of the parents toward the disability and their coping methods, the economic circumstances of the family, the communication among family members, and the degree of parental affection and attention received by the nondisabled child (Dyke et al, 2009; MCHB, 2013).

Adults

Having a physically disabled adult in a family causes enormous stress on the rest of the members. There may be a significant loss of income when a parent is unable to work because of a disability, and disability prevents people from earning a living. Another effect on multigenerational families is caregiver burden. Well children in the family may have unmet needs due to the disability of a parent. Moreover, the children may have to assume the role of caregiver if other supports are not available.

Adults who are responsible for caring for their own children as well as one or both of their parents have been termed the "sandwich generation." These adults often struggle with burnout as well as increased marital stress when faced with caring for an elderly parent with a disability (Roth et al, 2009; Council for Disability Awareness, 2013).

Effects on the Community

The presence of physically disabled people and their families in the community has far-reaching effects on all aspects of community life. The prevention of disability and providing community support for caretakers need to be priorities. The community may be called on to respond in new ways to these citizens as a result of federal laws affecting those who are disabled.

Children: Infancy Through Adolescence

Families of children with disabilities need the support of their communities as they care for their disabled children at home. Children with disabilities have rights, including the right to remain at home rather than become institutionalized. The concept of providing mainstream inclusive health care is essential. Moreover, family services should also include education regarding available services and how to access them (WHO, 2012).

Children who are chronically ill or disabled and who enter school for mainstream education require educational support from the public school system as mandated in the Individuals with Disabilities Education Act (IDEA). IDEA is outlined in Box 31-3. In addition, IDEA requires states to provide appropriate services to infants and children from birth to age 5 who have or are at risk for disability. Examples of such services include speech therapy, occupational therapy, physical therapy, play therapy, and behavioral therapy (U.S. Department of Education, 2010). As seen in Figure 31-5 preterm infants have many health care needs if they are to grow and develop to their highest potential.

Although the provision of appropriate services for disabled infants and children is mandated by IDEA, states vary in the nature and quantity of services they provide for eligible children. In addition, public schools must evaluate their effectiveness with students who are disabled. This can add to the cost of

BOX 31-3 Individuals with Disabilities Education Act (IDEA)

The Individuals with Disabilities Education Act federal law was developed:

- To ensure that all children with disabilities have available to them a free, appropriate public education that emphasizes special education and related services designed to meet their unique needs and prepare them for employment and independent living
- To ensure that the rights of children with disabilities and their parents are protected
- To assist states, localities, educational service agencies, and federal agencies to provide for the education of all children with disabilities
- To assess and ensure the effectiveness of efforts to educate children with disabilities

U.S. Department of Education: *Building the legacy: IDEA 2004*, 2010: author. Available at www.idea.ed.gov. Accessed April 8, 2014.

educating children. Increased education for pediatricians and nurses can increase supportive and knowledgeable collaboration for the development of early intervention programs in the schools ([National Dissemination Center for Children with Disabilities, 2012](#)). As seen in [Figure 31-6](#) having a disabled family member requires many adjustments and may cause enormous stress on the rest of the family.

Adults

Former Surgeon General Richard H. Carmona sought to improve the health and wellness of persons with disabilities. To achieve this goal, in 2005 he published a call to action which encouraged (1) health care providers to see and treat the whole person, not just the disability, (2) educators to teach about disability, (3) the public to focus on a person's abilities, not just the disability, and (4) the community to ensure accessible health care and wellness services to persons with disabilities ([Carmona, 2005](#)).

These goals have been only partially achieved as evidenced by the [WHO \(2011\)](#) World Report on Disability that again calls for action to address barriers and inequities for people with disabilities. The recommendations are as follows: enable access to all mainstream systems and services; invest in specific programs and services for people with disabilities; adopt a national disability strategy and plan of action; involve people with disabilities; improve human resource capacity; provide adequate funding and improve affordability; increase public awareness and understanding; improve disability data collection; and strengthen and support research on disability.

Persons with disabilities that affect mobility are at risk for health problems of the multiple body systems related to mobility/immobility. Persons with mobility-associated problems can suffer damage to any system. Some of the problems that develop with the musculoskeletal system include foot drop, muscular atrophy, contractures, or fractures. Respiratory and circulatory function can be compromised by pneumonia or deep vein thrombosis. Renal problems such as infection, incontinence, or renal calculi are common problems related to immobility. Decubiti and skin breakdown and rashes can develop from immobility and/or incontinence of bowel and bladder. Malnutrition or obesity could also be related to effects of immobility.

