Overarching Concept

- Community-oriented nursing practice

Subconcepts

- Public health nursing
- Population focused
- Population centered

Foundational Pillars

- Assurance
- Assessment
- Policy development

Settings

- Community
- Environment
- School
- Industry
- Church
- Prisons
- Playground
- Home

Clients

- Individuals
- Families
- Groups
- Populations
- Communities

Interventions

- Disease prevention
- Health promotion
- Health protection
- Health maintenance
- Health restoration
- Health surveillance

Services

- Personal health services
- Populations/Aggregate Services
- Community services

COMMUNITY NURSING DEFINITIONS

Community-Oriented Nursing Practice is a philosophy of nursing service delivery that involves the generalist or specialist public health and community health nurse providing “health care” through community diagnosis and investigation of major health and environmental problems, health surveillance, and monitoring and evaluation of community and population health status for the purposes of preventing disease and disability and promoting, protecting, and maintaining “health” in order to create conditions in which people can be healthy.

Public Health Nursing Practice is the synthesis of nursing theory and public health theory applied to promoting and preserving health of populations. The focus of practice is the community as a whole and the effect of the community’s health status (resources) on the health of individuals, families, and groups. Care is provided within the context of preventing disease and disability and promoting and protecting the health of the community as a whole. Public Health Nursing is population focused, which means that the population is the center of interest for the public health nurse. *Community Health Nurse* is a term that is used interchangeably with *Public Health Nurse*.

Community-Based Nursing Practice is a setting-specific practice whereby care is provided for “sick” individuals and families where they live, work, and go to school. The emphasis of practice is acute and chronic care and the provision of comprehensive, coordinated, and continuous services. Nurses who deliver community-based care are generalists or specialists in maternal–infant, pediatric, adult, or psychiatric–mental health nursing.

Select Examples of Similarities and Differences Between Community-Oriented and Community-Based Nursing

	COMMUNITY-ORIENTED NURSING		COMMUNITY-BASED NURSING
	PUBLIC HEALTH NURSING: POPULATION FOCUSED/ POPULATION CENTERED		
Philosophy	PRIMARY focus is on “health care” of communities and populations	SECONDARY focus is on “health care” of individuals, families, and groups in community to unserved clients by health care system	Focus is on “illness care” of individuals and families across the life span
Goal	Prevent disease; preserve, protect, promote, or maintain health	Prevent disease; preserve, protect, promote, or maintain health	Manage acute or chronic conditions
Service context	Community and population health care “the greatest good for the greatest number”	Personal health care to unserved clients	Family-centered illness care
Community type	Varied: local, state, nation, world community	Varied, usually local community	Human ecological
Client characteristics	<ul style="list-style-type: none"> • Nation • State • Community • Populations at risk • Aggregates • Healthy • Culturally diverse • Autonomous • Able to define problem • Client primary decision maker 	<ul style="list-style-type: none"> • Individuals/families at risk if unserved by health care system • Usually healthy • Culturally diverse • Autonomous • Able to define own problem • Client primary decision maker 	<ul style="list-style-type: none"> • Individuals • Families • Usually ill • Culturally diverse • Autonomous • Client able to define own problem • Client involved in decision making
Practice setting	<ul style="list-style-type: none"> • Community • Organization • Government • Community agencies 	<ul style="list-style-type: none"> • May be organization • May be government • Community agencies • Home • Work • School • Playground 	<ul style="list-style-type: none"> • Community agencies • Home • Work • School
Interaction patterns	<ul style="list-style-type: none"> • Governmental • Organizational • Groups • May be one-to-one 	<ul style="list-style-type: none"> • One-to-one • Groups • May be organizational 	<ul style="list-style-type: none"> • One-to-one
Type of service	<ul style="list-style-type: none"> • Indirect • May be direct care of populations 	<ul style="list-style-type: none"> • Direct care of at-risk persons • Indirect (program management) 	<ul style="list-style-type: none"> • Direct illness care
Emphasis on levels of prevention	<ul style="list-style-type: none"> • Primary 	<ul style="list-style-type: none"> • Primary • Secondary: screening • Tertiary: maintenance and rehabilitation 	<ul style="list-style-type: none"> • Secondary • Tertiary • May be primary

Select Examples of Similarities and Differences Between Community-Oriented and Community-Based Nursing—cont'd

COMMUNITY-ORIENTED NURSING			
	PUBLIC HEALTH NURSING: POPULATION FOCUSED/ POPULATION CENTERED		COMMUNITY-BASED NURSING
Roles	Client and delivery oriented: community/population <ul style="list-style-type: none"> • Educator • Consultant • Advocate • Planner • Collaborator • Data collector/evaluator • Health status monitor • Social engineer • Community developer/partner • Facilitator • Community care agent • Assessor • Policy developer/maker • Assurer of health care • Enforcer of laws/compliance • Disaster responder Population oriented <ul style="list-style-type: none"> • Program manager, aggregates • Health initiator • Program evaluator • Counselor • Change agent—population health • Educator • Population advocate 	Client and delivery oriented: individual, family, group <ul style="list-style-type: none"> • Individual/family oriented—as needed • Caregiver • Social engineer • Educator • Counselor • Advocate • Case manager Group Oriented <ul style="list-style-type: none"> • Leader, personal health management • Change agent, screening • Community advocate • Case finder • Community care agent • Assessment • Policy developer • Assurance • Enforcer of laws/compliance 	Client and delivery oriented: individual, family <ul style="list-style-type: none"> • Caregiver • Educator • Counselor • Advocate • Care manager Group Oriented <ul style="list-style-type: none"> • Leader, disease management • Change agent, managed care services
Priority of nurses' activities	<ul style="list-style-type: none"> • Community development • Community assessment/monitoring • Health policy/politics • Community education • Interdisciplinary practice • Program management • Community/population advocacy 	<ul style="list-style-type: none"> • For individual and family clients—as needed • Case finding • Client education • Community education • Interdisciplinary practice • Case management, direct care • Program planning, implementation • Individual and family advocacy 	<ul style="list-style-type: none"> • Care management, direct care • Patient education • Individual and family advocacy • Interdisciplinary practice • Continuity of care provider

Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

ABOUT THE AUTHORS

Marcia Stanhope, PhD, RN, FAAN

Marcia Stanhope is currently an education consultant with Berea College, Berea Kentucky, as in Berea, Kentucky an Associate with Tuft and Associate Search Firm, Chicago, Illinois, and Professor Emerita from the University of Kentucky, College of Nursing, Lexington, Kentucky. In recent years she received the Provost Public Scholar award for contributions to the communities of Kentucky. She was appointed to the Good Samaritan Endowed Chair in Community Health Nursing 12 years ago. She has practiced community and home health nursing, has served as an administrator and consultant in home health, and has been involved in the development of a number of nurse-managed centers. She has taught community health, public health, epidemiology, primary care nursing, and administration courses. Dr. Stanhope was the former Associate Dean and formerly directed the Division of Community Health Nursing and Administration at the University of Kentucky. She has been responsible for both undergraduate and graduate courses in population-centered, community-oriented nursing. She has also taught at the University of Virginia and the University of Alabama, Birmingham. Her presentations and publications have been in the areas of home health, community health and community-focused nursing practice, nurse-managed centers, and primary care nursing. Dr. Stanhope holds a diploma in nursing from the Good Samaritan Hospital, Lexington, Kentucky, and a bachelor of science in nursing from the University of Kentucky. She has a master's degree in public health nursing from Emory University in Atlanta and a doctorate of science in nursing from the University of Alabama, Birmingham. Dr. Stanhope is the co-author of four other Elsevier publications: *Handbook of Community-Based and Home Health Nursing Practice*, *Public and Community Health Nurse's Consultant*, *Case Studies in Community Health Nursing Practice: A Problem-Based Learning Approach*, and *Foundations of Community Health Nursing: Community-Oriented Practice*.

Jeanette Lancaster, PhD, RN, FAAN

Jeanette Lancaster is Professor and Dean Emerita at the University of Virginia, School of Nursing in Charlottesville, Virginia. She served as Dean of the School of Nursing at the University of Virginia from 1989 until 2008. From 2008 to 2009 she served as a visiting professor at the University of Hong Kong where she taught courses in public health nursing and worked with faculty to develop their scholarship programs. She then taught at the University of Virginia from 2010 until 2012. She also taught at Vanderbilt University and is an Associate with Tuft & Associates, Inc, an executive search firm. She has practiced psychiatric nursing and taught both psychiatric and community health nursing. She formerly directed the master's program in community health nursing at the University of Alabama, Birmingham, and served as Dean of the School of Nursing at Wright State University in Dayton, Ohio. Her publications and presentations have been largely in the areas of community and public health nursing leadership and change and the significance of nurses to effective primary health care. Dr. Lancaster is a graduate of the University of Tennessee Health Science Center Memphis. She holds a master's degree in psychiatric nursing from Case Western Reserve University and a doctorate in public health from the University of Oklahoma. Dr. Lancaster is the author of another Elsevier publication, *Nursing Issues in Leading and Managing Change*, and the co-author with Dr. Marcia Stanhope of *Foundations of Community Health Nursing: Community-Oriented Practice*.

ACKNOWLEDGEMENTS

Dr. Hale holds a BSN from the University of Wisconsin-Milwaukee, an MSN and FNP from the University of Virginia, and a PhD from the University of Maryland.

Dr. Turner holds a BSN and MSN from the University of Virginia and a PhD from the University of Kentucky.

INTRODUCING DRS HALE AND TURNER

In this edition, we are pleased to have Professor Patty Hale, RN, FNP, PhD, FAAN, Graduate Program Director, Department of Nursing, at James Madison University, Harrisburg, Virginia, and Lisa Turner, PhD, RN, PHCNS-BC, Assistant Professor of Nursing, Berea College, Berea, Kentucky, join us in this edition of the text as Assistant Editors.

A SPECIAL THANKS TO CONTRIBUTORS

Each edition our goal has been to offer special thanks to those who contributed to past editions of the text. To continue that tradition we want to extend heartfelt thanks to those who contributed to the 8th edition. They are Jean Bokinskie, Bonnie Jerome D'Emili, Diane Downing, James Fletcher, Karen Landenburger, Robert McKeown, Susan Patton, Molly Rose, Juliann Sebastian, Mary Silva, and Jeanne Sorrell.

Jeanette Lancaster and Marcia Stanhope

DEDICATIONS:

It has been my special privilege to be advised and mentored by a number of exemplary professionals and to be loved and supported by numerous friends, big and small. Their contributions have made significant differences to my life and career. This edition of the text is dedicated to the memory of Charlotte Denny and Lois Merrill, University of Kentucky; Mary Hall, Emory University; Atlanta, Dorothy Carter, my community partner, Pikeville, Kentucky, and Norma Mobley, University of Alabama, Birmingham; as well as to two special friends, John C. and CiCi.

Marcia Stanhope

I would like to dedicate my work on this 9th edition to my late husband, I. Wade Lancaster. He supported and encouraged me through the first eight editions of the text, and I am deeply grateful for his love, support, and encouragement.

Jeanette Lancaster

PREFACE

Since the last edition of this text, many changes have occurred in society as well as in health care. The rapid and often startling changes in society are influencing the amount and ways in which health care is delivered. Many of the industrialized nations around the world are engaged in health care reform, and a major driver for reform is the enormous cost of providing health care to citizens. The human, financial, infrastructure, and other costs associated with war, natural and human-made diseases, and civil uprising continue to affect many nations, including the United States. The world, as many people know, has changed dramatically in the past few decades because of such disruptions as war, hurricanes and tsunamis, terrorism, earthquakes, floods, and tornados that have cost lives, homes, and livelihoods. These destructive events have had enormous costs in terms of money and the damage to individuals, families, and communities. The need for stronger public health resources has grown as these disruptions have occurred in the United States and many other countries. Public health professionals play a key role in helping communities deal with both emergency and non-emergency aspects of their lives.

As is explained in [Chapter 1](#) and discussed in other chapters throughout the text, there are three core functions of public health: assessment, policy development, and assurance. The Centers for Disease Control and Prevention ([CDC, 2014, p. 1](#)) have developed 10 essential public health services, and the list below aligns these services with the core functions:

ASSESSMENT

1. Monitor health status to identify and solve community environmental health problems.
2. Diagnose and investigate health problems and health hazards in the community.

POLICY DEVELOPMENT

3. Inform, educate, and empower people about health issues.
4. Mobilize community partnerships and actions to identify and solve health problems.
5. Develop policies and plans that support individual and community health efforts.

ASSURANCE

6. Enforce laws and regulations that protect health and ensure safety.
7. Link people to needed health services and assure the provision of health services when otherwise unavailable.
8. Assure competent public and personal health care workforce.
9. Evaluate effectiveness, accessibility, and quality of personal and population-based health services.
10. Research for new insights and innovative solutions to health problems ([CDC, 2014, p. 1](#)).

Chapters in this text include all of the critical roles listed above as well as guidance in how to deal with other major issues, including the quality of care, the cost of care, and access to care. The growing shortage of nurses and other health care providers will only increase the concerns about these issues. One of the ways in which quality of care could be improved would include new uses of technology to manage an information revolution. Great improvements in quality would require a restructuring of how care is delivered, a shift in how funds are spent, changing the workplace, and using more effective ways to manage chronic illness. There will be costs associated with these quality improvements.

The United States' health care spending has slowed in recent years due to the economy. In 2013, the health care costs were at about 1.2 trillion dollars, or 16.7% of the gross domestic product. After the implementation of the Affordable Care Act, the numbers of uninsured dropped from 48 million to 41 million by 2013 ([KFF 2014](#)). However, the cost burden to employers and consumers needs to be explored to see if there has been any change. This number of uninsured is larger than the population of either Canada or Australia. Despite spending more money per person in the United States for illness care than any other country, Americans are not the healthiest of all people. The infant mortality and life expectancy rates—indexes of health care—while improving, are not close to what they should be given the amount spent on health care. Some of the most important factors leading to the high health care costs are diagnostic and treatment technologies, drugs, an aging population, more chronic illness, shortages in health care workers, and medical-legal costs. Lifestyle continues to play a big role in morbidity and mortality. It is embarrassing that, overall, citizens in the United States are the most obese citizens in any industrialized nation. In addition, half of all deaths are still caused by tobacco, alcohol, and illegal drug use; diet and activity patterns; microbial agents; toxic agents; firearms; sexual behavior; and motor vehicle accidents.

In the past two decades the greatest improvements in population health have come from public health achievements such as immunizations leading to eliminating and controlling infectious diseases, motor vehicle safety, safer workplaces, lifestyle improvements reducing the risk of heart disease and strokes, safer and healthier foods through improved sanitation, clean water and food fortification programs, better hygiene and nutrition to improve the health of mothers and babies, family planning, fluoride in drinking water, and recognition of tobacco as a health hazard. Continued changes in the public health system are essential if death, illness, and disability resulting from preventable problems are to continue to decline.

The need to focus attention on health promotion, lifestyle factors, and disease prevention led to the development of a major public policy about health for the nation. This policy was designed by a large number of people representing a wide range of groups interested in health. The policy, first introduced in

1979, was updated in 1990 and in 2000; it is reflected in the most recent document updated in 2010, titled *Healthy People 2020*. These four documents have identified a set of national health promotion and disease prevention objectives for each of four decades. Examples of these objectives are highlighted in chapters throughout the text.

The most effective disease prevention and health promotion strategies designed to achieve the goals and objectives of *Healthy People 2020* are developed through partnerships between government, businesses, voluntary organizations, consumers, communities, and health care providers. According to *Healthy People 2020*, the partners who join a newly established consortium will work to achieve the goals and objectives of *Healthy People 2020*.

Healthy People 2020 emphasizes the concept of social determinants of health—that is, the belief that health is affected by many social, economic, and environmental factors that extend far beyond individual biology of disease. This means that improving health requires a broad approach to including the concept of health in all policies and creating environments where the healthy choice is the easy choice. To develop healthy communities, individuals, families, communities, and populations must commit to these approaches. Also, society, through the development of health policy, must support better health care, the design of improved health education, and new ways of financing strategies to alter health status.

The regrettable fact is that few health indicators have been substantially improved since *Healthy People 2010* was released in 2000. *Healthy People 2020* retains many of the original objectives and adds new ones. What does this mean for nurses who work in public health? Because people do not always know how to improve their health status, the challenge of nursing is to create change. Nursing takes place in a variety of public and private settings and includes disease prevention, health promotion, health protection, surveillance, education, maintenance, restoration, coordination, management, and evaluation of care of individuals, families, and populations, including communities.

To meet the demands of a constantly changing health care system, nurses must have vision in designing new and changing current roles and identifying their practice areas. To do so effectively, the nurse must understand concepts, theories, and the core content of public health, the changing health care system, the actual and potential roles and responsibilities of nurses and other health care providers, the importance of health promotion and disease orientation, and the necessity of involving consumers in the planning, implementation, and evaluation of health care efforts.

Since its initial publication in 1984, this text has been widely accepted and is popular among nursing students and nursing faculty in baccalaureate, BSN-completion, and graduate programs. The text was written to provide nursing students and practicing nurses with a comprehensive source book that provides a foundation for designing population-centered nursing strategies for individuals, families, aggregates, populations, and communities. The unifying theme for the book is the integrating of health promotion and disease prevention concepts into

the many roles of nurses. The prevention focus emphasizes traditional public health practice with increased attention to the effects of the internal and external environment on health of communities. The focus on interventions for the individual and family emphasizes the aspects of population-centered practice with attention to the effects of all of the determinants of health, including lifestyle, on personal health.

CONCEPTUAL APPROACH TO THIS TEXT

The term *community-oriented* has been used to reflect the orientation of nurses to the community and the public's health. In 1998, the Quad Council of Public Health Nursing comprised of members from the American Nurses Association Congress on Nursing Practice, the American Public Health Association Public Health Nursing section, the Association of Community Health Nursing Educators, and the Association of State and Territorial Directors of Public Health Nursing developed a statement on the *Scope of Public Health Nursing Practice*. Through this statement, the leaders in public and community health nursing attempted to clarify the differences between public health nursing and the newest term introduced into nursing's vocabulary during health care reform of the 1990s, *community-based nursing*. The Quad Council recognized that the terms *public health nursing* and *community health nursing* have been used interchangeably since the 1980s to describe population-focused, community-oriented nursing and community-focused practice. They decided to make a clearer distinction between community-oriented and community-based nursing practice. In 2007, the definitions were further refined, and nurses once referred to as *public health nurses* and *community health nurses* are now referred to only as *public health nurses* in the revised standards of practice.

In this textbook, two different levels of care in the community are acknowledged: community-oriented care and community-based care. Two role functions for nursing practice in the community are suggested: public health nursing (community health nursing) and community-based nursing. This text focuses only on public health nursing (community health nursing), using the term *community-oriented nursing*, which encompasses a focus on populations within the community context or *population-centered nursing practice*.

For the fifth edition of this text, with consultation from C. A. Williams (author) and June Thompson (Mosby editor), Marcia Stanhope developed a conceptual model for community-oriented nursing practice. This model was influenced by a review of the history of community-oriented nursing from the 1800s to today. Marcia Stanhope studied Betty Neuman's model intensively while in school, which influenced this model.

The model itself is presented as a caricature of reality—or an abstract—with a description of the characteristics and the philosophy on which community-oriented nursing is built. The *model* is shown as a flying balloon (see inside front cover of this book). The balloon represents community-oriented nursing and is filled with the knowledge, skills, and abilities needed in this practice to carry the world (the basket of the balloon) or the clients of the world who benefit from this practice.

The *subconcepts* of public health nursing with the community and populations as the center of care are the *boundaries* of the practice. The public health foundation pillars of assurance, assessment, and policy development hold up the world of communities, where people live, work, play, go to school, and worship. The ribbons flying from the balloon indicate the interventions used by nurses. These ribbons (interventions) serve to provide lift and direction, tying the services together for the clients who are served. The intervention names and the services are listed on the inside cover of this book. The *propositions* (statements of relationship) for this model are found in the definitions of practice, public health functions, clients served, specific settings, interventions, and services. Many *assumptions* have served as the basis for the development of this model. Community-oriented nursing is a specialty within the nursing discipline. The practice has evolved over time, becoming more complex. The practice of nursing in public health is based on a philosophy of care rather than being setting specific. It is different from community-based nursing care delivery. The development of community-oriented nursing has been influenced by public health practice, preventive medicine, community medicine, and shifts in the health care delivery system. Community-oriented nursing requires nurses to have specific competencies to be effective providers of care.

The definition of community-oriented nursing appears on the inside front cover of this book. This practice involves public health nurses. Community-based nurses differ from community-oriented nurses in many ways. These differences are described in the table following the definitions. The differences are described as they relate to philosophy of care, goals, service, community, clients served, practice settings, ways of interacting with clients, type of services offered to clients, prevention levels used, goals, and priority of nurses' activities.

The four concepts of nursing, person (client), environment, and health are described for this model. These concepts appear in many works about nursing and in almost every educational curriculum for undergraduate students. Each of the four concepts may be defined differently in these works because of the beliefs of the persons writing the definitions.

In this text *nursing* is defined as community-oriented with a focus on providing health care through community diagnosis and investigation of major health and environmental problems. Health surveillance, monitoring, and evaluating community and population status are done to prevent disease and disability and to promote, protect, preserve, restore, and maintain health. This in turn creates conditions in which clients can be healthy. The person, or client, is the world, nation, state, community, population, aggregate, family, or individual.

The boundaries of the client *environment* may be limited by the world, nation, state, locality, home, school, work, playground, religion, or individual self. *Health*, in this model, involves a continuum of health rather than wellness, with the best health state possible as the goal. The best possible level of health is achieved through measures of prevention as practiced by the nurse.

The nurse engages in autonomous practice with the client, who is the primary decision maker about health issues. The nurse practices in a variety of environments, including, but not limited to, governments, organizations, homes, schools, churches, neighborhoods, industry, and community boards. The nurse interacts with diverse cultures, partners, other providers in teams, multiple clients, and one-to-one or aggregate relationships. Clients at risk for the development of health problems are a major focus of nursing services. Primary prevention-level strategies are the key to reducing risk of health problems. Secondary prevention is done to maintain, promote, or protect health, whereas tertiary prevention strategies are used to preserve, protect, or maintain health.

The community-oriented nurse has many roles related to community clients and roles that relate specifically to practice with populations (or population-centered). Community-oriented nurses engage in activities specific to community development, assessment, monitoring, health policy, politics, health education, interdisciplinary practice, program management, community/population advocacy, case finding, and delivery of personal health services when these services are otherwise unavailable in the health care system. This conceptual model is the framework for this text.

ORGANIZATION

The text is divided into seven sections:

- **Part 1, Influencing Factors in Health Care and Population-Centered Nursing**, describes the historical and current status of the health care delivery system and public health nursing practice, both domestically and internationally.
- **Part 2, Forces Affecting Health Care Delivery and Population-Centered Nursing**, addresses the economics, ethics, policy, and cultural issues that affect public health, nurses, and clients.
- **Part 3, Conceptual and Scientific Frameworks Applied to Population-Centered Nursing Practice**, provides conceptual models and scientific bases for public health nursing practice. Selected models from nursing and related sciences are also discussed.
- **Part 4, Issues and Approaches in Population-Centered Nursing**, examines the management of health care, quality and safety, and populations in select community environments and groups, as well as issues related to managing cases, programs, and disasters.
- **Part 5, Health Promotion with Target Populations Across the Life Span**, discusses risk factors and population-level health problems for families and individuals throughout the life span.
- **Part 6, Promoting and Protecting the Health of Vulnerable Populations**, covers specific health care needs and issues of populations at risk.
- **Part 7, Nurses' Roles and Functions in the Community**, examines diversity in the role of public health nurses and describes the rapidly changing roles, functions, and practice settings.

NEW TO THIS EDITION

New content has been included in the ninth edition of *Public Health Nursing: Population-Centered Health Care in the Community* to ensure that the text remains a complete and comprehensive resource:

- **NEW!** In each chapter, content is applied to Quality and Safety Education for Nurses (QSEN).

PEDAGOGY

Other key features of this edition are detailed below. Each chapter is organized for easy use by students and faculty.

Additional Resources

Additional Resources listed at the beginning of each chapter direct students to chapter-related tools and resources contained in the book's Appendixes or on its Evolve website.

Objectives

Objectives open each chapter to guide student learning and alert faculty to what students should gain from the content.

Key Terms

Key Terms are identified at the beginning of the chapter and defined either within the chapter or in the glossary to assist students in understanding unfamiliar terminology.

Chapter Outline

The Chapter Outline alerts students to the structure and content of the chapter.

How To Boxes

How To boxes provide specific, application-oriented information.

Evidence-Based Practice Boxes

Evidence-Based Practice boxes in each chapter illustrate the use and application of the latest research findings in public health, community health, and community-oriented nursing.

Practice Application

At the end of each chapter a case situation helps students understand how to apply chapter content in the practice setting. Questions at the end of each case promote critical thinking while students analyze the case.

Key Points

Key Points provide a summary listing of the most important points made in the chapter.

Clinical Decision-Making Activities

Clinical Decision-Making Activities promote student learning by suggesting a variety of activities that encourage both independent and collaborative effort.

Appendixes

The **Appendixes** provide additional content resources, key information, and clinical tools and references.

EVOLVE STUDENT LEARNING RESOURCES

Additional resources designed to supplement the student learning process are available on this book's website at <http://evolve.elsevier.com/Stanhope>, including:

- **Additional Resources for Students** in select chapters
- **Answer Key to Review Questions** with suggested solutions to the Practice Application questions at the end of each chapter
- **Audio Glossary** with complete definitions of all key terms and other important community and public health nursing concepts
- **Review Questions** questions with answers
- **Student Case Studies** with questions and answers

INSTRUCTOR RESOURCES

Several supplemental ancillaries are available to assist instructors in the teaching process:

- **TEACH for Nurses lesson plans** provided for each chapter, with Nursing Curriculum Standards, Teaching Strategies and Learning Activities, Case Studies, and more
- **Test Bank** with 1200 NCLEX®-style questions and answers
- **PowerPoint Lecture Slides** for each chapter
- **Image Collection** with illustrations from the text
- **Answers to Practice Application Questions**
- **Audio Glossary**

Influencing Factors in Health Care and Population-Centered Nursing

Population-centered nursing emphasizes the community where nursing is based in the population providing care on-site to individuals or group members of the population. It also emphasizes a focus on a defined population whereby the nurse seeks knowledge about the health issues or problems facing the total population so the nurse can then find ways to resolve the issues and problems for all members of the population. The focused approach seeks to improve health for all within the community's population. In this section information emerges to show how community-based nursing and community oriented (focused) nursing are different in approach but similar in the goal to improve health for the populations served.

Since the late 1800s, public health nurses have been leaders in making improvements in the quality of health care for individuals, families, and aggregates, including populations and communities. As nurses around the world collaborate with one another, it is clear that, from one country to another, population-centered nursing has more similarities than differences.

Important changes in health care have been taking place since the early 1990s, and there is data to show that changes are occurring as a result of the health care reform work in the United States. Although considerable controversy surrounded the implementation of the Patient Protection and Affordable Care Act of 2010, it is clear that change is providing more access to care and reductions in hospitalization. It is also reducing cost and providing more preventive care.

The areas in health care that have posed the greatest problems for persons over the years have been access, quality, and cost. These problems are being addressed but are still present. A number of people still have either no insurance or inadequate insurance, access to quality care is unevenly distributed across the country, and the cost of health care remains high for consumers, employers, insurers, and state and federal governments. Changes in the health care system and delivery are attempting to address these issues.

Some of the key areas of emphasis in the current efforts to reform health care include preventing disease, coordinating care, and shifting care from the hospital to the home or community facilities where possible. In the coming years, a large growth in the number of nurses employed in home health care and in nursing care facilities is expected. An area targeted for growth is that of the federal community health centers. Nurses comprise the largest category of employees in those centers. It is also expected that more new graduates will go directly into community health work rather than working for a few years in the hospital before making that transition. This trend supports the recommendations that nurses need to be prepared at the baccalaureate level.

Over the years, funding for public health has decreased, or remained neutral, while the needs for population-centered services have increased. The key question is whether health care reform will provide what is needed for population-centered care in America's communities. There is much discussion about the new emphasis on prevention, community-oriented care, continuity, and the important role that nurses will play in health care. With anticipation that many of these projections will become a reality and that nurses will become increasingly key practitioners in promoting the health of the people, they must understand the history of public health nursing and the current status of the public health system.

Part One presents information about significant factors affecting health in the United States. Changing the level and quality of services and the priorities for funding requires that nurses be involved, informed, courageous, and committed to the task. The chapters in Part One are designed to provide essential information so that nurses can make a difference in health care by understanding their own roles and their functions in population-centered

practice. Understanding how the public health system differs from the primary care system is described as well as the movement to integrate public health and primary care.

There is a core of knowledge known as “public health” that forms the foundation for population-centered public health nursing. This core has historically included epidemiology, biostatistics, environmental health, health services administration,

and social and behavioral sciences. In recent years, new areas of focus within public health have included informatics, genomics, communication, cultural competence, community-based participatory research, evidence-based practice, policy and law, global health, ethics, and forensics. This book covers both the traditional and the newer content either in a full chapter or as a section in one or more chapters.

Community and Prevention–Oriented, Population-Focused Practice: The Foundation of Specialization in Public Health Nursing

Carolyn A. Williams, RN, PhD, FAAN

Dr. Carolyn A. Williams is Dean Emeritus and Professor at the College of Nursing at the University of Kentucky, Lexington, Kentucky. Dr. Williams began her career as a public health nurse. She has held many leadership roles, including President of the American Academy of Nursing; membership on the first U.S. Preventive Services Task Force, Department of Health and Human Services; and President of the American Association of Colleges of Nursing. She received the Distinguished Alumna Award from Texas Woman's University in 1983. In 2001 she was the recipient of the Mary Tolle Wright Founder's Award for Excellence in Leadership from Sigma Theta Tau International, and in 2007 she received the Bernadette Arminger Award from the American Association of Colleges of Nursing. In 2011 she was awarded an Honorary Doctorate of Public Service from the University of Portland, Portland, Oregon. In 2014 she received the honor of being conducted into the University of Kentucky College of Public Health Hall of Fame for international, national, state and local contributions to public health and nursing.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. State the mission of and core functions of public health and the essential public health services and the quality performance standards program in public health.
2. Describe specialization in public health nursing and other nurse roles in the community and the practice goals of each.
3. Contrast clinical nursing practice with population focused practice in the community.
4. Describe what is meant by community and prevention–oriented, population-focused practice.
5. Name barriers to acceptance of community and prevention–oriented, population-focused practice.
6. State key opportunities for community and prevention–oriented, population-focused practice.

Public Health Nursing Specialists and Core Public Health Functions: Selected Examples**Public Health Nursing versus Community-Based Nursing Roles in Public Health Nursing****Challenges for the Future**

- Barriers to Specializing in Public Health Nursing
- Developing Population-Focused Nurse Leaders
- Shifting Public Policy toward Creating Conditions for a Healthy Population

The second decade of the twenty-first century finds the United States entering an era when more public attention is being given to efforts to protect and improve the health of the American people and the environment. Despite what many see as a failure to make fundamental changes in the delivery and financing of health care, significant change has occurred. Federal and state initiatives, private market forces, the development of new scientific knowledge and new technologies, and the expectations of the public are bringing about changes in the health care system. With the national legislation that passed in 2010—the Patient Protection and Affordable Care Act (ACA) (www.hhs.gov/opa/affordable-care-act)—which in part was designed to increase access to care; concerns have been raised about the availability of adequate numbers of professional personnel to provide services, particularly in primary care and strained health care facilities. Despite initial turbulence in implementation of the legislation, including difficulties with enrollments due to technological problems, initial reports are that good progress has been made in enrolling people and the Congressional Budget Office projected that by 2014 the number of uninsured people will decrease by 12 million and by 26 million by 2017 (Blumenthal and Collins, 2014). Blumenthal and Collins (2014) also reported that the Urban Institute projected that the proportion of uninsured people adults in the United States fell from 18% in the third quarter of 2013 to 13.4% in May of 2014. Before the passage of the ACA many at the national level were seriously concerned about the growing cost of medical care as a part of federal expenditures (Orszag, 2007; Orszag and Emanuel, 2010). The concern with the cost of medical care remains a national issue and Blumenthal and Collins (2014) argue that the sustainability of the expansions of coverage provided by the ACA will depend on whether the overall costs of care in the United States can be controlled. If costs are not controlled the resulting increases in premiums will become increasingly difficult for all—consumers, employers, and the federal government. Other health system concerns focus on the quality and safety of services, warnings about bioterrorism, and global public health threats such as infectious diseases and contaminated foods. Because of all of these factors, the role of public health in protecting and promoting health, as well as preventing disease and disability, is extremely important.

Whereas the majority of national attention and debate surrounding national health legislation has been focused primarily on insurance issues related to medical care, there are indications of a renewed interest in public health and in population-focused thinking about health and health care in the United States. For example, incorporated into the Patient Protection and Affordable Care Act are provisions that address health promotion and prevention of disease and disability. These include (1) establishment of the National Prevention, Health Promotion, and Public Health Council to coordinate federal prevention, wellness, and public health activities and to develop a national strategy to improve the nation's health (www.surgeongeneral.gov/initiatives/prevention/about), and (2) as indicated in Chapter 3 and 5, creation of a Prevention and Public Health Fund to expand and sustain funding for prevention and public health programs (Trust for America's Health, 2013), and (3) improvement of preventive efforts by covering only proven preventive services and eliminating state cost sharing for preventive services, including immunizations recommended by the U.S. Preventive Services Task Force (USPHS 2000) (www.uspreventiveservicestaskforce.org). Also, grants and technical assistance will be available to employers who establish wellness programs (www.dol.gov/ebsa/newsroom/2013/13).

Although populations have historically been the focus of public health practice, specifically defined populations are becoming a focus of the “business” of managed care; therefore more managed care executives are joining public health practitioners in becoming population oriented. Increasingly, managed care executives and program managers are using the basic sciences and analytic tools of the field of public health. However, their focus is on using such epidemiological and statistical strategies to develop databases and analytical approaches to making decisions at the level of a defined population or subpopulation enrolled in a particular care delivery organization or those covered by a particular insurance company. A population-focused approach to planning, delivering, and evaluating various aspects of care delivery is increasingly being used in an effort to achieve better outcomes in the population of interest and has never been more important.

Where is public health nursing in all of the changes swirling around in the world of health and health care? This is a crucial

time for public health nursing, a time of opportunity and challenge. The issue of growing costs together with the changing demography of the U.S. population, particularly the aging of the population, is expected to put increased demands on resources available for health care. In addition, the threats of bioterrorism, highlighted by the events of September 11, 2001, and the anthrax scares, will divert health care funds and resources from other health care programs to be spent for public safety. Also important to the public health community is the emergence of modern-day epidemics (such as the mosquito-borne West Nile virus, the H1N1 influenza virus, and the emerging Ebola virus crisis) and globally induced infectious diseases such as avian influenza and other causes of mortality, many of which affect the very young (see [Chapters 3 and 5](#)). Most of the causes of these epidemics are preventable. What has all of this to do with nursing?

Understanding the importance of community-oriented, population-focused nursing practice and developing the knowledge and skills to practice it will be critical to attaining a leadership role in health care regardless of the practice setting. The following discussion explains why those who practice community-based, prevention-oriented, population-focused nursing will be in a very strong position to affect the health of populations and decisions about how scarce resources will be used.

PUBLIC HEALTH PRACTICE: THE FOUNDATION FOR HEALTHY POPULATIONS AND COMMUNITIES

During the last 25 years, considerable attention has been focused on proposals to reform the American health care system. These proposals focused primarily on containing cost in medical care financing and on strategies for providing health insurance coverage to a higher proportion of the population. In the national health legislation that passed in 2010, the Patient Protection and Affordable Care Act, the majority of the provisions and the vast majority of the discussion of the bill focused on those issues (www.hhs.gov/opa/affordable-care-act).

Because physician services and hospital care combined account for over half of the health care expenditures in the United States, it is understandable that changes in how such services would be paid for would receive much attention (kaiserEDU.org, 2010). However, as stated in the [Public Health Functions Steering Committee Report on the Core Functions of Public Health \(1998\)](#), while it was important to make reforms in the medical insurance system there is a clear understanding among those familiar with the history of public health and its impact that such reforms alone will not be adequate to improve the health of Americans.

Historically, gains in the health of populations have come largely from public health efforts. Safety and adequacy of food supplies, the provision of safe water, sewage disposal, public safety from biological threats, and personal behavioral changes, including reproductive behavior, are a few examples of public health's influence. In 2008 Fielding and colleagues argued that

there is incontrovertible evidence that public health policies and programs were primarily responsible for increasing the average life span from 47 in 1900 to 78 in 2005, an increase of 66% in just a little over a century. They asserted that most of that increase was through improvements in sanitation, clean water supplies, making workplaces safer, improving food and drug safety, immunizing children, and improving nutrition, hygiene, and housing ([Fielding et al, 2008](#)).

In an effort to help the public better understand the role public health has played in increasing life expectancy and improving the nation's health, in 1999 the Centers for Disease Control and Prevention (CDC) began featuring information on the Ten Great Public Health Achievements in the 20th Century. The areas featured include Immunizations, Motor Vehicle Safety, Control of Infectious Diseases, Safer and Healthier Foods, Healthier Mothers and Babies, Family Planning, Fluoridation of Drinking Water, Tobacco as a Health Hazard, and Declines in Deaths from Heart Disease and Stroke ([CDC, 2014](#)). A case can be made that the payoff from public health activities is well beyond the resources directed to the effort. For example, recent data reported by the Centers for Medicare and Medicaid Services (CMS) showed that in 2012 only 3% (up from 1.5% in 1960) of all national expenditures supported by governmental entities supported public health functions ([CMS, 2012](#)). The expenditures in 2014 were the same.

Unfortunately, the public is largely unaware of the contributions of public health practice. After the passage of Medicare and Medicaid, federal and private monies in support of public health dwindled, public health agencies began to provide personal care services for persons who could not receive care elsewhere, and the health departments benefited by getting Medicaid and Medicare funds. The result was a shift of resources and energy away from public health's traditional and unique prevention-oriented, population-focused perspective to include a primary care focus ([U.S. Department of Health and Human Services \[USDHHS\], 2002](#)).

One consequence of a successful implementation of the Affordable Care Act might actually be that the majority of the population would be covered by insurance and public health agencies will not need to provide direct clinical services in order to assure that those who need them can receive them. If this occurs public health organizations can refocus their efforts on the core functions and emphasize community-oriented, population-focused health promotion and preventive strategies, if ways can be found to finance such efforts. An Institute of Medicine report, *For the Public's Health: Investing in a Healthier Future*, released in 2012, began with presentation of data showing that in comparison with other wealthy Western countries the United States lags well behind its peers on health status while outspending every country in the world on health. However, a key message was that health-related spending in the United States is primarily expended on clinical care costs for medical and hospital services; very little spending is for public health activities.

A central conclusion of the report was that “to improve health outcomes in the United States, there will need to be a

transforming of the way the nation invests in health to pay more attention to population-based prevention efforts; remedy the dysfunctional manner in which public health funding is allocated, structured, and used; and ensure stable funding for public health departments.” Further, the committee recommended that “a minimum package of public health services—those foundational and programmatic services needed to promote and protect the public’s health” be developed. The report concluded by recommending that “Congress authorize a dedicated, stable, and long-term financing structure—a national tax on all health care transactions—to generate the enhanced federal revenue required to deliver the minimum package of public health services in every community” (Institute of Medicine [IOM], 2012a).

Definitions in Public Health

In 1988 the Institute of Medicine published a report on the future of public health, which is now seen as a classic and influential document. In the report, public health was defined as “what we, as a society, do collectively to assure the conditions in which people can be healthy” (IOM, 1988, p. 1). The committee stated that the mission of public health was “to generate organized community efforts to address the public interest in health by applying scientific and technical knowledge to prevent disease and promote health” (IOM, 1988, p. 1; Williams, 1995).

It was clearly noted that the mission could be accomplished by many groups, public and private, and by individuals. However, the government has a special function “to see to it that vital elements are in place and that the mission is adequately addressed” (IOM, 1988, p. 7). To clarify the government’s role in fulfilling the mission, the report stated that assessment, policy development, and assurance are the **public health core functions** at all levels of government.

- **Assessment** refers to systematically collecting data on the population, monitoring the population’s health status, and making information available about the health of the community.
- **Policy development** refers to the need to provide leadership in developing policies that support the health of the population, including the use of the scientific knowledge base in making decisions about policy.
- **Assurance** refers to the role of public health in ensuring that essential community-oriented health services are available, which may include providing essential personal health services for those who would otherwise not receive them. Assurance also refers to making sure that a competent public health and personal health care workforce is available. Fielding (2009) subsequently made the case that assurance also should mean that public health officials should be involved in developing and monitoring the quality of services provided.

Because of the importance of influencing a population’s health and providing a strong foundation for the health care system, the U.S. Public Health Service and other groups strongly advocated a renewed emphasis on the population-focused essential public health functions and services that have been most effective in improving the health of the entire population.

As part of this effort, a statement on public health in the United States was developed by a working group made up of representatives of federal agencies and organizations concerned about public health. The list of essential services presented in Figure 1-1 represents the obligations of the public health system to implement the core functions of assessment, assurance, and policy development. The **How To** Box further explains these essential services and lists the ways public health nurses implement them (U.S. Public Health Service, 1994 [updated 2008]).

Public Health Core Functions

The Core Functions Project (U.S. Public Health Service, 1994 [updated 2008]) developed a useful illustration, the Health Services Pyramid (Figure 1-2), which shows that population-based public health programs support the goals of providing a foundation for clinical preventive services. These services focus on disease prevention; on health promotion and protection; and on primary, secondary, and tertiary health care services. All levels of services shown in the pyramid are important to the health of the population and thus must be part of a health care system with health as a goal. It has been said that “the greater the effectiveness of services in the lower tiers, the greater is the capability of higher tiers to contribute efficiently to health improvement” (U.S. Public Health Service, 1994 [updated 2008]). Because of the importance of the basic public health programs, members of the Core Functions Project argued that all levels of health care, including population-based public health care, must be funded or the goal of health of populations may never be reached.

Several new efforts to enable public health practitioners to be more effective in implementing the core functions of assessment, policy development, and assurance have been undertaken at the national level. In 1997 the Institute of Medicine published *Improving Health in the Community: A Role for Performance Monitoring* (IOM, 1997). This monograph was the product of an interdisciplinary committee, cochaired by a public health nursing specialist and a physician, whose purpose was to determine how a performance monitoring system could be developed and used to improve community health.

The major outcome of the committee’s work was the **Community Health Improvement Process (CHIP)**, a method for improving the health of the population on a community-wide basis. The method brings together key elements of the public health and personal health care systems in one framework. A second outcome of the project was the development of a set of 25 indicators that could be used in the community assessment process (see Chapter 18) to develop a community health profile (e.g., measures of health status, functional status, quality of life, health risk factors, and health resource use) (Box 1-1). A third product of the committee’s work was a set of indicators for specific public health problems that could be used by public health specialists as they carry out their assurance function and monitor the performance of public health and other agencies.

In 2000 the CDC established a Task Force on Community Preventive Services, which is in place and works to provide evidence-based findings and recommendations about a variety of community preventive services, programs, and policies to prevent morbidity and mortality (CDC, 2014b). The result

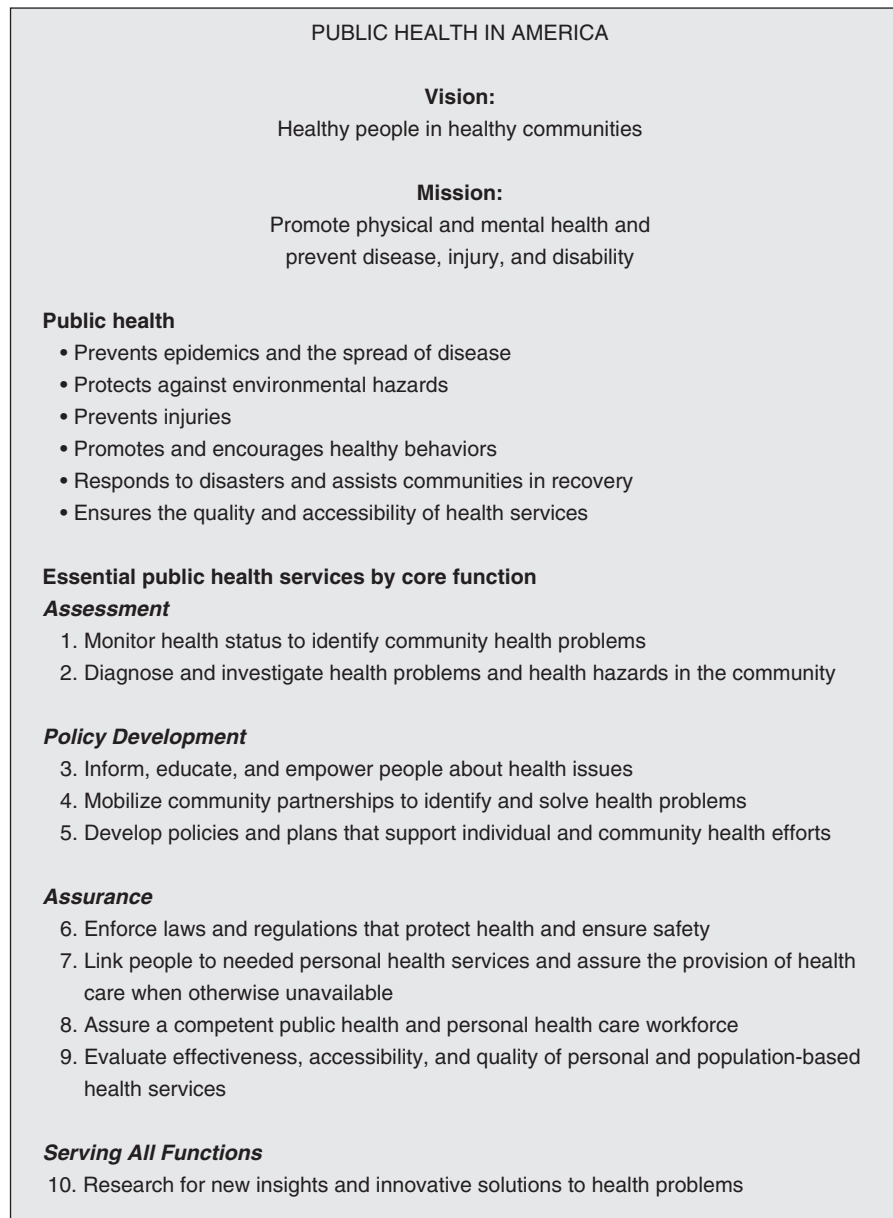

FIG 1-1 Public health in America. (From U.S. Public Health Service: *The Core Functions Project*. Washington, DC, 1994/update 2000, DC, Office of Disease Prevention and Health Promotion. Update 2008.)

is *The Community Guide: What Works to Promote Health*, a versatile set of resources available electronically at www.thecommunityguide.org/index.html that can be used by public health specialists and others interested in a community-level approach to health improvement and disease prevention. Information is available on 22 topics, which include health problems/issues such as obesity, mental health, asthma, cancer, diabetes, and concerns such as violence, tobacco, nutrition, vaccination, excessive consumption of alcohol, motor vehicle injury, emergency preparedness, and worksite initiatives (CDC, 2014b). The materials, which include systematic reviews of research, can be used to help make choices about policies and programs that have been shown to be effective (CDC, 2014b). Community Preventive Services are important because they provide tools for

public health practitioners, many of whom are public health nursing specialists, to enable them to be more effective in dealing with the core functions.

Core Competencies of Public Health Professionals

To improve the public health workforce's abilities to implement the core functions of public health and to ensure that the workforce has the necessary skills to provide the 10 essential services listed in Figure 1-1, a coalition of representatives from 17 national public health organizations (the Council of Linkages) began working in 1992 on collaborative activities to "assure a well-trained, competent workforce and a strong, evidence-based public health infrastructure" (U.S. Public Health Service, 1994 [updated 2008]). In the spring of 2010 the Council,

HOW TO Participate, as a Public Health Nurse, in the Essential Services of Public Health

1. Monitor health status to identify community health problems.
 - Participate in community assessment.
 - Identify subpopulations at risk for disease or disability.
 - Collect information on interventions to special populations.
 - Define and evaluate effective strategies and programs.
 - Identify potential environmental hazards.
2. Diagnose and investigate health problems and hazards in the community.
 - Understand and identify determinants of health and disease.
 - Apply knowledge about environmental influences of health.
 - Recognize multiple causes or factors of health and illness.
 - Participate in case identification and treatment of persons with communicable disease.
3. Inform, educate, and empower people about health issues.
 - Develop health and educational plans for individuals and families in multiple settings.
 - Develop and implement community-based health education.
 - Provide regular reports on health status of special populations within clinic settings, community settings, and groups.
 - Advocate for and with underserved and disadvantaged populations.
 - Ensure health planning, which includes primary prevention and early intervention strategies.
 - Identify healthy population behaviors and maintain successful intervention strategies through reinforcement and continued funding.
4. Mobilize community partnerships to identify and solve health problems.
 - Interact regularly with many providers and services within each community.
 - Convene groups and providers who share common concerns and interests in special populations.
 - Provide leadership to prioritize community problems and development of interventions.
 - Explain the significance of health issues to the public and participate in developing plans of action.
5. Develop policies and plans that support individual and community health efforts.
 - Participate in community and family decision-making processes.
 - Provide information and advocacy for consideration of the interests of special groups in program development.
 - Develop programs and services to meet the needs of high-risk populations as well as broader community members.
 - Participate in disaster planning and mobilization of community resources in emergencies.
 - Advocate for appropriate funding for services.
6. Enforce laws and regulations that protect health and ensure safety.
 - Regulate and support safe care and treatment for dependent populations such as children and frail older adults.
 - Implement ordinances and laws that protect the environment.
 - Establish procedures and processes that ensure competent implementation of treatment schedules for diseases of public health importance.
7. Link people to needed personal health services and ensure the provision of health care that is otherwise unavailable.
 - Participate in development of local regulations that protect communities and the environment from potential hazards and pollution.
 - Provide clinical preventive services to certain high-risk populations.
 - Establish programs and services to meet special needs.
 - Recommend clinical care and other services to clients and their families in clinics, homes, and the community.
 - Provide referrals through community links to needed care.
 - Participate in community provider coalitions and meetings to educate others and to identify service centers for community populations.
 - Provide clinical surveillance and identification of communicable disease.
8. Ensure a competent public health and personal health care workforce.
 - Participate in continuing education and preparation to ensure competence.
 - Define and support proper delegation to unlicensed assistive personnel in community settings.
 - Establish standards for performance.
 - Maintain client record systems and community documents.
 - Establish and maintain procedures and protocols for client care.
 - Participate in quality assurance activities such as record audits, agency evaluation, and clinical guidelines.
9. Evaluate effectiveness, accessibility, and quality of personal and population-based health services.
 - Collect data and information related to community interventions.
 - Identify unserved and underserved populations within the community.
 - Review and analyze data on health status of the community.
 - Participate with the community in assessment of services and outcomes of care.
 - Identify and define enhanced services required to manage health status of complex populations and special risk groups.
10. Research for new insights and innovative solutions to health problems.
 - Implement nontraditional interventions and approaches to effect change in special populations.
 - Participate in the collecting of information and data to improve the surveillance and understanding of special problems.
 - Develop collegial relationships with academic institutions to explore new interventions.
 - Participate in early identification of factors that are detrimental to the community's health.
 - Formulate and use investigative tools to identify and impact care delivery and program planning.