SPECIAL POPULATIONS

Low-Income Populations

Physically compromised individuals often experience poverty, as do other special population groups including single parents and their children, the aged, the unemployed, and members of racial and ethnic minorities. Persons with low income have less access to health care throughout their lives and are less likely to participate in all levels of prevention. Therefore, they are at greater risk for the onset of disabling conditions and for more rapid progression of disease processes. Those in poverty could also be at greater risk for disabling conditions resulting from lifestyle choices (e.g., injuries; tobacco, alcohol, or drug abuse; and inadequate nutrition).

FIG 31-3 Relationships of poverty and disability.

People who are disabled and live in poverty are less likely to have the resources to provide for their own special needs. Those who are disabled are often unemployed, even though they may be able to work and are seeking jobs. Employers may be reluctant to hire people whose conditions may increase employer-provided health insurance costs. This is another barrier to adequate insurance and access to health care for the disabled. Other factors that affect low-income, physically compromised clients' access to needed services are inadequate transportation, lack of coordination of care, and limited locally available services for those who cannot pay for them. [Figure 31-3](#) illustrates the relationship between poverty and disabilities.

SELECTED ISSUES

Abuse and Neglect

Individuals with disabilities are more likely to experience some form of abuse or neglect during their lifetime compared with individuals without disabilities. Examples of abuse and neglect include physical harm, inappropriate sexual contact, emotional or verbal threats, withholding care, not providing adequate supervision, and not providing needed medical care. Abuse and neglect also include withholding medical information, denying the opportunity to participate in decision making, including decisions about medical care and the right to refuse care, and financial exploitation ([Missouri Department of Health & Senior Services \(MDHSS\), 2014](#)). ([Figure 31-4](#) illustrates the relationships among the family member with a disability, the caregiver, the environment and the intersection with abuse).

While all individuals with disabilities are at risk for abuse and neglect, children, the elderly, and women are at particular risk. Children are dependent on adults and require care, supervision, guidance, and financial support to achieve normal growth and development. The responsibility for and care of healthy, nondisabled children poses many challenges for parents. When a child is born with or develops a disability the developmental, physical, and financial needs can become

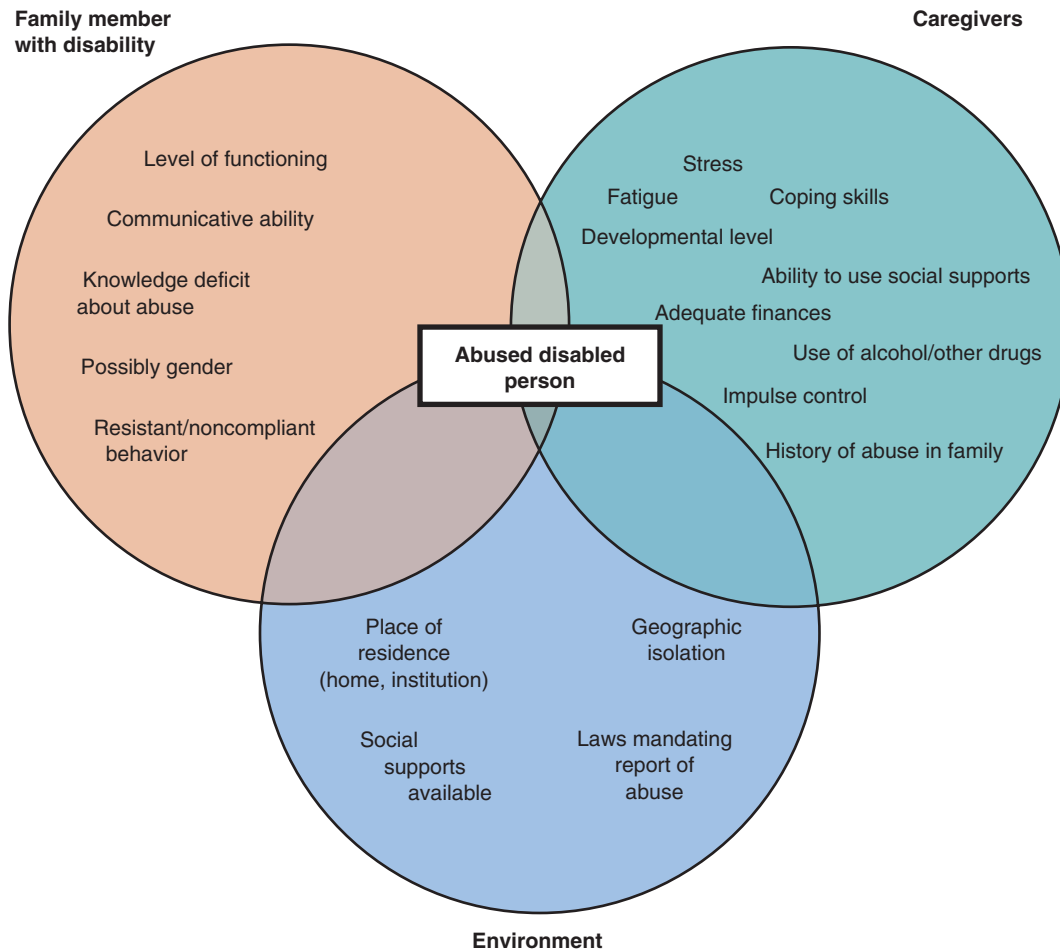

FIG 31-4 Factors influencing the abuse of those who are physically compromised.

overwhelming. According to the [U.S. Department of Health and Human Services \(2012\)](#) risk factors for the abuse/neglect of disabled children can be stratified to societal factors, such as believing disabled children are asexual or do not feel pain; family or parental factors, which include the child being viewed as different, parents who are embarrassed by their disabled child, or families with inadequate social support or resources; and child-related factors, which include being male, having challenging/difficult behaviors, or requiring extensive physical care.

An interesting study conducted by researchers with the Interactive Autism Network found that children with autistic spectrum disorders (ASD) were three times more likely to be bullied than children without ASD. One form of bullying is intentionally provoking a child with ASD to the point of emotional breakdown or physical violence. According to this study children with ASD are also more likely to be bullies, due to aggressive outbursts or poorly developed social skills. Many children with ASD are unable to make socially appropriate comments and may inappropriately comment on another child's physical characteristics, such as telling other children they are ugly or fat ([Anderson, 2012](#)).

In general, the elderly are at increased risk for abuse and neglect. The elderly who also have disabilities are at additional

risk due to their increased dependency needs. The most common type of abuse reported by disabled individuals is care related. Because many disabled individuals are dependent on others for basic care, they are at risk for experiencing neglect and at times cruel physical care from their care providers. Financial abuse is another common way elderly disabled persons are mistreated. Community-dwelling elderly living with family may be threatened with institutionalization in a nursing home if they report the abuse or complain ([Missouri Department of Health and Senior Services, 2014](#)).

Women and girls with disabilities face many challenges and often have to face “double discrimination.” There is worldwide gender discrimination in such areas as access to housing, education, training, employment, and salary equity. Being female also places one at risk for sexual exploitation, abuse, neglect, and violence. Women with disabilities are at increased risk of this type of abuse because of the powerlessness of women in many parts of the world, the lack of resources, and women being undervalued ([United Nations, 2010](#)).

Health Promotion

Health promotion usually focuses on the primary prevention of conditions that may lead to disability (e.g., smoking cessation to prevent lung cancer). Actually all three levels of prevention

FIG 31-5 **A**, An at-risk infant girl who was 1 month premature and delivered by cesarean section because of abruption. This child's Apgar scores were 1 at 1 minute of age and 3 at 5 minutes of age. **B**, The same child at 10 years of age. She is profoundly hearing impaired. Her parents' commitment has helped her to be mainstreamed successfully and she is able to do her own homework.

apply to physically compromised clients (see the [Levels of Prevention](#) box). They need information and counseling for health-promoting behaviors and for prevention of the progression of a condition or pathology.

Health promotion is a multidimensional concept that applies to all individuals regardless of disability. Strategies are needed to expand the knowledge base of health promotion for those who are disabled. Persons with chronic disabilities have frequently defined themselves in terms of their physical problems and sick role. However, they need all the prevention activities of the nondisabled. This includes immunizations, exercise, weight control, use of safety precautions, safe sex practices, stress reduction, as well as screening and treatment of disease not related to their disability.