BOX 1-1 Indicators Used to Develop a Community Health Profile**Sociodemographic Characteristics**

- Distribution of the population by age and race/ethnicity
- Number and proportion of persons in groups such as migrants, homeless, or the non-English speaking, for whom access to community services and resources may be a concern
- Number and proportion of persons aged 25 and older with less than a high school education
- Ratio of the number of students graduating from high school to the number of students who entered ninth grade 3 years previously
- Median household income
- Proportion of children less than 15 years of age living in families at or below the poverty level
- Unemployment rate
- Number and proportion of single-parent families
- Number and proportion of persons without health insurance

Health Status

- Infant death rate by race/ethnicity
- Numbers of deaths or age-adjusted death rates for motor vehicle crashes, work-related injuries, suicide, homicide, lung cancer, breast cancer, cardiovascular diseases, and all causes, by age, race, and sex as appropriate
- Reported incidence of AIDS, measles, tuberculosis, and primary and secondary syphilis, by age, race, and sex as appropriate
- Births to adolescents (ages 10 to 17) as a proportion of total live births
- Number and rate of confirmed abuse and neglect cases among children

Health Risk Factors

- Proportion of 2-year-old children who have received all age-appropriate vaccines, as recommended by the Advisory Committee on Immunization Practices
- Proportion of adults aged 65 and older who have ever been immunized for pneumococcal pneumonia; proportion who have been immunized in the past 12 months for influenza
- Proportion of the population who smoke, by age, race, and sex as appropriate
- Proportion of the population aged 18 and older who are obese
- Number and type of U.S. Environmental Protection Agency air quality standards not met
- Proportion of assessed rivers, lakes, and estuaries that support beneficial uses (e.g., approved fishing and swimming)

Health Care Resource Consumption

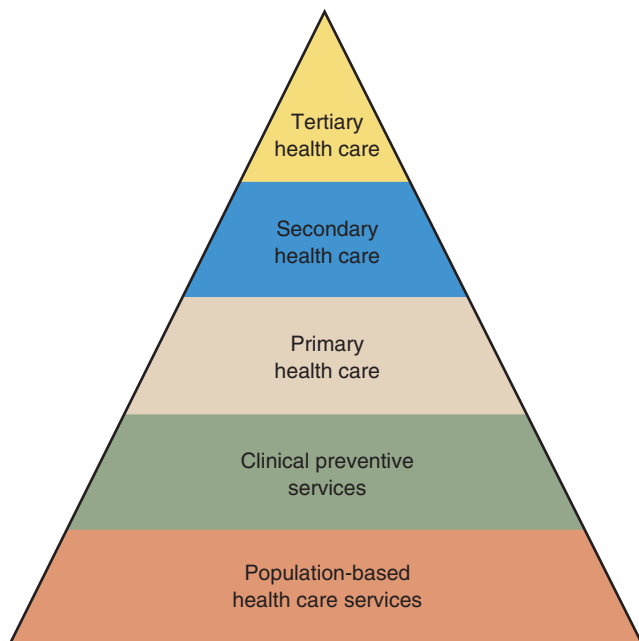

- Per capita health care spending for Medicare beneficiaries—the Medicare-adjusted average per capita cost (AAPCC)

Functional Status

- Proportion of adults reporting that their general health is good to excellent
- Average number of days (in the past 30 days) for which adults report that their physical or mental health was not good

Quality of Life

- Proportion of adults satisfied with the health care system in the community
- Proportion of persons satisfied with the quality of life in the community

**FIG 1-2** Health Services Pyramid.

funded by the CDC and USDHHS, adopted an updated set of Core Competencies (“a set of skills desirable for the broad practice of public health”) for all public health professionals, including nurses. In 2014 the Core Competencies were updated again (Council on Linkages, 2010/2014). The 72 Core Competencies are divided into 8 categories (Box 1-2). In addition, each competency is presented at three levels (tiers), which reflect the

BOX 1-2 Categories of Public Health Workforce Competencies

- Analytic/assessment
- Policy development/program planning
- Communication
- Cultural competency
- Community dimensions of practice
- Basic public health sciences
- Financial planning and management
- Leadership and systems thinking

Compiled from Centers for Disease Control and Prevention: Genomics and disease prevention: Frequently asked questions, 2010. Accessed 1/11/11 from <http://www.cdc.gov/genomics/faq.htm>; Centers for Disease Control and Prevention: Genomics and disease prevention.

different stages of a career. Specifically, Tier 1 applies to entry level public health professionals without management responsibilities. Tier 2 competencies are expected in those with management and/or supervisory responsibilities, and Tier 3 is expected of senior managers and/or leaders in public health organizations. It is recommended that these categories of competencies be used by educators for curriculum review and development and by agency administrators for workforce needs assessment, competency development, performance evaluation, hiring, and refining of the personnel system job requirements. A detailed listing of the 2014 competencies can be found at www.pfhf.org/corecompetencies.

Using an earlier version of the Council on Linkage’s Core Competencies as a starting point, a coalition of public health nursing organizations called the Quad Council developed levels

of skills to be attained by public health nurses for each of the competencies. Skill levels are specified and have been updated for the generalist/staff nurse and the specialist in public health nursing (Quad Council, 2003). (See Resource Tool 45.A on the Evolve website for the Public Health Nursing Core Competencies.)

Quality Improvement Efforts in Public Health

In 2003, the Institute of Medicine released a report, “Who Will Keep the Public Healthy?” that identified eight content areas in which public health workers should be educated—informatics, genomics, cultural competence, community-based participatory research, policy, law, global health, and ethics—in order to be able to address the emerging public health issues and advances in science and policy.

Two broad efforts designed to enhance quality improvement efforts in public health have been developed within the last 20 years: the National Public Health Performance Standards Program and the accreditation process for local and state health departments. The National Public Health Performance Standards Program is a high-level partnership initiative started in 1998 and led by the Office of Chief of Public Health Practice, CDC. The collaborative partners are the American Public Health Association, Association of State and Territorial Health Officials, National Association of County and City Health Officials, National Association of Local Boards of Health, National Network of Public Health Institutes, and the Public Health Foundation. The National Public Health Performance Standards (NPHPS) “provide a framework to assess capacity and performance of public health systems and public health governing bodies.” The program is “to improve the practice of public health, the performance of public health systems, and the infrastructure supporting public health actions” (CDC, 2014a). The performance standards, collectively developed by the participating organizations, set the bar for the level of performance that is necessary to deliver essential public health services. Four principles guided the development of the standards. First, they were developed around the 10 Essential Public Health Services (see the [How To Box](#) on [page 8](#)). Second, the standards focus on the overall public health system rather than on single organizations. Third, the standards describe an optimal level of performance. Finally, they are intended to support a process of quality improvement.

States and local communities seeking to assess their performance can access the Assessment Instruments developed by the program and other resources such as training workshops, on-site training, and technical assistance to work with them in conducting assessments (CDC, 2014a).

PUBLIC HEALTH NURSING AS A FIELD OF PRACTICE: AN AREA OF SPECIALIZATION

Most of the preceding discussion has been about the broad field of public health. Now attention turns to [public health nursing](#). What is public health nursing? Is it really a specialty, and if so, why? Public health nursing is a specialty because it has a distinct focus and scope of practice, and it requires a special knowledge

base. The following characteristics distinguish public health nursing as a specialty:

- *It is population-focused.* Primary emphasis is on populations whose members are free-living in the community as opposed to those who are institutionalized.
- *It is community-oriented.* There is concern for the connection between the health status of the population and the environment in which the population lives (physical, biological, sociocultural). There is an imperative to work with members of the community to carry out core public health functions.
- *There is a health and preventive focus.* The primary emphasis is on strategies for health promotion, health maintenance, and disease prevention, particularly primary and secondary prevention.
- *Interventions are made at the community or population level.* Target populations are defined as those living in a particular geographic area or those who have particular characteristics in common and political processes are used as a major intervention strategy to affect public policy and achieve goals.
- *There is concern for the health of all members of the population/community, particularly vulnerable subpopulations.*

In 1981 the public health nursing section of the American Public Health Association (APHA) developed *The Definition and Role of Public Health Nursing in the Delivery of Health Care* to describe the field of specialization (APHA, 1981). This statement was reaffirmed in 1996 (APHA, 1996). In 1999 the American Nurses Association, with input from three other nursing organizations—the Public Health Nursing Section of the APHA, the Association of State and Territorial Directors of Public Health Nursing, and the Association of Community Health Nurse Educators—published the *Scope and Standards of Public Health Nursing Practice* (Quad Council, 1999 [revised 2005]). In that document, the 1996 definition was supported. Since 1999 the scope and standards have been revised twice. In the latest version Public Health Nursing continues to be defined as “the practice of promoting and protecting the health of populations using knowledge from nursing, social, and public health sciences” (APHA, 1996 and Quad Council, 1999 [revised 2005], 2011) but the following statement was added in 2011: “Public Health Nurses engage in population-focused practice, but can and do often apply the Council of Linkages concepts at the individual and family level” (see Quad Council, 2011, p. 9).

Educational Preparation for Public Health Nursing

Targeted and specialized education for public health nursing practice has a long history. In the late 1950s and early 1960s, before the integration of public health concepts into the curriculum of baccalaureate nursing programs, special baccalaureate curricula were established in several schools of public health to prepare nurses to become public health nurses. Today it is generally assumed that a graduate of any baccalaureate nursing program has the necessary basic preparation to function as a beginning staff public health nurse.

Since the late 1960s, public health nursing leaders have agreed that a specialty in public health nursing requires a master’s

BOX 1-3 Areas Considered Essential for the Preparation of Specialists in Public Health Nursing

- Epidemiology
- Biostatistics
- Nursing theory
- Management theory
- Change theory
- Economics
- Politics
- Public health administration
- Community assessment
- Program planning and evaluation
- Interventions at the aggregate level
- Research
- History of public health
- Issues in public health

From Consensus Conference on the Essentials of Public Health Nursing Practice and Education, Rockville, MD, 1985, U.S. Department of Health and Human Services, Bureau of Health Professions, Division of Nursing.

degree. Today, a master's degree in nursing is necessary to be eligible to sit for a certification examination. In the future, a Doctor of Nursing Practice (DNP) degree will probably be required to sit for certification. The American Association of Colleges of Nursing has proposed the DNP should be the expected level of education for specialization in an area of nursing practice (AACN, 2004, 2006). The educational expectations for public health nursing were highlighted at the 1984 Consensus Conference on the Essentials of Public Health Nursing Practice and Education sponsored by the USDHHS Division of Nursing. The participants agreed "that the term 'public health nurse' should be used to describe a person who has received specific educational preparation and supervised clinical practice in public health nursing" (USDHHS, 1985, p. 4). At the basic or entry level, a public health nurse is one who "holds a baccalaureate degree in nursing that includes this educational preparation; this nurse may or may not practice in an official health agency but has the initial qualifications to do so" (USDHHS, 1985, p. 4). Specialists in public health nursing are defined as those who are prepared at the graduate level, with either a master's or doctoral degree, "with a focus in the public health sciences" (USDHHS, 1985, p. 4) (Box 1-3). The consensus statement specifically pointed out that the public health nursing specialist "should be able to work with population groups and to assess and intervene successfully at the aggregate level" (USDHHS, 1985, p. 11).

The Association of Community Health Nursing Educators reaffirmed the results of the 1984 Consensus Conference (ACHNE, 2003). The educational requirements were reaffirmed by ACHNE (2009) and in the revised *Scope and Standards of Public Health Nursing Practice* and include both clinical specialists and nurse practitioners who engage in population-focused care as advanced practice registered nurses in public health (Quad Council, 1999 [revised 2005]). The latest iteration of the *Scope and Standards of Practice for Public Health Nursing* was published by the American Nurses Association in 2013 (ANA, 2013).

BOX 1-4 Eight Principles of Public Health Nursing

1. The client or "unit of care" is the population.
2. The primary obligation is to achieve the greatest good for the greatest number of people or the population as a whole.
3. The processes used by public health nurses include working with the client(s) as an equal partner.
4. Primary prevention is the priority in selecting appropriate activities.
5. Selecting strategies that create healthy environmental, social, and economic conditions in which populations may thrive is the focus.
6. There is an obligation to actively reach out to all who might benefit from a specific activity or service.
7. Optimal use of available resources to assure the best overall improvement in the health of the population is a key element of the practice.
8. Collaboration with a variety of other professions, organizations, and entities is the most effective way to promote and protect the health of the people.

Sources: Quad Council of Public Health Nursing Organizations: Scope and standards of public health nursing practice, Washington, DC, 1999, revised 2005, 2007 with the American Nurses Association

Population-Focused Practice versus Practice Focused on Individuals

The key factor that distinguishes public health nursing from other areas of nursing practice is the focus on populations, a focus historically consistent with public health philosophy. Box 1-4 lists principles on which public health nursing is built. Although public health nursing is based on clinical nursing practice, it also incorporates the population perspective of public health. It may be helpful here to define the term *population*.

A **population**, or **aggregate**, is a collection of individuals who have one or more personal or environmental characteristics in common. Members of a community who can be defined in terms of geography (e.g., a county, a group of counties, or a state) or in terms of a special interest or circumstance (e.g., children attending a particular school) can be seen as constituting a population. Often there are **subpopulations** within the larger population, such as high-risk infants under the age of 1 year, unmarried pregnant adolescents, or individuals exposed to a particular event such as a chemical spill. In **population-focused practice**, problems are defined (by assessments or diagnoses), and solutions (interventions), such as policy development or providing a particular preventive service, are implemented for or with a defined population or subpopulation (examples are provided in the **Levels of Prevention** Box). In other nursing specialties, the diagnoses, interventions, and treatments are usually carried out at the individual client level.

Professional education in nursing, medicine, and other clinical disciplines focuses primarily on developing competence in decision making at the individual client level by assessing health status, making management decisions (ideally *with* the client), and evaluating the effects of care. Figure 1-3 illustrates three levels at which problems can be identified. For example, community-based nurse clinicians, or nurse practitioners, focus on individuals they see in either a home or a clinic setting. The focus is on an individual person or an individual family in a

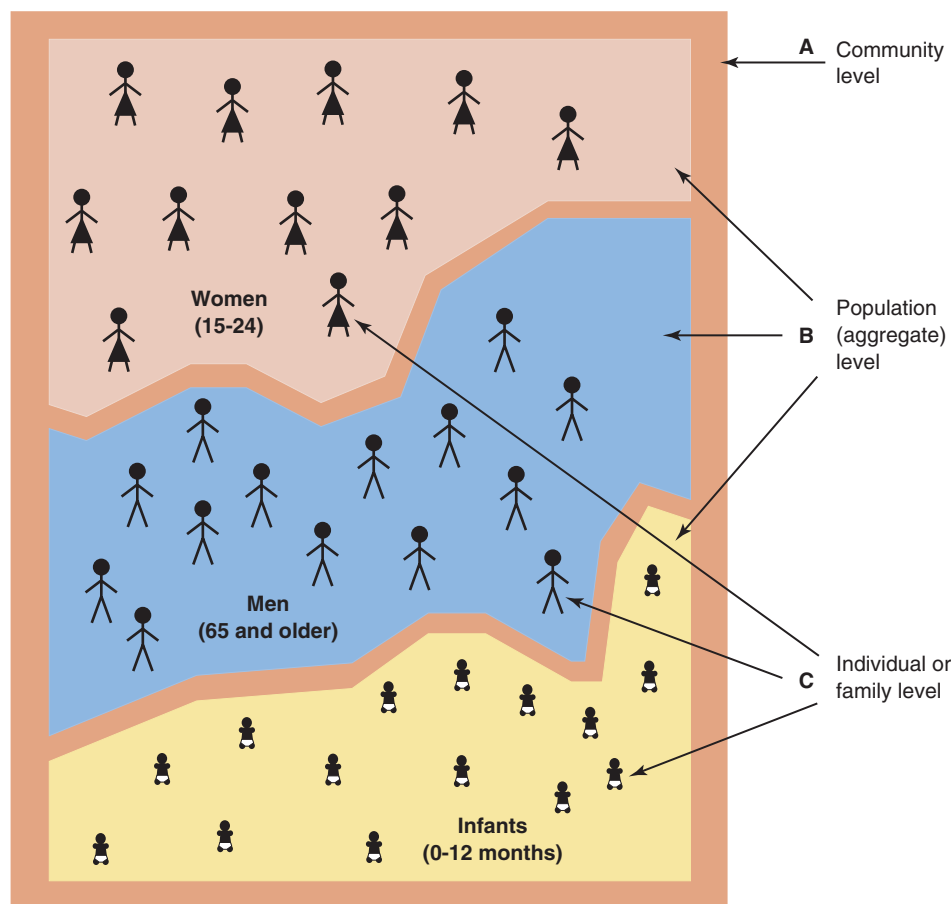

FIG 1-3 Levels of health care practice.

LEVELS OF PREVENTION

Examples in Public Health Nursing

Primary Prevention

Using general and specific measures in a population to promote health and prevent the development of disease (incidence) and using specific measures to prevent diseases in those who are predisposed to developing a particular condition.

Example: The public health nurse develops a health education program for a population of school-age children that teaches them about the effects of smoking on health.

Secondary Prevention

Stopping the progress of disease by early detection and treatment, thus reducing prevalence and chronicity.

Example: The public health nurse develops a program of toxin screenings for migrant workers who may be exposed to pesticides and refers for treatment those who are found to be positive for high levels.

Tertiary Prevention

Stopping deterioration in a patient, a relapse, or disability and dependency by anticipatory nursing and medical care.

Example: The public health nurse develops a diabetes clinic in which nursing care including educational programs for nutrition and self-care are provided for a defined population of adults in a low-income housing unit of the community.

subpopulation (the *C* arrows in Figure 1-3). The provider's emphasis is on defining and resolving a problem for the individual; the client is an individual.

In Figure 1-3 the individual clients are grouped into three separate subpopulations, each of which has a common characteristic (the *B* arrows in Figure 1-3). Public health nursing specialists often define problems at the population or aggregate level as opposed to an individual level. Population-level decision making is different from decision making in clinical care. For example, in a clinical, direct care situation, the nurse may determine that a client is hypertensive and explore options for intervening. However, at the population level, the public health nursing specialist might explore the answers to the following set of questions:

1. What is the prevalence of hypertension among various age, race, and sex groups?
2. Which subpopulations have the highest rates of untreated hypertension?
3. What programs could reduce the problem of untreated hypertension and thereby lower the risk of further cardiovascular morbidity and mortality for the population as a whole?

Public health nursing specialists are usually concerned with more than one subpopulation and frequently with the health of the entire community (in Figure 1-3, arrow A: the entire box

containing all of the subgroups within the community). In reality, of course, there are many more subgroups than those in Figure 1-3. Professionals concerned with the health of a whole community must consider the total population, which is made up of multiple and often overlapping subpopulations. For example, the population of adolescents at risk for unplanned pregnancies would overlap with the female population 15 to 24 years of age. A population that would overlap with infants under 1 year of age would be children from 0 to 6 years of age. In addition, a population focus requires considering those who may need particular services but have not entered the health care system (e.g., children without immunizations or clients with untreated hypertension).

Public Health Nursing Specialists and Core Public Health Functions: Selected Examples

The core public health function of *assessment* includes activities that involve collecting, analyzing, and disseminating information on both the health status and the health-related aspects of a community or a specific population. Questions such as whether the health services of the community are available to the population and are adequate to address needs are considered. Assessment also includes an ongoing effort to monitor the health status of the community or population and the services provided. Excellent examples of assessment at the national level are the efforts of the USDHHS to organize the goal setting, data collecting and analysis, and monitoring necessary to develop the series of publications describing the health status and health-related aspects of the U.S. population. These efforts began with *Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention* in 1980 and continued with *Promoting Health/Preventing Disease: Objectives for the Nation*, *Healthy People 2000*, and *Healthy People 2010*, and are now moving forward into the future with *Healthy People 2020* (U.S. Department of Health, Education, and Welfare, 1979; USDHHS, 1980, 1979, 1991, 2000, 2010; *Healthy People 2020* retrieved at www.healthypeople.gov).

Many states and other jurisdictions have developed publications describing the health status of a defined community, a set of communities, or populations. Unfortunately, it is difficult to find published descriptions of health assessments on particular communities unless they demonstrate new methods or reveal unusual findings about a community. Such working documents and data sets should be available in specific settings, such as a county or state health department, and should be used by public health practitioners to develop services.

In 2009 Turnock described a survey conducted to determine the extent to which local health departments were performing the core public health functions. The questions asked about *assessment* included the following:

1. Whether there was a needs assessment process in place that described the health status of the community and community needs
2. Whether there had been a survey of behavioral risk factors within the last 3 years
3. Whether an analysis had been done of “the determinants and contributing factors of priority health needs, adequacy of

existing health resources, and the population groups most affected”

The results were disappointing and suggested that in 1993 less than 40% of the population in the United States were served by a health department that was effectively addressing the core function of public health. In this study, compliance with the performance measures was highest for practices related to the assurance function and lowest for practices related to policy development (Turnock, 2012). It should be part of the public health nurse specialist's role within a local health department to participate in and provide leadership for assessing community needs, the health status of populations within the community, and environmental and behavioral risks; looking at trends in the health determinants; identifying priority health needs; and determining the adequacy of existing resources within the community (see Evidence-Based Practice Box 1), and engaging in policy development efforts.

EVIDENCE-BASED PRACTICE

This study used a randomized controlled design to evaluate the effectiveness of a community participatory research-grounded intervention among women with chronic health conditions who were receiving Temporary Assistance for Needy Families (TANF). Previous descriptive studies noted that women receiving TANF were likely to experience poor physical, mental, and general health. The 432 participants were assigned to either the intervention group or the wait-control group. Outcomes were assessed at baseline and at 3, 6, and 9 months. The intervention sought to (1) increase rates of health care visits for mental health and chronic health conditions, (2) increase the ability to navigate the Medicaid system, and (3) improve functional and health status over time among this group of women, using 9 months of public health nursing (PHN) case management and a one-time 2-hour Medicaid knowledge and skills training program. The PHN case management focused on health care access; care coordination; health education; health and social service referrals; obtaining preventive services, screening, and routine care; and assistance in meeting health goals that the participants had set for themselves. A Community Advisory Group consisting of diverse academic researchers, agency representatives, and lay community members guided the research team in developing the intervention. Furthermore, three women who were recently in the Welfare Transition Program were hired onto the research team and participated in personal and community capacity building.

Both groups showed improvement in Medicaid knowledge and skills. Those in the intervention group were more likely to have a new mental health visit as well as improvement in depression and functional status over time. No differences existed between the groups in routine or preventive care or general health.

Nurse Use

The results of this study suggest that public health interventions can improve health outcomes among women receiving Temporary Assistance for Needy Families. The intervention was developed with input from the community and used community members on the research team. The researchers noted that trust between the public health nurse and the client was crucial to the success of the intervention.

Modified from Kneipp SM, Kairalla JA, Lutz BJ, et al: Public health nursing case management for women receiving Temporary Assistance for Needy Families: a randomized controlled trial using community-based participatory research. *Am J Public Health* 101:1759–1768, 2011.

Policy development is both a core function of public health and a core intervention strategy used by public health nursing specialists. Policy development in the public arena seeks to build constituencies that can help bring about change in public policy. In an interesting case study of her experience as director of public health for the state of Oregon, Christine Gebbie (1999), a nurse, describes her experiences in developing a constituency for public health. This enabled her to mobilize efforts to develop statewide goals for *Healthy People 2000* as well as to update Oregon's disease-reporting laws. Gebbie's experiences as a state director of public health illustrate how a public health nursing specialist can provide leadership at a very broad level. Gebbie left Oregon to go to Washington, DC, to serve in the federal government as President Clinton's key official in the national effort to control acquired immunodeficiency syndrome (AIDS). Clearly, Gebbie is an example of an individual who has provided leadership in policy development at both state and national levels. Another public health nursing specialist who has and continues to provide strong policy leadership is Ellen Hahn, PhD, director of the [Kentucky Center for Smoke-Free Policy](http://www.mc.uky.edu/tobaccopolity/) (www.mc.uky.edu/tobaccopolity/), which is based at the University of Kentucky's College of Nursing. Through her research Dr. Hahn has developed considerable evidence to support important policy changes (antismoking ordinances) to reduce exposure to tobacco smoke in Kentucky, a state that has a long tradition of a tobacco culture, both in production of tobacco and in use. A number of studies conducted by Hahn and her colleagues can be found on the website identified above. Two particularly interesting ones are listed in the references at the end of this chapter (Hahn et al, 2010, 2011).

The third core public health function, *assurance*, focuses on the responsibility of public health agencies to make certain that activities have been appropriately carried out to meet public health goals and plans. This may result in public health agencies requiring others to engage in activities to meet goals, encouraging private groups to undertake certain activities, or sometimes actually offering services directly. Assurance also includes the development of partnerships between public and private agencies to make sure that needed services are available and that assessing the quality of the activities is carried out. A recent report suggested that much more attention should be paid by public health officials to the quality of direct care services provided by clinicians in their communities (Fielding, 2009). It is important to point out that when personal services to individuals are offered by public health agencies to ensure that they can get care they might not receive without the intervention of the official agency, the goal is to "promote knowledge, attitudes, beliefs, practices and behaviors that support and enhance health with the ultimate goal of improving... population health" (Quad Council, 1999 [revised 2005]; and see [Evidence-Based Practice](#) Box 2).

PUBLIC HEALTH NURSING VERSUS COMMUNITY-BASED NURSING

The concept of public health should include all populations within the community, both free-living and those living in

HEALTHY PEOPLE 2020

In 1979 the surgeon general issued a report that began a 30-year focus on promoting health and preventing disease for all Americans. The report, entitled *Healthy People*, used morbidity rates to track the health of individuals through the five major life cycles of infancy, childhood, adolescence, adulthood, and older age.

In 1989 *Healthy People 2000* became a national effort of representatives from government agencies, academia, and health organizations. Their goal was to present a strategy for improving the health of the American people. Their objectives were being used by public and community health organizations to assess current health trends, health programs, and disease prevention programs.

Throughout the 1990s, all states used *Healthy People 2000* objectives to identify emerging public health issues. The success of the program on a national level was accomplished through state and local efforts. Early in the 1990s, surveys from public health departments indicated that 8% of the national objectives had been met, and progress on an additional 40% of the objectives was noted. In the mid-course review published in 1995, it was noted that significant progress had been made toward meeting 50% of the objectives.

In light of the progress made in the past decade, the committee for *Healthy People 2010* proposed two goals. The hope was to reach these goals by such measures as promoting healthy behaviors, increasing access to quality health care, and strengthening community prevention.

The major premise of *Healthy People 2010* was that the health of the individual cannot be entirely separate from the health of the larger community. Therefore the vision for *Healthy People 2010* was "Healthy People in Healthy Communities."

The vision for *Healthy People 2020* is: A society in which all people live long, healthy lives (see [Chapter 8](#) for a listing of the goals for each of the decades and highlighting of the policy implications of *Healthy People*).

In contrast to previous years, *Healthy People 2020* has a web-accessible database that is searchable, multilevel, and interactive to be more useful. A progress report as of March 2014 on the leading indicators is available on the website:

www.healthypeople.gov/2020/hi/hi-progressreport-execsum.pdf

EVIDENCE-BASED PRACTICE

The purpose of this study was to evaluate whether a brief nurse home-visiting intervention offered postnatally would be beneficial in preventing emergency health care services and promote positive parenting. The participants were the parents of infants and infants who were delivered in one of the two hospitals in Durham, North Carolina between July 1, 2009 and December 31, 2010 and randomly assigned to either the intervention group or to a control group. The project was aimed at alleviating parental stress and improving parent-child interaction among parents who attended an inner-city clinic. Participants were 199 parents of children 1 through 36 months of age. Serious life stress including poverty, low social support, personal histories of childhood maltreatment, and substance abuse defined the parents at risk. Program effects were evaluated in terms of improvement in self-reported parenting stress and observed parent-child interaction. Positive effects were documented for the group as a whole and within each of three subgroups: two community samples and a group of mothers and children in a residential drug treatment program. Program attendance and the amount of gain in observed parenting skills were the factors related to a positive outcome.

Nurse Use

This program was offered in partnership with academic researchers and the public clinic. The nurses in this agency can ensure better outcomes in parenting by providing a long-term program for high-risk parents.

Dodge K, Goodman B, Murphy R. et al: Impelementation and randomized controlled trial evaluation of universal postnatal nurse home visiting, *AJPJ* 104(Suppl 1) S136-143m 2014.

institutions. Furthermore, the public health specialist should consider the match between the health needs of the population and the health care resources in the community, including those services offered in a variety of settings. Although all direct care providers may contribute to the community's health in the broadest sense, not all are primarily concerned with the population focus—the big picture. All nurses in a given community, including those working in hospitals, physicians' offices, and health clinics, may contribute positively to the health of the community. However, the special contributions of public health nursing specialists include looking at the community or population as a whole; raising questions about its overall health status and associated factors, including environmental factors (physical, biological, and sociocultural); and *working with the community* to improve the population's health status.

Figure 1-4 is a useful illustration of the arenas of practice. Because most nurses working in the community and many staff public health nurses, historically and at present, focus on providing direct personal care services—including health education—to persons or family units outside of institutional settings (either in the client's home or in a clinic environment), such practice falls into the upper right quadrant (section B) of Figure 1-4. However, specialization in public health nursing is population-focused and focuses on clients living in the community and is represented by the box in the upper left quadrant (section A).

There are three reasons, in addition to the population focus, that the most important practice arena for public health nursing is represented by section A of Figure 1-4, the population of free-living clients:

1. Preventive strategies can have the greatest impact on free-living populations, which usually represent the majority of a community.
2. The major interface between health status and the environment (physical, biological, sociocultural, and behavioral) occurs in the free-living population.

3. For philosophical, historical, and economic reasons, prevention-oriented population-focused practice is most likely to flourish in organizational structures that serve free-living populations (e.g., health departments, health maintenance organizations, health centers, schools, and workplaces).

What roles in the health care system do public health nursing specialists (those in section A of Figure 1-4) have? Options include director of nursing for a health department, director of the health department, state commissioner for health, director of maternal and child health services for a state or local health department, director of wellness for a business or educational organization, and director of preventive services for an integrated health system. Nurses can occupy all of these roles, but, with the exception of director of nursing for a health department, they are in the minority. Unfortunately, nurses who occupy these roles are often seen as “administrators” and not as public health nursing specialists. However, those who work in such roles have the opportunity to make decisions that affect the health of population groups and the type and quality of health services provided for various populations.

Where does the staff public health nurse or nurse working in the community fit on the diagram in Figure 1-4? That depends on the focus of the nurse's practice. In many settings, most of the staff nurse's time is spent in community-based direct care activities, where the focus is on dealing with individual clients and individual families, in which case the practice falls into section B of Figure 1-4. Although a staff public health nurse or a nurse practicing in the community may not be a public health nurse specialist, this nurse may spend some time carrying out core public health functions with a population focus, and thus that part of the role would be represented in section A of Figure 1-4. In summary, the field of public health nursing can be seen as primarily encompassing two groups of nurses:

- Public health nursing specialists, whose practice is community-oriented and uses population-focused strategies

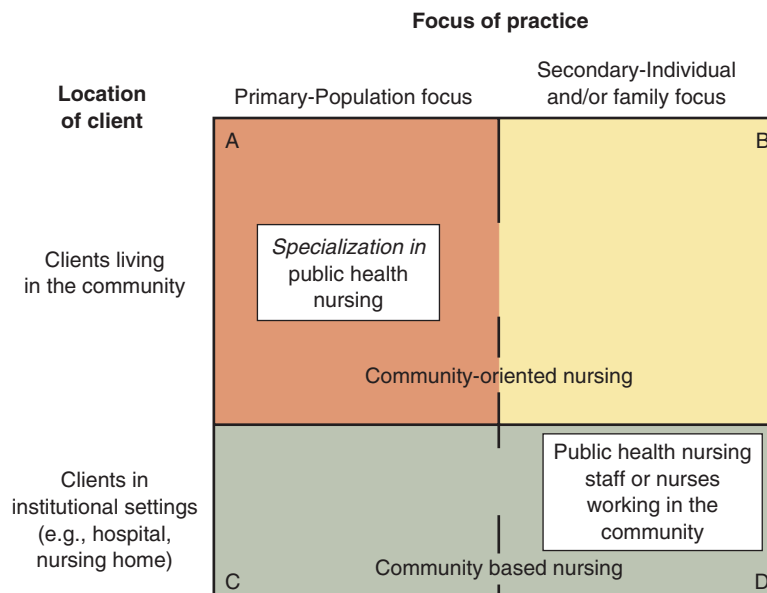

FIG 1-4 Arenas for health care practice.

for carrying out the core public health functions (section A of Figure 1-4)

- Staff public health nurses or clinical nurses working in the community nurses, who are community-based, who may be clinically oriented to the individual client, and who combine some primary preventive population-focused strategies and direct care clinical strategies in programs serving specified populations (section B of Figure 1-4)
- Sections C and D of Figure 1-4 represent institutionalized populations. Nurses who provide direct care to these clients in hospital settings fall into section D, and those who have administrative/managerial responsibility for nursing services in institutional settings fall into section C.

Figure 1-4 also shows that specialization in public health nursing, as it has been defined in this chapter, can be viewed as a specialized field of practice with certain characteristics within the broad arena of community. This view is consistent with recommendations developed at the Consensus Conference on the Essentials of Public Health Nursing Practice and Education (USDHHS, 1985). One of the outcomes of the historical conference was consensus on the use of the terms *community health nurse* and *public health nurse*. It was agreed that the term *community health nurse* could apply to all nurses who practice in the community, whether or not they have had preparation in public health nursing. Thus nurses providing secondary or tertiary care in a home setting, school nurses, and nurses in clinic settings (in fact, any nurse who does not practice in an institutional setting) could fall into the category of **community health nurse**. Nurses with a master's degree or a doctoral degree who practice in community settings could be referred to as *community health nurse specialists*, regardless of the area of nursing in which the degree was earned. According to the conference statement: "The degree could be in any area of nursing, such as maternal/child health, psychiatric/mental health, or medical-surgical nursing or some subspecialty of any clinical area" (USDHHS, 1985, p. 4). The definitions of the three areas of practice have changed, however, over time.

In 1998 the Quad Council began to develop a statement on the scope of public health nursing practice (Quad Council, 1999 [revised 2005]). The council attempted to clarify the differences between the term *public health nursing* and the term introduced into nursing's vocabulary during health care reform of the 1990s: **community-based nursing**. The authors recognized that the terms *public health nursing* and *community health nursing* had been used interchangeably since the 1980s to describe population-focused, community-oriented nursing practice and community-based practice. However, the Council decided to make a clearer distinction between community-oriented and community-based nursing practice. In contrast, community-based nursing care was described as the provision or assurance of personal illness care to individuals and families in the community, whereas community-oriented nursing was the provision of disease prevention and health promotion to populations and communities. It was suggested that there be two terms for the two levels of care in the community: *community-oriented care* and *community-based care*. (see the list of definitions presented in Box 1-5).

BOX 1-5 Definitions of the Key Nursing Areas in the Community

- *Community-oriented nursing practice* is a philosophy of nursing service delivery that involves the generalist or specialist public health and community health nurse. The nurse provides health care through community diagnosis and investigation of major health and environmental problems, health surveillance, and monitoring and evaluation of community and population health status for the purposes of preventing disease and disability and promoting, protecting, and maintaining health to create conditions in which people can be healthy.
- *Community-based nursing practice* is a setting-specific practice whereby care is provided for clients and families where they live, work, and attend school. The emphasis of community-based nursing practice is acute and chronic care and the provision of comprehensive, coordinated, and continuous services. Nurses who deliver community-based care are generalists or specialists in maternal/infant, pediatric, adult, or psychiatric/mental health nursing.

There is a need and a place for a nursing specialty in the community; the nurse in this specialty is more than a clinical specialist with a master's degree who practices in a community-based setting, as was suggested by the Consensus Conference more than 25 years ago. Although in 1984 these nurses were referred to as community health nurses, today they are referred to as nurses in community-based practice (see definitions in the inside cover of this text). Those who provide community-oriented service to specific subpopulations in the community and who provide some clinical services to those populations may be seen as nurse specialists in the community. Although such practitioners may be community-based, they are also community-oriented as public health specialists but are usually focused on only one or two special subpopulations. Preparing for this specialty includes a master's or doctoral degree with emphasis in a direct care clinical area, such as school health or occupational health, and ideally some education in the public health sciences. Examples of roles such specialists might have in direct clinical care areas include case manager, supervisor in a home health agency, school nurse, occupational health nurse, parish nurse, and a nurse practitioner who also manages a nursing clinic.

ROLES IN PUBLIC HEALTH NURSING

In community-oriented nursing circles, there has been a tendency to talk about public health nursing from the point of view of a role rather than the functions related to the role. This can be limiting. In discussing such nursing roles, there is a preoccupation with the direct care provider orientation. Even in discussions about how a practice can become more population focused, the focus is frequently on how an individual practitioner, such as an agency staff nurse, can adopt a population-focused practice philosophy. Rarely is attention given to how nurse administrators in public health (one role for public health nursing specialists) might reorient their practice toward a population focus, which is particularly important and easier for an

administrator to do than for the staff nurse. This is because many agencies' nursing administrators, supervisors, or others (sometimes program directors who are not nurses) make the key decisions about how staff nurses will spend their time and what types of clients will be seen and under what circumstances. Public health nursing administrators who are prepared to practice in a population-focused manner will be more effective than those who are not prepared to do so.

Although their opportunities to make decisions at the population level are limited, staff nurses benefit from having a clear understanding of population-focused practice for three reasons:

- First, it gives them professional satisfaction to see how their individual client care contributes to health at the population level.
- Second, it helps them appreciate the practice of others who are population-focused specialists.
- Third, it gives them a better foundation from which to provide clinical input into decision making at the program or agency level and thus to improve the effectiveness and efficiency of the population-focused practice.

A curriculum was proposed by representatives of key public health nursing organizations and other individuals that would prepare the staff public health nurse or generalist to function as a community-oriented practitioner ([Association of State and Territorial Directors of Nursing, 2000](#)). The AACN developed a supplement to the document "The Essentials of Baccalaureate Education for Professional Nursing Practice," which highlights this organization's recommendations for public health nursing (AACN, 2013).

Unfortunately, nursing roles as presently defined are often too limited to include population-focused practice, but it is important not to think too narrowly. Furthermore, roles that entail population-focused decision making may not be defined as nursing roles (e.g., directors of health departments, state or regional programs, and units of health planning and evaluation; directors of programs such as preventive services within a managed care organization). If population-focused public health nursing is to be taken seriously, and if strategies for assessment, policy development, and assurance are to be implemented at the population level, more consideration must be given to organized systems for assessing population needs and managing care. Clearly, public health nurse specialists must move into positions where they can influence policy formation. This means, however, that some nurses will have to assume positions that are not traditionally considered nursing.

Redefining nursing roles so that population-focused decision making fits into the present structure of nursing services may be difficult in some circumstances at the present time, but future needs will require that nurses be prepared to make such decisions ([IOM, 2010](#)). At this point, it may be more useful to concentrate on identifying the skills and knowledge needed to make decisions in population-focused practice (see Appendix G.1), to define where in the health care system such decisions are made, and then to equip nurses with the knowledge, skills, and political understanding necessary for success in such positions. Although some of these positions are in nursing settings (e.g., administrator of the nursing service and top-level staff

nurse supervisors), others are outside of the traditional nursing roles (e.g., director of a health department).

CHALLENGES FOR THE FUTURE

Barriers to Specializing in Public Health Nursing

One of the most serious barriers to the development of specialists in public health nursing is the mindset of many nurses that the only role for a nurse is at the bedside or at the client's side (i.e., the direct care role). Indeed, the heart of nursing is the direct care provided in personal contacts with clients. On the other hand, two things should be clear. First, whether a nurse is able to provide direct care services to a particular client depends on decisions made by individuals within and outside of the care system. Second, nurses need to be involved in those fundamental decisions. Perhaps the one-on-one focus of nursing and the historical expectations of the "proper" role of women have influenced nurses to view other ways of contributing, such as administration, consultation, and research, less positively. Fortunately, things are changing. Within and outside of nursing, women have taken on every role imaginable. Further, the number of male nurses is steadily growing; nursing can no longer be viewed as a profession practiced by women exclusively. These two developments have opened doors to new roles that may not have been considered appropriate for nurses in the past.

A second barrier to population-focused public health nursing practice consists of the structures within which nurses work and the process of role socialization within those structures. For example, the absence of a particular role in a nursing unit may suggest that the role is undesirable or inaccessible to nurses. In another example, nurses interested in using political strategy to make changes in health-related policy—an activity clearly within the domain of public health nursing—may run into obstacles if their goals differ from those of other groups. Such groups may subtly but effectively lead nurses to conclude that their involvement in political effort takes their attention away from the client and it is not in their own or in the client's best interest to engage in such activities.

A third barrier is that few nurses receive graduate-level preparation in the concepts and strategies of the disciplines basic to public health (e.g., epidemiology, biostatistics, community development, service administration, and policy formation). As mentioned previously, master's level programs for public health nursing do not give the in-depth attention to population assessment and management skills that other parts of the curriculum receive, such as the direct care aspects receive. In 1995 [Josten and colleagues](#) noted that with few exceptions, graduate programs in public health nursing have not aggressively developed the population-focused skills that are needed. For individuals who want to specialize in public health nursing, these skills are as essential as direct care skills, and they should be given more attention in graduate programs that prepare nurses for careers in public health. Fortunately, the curricular expectations for academic programs leading to the Doctor of Nursing Practice (DNP) degree include serious attention to preparing nurses to develop a population

perspective as well as the analytical, policy, and leadership skills necessary to be successful as a specialist in public health nursing (AACN, 2006).

Developing Population-Focused Nurse Leaders

The massive organizational changes occurring in the health delivery system present a unique opportunity to establish new roles for nurse leaders who are prepared to think in population terms. In a book that is now viewed as a classic, Starr (1982) described the trend toward the use of private capital in financing health care, particularly institution-based care and other health-related businesses. The movement can be thought of as the “industrialization” of health care, which operated very much like a **cottage industry** or a small business for a very long time. The implications and consequences of this movement are enormous. First, the goal was to provide investors a return on their investment. Other aspects included more attention to the delivery of primary and community-based care in a variety of settings; less emphasis on specialty care; the development of partnerships, alliances, and other linkages across settings in an effort to build **integrated systems**, which would provide a broad range of services for the population served; and in some situations adoption of **capitation**, a payment arrangement in which insurers agree to pay providers a fixed sum for each person per month or per year, independent of the costs actually incurred. With the spread of capitation, health professionals have become more interested in the concept of populations, sometimes referred to by financial officers and others as *covered lives* (i.e., individuals with insurance that pays on a capitated basis). For public health specialists, it is a new experience to see individuals involved in the business aspects of health care, and frequently employed by hospitals, thinking in population terms and taking a population approach to decision making.

This new focus on populations, coupled with the integration of acute, chronic, and primary care that is occurring in some health care systems, is likely to create new roles for individuals, including nurses, who will span inpatient and community-based settings and focus on providing a wide range of services to the population served by the system. Such a role might be director of client care services for a health care system, who would have administrative responsibility for a large program area. There will also be a demand for individuals who can design programs of preventive and clinical services to be offered to targeted subpopulations and those who can implement the services. Who will decide what services will be given to which subpopulation and by which providers? How will nurses be prepared for leadership in the emerging and future structures for health care delivery and health maintenance?

Physician leaders are recognizing that physicians need to be prepared to use population-focused methods, such as epidemiology and biostatistics, to make evidence-based decisions in the development of programs and protocols. The attention being given to preparing nurses for administrative decision making seems to be declining. This may be a result of (1) the recent lack of federal support for preparing nurse

administrators, and (2) the growing popularity of nurse practitioner programs. However, it is time that nurse leaders give more attention to preparing nurses for leadership in the area of population-focused practice. Perhaps it is time to combine the specialty in public health nursing and nursing administration. As suggested some time ago by Williams (1985), some DNP programs are combining much of the preparation for specialization in public health nursing and administration into a systems-oriented curriculum with differentiation in the application to practice. This is the approach that is being taken in the DNP program in the College of Nursing at the University of Kentucky (www.uknursing.uky.edu). This makes sense because regardless of how the population is defined, there will be a growing need for nurses with population-level assessment, management, and evaluation skills to assume leadership roles as urged in the Institute of Medicine’s report on the Future of Nursing (IOM, 2010).

The primary focus of the health care system of the future will be on community-oriented strategies for health promotion and disease prevention, and on community-based strategies for primary and secondary care. Directing more attention to developing the specialty of public health nursing as a way to provide nursing leadership may be a good response to the health care system changes. Preparing nurses for population-focused decision making will require greater attention to developing programs at the doctoral level that have a stronger foundation in the public health sciences, while providing better preparation of baccalaureate-level nurses for community-oriented as well as community-based practice.

Some observers of public health have anticipated that if access to health care for all Americans becomes more of a reality, public health practitioners can turn over the delivery of personal primary care services to other providers such as health maintenance organizations and integrated health plans, and return to the core public health functions. However, assurance (making sure that basic services are available to all) is a core function of public health. Thus even under the condition of improved access to care, there will still be a need to monitor subpopulations in the community to ensure that necessary care is available and that its quality is at an acceptable level. When these conditions are not met, public health practitioners will have to find a solution. If the Affordable Care Act is successful in enrolling the vast majority of the population and access to basic health services is available to them, public health organizations will be in a position to focus the majority of their attention on community-oriented and population-focused health promotion and primary prevention.

Shifting Public Policy toward Creating Conditions for a Healthy Population

In 2012 the Institute of Medicine published a report (IOM, 2012B), on shifting public policy from a primary focus of supporting medical care to creating conditions for a healthy population. A major challenge for the future is the need for public health nursing specialists to be more aggressive in their practice

of the core public health function of policy development, one of the major ways public health specialists intervene, with the focus on actively engaging in influencing public decisions that will create conditions for a healthy population. This is necessary at the local, state, and national levels and encompasses a wide range of concerns from the availability of adequate nutrition to the maintenance of a healthy and safe environment in schools, to the reduction of secondhand smoke, to assuring access to needed health services. Policy development is not a solitary activity; it involves working with many groups and coalitions. Also, policy development is not just the responsibility of public health specialists; it is important that all professional nurses become more serious and adept in the process of policy development.

In the just released report, *The Future of Nursing: Leading Change, Advancing Health* (IOM, 2010), a key message is that “Nurses should be full partners, with physicians and other health professionals, in redesigning health care in the United States” (IOM, 2010, pp. 1-11). In discussing this message, the report states that “to be effective in re-conceptualized roles, nurses must see policy as something they can shape rather than something that happens to them” (IOM, 2010, pp. 1-11). In other words, nurses need to be key actors. However, the report also makes clear that nurses need to be prepared for leadership in that area.

The history of public health nursing shows that a common attribute of leaders is to move forward to deal with unresolved problems in a positive, proactive way. This is the legacy of Lillian Wald at the Henry Street Settlement, and many others who have met a need by being innovative. Within the context of the core public health function of policy-making, public health nursing clearly has an opportunity to affect public decisions that will help create conditions for a healthy population and influence the provision of needed services to populations in the community, particularly those that are most vulnerable. As a specialty, public health nursing can have a positive impact on the health status of populations, but to do so “it will be necessary to have broad vision; to prepare nurses for leadership roles in policy making and in the design, development, management, monitoring, and evaluation of population-focused health care systems and to develop strategies to support nurses in these roles” (Williams, 1992, p. 268). With the focus on quality and safety education for nurses, public health nursing education will want to reflect this renewed focus and assist nurses who are population focused to develop the competencies noted in the QSEN box.

LINKING CONTENT TO PRACTICE

In this chapter emphasis is placed on defining and explaining public health nursing practice with populations. The three essential functions of public health and public health nursing are assessment, policy development, and assurance. The Council on Linkages “Core Competencies for Public Health Professionals” revised in 2014 describes the skills of public health professionals, including nurses. In assessment function, one skill is assessment of the health status of populations and their related determinants of health and illness. For policy development, one of the skills is development of a plan to implement policy and programs. For the assurance function, one skill that public health nurses will need is to incorporate ethical standards of practice as the basis of all interactions with organizations, communities, and individuals. These skills can also be linked to the 10 essential services of public health nursing found on page 8. Assessment of health status is a skill needed for implementing essential service 1, the monitoring of health status to identify community problems. Development of a plan for policy and program implementation is a skill needed for essential service 5, to support individual and community health efforts. Incorporating ethical standards is done in essential service 3 when informing, educating, and empowering people about health issues.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

QSEN

Competency	Competency Definition
Client-Centered Care	Recognize the client or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for client preferences, values, and needs
Teamwork and Collaboration	Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality care
Evidence-Based Practice	Integrate best current evidence with clinical expertise and client/family preferences and values for delivery of optimal health care
Quality Improvement	Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems
Safety	Minimize risk for harm to clients and providers through both system effectiveness and individual performance
Informatics	Use information and technology to communicate, manage knowledge, mitigate error, and support decision making

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

PRACTICE APPLICATION

Population-focused nursing practice is different from clinical nursing care delivered in the community. If one accepts that the specialist in public health nursing is population-focused and has a unique body of knowledge, it is useful to debate where and how public health nursing specialists practice. How does their practice compare with that of the nurse specialist in community or community-based nursing?

A. In your public health class, debate with classmates which nurses in the following categories practice population-focused nursing:

1. School nurse
2. Staff nurse in home care
3. Director of nursing for a home care agency
4. Nurse practitioner in a health maintenance organization

PRACTICE APPLICATION—cont'd

5. Vice president of nursing in a hospital
6. Staff nurse in a public health clinic or community health center
7. Director of nursing in a health department
- Provide reasons for your choices.

- B. Choose three categories in the preceding list, and interview at least one nurse in each of the categories. Determine the scope of practice for each nurse. Are these nurses carrying out population-focused practice? Could they? How?

Answers can be found on the Evolve site.

KEY POINTS

- Public health is what we, as a society, do collectively to ensure the conditions in which people can be healthy.
- Assessment, policy development, and assurance are the core public health functions; they are implemented at all levels of government.
- *Assessment* refers to systematically collecting data on the population, monitoring of the population's health status, and making available information about the health of the community.
- *Policy development* refers to the need to provide leadership in developing policies that support the health of the population; it involves using scientific knowledge in making decisions about policy.
- *Assurance* refers to the role of public health in making sure that essential community-wide health services are available, which may include providing essential personal health services for those who would otherwise not receive them. Assurance also refers to ensuring that a competent public health and personal health care workforce is available.
- The setting is frequently viewed as the feature that distinguishes public health nursing from other specialties. A more

useful approach is to use the following characteristics: a focus on populations that are free-living in the community, an emphasis on prevention, a concern for the interface between the health status of the population and the living environment (physical, biological, sociocultural), and the use of political processes to affect public policy as a major intervention strategy for achieving goals.

- According to the 1985 Consensus Conference sponsored by the Nursing Division of the U.S. Department of Health and Human Services, *specialists in public health nursing* are defined as those who are prepared at the graduate level, either master's or doctoral, "with a focus in the public health sciences" (USDHHS, 1985). This is still true today.
- Population-focused practice is the focus of specialists in public health nursing. This focus on populations and the emphasis on health protection, health promotion, and disease prevention are the fundamental factors that distinguish public health nursing from other nursing specialties.
- A *population* is defined as a collection of individuals who share one or more personal or environmental characteristics. The term *population* may be used interchangeably with the term *aggregate*.

CLINICAL DECISION-MAKING ACTIVITIES

1. Define the following for your personal understanding, and suggest ways to check whether your understanding is correct:
 - A. Essential functions of public health
 - B. Specialist in public health nursing
 - C. Nurse specialist in the community
2. State your opinion about the similarities and/or differences between a clinical nursing role and the population-focused role of the public health nursing specialist. What are some of the complex issues in distinguishing between these roles?
3. Review the model of public health nursing practice of the APHA as described in this chapter. Can you elaborate on the differences between the staff nurse and the specialist nurse?
4. With three or four classmates, identify some nurses in your community who are in an administrative role and discuss with them the following:
 - A. The way they define the populations they are serving
 - B. Strategies they use to monitor the population's health status
 - C. Strategies they use to ensure that the populations are receiving needed services
 - D. Initiatives they are taking to address problems
5. Do additional questions need to be asked to determine their views on population-focused practice and the responsibilities of the staff nurse? Elaborate.

History of Public Health and Public and Community Health Nursing

Janna Dieckmann, PhD, RN

Dr. Janna Dieckmann is a clinical associate professor at the University of North Carolina at Chapel Hill. She received her BSN from Case Western Reserve University and her MSN in Community Health Nursing and her PhD from the University of Pennsylvania. She has practiced as a public health nurse with both the Visiting Nurse Association of Cleveland, Ohio and the Visiting Nurse Association of Philadelphia. She uses written and oral historical materials to research the history of public health nursing and on the care of the chronically ill, and to comment on contemporary health policy.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Interpret the focus and roles of public health nurses through an historical approach.
2. Trace the ongoing interaction between the practice of public health and that of nursing.
3. Discuss the dynamic relationship between changes in social, political, and economic contexts and nursing practice in the community.
4. Outline the professional and practice impact of individual leadership on population-centered nursing, especially the leadership of Florence Nightingale and Lillian Wald.
5. Identify structures for delivery of nursing care in the community such as settlement houses, visiting nurse associations, official health organizations, and schools.
6. Recognize major organizations that contributed to the growth and development of population-centered nursing.

Community Organization and Professional Change

Public Health Nursing from the 1970s into the Twenty-First Century

Public Health Nursing Today

Nurses use historical approaches to examine both the profession's present and its future. In doing so, several questions are asked: First, who is the population-centered nurse? In the past, population-centered nurses have been called public health nurses, district nurses, and visiting nurses, as well as home health care nurses, school nurses, and occupational health nurses. Second, how does the past contribute to the work of the population-centered nurse today? Next, what are the times and places in which these nurses have worked and continue to work? When a conscious process of critique and insight is used to look into past actions of the specialty, what can be discovered? Must contemporary nurses agree with or endorse past actions of the profession? And last, how might knowledge of population-centered nursing history serve both as a source of inspiration, and also as a creative stimulus to solve the enduring and new problems of the current period? This chapter serves as an introduction to these questions through tracing the development and evolution of population-centered nursing.

CHANGE AND CONTINUITY

For more than 130 years, public health nurses in the United States have worked to develop strategies to respond effectively to prevailing public health problems. The history of population-centered nursing reflects changes in the specific focus of the profession while emphasizing continuity in approach and style. Nurses have worked in communities to improve the health status of individuals, families, and populations, especially those who belong to vulnerable groups. Part of the appeal of this nursing specialty has been its autonomy of practice and independence in problem solving and decision-making, conducted in the context of a multidisciplinary practice. Many varied and challenging public health nursing roles originated in the late 1800s when public health efforts focused on environmental conditions such as sanitation, control of communicable diseases, education for health, prevention of disease and disability, and care of aged and sick persons in their homes.

Although the manifestations of these threats to health have changed over time, the foundational principles and goals of public health nursing have remained the same. Many

communicable diseases, such as diphtheria, cholera, and typhoid fever, have been largely controlled in the United States, but others continue to affect many lives across the globe, including human immunodeficiency virus (HIV), poliomyelitis, Ebola virus, and tuberculosis. Emerging and re-emerging communicable diseases with widespread impact, for example, influenza A subtypes such as 2009 H1N1, underscore the truth that health concerns are international. Even though environmental pollution in residential areas now receives increased public attention, communities continue to be threatened by overcrowded garbage dumps and pollutants affecting the air, water, and soil. Natural disasters continue to challenge public health systems, and bioterrorism and other human-made disasters have the potential to overwhelm existing resources. Research has identified means to avoid or postpone chronic disease onset, and nurses implement strategies to modify individual and community risk factors and behaviors. Finally, with the growing population percentage of older adults in the United States and their preference to remain at home, additional nursing services are required to sustain the frail, the disabled, and the chronically ill in the community.

Contemporary nursing roles in the United States developed from several sources and are a product of various ongoing social, economic, and political forces. This chapter describes the societal circumstances that influenced nurses to establish community-based and population-centered practices. For the purposes of this chapter, the term *nurse* will be used to refer to nurses who rely heavily on public health science to complement their focus on nursing science and practice. The nation's need for community and public health nurses, the practice of population-centered nursing, and the organizations influencing public health nursing in the United States from the nineteenth century to the present are discussed.

PUBLIC HEALTH DURING AMERICA'S COLONIAL PERIOD AND THE NEW REPUBLIC

Concern for the health and care of individuals in the community has characterized human existence. All people and all cultures have been concerned with the events surrounding birth, death, and illness. Human beings have sought to prevent,

understand, and control disease. Their ability to preserve health and treat illness has depended on the contemporary level of science, use and availability of technologies, and degree of social organization.

In the early years of America's settlement, as in Europe, the care of the sick was usually informal and was provided by household members, almost always women. The female head of the household was responsible for caring for all household members, which meant more than nursing them in sickness and during childbirth. She was also responsible for growing or gathering healing herbs for use throughout the year. For the increasing numbers of urban residents in the early 1800s, this traditional system became insufficient.

American ideas of social welfare and community-based care of the sick were strongly influenced by the traditions of British settlers in the New World. Just as American law is based on English common law, colonial Americans established systems of care for the sick, poor, aged, mentally ill, and dependents based on England's Elizabethan Poor Law of 1601. In the United States, as in England, local poor laws guaranteed medical care for poor, blind, and "lame" individuals, even those without family. Early county or township government was responsible for the care of all dependent residents, but provided almshouse charity carefully, economically, and only for local residents. Travelers and wanderers from elsewhere were returned to their native counties for care. In 1751, Pennsylvania Hospital was founded in Philadelphia, the first hospital in what would become the United States. Yet until much later, hospitals were few and found only in large cities.

Early colonial public health efforts included the collection of vital statistics, improvements to sanitation systems, and

control of communicable diseases introduced through seaports. Colonists lacked an organized and on-going means to ensure support and enforcement of public health efforts. Epidemics intermittently taxed the limited local organization for health during the seventeenth, eighteenth, and nineteenth centuries (Rosen, 1958).

After the American Revolution, the threat of disease, especially yellow fever epidemics, encouraged public support for new government-sponsored, official boards of health. New York City, with a population of 75,000 by 1800, established basic public health services, which included monitoring water quality, constructing sewers and a waterfront wall, draining marshes, planting trees and vegetables, and burying the dead (Rosen, 1958).

Increased urbanization and early industrialization in the new United States contributed to increased incidence of disease, including epidemics of smallpox, yellow fever, cholera, typhoid, and typhus. Tuberculosis and malaria remained endemic at a high incidence rate, and infant mortality was about 200 per 1000 live births (Pickett and Hanlon, 1990). American hospitals in the early 1800s were generally unsanitary and staffed by poorly trained workers; institutions were a place of last resort. Physicians received a limited education through proprietary schools or simple apprenticeship. Medical care was difficult to secure, although public dispensaries (similar to outpatient clinics) and private charitable efforts attempted to address gaps in the availability of sickness services, especially for the urban poor and working classes. Environmental conditions in urban neighborhoods, including inadequate housing and sanitation, were additional risks to health. Table 2-1 presents milestones of public health efforts that occurred from 1601 to the present.

TABLE 2-1 Milestones in the History of Public Health and Community Health Nursing: 1601 to 2014

Year	Milestone
1601	The Act for the Relief of the Poor (the Elizabethan Poor Law) passed
1751	Pennsylvania Hospital founded in Philadelphia
1793	Baltimore Health Department established
1798	Marine Hospital Service established; in 1912 renamed the U.S. Public Health Service
1813	Ladies' Benevolent Society of Charleston, South Carolina, founded
1815	Sisters of Mercy established in Dublin, Ireland, where nuns visited the poor
1836	Lutheran deaconess movement founded in Kaiserswerth, Germany
1851	Florence Nightingale visits Kaiserswerth for 3 months of nurse training
1859	District nursing established in Liverpool, England, by William Rathbone
1860	Florence Nightingale Training School for Nurses established at St. Thomas Hospital in London, England
1866	New York Metropolitan Board of Health established
1872	American Public Health Association established
1873	New York Training School opens at Bellevue Hospital, New York City, as first Nightingale-model nursing school in the United States
1877	Women's Board of the New York Mission hires nurse Frances Root to visit the sick poor
1881	Clara Barton and a circle of her acquaintances found the American Red Cross in Washington, DC on May 21, 1881
1885	Visiting Nurse Association established in Buffalo, NY
1886	Visiting nurse agencies established in Philadelphia and Boston
1892	First organized movement against tuberculosis
1893	Lillian Wald and Mary Brewster organize a visiting nursing service for the poor of New York, which later became the famous Henry Street Settlement and the Visiting Nurse Service of New York
	Society of Superintendents of Training Schools of Nurses in the United States and Canada established (in 1912 it became known as the National League of Nursing Education)

TABLE 2-1 Milestones in the History of Public Health and Community Health Nursing: 1601 to 2014—cont'd

Year	Milestone
1896	Associated Alumnae of Training Schools for Nurses established (in 1911 it became the American Nurses Association)
1902	School nursing started in New York City, by Nurse Lina Rogers of Henry Street Settlement
1903	First Nurse Practice Acts passed
1908	National Association of Colored Graduate Nurses founded
1909	Metropolitan Life Insurance Company provides first insurance reimbursement for nursing care
1910	Public health nursing program instituted at Teachers College, Columbia University, NYC
1912	National Organization for Public Health Nursing formed; Lillian Wald is first president
1916	<i>Public Health Nursing</i> textbook by Mary Sewall Gardner published
1918	Vassar Training Camp for Nurses organized
	U.S. Public Health Service (USPHS) establishes division of public health nursing to work in the war effort
	Worldwide influenza epidemic begins
1921	Maternity and Infancy Act (Sheppard-Towner) passed; 2978 Prenatal and Child Health Centers
1925	Frontier Nursing Service using nurse-midwives established in Kentucky
1933	Pearl McIver is first nurse employed by the U.S. Public Health Service
1935	Social Security Act passed
	Association of State and Territorial Directors of Nursing founded
1941	United States enters World War II
1943	Bolton Act provides \$5 million for nursing education; establishes Cadet Nurse Corps, with Lucille Petry as chief; 124,000 nurses graduate by 1948 when Corps ends
	USPHS Division of Nurse Education begun; becomes Division of Nursing in 1946
1944	First basic program in nursing accredited as including sufficient public health content
1946	Nurses classified as professionals by U.S. Civil Service Commission
	Hill-Burton Act approved, providing funds for hospital construction in underserved areas and requiring these hospitals to provide care for poor people
	Passage of National Mental Health Act
1950	25,091 nurses employed in public health
1951	National organizations recommend that college-based nursing education programs include public health content
1952	National Organization for Public Health Nursing merges into the new National League for Nursing
	Closure of Metropolitan Life Insurance Nursing Program
1964	Passage of Civil Rights Act and Economic Opportunity Act
	Public health nurse defined by the American Nurses Association (ANA) as a graduate of a BSN program
1965	ANA position paper recommends that nursing education take place in institutions of higher learning
1966	Medicare and Medicaid (Titles 18 and 19, of the Social Security Act) are implemented on July 1 (legislation passed in 1965)
1977	Passage of Rural Health Clinic Services Act, which provided indirect reimbursement for nurse practitioners in rural health clinics
1978	Association of Graduate Faculty in Community Health Nursing/Public Health Nursing founded (later, Association of Community Health Nursing Educators)
1979	Publication of <i>Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention</i>
1980	Medicaid amendment to the Social Security Act to provide direct reimbursement for nurse practitioners in rural health clinics
	ANA and APHA develop statements on the role and conceptual foundations of community and public health nursing, respectively
1983	Beginning of Medicare prospective payment system
1985	National Center for Nursing Research established in the National Institutes of Health
1988	Institute of Medicine reports on <i>The Future of Public Health</i>
1990	<i>Essentials of Baccalaureate Nursing Education</i> , from Association of Community Health Nursing Educators
1991	More than 60 nursing organizations join in support of health care reform; publish <i>Nursing's Agenda for Health Care Reform</i>
1993	American Health Security Act of 1993: blueprint for national health care reform; legislation fails; states and the private sector left to design own programs
1994	National Institute of Nursing Research, as part of the National Institutes of Health (was NCNR)
1996	<i>The Definition and Role of Public Health Nursing</i> , updated: Public Health Nursing Section, American Public Health Association
1998	<i>The Public Health Workforce: An Agenda for the 21st Century</i> , U.S. Public Health Service; examines current workforce in public, health, and educational needs, and the use of distance learning strategies to prepare future public health workers
1999	The Public Health Nursing Quad Council works with American Nurses Association on new <i>Scope and Standards of Public Health Nursing Practice</i> ; differentiates between community-oriented and community-based nursing practice
2001	Public health gains a national presence in addressing concerns about biological and other terrorism, following September 11 attacks
2002	Department of Homeland Security established to provide leadership to protect against intentional threats to the health of the public

Continued

TABLE 2-1 Milestones in the History of Public Health and Community Health Nursing: 1601 to 2014—cont'd

Year	Milestone
2003	<i>Public Health Nursing Competencies</i> finalized by the Quad Council of Public Health Nursing Organizations
2003–2005	Multiple natural disasters including earthquakes, tsunamis, and hurricanes demonstrate the weak infrastructure for managing disasters in the United States and other countries and emphasize the need for strong public health programs that included disaster management
2007	An entirely new <i>Public Health Nursing: Scope and Standards of Practice</i> is released through the ANA, reflecting the efforts of the Quad Council of Public Health Nursing Organizations
2010	The Patient Protection and Affordable Care Act is signed by President Barack Obama
2012	The Association of State and Territorial Directors of Nursing (ASTDN) becomes the Association of Public Health Nurses (APHN)
2013	The revised <i>Public Health Nursing: Scope and Standards of Practice</i> , prepared by representatives of the Quad Council of Public Health Nursing Organizations, is released by the American Nurses Association

APHA, American Public Health Association; BSN, Bachelor of Science in Nursing; NCNR, National Center for Nursing Research; NYC, New York City.

The federal government's early efforts for public health aimed to secure America's maritime trade and major coastal cities by providing health care for merchant seamen and by protecting seacoast cities from epidemics. The U.S. Public Health Service, still the most important federal public health agency in the twenty-first century, was established in 1798 as the Marine Hospital Service. The first Marine Hospital opened in Norfolk, Virginia, in 1800. Additional legislation to establish quarantine regulations for seamen and immigrants was passed in 1878.

During the early 1800s, experiments in providing nursing care at home focused on moral improvement and less on illness intervention. The Ladies' Benevolent Society of Charleston, South Carolina, provided charitable assistance to the poor and sick beginning in 1813. In Philadelphia, following a brief training program, lay nurses cared for postpartum women and newborns in their homes. In Cincinnati, Ohio, the Roman Catholic Sisters of Charity began a visiting nurse service in 1854 (Rodabaugh and Rodabaugh, 1951). Although these early programs provided services at the local level, they were not adopted elsewhere and their influence on later public health nursing is unclear.

During the mid-nineteenth century, national interest increased for addressing public health problems and improving urban living conditions. New responsibilities for urban boards of health reflected changing ideas of public health, and these boards began to address communicable diseases and environmental hazards. Soon after it was founded in 1847, the American Medical Association (AMA) formed a hygiene committee to conduct sanitary surveys and to develop a system to collect vital statistics. The Shattuck Report, published in 1850 by the Massachusetts Sanitary Commission, called for major innovations: The establishment of a state health department and local health boards in every town; sanitary surveys and collection of vital statistics; environmental sanitation; food, drug, and communicable disease control; well-child care; health education; tobacco and alcohol control; town planning; and the teaching of preventive medicine in medical schools (Kalisch and Kalisch, 2004). However, these recommendations were not implemented even in Massachusetts until 1869, and in other states much later.

FIG 2-1 A New Orleans nurse visiting a family on the doorstep of their home. (Courtesy of the New Orleans Public Library WPA Photograph Collection.)

In some areas, charitable organizations addressed the gap between known communicable disease epidemics and the lack of local government resources. For example, the Howard Association of New Orleans, Louisiana, responded to periodic yellow fever epidemics between 1837 and 1878 by providing physicians, lay nurses, and medicine. The Association established infirmaries and used sophisticated outreach strategies to locate cases (Hanggi-Myers, 1995) (Figure 2-1).

NIGHTINGALE AND THE ORIGINS OF TRAINED NURSING

The origins of professional nursing are found in the work of **Florence Nightingale** in nineteenth-century Europe. With tremendous advances in transportation, communication, and other forms of technology, the Industrial Revolution led to deep social upheaval. Even with the advancement of science, medicine, and technology during the two previous centuries, nineteenth-century public health measures continued to be unsophisticated. Organization and management of cities

improved slowly, and many areas lacked systems of sewage disposal and depended on private enterprise for water supply. Previous caregiving structures, which relied on the assistance of family, neighbors, and friends, became inadequate in the early nineteenth century because of human migration, urbanization, and changing demand. During this period, a few groups of Roman Catholic and Protestant women provided nursing care for the sick, poor, and neglected in institutions and sometimes in the home. For example, Mary Aikenhead, also known by her religious name Sister Mary Augustine, organized the Irish Sisters of Charity in Dublin (Ireland) in 1815. These sisters visited the poor at home and established hospitals and schools (Kalisch and Kalisch, 2004).

In nineteenth-century England, the Elizabethan Poor Law continued to guarantee medical care for all. This minimal care, provided most often in almshouses supported by local government, sought as much to regulate where the poor could live as to provide care during illness. Many women who performed nursing functions in almshouses and early hospitals in Great Britain were poorly educated, untrained, and often undependable. As the practice of medicine became more complex in the mid-1800s, hospital work required skilled caregivers. Physicians and hospital administrators sought to advance the practice of nursing. Early innovations yielded some improvement in care, but Florence Nightingale's efforts were revolutionary.

Florence Nightingale's vision for trained nurses and her model of nursing education influenced the development of professional nursing and, indirectly, public health nursing in the United States. In 1850 and 1851, Nightingale had carefully studied nursing "system and method" by visiting Pastor Theodor Fliedner at his School for Deaconesses in Kaiserswerth, Germany. Pastor Fliedner also built on the work of others, including Mennonite deaconesses in the Netherlands who were engaged in parish work for the poor and the sick, and Elizabeth Fry, the English prison reformer. Thus mid-nineteenth century efforts to reform the practice of nursing drew on a variety of interacting innovations across Europe.

The Kaiserswerth Lutheran deaconesses incorporated care of the sick in the hospital with client care in their homes, and their system of **district nursing** spread to other German cities. American requests for the deaconesses to respond to epidemics of typhus and cholera in Pittsburgh provided only temporary assistance because local women were uninterested in joining the work. The early efforts of the Lutheran deaconesses in the United States ultimately focused on developing systems of institutional care (Nutting and Dock, 1935).

Nightingale also found a way to implement her ideas about nursing practice. During the Crimean War (1854–1856) between the alliance of England and France against Russia, the British military established hospitals for sick and wounded soldiers at Scutari (now Üsküdar, in modern Istanbul). The care of sick and wounded soldiers was severely deficient, with cramped quarters, poor sanitation, lice and rats, insufficient food, and inadequate medical supplies (Palmer, 1983; Kalisch and Kalisch, 2004). When the British public demanded improved conditions, Nightingale sought and received an appointment to address the chaos. Because of her wealth, social and political

connections, and knowledge of hospitals, the British government sent her 40 ladies, 117 hired nurses, 15 paid servants, and extensive supplies for patient care.

In Scutari, Nightingale progressively improved soldiers' health outcomes, using a population-based approach that strengthened environmental conditions and nursing care. Using simple epidemiological measures, she documented a decreased mortality rate from 415 per 1000 men at the beginning of the war to 11.5 per 1000 at the end (Palmer, 1983; Cohen, 1984). Paralleling Nightingale's efforts, public health nurses typically identify health care needs that affect the entire population, mobilize resources, and organize themselves and the community to meet these needs.

Nightingale's fame was established even before she returned to England in 1856 after the Crimean War. She then reorganized hospital nursing practice and established hospital-based nursing education to replace untrained lay nurses with trained Nightingale nurses. Nightingale also emphasized public health nursing: "The health of the unity is the health of the community. Unless you have the health of the unity, there is no community health" (Nightingale, 1894/1984, p. 455). She differentiated "sick nursing" from "health nursing." The latter emphasized that nurses should strive to promote health and prevent illness. Nightingale (1859/1946, p. v) wrote that the task of nurses is to "put the constitution in such a state as that it will have no disease, or that it can recover from disease." Proper nutrition, rest, sanitation, and hygiene were necessary for health. Nurses continue to focus on the vital role of health promotion, disease prevention, and environment in their practice with individuals, families, and communities.

Nightingale's contemporary and friend, British philanthropist William Rathbone, founded the first **district nursing association** in Liverpool, England. Rathbone's wife had received outstanding nursing care from a Nightingale-trained nurse during her terminal illness at home. He wanted to offer similar care to relieve the suffering of poor persons unable to afford private nurses. With Rathbone's advocacy and economic support between 1859 and 1862, the Liverpool Relief Society divided the city into nursing districts and assigned a committee of "friendly visitors" to each district to provide health care to needy people (Kalisch and Kalisch, 2004). Building on the Liverpool experience, Rathbone and Nightingale recommended steps to provide nursing in the home, leading to the organization of district nursing throughout England. Florence Sarah Lees Craven shaped the profession through her book *A Guide to District Nurses*, which highlighted, for example, that nursing care during the illness of one family member provided the nurse with influence to improve the entire family's health status (Craven, 1889/1984).

AMERICA NEEDS TRAINED NURSES

As urbanization increased during the Industrial Revolution in the 1800s, the number of occupations for American women rapidly increased. Educated women became elementary school teachers, secretaries, or saleswomen. Less educated women worked in factories of all kinds. The idea of becoming a trained

nurse increased in popularity when Nightingale's successes became known across the United States. During the 1870s, the first nursing schools based on the Nightingale model opened in the United States.

Trained nurse graduates of the early schools for nurses in the United States usually worked in private duty nursing or held the few positions as hospital administrators or instructors. Private duty nurses might live with families of clients receiving care, to be available 24 hours a day. Although the trained nurse's role in improving American hospitals was very clear, the cost of private duty nursing care for the sick at home was prohibitive for all but the wealthy.

The care of the sick poor at home was made more economical by using home-visiting nurses who would attend several families in a day, rather than only one patient as the private duty nurse did. In 1877 the Women's Board of the New York City Mission hired Frances Root, a graduate of Bellevue Hospital's first nursing class, to visit sick poor persons to provide nursing care and religious instruction (Bullough and Bullough, 1964). In 1878 the Ethical Culture Society of New York hired four nurses to work in dispensaries, a type of community-based clinic. In the next few years, visiting nurse associations (VNAs) were established in Buffalo, New York (1885), Philadelphia (1886), and Boston (1886). Wealthy people interested in charitable activities funded both settlement houses and VNAs. Upper-class women, freed of some of the social restrictions that had previously limited their public life, participated in the charitable work of creating, supporting, and supervising the new visiting nurses.

Public health nursing in the United States began with organizing to meet urban health care needs, especially for the disadvantaged. The public was interested in limiting disease among all classes of people, not only for religious reasons as a form of charity, but also because the middle and upper classes feared the impact of communicable diseases believed to originate in the large communities of new European immigrants. In New York City in the 1890s, about 2.3 million people lived in 90,000 tenement houses. Deplorable environmental conditions for immigrants in urban tenement houses and sweatshops were common across the northeastern United States and upper Midwest. People living in poor housing conditions were ravaged by epidemics of communicable diseases, including typhus, scarlet fever, smallpox, and typhoid fever; in the nineteenth century, tuberculosis was the leading cause of infectious disease mortality (Kalisch and Kalisch, 2004). From the beginning, nursing practice in the community included teaching and prevention.

For example, in 1886 two Boston women approached the Women's Education Association to seek local support for district nursing. To increase the likelihood of financial support, they used the term *instructive district nursing* to emphasize the relationship of nursing to health education. The Boston Dispensary provided support in the form of free outpatient medical care. In 1886 the first district nurse was hired, and in 1888 the Instructive District Nursing Association became incorporated as an independent voluntary agency. Sick poor persons, who paid no fees, were cared for under the direction of a trained physician (Brainard, 1922).

Nursing interventions, improved sanitation, economic improvements, and better nutrition were credited with reducing the incidence of acute communicable disease by 1910. New scientific explanations of communicable disease suggested that preventive education would reduce illness. Through home visits and well-baby clinics, the **visiting nurse** became the key to communicating this prevention campaign. Visiting nurses worked with physicians, gave selected treatments, and kept temperature and pulse records. Visiting nurses emphasized education of family members in the care of the sick and in personal and environmental prevention measures, such as hygiene and good nutrition. Most public health nursing practice in the early twentieth century was generalized practice with diverse responsibilities. Only a few public health nurses had a specialized practice, such as caring only for patients with tuberculosis or working only in an occupational health practice. Public health nurses also established **settlement houses**—neighborhood centers that became hubs for health care, education, and social welfare programs. For example, in 1893 **Lillian Wald** and Mary Brewster, both trained nurses, began visiting the poor on New York's Lower East Side. The nurses' settlement they established became the Henry Street Settlement and later the Visiting Nurse Service of New York City. By 1905 the public health nurses had provided almost 48,000 visits to more than 5000 clients (Kalisch and Kalisch, 2004). Other settlement houses influenced the growth of public health nursing including the Richmond (Virginia) Nurses' Settlement, which became the Instructive Visiting Nurse Association; the Nurses' Settlement in Orange, New Jersey; and the College Settlement in Los Angeles, California. See the box below for a photo of Lillian Wald (Figure 2-2).

Lillian Wald emerged as the key leader of public health nursing during its early decades. Wald took steps to increase access to public health nursing services nationally through insightful innovations: She persuaded the **American Red Cross** to sponsor rural health nursing services across the country, which stimulated local governments to sponsor public health nursing through county health departments. Beginning in 1909, Wald worked with Dr. Lee Frankel of the Metropolitan Life Insurance Company (MetLife) to implement the first insurance payment for nursing services. She argued that keeping working people and their families healthier would increase their productivity. MetLife found that nursing care for communicable diseases, injuries, and mothers and children reduced mortality and saved money for this life insurance company. MetLife nursing services continued for 44 years, with successes such as (1) providing home nursing services on a fee-for-service basis, (2) establishing an effective cost-accounting system for visiting nurses, and (3) reducing mortality from infectious diseases.

Convinced that environmental conditions as well as social conditions were the causes of ill health and poverty, Wald became actively involved in using epidemiological methods to campaign for health-promoting social policies. She advocated for creation of the U.S. Children's Bureau as a basis for improving the health and education of children nationally. She fought for better tenement living conditions in New York City, city recreation centers, parks, pure food laws, graded classes for mentally handicapped children, and assistance to immigrants.

FIG 2-2 Lillian Wald. (Courtesy of the Visiting Nurse Service of New York.)

She firmly believed in women's suffrage and considered its acceptance in 1917 in New York State to be a great victory. Wald supported efforts to improve race relations and championed solutions to racial injustice. She wrote *The House on Henry Street* (Wald, 1915) and *Windows on Henry Street* (Wald, 1934) to describe this public health nursing work.

Many public health nurses contributed to the development of the profession, including Jessie Sleet (Scales), a Canadian graduate of Provident Hospital School of Nursing (Chicago), who was the first African-American public health nurse; Ms. Sleet was hired by the New York Charity Organization Society in 1900. Although it proved difficult for her to find an agency willing to hire her as a district nurse, she persevered and was able to provide exceptional care for her clients until she married in 1909. At the Charity Organization Society in 1904 to 1905, she studied health conditions related to tuberculosis among African-American people in Manhattan, using interviews with families and neighbors, house-to-house canvases, direct observation, and speeches at neighborhood churches. Sleet reported her research to the Society board, recommending improved employment opportunities for African-Americans and better prevention strategies to reduce the excess burden of tuberculosis morbidity and mortality among the African-American population (Thoms, 1929; Hine, 1989; Mosley, 1994; Buhler-Wilkerson, 2001).

In 1909 Yssabella Waters published her survey, *Visiting Nursing in the United States*, which documented the concentration of visiting nurse services in the northeastern quadrant of

the nation (Waters, 1909). In 1901 New York City alone had 58 different organizations with 372 trained nurses providing care in the community. Despite the numbers, 68% of visiting nurses nationally were employed in single-nurse agencies. In addition to VNAs and settlement houses, a variety of other organizations sponsored visiting nurse work, including boards of education, boards of health, mission boards, clubs, churches, social service agencies, and tuberculosis associations. With tuberculosis then responsible for at least 10% of all mortality, visiting nurses contributed to its control through gaining "the personal cooperation of patients and their families" to modify the environment and individual behavior (Buhler-Wilkerson, 1987, p. 45). Most visiting nurse agencies depended financially on the philanthropy and social networks of metropolitan areas. As today, fund-raising and service delivery in less densely populated and rural areas was challenging.

The American Red Cross, through its Rural Nursing Service (later the **Town and Country Nursing Service**), provided a framework to initiate home nursing care in areas outside larger cities. Wald secured initial donations to support this agency, which provided care of the sick and instruction in sanitation and hygiene in rural homes. The agency also improved living conditions in villages and isolated farms. The Town and Country nurse dealt with diseases such as tuberculosis, pneumonia, and typhoid fever with a resourcefulness born of necessity. The rural nurse might use hot bricks, salt, or sandbags to substitute for hot water bottles; chairs as back-rests for the bedbound; and boards padded with quilts as stretchers (Kalisch and Kalisch, 2004). In the two years after World War I, the 100 existing Red Cross Town and Country Nursing Services expanded to 1800, and eventually to almost 3000 programs in small towns and rural areas. This service demonstrated the importance and feasibility of public health nursing across the country at local and county levels. Once established, ongoing responsibilities for these new agencies were passed on to local voluntary agencies or local government support.

Occupational health nursing began as industrial nursing and was a true outgrowth of early home-visiting efforts. In 1895 Ada Mayo Stewart began work with employees and families of the Vermont Marble Company in Proctor, Vermont. As a free service for the employees, Stewart provided obstetric care, sickness care (e.g., for typhoid cases), and some postsurgical care in workers' homes. Although her employer provided a horse and buggy, she often made home visits on a bicycle. Unlike contemporary occupational health nurses, Stewart provided few services for work-related injuries. Before 1900 a few nurses were hired in industry, such as in department stores in Philadelphia and Brooklyn. Between 1914 and 1943, industrial nursing grew from 60 to 11,220 nurses, reflecting increased governmental and employee concerns for health and safety in the workplace (American Association of Industrial Nurses, 1976; Kalisch and Kalisch, 2004).

SCHOOL NURSING IN AMERICA

In New York City in 1902, more than 20% of children might be absent from school on a single day. The children suffered from

the common conditions of pediculosis, ringworm, scabies, inflamed eyes, discharging ears, and infected wounds. Physicians began to make limited inspections of school students in 1897, but they focused on excluding sick children from school rather than on providing or obtaining medical treatment to enable children to return to school. Familiar with this community-wide problem from her work with the Henry Street Nurses' Settlement, Lillian Wald sought to place nurses in the schools and gained consent from the city's health commissioner and the Board of Education for a 1-month demonstration project.

Lina Rogers, a Henry Street Settlement resident, became the first school nurse. She worked with the children in New York City schools and made home visits to instruct parents and to follow up on children excluded or otherwise absent from school. The school nurses found that "many children were absent for lack of shoes or clothing, because of malnourishment, or because they were serving their families as babysitters" (Hawkins et al, 1994, p. 417). The school nurse experiment made such a significant and positive impact that it became permanent, with 12 more nurses appointed 1 month later. School nursing was soon implemented in Los Angeles, Philadelphia, Baltimore, Boston, Chicago, and San Francisco.

THE PROFESSION COMES OF AGE

Established by the Cleveland Visiting Nurse Association in 1909, the *Visiting Nurse Quarterly* initiated a professional communication medium for clinical and organizational concerns. In 1911 a joint committee of existing nurse organizations convened to standardize nursing services outside the hospital. Under the leadership of Lillian Wald and Mary Gardner, the committee recommended forming a new organization to address public health nursing concerns. Eight hundred agencies involved in public health nursing were invited to send delegates to a June 1912 organizational meeting in Chicago. After a heated debate on its name and purpose, the delegates established the **National Organization for Public Health Nursing** (NOPHN) and chose Wald as its first president (Dock, 1922). Unlike other professional nursing organizations, the NOPHN membership included both nurses and their non-nurse supporters. The NOPHN sought "to improve the educational and services standards of the public health nurse, and promote public understanding of and respect for her work" (Rosen, 1958, p. 381). With greater administrative resources than other contemporary national nursing organizations, the NOPHN was soon the dominant force in public health nursing (Roberts, 1955).

The NOPHN also sought to standardize public health nursing education. Visiting nurse agencies found that hospital training school graduates were unprepared for home visiting. Hospital training schools emphasized hospital care of sick patients, but public health nurses required additional educational preparation to provide services through home-visiting and population-focused programs. In 1914, in affiliation with the Henry Street Settlement, Mary Adelaide Nutting began the first post-training-school course in public health nursing at Teachers College in New York City (Deloughery, 1977). The

American Red Cross provided scholarships for training school graduates to attend the public health nursing course. Its success encouraged the development of other programs, using curricula that might seem familiar to today's nurses. During the 1920s and 1930s, many newly hired public health nurses had to verify completion or promptly enroll in a certificate program in public health nursing. Others took leave for a year to travel to an urban center to obtain this further education.

Public health nurses were also active in the **American Public Health Association** (APHA), which had been established in 1872 to facilitate interprofessional efforts and promote the "practical application of public hygiene" (Scutchfield and Keck, 1997, p. 12). The APHA targeted reform efforts toward contemporary public health issues, including sewage and garbage disposal, occupational injuries, and sexually transmitted diseases. In 1923 the Public Health Nursing Section was formed within the APHA to provide a forum for nurses to discuss their concerns and strategies within the larger APHA. The PHN Section continues to serve as a focus of leadership and policy development for public health nursing in the twenty-first century.

PUBLIC HEALTH NURSING IN OFFICIAL HEALTH AGENCIES AND IN WORLD WAR I

Public health nursing in voluntary agencies and through the Red Cross grew more quickly than public health nursing in official agencies, those sponsored by state, local, and national government. By 1900, 38 states had established state health departments; however, these early state boards of health had limited impact. Only three states—Massachusetts, Rhode Island, and Florida—annually spent more than 2 cents per capita for public health services (Scutchfield and Keck, 1997).

The federal role in public health gradually expanded. In 1912 the federal government redefined the role of the U.S. Public Health Service, empowering it to "investigate the causes and spread of diseases and the pollution and sanitation of navigable streams and lakes" (Scutchfield and Keck, 1997, p. 15). The NOPHN loaned a nurse to the U.S. Public Health Service during World War I to establish a public health nursing program for military outposts. This led to the first federal government sponsorship of nurses (Shyrock, 1959; Wilner et al, 1978).

During the 1910s, public health organizations began to target infectious and parasitic diseases in rural areas. The Rockefeller Sanitary Commission, a philanthropic organization active in hookworm control in the southeastern United States, concluded that concurrent efforts for all phases of public health were necessary to successfully address any individual public health problem (Pickett and Hanlon, 1990). For example, in 1911, efforts to control typhoid fever in Yakima County, Washington, and to improve health status in Guilford County, North Carolina, led to the establishment of local health units to serve local populations. Public health nurses were the primary staff members of local health departments. These nurses assumed a leadership role on health care issues through collaboration with local residents, nurses, and other health care providers.

The experience of Orange County, California, during the 1920s and 1930s illustrates the role of the public health nurse

in these new local health departments. Following the efforts of a private physician, social welfare agencies, and a Red Cross nurse, the county board created the public health nurse's position, which began in 1922. Presented with a shining new Model T car sporting the bright orange seal of the county, the nurse focused on the serious communicable disease problems of diphtheria and scarlet fever. Typhoid became epidemic when a drainage pipe overflowed into a well, infecting those who drank the well water or raw milk from an infected dairy. Almost 3000 residents were immunized against typhoid. Weekly well-baby conferences provided an opportunity for mothers to learn about care of their infants, and the infants were weighed and given communicable disease immunizations. Children with orthopedic disorders and other disabilities were identified and referred for medical care in Los Angeles. At the end of a successful first year of public health nursing work, the Rockefeller Foundation and the California Health Department recognized the favorable outcomes and provided funding for more public health professionals.

The personnel needs of World War I in Europe depleted the ranks of public health nurses, at the same time the NOPHN had identified a need for more public health nurses within the United States. Jane Delano of the Red Cross (which was sending 100 nurses a day to the war) agreed that despite the sacrifice, the greatest patriotic duty of public health nurses was to stay at home. In 1918 the worldwide influenza pandemic swept the United States from coast to coast within 3 weeks, and was met by a coalition of the NOPHN and the Red Cross. Houses, churches, and social halls were turned into hospitals for the immense numbers of sick and dying. Some of the nurse volunteers died of influenza as well (Shyrock, 1959; Wilner et al, 1978).

PAYING THE BILL FOR PUBLIC HEALTH NURSES

Inadequate funding was the major obstacle to extending nursing services in the community. Most early VNAs sought charitable contributions from wealthy and middle-class supporters. Even poor families were encouraged to pay a small fee for nursing services, reflecting social welfare concerns against promoting economic dependency by providing charity. In 1909, as a result of Wald's collaboration with Dr. Lee Frankel, the **Metropolitan Life Insurance Company** began a cooperative program with visiting nurse organizations that expanded availability of public health nursing services. The nurses assessed illness, taught health practices, and collected data from policyholders. By 1912, 589 Metropolitan Life nursing centers provided care through existing agencies or through visiting nurses hired directly by the Company. In 1918 Metropolitan Life calculated an average decline of 7% in the mortality rate of policyholders and almost a 20% decline in the mortality rate of policyholders' children under age 3. The insurance company attributed this improvement and their reduced costs to the work of visiting nurses. Voluntary health insurance was still decades in the future; public and professional efforts to secure compulsory health insurance seemed promising in 1916, but had evaporated by the end of World War I.

Nursing efforts to influence public policy bridged World War I, including advocacy for the Children's Bureau and the Sheppard-Towner Program. Responding to lengthy advocacy by Wald and other nurse leaders, the Children's Bureau was established in 1912 to address national problems of maternal and child welfare. Children's Bureau experts conducted extensive scientific research on the effects of income, housing, employment, and other factors on infant and maternal mortality. Their research led to federal child labor laws and the 1919 White House Conference on Child Health.

Problems of maternal and child morbidity and mortality spurred the passage of the Maternity and Infancy Act (often called the **Sheppard-Towner Act**) in 1921. This act provided federal matching funds to establish maternal and child health divisions in state health departments. Education during home visits by public health nurses stressed promoting the health of mother and child as well as seeking prompt medical care during pregnancy. Although credited with saving many lives, the Sheppard-Towner Program ended in 1929 in response to charges by the AMA and others that the legislation gave too much power to the federal government and too closely resembled socialized medicine (Pickett and Hanlon, 1990). Federal funding during the 1930s and 1940s established maternal-child health programs that continued some of the successes of Sheppard-Towner.

Some nursing innovations were the result of individual commitment and private financial support. In 1925 Mary Breckinridge established the **Frontier Nursing Service** (FNS), based on systems of care used in the Highlands and islands of Scotland. The unique pioneering spirit of the FNS influenced the development of public health programs geared toward improving the health care of the rural and often inaccessible populations in the Appalachian region of southeastern Kentucky (Browne, 1966; Tirpak, 1975). Breckinridge introduced the first nurse-midwives into the United States when she deployed FNS nurses trained in nursing, public health, and midwifery. Their efforts led to reduced pregnancy complications and maternal mortality, and to one-third fewer stillbirths and infant deaths in an area of 700 square miles (Kalisch and Kalisch, 2004). The early efforts of the Frontier Nursing Service are recorded in the book, *Wide Neighborhoods* (Breckinridge, 1952). Today the FNS continues to provide comprehensive health and nursing services to the people of that area and sponsors Frontier Nursing University, which provides advanced practice nursing education for midwifery and other specialties.

AFRICAN-AMERICAN NURSES IN PUBLIC HEALTH NURSING

African-American nurses seeking to work in public health nursing faced many challenges. Nursing education was absolutely segregated in the South until at least the 1960s, and elsewhere was also generally segregated or rationed until mid-century. Even public health nursing certificate and graduate education programs were segregated in the South; study outside the South for southern nurses was difficult to afford and study leaves from the workplace were rarely granted. The situation

improved somewhat in 1936, when collaboration between the U.S. Public Health Service and the Medical College of Virginia (Richmond) established a certificate program in public health nursing for African-American nurses, with tuition provided by the federal government. Discrimination continued during nurses' employment: African-American nurses in the American South were paid significantly lower salaries than their white counterparts for the same work. In 1925 just 435 African-American public health nurses were employed in the United States, and in 1930 only 6 African-American nurses held supervisory positions in public health nursing organizations (Thoms, 1929; Hine, 1989; Buhler-Wilkerson, 2001).

African-American public health nurses had a significant impact on the communities they served. The National Health Circle for Colored People was organized in 1919 to promote public health work in African-American communities in the South. One approach provided scholarships to assist African-American nurses to pursue university-level public health nursing education. Bessie B. Hawes, the first recipient of the scholarship, completed the Columbia University program in New York City. The Circle sent Hawes to Palatka, Florida, a small, isolated lumber town. Hawes' first project recruited local school girls to promote health by dressing as nurses and marching in a parade while singing community songs. She conducted mass meetings, led mother's clubs, provided school health education, and visited the homes of the sick. Eventually she gained the community's trust, overcame opposition, and built a health center for nursing care and treatment (Thoms, 1929).

BETWEEN THE TWO WORLD WARS: ECONOMIC DEPRESSION AND THE RISE OF HOSPITALS

The economic crisis during the Depression of the 1930s deeply influenced the development of nursing. Not only were agencies and communities unprepared to address the increased needs and numbers of the impoverished, but decreased funding for nursing services reduced the number of employed nurses in hospitals and in community agencies. The NOPHN's tenacious effort to ensure inclusion of public health nursing in federal relief programs secured success after a flurry of last-minute telegrams and lobbying efforts. Federal funding led to a wide variety of programs administered at the state level, including new public health nursing programs.

The Federal Emergency Relief Administration (FERA) supported nurse employment through increased grants-in-aid for state programs of home medical care. FERA often purchased nursing care from existing visiting nurse agencies, thus supporting more nurses and preventing agency closures. The FERA program varied among states; the state FERA program in New York emphasized bedside nursing care, whereas in North Carolina, the state FERA prioritized maternal and child health, and school nursing services. Some Depression-era federal programs built new services; public health nursing programs of the Works Progress Administration (WPA) were sometimes later incorporated into state health departments. In West Virginia, as

elsewhere, the Relief Nursing Service had a dual purpose—to assist unemployed nurses and to provide nursing care for families on relief. Fundamental services included “(1) providing bedside care and health supervision for the family in the home; (2) arranging for medical and hospital care for emergency and obstetric cases; (3) supervising the health of children in emergency relief nursery schools; and (4) caring for patients with tuberculosis” (Kalisch and Kalisch, 2004, p. 283).

In another Depression-era program, more than 10,000 nurses were employed by the Civil Works Administration (CWA) and assigned to official health agencies. “While this facilitated rapid program expansion by recipient agencies and gave the nurses a taste of public health, the nurses' lack of field experience created major problems of training and supervision for the regular staff” (Roberts and Heinrich, 1985, p. 1162).

A 1932 survey of public health agencies found that only 7% of nurses employed in public health were adequately prepared (Roberts and Heinrich, 1985). Basic nursing education focused heavily on the care of individuals, and students received limited information on groups and the community as a unit of service. Thus in the 1930s and early 1940s, new hospital training school graduates continued to be inadequately prepared to work in public health and required considerable remedial orientation and education from the hiring agencies (NOPHN, 1944).

Public health nurses continued to weigh the relative value of preventive care compared with bedside care of the sick. They also questioned whether nursing interventions should be directed toward groups and communities, or toward individuals and their families. Although each nursing agency was unique and services varied from region to region, voluntary VNAs tended to emphasize care of the sick, whereas official public health agencies provided more preventive services. Compared with nursing in VNAs, nurses in official agencies may have had less control over their practice roles because physicians and politicians often determined services and personnel assignments in public health departments. See [Figure 2-1](#) for a photo of a nurse making a home visit to a family in New Orleans.

Not surprisingly, the conflicting visions and splintering of services between “visiting” and “public health” nurses further impeded development of comprehensive population-centered nursing services (Roberts and Heinrich, 1985). In addition, some households received services from several community nurses representing several agencies, for example, visits to the same home (1) for a postpartum woman and new baby, (2) for a child sick with scarlet fever, and (3) for an older adult sick in bed. Nurses believed that multiple caregivers and agencies confused families and duplicated scarce nursing resources. Interest grew in the “combination service”—the merger of sick care services and preventive services into one comprehensive agency, administered jointly between a voluntary agency and an [official health agency](#).

INCREASING FEDERAL ACTION FOR THE PUBLIC'S HEALTH

Expansion of the federal government during the 1930s affected the structure of community health resources. Credited as “the

beginning of a new era in public nursing” (Roberts and Heinrich, 1985, p. 1162), Pearl McIver in 1933 became the first nurse employed by the U.S. Public Health Service. In providing consultation services to state health departments, McIver was convinced that the strengths and ability of each state’s director of public health nursing would determine the scope and quality of local health services. Together with Naomi Deutsch, director of nursing for the federal Children’s Bureau, and with the support of nursing organizations, McIver and her staff of nurse consultants influenced the direction of public health nursing. Between 1931 and 1938, greater than 40% of the increase in public health nurse employment was in local health agencies. Even so, nationally more than one-third of all counties still lacked local public health nursing services.

The **Social Security Act of 1935** was designed to prevent reoccurrence of the problems of the Depression. Title VI of this act provided funding for expanded opportunities for health protection and promotion through education and employment of public health nurses. More than 1000 nurses completed educational programs in public health in 1936. Title VI also provided \$8 million to assist states, counties, and medical districts in the establishment and maintenance of adequate health services, as well as \$2 million for research and investigation of disease (Buhler-Wilkerson, 1985, 1989; Kalisch and Kalisch, 2004).

A categorical approach to federal funding for public health services reflected the U.S. Congress’s preference for funding specific diseases or specific groups, rather than providing dollar allocations to local agencies. In categorical funding, resources are directed toward specific priorities rather than toward a comprehensive community health program. When funding is directed by established national preferences, it becomes more difficult to respond to local and emerging problems. Even so, local health departments shaped their programs according to the pattern of available funds, including maternal and child health services and crippled children (in 1935), venereal disease control (in 1938), tuberculosis (in 1944), mental health (in 1947), industrial hygiene (in 1947), and dental health (in 1947) (Scutchfield and Keck, 1997). Categorical funding continues to be a preferred federal approach to address national health policy objectives.

WORLD WAR II: EXTENSION AND RETRENCHMENT IN PUBLIC HEALTH NURSING

The U.S. involvement in World War II in 1941 accelerated the need for nurses, both for the war effort and at home. The Nursing Council on National Defense was a coalition of the national nursing organizations that planned and coordinated activities for the war effort. National interests prioritized the health of military personnel and workers in essential industries. Many nurses joined the Army and Navy Nurse Corps. Through the influence and leadership of U.S. Representative Frances Payne Bolton of Ohio, substantial funding was provided by the Bolton Act of 1943 to establish the Cadet Nurse Corps, supporting increased enrollment in schools of nursing at undergraduate and graduate levels. Under management by

the U.S. Public Health Service, the Nursing Council for National Defense received \$1 million to expand facilities for nursing education. Additional programs that expanded both the total number of nurses and the number of nurses with preparation in public health nursing included the Training for Nurses for National Defense, the GI Bill, the Nurse Training Act of 1943, and Public Health and Professional Nurse Traineeships (McNeil, 1967).