LEVELS OF PREVENTION

Physically Compromised Clients

Primary Prevention

- Educate community residents about behaviors during pregnancy that will reduce the risk of having a baby with a disability.
- Push for a congressional mandate for addition of folic acid to cereals in the United States to reduce neural tube defect in infants.
- Promote exercise and physical fitness programs in schools to lessen obesity in that population and decrease incidence of metabolic syndrome.

Secondary Prevention

- Initiate early detection actions to identify any chronic or disabling condition.
- Initiate blood pressure screening programs to identify those at risk for strokes or heart damage as soon as possible.
- Push programs for early detection of cancer (e.g., mammography, malignant melanoma), since co-occurring morbidities are more common with later detection of cancer.

Tertiary Prevention

- Take action to maintain or increase functional abilities for persons who have a physically compromising condition.
- Encourage exercise programs for sedentary clients with osteoporosis to reduce the likelihood of fractures.
- Initiate a diabetes type 1 education program for children and parents, with a focus on disease management and prevention of disease complications.

In addition, health promotion and prevention programs for persons with disabilities should focus on preventing complications from the effects of immobility and the disease process. The complications of immobility and the disease process need to be prevented to ensure optimal independent and healthy living, thus allowing the individual with disabilities the opportunity to have a productive and happy life.

Many health promotion and disease prevention needs are similar across the life span (e.g., exercise, diet, avoidance of excess substance use, and injury prevention). However, specific problems and interventions to deal with these needs vary according to age, specific disabling condition, and developmental status. For example, nutritional needs of premature infants are related to obtaining adequate energy, protein, fat, vitamins, and minerals. An older adult with type 2 diabetes mellitus may be concerned primarily with reducing the risk of experiencing a myocardial infarction.

Persons with disabilities need appropriate nutrition. Therefore, nurses may consult with dietitians or refer clients to them for assistance. Speech therapists may also be needed for persons with chewing or swallowing difficulties. Occupational health professionals focus on the activities of daily living and often use adaptive equipment to promote success and independence with ADLs. Families and professionals can work together to meet the nutritional needs of persons with disabilities and chronic health care problems.

Health promotion and disease prevention for those who are physically compromised have not been emphasized in primary care or in rehabilitation. It is especially important to establish

FIG 31-6 This disabled woman is able to live in and maintain her own home, including growing plants and flowers, with the help of easy-access devices and lower light fixtures and cabinets.

lifelong health-promoting behaviors in children who are disabled. Unfortunately, parents may be so overwhelmed by caring for such children that this aspect of care is not considered.

Healthy People 2020 Objectives

Selected objectives from *Healthy People 2020* for persons with disabilities are highlighted in the [Healthy People 2020](#) box. Many of the objectives address concerns discussed in this chapter regarding increasing health promotion and wellness activities for individuals with disabilities. In addition, there is greater emphasis on increasing access to services, which can increase independence and foster community living.

The *Healthy People 2020* objectives are a useful tool available to nurses to evaluate if individuals with disabilities are receiving adequate services. Moreover, these objectives can serve as national benchmarks for individuals with disabilities with regard to their health, use of community services, leisure activities, and overall quality of life. Nurses can use the *Healthy People 2020* objectives to advocate for increased physical activity and wellness programs for the disabled. This can be done by working with community and disability organizations to ensure compliance with the ADA and by educating others about the *Healthy People 2020* objectives. (U.S. Department of Health and Human Services, 2013).

HEALTHY PEOPLE 2020

Selected objectives are listed here that pertain to persons with disabilities.

Systems and DH-1 Policies

- DH-1: Increase the number of population-based data systems used to monitor *Healthy People 2020* objectives that include in their core a standardized set of questions that identify people with disabilities.
- DH-2: Increase the number of tribes, states, and the District of Columbia that have public health surveillance and health promotion programs for people with disabilities and caregivers.

Barriers to Health Care

- DH-5: Increase the proportion of youth with special health care needs whose health care provider has discussed transition planning from pediatric to adult health care.
- DH-7: Reduce the proportion of older adults with disabilities who use inappropriate medications.

Environment

- DH-8: Reduce the proportion of people with disabilities who report having physical or program barriers to local health and wellness programs.
- DH-9: Reduce the proportion of people with disabilities who encounter barriers to participating in home, school, work or community activities.

Activities and Participation

- DH-13: Increase the proportion of people with disabilities who participate in social, spiritual, recreational, community, and civic activities to the degree that they wish.
- DSC-14: Reduce the proportion of people with disabilities reporting delays in receiving primary and periodic preventive care due to specific barriers.