As more and more nurses and physicians left civilian hospitals to meet the needs of the war, responsibility for client care was shifted to families, non-nursing personnel, and volunteers. “By the end of 1942, over 500,000 women had completed the American Red Cross home nursing course, and nearly 17,000 nurse’s aides had been certified” (Roberts and Heinrich, 1985, p. 1165). By the end of 1946, more than 215,000 volunteer nurse’s aides had received certificates.

In some cases, public health nursing expanded its scope of practice during World War II. For example, nurses increased their presence in rural areas, and many official agencies began to provide bedside nursing care (Buhler-Wilkerson, 1985; Kalisch and Kalisch, 2004). The federal Emergency Maternity and Infant Care Act of 1943 (EMIC) provided funding for medical, hospital, and nursing care for the wives and babies of servicemen. Health services seeking EMIC funds were required to meet the high standards of the U.S. Children’s Bureau, which resulted in increased quality of care for all. In other situations, nursing roles were constrained by wartime and postwar nursing shortages. For example, the Visiting Nurse Society of Philadelphia ceased home birth services, drastically reduced industrial nursing services, and deferred care for the long-term chronically ill client.

Reflecting the complex social changes that had occurred during the war years, in the late 1940s local health departments faced sudden increases in client demand for care of emotional problems, accidents, alcoholism, and other responsibilities new to the domain of official health agencies. Changes in medical technology offered new possibilities for screening and treatment of infectious and communicable diseases, such as antibiotics to treat rheumatic fever and venereal diseases, and photofluorography for mass case finding of pulmonary tuberculosis. Local health departments expanded, both to address underserved areas and to expand types of services, and they often fared better economically than voluntary agencies.

Job opportunities for public health nurses grew because they continued to constitute a large proportion of health department personnel. Between 1950 and 1955, the proportion of U.S. counties with full-time local health services increased from 56% to 72% (Roberts and Heinrich, 1985). With more than 20,000 nurses employed in health departments, VNAs, industry, and schools, public health nurses at the middle of the twentieth century continued to have a crucial role in translating the advances of science and medicine into saving lives and improving health.

In 1946, representatives of agencies interested in community health met to improve coordination of various types of community nursing and to prevent overlap of services. The resulting guidelines proposed that a population of 50,000 be required to

support a public health program and that there should be 1 nurse for every 2200 people. Nursing functions should include health teaching, disease control, and care of the sick. Communities were encouraged to adopt one of the following organizational patterns (NOPHN, 1946):

- Administration of all community health nurse services by the local health department;
- Provision of preventive health care by health departments, and provision of home visiting for the sick by a cooperating voluntary agency; or
- A combination service jointly administered and financed by official and voluntary agencies with all services provided by one group of nurses.

THE RISE OF CHRONIC ILLNESS

Between 1900 and 1955, the national crude mortality rate decreased by 47%. Many more Americans survived childhood and early adulthood to live into middle and older ages. Although in 1900 the leading causes of mortality were pneumonia, tuberculosis, and diarrhea/enteritis, by mid-century the leading causes had become heart disease, cancer, and cerebrovascular disease. Nurses helped to reduce communicable disease mortality through immunization campaigns, nutrition education, and provision of better hygiene and sanitation. Additional factors included improved medications, better housing, and innovative emergency and critical care services. Studies such as the National Health Survey of 1935-1936 had documented the national transition from communicable to chronic disease as the primary cause of significant illness and death. However, public policy and nursing services were diverted from addressing the emerging problem, first by the 1930s Depression and then by World War II.

As the aged population grew from 4.1% of the total in 1900, to 9.2% in 1950, so did the prevalence of chronic illness. Faced with a client population characterized by extended life spans and increased longevity after chronic illness diagnosis, nurses addressed new challenges related to chronic illness care, long-term illness and disability, and chronic disease prevention. In official health agencies, categorical programs focusing on a single chronic disease emphasized narrowly defined services, which might be poorly coordinated with other community programs. Screening for chronic illness was a popular method of both detecting undiagnosed disease and providing individual and community education.

Some VNAs adopted coordinated home care programs to provide complex, long-term care to the chronically ill, often after long-term hospitalization. These home care programs established a multidisciplinary approach to complex client care. For example, beginning in 1949, the Visiting Nurse Society of Philadelphia provided care to clients with stroke, arthritis, cancer, and fractures using a wide range of services, including physical and occupational therapy, nutrition consultation, social services, laboratory and radiographic procedures, and transportation services. During the 1950s, often in response to family demands and the shortage of nurses, many visiting nurse agencies began experimenting with auxiliary nursing personnel,

variously called housekeepers, homemakers, or home health aides. These innovative programs provided a substantial basis for an approach to bedside nursing care that would be reimbursable by commercial health insurance (such as Blue Cross) and later by Medicare and Medicaid.

The increased prevalence of chronic illness also encouraged a resurgence in combination agencies—the joint operation of official (city or county) health departments and voluntary visiting nurse agencies by a unified staff. The nursing profession preferred that services be provided in a coordinated, cost-effective manner respectful to the families served, as well as to avoid duplication of care. Where nursing services were specialized, one household might simultaneously receive care from three different agencies for postpartum and newborn care, tuberculosis follow-up, and stroke rehabilitation. In cities with combination agencies, a minimal number of nurses provided improved services, ensuring continuity of care at a cheaper price. No longer would an agency “pick up and drop a baby,” but instead would follow the child through infancy, preschool, school, and into adulthood as part of one public health nursing program using one client record. The “ideal program” of the combination agency proved difficult to fund and administer, and many of the combination services implemented between 1930 and 1965 later retrenched into their former divided, public and private structures.

During the 1950s, public health nursing practice, like nursing in general, increased its focus on the psychological elements of client, family, and community care. To be more effective as helping professionals, nurses sought improved understanding of their own behavior, as well as the behavior of their clients and their coworkers. The nurse’s responsibility for health and human needs expanded to include stress and anxiety reduction associated with situational or developmental stressors, such as birth, adolescence, and parenting. Public health nurses sought a comprehensive approach to mental health that avoided dividing persons into physical components and emotional components (Abramovitz, 1961). The following Evidence-Based Practice example traces the development of nursing and home health care in the United States.

DECLINING FINANCIAL SUPPORT FOR PRACTICE AND PROFESSIONAL ORGANIZATIONS

During the 1930s and 1940s hospitals became the preferred place for illness care and childbirth. Improved technology and the concentration of physicians’ work in the acute care hospital were influential, but the development of health insurance plans such as Blue Cross provided a means for the middle class to seek care outside the traditional arena of the home. Federal health policy after World War II supported the growth of institutional care in hospitals and nursing homes rather than community-based alternatives. Figure 2-3 depicts a public health nurse speaking with a family on their porch. Home visiting although valuable to health care was not consistently supported by insurance companies.

EVIDENCE-BASED PRACTICE

No Place Like Home: A History of Nursing and Home Care in the United States (Buhler-Wilkerson, 2001) is a book-length analysis of the development of nursing care for those at home. Buhler-Wilkerson traces how the care of the sick moved from a domestic function to a charitable or public responsibility provided through visiting nurse associations and official health agencies. The central dilemma she raises is, “why, despite its potential as a preferred, rational, and possibly cost-effective alternative to institutional care, home care remains a marginalized experiment in caregiving” (p. xi).

Buhler-Wilkerson follows the origins of home care from its beginnings in Charleston, South Carolina, to its expansion into northern cities at the end of the nineteenth century. She interprets the founding of public health nursing by Lillian Wald “as a new paradigm for community-based nursing practice within the context of social reform” (p. xii), and she particularly analyzes the effects of ethnicity, race, and social class. She traces the difficulties of organizing and financing care of the sick in the home, including the work of private duty nurses and the role of health insurance in shaping home services. The concluding section of the book highlights contemporary themes of “chronic illness, hospital dominance, financial viability, and struggles to survive” (p. xii) and projects the future of home care.

Buhler-Wilkerson brings to bear the stories of patients’ needs and nurses’ work against the financial challenges that have characterized home care. While focusing on one element, this book raises important questions for nurses’ work across elements of community/public health nursing. Clearly identified need does not by itself open the doors to adequate financing for nursing care of the sick, for public health nursing, or for population care for health promotion.

Nurse Use

This book points out the complex issues involved in trying to provide the most effective care to patients. The needs of patients and their families may not entirely correlate with what is financially available. A lesson for each of us to learn is the following: Identified need does not always influence the availability of funds to provide the desired care.

From Buhler-Wilkerson K: *No Place Like Home: A History of Nursing and Home Care in the United States*. Baltimore, 2001, Johns Hopkins Press.

FIG 2-3 A public health nurse talks with a young woman and her mother about childbirth, as they sit on a porch. (U.S. Public Health Service photo by Perry, Images from the History of Medicine, National Library of Medicine, Image ID 157037.)

Financing for voluntary nursing agencies was greatly reduced in the early 1950s when both the Metropolitan and John Hancock Life Insurance Companies stopped funding visiting nurse services for their policyholders. The life insurance companies had found nursing services financially beneficial when communicable disease rates were high in the 1910s and 1920s, but reductions in communicable disease rates, improved infant and maternal health, and the increased prevalence of expensive chronic illnesses reduced sponsor interest in financing home visiting. The American Red Cross also discontinued its programs of direct nursing service by the mid-1950s.

The NOPHN had long sought additional approaches for funding public health nursing. Beginning in the 1930s, the NOPHN collaborated with the American Nurses Association (ANA) through the Joint Committee on Prepayment. Both organizations had identified the growth potential of early health insurance innovations. Voluntary nursing agencies developed a variety of initiatives to secure health insurance reimbursement for nursing services, including demonstration projects and educational campaigns directed toward nurses, physicians, and insurers. Blue Cross and other hospital insurance programs gradually adopted a formula that exchanged unused days of hospitalization coverage for postdischarge nursing care at home. Unlike organized medicine and hospital associations, nursing organizations contributed substantially to securing federal medical insurance for the aged, which was implemented as the Medicare program in 1966. The support of the ANA, so integral to the passage of Medicare legislation, was publicly recognized by President Lyndon Baines Johnson at the 1965 ceremony to sign the bill.

Despite the successes and importance of the NOPHN, by the late 1940s its membership had declined and financial support was weak. At the same time, the nursing profession as a whole sought to reorganize its national organizations to improve unity, administration, and financial stability. Three existing organizations—the NOPHN, the National League for Nursing Education, and the Association of Collegiate Schools of Nursing—were dissolved in 1952. Their functions were distributed primarily to the new **National League for Nursing**. The **American Nurses Association**, which merged with the National Association of Colored Graduate Nurses, continued as the second national nursing organization. Occupational health nursing and nurse-midwifery organizations declined to join the consolidation, and both nursing specialties have continued to set their own course. School nurses also soon established a separate specialty organization. Despite the optimism of the national reorganization and its success in some areas, the subsequent loss of independent public health nursing leadership and focus resulted in a weakened specialty.

PROFESSIONAL NURSING EDUCATION FOR PUBLIC HEALTH NURSING

The National League for Nursing enthusiastically adopted the recommendations of Esther Lucile **Brown's** 1948 study of nursing education, reported as *Nursing for the Future* (Brown, 1948). Her recommendation to establish basic nursing

preparation in colleges and universities was consistent with the NOPHN's goal of including public health nursing concepts in all basic baccalaureate programs. The NOPHN believed that this would remedy the preparation problems found among many nurses new to the practice and would thus upgrade the public health nursing profession. Unfortunately, the implementation of the plan fell short, and training programs in public health nursing for college and university faculty were very brief and inadequate. The population focus of public health nursing toward groups and the larger community was compromised and became less distinct in the hands of educators who themselves lacked education and practice in public health nursing.

During the 1950s, public health nursing educators carefully considered steps to enhance undergraduate and graduate education. Educational programs for public health nurses were then found in schools of nursing, schools of public health, and other university departments. Although all claimed legitimacy, collegiate education for nurses gradually moved completely into schools of nursing. The Haven Hill Conference (NOPHN, 1951) and Gull Lake Conference (Robeson and McNeil, 1957) clarified roles and definitions, built expectations for graduate education, and set standards for undergraduate field experiences. As public health nursing education drew closer to university schools of nursing, it adopted and applied broad principles characteristic of general nursing education. For example, rather than have the education director of the placement agency teach nursing students as done previously, collegiate programs themselves hired faculty who provided direct student supervision at community placements (NOPHN, 1951; Robeson and McNeil, 1957). The How To box describes the way to conduct an oral history interview in order to preserve vital information about public health nursing.

HOW TO

Nurse historians are increasingly using oral history methodology to uncover and preserve the history of public health nursing and individual nurses on audio files and written transcripts.

Conduct an Oral History Interview

1. Identify an issue or event of interest.
2. Research the issue or event, using a variety of written and/or photographic materials.
3. Locate a potential oral history interviewee or narrator.
4. Obtain the agreement of the narrator to be interviewed. Arrange an interview appointment.
5. Research the narrator's background and the time period of interest.
6. Write an outline of questions for the narrator. Open-ended questions are especially helpful.
7. Meet with the narrator. Bring an audio recorder to the interview.
8. Interview the narrator. Ask one brief question at a time. Give the narrator time to consider your question and answer it.
9. Ask clarifying questions. Ask for examples. Give encouragement. Allow the narrator to tell his or her story without interruption.
10. After the interview, transcribe the interview tape and prepare a written transcript (some digital programs can immediately produce a written transcript).
11. Carefully compare the written transcript with the narrator's recorded interview. It may be appropriate to have the narrator review and edit the written transcript.

12. If you have made written arrangements with the narrator, place the oral history audio and transcripts in an appropriate archive or library (highly recommended).

Keep In Mind: Oral history is a type of nursing research. Please consider that oral history interviews may require formal consent by the interviewee or narrator before the interview, as well as prior approval of the research from an institutional review board.

Consult the Literature: An example of oral history is presented in an article on the Michigan Oral History Project (Gates et al, 1994).

NEW RESOURCES AND NEW COMMUNITIES: THE 1960s AND NURSING

Beginning in earnest in the late 1940s but on the basis of advocacy begun in the late 1910s, policymakers and social welfare representatives sought to establish national health insurance. In 1965 Congress amended the Social Security Act to include health insurance benefits for older adults (Medicare) and increased care for the poor (Medicaid). Unfortunately, the revised Social Security Act did not include coverage for preventive services, and home health care was reimbursed only when ordered by a physician. Nevertheless, this latter coverage prompted the rapid proliferation of home health care agencies, with for-profit agencies responding to new financial opportunities. Many local and state health departments rapidly changed their policies to include reimbursable home health care as bedside nursing. This could result in reduced health promotion and disease prevention activities, as funding for these activities was less stable. From 1960 to 1968, the number of official agencies providing home care services grew from 250 to 1328, and the number of for-profit agencies continued to grow (Kalisch and Kalisch, 2004).

COMMUNITY ORGANIZATION AND PROFESSIONAL CHANGE

Social changes during the 1960s and 1970s influenced both nursing and public health. "The emerging civil rights movement shifted the paradigm from a charitable obligation to a political commitment to achieving equality and compensation for racial injustices of the past" (Scutchfield and Keck, 1997, p. 328). New programs addressed economic and racial differences in health care services and delivery. Funding was increased for maternal and child health, mental health, mental retardation, and community health training. Beginning in 1964, the federal Economic Opportunity Act provided funds for neighborhood health centers, Head Start, and other community action programs. Neighborhood health centers increased community access for health care, especially for maternal and child care. The work of Nancy Milio in Detroit, Michigan, is an example of this commitment to action with the community. Milio built a dynamic decision-making process that included neighborhood residents, politicians, the Visiting Nurse Association and its board, civil rights activists, and church leaders. The Mom and Tots Center emerged as a neighborhood-centered service to provide maternal and child health services and a day-care center. Milio (1971) recorded this story in her book, 9226

FIG 2-4 A Visiting Nurse Association nurse demonstrates proper infant care and bathing techniques to the parents. (Images from the History of Medicine, National Library of Medicine, Image ID 144048.)

Kercheval: The Storefront That Did Not Burn. As shown in [Figure 2-4](#) visiting nurses provided vital services to families.

New personnel also added to the flexibility of the public health nurse to address the needs of communities. Beginning in 1965 at the University of Colorado, the nurse practitioner movement opened a new era for nursing involvement in primary care that affected the delivery of services in community health clinics. Initially, the nurse practitioner was often a public health nurse with additional skills in the diagnosis and treatment of common illnesses. Although some nurse practitioners chose to practice in other clinical areas, those who continued in public health settings made sustained contributions to improving access and providing primary care to people in rural areas, inner cities, and other medically underserved areas ([Roberts and Heinrich, 1985](#)). As evidence of the effectiveness of their services grew, nurse practitioners became increasingly accepted as cost-effective providers of a variety of primary care services.

PUBLIC HEALTH NURSING FROM THE 1970s INTO THE TWENTY-FIRST CENTURY

During the 1970s, nursing was viewed as a powerful force for improving the health care of communities. Nurses made significant contributions to the hospice movement, the development of birthing centers, day care for older adult and disabled persons, drug abuse programs, and rehabilitation services in long-term care. Federal evaluation of the effectiveness of care was emphasized ([Roberts and Heinrich, 1985](#)).

By the 1980s, concern grew about the high costs of health care in the United States. Programs for health promotion and disease prevention received less priority as funding was shifted to meet the escalating costs of acute hospital care, medical procedures, and institutional long-term care. The use of ambulatory services including health maintenance organizations was

encouraged, and the use of nurse practitioners increased. Home health care weathered several threats to adequate reimbursement and, by the end of the decade, had secured favorable legal decisions that increased its impact on the care of the sick at home. Individuals and families assumed more responsibility for their own health because health education, always a part of nursing, became increasingly popular. Advocacy groups representing both consumers and professionals urged the passage of laws to prohibit unhealthy practices in public such as smoking and driving under the influence of alcohol. Sophisticated media campaigns contributed to changing health behaviors and improving health status. As federal and state funds grew scarce, fewer nurses were employed by official public health agencies. Committed and determined to improve the health care of Americans, nurses continued to press for greater involvement in official and voluntary agencies ([Roberts and Heinrich, 1985](#); [Kalisch and Kalisch, 2004](#)).

The National Center for Nursing Research (NCNR), established in 1985 within the federal National Institutes of Health near Washington, DC, had a major impact on promoting the work of nurses. Through research, nurses analyze the scope and quality of care provided by examining the outcomes and cost-effectiveness of nursing interventions. With the concerted efforts of many nurses, the NCNR gained official institute status within the National Institutes of Health in 1993, becoming the National Institute of Nursing Research (NINR).

By the late 1980s, public health as a whole had declined significantly in its effectiveness in accomplishing its mission and in shaping the public's health. Significant reductions in local and national political support, financing, and outcomes were vividly described in a landmark report by the Institute of Medicine, *The Future of Public Health* ([Institute of Medicine \[IOM\], 1988](#)). The IOM study group found America's public health system in disarray and concluded that, although there was widespread agreement about what the mission of public health should be, there was little consensus on how to translate that mission into action. Not surprisingly, the IOM reported that the mix and level of public health services varied extensively across the United States ([Williams, 1995](#)).

The Future of Public Health ([IOM, 1988](#)) determined that "contemporary public health is defined less by what public health professionals know how to do than by what the political system in a given area decides is appropriate or feasible" (p. 4). Nurses working in health departments saw underfunding reduce the breadth and depth of their role. When local public health departments provided insufficient care, voluntary agencies such as VNAs stepped in to assist vulnerable groups. However, without adequate funding for care of the poor, VNAs and other voluntary home health agencies faced hard economic choices, and some closed their doors.

America's *Healthy People* initiative has influenced goals and priority setting in both public health and nursing, beginning in 1979 ([U.S. Department of Health, Education, and Welfare, 1979](#)), with the current objectives detailed in *Healthy People 2020* ([U.S. Department of Health and Human Services \[USDHHS\], 2010](#)). Evidence-based practice recommendations that complement the *Healthy People* initiative are detailed

for health promotion, disease prevention, and screening in primary care through the clinical guidelines from the *U.S. Preventive Services Task Force, Guide to Clinical Preventive Services* (2014), and for groups and communities, through *The Guide to Community Preventive Services*, now known also as *The Community Guide* (Community Preventive Services Task Force, 2014). Implementation of these strategies has influenced the work of public health nurses through their employment in health agencies and through participation in state or local health coalitions. See the *Healthy People* box that follows and that traces the development of this important series of documents.

The health care debate in the 1990s focused on cost, quality, and access to direct care services. Despite considerable interest in health care reform and securing universal health insurance coverage, the core economic debate—who will pay for what—emphasized reform of medical care rather than comprehensive changes in health promotion, disease prevention, and health care. In 1993, the American Health Security Act received insufficient Congressional support. Reflecting the weakness of public health, the aims of public health were never clearly considered in the proposed program. Proposals to reform existing services also failed to apply the lesson learned from the *Healthy People* initiative—that health promotion and disease prevention appear to yield reductions in costs and illness/injury incidence while increasing years of healthy life.

In 1991 the ANA, the American Association of Colleges of Nursing, the National League for Nursing, and more than 60 other specialty nursing organizations joined to support health care reform. The coalition of nursing organizations emphasized key health care issues of access, quality, and cost, and proposed a range of interventions designed to build a healthy nation through improved primary care and public health efforts. Professional nursing's continued support for improved health care access and reduced cost was rewarded in 2010 with the passage of the federal Patient Protection and Affordable Care Act. These successes emphasize that public health nursing must continue to advocate for extension of public health services to prevent illness, promote health, and protect the public.

The Quad Council of Public Health Nursing Organizations was founded in the early 1980s, and is composed of representatives from four organizations that include public health nurses: The Association of State and Territorial Directors of Nursing (ASTDN, established in 1935), known since 2012 as the Association of Public Health Nurses (APHN); the Association of Community Health Nursing Educators (ACHNE, established in 1977); the Public Health Nursing Section of the American Public Health Association (PHN-APHA; the Section was formed in 1923); and the American Nurses Association Council on Nursing Practice and Economics (ANA).

HEALTHY PEOPLE 2020

History of the Development of *Healthy People*

In 1979 the groundbreaking *Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention* asserted that “the health of the American people has never been better” (U.S. Department of Health, Education, and Welfare [USDHEW], 1979, p. 3). But this was only the prologue to deep criticism of the status of American health care delivery. Between 1960 and 1978, health care spending increased 700%—without related improvements in mortality or morbidity. During the 1950s and 1960s, evidence had accumulated about chronic disease risk factors, particularly cigarette smoking, alcohol and drug use, occupational risks, and injuries. But these new research findings were not systematically applied to health planning and to improving population health.

In 1974 the Government of Canada published *A New Perspective on the Health of Canadians* (Lalonde, 1974), which found death and disease to have four contributing factors: inadequacies in the existing health care system, behavioral factors, environmental hazards, and human biological factors. Applying the Canadian approach, in 1976 U.S. experts analyzed the 10 leading causes of U.S. mortality and found that 50% of American deaths were the result of unhealthy behaviors, and only 10% were the result of inadequacies in health care. Rather than just spending more to improve hospital care, clearly prevention was the key to saving lives, improving the quality of life, and saving health care dollars.

A multidisciplinary group of analysts conducted a comprehensive review of prevention activities. They verified that the health of Americans could be significantly improved through “actions individuals can take for themselves” and through actions that public and private decision makers could take to “promote a safer and healthier environment” (p. 9). Similar to Canada's *New Perspectives*,

America's *Healthy People* (USDHEW, 1979) identified priorities and measurable goals. *Healthy People* grouped 15 key priorities into three categories: key preventive services that could be delivered to individuals by health providers, such as timely prenatal care; measures that could be used by governmental and other agencies, as well as industry, to protect people from harm, such as reduced exposure to toxic agents; and activities that individuals and communities could use to promote healthy lifestyles, such as improved nutrition.

In the late 1980s, success in addressing these priorities and goals was evaluated, new scientific findings were analyzed, and new goals and objectives were set for the period from 1990 to 2000 through *Healthy People 2000: National Health Promotion and Disease Prevention Objectives* (U.S. Department of Health and Human Services [USDHHS], 1991). This process was repeated 10 years later to develop goals and objectives for the period 2000 to 2010 (USDHHS, 2000), and for the current decade of 2010 to 2020—*Healthy People 2020: Improving the Health of Americans* (USDHHS, 2010). Recognizing the continuing challenge to using emerging scientific research to encourage modification of health behaviors and practices, *Healthy People 2020* addresses health equity, elimination of disparities, and improved health for all groups across the life span through disease prevention, improved social and physical environments, and healthy development and health behaviors.

Just as the public health nurse in the early twentieth century spread the “gospel of public health” to reduce communicable diseases, today's population-centered nurse uses *Healthy People* to reduce chronic and infectious diseases and injuries through health education, environmental modification, and policy development.

Lalonde M: *A New Perspective on the Health of Canadians*. Ottawa, Canada, 1974, Information Canada; U.S. Department of Health and Human Services: *Healthy People 2010: Understanding and Improving Health*, ed 2. Washington, DC, 2000, U.S. Government Printing Office; U.S. Department of Health and Human Services: *Healthy People 2020: The Road Ahead*. Available at: <http://www.healthypeople.gov/hp2020/>. Accessed December 2, 2010; U.S. Department of Health, Education, and Welfare: *Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention*. DHEW Publication No. 79-55071, Washington, DC, 1979, U.S. Government Printing Office; U.S. Public Health Service: *Healthy People 2000: National Health Promotion and Disease Prevention Objectives*. Washington, DC, 1991, U.S. Government Printing Office.

During the 1990s and 2000s the Quad Council of Public Health Nursing Organizations supported the efforts of its organizational members and public health organizations to establish mechanisms to improve quality of care and to advance the public health nursing profession in the twenty-first century. For example, the certification of public health nurses with graduate degrees was reinforced through collaborative agreements with the American Nurses Credentialing Center (ANCC). The Quad Council also revised its *Competencies for Public Health Nurses* in 2011. The competencies are separated into three tiers: Tier 1 for generalist public health nurses who conduct clinical, home visiting and population-based services; Tier 2 for public health nurses with management and/or supervisory responsibilities; and Tier 3 for public health nurses at executive, senior management, or leadership levels in public health nursing organizations. Under Domain #6, a public health nurse “Describes the historical foundation of public health and public health nursing” (Quad Council, 2011, p. 17).

In addition to the actions of the Quad Council itself, the four constituent members of the Council have also worked in their areas of expertise to link content to the practice of public health nursing through their development of standards and competencies that influence practice in various ways.

The Association of Community Health Nursing Educators developed important position papers, including *Graduation Education for Advanced Practice Public Health Nursing* (ACHNE, 2007) and *Academic Faculty Qualifications for Community/Public Health Nursing* (ACHNE, 2009). The Association of State and Territorial Directors of Nursing asserted the importance of public health nurses within public health systems through the publication of *Every State Health Department Needs a Public Health Nurse Leader* (ASTDN, 2008). And the Association of Public Health Nurses revised the ASTDN position paper on *The Role of the Public Health Nurse in Disaster Preparedness, Response, and Recovery* (APHN, 2014).

The Council on Linkages between Academia and Public Health Practice provides exchanges and collaborations among all public health disciplines, including public health nursing. The Council’s *Core Competencies for Public Health Professionals* (2014) features a core competency under the domain of public health sciences skills: “Identifies prominent events in the history of the public health profession” (p. 17).

The American Nurses Association’s *Scope and Standards of Public Health Nursing Practice* (ANA, 2013) is a key guide for the practice of public health nursing. Periodically revised, the *Scope and Standards* is developed by a group of public health nursing leaders representing the major public health nursing organizations and reflects the central ideas of public health nursing. As there is substantial agreement about the characteristics and goals of public health nursing across organizations, it is not surprising that the ANA *Scope and Standards* and the Quad Council’s *Public Health Nursing Competencies* both include the processes of assessment, analysis, and planning. Each also incorporates the importance of communication, cultural competency, policy, and public health skills in their recommendations for effective public health nurse practice. The Linking Content to Practice box describes how historically public health nursing journals have preserved the history of public health nursing.

LINKING CONTENT TO PRACTICE

Public Health Nursing, a major journal in the field of public health nursing, publishes articles that very broadly reflect contemporary research, practice, education, and public policy for population-based nurses. Begun in 1984, *Public Health Nursing (PHN)* was published quarterly through 1993, and has been a bimonthly journal since 1994. Marilyn G. King, DNSc, RN, is the historical editor and Patricia J. Kelly, PhD, MPH, APRN, is the journal’s current editor (2014).

More than any other journal, *PHN* has assumed responsibility for preserving the history of public health nursing and for publishing new historical research on the field. The contemporary *Public Health Nursing* shares its name with the official journal of the National Organization for Public Health Nursing in the period 1931 to 1952 (earlier names were used for the official journal from 1913 to 1931, which built on the *Visiting Nurse Quarterly*, published 1909 to 1913).

The contemporary *Public Health Nursing* presents a wide variety of articles, including both new historical research and reprints of classic journal articles that deserve to be read and reapplied by modern public health nurses. One historical article reprinted in *PHN* addressed a nurse’s 1931 work on county drought relief that underscores continuing professional themes of case-finding, collaboration, and partnership (Wharton, 1999). Another historical reprint recalled the important 1984 dialogue between two public health nurse leaders, Virginia A. Henderson and Sherry L. Shamansky, with an added contextual introduction from Sarah Abrams (Abrams, 2007). Original historical research presented in *PHN* is extremely varied, from public health nursing education, to public health nurse practice in Alaska’s Yukon, to excerpts from the oral histories of public health nurses.

Contemporary nurses find inspiration and possibilities for modern innovations in reading the history of public health nursing in the pages of *PHN*.

Abrams SE: Nursing the community, a look back at the 1984 dialogue between Virginia A. Henderson and Sherry L. Shamansky. *PHN* 24:382, 2007; reprinted from *PHN* 1:193, 1984; Wharton AL: County drought relief: a public health nurse’s problem. *PHN* 16(4):307–308, 1999; reprinted from *PHN* 23, 1931.

PUBLIC HEALTH NURSING TODAY

In the last decades, new and continuing challenges have triggered growth and change in nursing. Where existing organizations have been unable to meet community and neighborhood needs, nurse-managed health centers provide a diversity of nursing services, including health promotion and disease/injury prevention. New populations in communities continue to challenge schools of nursing, health departments, rural health clinics, and migrant health services to provide the range of services to meet specific needs, including the needs of new immigrants. Transfer of official health services to private control has sometimes reduced professional flexibility and service delivery. Nurses also make the difficult choice to leave public health nursing to work in acute care, where the salaries are often higher. This is even more prominent in times of a nursing shortage. The Association of Community Health Nurse Educators calls for increased graduate programs to educate public health nurse leaders, educators, and researchers. Natural disasters (such as floods, hurricanes, and tornados) and human-made disasters (including explosions, building collapses, and airplane crashes) require innovative and time-consuming responses. Preparation for future disasters and potential bioterrorism demands the presence of well-prepared nurses. Many of these stories are detailed in the chapters that follow.

Some states have heard renewed persuasion to deploy school nurses in every school; a new recognition of the link between

school success and health is again making the school nurse essential. Evidence from cost-benefit research on school nursing services underscores modern financial advantages for families and communities (Wang et al, 2014). Renewed evidence is also available from research on the use of nurses for prenatal and infant/toddler home visits to reduce “all-cause mortality among mothers and preventable-cause mortality in their first-born children living in highly disadvantaged settings” (Olds et al, 2014, p. E1). Even though both of these research inquiries have related precedents in the history of nursing, contemporary public health nurses must seek research approaches to demonstrate the outcomes of this work.

Today, public health nurses’ past contributions ground twenty-first century public health nurses in a narrative that explains and gives importance to contemporary work. Nurses

look to their history for inspiration, explanation, and prediction. Information and advocacy are used to promote a comprehensive approach to address the multiple needs of the diverse populations served. In the twenty-first century, public health nursing both reflects the past and builds on and beyond it.

Nurses will seek to learn from the past and to avoid known pitfalls, even as they seek successful strategies to meet the complex needs of today’s vulnerable populations. As plans for the future are made, and as the public health challenges that remain unmet are acknowledged, it is this vision of what nursing can accomplish that sustains these nurses. In public health nursing as in all other specialty areas, quality and safety are key issues. The box below outlines the six Quality and Safety in Nursing Education (QSEN) competencies and describes the development of these competencies.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Although the scope and responsibilities of public health nurses have changed over time, the commitment to quality and safety has remained constant. Since the beginning of population-centered nursing in the United States, the nurses who worked in this specialty have been committed to preserving health and preventing disease. They have focused on environmental conditions such as sanitation and control of communicable diseases, education for health, prevention of disease and disability, and at times care of the sick and aged in their homes. This long-standing commitment to quality and safety is consistent with the work of *Quality and Safety Education for Nurses* (QSEN), a national initiative designed to transform nursing education by including in the curriculum content and experiences related to building knowledge, skills and attitudes for six quality and safety initiatives (Cronenwett, Sherwood, and Gelmon, 2009). The QSEN work, led by Drs. Linda Cronenwett and Gwen Sherwood at the University of North Carolina, has made great progress in bridging the gap between quality and safety work in both practice and academic settings (Brown, Feller, and Benedict, 2010). The six QSEN competencies for Nursing are:

- 1. Patient-centered care:** Recognizes the client or designee as the source of control and as a full partner in providing compassionate and coordinated care that is based on the preferences, values, and needs of the client.
- 2. Teamwork and collaboration:** Refers to the ability to function effectively with nursing and interprofessional teams and to foster open communication, mutual respect, and shared decision making to provide quality client care.
- 3. Evidence-based practice:** Integrates the best current clinical evidence with client and family preferences and values to provide optimal client care.
- 4. Quality improvement:** Uses data to monitor the outcomes of the care processes and uses improvement methods to design and test changes to continually improve quality and safety of health care systems.
- 5. Safety:** Minimizes the risk for harm to clients and provides through both system effectiveness and individual performance.
- 6. Informatics:** Use information and technology to communicate, manage knowledge, mitigate error, and support decision making (Brown et al, 2010, p. 116).

Of the six QSEN competencies, all but safety were derived from the Institute of Medicine report, *Health Professions Education* (2003). The QSEN team added safety because this competency is central to the work of nurses. Articles have been published to teach educators about QSEN, and national forums have been held. Also the American Association of Colleges of Nursing (AACN) has held faculty development institutes for faculty and academic administrators using a train-the-trainer model, and safety and quality objectives have been built in the

AACN essentials for nursing education. Similarly, the National League for Nursing has incorporated the “NLN Educational Competencies Model” into their educational summits. The six QSEN competencies will be integrated in the chapters throughout the text to emphasize the importance of quality and safety in public health nursing today. *NOTE:* The terms *patient* and *care* will be changed to *client* and *intervention* to reflect a public health nursing approach.

Specifically related to the history of nursing, the following targeted competency can be applied:

- **Targeted Competency: Safety**—Minimizes risk for harm to clients and providers through both system effectiveness and individual performance.

Important aspects of safety include:

- **Knowledge:** Discuss potential and actual impact of national client safety resources initiatives and regulations
- **Skills:** Participate in analyzing errors and designing system improvements
- **Attitudes:** Value vigilance and monitoring by clients, families, and other members of the health care team

Safety Question

Updated definitions around client safety include addressing safety at the individual level and at the systems level. The history of public health nursing demonstrates the myriad ways that public health nurses have addressed client safety in their evolving practice. Public health nurses support safety through caring for individuals and providing care for communities and groups. Historically, how have public health nurses addressed safety at the individual client level? How have public health nurses addressed client safety at the systems level? How have public health nurses been involved in system improvements?

Answer: *Individual level: A rich part of public health nursing’s history has been the development of home visitation, in which clients are cared for in their own environment. Similarly, public health nurses have improved client outcomes by pioneering new models of interventions for maternal–child health and individuals in rural communities.*

Systems level: *Through their work with communities, public health nurses were an integral part of reducing the incidence of communicable diseases by the mid-twentieth century. More recently, public health nursing has contributed to health care system improvements through the development of the hospice movement, birthing centers, day care for elderly and disabled persons, and drug-abuse and rehabilitation services. These initiatives have updated the health care system to provide targeted care for previously overlooked populations.*

PRACTICE APPLICATION

Mary Lipsky has worked for the county health department in a major urban area for almost 2 years. Her nursing responsibilities include a variety of services, including consultations at a senior center, maternal/newborn home visits, and well-child clinics. As she leaves work each evening and returns to her own home, she keeps thinking about her clients. Why was it so difficult today to qualify a new mother and her baby to receive WIC (Women, Infants, and Children) nutrition services? Why must she limit the number of children screened for high lead levels, when last year the health department screened twice as many children? Several children last month seemed asymptomatic, but the laboratory found lead levels that were high enough

to cause damage. One of the mothers Ms. Lipsky is acquainted with is having a difficult time emotionally. Why is it so difficult to find a behavioral health provider for her? And the health department still cannot find a new staff dentist! And families on welfare cannot find a private dentist to care for their children.

- A. Why might it be difficult to solve these problems at the individual level, on a case-by-case basis?
- B. What information would you need to build an understanding of the policy background for each of these various populations?

Answers can be found on the Evolve site.

KEY POINTS

- A historical approach can be used to increase understanding of public health nursing in the past, as well as its current dilemmas and future challenges.
- The history of public health nursing can be characterized by change in specific focus of the specialty but continuity in approach and style of the practice.
- Public health nursing, referred to in this text as population-centered nursing, is a product of various social, economic, and political forces; it incorporates public health science in addition to nursing science and practice.
- Federal responsibility for health care was limited until the 1930s, when the economic challenges of the Depression permitted reexamination of local responsibility for care.
- Florence Nightingale designed and implemented the first program of trained nursing, and her contemporary, William Rathbone, founded the first district nursing association in England.
- Urbanization, industrialization, and immigration in the United States increased the need for trained nurses, especially in public health nursing.
- Increasing acceptance of public roles for women permitted public health nursing employment for nurses, as well as public leadership roles for their wealthy supporters.
- In 1887 the Women's Board of the New York City Mission hired Frances Root, a trained nurse, to provide care to sick persons at home.
- The first visiting nurses' associations were founded in 1885 and 1886 in Buffalo, Philadelphia, and Boston.
- Lillian Wald established the Henry Street Settlement, which became the Visiting Nurse Service of New York City, in 1893. She played a key role in innovations that shaped public health nursing in its first decades, including school nursing, insurance payment for nursing, national organization for public health nurses, and the United States Children's Bureau.
- Founded in 1902 with the vision and support of Lillian Wald, school nursing sought to keep children in school so that they could learn.
- The Metropolitan Life Insurance Company established the first insurance-based program in 1909 to support community health nursing services.
- The National Organization for Public Health Nursing (founded in 1912) provided essential leadership and coordination of diverse public health nursing efforts; the organization merged into the National League for Nursing in 1952.
- Official health agencies slowly grew in numbers between 1900 and 1940, accompanied by a steady increase in public health nursing positions.
- The innovative Sheppard-Towner Act of 1921 expanded community health nursing roles for maternal and child health during the 1920s.
- Mary Breckinridge established the Frontier Nursing Service in 1925, which influenced provision of rural health care.
- African-American nurses seeking to work in public health nursing faced many challenges, but ultimately had significant impact on the communities they served.
- Tension between the nursing role of caring for the sick and the role of providing preventive care, and the related tension between intervening for individuals and intervening for groups, have characterized the specialty since at least the 1910s.
- As the Social Security Act attempted to remedy some of the setbacks of the Depression, it established a context in which public health nursing services expanded.
- The challenges of World War II sometimes resulted in extension of nursing care and sometimes in retrenchment and decreased public health nursing services.
- By the mid-twentieth century, the reduced prevalence of communicable diseases and the increased prevalence of chronic illness, accompanied by large increases in the population more than 65 years of age, led to examination of the goals and organization of public health nursing services.
- Between the 1930s and 1965, organized nursing and community health nursing agencies sought to establish health insurance reimbursement for nursing care at home.
- Implementation of Medicare and Medicaid programs in 1966 established new possibilities for supporting community-based nursing care but encouraged agencies to focus on services provided after acute care rather than on prevention.
- Efforts to reform health care organization, pushed by increased health care costs during the last 40 years, have

KEY POINTS—cont'd

- focused on reforming acute medical care rather than on designing a comprehensive preventive approach.
- The 1988 Institute of Medicine report documented the reduced political support, financing, and impact that increasingly limited public health services at national, state, and local levels.
- In the late 1990s, federal policy changes dangerously reduced financial support for home health care services, threatening the long-term survival of visiting nurse agencies.
- Healthy People 2000* (USDHHS, 1991), *Healthy People 2010* (USDHHS, 2000), and recent disasters and acts of terrorism have brought renewed emphasis on prevention to nursing.

CLINICAL DECISION-MAKING ACTIVITIES

- Interview nurses at your clinical placement about the changes they have seen during their years in a population-centered nursing practice. How do these changes relate to the changing needs of the community or the population?
- Identify the visible record of nursing agencies in your community. Note the buildings, plaques, and display cases that document the past provision of nursing care in community settings. What forces have influenced these agencies over time? Which factors do they wish to make known publicly, and which factors are less apparent?
- Secure a copy of your clinical agency's recent annual report. How is the history of the agency presented? How does this agency's history fit in with the points made in this chapter? What are your conclusions about how this agency's past influences its present?
- Interview older relatives for their memories of public health nursing care received by them, their families, and their friends. When they were younger, how was the public health nurse perceived in their community? What interventions were used by the public health nurse? How was the public health nurse dressed? How has the position of the public health or community health nurse changed?
- Of what element or aspect of the history of public health nursing would you like to learn more? At your nursing library, review a period of 10 years of one journal from the past to identify trends in how this element or aspect was addressed. What conclusions do you reach?
- The work and impact of several nursing leaders is reviewed or noted in this chapter. Of these leaders, which one strikes you as most interesting? Why? Locate and read further articles or books about this leader. What personal strengths do you note that supported this nurse's leadership?

The Changing U.S. Health and Public Health Care Systems

Marcia Stanhope, PhD, RN, FAAN

Dr. Marcia Stanhope is currently an Associate of the Tufts and Associates Search Firm, Chicago, Ill. She is also a consultant for the nursing program at Berea College, Kentucky. She has practiced community and home health nursing, has served as an administrator and consultant in home health, and has been involved in the development of two nurse-managed centers. At one time in her career, she held a public policy fellowship and worked in the office of a U.S. Senator. She has taught community health, public health, epidemiology, policy, primary care nursing, and administration courses. Dr. Stanhope formerly directed the Division of Community Health Nursing and Administration and served as Associate Dean of the College of Nursing at the University of Kentucky. She has been responsible for both undergraduate and graduate courses in population-centered nursing. She has also taught at the University of Virginia and the University of Alabama, Birmingham. During her career at the University of Kentucky she was appointed to the Good Samaritan Foundation Chair and Professorship in Community Health Nursing, and was honored with the University Provost's Public Scholar award. Her presentations and publications have been in the areas of home health, community health and community-focused nursing practice, as well as primary care nursing.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Describe the events and trends that influence the status of the health care system.
2. Discuss key aspects of the private health care system.
3. Compare the public health system to primary care.
4. Explain the model of primary health care.
5. Assess the effects of health care and insurance reform on health care delivery.
6. Evaluate the changes needed in public health and primary care to have an integrated health care delivery system.

KEY TERMS

advanced practice nursing (APN), p. 47

Affordable Care Act, p. 48

community participation, p. 54

Declaration of Alma-Ata, p. 45

disease prevention, p. 45

electronic health record (EHR), p. 47

health, p. 45

health promotion, p. 45

managed care, p. 50

primary care, p. 50

primary health care (PHC), p. 54

public health, p. 50

for the Nation

Health Care Delivery Reform Efforts—United States

As is known, the U.S. government began providing public health services in the 1700s, and public health nursing was first recognized 125 years ago (see [Chapter 2](#)). Although there were physicians in England in the 1600s and 1700s and in the United States since the 1700s, official recognition of the general practitioner (GP) occurred in England only in 1844. In the 1950s and 1960s in the United States, discussions were held to elevate the GP to a specialty practice in medicine. Thus family practice medicine became a reality in the 1960s ([ABFM, 2005](#)). After this development in medicine the first nurse practitioner program was begun in 1965 ([Medscape, 2000](#)). Then, in September 1978, an international conference was held in the city of Alma-Ata, which at that time was the capital of the Soviet Republic of Kazakhstan. During this conference, the [Declaration of Alma-Ata](#) and the primary health care model emerged (Appendix A.3). This declaration states that [health](#) is a human right and that the health of its people should be the primary goal of every government. One of the main themes of this declaration was the involvement of community health workers and traditional healers in a new health system ([World Health Organization \[WHO\], 1978](#)).

It was through this conference that the concept of primary health care (PHC) was introduced, defined, and described. In 2008, the WHO renewed its call for health care improvements and reemphasized the need for public policymakers, public health officials, primary care providers, and leadership within countries to improve health care delivery. The WHO said: “Globalization is putting the social cohesion of many countries under stress, and health systems ... are clearly not performing as well as they could and should. People are increasingly impatient with the inability of health services to deliver. ... Few would disagree that health systems need to respond better—and faster—to the challenges of a changing world. PHC can do that” ([WHO, 2008](#); and see [Chapter 4](#)).

As defined by the WHO, PHC reflects and evolves from the economic conditions and sociocultural and political characteristics of the country and its communities, and is based on the application of social, biomedical, and health services research and public health experience. It addresses the main health problems in the community, providing for [health promotion](#), [disease prevention](#), and curative and rehabilitative services ([WHO, 1978](#)).

Defined differently than primary care or public health, PHC promotes the integration of all health care systems within a community to come together to improve the health of the community, including primary care and public health.

HEALTH CARE IN THE UNITED STATES

Despite the fact that health care costs in the United States are the highest in the world and comprise the greatest percentage of the gross domestic product, the indicators of what constitutes good health do not document that Americans are really getting their money’s worth. In the first decade of the twenty-first century there have been massive and unexpected changes to health, economic, and social conditions as a result of terrorist attacks, hurricanes, fires, floods, infectious diseases, and an economic turndown in 2008. New systems have been developed to prevent and/or deal with the onslaught of these horrendous events. Not all of the systems have worked, and many are regularly criticized for their inefficiency and costliness. Simultaneously, new, nearly miraculous advances have been made in treating health-related conditions. Organs and joints are being replaced and medicines are keeping people alive who only a few years ago would have suffered and died. These advances and “wonder drugs” save and prolong lives, and a number of deadly and debilitating diseases have been eliminated through effective immunizations and treatments. In addition, sanitation, water supplies, and nutrition have been improved, and animal cloning has begun.

However, attention to all of these advances may overshadow the lack of attention to public health and prevention. Several of the most destructive health conditions can be prevented either through changes in lifestyle or interventions such as immunizations. The increasing rates of obesity, especially among children; substance use; lack of exercise; violence; and accidents are alarmingly expensive, particularly when they lead to disruptions in health.

This chapter describes a health care system in transition as it struggles to meet evolving global and domestic challenges. The overall health care and public health systems in the United States are described and differentiated, and the changing priorities are identified. Nurses play a pivotal role in meeting these needs, and the role of the nurse is described.

FORCES STIMULATING CHANGE IN THE DEMAND FOR HEALTH CARE

In recent years, enormous changes have occurred in society, both in the United States and most other countries of the world. The extent of interaction among countries is stronger than ever, and the economy of each country depends on the stability of other countries. The United States has felt the effects of rising

labor costs as many companies have shifted their production to other countries with lower labor costs. It is often less expensive to assemble clothes, automobile parts, and appliances and to have call distribution centers and call service centers in a less industrialized country and pay the shipping and other charges involved than to have the items fully assembled in the United States. In recent years the vacillating cost of fuel has affected almost every area of the economy, leading to both higher costs of products and layoffs as some industries have struggled to stay solvent. This has affected the employment rate in the United States. The economic downturn of 2008 left many people unemployed, and many lost their homes because they could not pay their mortgages. When the unemployment rate is high, more people lack comprehensive insurance coverage, since in the United States this has been typically provided by employers. In late November 2008, the U.S. unemployment rate was 6.7%. This represented an increase from 4.6% in 2007. In July 2012 the unemployment rate had increased to 8.2%, close to double the rate in 2007. In recent years the economy has begun to recover. In 2014, for example, the unemployment rate decreased to 6.1%—down by 2.1 percentage points from 2012 ([Bureau of Labor Statistics \[BLS\], 2014a](#)). Also, health care services and the ways in which they are financed are changing, with the continuing implementation of the Patient Protection and Affordable Care Act (ACA, enacted in 2010).

Demographic Trends

The population of the world is growing as a result of increased fertility and decreased mortality rates. The greatest growth is occurring in underdeveloped countries, and this is accompanied by decreased growth in the United States and other developed countries. The year 2000, however, marked the first time in more than 30 years that the total fertility rate in the United States was above the replacement level. *Replacement* means that for every person who dies, another is born ([Hamilton et al, 2010](#)). Both the size and the characteristics of the population contribute to the changing demography.

Seventy-seven million babies were born between the years of 1946 and 1963, giving rise to the often discussed baby boomer generation ([Office of National Statistics, 2014](#)). The oldest of these boomers reached 65 years of age in 2011, and they are expected to live longer than people born in earlier times (see [Chapter 5](#)). The impact on the federal government's insurance program for people 65 years of age and older, Medicare, is expected to be enormous, and this population is expected to double between the years 2000 and 2030, representing 20% of the total population ([CDC, 2013a](#)).

In 2014, the U.S. population was 318,804 million people, representing the third most populated country in the world. From 1990 to 2012, the U.S. foreign-born immigrant population grew from about 19 million to about 41 million and is continuing to increase every year ([US Census Bureau, 2014](#)).

At the time of the 1990 census, African Americans were the largest minority group in the United States (U.S. Census Bureau, 1996). However, in 2014, the U.S. Census Bureau announced that Hispanic persons outnumbered African Americans, with non-Hispanic whites being the largest single ethnic group in the

United States ([Office of National Statistics \[ONS\], 2014](#)). The nation's foreign-born population is growing, and it is projected that from now until 2050 the largest population growth will be due to immigrants and their children. States with the largest percentage of foreign-born populations are California, New York, Hawaii, Florida, and New Jersey. The states with the fastest-growing immigrant populations in 2012 were Nevada, Texas, Maryland, Illinois, and Arizona ([Migration Policy Institute, 2014](#); [Pew Research Center, 2012](#)).

The composition of the U.S. household is also changing (see [Chapter 25](#) for changes in families). From 1935 to 2010, mortality for both genders in all age groups and races declined ([Hoyert, 2012](#)) as a result of progress in public health initiatives, such as antismoking campaigns, AIDS prevention programs, and cancer screening programs. The leading causes of death have changed from infectious diseases to chronic and degenerative diseases ([NCHS, 2014](#)). New infectious diseases are emerging, such as Ebola virus, which affected the United States in 2014 with the first case in Dallas, Texas ([CDC, 2014a](#)). New treatments for infectious diseases have resulted in steady declines in mortality among children, as long as parents participate in immunization programs. A recent measles outbreak in Orange County, California shows that continuous focus on control of infectious diseases is essential ([Orange County Health Care Agency, 2014](#)). The mortality for older Americans has also declined. However, people 50 years of age and older have higher rates of chronic and degenerative illness and they use a larger portion of health care services than other age groups.

Social and Economic Trends

In addition to the size and changing age distribution of the population, other factors also affect the health care system. Several social trends that influence health care include changing lifestyles, a growing appreciation of the quality of life, the changing composition of families and living patterns, changing household incomes, and a revised definition of quality health care.

Americans spend considerable money on health care, nutrition, and fitness ([Bureau of Labor Statistics, 2012](#)), because health is seen as an irreplaceable commodity. To be healthy, people must take care of themselves. Many people combine traditional medical and health care practices with complementary and alternative therapies to achieve the highest level of health. Complementary therapies are those that are used in addition to traditional health care, and alternative therapies are those used instead of traditional care. Examples include acupuncture, herbal medications, and more ([National Center for Complementary and Alternative Medicine, 2014](#)). People often spend a considerable amount of their own money for these types of therapies because few are covered by insurance. In recent years, some insurance plans have recognized the value of complementary therapies and have reimbursed for them. State offices of insurance are good sources to determine whether these services are covered and by which health insurance plans.

About 65 years ago, income was distributed in such a way that a relatively small portion of households earned high incomes; families in the middle-income range made up a

somewhat larger proportion and households at the lower end of the income scale made up the largest proportion. By the 1970s, household income had risen, and income was more evenly distributed, largely as a result of dual-income families.

Since 1970 and to 2008, two trends in income distribution have emerged. The first is that the average per-person income in America has increased. Income of households in the top 1% of earners grew by 275%, compared with 65% for the next 19%, just under 40% for the next 60%, and 18% for the bottom fifth of households ([Congressional Budget Office \[CBO\], 2011](#)). However, as a result of what is being called the Great Recession, which began in 2008, and in recent years with layoffs, outsourcing, and other economic forces, many families are seeing decreases in wages. The second trend is that the gap between the richest 25% and the poorest 25% is widening because of the percent wage increase in the higher income levels ([CBO, 2011](#)). [Chapter 5](#) provides a detailed discussion of the economics of health care and how financial constraints influence decisions about public health services.

Health Workforce Trends

The health care workforce ebbs and flows. The early years of the twenty-first century saw the beginning of what is expected to be a long-term and sizable nursing shortage. Similarly, most other health professionals are documenting current and future shortages. Historically, nursing care has been provided in a variety of settings, primarily in the hospital. Approximately 56% of all registered nurses (RNs) continue to be employed in hospitals ([American Nurses Association, 2012](#)). A few years ago hospitals began reducing their bed capacity as care became more community based. Now they are expanding, including building for both acute and longer term chronic care. This growth is due to the factors previously discussed: the ability to treat and perhaps cure more diseases, the complexity of the care and the need for inpatient services, and the growth of the older age group.

The nursing shortage has been discussed in recent years, yet new graduates often have difficulty finding positions on graduation ([American Association of Colleges of Nursing \[AACN\], 2014](#)). Participating in a nurse internship program and being a bachelor of science in nursing (BSN) graduate or higher provides more opportunities for the new graduate. By 2016 there are expected to be 527,000 new nursing positions ([BLS, 2014b](#)). In addition, 55% of nurses reported in a recent survey that they intended to retire between 2011 and 2020, which will open positions for others ([Fears, 2010](#)).

There tend to be periodic shortages, especially in the primary care workforce in the United States, as providers choose to be specialists in fields such as medicine and nursing. Primary care providers include generalists who are skilled in diagnostic, preventive, and emergency services. The health care personnel trained as primary care generalists include family physicians, general internists, general pediatricians, nurse practitioners (NPs), clinical nurse specialists (CNSs), physician assistants, and certified nurse-midwives (CNMs) ([Steinwald, 2008](#)).

NPs, CNSs, and CNMs, considered [advanced practice nursing \(APN\)](#) specialties, are vital members of the primary

care teams (see [Chapter 39](#)). Although there is a shortage of primary care physicians, nurse practitioners may or may not be able to fill the gap because of state nurse practice acts and medical practice acts, which influence the practice of both groups.

In terms of the nursing workforce, increasing the number of minority nurses remains a priority and a strategy for addressing the current nursing shortage. In 2013 minority nurses represented about 22% of the registered nurse population. It is thought that increasing the minority population will help close the health disparity gap for minority populations ([AACN, 2014](#)). For example, persons from minority groups, especially when language is a barrier, often are more comfortable with and more likely to access care from a provider from their own minority group.

Technological Trends

The development and refinement of new technologies such as telehealth have opened up new clinical opportunities for nurses and their clients, especially in the areas of managing chronic conditions, assisting persons who live in rural areas, and in providing home health care, rehabilitation, and long-term care. On the positive side, technological advances promise improved health care services, reduced costs, and more convenience in terms of time and travel for consumers (see [Chapter 5](#)). Reduced costs result from a more efficient means of delivering care and from replacement of people with machines. It also reduces paperwork, gets accurate information to providers and clients and agencies, assists with care coordination and safety, and provides direct access to health records between agencies and to clients ([HealthIT.gov, 2013](#)). Contradictory as it may seem, cost is also the most significant negative aspect of advanced health care technology. The more high-technology equipment and computer programs become available, the more they are used. High-technology equipment is expensive, quickly becomes outdated when newer developments occur, and often requires highly trained personnel. There are other drawbacks to new technology, particularly in the area of home health care. These include increased legal liability, the potential for decreased privacy, too much reliance on technological advances, and the inconsistent quality of resources available on the Internet and other places ([Palma, 2014](#)).

Advances in health care technology will continue. One example of an effective use of technology is the funding provided by the U.S. Department of Health and Human Services, Health Resources and Services Administration (HRSA) to health centers so they can adopt and implement [electronic health records \(EHRs\)](#) and other health information technology ([HRSA, 2008](#)). HRSA's Office of Health Information Technology (HIT) was created in 2005 to promote the effective use of HIT as a mechanism for responding to the needs of the uninsured, underinsured, and special-needs populations ([HRSA, 2014](#)). Specifically, in December 2012, an award of \$18 plus million through the Affordable Care Act was announced to expand health information technology in 600 health centers ([HRSA, 2012](#)). One innovative use of the EHR in public health is to embed reminders or guidelines into the system. For

example, the CDC published health guidelines that contain clinical recommendations for screening, prevention, diagnosis, and treatment. To find and keep current on these guidelines, clinicians must visit the CDC website. The availability of an EHR system allows the embedding of reminders so that the clinician can have access to practice guidelines at the very point of care. Some additional benefits in public health (and these are some of the uses health centers make of such records) include the following:

- 24-hour availability of records with downloaded laboratory results and up-to-date assessments
- Coordination of referrals and facilitation of interprofessional care in chronic disease management
- Incorporation of protocol reminders for prevention, screening, and management of chronic disease
- Improvement of quality measurement and monitoring
- Increased client safety and decline in medication errors

Two federal programs, Medicaid and the State Children's Health Insurance Program (SCHIP), have effectively used health information technology (HIT) in several key functions including outreach and enrollment, service delivery, and care management, as well as communications with families and the broader goals of program planning and improvement. In early 2009, the surgeon general's office reopened a web site that had been tried first in 2004, and then closed: an electronic family tree for your health ([National Institutes of Health \[NIH\], 2010](http://familyhistory.hhs.gov/FHH/html/index.html)). This is described as an easy-to-use computer application for people to keep a personal record of their family health history (<https://familyhistory.hhs.gov/FHH/html/index.html>). Before the initiative described above, the CDC began a family history public health initiative through the Office of Public Health Genomics to increase awareness of family history as an important risk factor for common chronic diseases. This initiative had four main activities:

1. Research to define, measure, and assess family history in populations and individuals
2. Development and evaluation of tools for collecting family history
3. Evaluation of how family history-based strategies work
4. Promotion of evidence-based applications of family history to health professionals and the public ([CDC, 2013b](#)).

CURRENT HEALTH CARE SYSTEM IN THE UNITED STATES

Despite the many advances and the sophistication of the U.S. health care system, the system has been plagued with problems related to cost, access, and quality (see more discussion in [Chapters 5, 21, and 26](#)). These problems are different for each person and have been affected by the ability of individuals to obtain health insurance. Most industrialized countries want the same things from their health care system. Several give their government a greater role in health care delivery and eliminate or reduce the use of market forces to control cost, access, and quality. Seemingly, there is no one perfect health care system in the world.

Cost

Beginning in 2008, a historic weakening of the national and global economy—the “Great Recession”—led to the loss of 7 million jobs in the United States ([Economic Report, 2010](#)). Even as the gross domestic product (GDP), an indicator of the economic health of a country, declined in 2009, health care spending continued to grow and reached \$2.5 trillion in the same year ([Truffer et al, 2010](#)). In the years between 2010 and 2019, national health spending is expected to grow at an average annual rate of 6.1%, reaching \$4.5 trillion by 2019, for a share of approximately 19.3% of the GDP. This translates into a projected increase in per capita spending (see [Chapter 5](#)).

In [Chapter 5](#), additional discussion illustrates how health care dollars are spent. The largest share of health care expenditures goes to pay for hospital care, with physician services being the next largest item. The amount of money that has gone to pay for public health services is much lower than for the other categories of expenditures. Other significant drivers of the increasingly high cost of health care include prescription drugs, technology, and chronic and degenerative disease.

Following the “Great Recession,” the economic rebound will likely coincide with the burgeoning Medicare enrollment of the aging baby boomer population. It was projected that these new Medicare enrollees will increase Medicare expenditures for the foreseeable future. Medicaid recipients can be expected to decline as jobs are added to the economy, and the percentage of workers covered by employer-sponsored insurance should rise to reflect that growth. Although workers' salaries have not kept pace, employer-sponsored insurance premiums have grown 119% since 1999 ([Kaiser Family Foundation, 2009a](#)), and the inability of workers to pay this increased cost has led to a rise in the percentage of working families who are uninsured. It is essential to read about the changes in the above facts as the American [Affordable Care Act](#) is implemented.

Access

Another significant problem is poor access to health care (case study in [Box 3-1](#)). The American health care system is described as a two-class system: private and public. People with insurance or those who can personally pay for health care are viewed as receiving superior care; those who receive lower quality care are

BOX 3-1 Case Study

Public health nurses who worked with local Head Start programs noted that many children had untreated dental caries. Despite qualifying for Medicaid, only two dentists in the area would accept appointments from Medicaid patients. Dentists asserted that Medicaid patients frequently did not show up for their appointments and that reimbursement was too low compared with other third-party payers. They also said the children's behavior made it difficult to work with them. So the waiting list for local dental care was approximately 6 years long. Although some nurses found ways to transport clients to dentists in a city 70 miles away, it was very time consuming and was feasible for only a small fraction of the clients. When decayed teeth abscessed, it was possible to get extractions from the local medical center. The health department dentist also saw children, but he, too, was booked for years.

Created by Deborah C. Conway, Assistant Professor, University of Virginia School of Nursing.

(1) those whose only source of care depends on public funds or (2) the working poor, who do not qualify for public funds either because they make too much money to qualify or because they are illegal immigrants. Employment-provided health care is tied to both the economy and to changes in health insurance premiums. By 2009, 61% of the nonelderly population continued to obtain health insurance through their employer as a benefit; however, employment did not guarantee insurance (Rowland et al, 2009). This became clear when considering that 9 in 10 (91%) of the middle-class uninsured came from families with at least one full-time worker in jobs that did not offer health insurance or where coverage was unaffordable (Rowland et al, 2009).

In 2012, the total number of uninsured persons in the United States was 48 million. As discussed, there was a strong relationship between health insurance coverage and access to health care services. Insurance status determines the amount and kind of health care people are able to afford, as well as where they can receive care. During this same year 15% of the total population was uninsured and 48% were covered by employer health insurance. All but 5% of the remaining, or 32%, were covered by government insurance programs (Kaiser Health News 2012; Kaiser Family Foundation, 2014).

The uninsured receive less preventive care, are diagnosed at more advanced disease states, and once diagnosed tend to receive less therapeutic care in terms of surgery and treatment options. There is a safety net for the uninsured or underinsured. As discussed later in this chapter, there are more than 1300 federally funded community health centers throughout the country. Federally funded community health centers provide a broad range of health and social services, using nurse practitioners and RNs, physician assistants, physicians, social workers, and dentists. Community health centers serve primarily in medically underserved areas, which can be rural or urban. These centers serve people of all ages, races, and ethnicities, with or without health insurance.

Quality

The quality of health care leaped to the forefront of concern following the 1999 release of the Institute of Medicine (IOM) report *To Err Is Human: Building a Safer Health System* (IOM, 2000). As indicated in this groundbreaking report, as many as 98,000 deaths a year could be attributed to preventable medical errors. Some of the untoward events categorized in this report included adverse drug events and improper transfusions, surgical injuries and wrong-site surgery, suicides, restraint-related injuries or death, falls, burns, pressure ulcers, and mistaken client identities. It was further determined that high rates of errors with serious consequences were most likely to occur in intensive care units, operating rooms, and emergency departments. Beyond the cost in human lives, preventable medical errors result in the loss of several billions of dollars annually in hospitals nationwide. Categories of error include diagnostic, treatment, and prevention errors as well as failure of communication, equipment failure, and other system failures. Significant to nurses, the IOM estimated the number of lives lost to preventable errors in medication alone represented more than 7000 deaths annually, with a cost of about \$2 billion nationwide.

Although the IOM report made it clear that the majority of medical errors today were not produced by provider negligence, lack of education, or lack of training, questions were raised about the nurse's role and workload and its effect on client safety. In a follow-up report, *Keeping Patients Safe: Transforming the Work Environment of Nurses*, the IOM (2003) stated that nurses' long work hours pose a serious threat to patient safety, because fatigue slows reaction time, saps energy, and diminishes attention to detail. The group called for state regulators to pass laws barring nurses from working more than 12 hours a day and 60 hours a week—even if by choice (IOM, 2003). Although this information is largely related to acute care, many of the patients who survive medical errors are later cared for in the community.

The culture of quality improvement and safety has made providers and consumers more conscious of safety, but medical errors and untoward events continue to occur. As a means to improve consumer awareness of hospital quality, the Centers for Medicare and Medicaid Services (CMS) began publishing a database of hospital quality measures, Hospital Compare, in 2005. Hospital Compare, a consumer-oriented website that provides information on how well hospitals provide recommended care in such areas as heart attack, heart failure, and pneumonia, is available through the CMS website (www.cms.gov). In a further effort, the CMS, in 2008, announced that it will no longer reimburse hospitals, under Medicare guidelines, for care provided for “preventable complications” such as hospital-acquired infections. This reimbursement policy was extended to Medicaid reimbursement in 2011 (Galewitz, 2011; CMS, 2009).

The accreditation process for public health is new and the impact of quality and safety monitoring has not yet been determined. The ability of a public health agency or a community to respond to community disasters is one event that will be monitored. In December 2014, 60 of 303 local, tribal, and state centralized integration systems, and multijurisdictional health departments, have received accreditation in this new process. The accredited health departments served a 111 million population base. The purpose of this process is to

- Assist and identify quality health departments to improve performance and quality, and to develop leadership
- Improve management
- Improve community relationships (Public Health Accreditation Board [PHAB], 2014)

ORGANIZATION OF THE HEALTH CARE SYSTEM

An enormous number and range of facilities and providers make up the health care system. These include physicians' and dentists' offices, hospitals, nursing homes, mental health facilities, ambulatory care centers, freestanding clinics and clinics inside stores such as drugstores, as well as free clinics, public health, and home health agencies. Providers include nurses, advanced practice nurses, physicians and physician assistants, dentists and dental hygienists, pharmacists, and a wide array of essential allied health providers such as physical, occupational, and recreational therapists; nutritionists; social workers; and a range of technicians. In general, however, the American health

care system is divided into the following two, somewhat distinct, components: a private or personal care component and a public health component, with some overlap, as discussed in the following sections. It is important to discuss primary health care and examine the interest in developing such a system.

Primary Care System

Primary care, the first level of the private health care system, is delivered in a variety of community settings, such as physicians' offices, urgent care centers, in-store clinics, community health centers, and community nursing centers. Near the end of the past century, in an attempt to contain costs, managed care organizations grew. **Managed care** is defined as a system in which care is delivered by a specific network of providers who agree to comply with the care approaches established through a case management approach. The key factors are a specified network of providers and the use of a gatekeeper to control access to providers and services. This form of care has not become as prominent as the original concept outlined.

The government tried to reap the benefits of cost savings by introducing the managed care model into Medicare and Medicaid, with varying levels of success. The traditional Medicare plan involves Parts A and B. Part C, the Medicare Advantage program, incorporates private insurance plans into the Medicare program including HMO (health maintenance organization) and PPO (preferred provider organization) managed care models and private fee-for-service plans. In addition, Medicare Part D has been added to cover prescriptions (see [Chapter 5](#)).

Public Health System

The **public health** system is mandated through laws that are developed at the national, state, or local level. Examples of public health laws instituted to protect the health of the community include a law mandating immunizations for all children entering kindergarten and a law requiring constant monitoring of the local water supply. The public health system is organized into many levels in the federal, state, and local systems. At the local level, health departments provide care that is mandated by state and federal regulations.

The Federal System

The **U.S. Department of Health and Human Services** (USDHHS; or simply HHS) is the agency most heavily involved with the health and welfare concerns of U.S. citizens. The organizational chart of the HHS ([Figure 3-1](#)) shows the office of the secretary, 11 agencies, and a program support center ([USDHHS, 2014a](#)). Ten regional offices are maintained to provide more direct assistance to the states. Their locations are shown in [Table 3-1](#). The HHS is charged with regulating health care and overseeing the health status of Americans. See [Box 3-2](#) for the goals and objectives of the HHS strategic plan for fiscal years 2010-2015. Newer areas in the HHS are the Office of Public Health Preparedness, the Center for Faith-Based and Neighborhood Partnerships and the Office of Global Affairs. The Office of Public Health Preparedness was added to assist the nation and states to prepare for bioterrorism after September 11, 2001. The Faith-Based Initiative Center was developed by President George W. Bush to allow faith communities to compete for

TABLE 3-1 Regional Offices of the U.S. Department of Health and Human Services

Region	Location	Territory
1	Boston	Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, Vermont
2	New York	New Jersey, New York, Puerto Rico, Virgin Islands
3	Philadelphia	Delaware, District of Columbia, Maryland, Pennsylvania, Virginia, West Virginia
4	Atlanta	Alabama, Florida, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, Tennessee
5	Chicago	Illinois, Indiana, Michigan, Minnesota, Ohio, Wisconsin
6	Dallas	Arkansas, Louisiana, New Mexico, Oklahoma, Texas
7	Kansas City	Iowa, Kansas, Missouri, Nebraska
8	Denver	Colorado, Montana, North Dakota, South Dakota, Utah, Wyoming
9	San Francisco	Arizona, California, Hawaii, Nevada, American Samoa, Commonwealth of the Northern Mariana Islands, Federated States of Micronesia, Guam, Republic of the Marshall Islands, Republic of Palau
10	Seattle	Alaska, Idaho, Oregon, Washington

federal money to support their community activities. The goal of the Office of Global Affairs is to promote global health by coordinating HHS strategies and programs with other governments and international organizations ([USDHHS, 2014a](#)).

The U.S. Public Health Service (USPHS; or simply PHS) is a major component of the Department of Health and Human Services. The PHS consists of eight agencies: Agency for Healthcare Research and Quality, Agency for Toxic Substances and Diseases Registry, Centers for Disease Control and Prevention, Food and Drug Administration, Health Resources and Services Administration, Indian Health Service, National Institutes of Health, and Substance Abuse and Mental Health Services Administration. Each has a specific purpose (see [Chapter 8](#) for relevancy of the agencies to policy and providing health care). The PHS also has a Commissioned Corps, which is a uniformed service of more than 6500 health professionals who serve in many HHS and other federal agencies. The surgeon general is head of the Commissioned Corps. The corps fills essential services for public health, clinic and provides leadership within the federal government departments and agencies to support the care of the underserved and vulnerable populations ([USPHS, 2014](#)).

An important agency and a recent addition to the federal government, the U.S. Department of Homeland Security (USDHS, or simply DHS), was created in 2003 ([USDHS, 2014](#)). The mission of the DHS is to prevent and deter terrorist attacks and protect against and respond to threats and hazards to the nation. The goals for the department include awareness, prevention, protection, response, and recovery. The DHS works with first responders throughout the United States, and through the development of programs such as the Community

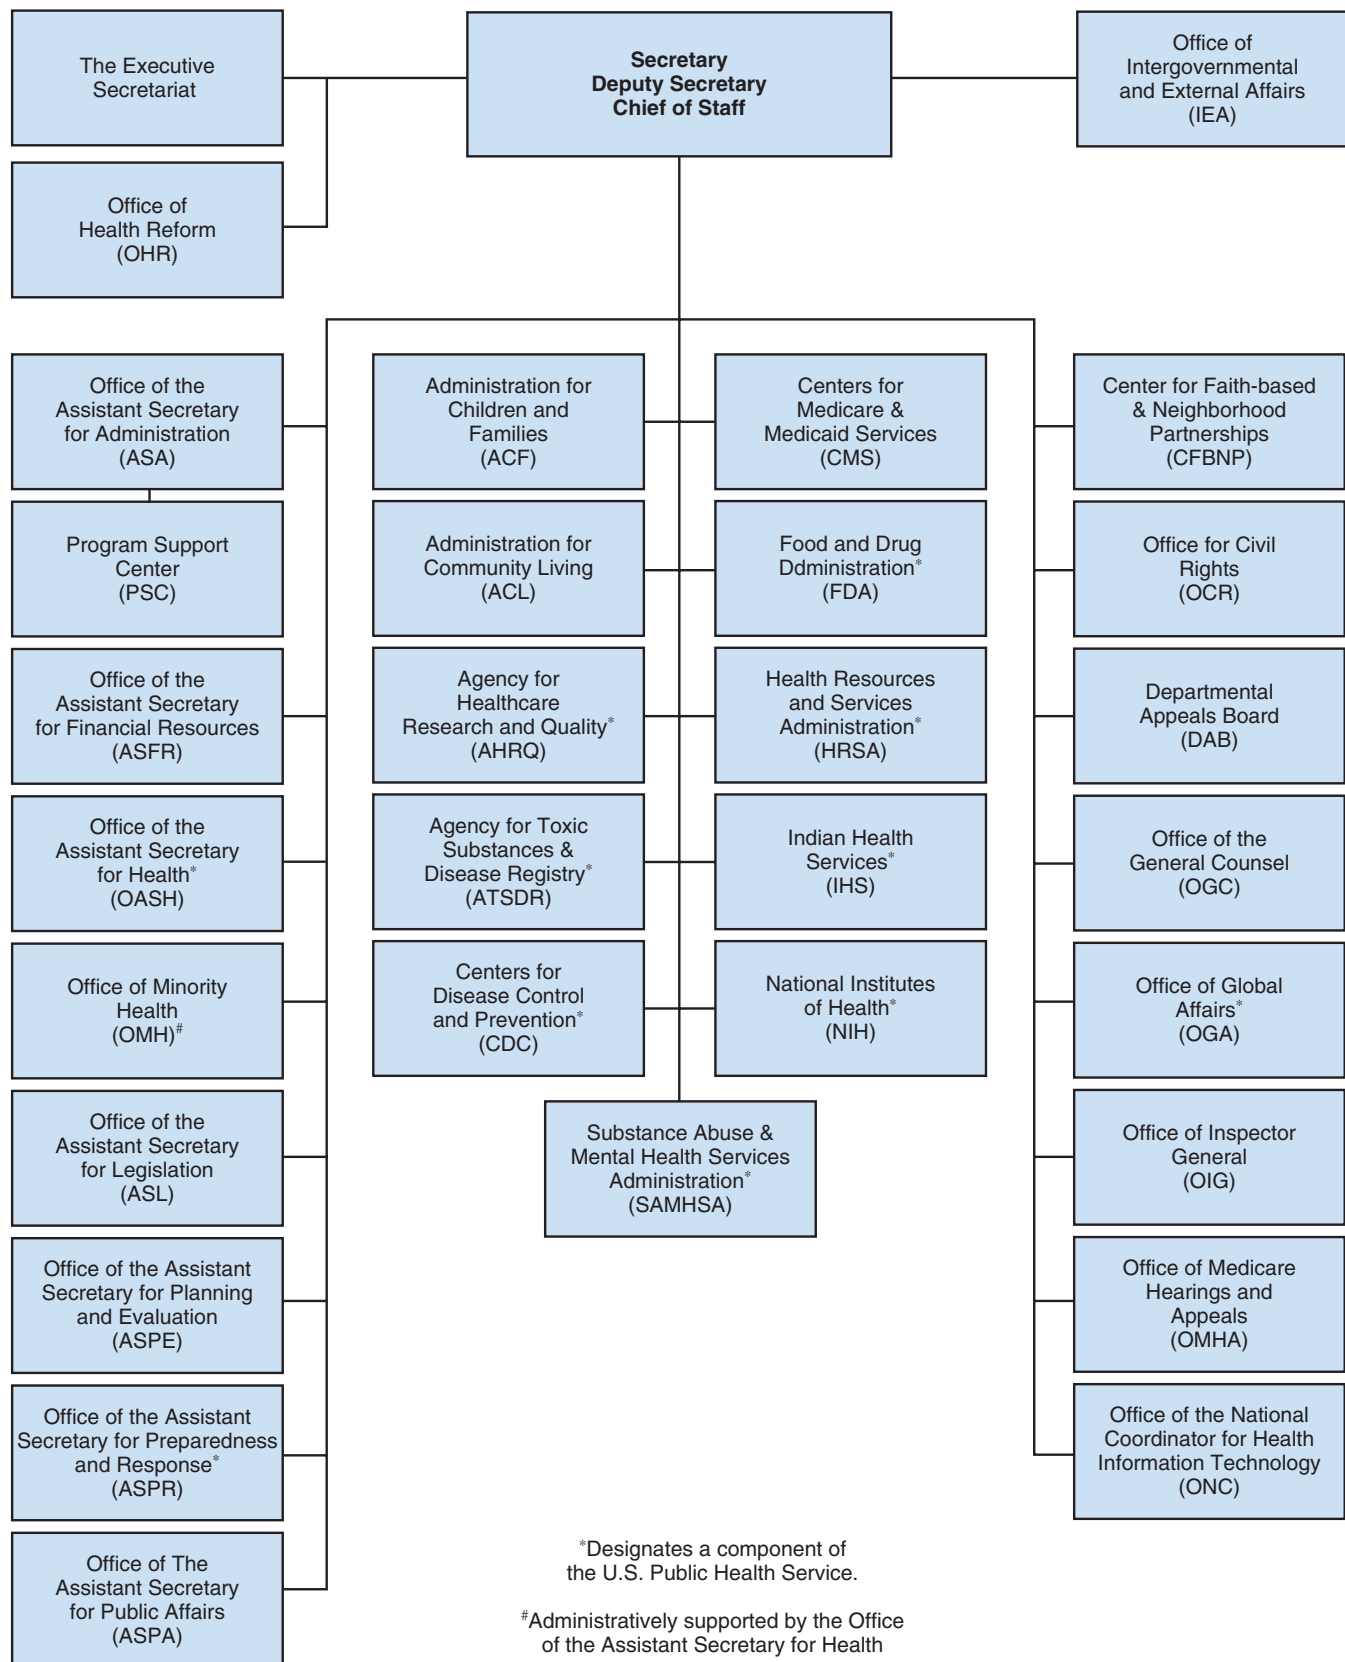

FIG 3-1 Organization of the U.S. Department of Health and Human Services. (From U.S. Department of Health and Human Services; Available at <http://www.hhs.gov/about/orgchart/>.)

BOX 3-2 USDHHS Strategic Plan Goals and Objectives—Fiscal Years 2010-2015***GOAL 1: Strengthen Health Care**

- Objective A Make coverage more secure for those who have insurance, and extend affordable coverage to the uninsured.
- Objective B Improve health care quality and patient safety.
- Objective C Emphasize primary and preventive care linked with community prevention services.
- Objective D Reduce the growth of health care costs while promoting high-value, effective care.
- Objective E Ensure access to quality, culturally competent care for vulnerable populations.
- Objective F Promote the adoption and meaningful use of health information technology.

GOAL 2: Advance Scientific Knowledge and Innovation

- Objective A Accelerate the process of scientific discovery to improve patient care.
- Objective B Foster innovation to create shared solutions.
- Objective C Invest in the regulatory sciences to improve food and medical product safety.
- Objective D Increase our understanding of what works in public health and human service practice.

GOAL 3: Advance the Health, Safety, and Well-Being of the American People

- Objective A Promote the safety, well-being, resilience, and healthy development of children and youth.
- Objective B Promote economic and social well-being for individuals, families, and communities.
- Objective C Improve the accessibility and quality of supportive services for people with disabilities and older adults.
- Objective D Promote prevention and wellness.
- Objective E Reduce the occurrence of infectious diseases.
- Objective F Protect Americans' health and safety during emergencies, and foster resilience in response to emergencies.

GOAL 4: Increase Efficiency, Transparency, Accountability and Effectiveness of HHS Programs

- Objective A Ensure program integrity and responsible stewardship of resources.
- Objective B Fight fraud and work to eliminate improper payments.
- Objective C Use HHS data to improve the health and well-being of the American people.
- Objective D Improve HHS environmental, energy, and economic performance to promote sustainability.

GOAL 5: Strengthen the Nation's Health and Human Service Infrastructure and Workforce

- Objective A Invest in the HHS workforce to meet America's health and human service needs today and tomorrow.
- Objective B Ensure that the Nation's health care workforce can meet increased demands.
- Objective C Enhance the ability of the public health workforce to improve public health at home and abroad.
- Objective D Strengthen the Nation's human service workforce.
- Objective E Improve national, state, local, and tribal surveillance and epidemiology capacity.

*In process of being updated for 2014-2018.

Emergency Response Team (CERT) program trains people to be better prepared to respond to emergency situations in their communities. Nurses working in state and local public health departments as well as those employed in hospitals and other health facilities may be called on to respond to acts of terrorism or natural disaster in the course of their careers, and the DHS, along with the Food and Drug Administration (FDA) and CDC, is developing programs to ready nurses and other health care providers for an uncertain future (USDHS, 2014).

The State System

When the United States faced a pandemic flu outbreak in 2009, the federal government and the public health community quickly prepared to meet the challenge of educating the public and health professionals about the H1N1 flu and making vaccinations available. In 2014 public health within the states was responding to an enterovirus affecting large numbers of children with systems of upper respiratory disease and weakness in arms and legs. The virus was considered life-threatening (CDC, 2014b). In addition to standing ready for disaster prevention or response, state health departments have other equally

important functions, such as health care financing and administration for programs such as Medicaid, providing mental health and professional education, establishing health codes, licensing facilities and personnel, and regulating the insurance industry. State systems also have an important role in direct assistance to local health departments, including ongoing assessment of health needs (see Chapter 46).

LEVELS OF PREVENTION

Related to the Public Health Care System

Primary Prevention

Implement a community-level program such as walking for exercise to assist citizens in improving health behaviors related to lifestyle.

Secondary Prevention

Implement a family-planning program to prevent unintended pregnancies for young couples who attend the local community health center.

Tertiary Prevention

Provide a self-management asthma program for children with chronic asthma to reduce their need for hospitalization.

Nurses serve in many capacities in state health departments; they are consultants, direct service providers, researchers, teachers, and supervisors. They also participate in program development, planning, and the evaluation of health programs.

The Local System

The local health department has direct responsibility to the citizens in its community or jurisdiction. Services and programs offered by local health departments vary depending on the state and local health codes that must be followed, the needs of the community, and available funding and other resources. For example, one health department might be more involved with public health education programs and environmental issues, whereas another health department might emphasize direct client care. Local health departments vary in providing sick care or even primary care (see [Chapter 46](#)). More often than at other levels of government, public health nurses at the local level provide population level or direct services. Some of these nurses deliver special or selected services, such as follow-up of contacts in cases of tuberculosis or venereal disease or providing child immunization clinics. Others provide more general care, delivering services to families in certain geographic areas. This method of delivery of nursing services involves broader needs and a wider variety of nursing interventions. The local level often provides an opportunity for nurses to take on significant leadership roles, with many nurses serving as directors or managers.

Since the tragedy of September 11, 2001, state and local health departments have increasingly focused on emergency preparedness and response. In case of an event, state and local health departments in the affected area will be expected to collect data and accurately report the situation, to respond appropriately to any type of emergency, and to ensure the safety of the residents of the immediate area, while protecting those just outside the danger zone. This level of knowledge—to enable public health agencies to anticipate, prepare for, recognize, and respond to terrorist threats or natural disasters such as hurricanes or floods—has required a level of interstate and federal-local planning and cooperation that is unprecedented for these agencies. Whether participating in disaster drills or preparing a local high school for use as a shelter, nurses play a major role in meeting the challenge of an uncertain future.

FORCES INFLUENCING CHANGES IN THE HEALTH CARE SYSTEM

Although most people are personally satisfied with their own physicians or nurse practitioners, at present few people are satisfied with the health care system in general. Costs have been high and have continued to rise while quality and access have been uneven across the country and within communities, depending on the ability to pay. What, then, were some of the factors that might influence health care to change? First, as a nation, citizens must decide what has to be provided for all people, who will be in charge of the system, and who will pay for what. In recent years, federal and state services have been reduced and more responsibility for health care delivery has been moved to the private sector. Health care has become big business. Health care

company stocks are now traded by major stock exchanges, directors receive benefits when profits are high, and the locus of control had shifted from the provider to the payer. Many competing forces have influenced the changing design of the health care system, some of which are consumers, employers (purchasers), care delivery systems, and state and federal legislation.

First, consumers want lower costs and high-quality health care without limits and with an improved ability to choose the providers of their choice. Second, employers (purchasers of health care) want to be able to obtain basic health care plans at reasonable costs for their employees. Many employers have seen their profits diminish as they put more money into providing adequate health care coverage for employees. Third, health care systems want a better balance between consumer and purchaser demands. Thus they continually watch their own budget and expenses. To maintain a profit while providing quality care, many health care delivery groups have downsized and created alliances, mergers, and other joint ventures. Finally, legislation, especially concerning access and quality, continues to be enacted, thus creating one more force helping shape a health care system. The goal of “evidence-based care” is to ensure quality.

Many have said that solving the health care crisis requires the institution of a rational health care system that balances equity, cost, and quality. The fact that millions of people have been uninsured, that wide disparities have existed in access, and that a large proportion of deaths each year seem attributable to preventable causes (errors as well as tobacco, alcohol abuse, preventable injuries, and obesity) has indicated that the American system is currently not serving the best interests of the American population. The WHO has suggested that integrating primary care and public health into a primary health care system will be the basis for better health for all world citizens ([WHO, 1986a](#)).

Integration of Public Health and the Primary Care Systems

Although primary care and public health share a goal of promoting the health and well-being of all people, these two disciplines historically have operated independently of one another. Problems that stem from this separation have long been recognized, but new opportunities are emerging for bringing these systems together to promote lasting improvements in the health of individuals, communities, and populations ([IOM, 2012](#)).

In recognition of this potential, the Centers for Disease Control and Prevention (CDC) and the Health Resources and Services Administration (HRSA), both agencies of the Department of Health and Human Services (HHS), asked the Institute of Medicine (IOM) to convene a committee of experts, including input from nursing, to examine the integration of primary care and public health ([IOM, 2012](#)).

To recognize the differences in these two systems, definitions were used to guide the work of the experts. Primary care was defined as “the providing of integrated, accessible health care services by clinicians who are accountable for addressing a large majority of personal health care needs, while developing partnerships with patients and practicing in the context of family and community” ([IOM, 1996](#), p. 1). Public health was defined as “fulfilling society’s interest in assuring conditions in

which people can be healthy” (IOM, 1988, p. 140). The purpose of the integration is to achieve the WHO goal of primary health care.

Potential Barriers to Integration

Contrasting the two systems, primary care, which can be either a public or a private entity, is person focused, provides a point of first contact for individuals to address health problems, and is considered comprehensive and provides coordination of individual care; public health can also be delivered through public and private entities to contribute to the health of society, but government plays a major role in public health. Health departments are legally bound to provide essential public health services, and to work with the total community and multiple stakeholders to address community-level health problems. Public health also has specific functions of assurance, assessment, and policy development to address community-level health issues and has a charge to create healthy communities (see Chapter 1).

In addition to differing roles and functions and issues related to funding, different clients and different foci will need to be addressed to form a solid foundation for a partnership. Primary care is largely funded through individual client payments, health insurance, and sometimes through federal grants. Public health is largely funded through tax dollars, federal and state grants, and sometimes health insurance payments through Medicare and Medicaid. Primary care serves the individuals who present to the practice while public health serves to assess the health problems of the population. Both focus on meeting the most prevalent health needs of the population. Primary care focuses more on the curative aspect of care while public health focuses more on the prevention of health problems (Levesque et al, 2013).

The common goal of public health and primary care, although these systems operate independently, is to ensure a healthier population. Integration of these two systems has the potential to produce a greater impact on the health of populations than either could have working alone, said the committee of experts convened by the IOM (2012).

The Healthy People initiatives, beginning with the U.S. surgeon general’s 1979 report, indicate the long-standing desire to improve population health in the United States.

Primary Health Care

Primary health care (PHC), the goal of the integration of public health and primary care, includes a comprehensive range of services including public health and preventive, diagnostic, therapeutic, and rehabilitative services. This system is composed of public health agencies, community-based agencies and primary care clinics, and health care providers. From a conceptual point of view, PHC is essential care made universally accessible to individuals, families, and the community. Health care is made available to them with their full participation and is provided at a cost that the community and country can afford. This care is not uniformly available and accessible to all people in many countries including the United States. Full **community participation** means that individuals within the community

help in defining health problems and in developing approaches to address the problems. The setting for primary health care is within all communities of a country and involves all aspects of society (WHO, 1978).

The primary health care movement officially began in 1977 when the 30th World Health Organization (WHO) Health Assembly adopted a resolution accepting the goal of attaining a level of health that permitted all citizens of the world to live socially and economically productive lives. At the international conference in 1978 in Alma-Ata, in the former Soviet Union (Russia), it was determined that this goal was to be met through PHC. This resolution, the Declaration of Alma-Ata, became known by the slogan “Health for All (HFA) by the Year 2000,” which captured the official health target for all the member nations of the WHO. In 1998 the program was adapted to meet the needs of the new century and was deemed “Health for All in the 21st Century.”

In 1981 the WHO established global indicators for monitoring and evaluating the achievement of HFA. In the *World Health Statistics Annual* (WHO, 1986b), these indicators are grouped into the following four categories: health policies, social and economic development, provision of health care, and health status. The indicators suggest that health improvements are a result of efforts in many areas, including agriculture, industry, education, housing, communications, and health care. Because PHC is as much a political statement as a system of care, each United Nations member country interprets PHC according to its own culture, health needs, resources, and system of government. Clearly, the goal of PHC has not been met in most countries including the United States.

Promoting Health/Preventing Disease: Year 2020 Objectives for the Nation

As a WHO member nation, the United States has endorsed primary health care as a strategy for achieving the goal of “Health for All in the 21st Century.” However, the PHC emphasis on broad strategies, community participation, self-reliance, and a multidisciplinary health care delivery team is not the primary strategy for improving the health of the American people. The national health plan for the United States identifies disease prevention and health promotion as the areas of most concern in the nation. Each decade since the 1980s has been measured and tracked according to health objectives set at the beginning of the decade. The U.S. Public Health Service of the HHS publishes the objectives after gathering data from health professionals and organizations throughout the country.

Healthy People 2020, which was officially launched in December 2010 (USDHHS, 2010a), is composed of a large number of objectives related to 42 topic areas. These objectives are designed to serve as a road map for improving the health of all people in the United States during the second decade of the twenty-first century. These objectives are described by four main goals (USDHHS, 2010b):

- Attain high-quality, longer lives free of preventable disease, disability, injury, and premature death
- Achieve health equity, eliminate disparities, and improve the health of all groups

- Create social and physical environments that promote good health for all
- Promote quality of life, healthy development, and healthy behaviors across all life stages

These goals provide the framework with which measurable health indicators can be tracked. The emphasis on the social and physical environment moves *Healthy People 2020* from the traditional disease-specific focus to a more holistic view of health consistent with a public health frame of reference (*Healthy People 2020, 2012*). This in turn will encourage public health nurses to broaden their scope to all aspects of their clients' lives that may need assessment and intervention, including where they live, the condition of their home, and how the

appropriateness of their environment may change as the client ages. The *Healthy People 2020* box presents indicators of *Healthy People 2020* related to the strengthening of the public health infrastructure. These objectives will assist nurses in having data to show that their assessments and interventions are changing practice.

HEALTH CARE DELIVERY REFORM EFFORTS—UNITED STATES

Over the centuries, both health insurance and health care reform have been the focus of numerous discussions and political battles. As can be seen in *Chapter 2*, the first health insurance plan, established in about 1798 in the United States, was for the Merchant Marines to assist in treating infectious diseases and protecting the ports of entry into the United States. The United States has discussed national health care reform since the 1900s (see *Chapter 5*). In 1912 Theodore Roosevelt campaigned on a health insurance proposal for industry. Then in 1915 the “progressive reformers” campaigned for a state-based system of compulsory health insurance. In the 1920s, the Committee on the Costs of Medical Care suggested group medicine and voluntary insurance, and this movement was labeled as promoting “socialized medicine.” Since the 1930s, through surveys, Americans have generally shown support of the goals of guaranteed access to health care and health insurance, and a governmental role in financing of care. Some strides were made in improving access and defining the role of government financing through

HEALTHY PEOPLE 2020

Selected Objectives That Pertain to Strengthening the Public Health Infrastructure

- **PHI-7** (Developmental): Increase the proportion of population-based *Healthy People 2020* objectives for which national data are available for all major population groups.
- **PHI-8**: Increase the proportion of *Healthy People 2020* objectives that are tracked regularly at the national level.

From U. S. Department of Health and Human Services. *Healthy People 2020*. Available at <http://www.healthypeople.gov/2020/topics/objectives2020/default.aspx>. Accessed December 27, 2010.

EVIDENCE-BASED PRACTICE

It is often said that the states are the laboratories of democracy. One state, Massachusetts, began an experiment in health reform in 2006. Two years after health reform legislation became effective, only 2.6% of Massachusetts residents were uninsured, the lowest percentage ever recorded in any state (*Dorn et al, 2009*). However, the program became one of the most successful and a model for the Affordable Care Act. After 5 years approximately 98% to 99% of all of the commonwealth's citizens were covered by the plan.

Although other states have experimented with various programs to decrease the number of uninsured, the Massachusetts plan has had the most success. The health reform plan rests on an individual mandate that requires everyone who can afford insurance to purchase coverage. Those unable to afford insurance receive subsidies that allow low-income individuals and families to purchase coverage. A new state-run program, Commonwealth Care (CommCare), provides benefits to adults who are not eligible for Medicaid but whose incomes fall below 300% of the federal poverty level.

To understand how the state was so successful in this effort toward universal coverage, a group of evaluators met with 15 key informants representing hospitals, community health centers, insurance companies, Medicaid, and CommCare. Several factors, it was found, have contributed to the historic level of coverage seen in the state. Rather than requiring consumers to complete separate applications for programs such as Medicaid, the Children's Health Insurance Program (CHIP), or CommCare, a single application system provides entry to all the state programs. If an uninsured client was admitted to a hospital or visited a community

health center, his or her eligibility was automatically evaluated and, if eligible, the client would be automatically converted to CommCare coverage, even without completing an application. A “Virtual Gateway” has been developed through which staff of community-based organizations have been trained to complete online applications on behalf of consumers, and to provide education and counseling about insurance options to underserved communities. By holding back reimbursement to providers who do not help consumers sign up for one of the available insurance options, hospitals and health centers are motivated to dedicate staff to provide education and counseling to the formerly uninsured. The result is that at least half of the new enrollees in Medicaid and CommCare have been enrolled without filling out any forms on their own. In addition to these efforts, shortly after the reform legislation was enacted, the state financed a massive public education effort to inform consumers about their new options.

Nurse Use

As health reform begins on the national level, nurses can play a crucial role in driving down the number of uninsured. Nurses should educate themselves so that they can encourage clients to apply and take advantage of all available coverage options. Taking an active role in consumer educational programs is a natural extension of a nurse's role as a client advocate. Nurses can promote legislation to simplify enrollment processes and encourage the development of shared databases for community health care providers, thus preventing consumers from falling through the cracks in our fragmented health care system.

Dorn S, Hill I, Hogan S: *The secrets of Massachusetts's success: why 97 percent of state residents have health coverage: state health access reform evaluation, Romneycare-The truth about Massachusetts health care*. 2014, accessed at mittromneycentral.com/resources/romneycare.9/25/20142009, Robert Wood Johnson Foundation. Available at http://www.urban.org/uploadedpdf/411987_massachusetts_success_brief.pdf. Accessed September 19, 2012.

the passing of Medicare in 1965, with Medicaid as a part of the proposal for social security amendments, and the Children's Health Insurance Program bill passed in 1996. Many proposals have been put forward over the decades for health care reform, as well as health insurance reform. Beginning in the 1970s Senator Ted Kennedy, President Richard Nixon, President Gerald Ford, and President Jimmy Carter all made health-related proposals, all followed by the Health Security Act of President Bill Clinton. None were accepted by Congress (Kaiser Family Foundation, 2009b).

Nurses and the American Nurses Association have been involved in the debates about health care reform over time. In its 2005 Healthcare System Reform Agenda, the American Nurses Association (American Nurses Association, 2008) promoted a blueprint for reform that includes the following:

- Health care is a basic human right, and so a restructured health care system with universal access to a standard package of essential health care services for all citizens and residents must be assured.
- The development and implementation of health policies that reflect the aims put forth by the Institute of Medicine (safe, effective, patient centered, timely, efficient, equitable) and are based on outcomes research will ultimately save money.
- The overuse of expensive, technology-driven, acute, hospital-based services must give way to a balance between high-tech treatment and community-based and preventive services, with emphasis on the latter.
- A single-payer mechanism is the most desirable option for financing a reformed health care system.

In 2010 the Affordable Care Act (ACA) was passed, after introduction by the Obama team and after much debate. This act reflects many of the tenets offered by the ANA in its Health System Reform Agenda and puts into place comprehensive health insurance reforms that are to be implemented by 2014 and beyond. The act was passed to improve quality and lower health care costs, provide access to care, and provide for consumer protection. Table 3-2 provides an overview of the key features of the act by year. The ACA has a major focus on prevention. This focus is designed to improve the health of Americans, but also help to reduce health care costs and improve quality of care. Through the Prevention and Public Health Fund, the ACA will address factors that influence health—housing, education, transportation, the availability of quality affordable food, and conditions in the workplace and the environment. By concentrating on the causes of chronic disease, the ACA will move the nation from a focus on sickness and disease to one based on wellness and prevention.

To improve the health of Americans, ways to make the healthy choice in each community an easy and affordable choice must be found. In addition, within the law there are specific benefits for women, young adults, and families. It strengthens Medicare and holds insurance companies accountable (USDHHS, 2014b).

Since the close of the first enrollment period for the ACA in early 2014, the numbers of uninsured have declined (see Chapter 1). Because of a lag in data, the effects of the health care reform will not be known until 2015.

Discussions and debates will continue about the impact of the ACA, and the IOM's discussions of integrating public health and primary care, reducing cost, increasing quality, and access for all Americans. It is important not to lose sight of the goal: to protect and improve the health of all populations. After spending 18 months in a public policy fellowship and working with the Ways and Means Committee in Congress, Nancy Ridenour, PhD, RN and dean of the College of Nursing at the University of New Mexico, described her opportunity to work with others as the ACA was being developed. At a board of nursing celebration in Kentucky in the summer of 2014, Dr. Ridenour explained to the audience that it would be important for nurses to be involved in the implementation of the ACA to promote the success of the health care changes proposed. It is all about the influence of nurses and the nursing profession! (Kentucky Board of Nursing, 2014).

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Informatics—Use information and technology to communicate, manage knowledge, mitigate error, and support decision making.

Important aspects of Informatics include the following:

Knowledge: Identify essential information that must be available in a common database to support interventions in the health care system.

Skills: Use information management tools to monitor outcomes of intervention processes.

Attitudes: Value technologies that support decision making, error prevention, and case coordination.

Informatics Question: Updated informatics definitions focus on having access to the necessary client and system information at the right time, to make the best clinical decision. In the U.S. Department of Health and Human Services (USDHHS) Strategic Plan for 2010 to 2015, there are five overarching goals.

Goal 1, Objective C focuses on "Emphasizing primary and preventive care linked with community prevention services." Which community data would a public health nurse assess to determine the work that needs to be done in a community related to this USDHHS strategic goal?

Answer: To assess future work that could be done to effectively address Goal 1, Objective C, public health nurses might gather data in the following areas:

- How informed are members of the community about existing community services that support health promotion (e.g., exercise classes, educational classes, self-management training, and nutrition counseling)?
- How relevant are the services offered by health centers to the needs of a community?
- Do payment or insurance barriers exist for individuals to access preventive health services?
- How accessible is entry to care for vulnerable populations such as pregnant women and infants?
- What community-based prevention programs exist for individuals with and at risk for chronic diseases and conditions?
- How available are substance abuse screening and intervention programs?
- How linked are primary care and health promotions and wellness programs in a community?

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

TABLE 3-2 Overview of Key Features of the Affordable Care Act by Year**2010*****New Consumer Protections***

- Putting information for consumers online.
- Prohibiting denying coverage of children based on pre-existing conditions.
- Prohibiting insurance companies from rescinding coverage.
- Eliminating lifetime limits on insurance coverage.
- Regulating annual limits on insurance coverage.
- Establishing consumer assistance programs in the states.

Improving Quality and Lowering Costs

- Providing small business health insurance tax credits.
- Offering relief for 4 million seniors who hit the Medicare prescription drug “donut hole.”
- Providing free preventive care.
- Preventing disease and illness.
- Cracking down on health care fraud.