U.S. Department of Health and Human Services: *Healthy People 2020: Disability and Health*, 2013; author. Available at www.healthypeople.gov. Accessed April 11, 2014.

ROLE OF THE NURSE

Many factors influence the role of nurses who work with individuals with disabilities. These factors include the community's awareness of these persons and the commitment to their health needs. Also, the missions of the agencies where nurses work influence the type of services they provide to special groups. For example, the structure and priorities of a community-based agency determine whether a nurse will care for the general population or focus on service to a specific population. If funding sources are dedicated to particular programs (e.g., tuberculosis control, maternal-child health services), care for those who are disabled may be dispersed throughout several program areas and may be difficult to identify.

In dealing with those who are disabled, a nurse's role may also change as the focus varies among the levels of individuals, families, groups, or entire communities. For example, at the level of the individual, nurses may provide nursing care for ventilated patients at home. Nurses also serve as educators who provide clients at any level with sufficient knowledge to enable them to care for their own needs. At the community level, nurses may provide information about certain causes of disability and aim to reduce the behaviors that precede the development of disability, such as spinal cord injury. The closely

HOW TO Promote Appropriate Use of Asthma Medications by Children

A. Collaborate/coordinate efforts with health care provider managing child's asthma.

1. Personnel in all areas in which a child uses drugs need to be informed of regimen.
2. Be aware of factors that could affect adherence to regimen:
 - Prolonged therapy
 - Medications used prophylactically
 - Delayed consequences of nonadherence
 - Drugs expensive, hard to use
 - Family concerns about side effects
 - Adherence less likely with mild or severe asthma; most likely with moderate asthma
 - Child with cognitive or emotional problems
 - Poorly functioning family
 - Strong alternative health beliefs
 - Multiple caregivers

B. Assess child's adherence to regimen.

1. Count pills; use float test for remaining amount in inhalers (gross estimate).
2. Ask child, "In an average week, how many puffs of your inhaler do you actually get?"
3. Obtain refill history from pharmacist (information can be obtained from child's health care provider).

C. Interventions

1. Educate child, parents, and other caregivers.
2. Encourage adaptation of regimen to family's needs.
 - Health care provider may need additional information about family situation.
 - Signed, dated, written permission to exchange information with such a provider is needed.
3. Encourage consideration of acceptability of medication to child, family.
4. Be encouraging, caring, supportive, and willing to work with family.
5. Follow-up and monitor progress closely, including school attendance, when appropriate.
6. Consider home visits (e.g., to assess/manage environmental triggers).
7. Identify an "asthma partner" (i.e., another adult besides parents when they do not reliably monitor child).
8. Use a contract for adherence.
9. In extreme cases, especially with young and/or ill children, consider reporting family to child protective services for medical neglect.

related counseling role is of value because clients learn to improve their problem-solving skills with guidance from the nurse. The **How To** box that follows discusses ways to promote the appropriate use of asthma medications by children.

Nurses serve as advocates for individuals and families or groups. An advocate is a person who speaks on behalf of those who are unable to speak for themselves. One of the potential problems with this role is that nurses may unintentionally foster excessive dependence by individuals, families, or other groups. Nurses should focus on using advocacy to support those who need this service. Moreover, having an opportunity to observe nurses using their advocacy skills may assist clients to feel more comfortable in being advocates for themselves or for family

members. For example, nurses might advocate for a school environment that is adapted to the specific needs of children who require wheelchairs but who do not necessarily have to be limited to their chairs, without explicitly telling the children when they should use their wheelchairs. In addition, nurses may help family caregivers of disabled individuals by validating that the caregiver may have unmet needs and by helping them to identify ways their needs can be met.

As referral agents, nurses maintain current information about agencies with services that are of potential use to those who are disabled. Referral, a common practice for nurses, is the process of directing clients to the resources that can meet their needs. For self-directed clients and families, information about an agency's services, phone number, and address may be adequate. For families with little understanding of how systems work, more specific guidance and case conferences may be necessary to coordinate clients' health-related and educational needs.

As health care providers with a goal of making basic care universally accessible, nurses are positioned well to ensure that the full range of prevention and information about health promotion is made available to individuals with disabilities. On a more individualized basis, the nurse in a case manager role works to meet the needs of clients by developing a plan of care for them to help them reach individual goals. Although nurses may direct others to carry out the plan, they are responsible for evaluating the plan's effectiveness. For example, clients who have been disabled because of complications from diabetes mellitus may have several immediate problems. They may need to adjust to the amputation of one or more limbs, as well as learn new skills to improve management of their diabetes in an effort to prevent additional complications. Nurses (as case managers) will develop plans with clients and families to meet these needs and establish time frames to evaluate specific outcomes.