Increasing Access to Affordable Care

- Providing access to insurance for uninsured Americans with pre-existing conditions.
- Extending coverage for young adults.
- Expanding coverage for early retirees.
- Rebuilding the primary care workforce.
- Holding insurance companies accountable for unreasonable rate hikes.
- Allowing states to cover more people on Medicaid.
- Increasing payments for rural health care providers.
- Strengthening community health centers.

2011***Improving Quality and Lowering Costs***

- Offering prescription drug discounts.
- Providing free preventive care for seniors.
- Improving health care quality and efficiency.
- Improving care for seniors after they leave the hospital.
- Introducing new innovations to bring down costs.

Increasing Access to Affordable Care

- Increasing access to services at home and in the community.

Holding Insurance Companies Accountable

- Bringing down health care premiums.
- Addressing overpayments to big insurance companies and strengthening Medicare Advantage.

2012***Improving Quality and Lowering Costs***

- Linking payment to quality outcomes.
- Encouraging integrated health systems.
- Reducing paperwork and administrative costs.
- Understanding and fighting health disparities.

Increasing Access to Affordable Care

- Providing new, voluntary options for long-term care insurance.

2013***Improving Quality and Lowering Costs***

- Improving preventive health coverage.
- Expanding authority to bundle payments.

Increasing Access to Affordable Care

- Increasing Medicaid payments for primary care doctors.
- Open enrollment in the health insurance marketplace begins.

2014***New Consumer Protections***

- Prohibiting discrimination due to pre-existing conditions or gender.
- Eliminating annual limits on insurance coverage.
- Ensuring coverage for individuals participating in clinical trials.

Improving Quality and Lowering Costs

- Making care more affordable.
- Establishing the health insurance marketplace.
- Increasing the small business tax credit.

Increasing Access to Affordable Care

- Increasing access to Medicaid.
- Promoting individual responsibility.

2015***Improving Quality and Lowering Costs***

- Paying physicians based on value, not volume.

For more detail about each of the bulleted statements please refer to [HHS.gov/HealthCare](http://www.hhs.gov/healthcare/facts/timeline/) (Key Features of the Affordable Care Act, 2014: <http://www.hhs.gov/healthcare/facts/timeline/>).

PRACTICE APPLICATION

During a well-child clinic visit, Jenna Wells, RN, met Sandra Farr and her 24-month-old daughter, Jessica. The Farris had recently moved to the community. Mrs. Farr stated that she knew that Jessica needed the last in a series of immunizations and because they did not have health insurance, she brought her daughter to the public health clinic. On initial assessment, Mrs. Farr told the nurse that her husband would soon be employed, but the family had no health care coverage for the next 30 days. The Farris also needed to decide which health care package they wanted. Mr. Farr's company offers a preferred provider organization (PPO), a health maintenance organization (HMO), and

a community nursing clinic plan to all employees. Neither Mr. nor Mrs. Farr has ever used an HMO or a community nursing clinic, and they are not sure what services are provided.

Mrs. Farr asks Nurse Wells what she should do.

Nurse Wells should do which of the following?

- Encourage Mrs. Farr to choose the HMO because it will pay more attention to the family's preventive needs, and direct Mrs. Farr to other sources of health care should the family need to see a provider while they are uninsured.
- Encourage Mrs. Farr to choose the PPO because it will have a greater number of qualified providers from which to

PRACTICE APPLICATION—cont'd

choose, and direct Mrs. Farr to other sources of health care should the family need to see a provider while they are uninsured.

- C. Encourage Mrs. Farr to choose the local community nursing center because it is staffed with nurse practitioners who are well qualified to provide comprehensive health care with an emphasis on health education, and direct Mrs. Farr to other sources of health care should the family need to see a provider while they are uninsured.

- D. Explain the differences between a PPO, HMO, and community nursing clinic and encourage Mrs. Farr to discuss the options with her husband about signing up for a health insurance plan under the ACA plans, and direct Mrs. Farr to other sources of health care should the family need to see a provider while they are uninsured.

Answers can be found on the Evolve site.

KEY POINTS

- Health care in the United States is made up of a personal care system and a public health system, with overlap between the two systems.
- Primary care is a personal health care system that provides for first contact and continuous, comprehensive, and coordinated care.
- Primary health care is essential care made universally accessible to individuals and families in a community. Health care is made available to them through their full participation and is provided at a cost that the community and country can afford.
- Primary care and the public health systems are part of primary health care.
- Public health refers to organized community efforts designed to prevent disease and promote health.
- Important trends that affect the health care system include demographic, social, economic, political, and technological trends.
- More than 48 million people in the United States were uninsured in 2012, and many more simply lacked access to adequate health care.
- With the implementation of the Affordable Care Act (ACA), by 2014 the numbers of uninsured dropped by 8%.
- Many federal agencies are involved in government health care functions. The agency most directly involved with the health and welfare of Americans is the U.S. Department of Health and Human Services (USDHHS).
- Most state and local jurisdictions have government activities that affect the health care field.
- Health care and insurance reform measures seek to make changes in the cost and quality of and access to the present system, such as the ACA passed in 2010.
- To achieve the specific health goals of programs such as *Healthy People 2020*, primary care and public health must work within the community for community-based care.
- The most sustainable individual and system changes come when people who live in the community have actively participated.
- Nurses are more than able to fill the gap between personal care and public health because they have skills in assessment, health promotion, and disease and injury prevention; knowledge of community resources; and the ability to develop relationships with community members and leaders.
- Nurses are important to the success of the ACA.

CLINICAL DECISION-MAKING ACTIVITIES

1. Compare local and state services. How have they been affected by the implementation of the ACA? What changes would you recommend to your local health department to improve public health and primary care?
2. Debate the following with a classmate. The major problem with the health care system is (choose one of the following topics):
 - a. Escalating costs (including those from increased technology)
 - b. Fragmentation of services
 - c. Limited access to care
 - d. Quality of care
3. Visit your local health department and determine how its services fit into a primary care, public health, community-based health care system. Illustrate what you mean by your answer with examples.
4. Determine whether there is a federally funded health center in your community. If yes, learn what services are provided. Are there services that are needed in the community that are not being provided? If so, what are they?

Perspectives in Global Health Care

Anita Hunter, PhD, APRN-CPNP

Dr. Anita Hunter, a pediatric nurse practitioner since 1975, has worked with vulnerable populations of children and families living in poor urban and rural communities. Her work with culturally diverse populations expanded to the international arena in 1994 when she began taking students and faculty on clinical immersion experiences into Northern Ireland, Ghana, Mexico, the Dominican Republic, and Uganda; each trip evolved into sustainable health initiatives within the country. Dr. Hunter serves as an Executive Board Member for the Holy Innocents Children's Hospital Uganda NGO (nongovernmental organization) that oversees the development and management of the Holy Innocents Children's Hospital in Uganda. Dr. Hunter holds the BSN from Elms College; the PNP from Northeastern University; an MSN-CNS from the University of Massachusetts and the PhD from the University of Connecticut. Currently, Dr. Hunter is Professor and Co-Coordinator of the FNP track at Washington State University, Vancouver, WA.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Identify the major aims and goals for global health that have been presented by the *Millennium Global Developmental Goals: 2013 Report*
2. Identify the health priorities of Health for All in the 21st Century (HFA21) and *Healthy People 2020*.
3. Analyze the role of nursing in global health.
4. Explain the role and focus of a population-based approach for global health.
5. Discuss the many causes of global health problems.
6. Identify some solutions for at least one of these global health problems.
7. Describe how global health is related to economic, industrial, environmental, and technological development.
8. Compare and contrast the health care system in a developed country with one in a less developed country.
9. Define *burden of disease*.
10. Explain how countries can prepare for natural and manmade disasters and the role of nurses in these efforts.
11. Describe at least five organizations that are involved in global health.

Nutrition and World Health

Natural and Man-Made Disasters

This chapter presents an overview of the major public health problems of the world, along with a description of the role and involvement of nurses in global and community health care settings. It describes health care delivery from a global and population health perspective, illustrates how health systems operate in different countries, presents examples of organizations that address global health, and explains how economic development relates to health care throughout the world.

OVERVIEW AND HISTORICAL PERSPECTIVE OF GLOBAL HEALTH

Global warming and the melting of the polar ice caps; world-wide droughts and the natural disasters of blizzards, hurricanes, tornadoes, volcanoes, typhoons, and earthquakes; war; growing populations and the impoverished, destitute populations of the world make it imperative that nurses know about global health. Recent movements in the global arena identify the need for nurses to practice global health diplomacy, expanding beyond the tenets of health care and education we once provided (Hunter et al, 2013). Evidence indicates that contamination of water sources by heavy metals such as arsenic, copper, cadmium, mercury, and lead, to name a few, arising from the earth's crust appears to be increasing around the globe because of the changing environmental conditions (Fernández-Luqueño et al, 2013; Bolender et al, 2012, 2013; World Health Organization. *Heavy metals in children*, 2011). What once were the unique health challenges of people in less developed countries, such as loss of human rights; and lack of access to food, housing, safety, and health care, are now common problems of people all over the world. Contamination of the water sources in many countries, abject poverty, increasing global violence, the declining global economy, and the depletion of food supplies all contribute to the current global health crisis. See the Evidence-Based Practice box to learn how diarrheal outbreaks in Botswana correlate with poor water quality.

Preventable conditions such as malaria, malnutrition, communicable diseases, chronic health problems, and conditions related to environmental pollution are taxing the health care systems of many nations. Immigrants from developing nations often bring these conditions with them because of lack of access to health care services that could successfully diagnose or treat these issues in their home country. Understanding global health

EVIDENCE-BASED PRACTICE

Alexander and Blackburn (2013) did a historical analysis surveying data (2006–2009) to examine the temporal pattern of recurrent diarrheal outbreaks in Chobe District in Botswana in patients less than 5 years of age; as well as had patients of all ages presenting with diarrheal disease and medical staff complete a questionnaire survey tool during two diarrheal outbreaks (2011–2012). Cluster analysis and classification and regression trees (CART) were used to evaluate patient attributes by outbreak. Results showed that peak outbreaks appeared to coincide with major hydrological phenomena (rainfall/flood recession), water shortages, and water quality deficiencies. Public health strategy should be directed at securing improved water service and correcting water quality deficiencies. Public health education should include increased emphasis on sanitation practices when providing care to household members with diarrhea.

Nurse Use

Being culturally sensitive and responsive means that nurses need to understand where patients come from, what barriers exist that contribute to the public health problems they develop, and what can reasonably be done to reduce the health consequences of poverty and access deprivation. Given this research study, how could you as a nurse help reduce the incidence of diarrhea contamination in a family and across the village? One example might be to gather all the women together who have sick children and teach them how to improve sanitation and provide clean water; then have them go and teach the remainder of the village and expand that teaching to other villages. What might be other examples?

and factors that contribute to the immigrant's health problems better prepares the nurse to develop interventions that are culturally congruent, culturally responsive, and culturally acceptable to the people for whom interventions are planned. It is well known that nurses provide more than 90% of all the health care services for people around the globe (Bryar et al, 2012), and the vision of the International Council of Nurses (ICN)'s Leadership for Change program is that nursing is to take a leadership role in helping achieve better health for all. Yet, in sub-Saharan Africa, reported to have 25% of the world's disease burden, the patients are cared for by only 1.3% of the world's trained health workforce, most of those being nurses (Bryar et al, 2012).

In 1977 attendees at the annual meeting of the World Health Assembly stated that all citizens of the world should enjoy a level of health that would permit them to lead a socially and economically productive life. This goal was to have been

achieved by the year 2000; however, man-made and natural disasters, political corruption, lack of infrastructure in less developed nations, and unforeseen obstacles have inhibited this goal from being achieved. The goals of Health for All by the Year 2000 (HFA2000) were extended into the next century with the document **Health for All in the 21st Century (HFA21)**: <http://www.euro.who.int/en/publications/policy-documents/health21-health-for-all-in-the-21st-century>). The four main HFA21 strategies for action to ensure that scientific, economic, social and political sustainability were those designed as follows:

1. To tackle the determinants of health, taking into account physical, economic, social, cultural, and gender perspectives, and ensuring the use of health impact assessment
 2. As health-outcome-driven programs and investments for health development and clinical care
 3. For integrated family- and community-oriented primary health care, supported by a flexible and responsive hospital system
 4. As a participatory health development process that involves relevant partners for health at home, school, and work and at local community and country levels, and that promotes joint decision making, implementation and accountability
- HFA laid the foundation for the Healthy People agendas of *Healthy People 2020*.

HEALTHY PEOPLE 2020

Selected Objectives That Apply to Global Health Care

- EH-4: Increase the proportion of persons served by community water systems who receive a supply of drinking water that meets the regulations of the Safe Drinking Water Act.
- EH-5: Reduce waterborne disease outbreaks arising from water intended for drinking among persons served by community water systems.
- FP-1: Increase the proportion of pregnancies that are intended.
- GH-1: Reduce the number of cases of malaria reported in the United States.
- HIV-1: Reduce the number of new HIV diagnoses among adolescents and adults.
- MICH-3: Reduce the rate of child deaths.

EH, Environmental Health; FP, Family Planning; GH, Global Health; HIV, Human Immunodeficiency Virus; MICH, Maternal, Infant, and Child Health.

From U.S. Department of Health and Human Services: *Healthy People: 2020 Topics and Objectives*. Retrieved December 2014 from <http://www.healthypeople.gov/2020/topicsobjectives2020/default.aspx>. Accessed January 1, 2011.

Each of the previous goals has relevance to the global arena. The millions of deaths related to unsafe water and poor hygiene is most pronounced in Africa and Southeast Asia. This relates to objectives EH-4 and EH-5 (see the **Healthy People 2020** Box). Six in ten pregnancies in developing nations are unintended and relate to objective FP-1 (Kott, 2011). Malaria caused an estimated 627,000 deaths, mostly among African children (World Health Organization [WHO] **Malaria Fact Sheet, 2013a**), which relates to objective GH-1. Sub-Saharan Africa remains most severely affected with HIV/AIDS, with nearly 1 in every 20 adults (4.9%) living with HIV and accounting for

69% of the people living with HIV worldwide (WHO **Fact Sheet on Global HIV/AIDS, 2012a**), which relates to objective HIV-1. Last, the leading causes of death in under-five children are pneumonia, preterm birth complications, birth asphyxia, diarrhea, and malaria (about 45% of all child deaths are linked to malnutrition). Children in sub-Saharan Africa are about 16 times more likely to die before the age of five than children in developed regions (WHO **Child Deaths Fact Sheet, 2013b**); this relates to objective MICH-3. See the **Quality and Safety in Nursing Education** box for suggestions for how to deal with malaria through a team approach.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

As described in earlier chapters of the text, including **Chapter 2**, there are six QSEN competencies for nursing. Because of the complex and multifaceted nature of providing public health nursing care in countries around the world, competency number two, teamwork and collaboration, is emphasized here.

Teamwork and collaboration refer to the ability to function effectively with nursing and interprofessional teams and to foster open communication, mutual respect, and shared decision making in order to best provide safe and quality care. One of the United Nations Millennium Development Goals is to combat HIV/AIDS, malaria, and other diseases (see **Box 4-1**).

The quality and safety question is as follows: How would nurses working in a country that is plagued by malaria develop a team to help control this mosquito-borne disease?

Answer: The spread of malaria can be interrupted by prevention, treatment, and control measures such as using insecticide-treated bed nets and spraying in and near where people live, work, and go to school. Nurses would develop a team including representatives from funding agencies, environmental health, NGOs, medical practitioners, and local governments to locate funds and develop, implement, and evaluate prevention, control, and treatment measures.

Because of the ease of global travel, contagious and preventable health conditions are not endemic in just an isolated country; they are prevalent around the world. Health professionals and world leaders want to be enlightened about these health issues and want answers on how to address them, which becomes problematic in the countries most afflicted but without the technological infrastructure to help their people.

Many terms are used to describe nations that have achieved a high level of industrial and technological advancement (along with a stable market economy) and those that have not. For the purposes of this chapter, the term **developed country** refers to those countries with a stable economy and a wide range of industrial and technological development, low child mortality, high gross national income, and a high human asset index (e.g., the United States, Canada, Japan, the United Kingdom, Sweden, France, and Australia). A country that does not meet these criteria is referred to as a **less developed country** (e.g., Congo, Bangladesh, Somalia, Haiti, Guatemala, most countries in sub-Saharan Africa, and the island nation of Indonesia). Both developed and lesser-developed countries are found in all parts of the world and in all geographic and climatic zones (UN **Department of Economic and Social Affairs [DESA], 2013c**).

Health problems exist throughout the world, but the lesser-developed countries often have more unusual health care problems. There are more than 6000 rare diseases (Forman et al, 2012) and in developing countries such conditions as Buruli ulcers, leishmaniasis, river blindness, schistosomiasis, brucellosis, typhus, yellow fever, scurvy, and malaria are often unknown entities in the world of Western medicine (Molyneux and Sayioli, 2013). Ongoing health problems needing control in lesser-developed countries include measles, mumps, rubella, and polio; the current health concerns of the more-developed countries are problems such as hepatitis, infectious diseases, and new viral strains such as hantavirus, SARS (severe acute respiratory syndrome), H1N1, and avian flu. Chronic health problems such as hypertension, diabetes, cardiovascular disease, obesity, cancer, the resurgence of human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS) among adolescents and young adults, drug-resistant tuberculosis (TB); and the larger social, yet health-related, issues such as terrorism, warfare, violence, and substance abuse are now global issues (Shah, 2014). World travelers may expose themselves to diseases and environmental health hazards that are unknown or rare in their home country, and may serve as hosts to various types of disease agents. Two recent examples of diseases that were once fairly isolated and rare but are now widespread throughout the world are AIDS and drug-resistant TB (Institute of Medicine [IOM], 2010b; U.N. Global Health Report, 2013d) (Figure 4-1).

In addition to direct health problems, increasing populations, migration within countries, political corruption, lack of natural resources, and natural disasters affect the health and well-being of populations. Dr. Paul Farmer in his book *Pathologies of Power* (2005) talks about the war on the poor; how many migrate to the city to find employment, where limited employment opportunities exist. Such migration leads to the development of shanty towns often built on the outskirts of cities, on unstable ground, and in areas vulnerable to natural disasters such as hurricanes, tsunamis, and earthquakes such as those in

Haiti, Chile, and Indonesia. These environments are unsanitary, unsafe, and a breeding ground for TB, dysentery, malnutrition, abuse of women and children, and mosquito and other insect or animal-borne diseases.

Nations plagued by civil war and political corruption are faced with chronic poverty, unstable leadership, and lack of economic development. The effects of war and conflict also have devastating effects on a country and the health of its population. The wars in Afghanistan, Iraq, and the West Bank of Palestine, to name a few, have had devastating mental and physical health consequences, leaving each country and its people with few health care services or other resources to sustain life. A recent research study about the long-term effects of children exposed to war (Asia, 2009) supports the negative health consequences of such exposure. For example, changes in biomarkers can lead to future chronic health conditions such as cardiovascular disease, autoimmune conditions, cancer, and mental health problems.

As countries promote the objectives of HFA21, they realize that they need to improve their economies and infrastructures. They often seek funds and technological expertise from the wealthier and more-developed countries (World Bank, Concessional Finance and Global Partnership Report, 2013a). According to the WHO (2013c), HFA21 is not a single, finite goal but a strategic process that can lead to progressive improvement in the health of people. In essence, it is a call for social justice and solidarity. Unfortunately, the lesser-developed nations still lack the infrastructure necessary to achieve health promotion and living conditions, as many of these countries continue to deteriorate for the poor, and environments that breed infections are the norm (Figure 4-2).

The UN Millennium Development Goals (MDGs) were first agreed on by world leaders at the Millennium Summit in 2000 (see Resource Tool 4.A on the book's Evolve site). The MDGs were developed to relieve poor health conditions around the world and to establish positive steps to improve living conditions by the year 2015 (UN, 2013a; see goals in Box 4-1).

FIG 4-2 The streets of a typical town in Uganda. (Courtesy A. Hunter.)

BOX 4-1 Millennium Goals**Millennium Development Goals**

MDG 1: Eradicate extreme poverty and hunger.
 MDG 2: Achieve universal primary education.
 MDG 3: Promote gender equality and empower women.
 MDG 4: Reduce child mortality.
 MDG 5: Improve maternal health.
 MDG 6: Combat HIV/AIDS, malaria, and other diseases.
 MDG 7: Ensure environmental sustainability.
 MDG 8: Develop a global partnership for development.

From United Nations: UN millennium development goals (MDGs). 2005. Available at <http://www.un.org/millenniumgoals/>. Accessed August 25, 2014.

These goals have continued to evolve as natural disasters and internal strife continue to affect the poor and the vulnerable. The Millennium Report ([UN Millennium Development Report, 2013a](#)) describes the developed nations' responsibility to the betterment of those in lesser-developed nations. The revised goals highlight the global responsibility to eradicate poverty and hunger; achieve universal primary education for all children; promote gender equality and empower women; reduce child mortality; improve maternal health; combat HIV/AIDS, malaria, and other diseases; ensure environmental sustainability; and develop a global partnership for development. Unfortunately, the 2013 report indicated that one in eight people worldwide remains hungry; death in childbirth is still a major problem; more than 2.5 billion people still lack improved sanitation facilities; and climate change has caused the loss of forests, species and fish stocks. The United States supports the Millennium Development Goals in its Global Health Initiatives (www.ghi.gov Accessed December 20, 2014) as has the ICN. Continued work to develop economic agreements between countries so as to remove financial and political barriers has stimulated growth and development; but, is it enough?

Despite efforts by individual governments and international organizations to improve the general economy and welfare of all countries, many health problems continue to exist, especially among poorer people. Many countries lack both political commitment to health care and recognition of basic human rights. They may fail to achieve equity in access to primary health care, demonstrate inappropriate use and allocation of resources for high-cost technology, and maintain a low status of women. At present, the lesser-developed countries experience high infant and child death rates (http://gamapserver.who.int/gho/interactive_charts/MDG4/atlas.html), with diarrheal and respiratory diseases as major contributory factors (under-five and infant mortality rates, by [WHO region](#); [WHO, 2013d](#)).

Other major worldwide health problems include nutritional deficiencies in all age groups, women's health and fertility problems, sexually transmitted infections (STIs), and illnesses related to the human immunodeficiency virus (HIV), malaria, drug-resistant TB, neonatal tetanus, leprosy, occupational and environmental health hazards, and abuses of tobacco, alcohol, and drugs. Because of these continuing problems, the director general of the WHO has made a commitment to renew all of

FIG 4-3 A community living in a dump in Miacatlán, Mexico. (Courtesy A. Hunter.)

the policies and actions of HFA21. The [WHO \(2013c\)](#) continues to develop new and holistic health policies that are based on the concepts of equity and solidarity, with an emphasis on the individual's, family's, and community's responsibility for health. Strategies for achieving the continuing goals of HFA21 include building on past accomplishments and the identification of global priorities and targets for the first 20 years of the new century.

Nurses need to be informed about global health. Many of the world's health problems directly affect the health of individuals who live in the United States. For example, the One Hundred Third U.S. Congress passed the North American Free Trade Agreement (NAFTA), which opened trade borders between the United States, Canada, and Mexico in 1994 and allowed increased movement of products and people. Along the United States–Mexico border, an influx of undocumented immigrants in recent years has raised concerns for the health of people who live in this area. For example, many immigrants have settled on unincorporated land, known as *colonias*, outside the major metropolitan areas in California, Arizona, New Mexico, and Texas. These colonies may have no developed roads, transportation, water, or electrical services ([U.S. Geological Survey \[USGS\]: U.S.–Mexico Border Environmental Health Report, 2011](#)) (Figures 4-3 and 4-4).

Conditions in these settlements have led to an increase in disease conditions such as amebiasis and respiratory and diarrheal diseases. Environmental health hazards in the *colonias* are associated with poverty, poor sanitation, and overcrowded conditions ([USGS: U.S.–Mexico Border Environmental Health Report, 2011](#)). On a more positive note, NAFTA has provided an impetus and framework for the government of Mexico to modernize their medical system so that they can compete and respond to the demands of more global competition. Although some improvements have been made, there is still an overriding concern that environmental and health regulations in Mexico have not kept up with the pace of increased border trade ([California Department of Public Health, Office of Binational](#)

FIG 4-4 Diseases in the colonias. (From PBS Online, *The Forgotten Americans*. Available at <http://www.pbs.org/klru/forgottenamericans/focus/health.htm> and <http://abcnews.go.com/US/hidden-america-forgotten-struggle-survive-texas-barren-colonias/story?id=16213828> and <http://www.cinelasamericas.org/special-events/1060-the-forgotten-americans-a-film-by-hector-galan> (Accessed March 20, 2014).)

Border Health, Border Health Status Report, 2011). The Mexican National Academy of Medicine continues to make health and environmental recommendations to the government, which illustrates the beneficial interactions that are occurring between Mexico, Canada, and the United States as part of this trade agreement. Nurses play a significant role in obtaining health for the indigent and undocumented persons who live along the border regions in Texas, New Mexico, Arizona, and California. Nurses supported by private foundations and by local and state public health departments often provide the only reliable health care in these areas.

Interestingly, Canadian worker groups were concerned that NAFTA would eventually lead to worsened working conditions as manufacturing plants move to the lower-wage and largely non-unionized southern United States and Mexico; however, reports indicate that trade, standard of living, and employment opportunities have risen (Ibbitson, 2012).

THE ROLE OF POPULATION HEALTH

Population health refers to the health outcomes of a group of individuals, including the distribution of such outcomes within the group, and includes health outcomes, patterns of health determinants, and policies and interventions that link these two. It is an approach and perspective that focuses on the broad range of factors and conditions that have a strong influence on the health of populations (environment, genetics, ethnicity, pollution, and physical and mental stressors affecting a community). Using epidemiologic trends, population health emphasizes health for groups at the population level rather than at the individual level and focuses on reducing inequities, improving health in these groups to reduce morbidity and mortality, and

BOX 4-2 Examples of the Healthy Cities Movement

Toronto, Ontario, Canada was one of the first cities in North America to become involved in the Healthy Cities movement. Toronto began with a strategic planning committee to develop an overall strategy for health promotion. The committee conducted vision workshops in the community and a comprehensive environmental scan to help identify health needs in Toronto. The outcome was a final report outlining major issues, and it included a strategic mission, priorities, and recommendations for action. The Toronto Healthy City program involved a number of projects. One of them, the Healthiest Babies Possible project, was an intensive antenatal education and nutritional supplement program for pregnant women who were identified by health and social agencies as being at high risk. The program included intensive contact and follow-up of women, along with food supplements. It has been successful in decreasing the incidence of low-birth-weight infants.

Another example is Chengdu, China. Chengdu is located on the upper parts of the Yangtze River. It is surrounded on four sides by the Fu and Nan Rivers and was one of the most polluted cities in southwestern China. The pollution created severe environmental problems as a result of industrial waste, raw sewage, and the intensive use of fresh water. The proliferation of slum and squatter settlements exacerbated the social, economic, and environmental problems of the city. The Fu and Nan Rivers Comprehensive Revitalization Plan was started in 1993 as a Healthy Community and City initiative to deal with the growing environmental problems. The principles of participatory planning and partnership were used to raise awareness of the problem among the general public and to mobilize major stakeholders to invest in a sustainable future for Chengdu and its inhabitants. The plan resulted in providing 30,000 households living in the slum and squatter settlements with decent and affordable housing, and with projects to deal with sewage and industrial waste. In addition, the plan was able to improve parks and gardens, turning Chengdu into a clean and green city within the natural flow of its rivers.

From Flynn B, Ivanov L: Health promotion through healthy communities and cities. In *Community & Public Health Nursing*, ed 6, St. Louis, 2004, Mosby, pp 396–411.

assessing emerging diseases and other health risks to a community (IOM, 2010a). A population can be defined by a geographic boundary, by the common characteristics shared by a group of people such as ethnicity or religion, or by the epidemiologic and social conditions of a community.

The factors and conditions that are important considerations in population health are called **determinants**. Population health determinants may include income and social factors, social support networks, education, employment, working and living conditions, physical environments, social environments, biology and genetic endowment, personal health practices, coping skills, healthy child development, health services, sex, and culture (WHO, *Health Impact Assessment*, 2014a). The determinants do not work independently of each other but form a complex system of interactions.

Canada is a leader in promoting the population health approach. Canada has been implementing programs using this framework since the mid-1990s and builds on a tradition of public health and health promotion. Box 4-2 presents the development of the Healthy Cities movement in Toronto. This successful project has been adopted by the WHO and is being implemented in several countries around the world—most specifically Europe, Southeast Asia, Africa, and the Western Pacific

(WHO, *Healthy Cities*, 2014b). A key to the success of this project has been the identification and definition of health issues and of the investment decisions within a population that were guided by evidence about what keeps people healthy. Therefore a population health approach directs investments that have the greatest potential to influence the health of that population in a positive manner. A Healthy City aims to create a health-supportive environment, achieve a good quality of life, provide basic sanitation and hygiene needs, and supply access to health care. The most successful Healthy Cities programs have a commitment of local community members, a clear vision, ownership of policies, a wide array of stakeholders, and a process for institutionalizing the program.

Integration of health determinants into public policies is apparent on the global stage. At the 2009 Nairobi Global Conference on Health Promotion, more than 600 participants representing 100 countries adopted a Call to Action on addressing population health and finding ways to promote health at the global level. Health and development today face unprecedented threats by the financial crisis, global warming and climate change, and security threats. Since 1986, with the development of the first Global Conference, until 2009, a large body of evidence and experience has accumulated about the importance of health promotion as an integrative, cost-effective strategy, and as an essential component of health systems primed to respond adequately to emerging concerns (WHO, 2010a, 2014c).

As nurses work with immigrants from global arenas or become active participants in health care around the world, understanding such concepts as population health and the determinants of health for a population becomes more important than the most advanced acute care skills. These skills, though important, are intended to help an individual; population health skill sets can help the world.

PRIMARY HEALTH CARE

The ultimate goal of **primary health care** (PHC) is to achieve better health for all. WHO (2014c) has identified five key elements to achieving that goal:

1. Reducing exclusion and social disparities in health
2. Organizing health services around people's needs and expectations
3. Integrating health into all sectors
4. Pursuing collaborative models of policy dialogue
5. Increasing stakeholder participation

These aims continue to be reinforced and modified and were recently updated to incorporate MDGs (WHO, 2014c). Such services included the following:

- An organized approach to health education that involves professional health care providers and trained community representatives
- Aggressive attention to environmental sanitation, especially food and water sources
- Involvement and training of community and village health workers in all plans and intervention programs
- Development of maternal and child health programs that include immunization and family planning

- Initiation of preventive programs that are specifically aimed at local endemic problems such as malaria and schistosomiasis in tropical regions
- Accessibility and affordability of services for the treatment of common diseases and injuries
- Availability of chemotherapeutic agents for the treatment of acute, chronic, and communicable diseases
- Development of nutrition programs
- Promotion and acceptance of traditional medicine

Global leaders have recognized the need to get nations committed to the health care agenda. An important effort is needed at the level of recruitment, education, and retention of primary health care workers, including primary care nurses, family physicians, and mid-level care workers. Professional organizations, clinical agencies, universities, and other institutions for higher education should continue to demonstrate their "social accountability" by training appropriate providers.

It is well documented that PHC practiced in high-income countries exerts a positive influence on health costs, appropriateness of care, and outcomes for most of the major health indicators. They also have more equitable health outcomes than systems oriented toward specialty care. In low and middle income countries the research studies did find consistent evidence of the impact of PHC on improved health outcomes; however, there were problems with the research rigor and validity of instrumentation to make any further statement than that health outcomes did improve.

NURSING AND GLOBAL HEALTH

Nurses play a leadership role in health care throughout the world. Those with public health experience provide knowledge and skill in countries where nursing is not an organized profession, and they give guidance to the nurses as well as to the auxiliary personnel who are part of the primary health care team (Bryar et al, 2012). In many areas in the developed world, nurses provide direct client care and help meet the education and health promotion needs of the community. They are viewed as strong advocates for primary health care, through social commitment to equality of health care and support of the concepts that are contained in the Declaration of Alma-Ata (Bryar et al, 2012).

Unfortunately, in the lesser-developed countries, the role of the nurse is defined poorly, if at all, and care often depends on and is directed by physicians. I have seen health care systems in Africa, Mexico, and the Dominican Republic in which nursing is not valued and the ability of nurses to contribute to improving an individual's health, much less a community's health, is minimal. Much work is needed to raise the bar in the education of nurses in these countries so they have the skills necessary to make a difference; however, overcoming some of the cultural and gender-role barriers makes this process laborious (Figure 4-5).

Nurses have led in care delivery after the devastating tsunami in South Asia, and more recently after the earthquakes in Haiti and Chile in 2010. Other health interventions have been the interprofessional work of nursing and science to build and open a dedicated children's hospital in Uganda (Bolender and Hunter,

FIG 4-5 Uganda hospital information for nurses assisting in labor and delivery. (Courtesy A. Hunter.)

2010; Bolender, McDonald and Hunter, 2013), the nurse-developed Ghana Health Mission (Hunter and McKenry, 2005; <https://ghanahealthmission.wordpress.com/>), a nurse-led chronic illness management program in Thailand (Sindhu et al, 2010), and a nurse-led mental health program for Chinese patients (Chien et al, 2012) are just a few examples of nurse-initiated health programs around the globe.

The role of nursing in China and Taiwan is noteworthy. Nursing in China is undergoing a dramatic change, largely because of an evolving political and economic environment. In the past, nursing was viewed as a trade, and the acquisition of nursing skills and knowledge took place in the equivalent of a middle school or junior high school in the United States. Increasing pressure on the health care system in China is providing an impetus for education at the university level. The Chinese government has sent many nurses to the United States, Europe, and Australia to receive university-level education in nursing at the undergraduate and graduate levels in hopes that these individuals will return to China to provide the nursing and nursing education needed there; but very few do, and a recent poll in China indicated that if the nurses could leave China to practice elsewhere, they would (*Global Times*, 2011). I, in conjunction with a colleague (Dr. Mary Jo Clark), have consulted in Taiwan, helping them establish their nurse practitioner programs and to implement their doctoral programs in nursing. Part of that consultation involved the use of standardized clients as a component for certification and license to practice as a nurse practitioner. The United States has entertained this idea.

In some countries, such as Chile, the physician-to-population ratio is higher than the nurse-to-population ratio. In these cases, physicians influence nursing practice and place economic and political pressure on local, regional, and national governments to control the services that nurses provide. In

Chile, nurses have set up successful and cost-effective clinics to deliver quality primary care services. However, the nurses often are being threatened by physicians who want to remove the nurses and replace them with the more costly services of physicians (Organization for Economic Cooperation and Development [OECD], *Health at a Glance*, 2011). Box 4-3 describes nursing and health care efforts in Zambia.

Several nursing initiatives from the United States have been developed to help address some of these global health problems. According to Sheila Davis, ANP-BC, FAAN, Director of Global Nursing, Partners in Health, the Dana Farber Cancer Institute has supported the creation of a nursing oncology partnership with Inshuti Mu Buzima (IMB) in Rwanda. Four experienced oncology nurses have committed to working alongside local nurses and physicians at IMB for 3-month rotations, to help Rwandan nurses develop the specialized skills and experience needed to raise the quality of oncology care. Another is Regis College in Massachusetts, which has partnered with the Haitian Ministry of Health to tackle the nursing education shortage in Haiti by developing a comprehensive 3-year master's program for 12 Haitian nursing faculty members. Another is out of the University of San Diego, in collaboration with the Holy Innocents Children's Hospital in Uganda. Nurses and physicians have been actively involved in building the first children's hospital in the country and training the staff in pediatric care. A new entry into this global nursing arena is the development of the Global Nurse Initiative, a nonprofit organization that links health professionals with opportunities to volunteer in underprivileged areas (Global Nurse Initiative, 2013).

MAJOR GLOBAL HEALTH ORGANIZATIONS

Many international organizations have an ongoing interest in global health. Despite the presence of these well-meaning

BOX 4-3 Community Health Nursing in Zambia

The Ministry of Health, Churches Health Association, the private Medical Practitioners, and the Traditional Healer Services provide health care in Zambia. By 1995 there were 86 hospitals and 1345 health centers in the country. About 60% of the bed capacity is provided by the government hospitals and health centers, 26% by mission hospitals, and 13% by the Zambia Consolidated Copper Mines. At the time of independence, the population of Zambia was sparsely distributed, especially in the rural area, and there were inadequate health facilities. Health facilities were concentrated along the line of rail, and the provision of care was poor. This prompted the government to review the health care provision system after independence in 1964. The government then declared that health care services would be free for all, with the main health care services being curative rather than preventive. This policy was detrimental to Zambia, whose population was increasing.

In 1991 the government of the Republic of Zambia, under the leadership of the Movement for Multiparty Democracy, introduced the concept of National Health Reforms, the vision being to provide equitable access to high-quality, cost-effective health care intervention as close to the family as possible. Health reforms stress the need for families and communities to be self-reliant and to participate in their own health care provision and development. The major component of the health policy reform is the restructured primary health care (PHC) program. This has been defined as the essential health care made universally accessible to individuals and families by means acceptable to them through their full participation and at a cost that the community and country can afford. The principles of PHC include community participation and intersectoral collaboration. Families are considered a unit of service, as most health care provision starts with the family setting. The Zambian government is committed to the fundamental and humane principle in the development of the health care system to provide Zambians with the equity of access to cost-effective quality health care as close to the family as possible.

The National Health Reforms decentralized power to districts, and home-based care (HBC) was introduced. HBC was adopted and implemented in all districts as a way of cost sharing between the government, families, and community. HBC led to reduced congestion in hospitals, and government resources were not overstrained as families also took part in supplying the needed resources, time, and personnel (caregivers) when the clients were cared for at home.

Nurses provide about 75% of the health force in Zambia. The community health nursing component is one of the major components of the nursing curriculum at all levels of training. Basically, every general nurse is taught to operate as a community health nurse. However, to be registered as a public health nurse by the General Nursing Council of Zambia, one must undergo the following levels of training. The individual undergoes 3 years of training as a registered nurse followed by 1 year of training as a midwife. In the past they would then undergo 2 years of training at the University of Zambia to obtain a diploma in public health nursing. This was phased out when the bachelor of science in nursing degree was initiated. At present, the individual pursues the bachelor of science in nursing degree and majors in community health nursing in the final year.

The main role of the community health nurse includes competence and skill in the care of individuals, families, and communities in the following ways:

1. Critically explore and analyze current developments in community health as they relate to different populations at different levels of care.
2. Apply health promotion models and theories to community health nursing practice.
3. Design, implement, and manage community-based projects, programs, and services.
4. Integrate community-based agents into the health care system.
5. Use epidemiology concepts in the management of communicable and non-communicable diseases.

Courtesy Prudencia Mweemba, University of Zambia, School of Medicine, Department of Post Basic Nursing, Lusaka, Zambia, 2006.

organizations, it is estimated that the less developed countries still bear most of the cost for their own health care and that contributions from major international organizations actually provide for less than 5% of needed costs. Recent reports indicate that the majority of funds raised by international organizations are used for food relief, worker training, and disaster relief (Shah, 2012; World Food Program, 2014). Shah (2012) reports that aid is often wasted by requiring recipients to use overpriced goods and services from donor countries; most aid does not go to the country in greatest need as aid is often used in order for the richer country to get their foot in the door of the poorer country to access its resources; and graft is still a major problem in developing countries—promised monies are funneled into the pockets of the local politicians who were chosen to help the people.

International health organizations are classified as **multilateral organizations**, bilateral organizations, or **nongovernmental organizations (NGOs)** or **private voluntary organizations (PVOs)** (including philanthropic organizations). Multilateral organizations are those that receive funding from multiple government and nongovernment sources. The major organizations are part of the United Nations (UN), and they include the World Health Organization (WHO), the United Nations Children's Fund (UNICEF), the Pan American Health Organization (PAHO), and the World Bank. A **bilateral organization**

is a single government agency that provides aid to less developed countries, such as the U.S. Agency for International Development (USAID). NGOs or PVOs, including the philanthropic organizations, are represented by such agencies as Oxfam, Project Hope, the International Red Cross, various professional and trade organizations, Catholic Relief Services (CRS), church-sponsored health care missionaries, and many other private groups.

Specifically, the **World Health Organization (WHO)** is a separate, autonomous organization that, by special agreement, works with the United Nations through its Economic and Social Council. The idea for this worldwide health organization developed from the First International Sanitary Conference in 1902, a precursor to the WHO. The WHO was created in 1946 as an outgrowth of the League of Nations and the UN charter that provided for the formation of a special health agency to address the wide scope and nature of the world's health problems. The WHO, headed by a director general and five assistant generals, has three major divisions: (1) the World Health Assembly approves the budget and makes decisions about health policies, (2) the executive board serves as the liaison between the assembly and the secretariat, and (3) the secretariat carries out the day-to-day activities of the WHO. The principal work of the WHO is to direct and coordinate international health activities and to provide technical medical assistance to countries in need.

More than 1000 health-related projects are ongoing within the WHO at any one time. Requests for assistance may be made directly to the WHO by a country for a project, or the project may be part of a larger collaborative endeavor involving many countries. Examples of current collaborative, multinational projects include comprehensive family planning programs in Indonesia, Malaysia, and Thailand; applied research on communicable disease and immunization in several East African nations; and projects that investigate the viability of administering AIDS vaccines to pregnant women in South Africa and Namibia. For further information about the WHO, visit <http://www.who> and find the tab such as publications, countries, programmes, or health topics that meets your need. The WHO has supported the development of multiple health training programs for professionals in developing nations. An example of one is the Tanzania Nurse Initiative, which has been successful in strengthening nursing education in Tanzania by educating 415 nurses in HIV/AIDS prevention, care, and treatment; providing technical assistance and support on curriculum development and revision; and providing support to Tanzanian nursing schools (*Global Health Workforce Alliance*, 2014).

Another multilateral agency is the **United Nations Children's Fund (UNICEF)** (<http://www.unicef.org>). Formed shortly after World War II (WWII) to assist children in the war-ravaged countries of Europe, it is a subsidiary agency to the UN Economic and Social Council. After WWII, many social agencies realized that the world's children needed medical and other kinds of support. With financial assistance from the newly formed UN General Assembly, post-WWII programs were developed to control yaws, leprosy, and TB in children. Since then, UNICEF has worked closely with the WHO as an advocate for the health needs of women and children under the age of 5. In particular, there have been multinational programs aimed at the provision of safe drinking water, sanitation, education, and maternal and child health.

The **Pan American Health Organization (PAHO)** is one of the oldest continuously functioning multilateral agencies, founded in 1902, and predates the WHO. At present, PAHO serves as a regional field office for the WHO in Latin America, with a focused effort to improve the health and living standards of the Latin American countries. PAHO distributes epidemiologic information, provides technical assistance over a wide range of health and environmental issues, supports health care fellowships, and promotes health and environmentally related research, along with professional education. Focusing primarily on reaching people through their communities, PAHO works with a variety of governmental and nongovernmental entities to address the health issues of the people of the Americas. At present, a primary concern of PAHO is the prevention and control of AIDS and other sexually transmitted diseases amongst the most vulnerable: mothers and children, workers, the poor, older adults, refugees, and displaced persons. With the earthquakes in Haiti and Chile, and the drought and starvation in Guatemala, PAHO's attentions are being directed toward crisis intervention (<http://www.paho.org>). Other focused efforts include the provision of public information, the control and eradication of tropical diseases, and the development of health

system infrastructure in the poorer Latin American countries. PAHO collaborates with individual countries and actively promotes multinational efforts as well. Recently, PAHO has examined the effects of health care reform on nurses and midwifery in the Latin American countries and found that the reform changed the work environments, the scope of practice, and the relationship of nurses with other health care workers and providers. The role of PAHO in the development of healthy communities is discussed in [Chapter 20](#).

The **World Bank** (<http://www.worldbank.org>) is another multilateral agency that is related to the United Nations. Although the major aim of the World Bank is to lend money to the less developed countries so that they might use it to improve the health status of their people, it has collaborated with the field offices of the WHO for various health-related projects such as the control and eradication of the tropical disease onchocerciasis in West Africa, as well as programs aimed at providing safe drinking water and affordable housing, developing sanitation systems, and encouraging family planning and childhood immunizations. The World Bank also sponsors programs to protect the environment, as reflected by the \$30 million project in Brazil to protect the Amazon ecosystem and reduce the effects on the ozone layer; to support people in less developed countries to pursue careers in health care; and to improve internal infrastructure, including communication systems, roads, and electricity, all of which ultimately affect health care delivery.

Bilateral agencies operate within a single country and focus on providing direct aid to less developed countries. The U.S. Agency for International Development (USAID) (<http://www.usaid.gov>) is the largest of these and supports long-term and equitable economic growth and advances U.S. foreign policy objectives by supporting economic growth, agriculture, and trade; global health; and democracy, conflict prevention, and humanitarian assistance. It provides assistance in five regions of the world: sub-Saharan Africa, Asia, Latin America and the Caribbean, Europe and Eurasia, and the Middle East. All bilateral organizations are influenced by political and historical agendas that determine which countries receive aid. Incentives for engaging in formal arrangements may include economic enhancements for the benefit of both countries, national defense of one or both countries, or the enhancement and protection of private investments made by individuals in these nations. Something similar is present in other developed nations around the globe. For example, the Japanese government currently has an active collaborative arrangement with Indonesia to study ways to control the spread of yellow fever and malaria. France gives most of its aid to its former colonies.

Nongovernmental organizations (NGOs) or private voluntary organizations (PVOs), as well as philanthropic organizations, provide almost 20% of all external aid to less developed countries. NGOs and PVOs are represented by many different kinds of religious and secular groups. Representatives of these independent citizen organizations are increasingly active in policymaking at the United Nations. These organizations are often the most effective voices for the concerns of ordinary

people in the international arena. NGOs include the most outspoken advocates of human rights, the environment, social programs, women's rights, and more (Kaiser Family Foundation, 2010). An example of an NGO is the Holy Innocents Children's Hospital in Mbarara, Uganda (<http://www.holyinnocentsuganda.com>) (the result of a nurse-led initiative and a U.S.-based NGO that acquired the funds, built the hospital, trained the staff, and then turned it over to the Ugandans to operate and expand) is a 50-bed dedicated children's hospital that since its opening in 2009 has cared for more than 100,000 children. Its mortality rate is one quarter that of the local government hospital because the goal of the hospital was to save lives and to have available the necessary supplies to achieve this goal. The administrative and professional staff training has helped this hospital be self-sustaining with minimal continued assistance from the U.S.-based NGO and its donors.

The International Red Cross (<http://www.icrc.org>) is one of the best-known NGOs. Although the Red Cross is most often associated with disaster relief and emergency aid, it lays the groundwork for health intervention as a result of a country's emergency. It is a volunteer organization that consists of approximately 160 individual Red Cross societies around the world, and it prides itself on its neutrality and impartiality with respect to politics and history. Therefore, it seeks permission from the country in which the disaster occurs before services are rendered.

Another NGO that provides health services and aid to countries experiencing warfare or disaster is Médecins sans Frontières (MSF) (<http://www.msf.org>), also home of Doctors without Borders. It is an international, independent, medical humanitarian organization that delivers emergency aid to people affected by armed conflicts, epidemics, health care exclusion, and natural or man-made disasters. Unlike the Red Cross, MSF does not seek government approval to enter a country and provide aid and it often speaks out against observed human rights abuses in the country it serves. MSF was the recipient of the Nobel Peace Prize in 1999 and the Conrad Hilton Prize in 1998. In Uganda, Doctors without Borders is involved with the local medical school in Mbarara to help develop an intensive malaria intervention approach to help improve the survival rate of children affected by cerebral malaria (personal communication with Dr. Bitariho Deogratias, Professor of Orthopedics at Mbarara Science and Technology University School of Medicine, January 2013).

The professional and trade organizations are PVOs that are found mostly in the more developed and industrialized countries. One of the most famous of the professional and technical organizations is the Institut Pasteur (<http://www.pasteur.fr/ip/easysite/pasteur/en/institut-pasteur>), which began in the 1880s. Its laboratories have facilitated the development of sera and vaccines for countries in need, disseminated current health information, and trained and provided fellowships for medical training and study in France. They have facilities in Africa, South and Central America, and Southeast Asia.

Religious organizations, reflecting several denominations and religious interests, support many health care programs, including hospitals in rural and urban areas, refugee centers,

orphanages, and leprosy treatment centers. For example, the Maryknoll Missionaries, sponsored by the Roman Catholic Church, carry out health service projects around the world. The missionaries comprise a large group of religious as well as lay people trained and educated in a variety of educational and health care professions. The Catholic Relief Services (CRS) (<http://crs.org>) is the official international humanitarian agency of the Catholic community in the United States. CRS alleviates suffering and provides assistance to people in need who are affected by war, starvation, famine, drought, and natural disasters, in more than 100 countries, without regard to race, religion, or nationality. Many Protestant and evangelical groups throughout the world function both as separate entities and as part of the Church World Service, which works jointly with secular organizations to improve health care, community development, and other needed projects. Other private and voluntary groups that assist with the worldwide health effort include CARE (<http://www.care.org>), Oxfam (www.oxfam.org.uk), and Third World First. Several of these organizations receive additional funding from developed countries including the United States, the United Kingdom, Sweden, Canada, and countries in Western Europe.

Philanthropic organizations receive funding from private endowment funds. A few of the more active philanthropic organizations that are involved in world health care include the W. K. Kellogg Foundation, the Milbank Memorial Fund, the Pathfinder Fund, the Hewlett Foundation, the Ford Foundation, the Rockefeller Foundation, the Carnegie Foundation, and the Gates Foundation. The purpose and programmatic goals of each organization differ widely with respect to funding, and their purposes often change as their governing boards change. Some of the worldwide health care activities that have been sponsored in the past include projects in public and preventive health; vital statistics; medical, nursing, and dental education; family planning programs; economic planning and development; and the formation of laboratories to investigate communicable diseases.

Many private and commercial organizations such as Nestlé and the Johnson & Johnson Company provide financial and technical backing for investment, employment, and access to market economies and to health care. Although these organizations have been present throughout the world for more than 30 years, they have come under criticism for the promotion and marketing of infant formulas, pharmaceuticals, and medical supplies, especially to lesser-developed countries. The intense marketing that is done in these countries is known as *commodification*, turning health care into a business with clients as consumers and health care professionals from altruistic healers to business technicians. Breast cancer awareness is the best known of these practices in the United States (<http://www.theguardian.com/commentisfree/2012/oct/03/pinkification-breast-cancer-awareness-commodified>).

There is global controversy as to the legitimacy of commodification. For example, in the sentinel article by Segal, Demos, and Kronenfeld (2003) the **health commodification** of pharmaceuticals in southern India was a concern because the companies gave little consideration to the cultural and social

structure of the country, thus interfering with the long-standing traditional Indian medical system. In southern India, good health and prosperity are related to certain social parameters bestowed to families and communities as a result of their conformity to the socio-moral order that was established by their ancestors, gods, and patron spirits. The taking of pharmaceutical agents thus disrupts the social and cultural order of things that have been traditionally addressed by cultural practices.

Information about volunteering for many NGOs and PVOs can be obtained from the Internet web sites included in the text. Nurses have developed global initiatives, participate in global health projects, and lead global health organizations such as Doctors without Borders. Becoming a global citizen is the responsibility of all (<http://www.globalnurseinitiative.org/>).

GLOBAL HEALTH AND GLOBAL DEVELOPMENT

Global health is not just a global public health agenda; it does not begin and end with the individual; it must consider all factors within a country that affect health, such as environment, education, national and local policies, health care and access to health care, economics (importing and exporting of goods, industry, technology), war, and public safety. This paradigm shift is called **global health diplomacy**, which refers to multilevel and multi-factor negotiation processes involving environment, health, emerging diseases, and human safety. It is now recognized that to solve global health problems, one must build capacity for global health diplomacy by training public health professionals and diplomats, respectively, to prevent the imbalances that emerge between foreign policy and public health experts and the imbalances that exist in negotiating power and capacity between developed and developing nations (Hunter et al, 2013). The cutting edge of global health diplomacy raises certain cautions regarding health's role in trade and foreign policies. Unfortunately, securing health's fullest participation in foreign policy does not ensure health for all, but it supports the principle that foreign policy achievements by any country in promoting and protecting health will be of value to all (Hunter et al, 2013).

Nurses cannot think in isolation about health for the global population; they must think more broadly to achieve their goals through a multidisciplinary, multilevel approach involving such dimensions as economic, industrial, and technological development. An example of this global health diplomacy approach, developed by the author and her colleagues, is the Uganda Project. What began as a simple request to help a community in Uganda save the lives of children dying unnecessarily from preventable diseases has turned into a sustainable community development project. Serving as consultants to an NGO, led by the school of nursing at the University of San Diego, and working collaboratively with the departments of environmental science and business, students and faculty have provided volunteer service and consultation to the people of Mbarara, Uganda on the building, implementation, and sustainability of a children's hospital in their community. Such consultation involved addressing the training of health care professionals on pediatric care and lay health educators to help improve the health of the community; assessing and intervening on water

quality issues affecting public health; and assessing and making recommendations for business ventures that could help support the fiscal sustainability of the hospital and improve the economics of the community. It is hoped that future projects will include faculty and students from the school of peace studies to help the community learn how to deal with conflict and social justice issues and the school of education to help support the teacher training that might better serve the education of the children (Bolender and Hunter, 2010).

Access to services and the removal of financial barriers alone do not account for the public's use of health services. In fact, the introduction of health care technology from developed countries to less developed countries has led to less-than-satisfactory results. For example, equipment donated to the Holy Innocents Children's Hospital (HICH) in 2009-2012 has not been as usable as the donors had hoped because of the significant difference in power voltage necessary to run the machines; power outages in Uganda with secondary power surges, which have burnt out the equipment's power components; and power outages requiring the use of a gas generator, which may or may not produce enough power to effectively run the machines (personal communication with John Baptist Mujuni, HICH administrator, January 2012). The World Bank reported that during the 1980s in an eastern Mediterranean country, two thirds of the high-output x-ray machines were not in use because of a lack of qualified and trained individuals to carry out routine maintenance and repairs. Even in Uganda, there are minimal qualified technicians to repair broken x-ray units, rebreathing units for the neonatal intensive care unit (NICU) area, and EKG machines for monitoring the critically ill children (personal communication with John Baptist Mujuni, HICH administrator, January 2012).

Countries devastated by war have lost their total infrastructure for food, trade, social justice, health, water, and public security as evident today in Afghanistan, the West Bank, Gaza, Darfur, Syria, and other war-torn countries. When implementing services for less developed nations, it is essential to conduct needs assessments to learn what a community has, what a community wants, and what it can sustain. Quite simply, well-intended projects can fail because first, the project served the purpose of the donors and not the needs of the people; second, because no assessment was done to ascertain what resources the country had and what services the country could sustain.

When projects are developed that pay attention to the intent of global health diplomacy, then there is improvement in the overall health status of a population, which secondarily can contribute to the economic growth of a country in several ways (WHO, 2013c):

- Reduction in production loss caused by workers who are absent from work because of illness
- Increase in the use of natural resources that, because of the presence of disease entities, might have been inaccessible
- Increase in the number of children who can attend school and eventually participate in their country's economic growth
- Increase in monetary resources, formerly spent on treating disease and illness, now available for the economic development of the country

FIG 4-6 “NICU” in a local Ugandan community hospital: one oxygen concentrator and one suction machine. (Courtesy A. Hunter.)

Because the economics of international development are complex, it is often difficult to convince governments to direct their resources away from perceived needs such as military and technology and, instead, place resources in health and educational programs. Ideally, the role of the more-developed countries is to assist less developed countries to identify internal needs and to support cost-efficient measures and share their technology and industrial expertise. It is important that nurses who work in international communities acknowledge the importance of global health diplomacy and its various parameters: culture, politics, economics, technology, public health, social justice, foreign policy, and public safety. Provision of health services alone will not ease a country’s health care plight (Figure 4-6).

HEALTH CARE SYSTEMS

The countries of the world present many different kinds of health care systems. Most consist of the population to be served, health care providers, third-party payers, health care facilities, and those who control access and usability of the system (Shakarishvili et al, 2010). Understanding some of these principles is highlighted when one compares the health care systems in the Netherlands, Mexico, Uganda, Ecuador, the United Kingdom, and China. For more information on the lists of countries and the per capita expenditures on health care, please see the report at <http://dpeaflcio.org/the-u-s-health-care-system-an-international-perspective/>.

The Netherlands

In the Netherlands, under a health policy reform movement in 2006, residents are required to purchase health insurance, which is provided by private health insurers (for-profit or nonprofit) that compete for business. Everyone must be insured and the insurers are required to accept every resident in their coverage area, regardless of preexisting conditions. The government

provides larger subsidies to insurers for participants who are sicker, are elderly, or have preexisting conditions. Tax credits are given to low-income clients to help them purchase insurance. People under age 18 are insured at no cost. There is a separate universal national social insurance program for long-term care, known as the AWBZ, or Exceptional Medical Expenses Act. Insurers offer a choice of policies at a range of costs. In some of the plans, the insurer negotiates and contracts with the health provider, whereas more costly plans allow clients to choose their health provider and be reimbursed by the insurer. The insured also pay a flat-rate premium to their insurer for a policy. Everyone with the same policy pays the same premium, and lower-income residents receive a health care allowance from the government to help make payments (Daley and Gubb, 2013).

Mexico

Mexico has a fractionalized system with a variety of public programs. There is no universal coverage, but a social security-administered system does cover those who are employed. The private insurance market is used mostly by wealthy residents. The Seguro Popular program, created in 2003, has been set up to help cover more of the uninsured population. Poor families can participate in Seguro Popular for free, and people who do not participate in the insurance program can still access services through the Ministry of Health, although sometimes with some difficulty. The different public set-ups and private insurers all use different systems of medical facilities and providers, with a wide range of quality reported in those services. The social security system provides broad coverage for medical services, including primary care, acute care, ambulatory and hospital care, pregnancy and childbirth, as well as prescription medications. The Seguro Popular system provides access to an established set of essential medical services and the needed drugs for those conditions, as well as 17 high-cost interventions such as breast cancer treatment. The services are provided through government, usually state-run, facilities. Out-of-pocket payments by clients represent over half of financing for the Mexican health care system, whereas the public schemes are financed through general taxes and payment from the employer and employee, determined by salary. The Seguro Popular is also funded by taxes, contributions from the state and federal government, and payments by the families, as a percentage of income. Participants in Seguro Popular pay nothing at the time of delivery of the service (Puig et al, 2009).

Uganda

Uganda’s health care system is a national service, meaning that health care is supposed to be free and accessible to all. There are five clinic and hospital facilities that patients can access (if they are staffed, if the staff workers are not extorting money from the people, and if they have supplies). These clinics and hospitals work on a referral basis; if a level I or II facility cannot handle a case, it refers it to a unit the next level up. Often units do not have the essential drugs, meaning the patients have to buy them from pharmacies or other drug sellers. Level I clinics do health counseling; level II can take care of common diseases such as malaria and antenatal care; level III clinics are where

outpatients are seen and treated, a maternity ward exists, and minimal (screening) laboratory services are provided; level IV is a mini-hospital with the kind of services found at level III clinics, but with wards for men, women, and children who can be admitted for short stays; and level V is a tertiary hospital for patients who are trauma victims, have major health problems, or are in need of mental health, dentistry, and surgery services. Although this sounds like an excellent system, my years of experience in Uganda can attest to both its strengths and weaknesses, with the greatest weakness being the lack of health professionals and the lack of supplies—too many children die because they have no oxygen, no intravenous (IV) fluids, and no antibiotics. Other aspects of the health system in Uganda are the faith-based hospitals; private medical practices/clinics set up by individual doctors or nurses as an income generator for themselves; and the traditional healers who practice herbal therapy, magic, bloodletting, and other nontherapeutic activities that often cause more harm than good (Kamwesiga, 2011; Kelly, 2009).

Ecuador

The health system in Ecuador has both a public sector and a private sector, with the public sector providing health care services to the whole working and uninsured populations. Private insurance is for the middle and high-income group, which includes about 3% of the population. In addition, there are about 10,000 private physicians' offices, generally equipped with basic infrastructure and technology, located in major cities, and the population tends to make direct payments out of pocket at the time they receive care. There are special government programs to provide nutrition for the poor and maternity services to ensure healthy pregnancies and deliveries (Lucio et al, 2011). Recent reports by expatriate visitors to Ecuador indicate that the greatest perk for foreign residents is the high-quality, low-cost health care. There is personal attention from medical practitioners not seen in the United States since the 1960s; and in the bigger cities, one will find hospitals with state-of-the-art equipment, as well as specialists in all fields and physicians with private clinics.

The United Kingdom

It is also useful to examine the United Kingdom, with a tax-supported health system that is owned and operated by the government. Services are available to all citizens without cost or for a small fee. Administration of health services is conducted through a system of health authorities (Trusts). Each Trust plans and provides services for 250,000 to 1 million people. The services offered by each Trust are comprehensive, in that health care is available to all who want it and covers all aspects of general medicine, disability and rehabilitation, and surgery. Although physicians are the primary providers in this system, nurses and allied health professionals are also recognized and used. Services are made available through hospitals, private physicians and allied health professional clinics, and health outreach programs such as hospice, and environmental health services. Physicians are paid by the number of clients they serve and not by individual visits (Boyle, 2011).

Although the British system has come under criticism in past years, individual citizens still maintain a high level of support for government funding and control of their health services. Clients, especially the elderly and new mothers, receive assistance from the district nurses (public health nurses). One of the hallmarks of the British system is a reduction in infant mortality, from 14.3 deaths per 1000 births in 1975 to 5.4 in 2002. Overall life expectancy in Great Britain also improved during the same period (77.2 years in 2000). This has been done while holding down gross spending on health care. A 2009 report by Sutherland found that the United Kingdom has seen a significant fall in mortality rates from the major killers: cancer, coronary heart disease, and stroke. Client ratings of quality care are high all across the United Kingdom; however, there is concern about rising health expenditure over the past 10 years (Sutherland, 2009).

China

China has made tremendous strides since 1949 in providing access to health care for its citizens. At present, China is a large developing country with many human resources (Yun et al, 2010). Nursing comprises a large segment of the health care workforce, yet there are too few nurses to meet the needs of the population. China, like the United States, is engaged in health care reform. China also has more physicians than nurses, which is different than in most other areas of the world. Nurse density in China is higher in urban than in rural areas, and this poses a problem in a large country in which much of the territory is rural in nature. Like many other countries, China has made public health advances by controlling contagious diseases such as cholera, typhoid, and scarlet fever, and by reducing infant mortality (Yun et al, 2010). These accomplishments in public health were credited to a political system that was and is largely socialistic and features a health care system that is described in socialistic terms as collective. The Chinese collective system emphasized the common good for all people, not individuals or special groups. This system was financed through cooperative insurance plans. The collective health care system was owned and controlled by the state and used "barefoot" doctors. Barefoot doctors were medical practitioners trained at the community level and who could provide a minimal level of health care throughout the country. Barefoot doctors combined Western medicine with traditional techniques such as acupuncture and herbal remedies. The government focused on improving the quality of water supplies and disease prevention, and implemented massive public health campaigns against sanitation problems, such as flies, mosquitoes, and the snails that spread schistosomiasis. Box 4-2 describes a Healthy Cities initiative that took place in Chengdu, China.

Today, health care in China is managed by the Ministry of Public Health, which sets national health policy. The current Chinese government continues to make health care a priority and has set goals to provide medical care to all of its citizens. The Chinese government published its health care reform plan in 2009. In developing this plan the government took into account recommendations from the WHO and the World Bank. Among the aims of the plan are to develop a system of health

insurance to help people pay for catastrophic illness, to increase and improve the education for nurses in order to intervene in the growing nursing shortage, and to develop urban health centers. At present, a small percentage of Chinese nurses work in public health, and some authors attribute this to the low pay in these settings. Hospitals and clinics are typically located in urban areas, which means that people in rural areas must travel a great distance for care, and even then, the care may be substandard and the wait time to receive care may be long. It is estimated that approximately 200 million people in China lack health insurance. When the State Council published its health care reform plan in April of 2009, a 3-year goal of “covering 90% of the Chinese population by 2011 and achieving universal health care by 2020” was established.

The nursing education system in China has developed rapidly. All college-based nursing education was terminated during the period of the Cultural Revolution and began again only in the mid-1980s. At present the nursing education system includes associate degree, baccalaureate, master's degree, and doctoral programs. Interestingly, the image of nursing has improved, based on the effectiveness of nurses during recent public health crises and events that claimed international attention. Specifically, nurses played important and effective roles in caring for people during the disasters caused by the SARS virus in 2003 and the Sichuan earthquake in 2008. More recently, nurses were well recognized in China for their considerable work during the 2008 Olympic Games in Beijing (Yun et al, 2010). Unfortunately, pay and working conditions are contributing to the desire of many Chinese nurses to leave the country.

MAJOR GLOBAL HEALTH PROBLEMS AND THE BURDEN OF DISEASE

Despite the gains that have been made in improving the health of so many around the globe, the increasing population, decreasing food and water sources, and increasing poverty related to a global economic crisis are all contributing to a critical demise in health. The amount of debt incurred by less developed countries has increased steadily over the last 20 years, and money that was once used for health care has been used to pay off growing debt. Communicable diseases that are often preventable are still common throughout the world and are more common in less developed countries. Also, both developed and less developed countries are seeking ways to cope with the aging of their populations—a population that presents governments with the burden of providing care for those who become ill with more expensive noncommunicable and chronic forms of diseases and disabilities. Illnesses such as AIDS continue to raise concerns, especially in child-bearing women, adolescents, and young adults. Long-standing diseases such as TB, dysentery, and mosquito-borne diseases, especially malaria, still persist and have become drug resistant, adding to the growing burden of overextended health care delivery systems.

Mortality statistics do not adequately describe the outlook of health in the world. The WHO (2014d) has developed an indicator called the **global burden of disease** (GBD). The GBD combines losses from premature death and losses of healthy life

BOX 4-4 Calculating Disability-Adjusted Life-Years

DALYs are composed of years lived with disability (YLDs) and years of life lost due to premature mortality (YLLs). YLDs, the morbidity component of the DALYs, are calculated as follows: $YLD = \frac{1}{4} \text{ Number of cases} \times \text{duration till remission or death} \times \text{disability weight}$.

Within the DALY calculation are the social weighting factors:

1. *Duration of time lost because of a death at each age:* Measurement is based on the potential limit for life, which has been set at 82.5 years for women and 80 years for men.
2. *Disability weights:* The degree of incapacity associated with various health conditions. Values range from 0 (perfect health) to 1 (death). Four prescribed points between 0 and 1 represent a set of accepted disability classes.
3. *Age-weighting function, $Cxe^{-\beta x}$,* where $C = 0.16243$ (a constant), $\beta = 0.04$ (a constant), $e = 2.71$ (a constant), and $x = \text{age}$; this function indicates the relative importance of a healthy life at different ages.
4. *Discounting function, $e^{-r(x-a)}$,* where $r = 0.03$ (the discount rate), $e = 2.71$ (a constant), $a = \text{age at onset of disease}$, and $x = \text{age}$; this function indicates the value of health gains today compared with the value of health gains in the future.
5. *Health is added across individuals:* 2 people each losing 10 DALYs are treated as showing the same loss as 1 person losing 20 years.

“In summary, one DALY can be thought of as one lost year of ‘healthy’ life. The sum of these DALYs across the population, or the burden of disease, can be thought of as a measurement of the gap between current health status and an ideal health situation where the entire population lives to an advanced age, free of disease and disability. DALYs for a disease or health condition are calculated as the sum of the Years of Life Lost (YLL) due to premature mortality in the population and the Years Lost due to Disability (YLD) for people living with the health condition or its consequences” (see http://www/who.int/healthinfo/global_burden_disease/)

<http://www.cbpa.be/publications/Devleeschauwer2014b.pdf>

that result from disability. Premature death is defined as the difference between the actual age at death and life expectancy at that age in a low-mortality population. People who have debilitating injuries or diseases must be cared for in some way, most often by family members, and thus they no longer can contribute to the family's or a community's economic growth. The GBD represents units of **disability-adjusted life-years** (DALYs) (WHO, 2014e) (Box 4-4). Thirty-five percent of the health factors contributing to the DALY numbers in 2011 were related to communicable diseases, maternal and perinatal conditions, and nutritional deficits; 54% of DALYs were in noncommunicable conditions such as respiratory, cardiac, musculoskeletal, and other conditions; and the rest were related to injuries. Tables 4-1 and 4-2 reflect the conditions with the greatest impact on the 2011 DALYs (WHO, 2014e).

Table 4-1 indicates that in 2011, 88% of the disability-adjusted life-years were the result of the top 10 conditions. Psychiatric disorders, although traditionally not regarded as a major epidemiologic problem, are shown by consideration of disability-adjusted life-years to have a huge impact on population ranking in the top 10 on the global burden of disease index. From just this table, 2.4 billion DALYs were lost worldwide, which equates to 70 million deaths of newborn children or to 150 million deaths of people who reach age 50. Approximately 2.5 million neonatal deaths occurred and more than 20 million

TABLE 4-1 Top 20 DALY Conditions

2011					
Rank	GHE Code	Cause	DALYs (000s)	% DALYs	DALYs per 100,000 Population

children under age 5 died during the same year in less developed countries. If these children could face the same risks as those in developed nations, the deaths would decrease by 90%. This example demonstrates the importance of having accessible and affordable disease prevention programs for children around the world (WHO, 2014e). Infections and parasitic diseases remain a threat to the health of the majority of the world and are diseases seen in the United States in newly arriving immigrants. Studies demonstrate the continuing need for intervention for infectious and other kinds of communicable diseases. Conditions that contribute to one fourth of the GBD throughout the world include diarrheal disease, respiratory tract infections, worm infestations, malaria, and childhood diseases such as measles and polio. Sub-Saharan Africa demonstrated a GBD of 43% DALYs lost, largely because of preventable diseases among children (WHO, 2014e).

According to the U.S. Global Health Policy fact sheet published by the Kaiser Family Foundation (2010), globally there were 33 million people living with HIV in 2007, up from 29.5 million in 2001, the result of continuing new infections, people living longer with HIV, and general population growth. HIV is a leading cause of death worldwide and the number one cause of death in Africa. An estimated 8 in 10 people infected with HIV do not know it. HIV has led to a resurgence of TB, particularly in Africa, and TB is a leading cause of death for people with HIV worldwide. Women represent half of all people living with HIV worldwide, and more than half (60%) in sub-Saharan Africa. Globally, there were 2.5 million children living with HIV in 2009, 370,000 new infections among children, and 260,000 AIDS deaths. There are approximately 16.6 million AIDS orphans today (children who have lost one or both parents to HIV), most of whom live in sub-Saharan Africa (89%).

Uganda's emphasis on ameliorating HIV/AIDS is a model for all African nations; however, there are still too many Ugandan children under 5 years old who are AIDS orphans. Unfortunately, despite the efforts of advocates, donors, and affected countries, there needs to be greater attention given to the long overdue effort to expand access to antiretroviral therapy, which is still available to less than 10% of those who urgently require it.

Determining the total amount of loss, even using the GBD, is difficult because it does not address the many consequences of disease and injury such as post-trauma and infectious physical disabilities. Nor can it measure the short- or long-term effects of familial and marital dysfunction, family violence, or war. The following further elaborates on selected communicable diseases that still contribute substantially to the worldwide disease burden (TB, AIDS, and malaria) and other health problems such as maternal and women's health, diarrheal disease in children, nutrition, natural and man-made disasters.

Communicable Diseases

Prevention of communicable diseases is through immunization and improving environmental conditions. One example of the long-term benefits of immunizing children against communicable diseases is the successful campaign against smallpox that the WHO conducted during the 1960s and 1970s. Smallpox has been virtually eliminated throughout the world, with only occasional and incidental reporting from laboratory accidents and inoculation complications. The systematic and planned smallpox program formed the basis for a series of worldwide efforts that are now being implemented to control and eradicate other infectious and communicable diseases.

In 1974 the WHO formed the Expanded Program on Immunization, which sought to reduce morbidity and mortality from diphtheria, pertussis, tetanus, TB, measles, and poliomyelitis throughout the world (WHO, 2010). In the 2010 State of the World Report on immunizations and vaccines, the WHO noted that for the first time in documented history the number of children dying every year had fallen below 10 million. This appears to be the result of improved access to clean water and sanitation, increased immunization coverage, and the integrated delivery of essential health interventions. Unfortunately, almost 20% of the children born each year do not get the complete routine immunizations scheduled for their first year of life. This is most prevalent in developing countries and for those children born in the very rural communities. In developing countries, more vaccines are available and more lives are being saved; however, death from pertussis in developing countries is 40 per 1000 infants, and 10 per 1000 in older children. It still occurs in industrialized countries but at less than 1 per 1000 cases. Although free vaccination clinics are brought to the people, they are often not used because of lack of knowledge, fear propagated by the traditional healers, and suspicion of anything offered by the government. Reaching these vulnerable children—typically in poorly served remote rural areas, deprived urban settings, fragile states, and strife-torn regions—is essential in order to meet the Millennium Development Goals (MDGs; United Nations, 2013b).

The WHO has estimated that if all the vaccines now available against childhood diseases were widely adopted, and if countries could raise vaccine coverage to a global average of 90%, by 2015 an additional 2 million deaths a year could be prevented among children under age 5. This level of vaccination would reduce child deaths by two thirds and achieve one of the MDG goals. It would also greatly reduce the burden of illness and disability from vaccine-preventable diseases and contribute to improving child health and welfare, as well as reducing hospitalization costs (WHO, Immunizations, 2010b).

As discussed in Chapter 10, **environmental sanitation** is critical to the well-being of people around the globe. Many of the major health risks relate to interactions between people and their environment. For example, in developing nations, community drinking water sources can be contaminated by agricultural runoffs containing toxic pesticides and fertilizers, but they can also be contaminated by naturally occurring elements in the earth such as arsenic and fluoride. This author and her colleagues have found gross heavy metal (primarily arsenic) contamination of the water sources in Uganda including the government filtered water, bottled water from clean water bottling companies in Uganda, bore holes (wells), river, swamps, and springs (Bolender et al, 2012, 2013; Jameel et al, 2012). Efforts are underway to assess the extent of this problem across Uganda and to assess the effects on the population. We have already discovered unexplained neurological symptoms in the adults and persistent anemia in the children; which could have its causative origin in the arsenic-contaminated water consumed by the people. Long-term absorption of arsenic in humans has been associated with skin cancer, cancer of the bladder and lungs, developmental effects, neurotoxicity, diabetes, and cardiovascular disease (Global Poverty Project, 2013; WHO, Fact Sheet on Arsenic, 2012c).

In developing nations, it is not uncommon for hospitals and HIV testing centers to dump waste products into the local rivers that often supply the local household water. Worldwide, environmental factors play a role in more than 80% of adverse outcomes reported by the WHO, including infectious diseases, injuries, mental retardation, and cancer, to name a few. Globalization and industrialization in the developing world have increased daily exposure to pollution and a wide array of chemicals in air, water, and food. At the same time, fecal pollution of drinking water sources caused by a lack of basic sanitation still exists. The effects of environmental risk factors are magnified by conditions often prevalent in poorer, undeveloped countries such as poor nutrition, poverty, lack of education about risks, and conflicts. Children are particularly susceptible to environmental risks because their systems are still developing. It is estimated that about one quarter of global disease is caused by avoidable environmental exposures; for young children in the developing world, causes of environmentally related deaths are acute respiratory infections, related to poor air quality; and diarrhea, related to poor drinking water quality. Annually, about 3 million children under the age of 5 die of environment-related diseases. There are projects that train and give technical assistance, data collection and analysis, laboratory analyses, research, surveillance, and emergency responses to

international communities ([American Society of Hematology, 2013](#); [WHO, Fact Sheet on Child Deaths, 2013b](#)).

As of 2013, 783 million people still do not have access to clean water, and their water sources are often far away, unclean, and unaffordable; 2.5 billion people or 40% of the world's population lack an adequate toilet or latrine. Getting hold of clean water is not good enough if the water is being made dirty because there are no toilets, and toilets are not good enough if there is no hygiene promotion to persuade whole communities to change the habits of generations and use the latrines. Estimates by the Joint Monitoring Program of UNICEF and the WHO predict that at the current rate of progress, approximately 2 billion people will still lack access to a clean environment by 2015. In sub-Saharan Africa 50% of people lack this basic human right, and their need may not be met until 2072 if the current rate continues ([UNICEF, Water, Sanitation and Hygiene, 2010](#)).

Tuberculosis

In 2012, according to the [WHO \(Tuberculosis Fact Sheet, 2012d\)](#) about 8.6 million people fell ill with tuberculosis and 1.3 million died of the disease. Ninety-five percent of TB deaths occur in low to middle income countries, and TB is one of the top three causes of death for women ages 15-44. Children are not immune to this bacterium, as the WHO report indicates that more than 530,000 children diagnosed with the disease and 74,000 HIV-negative children died of TB. It is a leading killer of people with HIV, and up to 80% of TB clients are HIV positive in countries with a high prevalence of HIV. People with HIV are much more likely to develop TB; as are those infected with malaria, especially children, because of the physiological damage to the liver, spleen, and hematological systems. A child or adult with any one of the three diseases mentioned is more prone to the other two, and this triad is the new scourge of impoverished nations. The WHO estimates that more than one third of infectious disease deaths are due to this deadly triad of AIDS, TB, and malaria ([WHO, Tuberculosis Fact Sheet, 2012d](#)).

It is expected that at least one third of the world's population, or 1.7 billion people, harbor the TB pathogen *Mycobacterium tuberculosis*. The Stop TB Partnership, engaging nearly 300 governments and agencies, has brought consensus on approaches to global control of this disease, galvanized support, and launched new support mechanisms, such as the Global TB Drug Facility, an initiative to increase access to high-quality TB drugs. The Working Group on Tuberculosis recommends seven priorities to meet the MDG targets for this disease for 2015. All this effort has resulted in some good news. It has been shown that the number of people falling ill with tuberculosis each year is declining, although very slowly. The world appears to be on track to achieve the Millennium Development Goal to reverse the spread of TB by 2015, especially given that the TB death rate dropped 45% between 1990 and 2010.

Two factors are a threat to TB control and eradication. The first is the AIDS virus. The appearance of HIV has added to the difficulty of treatment programs in both developed and less developed countries. More important, HIV-positive individuals with infectious TB have an increased likelihood of transmitting

TB to their families and to the community, further increasing the prevalence of this condition.

The second is the growing multidrug resistance of the TB bacillus to isoniazid and rifampin, the two drugs used to treat it. Resistance to these drugs is already evident around the world, including in the Mexico-Texas border communities. The WHO and other organizations maintain that a high priority should be given to TB control and eradication programs around the world. They advocate a short-term chemotherapy regimen for smear-positive clients as being one of the most cost-effective health interventions available ([Forman et al, 2012](#); [WHO, Tuberculosis Fact Sheet, 2012d](#)). The bacille Calmette-Guérin (BCG) vaccine, which has been available since the 1920s, was promoted as an effective vaccine to induce active immunity against TB, especially among children living in TB-endemic or high-risk TB areas that are impoverished and crowded. The BCG vaccine has a documented protective effect against meningitis and disseminated TB in children. It does not prevent primary infection and, more importantly, does not prevent reactivation of latent pulmonary infection, the principal source of bacillary spread in the community. The impact of BCG vaccination on transmission of TB is therefore limited ([WHO, 2012d](#)). The standard chemotherapeutic agents used in many countries for TB are isoniazid, thioacetazone, and streptomycin, and they are effective at converting sputum-positive cases to noninfectivity. The drugs and the combinations that are used vary from country to country. To be effective, however, treatment must be carried out on a consistent basis, and many less developed countries have difficulty persuading clients to purchase the medications and to adhere to any treatment regimen. In 1990 the WHO Global Tuberculosis Program (GTB) promoted the revision of national TB programs to focus on short-course chemotherapy (SCC), with directly observed treatment (DOT). DOT programs have been successful in the United States and in several less developed countries, including Malawi, Mozambique, Nicaragua, and Tanzania, producing a cure rate of approximately 80%. The SCC program involves aggressive administration of chemotherapeutic drugs combined with short-term hospitalization. The key to the program lies in a well-managed system with a regular supply of anti-TB drugs to the treatment centers, follow-up care, and rigorous reporting and analysis of client information ([IOM, 2011](#)).

Lasting control of AIDS, TB, and/or malaria will depend on strengthening the health, economic, political, education, and other infrastructure necessary to sustain life and promote the well-being of the people. It will require sustained investment in physical infrastructure, drug distribution systems, management at all levels, and, most importantly, human resources such as the training and appropriate use of community health workers to deliver some essential services and education. Unfortunately, the failure of developed countries to fulfill their pledges of more development aid, and the failure of developing countries themselves to invest in health, are overarching barriers to health systems development. HIV/AIDS, TB, and malaria are only three of the challenges facing poor people. Only stronger, integrated health systems can provide a platform to sustain a successful fight against these diseases while advancing the other

health priorities of developing countries, including child and maternal health and chronic disease.

It is important, when conducting a health assessment interview, always to ask whether the client has recently traveled out of the United States or to one of the border areas along the United States–Mexico perimeter. People who travel abroad may bring back diseases that are difficult to diagnose. In addition, people often cross the border into Mexico to fill a prescription for medicine because it is often less expensive than in the United States. Unfortunately, many times the medications brought back have been relabeled and are out of date.

Acquired Immunodeficiency Syndrome

As discussed in [Chapter 14](#), AIDS remains a major cause of morbidity and mortality throughout the world. More than 70 million people have been infected with HIV since the beginning of the epidemic; approximately 35 million people have died of AIDS. At the end of 2011, 34.0 million people globally were living with HIV with an estimated 0.8% of the adult population aged 15–49 years infected. The burden of the epidemic continues to vary considerably between countries and regions; however, sub-Saharan Africa remains most severely affected, with nearly 1 in every 20 adults (4.9%) living with HIV and accounting for 69% of the global population infected with this virus ([IOM, 2012](#); [WHO, HIV/AIDS, 2014f](#)). For more information, go to http://www.who.int/gho/hiv/hiv_013.jpg?ua=1 ([WHO, Global Health Observatory—HIV/AIDS, 2014f](#)).

The [Kaiser Family Foundation report \(2013a\)](#) stated that approximately 35.3 million people were living with HIV in 2012, up from 29.4 million in 2001. This rise appears to be the result of continuing new infections (averaging 6300 per day), people living longer with HIV, and general population growth. When comparing the population growth with the HIV incidence rates, overall new HIV infections have declined by 33% since 2001. Of interest is that 1.6 million people died of AIDS in 2012, which was a 30% decrease since 2005. Such results appear to be the result of antiretroviral treatment (ART) scale-up.

The majority of new infections are being transmitted heterosexually, placing women and children at increased risk for acquiring the infection. Gender inequalities, lack of access to services, and sexual violence against women and children increase their vulnerability to HIV. Women represent about half (52%) of all people living with HIV worldwide and younger women are biologically more susceptible to HIV. Unfortunately, young people often believe the disease can be cured with drugs and thus they can be less cautious; in addition, cultural practices exist whereby older men marry virgins to cure them of AIDS or to prevent them from getting AIDS.

By 2012, there were 3.3 million children globally living with HIV, with 260,000 new infections identified and 210,000 children who lost their lives to AIDS. Sadly, there are approximately 17.3 million children with AIDS who have lost one or both parents to HIV; most of these children live in sub-Saharan Africa (88%) and will either die from the disease or be treated as social outcasts by the community at large ([Kaiser Family Foundation, 2013a](#)).

Worldwide prevention programs are important because failing to control this virulent disease will result in damaging and costly consequences for all countries in the future. Ideally, the goal is primary prevention of HIV. When prevention efforts fail at this level, the next goal is secondary prevention, or early diagnosis and treatment. Aggressive interventions in many African nations have begun to make a difference in the life potential for patients diagnosed with HIV.

Combination ART has contributed to the reduced morbidity and mortality rate since 2001 and in sub-Saharan Africa alone, the number of people receiving ART increased significantly from 50,000 in 2002 to 7.5 million in 2012. In 2012, ART covered 61% of individuals who were eligible for treatment, representing 65% of the 2011 U.N. General Assembly Special Session target of treating 15 million by 2015. New WHO guidelines recommend starting treatment of HIV earlier in the course of illness. Given these new recommendations, 25.9 million people are now eligible for treatment ([Kaiser Family Foundation, 2013a](#)). See the [levels of prevention](#) box below to learn about prevention of HIV.

LEVELS OF PREVENTION

Global Health Care

Primary Prevention

Teach people how to avoid or change risky behaviors that might lead to contracting human immunodeficiency virus (HIV).

Secondary Prevention

Initiate screening programs for HIV.

Tertiary Prevention

Manage symptoms of HIV, provide psychosocial support, and teach clients and significant others about care and other forms of symptom management.

Malaria

Malaria affects more than 50% of the world's population and hits tropical Africa the hardest. However, there have been major global efforts to control and eliminate malaria that have saved an estimated 3.3 million lives since 2000, reducing malaria mortality rates by 45% globally and by 49% in Africa, according to the “World Malaria Report 2013” published by the WHO (see http://www.who.int/malaria/publications/world_malaria_report_2013/en/).

The large majority of the 3.3 million lives saved between 2000 and 2012 were in the 10 countries with the highest malaria burden, and among children under 5 years of age, which is the group most affected by the disease. Over the same period, malaria mortality rates among children in Africa were reduced by an estimated 54%. An expansion of prevention and control measures has contributed to a consistent decline in malaria deaths and illness. Unfortunately, the new WHO report notes a slowdown in the expansion of interventions to control mosquitoes for the second successive year, particularly in providing access to insecticide-treated bed nets, because of lack of funds to procure bed nets. My experience in Uganda still finds that

malaria and its sequelae are the number one cause of death in children less than 8 years of age.

Malaria is caused by the *Anopheles* mosquito and is the only mosquito-borne disease that can be prevented and cured by pharmacological management (WHO, Malaria Report, 2013e). It is caused by parasitic transmission from the infected female mosquito to its host. There are four parasite species that cause malaria, the most serious being *Plasmodium falciparum*, which causes microvascular sequestration and obstruction in the brain, kidney, and liver leading to cerebral malaria, anemia, kidney failure, hypoglycemia, disseminated intravascular coagulation (DIC), fluid-electrolyte imbalance, and death (CDC, 2013a). Symptoms vary and range from mild to severe physiological responses (mild fever and chills to temperatures of 106° F with prolonged chills, seizures, and dehydration).

A range of effective antimalarial interventions exists for the prevention, treatment, and control of malaria. These include the use of insecticide-treated bed nets (ITNs); indoor residual spraying; intermittent presumptive treatment during pregnancy; early diagnosis and prompt treatment with effective antimalarials; management of the environment to control mosquitoes; health education; and epidemic forecasting, prevention, and response (CDC, 2013a; WHO, 2013e). Methods of vector control vary widely, from using the larvae-eating fish tilapia to the use of insecticidal sprays and oils. Needless to say, the latter poses a potential threat to the environment in tropical areas where a delicate ecosystem is already threatened by other potential hazards such as lumbering and mining.

Countries that do not have strict environmental laws continue to use dichlorodiphenyltrichloroethane (DDT) sprays to control mosquito populations despite the advent of DDT-resistant mosquitoes. The non-DDT insecticide sprays, such as malathion, generally cost more, presenting an extra financial burden to less developed countries. Methods for control and eradication that are being considered by malaria-ridden countries are environmental management, reduction and control of the source, and elimination of the adult mosquito. There are significant global efforts being made to “blanket” endemic communities with insecticide-treated mosquito nets. A multitude of NGO projects are distributing ITNs to contribute to this initiative: Project Mosquito Net in Kenya (www.projectmosquitonet.org), Nothing But Nets (www.nothingbutnets.net/), Global Giving for Africa (www.globalgiving.org/projects/mosquito-nets-for-africa-families), Angola Mosquito Net Project (<https://angolamosquitonetproject.wordpress.com/>) and Holy Innocents Children’s Hospital Uganda (www.holyinnocentsuganda.org) are examples of organizations actively engaged in preventing malaria and saving lives.

However, coverage levels are inadequate in endemic countries, especially in poor communities. Without adequate and predictable funding, the progress against malaria is also threatened by emerging parasite resistance to artemisinin, the core component of artemisinin-based combination therapies (ACTs), and mosquito resistance to insecticides. Artemisinin resistance has been detected in four countries in Southeast Asia, and insecticide resistance has been found in at least 64 countries.

Although chemotherapeutic agents can be used for both protection and treatment of the disease, they are expensive and often cause side effects. However, evidence suggests that the *Plasmodium* sporozoites are becoming resistant to both treatment and preventive chemotherapeutic agents, especially chloroquine and its derivatives. Alternative therapies and/or combinations of medications such as sulfadoxine/pyrimethamine (Fansidar), amodiaquine, artemisinin, artemether, and atovaquone/proguanil (Malarone) are somewhat effective in treating malaria. Recent reports indicate that drug manufacturers in these endemic countries are diluting the drugs so that clients, especially children, are not receiving therapeutic levels of the medications. Many children suffer the effects of partially treated malaria, and once hospitalized, IV quinine is the drug of choice. Unfortunately, quinine has significant neurotoxic and cardiovascular side effects that need monitoring (CDC, 2013a). Efforts are underway to develop an antimalarial vaccine and one candidate vaccine, known as RTS,S/AS01, has been shown to almost halve the number of malaria cases in young children (aged 5 to 17 months at first vaccination) and to reduce by about one fourth the malaria cases in infants (aged 6 to 12 weeks at first vaccination) (Malaria Vaccine Initiative, 2013). As discussed in Chapter 13, persons who live or travel to *Anopheles*-infested areas should protect themselves with mosquito netting, clothing that protects vulnerable parts of the body, repellents for both their bodies and their clothes, and antimalarial medications such as Malarone or doxycycline.

Diarrheal Disease

The normal intestinal tract regulates the absorption and secretion of electrolytes and water to meet the body’s physiological needs. More than 98% of the 10 L of fluid per day entering the adult intestines is reabsorbed (Ahs et al, 2010; Alexander and Blackburn, 2013). The remaining stool water, related primarily to the indigestible fiber content, determines the consistency of normal feces from dry, hard pellets to mushy, bulky stools, varying from person to person, day to day, and stool to stool. This variation complicates the definition of *diarrhea*. For adults diarrhea is present when three or more liquid stools are passed in 24 hours. The frequent passage of formed stool is not diarrhea. Although young nursing infants tend to have five or more bowel movements per day, stools that are liquid without any formation and/or are more than what is normal for the child constitute diarrhea (Ahs et al, 2010; Farthing et al, 2012). Definitions are complicated by the observable presence of blood, mucus, or parasites and the age of the affected person.

Diarrhea, one of the leading causes of illness and death in children less than 5 years of age throughout the world, is most prominent in the less developed countries despite recent initiatives by the WHO to correct this problem. Each year there are 760,000 diarrhea deaths in children under five; there are 1.7 billion cases of diarrheal disease every year related to unsafe water, sanitation, and hygiene; and it is the leading cause of malnutrition in children under five (WHO, Diarrhea Fact Sheet, 2013f). Causes of diarrhea are just as varied and diverse as its definitions and perceptions. Some of the causes include (1) viruses such as the rotavirus and Norwalk-like agents, (2)

bacteria, including *Campylobacter jejuni*, *Clostridium difficile*, *Escherichia coli*, *Salmonella*, and *Shigella*, (3) environmental toxins, (4) parasites such as *Giardia lamblia* and *Cryptosporidium*, and (5) worms. Nutritional deficiencies can also cause diarrhea and are most often a result of infectious agents. Of these, the rotavirus has emerged as a major world concern, hospitalizing 55,000 American children and killing 1 million children in the world each year (Farthing et al, 2012; WHO, *Diarrhea Fact Sheet*, 2013f). Three major diarrhea syndromes exist:

- Acute watery diarrhea, which results in varying degrees of dehydration and fluid losses that quickly exceed total plasma and interstitial fluid volumes and is incompatible with life unless fluid therapy can keep up with losses. Such dramatic dehydration is usually due to rotavirus, enterotoxigenic *E. coli*, or *Vibrio cholerae* (the cause of cholera), and it is most dangerous in the very young.
- Persistent diarrhea, which lasts 14 days or longer, and is manifested by malabsorption, nutrient losses, and wasting; it is typically associated with malnutrition, either preceding or resulting from the illness itself. Even though persistent diarrhea accounts for a small percentage of the total number of diarrhea episodes, it is associated with a disproportionately increased risk of death.
- Bloody diarrhea, which is a sign of the intestinal damage caused by inflammation. Bloody diarrhea, defined as diarrhea with visible or microscopic blood in the stool, is associated with intestinal damage and nutritional deterioration, often with secondary sepsis. Mild dehydration and fever may be present. Bloody diarrhea should not be confused with dysentery, because dysentery is a syndrome consisting of the frequent passage of characteristic, small-volume, bloody mucoid stools, abdominal cramps, and tenesmus (a severe pain that accompanies straining to pass stool). Agents that cause bloody diarrhea or dysentery can also provoke a form of diarrhea that clinically is not bloody diarrhea, although mucosal damage and inflammation are present microscopically. The release of host-derived cytokines alters host metabolism and leads to the breakdown of body stores of protein, carbohydrate, and fat and the loss of nitrogen and other nutrients. Those losses must be replenished during the expected prolonged convalescence. For these reasons, bloody diarrhea calls for management strategies that are markedly different than those for watery or persistent diarrhea. New bouts of infection that occur before complete restoration of nutrient stores can initiate a downward spiral of nutritional status terminating in fatal protein-energy malnutrition (Farthing et al, 2012).

Diarrheal diseases are rampant among the impoverished. Poverty is associated with poor housing, crowding, dirt floors, lack of access to sufficient clean water or to sanitary disposal of fecal waste, cohabitation with domestic animals and zoonotic transmission of pathogens, and a lack of refrigerated storage for food. Unfortunately, even when the cause of the diarrhea is eliminated, poverty can restrict the ability to provide age-appropriate, nutritionally balanced diets or to modify diets so as to mitigate and repair nutrient losses. The lack of adequate,

available and affordable medical care increases the problem. Children suffer from an apparently never-ending sequence of infections and rarely receive appropriate preventive care, and too often their parents seek health care only when the children have become severely ill.

Dehydration is an immediate result of diarrhea and leads to a loss of fluid and electrolytes. The loss of up to 10% of the body's electrolytes can lead to shock, acidosis, stupor, and failure of the body's major organs (e.g., kidneys, heart). Persistent diarrhea often leads to loss of body protein, an increased time-limited inability to digest and absorb dairy products, and increased susceptibility to infection. Every country should have as a major aim the prevention and control of diarrheal disease, especially in infants and children. Many countries have developed diarrhea control programs that improve childhood nutrition. These programs instruct in breastfeeding and weaning practices and promote oral rehydration therapy and the use of supplementary feeding programs (Farthing et al, 2012). However, all these programs must be considered in conjunction with improving the social and economic conditions that contribute to safe environmental, sanitary, and general living conditions of populations around the world. The following **How To** box provides useful resources for keeping well informed about public health issues including water quality.

HOW TO Stay Current about Global Health

One way to stay current with the world's health problems and advances is by reading the newspaper daily. Examples of newspapers that cover international health on an ongoing basis include the *Wall Street Journal*, *USA Today*, the *Washington Post*, and the *New York Times*. The following websites are examples of sources that pertain to international or global health:

- U.S. Department of Health and Human Services: <http://www.globalhealth.gov/>
- Global Health Council: <http://www.globalhealth.org/>
- Centers for Disease Control and Prevention: <http://www.cdc.gov/globalhealth/>
- World Health Organization: <http://www.who.int/en/>
- Pan American Health Organization: <http://new.paho.org/>
- World Bank: <http://www.worldbank.org/>
- Institute of Medicine: <http://www.iom.edu/>
- Millennium Development Goals: <http://www.undp.org/mdg/>

Maternal and Women's Health

Maternal health is central to the health of women, as well as the well-being of their children and families, and the economic productivity of their countries. A woman's ability to survive pregnancy and childbirth is closely related to how effectively societies invest in and realize the potential of women not only as mothers, but as critical contributors to sustaining families and transforming nations. When investments in women—as mothers, as individuals, as family members, and as citizens—lag, the economic cost of maternal death and illness is enormous. Ostrowski (2010) stated that when women have better education and health, then mothers have greater household decision-making power and their children are better educated, becoming productive adults able to help build long-term

economic growth. The World Bank found that during economic crises, poor families who sent women to work were better able to make ends meet.

Progress and investment in maternal health have lagged far behind estimates of what is needed to achieve MDG 5, Improve Maternal Health. Progress in the last 20 years on key maternal health indicators varies by outcome and region, but it has been uneven, inequitable, and inadequate overall. The two regions of the world with the worst maternal health status—South Asia and sub-Saharan Africa—show minimal signs of improvement largely because of poverty, disempowerment of women, and overall poor health status of women in developing countries. Women's reproductive health, especially their ability to control their fertility and avoid HIV infection, is also closely associated with their health as mothers. Although maternal death and disability represent a high burden of disease in the developing world, interventions to improve maternal health are available and cost-effective (Kaiser Family Foundation, 2013c; Kott, 2011; WHO, Family Planning Fact Sheet, 2013g).

In Uganda, Reproductive Health Uganda (RHU), formerly the Family Planning Association of Uganda (FPAU), provides services in 29 of the country's districts, targeting young people and marginalized groups to improve reproductive health. They offer family planning; HIV/AIDS testing and counseling; diagnosis and treatment of sexually transmitted infections (STIs); advocacy against female genital mutilation (FGM); and post-abortion care to high-risk constituencies such as internally displaced persons (IDPs), people at high risk of HIV/AIDS, young women in conflict-affected areas, sex workers, hawkers, saloonists, bicycle taxi drivers, maids—any group subject to violence and disempowerment (www.rhu.or.ug). Despite FPAU's intent to improve the reproductive health of Ugandan women, there are barriers to the success of this initiative: continued cultural practices related to submissiveness of women and dependency on men for well-being of self and the children; bride wealth practices that give ownership to the man and permit beatings and other abuses of his wife; kinship patterns in which widowed women belong to the oldest brother; the fact that child care and all work related to the home and the children are performed by the women and girls; the fact that a woman's worth is still dependent on her ability to reproduce, even knowing that the more pregnancies a woman incurs, the less healthy the newborn and mother; and the practice of polygamy, allowing for transmission of STIs and HIV/AIDS.

The WHO and UNICEF have continued their worldwide initiatives to reform the health care received by women and children in less developed countries (WHO, Maternal Health Fact Sheet, 2013h). However, studies on women's health indicate that more than one third (35%) of all maternal deaths around the world are due to severe bleeding, primarily postpartum hemorrhage; sepsis (8%); unsafe abortion (9%); hypertension (18%); and conditions that complicate pregnancy such as malaria, anemia, and HIV (20%). In developing nations there is a significant incidence of lack of prenatal care during pregnancy and high fertility rates, often due to a lack of access to contraception and other family planning and reproductive

health services, as well as cultural belief systems that increase the lifetime risk of maternal death.

Every year, more than half a million women die in pregnancy and childbirth around the world. This figure has altered little in the last 30 years. In sub-Saharan Africa, a number of countries have halved their levels of maternal mortality since 1990 but not in the more impoverished nations such as the Congo, Uganda, Ghana, and others. However, between 1990 and 2010, the global maternal mortality ratio declined by only 3.1% per year. This is far from the annual decline of 5.5% required to achieve MDG 5 (WHO, Maternal Mortality Fact Sheet, 2012e).

Equally distressing is the fact that worldwide, the ratio of maternal deaths to live births (the maternal mortality ratio) has remained essentially static during this period. Africa continues to have the highest maternal-child morbidity and mortality rate, with 51% of all maternal deaths occurring in sub-Saharan Africa. The maternal mortality ratio in developing countries is 240 per 100,000 births versus 16 per 100,000 in developed countries. The risk of maternal mortality is highest for adolescent girls under 15 years old. HIV currently accounts for 6.2% of maternal deaths in Africa and has reversed the progress made in maternal health in some countries.

In sub-Saharan Africa, infectious diseases, childhood illnesses, and maternal causes of death account for as much as 70% of the burden of disease. By comparison, these conditions account for only one third of the burden in South Asia and Oceania, and less than 20% in all other regions. In addition, whereas the average age of death throughout Latin America, Asia, and North Africa increased by more than 25 years between 1970 and 2010, it rose by less than 10 years in most of sub-Saharan Africa (WHO, Global Burden of Disease Report, 2012b). The WHO found that some of the sociocultural factors that prevent women and girls from benefiting from quality health services and attaining the best possible level of health include the following (WHO, Women's Health Fact Sheet, 2013h):

- Unequal power relationships between men and women
- Social norms that decrease education and paid employment opportunities
- An exclusive focus on women's reproductive roles
- Potential or actual experience of physical, sexual and emotional violence

Within Africa, the greatest disease burden remains from maternal health, child health, HIV, TB, and malaria; outside Africa the greatest disease burden is the rising incidence of noncommunicable diseases and rising life expectancy (Summers, 2013). Throughout the world, women between 15 and 44 years of age account for approximately one third of the world's disease burden, and women between 45 and 59 for one fifth of the burden. This burden comprises diseases and conditions that are either exclusively or predominantly found in women, including maternal mortality and morbidity, cervical cancer, anemia, STIs, osteoarthritis, and breast cancer, with HIV/AIDS leading the statistics (Mathers, 2009).