In the coordinator role, nurses are not responsible for developing overall plans of client care. Instead, responsibilities include assisting clients and families by organizing and integrating the resources of other agencies or care providers to meet clients' needs most efficiently. For example, with the family's agreement, a nurse may arrange for the family to see a social worker on the same day they bring their children to an appointment in a pediatric cardiology clinic.

Nurses are collaborators when they take part in joint decision making with clients, families, groups, and communities. Collaboration with other care providers is of particular importance in coordinating care and assisting a disabled person to understand the full range of services available. For example, nurses may work with agencies or groups who make decisions about community housing for those who are physically disabled.

In the nursing as case finder role, nurses identify individuals with disabilities who have unmet service needs. For example, nurses may arrange developmental, vision, and hearing screenings for young children. Although a nurse's efforts are for particular clients, the focus of case finding is on monitoring the health status of entire groups or communities. Nurses may also identify those who are members of vulnerable populations and who, although not presently affected by an illness, are at high risk for acquiring the disease. Such people

may have limited or no access to health promotion or disease prevention services, or they may be unaware of those for which they are eligible.

Nurses may function as change agents at all levels, including the health care delivery system. A change agent is one who originates and creates change. This process includes identifying a need for change, enlightening and motivating others as to this need, as well as starting and directing the proposed change. Nurses may function in the role by helping to obtain more appropriate health care services for those who are disabled. The most up-to-date information on national and local resources for individuals with disabilities can be found on the Internet. Two excellent resources are Connecting the Disability Community to Information and Opportunities (www.disability.gov) and Disability Resource (www.disabilityresources.org). The following **Quality and Safety in Nursing Education** box provides useful information regarding teamwork and collaboration in caring for a person who is part of a special needs population.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Quality and Safety Focus

Targeted Competency: Teamwork and Collaboration

Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality patient care.

Important aspects of teamwork and collaboration include:

- **Knowledge:** Recognize contributions of other individuals and groups in helping patient/family achieve health goals
- **Skills:** Integrate the contributions of others who play a role in helping patient/family achieve health goals
- **Attitudes:** Respect the unique attributes that members bring to a team, including variations in professional orientations and accountabilities

Teamwork and Collaboration Question

You are a VA home care nurse who has extensive experience in caring for returned veterans who are recovering from spinal cord injuries. You have been approached by the VA Hospital to help develop a program to reduce recurring admissions to the acute care setting for this population. Specifically, there are models from leading rehabilitation hospitals that a Spinal Cord Injury Nurse Advice Line can effectively help clients and families address commonly recurring complications like neurogenic bladder and skin breakdown. Employing an "Ask-A-Nurse" model, a Spinal Cord Injury Nurse Advice Line is a call-in resource. The development team is asking your input on which team members should be involved in development of this local initiative. If successful, the model may be implemented nationally across the VA Medical System.

What contributions will the following team members make to a Spinal Cord Injury Nurse Advice Line?

- Patients with spinal cord injuries
- Families of patients with spinal cord injuries
- Primary care providers
- Neurologists
- Urologists
- Wound care nurses
- Emergency room physicians
- Case managers

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing

BOX 31-4 Categories of Federal Legislation for Those With Disabilities

Education

- Early childhood special education
- Elementary and Secondary Education Act and amendments
- Vocational education for those who are disabled

Rehabilitation

- Vocational
- Medical, including Medicare and Medicaid
- Rehabilitation

Services

- Economic assistance
- Facility construction and architectural design
- Deinstitutionalization and independent living
- Civil rights and advocacy

The International Center for Disability Resources on the Internet: *Legal, Advocacy, Policy, and Political Issues*, 2010: author. Available at www.icdri.org/legal. Accessed April 11, 2014.

BOX 31-5 Summary of Legislation

- Communications Act of 1934 and Telecommunications Act of 1996
- Elementary and Secondary Education Act of 1965
- Architectural Barriers Act of 1968
- Rehabilitation Act of 1973
- Individuals with Disabilities Education Act (IDEA) of 1975
- Civil Rights of Institutionalized Persons Act of 1980