Although most of these conditions can be dealt with by cost-effective prevention and screening programs, many less

Lifetime Risk of Maternal Deaths in Sub-Saharan Africa versus Industrialized Nations. (From ChildInfo: Monitoring the situation of children and women. Available at http://www.childinfo.org/maternal_mortality.html. Accessed March 20, 2014)

developed countries have ignored women's health issues other than those directly related to pregnancy and childbirth for two major reasons: (1) women are not seen as valued members of society, and (2) most of the afflicted women are poor, malnourished, and cannot pay for health care services.

Sub-Saharan Africa accounts for the majority of the world's births. Although all countries profess to offer prenatal services and safe birthing services, most are unavailable, inaccessible, and unaffordable by women (WHO, *Maternal Health Fact Sheet*, 2013h). An African woman's risk of dying from pregnancy-related causes is 1 in 20, followed by Bangladesh, Pakistan, and India. These three countries account for nearly half of the world's maternal deaths, but only 29% of the world's births; they have more maternal deaths each week than Europe has in a year. Still, an accurate reporting of maternal deaths is difficult to obtain because many of the women who die are poor and live in remote areas, and their deaths are considered by many to be unimportant (Mathers, 2009) (See table above).

Risk factors for maternal mortality include poor nutritional status, disease conditions, high parity, and age less than 20 years and greater than 35 years. To date, little attention has been paid to the problem of maternal mortality, even though the reported incidences are high throughout the world. The WHO and the UN are addressing this problem by calling for government initiatives and actions to address maternal morbidity and mortality from obstetrical deaths as well as those that arise from indirect causes. MDG 5 aims to reduce the maternal mortality ratio by three quarters, improve the proportion of births attended by skilled health personnel, promote universal access to reproductive health, improve contraceptive rates, decrease adolescent birth rates, provide antenatal care coverage, and

address the unmet need for family planning by 2015 (WHO, 2012c). In some countries it is difficult to counsel women on family planning and spacing their children so as to promote maternal and fetal health when a woman's value depends on her ability to reproduce and more than 50% of children die before they reach adolescence.

The result of poor maternal health accounts for the increase in premature births and the increased risk for high morbidity rates in children less than 5 years because of their own compromised nutritional and immune state. Low birth weight is a major risk factor for premature births, which account for more than one quarter (29%) of newborn deaths, followed by asphyxia (22%), sepsis (15%), pneumonia (10%), congenital abnormalities (7%), diarrhea (2%), and tetanus (2%). Undernutrition and lack of access to clean water and sanitation significantly increase children's vulnerability to death. Newborn deaths account for most child deaths (41%), followed by diarrhea (14%), pneumonia (14%), malaria (8%), injuries (3%), HIV/AIDS (2%), and other infectious or noncommunicable diseases (18%, including measles [1%]) (Kaiser Family Foundation, *Global Health Policy*, 2013b). In 2012 approximately 6.6 million children died before the age of 5 which is nearly one half the number that died in 1990 but still much too high a number of deaths (World Bank, 2013b).

Even though programs in many countries have been initiated, safe motherhood initiatives are still needed throughout the world. These programs and initiatives need to include providing accessible family planning services and prenatal and postnatal health care services, ensuring access to safe abortion procedures, and improving the nutritional status of all women.

Nutrition and World Health

Many children around the world are underweight and have multiple micronutrient deficiencies such as for iron, zinc, and vitamin A. Poor nutrition by itself or that associated with infectious disease accounts for a large portion of the world's disease burden (Mathers, 2009; WHO, 2013d). Improved nutrition is related to stronger immune systems, decreased illness, better maternal and child health, longer life spans, and improved learning outcomes for children. Healthy protein balances are able to support major physiological stress with improved healing and ability to utilize protein-binding drugs; better nutrition is a prime entry point to ending poverty and a milestone to achieving better quality of life. Environmental and economic conditions related to poverty contribute to underconsumption of nutrients, especially those nutrients needed for protein building such as iodine, vitamin A, and iron. Worldwide, women and children suffer disproportionately from nutrition deficits, especially the micronutrients just mentioned (Mathers, 2009).

Children in Haiti die daily from hunger; more than 60% of the population is undernourished and children under the age of 5 suffer an even higher percentage. more than 800 million people (or one out of every five people in developing nations) are undernourished; and every few seconds, about every time one takes a breath, a child in the developing world dies of hunger and related diseases (Global Nutrition Alliance, 2010). Poor nutrition also leads to stunting, or low height and weight for a given age. Stunting often results from eating foods that do not provide adequate energy or protein. Because protein foods are usually more expensive than nonprotein food sources, many households reduce, or unconsciously eliminate, protein-rich foods to save money (Hunter, unpublished research, 2012). I have cared for and watched many children with marasmus (total caloric deprivation) and Kwashiorkor (protein deficiency starvation) die who could have been saved if affordable protein and nutritious food were available. Usually this condition begins because an infant has been weaned away from breastfeeding after a year to make room for the next baby, and the food used in its place is mainly sugar and water or a starchy gruel. Kwashiorkor symptoms are apathy, muscular wasting, edema, and pigmentation loss in the skin and hair. Marasmus is a wasting away of the body tissues and symptoms are like kwashiorkor with fretfulness and an appearance of "skin and bones."

Iron deficiencies are also common in less developed countries and severely affect women and children. When iron is low, fewer red blood cells are produced, and this reduces the capacity of the blood to transport oxygen. As a result, symptoms ranging from fatigue and inability to concentrate to impaired physical and cognitive development of children can occur. Iron deficiency anemia may also cause problems during pregnancy, particularly in developing countries where it can increase the risk of premature delivery, as well as the risk of maternal and fetal complications and death. Inadequate iron from food is the most common reason for iron deficiency anemia, especially among infants and children. Parasites, infections, stomach and

digestive diseases, and blood loss during menstruation may also worsen anemia. A deficiency of iron in the diet can reduce appetite, physical productivity, the ability to learn, and growth.

The American Society of Hematology (2013) reported that while the global prevalence of anemia decreased between 1990 and 2010 (from 40.2% to 32.9%), the disease has demonstrated an increase in global YLDs from 65.5 million to 68.4 million. The DALY burdens associated with major depression (63.2 million YLDs), chronic respiratory diseases (49.3 million YLDs), and general injuries (47.2 million YLDs) are less than the DALY burden of anemia. This is due to the increased incidence of anemia in children <5 years. This age group accounted for more cases of anemia than any other age group and had the highest severity of disease in low- and middle-income regions. Unfortunately the data also demonstrated a widening gender gap in anemia burden over time with female prevalence rates remaining higher in most regions and age groups.

Other common dietary deficiencies include zinc, iodine, vitamin A, folic acid, and calcium. Zinc is important because it is an essential part of many enzymes and plays an important role in protein synthesis and cell division. The health consequences of zinc deficiency include poor immune system function, growth retardation, and delayed sexual maturity in children. Zinc deficiency is caused by low intake and/or low absorption of bioavailable zinc. Diets low in meat and fish increase the risk of zinc deficiency, because zinc is poorly bioavailable in cereals. Vitamin A is another essential nutrient in the human diet, contributing to the functioning of the retina, the growth of bone, and the immune response. Apart from preventable, irreversible blindness, vitamin A deficiency also causes reduced immune function, leading to an increased risk of severe infectious disease and anemia. It also increases the risk of death during pregnancy for both the mother and fetus and after birth for the newborn. An estimated 250 million preschool children in developing countries are affected by vitamin A deficiency, although severe deficiency that causes blindness is declining (Kaiser Family Foundation, 2013c; WHO, Global Prevalence of Vitamin A Deficiency, 2013i).

The impact of malnutrition and dietary deficiencies is significant. Any malnourished condition in a population can increase susceptibility to illness. For example, the principal causes of death among malnourished persons are measles, diarrheal and respiratory disease, TB, pertussis, and malaria. The loss of life from these diseases can be measured as 231 DALYs worldwide, with one fourth of the 231 being directly attributable to malnourishment and dietary deficiencies. Individual governments and organizations such as the International Red Cross, WHO, and many international religious and private foundations have been active in promoting better nutrition. Worldwide initiatives directed at overcoming nutritional deficits include the following (Global Nutrition Alliance, 2010): control of infectious diseases, nutritional education, control of intestinal parasites, micronutrient fortification of food, food supplementation, and food price subsidies.

Médecins sans Frontières (Doctors without Borders) was the first to use the life-saving supplement, invented in 2003 by a French scientist, called Plumpy'nut. Plumpy'nut requires no

water preparation or refrigeration and has a 2-year shelf life, making it easy to deploy in difficult conditions to treat severe acute malnutrition. It is distributed under medical supervision, to humanitarian organizations for food aid distribution. The ingredients include peanut paste; vegetable oil; powdered milk; powdered sugar; vitamins A, B-complex, C, D, E, and K; and minerals including calcium, phosphorus, potassium, magnesium, zinc, copper, iron, iodine, sodium, and selenium. These are combined in a foil pouch and each 92-g pack provides 500 kilocalories (kcal) or 2.1 megajoules (MJ).

Natural and Man-Made Disasters

As discussed in [Chapter 23](#), earthquakes, floods, drought, and other natural hazards continue to cause tens of thousands of deaths, hundreds of thousands of injuries, and billions of dollars in economic losses each year around the world. Disasters represent a major source of risk for the poor and wipe out development gains and accumulated wealth in developing countries. In 2012, only 357 natural triggered disasters were registered; a decrease from 394 observed in the years past. However, natural disasters still killed a significant number, even though there was a decline in deaths. Contrary to other indicators, economic damages from natural disasters did show an increase to above average levels (143 billion 2012 US\$), with estimates placing the figure at US\$ 157 billion. Over the last decade, China, the United States, the Philippines, India, and Indonesia together constitute the top five countries that are most frequently hit by natural disasters. In 2012, China had its fourth highest number of natural disasters over the last decade with 13 floods and landslides, 8 storms, 7 earthquakes, and 1 period of extreme temperature. The single deadliest disaster in 2012 was Typhoon Bopha, which killed 1901 people in the Philippines ([Center for Research on the Epidemiology of Disaster, 2013](#)).

Natural disasters such as earthquakes, tsunamis, and floods can often come at the least expected time. Others, such as hurricanes and cyclones, are increasing in severity and destruction. Droughts are increasing as the threat of global warming rises. Typically, the poor are the worst hit, for they have the least resources to cope and rebuild. Hurricane Katrina resulted in a 90,000 square mile disaster zone, equivalent to the area of Great Britain, and more than 1800 died. The Indonesian tsunami of 2005 killed at least 230,000 people, and the livelihoods of millions were destroyed in more than 10 countries affected by the tsunami. The earthquake in Haiti in 2010 destroyed a country and crushed the hopes of thousands of Haitians. Human activity is contributing to massive extinctions, from various animal species, to forests, and the ecosystems that support marine life. The costs associated with deteriorating or vanishing ecosystems are high. The World Resources Institute reports that there is a link between biodiversity and climate change, and rapid global warming can affect an ecosystem's chance to adapt naturally ([World Resources Institute, 2012](#)). The four worst types of natural disasters are as follows:

- *Earthquakes and tsunamis:* Examples are January 12, 2010—more than 230,000 people were killed when a 7.0-magnitude earthquake struck Haiti; May 12, 2008—about 70,000 people

were killed and 18,000 people were reported missing after a 7.9-magnitude earthquake struck Sichuan, China; October 8, 2005—at least 80,000 people were killed and 3 million left homeless after a quake struck the mountainous Kashmir district in Pakistan.

- *Volcanic eruptions:* Examples are July 15, 1991 when Mount Pinatubo on Luzon Island in the Philippines erupted, blanketing 750 square kilometers with volcanic ash and more than 800 died; November 13-14, 1985 when at least 25,000 were killed near Armero, Colombia, when the Nevado del Ruiz volcano erupted, triggering mudslides.
- *Hurricanes, cyclones, and floods:* Examples are July-August 2010, when monsoon rains hit northwest Pakistan and more than one fifth of the country was under water, more than 1700 people were killed, and 17.2 million people were victims; May 3, 2008, when Cyclone Nargis, with winds that exceeded 190 km/hour and waves six meters high, struck Myanmar, leaving as many as 100,000 dead, according to U.S. estimates; October 26-November 4, 1998, when Hurricane Mitch killed 11,000 in Honduras and Nicaragua and left 2.5 million homeless.
- *Pandemics and famines:* 1900-present, malaria has been the leading cause of death in the developing world, causing severe illness in 500 million people each year and killing more than 1 million annually; 1984-1985, the Ethiopian famine that killed at least 1 million in Ethiopia; and 1980-present, the toll from AIDS worldwide is estimated at 25 million, with 40 million others infected with HIV (<http://www.cbc.ca/news/world/the-world-s-worst-natural-disasters-1.743208>).

When poor countries face natural disasters, such as hurricanes, floods, earthquakes, and fires, the cost of rebuilding becomes even more of an issue when they are already burdened with debt. Often, poor countries suffer with many lost lives and/or livelihoods. Aid and disaster relief often do come in from international relief organizations, rich countries, and international institutions, but poor countries often pay millions of dollars a week back in the form of debt repayment.

The aftermath of a natural disaster may be as devastating as the disaster itself. Inadequate shelter, unclean water, and lack of security are some of the most commonly reported problems, even a year after the event. The physical force of a disaster not only causes immediate injury and death, but each type of disaster can result in its own combination of physical injuries. In earthquakes, buildings and the objects inside them can fall, injuring those who live or work there. Floods can result in drowning, and wildfires can cause burns and illness from smoke inhalation.

In addition to the direct injury and death caused by the disaster's force, there can be other serious adverse effects on the well-being of those living in the area. The large numbers of people who are suddenly ill or injured can exceed the capacity of the local health care system to care for them. In addition to the burden of increased numbers of clients, the system itself can become a victim of the disaster. Hospitals may be damaged, roads blocked, and personnel unable to perform their duties. The loss of these resources occurs at a time when they are most

critically needed. The disaster can also hamper the ability to provide routine, nonemergency health services. Many people may be unable to obtain care and medications for their ongoing health problems. The disruption of these routine services can result in an increase in illness and death in segments of the population that might not have been directly affected by the disaster. The most serious consequences of natural disasters are related to mass population displacements, unsanitary conditions, lack of clean water, lack of nutritious foods, lack of safe housing, and the increased risk of diseases prevalent in crowded and unsanitary living conditions: typhoid fever, cholera, dysentery, TB, and infectious respiratory conditions (Petrucci, 2012).

Man-made disasters may include bioterrorism, chemical agents, pandemics and epidemics, radiation, and terrorism. The five worst man-made disasters in recent history are as follows:

- *Bhopal Gas Tragedy, India* in 1984 where more than 500,000 people were exposed to methyl isocyanide gas and other chemicals. Thousands of people died within the first hours of the leak, but over time estimates of 5000 to 16,000 deaths from the leak have been made.
- *Deepwater Horizon Oil Spill, Gulf of Mexico* in 2010 that killed 11; leaked anywhere from 40,000 to 162,000 barrels of oil a day; took 47,829 people 89 days to finally cap the well; and 3500 workers and volunteers on the clean-up site are suffering liver and kidney damage from their exposure to the 1.8 million gallons of toxic oil.
- *Chernobyl Meltdown, Ukraine* in 1986. Thirty-one volunteers died trying to shut the reactor down and nearly 4000 deaths so far have been thought to be attributable to the radiation poisoning people living near Chernobyl underwent. To this day, no one is sure what the final death toll from the Chernobyl meltdown will be.
- *Fukushima Meltdown, Japan* in 2011 with more than 100,000 people evacuated and displaced from the surrounding areas; 600 people dying during the evacuation; 300 cleanup workers receiving excessive exposure to radioactive waste; and the resulting unknown long-term health effects that could include people as far away from the meltdown as North America.
- *Global Warming* that impacts rising sea levels, desertification, animal extinction, and damage from intense superstorms such as Hurricane Katrina, Hurricane Sandy, and Typhoon Haiyan in the Philippines has already created some of the first groups of climate-change refugees, and some estimate that number will rise to 150 million by 2050 (<http://www.policymic.com/articles/23620/5-worst-man-made-disasters-in-history>).

Other man-made disasters are the **bioterrorism** attack and the deliberate release of viruses, bacteria, or other germs (agents) used to cause illness or death of people, animals, or plants, which may lead to pandemics and epidemics (anthrax, cholera, Ebola virus, Lassa fever, plague, and smallpox, to name a few). A pandemic is an epidemic of infectious diseases that spread through human populations across a large region such as a continent or the globe (e.g., HIV/AIDS, smallpox, TB, H1N1, SARS); whereas an epidemic is when new cases of a certain disease in a given human population exceed what is expected (cancer, heart disease, seasonal flu).

These agents are typically found in nature, but it is possible that they could be changed to increase their ability to cause disease, to make them resistant to current medicines, or to increase their ability to be spread into the environment in order to threaten a government or intimidate or coerce a civilian population (CDC, *Bioterrorism*, 2013b; *Infectious disease: Global Challenges. Bioterrorism*, 2013). Bioterrorism is a significant public health threat that could produce widespread, devastating, and tragic consequences, and it would impose particularly heavy demands on international public health and health care systems. Nurses and other health personnel need to be aware and vigilant to the health consequences of terrorism and the potential use of biological agents to instill fear and to spread disease.

A nation's capacity to respond to the threat of bioterrorism depends in part on the ability of health care professionals and public health officials to rapidly and effectively detect, diagnose, respond, and communicate during a bioterrorism event. The national health care community—including public health agencies, emergency medical services, hospitals, and health care providers—would bear the brunt of the consequences of a biological attack. Attacks with biological agents are likely to be covert, rather than overt (CDC, 2013b). Terrorists may prefer to use biological agents because they are difficult to detect; they do not cause illness for several hours to several days.

A **chemical emergency** occurs when a hazardous chemical has been released and the release has the potential to harm people's health. Chemical releases can be unintentional, as in the case of an industrial accident, or intentional, as in the case of a terrorist attack. Sarin and ricin are the two most recent notorious chemicals used; however, mustard gas, cyanide, and tear gas have existed for decades. Agent Orange was used by the American troops in Vietnam, and mustard gas was commonly used during World War I and even during the Gulf War (<http://www.policymic.com/articles/62023/10-chemical-weapons-attacks-washington-doesn-t-want-you-to-talk-about>; <http://science.howstuffworks.com/mustard-gas4.htm>).

Radiation poisoning occurs when an excess amount of radiation is released to harm people's health. These may be unintentional and intentional events. Intentional terrorist events are those designed to contaminate food and water with radioactive material; spread radioactive material into the environment by using conventional explosives (e.g., dynamite), called a dirty bomb, or by using wind currents or natural traffic patterns; bomb or destroy a nuclear reactor; cause a truck or train carrying nuclear material to spill its load; or explode a nuclear weapon.

The word **genocide** was developed by a jurist named Raphael Lemkin in 1944. By combining the Greek word *genos* (race) with the Latin word *cide* (killing), genocide was defined by the United Nations in 1948 to mean any of the following acts committed with intent to destroy, in whole or in part, a national, ethnic, racial, or religious group, including (1) killing members of the group, (2) causing serious bodily or mental harm to members of the group, (3) deliberately inflicting on the group conditions of life calculated to bring about its physical destruction in whole or in part, (4) imposing measures intended to prevent births

within the group, and (5) forcibly transferring children of the group to another group ([Genocide Watch, International Alliance to End Genocide, 2013](#); <http://www.genocidewatch.org/>). The most notable genocides were the *Al-Anfal genocide* of the Kurds in Iraq, with more than 280,000 killed and many thousands unaccounted for; the *Rwandan genocide*, where the Hutus slaughtered hundreds of thousands (possibly 1 million) of their Tutsi relatives; the *Irish potato famine*, where more than a million Irish died because of lack of intervention by the British to feed the starving populace; the Native American genocide, with the loss of more than 1 million indigenous people to intentional infections with smallpox, war, and starvation; the *Bosnian genocide* and the annihilation of the Bosnian Muslims and Serbs to ethnically cleanse the country; and the most notable, the *Holocaust*, in which more than 6 million Jews and other ethnically disenfranchised populations were lost (<http://listverse.com/2013/05/03/10-atrocious-genocides-in-human-history/>). Genocide continues today in Syria, Darfur, and the Central African Republic.

Following genocide, there are biopsychological changes such as physical stress reactions (cardiovascular, neurological) and mental stress responses, especially post-traumatic stress disorders and depression. Many people flee and become refugees or internationally displaced people. These refugees flee to neighboring countries, placing social, political, and economic burdens on these countries. I have been to the refugee camps in Uganda for refugees from Rwanda, the Congo, Kenya, and even northern Uganda, whose people have been victims of the Liberation Rebel Army (LRA) as political turmoil continues to plague the civilians in East Africa. The victims of genocide often face discrimination in refugee camps or in their new country of permanent residence if they do not return home. Individuals who return to their home countries are often plagued with uncertainty regarding lost property and other belongings.

The biological and psychosocial effects of genocide are not exclusive to the child and adult victims, but affect the perpetrators as well. Marginalization and dehumanization place a mental toll on the victims that often results in negative cognitive, behavioral, affective, relational, and spiritual effects. Many perpetrators are forced into committing these acts, and achieving desensitization is necessary for a nonviolent person to kill or to commit violent acts. This is evident in the boy soldiers of the LRA (some as young as 6 years old) who are forced to kill or be killed and become desensitized through the use of alcohol, drugs, and repeated exposure to death ([Vollhardt and Bilewicz, 2013](#)).

After genocidal conflicts have ceased, restoration of a country's infrastructure, as well as reconciliation, must begin. The ramifications of genocide are widespread, and community leaders must find the most effective ways of initiating the healing process. The United Nations has tried to develop strategies to prevent genocide from occurring and is encouraging initiatives that include appropriate comprehensive cultural competence in the delivery of services; supporting and organizing treatment and care that is fair and just to all members of specific societies, regardless of age, gender, race, cultural beliefs, religion, sexual orientation, affiliation, and civil status;

encouraging international organizations to make mental and behavioral health a priority in conflict assistance throughout the various stages of genocide; and encouraging its member organizations to emphasize the importance of social work in regard to genocide in their respective countries ([Vollhardt and Bilewicz, 2013](#)).

Surveillance Systems

Surveillance systems, discussed in [Chapter 24](#), are used to track potential risks for intentional harm to the people of the world. There are systems in place to assess the risks for man-made and natural disasters to prevent the atrocities to mankind discussed previously. These systems may be on-the-ground specialists who acquire information about the political stability of nations, or they may be satellite systems that track weather, volcanic, and earthquake activities.

How would a government find out that a deliberate outbreak had taken place? For the international system, the WHO monitors disease outbreaks through the Global Outbreak Alert and Response Network ([Center for Research on the Epidemiology of Disaster, 2012](#); [WHO, 2014g](#)). This network, formally launched in April 2000, electronically links the expertise and skills of 72 existing networks from around the world, several of which were uniquely designed to diagnose unusual agents and handle dangerous pathogens. Its purpose is to keep the international community constantly alert to the threat of outbreaks and ready to respond. It has four primary tasks:

1. *Systematic disease intelligence and detection:* The first responsibility of the WHO network is to systematically gather global disease intelligence, drawing from a wide range of resources, both formal and informal. Ministries of Health, WHO country offices, government and military centers, and academic institutions all file regular formal reports with the Global Outbreak Alert and Response Network. An informal network scours world communications for rumors of unusual health events.
2. *Outbreak verification:* Preliminary intelligence reports from all sources, both formal and informal, are reviewed and converted into meaningful intelligence by the WHO Outbreak Alert and Response Team, which makes the final determination on whether a reported event warrants cause for international concern.
3. *Immediate alert:* A large network of electronically connected WHO member nations, disease experts, health institutions, agencies, and laboratories is kept continually informed of rumored and confirmed outbreaks. The network also maintains and regularly updates an Outbreak Verification List, which provides a detailed status report on all currently verified outbreaks.
4. *Rapid response:* When the Outbreak Alert and Response Team determines that an international response is needed to contain an outbreak, it enlists the help of its partners in the global network. Specific assistance available includes targeted investigations, confirmation of diagnoses, handling of dangerous biohazards (biosafety level IV pathogens), client care management, containment, and logistical support in terms of staff and supplies.

In summary, if health care professionals and emergency responders are to be prepared to manage natural or manmade disasters, it is critical that there be cooperative efforts at the international, national, state, and local levels (Box 4-5). Such disaster response is not the domain of any one specialty; nurses, doctors, mental health experts, first responders, EMTs,

volunteers, engineers, and many more need to be part of the team that helps people overcome the physical, emotional, social, and economic devastation. Nurses need to have political, historical, social, medical, nursing, and public health knowledge in order to be more effective in finding the resources their clients need to recover successfully.

BOX 4-5 What Can Nursing Do in the Event of a Disaster?

The International Council of Nursing (ICN, 2009) policy paper on disaster preparedness outlines actions, including risk assessment and multidisciplinary management strategies, as critical to the delivery of effective responses to the short-, medium-, and long-term health needs of a disaster-stricken population. These actions include the following:

Help People to Cope with Aftermath of Terrorism

- Assist people to deal with feelings of fear, vulnerability, and grief.
- Use groups that have survived terrorist attacks as useful resources for victims.

Allay Public Concerns and Fear of Bioterrorism

- Disseminate accurate information on the risks involved, preventive measures, use of antibiotics and/or vaccines, and reporting suspicious letters or packages to the police or other authorities.
- Address hoax messages, false alarms, and threats; any perceived threat to the public health must be investigated.

Identify the Feelings That You and Others May be Experiencing

- In the aftermath of terror, even health care professionals can feel bias, hatred, vengeance, and violence toward ethnic or religious groups that are associated with terrorism. These feelings can compromise their ability to provide care for these groups. Yet as the ICN *Code of Ethics for Nurses* affirms, nurses are ethically bound to provide care to all people. Explain that feelings of fear, helplessness, and loss are normal reactions to a disruptive situation.

- Help people remember methods they may have used in the past to overcome fear and helplessness.
- Encourage people to talk to others about their fears.
- Encourage others to ask for help and provide resources and referrals.
- Remember that those in the helping professions (e.g., nurses, physicians, social workers) may find it difficult to seek help.
- Convene small groups in workplaces with counselors/mental health experts.

Assist Victims to Think Positively and to Move Toward the Future

- Remind others that things will get better.
- Be realistic about the time it takes to feel better.
- Help people to recognize that the aim of terrorist attacks is to create fear and uncertainty.
- Encourage people to continue with the things they enjoy in their lives and to live their normal lives.

Prepare Nursing Personnel to be Effective in a Crisis/Emergency Situation

- Incorporate disaster preparedness awareness in educational programs at all levels of the nursing curriculum.
- Provide continuing education to ensure a sound knowledge base, skill development, and ethical framework for practice.
- Network with other professional disciplines and governmental and nongovernmental agencies at local, regional, national, and international levels.

From ICN. Nursing Matters: Terrorism and bioterrorism: nursing preparedness. Available at <http://www.icn.ch/publications/disaster-planning-and-relief>. Accessed December 27, 2010; International Council of Nurses (ICN): *Code of Ethics for Nurses*, Geneva, 2000, ICN.

LINKING CONTENT TO PRACTICE

The role and involvement of nurses in global health relies heavily on nursing standards of practice and core competencies of both nurses and other public health professionals. The role also varies from country to country. It is not surprising to learn that nursing plays a more active role in health care delivery in the more technologically advanced countries. The more developed countries have a defined role for nurses, whereas the role is less well defined, if it is defined at all, in less developed countries. However, nurses need to remember that addressing the health of the people of the world is not restricted to meeting the physical health needs but, in order to be successful, must incorporate the concept of global health diplomacy. Physical, environmental, mental, political, fiscal, economic, safety, and educational “health” are intertwined in achieving the goals we all have for helping the people of the world obtain optimal well-being. Assessment of each of these areas is cited in standards of practice for nursing and public health professionals and is essential in the global nursing role. See the Quad Council on Nursing’s competencies (Swider et al, 2014), which incorporate those of the Council on Linkages core competencies for public health professionals. Each set of competencies recommends analytic/assessment skills that are crucial to working in a global health arena. They also talk about the importance of cultural competence skills and communication skills that are relevant to the people with whom you are working.

During the last decade, some less developed countries have implemented primary health care programs directed at prevention and management of important public health problems. With the increasing migration between and within countries because of war and famine, a greater need for nursing expertise to alleviate suffering of refugees and displaced persons has emerged. Starvation, disease, death, war, and migration underscore the need for support from the wealthier nations of the world.

More than 30 million refugees and internally displaced persons in less developed countries currently depend on international relief assistance for survival. Death rates in these populations during the acute phase of displacement have been up to 60 times the expected rates. Displaced populations in Ethiopia and southern Sudan have suffered the highest death rates. In Afghanistan and in war-torn Iraq, infectious diseases accounted for one half of all admissions to the hospital—mostly malaria and typhoid fever. The greatest death rate has been in children 1 to 14 years old. The major causes of death have been measles, diarrheal diseases, acute respiratory tract infections, and malaria. In addition, poor sanitation in many hospitals and clinics and shortages of drugs and qualified health care workers produce huge gaps for needed health care services. Continued violence accounts for a population afraid to leave home to seek medical help.

Public Health Foundation/Health Resources and Services Administration. Quad Council of Public Health Nursing Organizations. Competencies for Public Health Nursing Practice, Washington, DC, 2003, ASTDN, revised 2009.

LINKING CONTENT TO PRACTICE—cont'd

Nurses from more developed countries are recruited to combat the major mortality in refugee camps: malnutrition, measles, diarrhea, pneumonia, and malaria. Nurses, collaborating with other experts, are following the principles of primary health care and are promoting adequate food intake, safe drinking water, shelter, environmental sanitation, and immunizations. These life-saving practices have been implemented in the following countries: Thailand (Myanmar refugees), Rwanda, Zaire, Angola, Afghanistan, the Sudan, Uganda, and the former Yugoslavia. Nurses are making a difference; however, nurses involved in

this work must be culturally astute and responsive, be well educated about the world and well versed in the tasks required to achieve positive outcomes, able to critically reason, able to make decisions, able to identify who are appropriate team members, and be able to collaborate with the team. They ought not be afraid of taking risks, they should be action-oriented, and they need to be flexible and altruistic. Global health work is a labor of love, it is a giving of self to make a difference in the lives of others less fortunate, and it is the most rewarding work in which many nurses have ever been engaged.

PRACTICE APPLICATION

You are sent to a country ravaged by war, in which many people are refugees. You are asked to work side by side with other nurses, both foreign and native to the country.

A. What would you do first to develop this group of nurses into a functioning team?

B. Which health and environmental problems would you attempt to handle early in your work?

C. Identify second-stage interventions and prevention once the initial crisis stage is relieved.

Answers can be found on the Evolve site.

KEY POINTS

- Global health is a collective goal of nations and is promoted by the world's major health organizations.
- Global health cannot be achieved without using the constructs of global health diplomacy: addressing and finding solutions to physical, environmental, fiscal, economic, political, safety, educational, and trade issues.
- As the political and economic barriers between countries fall, the movement of people back and forth across international boundaries increases. This movement increases the spread of various diseases throughout the world.
- Nurses play an active role in the identification of potential health risks at U.S. borders, with immigrant populations throughout the United States, and as participants in global health care delivery.
- Understanding a population approach is essential for understanding the health of specific populations.
- Universal access to health care for the world's populations relies on strong primary care.
- The major organizations involved in world health are (1) multilateral, (2) bilateral and nongovernmental or private voluntary, and (3) philanthropic.
- The health status of a country is related to its economic and technical growth. More technologically and economically advanced countries are referred to as *developed*, whereas those that are striving for greater economic and technological growth are termed *less developed*. Many less developed countries shift financial resources from health and education to other internal needs, such as defense or economic development, and this shift does not help the poor.
- The global burden of disease (GBD) is a way to describe the world's health. The GBD combines losses from premature death and losses that result from disability. The GBD represents units of disability-adjusted life-years (DALYs).
- Critical global health problems still exist and include communicable diseases such as tuberculosis, measles, mumps, rubella, and polio; maternal and child health; diarrheal diseases; nutritional deficits; malaria; and AIDS.
- Natural and man-made disasters have become global health concerns.

CLINICAL DECISION-MAKING ACTIVITIES

1. In your class, divide into small groups and discuss how you might find out if there are immigrant communities in your area (you may need to contact your local health department, area social workers, or community social organizations and churches).
2. Discuss how you can gain access to one of these immigrant groups.
3. On gaining access, how would you go about determining what specific kinds of services the people need? What are their beliefs about health and health care? What customs regarding health were followed in their country of origin?

How does the American health care system differ from the health care system in their country?

4. As a nurse, what kinds of interventions can you implement with immigrant populations? What special skills or knowledge do you need to provide care to immigrant populations?
5. Write to one of the major international health organizations or visit their Internet web page and obtain their mission and goal statements. What is the focus of their health-related activities? Does the organization that you identified have a specific role defined for nurses? How can a nurse who is interested become involved in their programs and activities?

CLINICAL DECISION-MAKING ACTIVITIES—cont'd

6. Pick a country or area of the world outside the United States that interests you. Go to the library or use the Internet to obtain information about the following:
 - a. Status of health care in that country
 - b. Major health concerns
 - c. Global burden of disease (GBD)
 - d. Whether this country is developed or lesser developed
 - e. Which, if any, global health care organizations are involved with the delivery of health care in that country
7. Choose one or more of the following countries, and find out from your local or state health department the health risks that are involved in visiting that country: Indonesia, Zaire, Paraguay, Bangladesh, Kuwait, Kenya, Mexico, China, and Haiti.
8. Establish communication with nurses in a country of interest (via telecommunication [e.g., web, phone, blog]) to discuss the state of nursing in that country, their problems, and plans to overcome some of the barriers that obstruct them from achieving their professional goals.

Forces Affecting Health Care Delivery and Population-Centered Nursing

As has been discussed in Part One, the U.S. health care system has been criticized for its rapidly rising health care costs, unevenness in the level and quality of services provided from one area of the country to another and for people in different age and socioeconomic groups. There has also been concern about the equality of access to health services. By 2008, when the recession began in the United States, the number of people who lived in poverty was increasing. In 2007 it was estimated that 12.5% of the people in the United States were living in poverty. Between 2007 and 2011 the poverty rate increased to 15%. Some of the reasons for the poverty increase had to do with the decreased numbers of people who had full-time year-round jobs. From 2008, with an unemployment rate of 4.9%, the rate grew to a high of 9.0% in 2010. Without job stability, many people were without adequate health insurance, and a sizable number of individuals and families lost their homes because of foreclosures. There were many other Americans who remained employed yet their salaries did not increase. These flat salaries did not allow the workers to keep pace with the increasing costs of consumer products and services. In 2011 the economy began to recover, but slowly. In 2015 the unemployment rate had dropped to 5.5%. Also by 2015 the number of persons living in poverty had dropped slowly.

Although the costs of health care have grown in recent years, local, state, and federal funding for public health care has not grown. The vast majority of the money spent on health care in the United States is for acute care. Approximately 3% of the total health care budget is spent on the aspects of public health that could make a difference in the health of the citizens: health promotion and disease prevention. The allocation of funds, especially for preventive care, has begun to shift as health care reform occurs.

As mentioned, there are early indications that prevention, coordination, and community-based care will be increasingly supported. As a result of the national debates—and some say “arguments” about health care reform—legal, economic, ethical, social, cultural, political, and health policy issues have grown in importance. Now more than ever in the history of population-centered nursing, nurses must understand how these issues affect their practice and the outcomes of care. Nurses will continue learning how their knowledge, skills, and voice can influence the decisions about health care. As health care changes, including public health care, nurses as the largest public health provider workforce must be a force in redefining the renewed public health system. Understanding the issues that affect decisions about health care priorities is imperative. Knowledge is power.

The chapters in Part Two discuss important economic, ethical, cultural, and policy issues that affect nurses in general and population-centered nurses specifically.

Economics of Health Care Delivery

Marcia Stanhope, PhD, RN, FAAN

Dr. Marcia Stanhope is currently an Associate of the Tufts and Associates Search Firm, Chicago, Ill. She is also a consultant for the nursing program at Berea College, Kentucky. She has practiced community and home health nursing, has served as an administrator and consultant in home health, and has been involved in the development of two nurse-managed centers. At one time in her career, she held a public policy fellowship and worked in the office of a U.S. Senator. She has taught community health, public health, epidemiology, policy, primary care nursing, and administration courses. Dr. Stanhope formerly directed the Division of Community Health Nursing and Administration and served as Associate Dean of the College of Nursing at the University of Kentucky. She has been responsible for both undergraduate and graduate courses in population-centered nursing. She has also taught at the University of Virginia and the University of Alabama, Birmingham. During her career at the University of Kentucky she appointed to the Good Samaritan Foundation Chair and Professorship in Community Health Nursing, and was honored with the University Provost's Public Scholar award. Her presentations and publications have been in the areas of home health, community health and community-focused nursing practice, as well as primary care nursing.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Relate public health and economic principles to nursing and health care.
2. Describe the economic theories of microeconomics and macroeconomics.
3. Identify major factors influencing national health care spending.
4. Analyze the role of government and other third-party payers in health care financing.
5. Identify mechanisms for public health financing of services.
6. Discuss the implications of health care rationing from an economic perspective.
7. Evaluate levels of prevention as they relate to public health economics.

There is strong evidence to suggest that poverty can be directly related to poorer health outcomes. Poorer health outcomes lead to reduced educational outcomes for children, poor nutrition, low productivity in the adult workforce, and unstable economic growth in a population, community, or nation. However, improving health status and economic health is dependent on the “degree of equality” in policies that improve living standards for all members of a population including the poor. To move toward improving a population’s health, there must be an “**investment in public health**” by all levels of government (Robert Wood Johnson Foundation, 2013).

Estimates indicate that public spending on health care makes a difference, but a sustained and sufficient level of investment in prevention at the federal, state, and local levels is needed to improve the overall health status of populations (Trust for America’s Health, 2013a,b and 2014). Several facts are known from the literature (Kaiser Family Foundation, 2013; Robert Wood Johnson Foundation, 2013; DeNavas-Walt et al, 2013; U.S. Department of Health and Human Services [USDHHS], 2012):

- In 2012, approximately 48 million (15.4%) of the estimated 311.1 million people in the United States were without health insurance (DeNavas-Walt et al, 2013). Over the past decade, the number of uninsured individuals has increased,

largely due to the struggling economy and weak job market (Kaiser Family Foundation, 2012a). As the Affordable Care Act is implemented, new and affordable options will become available, hopefully reducing the number of uninsured individuals and families (Kaiser Family Foundation, 2012a).

- The rate of uninsured was higher among people with lower incomes and lower among those with higher incomes. For households with less than \$25,000 annual income, 24.9% did not have health insurance coverage in 2012 (DeNavas-Walt et al, 2013).
- Adults are more likely to be uninsured than children (Kaiser Family Foundation, 2013).
- Young adults (ages 19-25 years) account for a disproportionately large share of the uninsured, largely due to their low incomes (Kaiser Family Foundation, 2013; USDHHS, 2012).
- The uninsured rate for all children was 8.9% in 2012. For children living in poverty the uninsured rate was 12.9%, which was higher than the rate of children not in poverty (7.7%) (DeNavas-Walt et al, 2013).
- Minorities are more likely to be uninsured than whites. About 32% of Hispanics and 21% of black Americans were uninsured in 2011, compared with 13% of non-Hispanic whites (Kaiser Family Foundation, 2012a; USDHHS, 2012).

- More than 8 in 10 (80%) of the uninsured are in working families (Kaiser Family Foundation, 2012a).
 - About 62% are from families with one or more full-time workers.
 - About 16% are from families with part-time workers.
- Individuals without health insurance are less likely to receive preventive care, such as blood pressure, cholesterol, and cancer screenings, than those with insurance coverage (Kaiser Family Foundation, 2012a).
- Those without health insurance are more likely to be hospitalized for preventable problems, and when hospitalized receive fewer diagnostic and therapeutic services; they also have higher mortality rates than those with insurance (Kaiser Family Foundation, 2012a).
- Adults without insurance are nearly twice as likely to report being in fair or poor health than those with private insurance (Kaiser Family Foundation, 2012a).
- Studies indicate that gaining health insurance restores access to health care considerably and reduces the adverse effects of having been uninsured (Kaiser Family Foundation, 2012a).
- The poor are more likely to receive health care through publicly funded agencies.
- An emphasis on individual health care will not guarantee improvement of a population or a community's health (see Chapter 3 for more discussion).

Approximately 97% of all health care dollars are spent for individual care whereas only 3% are spent on population-level health care. The 3% includes monies spent by the government on public health as well as the preventive health care dollars spent by private sources. These numbers indicate that there has not been a large investment in the public's health or population health in the United States (National Center for Health Statistics [NCHS], 2012).

The United States spends more on health care than any other nation. The cost of health care has been rising more than the rate of inflation since the mid-1960s, yet the U.S. population does not enjoy better health as compared with nations that spend far less than the United States. The current health care system has been reaching the point where it is not affordable (Turnock, 2011; Trust for America's Health, 2013b). An estimated \$10 per person invested in community-based prevention programs can lead to improved health status of the population and reduced health care costs (Robert Wood Johnson Foundation, 2012). This return on investment represents medical cost savings only and does not include the significant gains that could be achieved in worker productivity, reduced absenteeism at work and school, and enhanced quality of life.

Nurses are challenged to implement changes in practice and participate in research, evidence-based practice, and policy activities designed to provide the best return on investment of health care dollars (i.e., to design models of care, at a reasonable price, that improve access or quality of care). Meeting this challenge requires a basic understanding of the economics of the U.S. health care system. Nurses should be aware of the effects of nursing practice on the delivery of cost-effective care. In 2010, a new health reform law, the Patient Protection and Affordable

Care Act (PL 111-148) was passed by Congress and signed into law on March 23, 2010. There is now a greater emphasis in the Affordable Care Act (ACA) on improving participation and the outcomes of prevention, and population health.

PUBLIC HEALTH AND ECONOMICS

Economics is the science concerned with the use of resources, including the production, distribution, and consumption of goods and services. **Health economics** is concerned with how scarce resources affect the health care industry (McPake et al, 2013; Phelps, 2012). **Public health economics**, then, focuses on the production, distribution, and consumption of goods and services as related to public health and where limited public resources might best be spent to save lives or best increase the quality of life (Centers for Disease Control and Prevention [CDC], 2015).

Economics provides the means to evaluate society's attainment of its wants and needs in relation to limited resources. In addition to the day-to-day decision making about the use of resources, there is a focus on evaluating economics in health care (McPake et al, 2013; Phelps, 2012). While in the past there has been limited focus on evaluating public health economics, it is becoming more obvious what evaluating public health and preventive care can do in terms of cost savings and, more importantly, quality of life (Trust for America's Health, 2013b). This type of evaluation will help to present challenges to public policymakers (legislators).

Public health financing often causes conflict because of the views and priorities of individuals and groups in society, which may differ from those of the public health care industry. If money is spent on public health care, then money for other public needs, such as education, transportation, recreation, and defense, may be limited. When trying to argue that more money should be spent for population-level health care or prevention, data are becoming available that show the investment is a good one. **Public health finance** is a growing field of science and practice that involves the acquiring, managing, and using of monies to improve the health of populations through disease prevention and health promotion strategies. This field of study also focuses on evaluating the use of the money and the impact on the public health system (Honoré, 2012).

Although the public health system had been considered for many years as involving only government public health agencies such as health departments, today the public health system is known to be much broader and includes schools, industry, media, environmental protection agencies, voluntary organizations, civic groups, local police and fire departments, religious organizations, industry/business, and private sector health care systems, including the insurance industry. All can play a key role in improving population health (Institute of Medicine, 2003; Trust for America's Health, 2013a).

The goal of public health finance is "to support population focused preventive health services" (Honoré, 2012). Four principles are suggested that explain how public health financing may occur (Sturchio and Goel, 2012):

- The source and use of monies are controlled solely by the government.

- The government controls the money, but the private sector controls how the money is used.
- The private sector controls the money, but the government controls how the money is used.
- The private sector controls the money and how it is used.

When the government provides the funding and controls the use, the monies come from taxes, user fees (e.g., license fees and purchase of alcohol/cigarettes), and charges to consumers of the services. Services offered at the federal government level include the following:

- Policymaking
- Public health protection
- Collecting and sharing information about U.S. health care and delivery systems
- Building capacity for population health
- Direct care services

Select examples of services offered at the state and local levels include the following:

- Environmental health monitoring
- Population health planning
- Disaster management
- Preventing communicable and infectious diseases
- Direct care services (see [Chapter 46](#) for more examples)

When the government provides the money but the private sector decides how it is used, the money comes from business and individual tax savings related to private spending for illness prevention care. When a business provides disease prevention and health promotion services to its employees and sometimes families, such as immunizations, health screenings, and counseling, the business taxes owed to the government are reduced. This is considered a means by which the government provides money through tax savings to businesses to use for population health care.

When the private sector provides the money but the government decides how it is used, either voluntarily or involuntarily, the money is used for preventive care services for specific populations. A voluntary example is the private contributions made to reaching *Healthy People 2020* goals. An involuntary example is the Occupational Safety and Health Administration requiring industry to provide the financing to adhere to certain safety standards for use of machinery, air quality, ventilation, and eyewear protection to reduce disease and injury. This, for example, has the effect of reducing occupation-related injuries in the population as a whole.

When the private sector is responsible for both the money and its use of resources, the benefits incurred are many. For example, an industry may offer influenza vaccine clinics for workers and families that may lead to “herd immunity” in the community (see [Chapter 12](#) on epidemiology). A business or community may institute a “no-smoking” policy that reduces the risk of smoking-related illnesses to workers, family, and the consumers of the businesses’ services. A voluntary philanthropic organization may give a local community money to provide services for assisting low-income communities to improve their environment ([Fortunato and Sessions, 2011](#)).

These are but a few examples of how public health services and the ensuring of a healthy population are not only

government related. The partnerships between government and the private sector are necessary to improve the overall health status of populations. This partnership is emphasized in the ACA.

PRINCIPLES OF ECONOMICS

Knowledge about health economics is particularly important to nurses because they are the ones who are often in a position to allocate resources to solve a problem or to design, plan, coordinate, and evaluate community-based health services and programs. Two branches of economics are important to understand for their application in health care: microeconomics and macroeconomics. **Microeconomic theory** deals with the behaviors of individuals and organizations and the effects of those behaviors on prices, costs, and the allocating and distributing of resources. Economic behaviors are based on (1) individual or organization choices and the consumer’s level of satisfaction with a particular good (product) or service, or use of a service, and (2) the amount of money available to an individual or organization to spend on a particular good or service (its **budget limits**). Microeconomics applied to health care looks at the behaviors of individuals and organizations that result from tradeoffs in the use of a service and budget limits. A good example of reducing services because of cost by an organization is the reduction in school health nursing services by health departments.

The microeconomic example of the industry providing preventive services to its employees represents a behavior by the industry that provides for the use of a service and helps the industry’s budget by reducing health care insurance premium costs. The terms of the Patient Protection and Affordable Health Care Act (2010) allow employers to provide incentive rewards to employees for participation in wellness programs. Providing the service may also increase worker productivity and promote a healthier workforce, thus enhancing economic growth ([Hall, 2010](#)).

Because of the unique characteristics of health care, some economists believe that health care is special. There are debates about whether health care markets can ensure that health care is delivered efficiently to consumers. Cost-benefit and cost-effectiveness analyses are techniques used to judge the effect of interventions and policies on a particular outcome, such as health status ([Feldstein, 2012](#)).

Supply and Demand

Two basic principles of microeconomic theory are **supply** and **demand**, both of which are affected by price. A simple illustration of the relationship between supply and demand is provided in [Figure 5-1](#). The upward-sloping supply curve represents the seller’s side of the **market**, and the downward-sloping demand curve reflects the buyer’s desire for a given product.

As shown in [Figure 5-1](#), suppliers are willing to offer increasing amounts of a good or service in the market for an increasing price ([Colander, 2012](#)). The demand curve represents the amount of a good or service the consumer is willing to purchase at a certain price. This curve illustrates that when few quantities of a

FIG 5-1 Supply-and-demand curve.

BOX 5-1 Principles of the Laws of Supply and Demand

The Law of Supply

- At higher prices, producers are willing to offer *more* products for sale than at lower prices.
- The supply increases as prices increase and decreases as prices decrease.
- Those already in business will try to increase production as a way of increasing profits.

The Law of Demand

- People will buy more of a product at a lower price than at a higher price, if nothing changes.
- At a lower price, more people can afford to buy more goods and more of an item more frequently than they can at a higher price.
- At lower prices, people tend to buy some goods as a substitute for more expensive goods.

Data from Curriculum Link, 2010.

good or service are available in the marketplace, the price tends to be higher than when larger quantities are available. The point on the curve where the supply and demand curves cross is the equilibrium, or the point where producer and consumer desires meet (See Box 5-1). Supply and demand curves can shift up or down as a result of the following factors (McPake et al, 2013):

- Competition for a good or service
 - An increase in the costs of materials used to make a product
 - Technological advances
 - A change in consumer preferences
 - Shortages of goods or services
- Provides a review of the laws of supply and demand.

Using the example of industry-offered health care, it was not likely that a small industry of fewer than 50 employees would be able to offer incentive-based on-site illness prevention services. The demand might be great to keep employees healthy and on the job. The supply has been limited by the cost and numbers of services available in the community. Therefore, the cost was likely to be higher for the small business than for the large

BOX 5-2 Efficiency versus Effectiveness

To illustrate the differences between efficiency and effectiveness, consider the case of a nurse who is designing a community outreach program to educate high-risk, first-time mothers about the importance of childhood immunizations. The most *efficient* method to disseminate the information to a large number of mothers might be to have the child health team from the public health department hold an evening educational session, open to the public, at the health department. The most *effective* means of offering the program might be to link public health nurses with new mothers for one-on-one, in-home counseling, demonstration, and follow-up. The goals of the program could be stated as follows:

- To change the behavior of the mothers regarding providing immunizations for their children
- To increase community mothers' knowledge and awareness of infectious diseases
- To reduce the incidence of preventable infections in the community
- To decrease the number of hospital admissions

industry that offers its own services. The ACA proposes to offer preventive services free to the consumer, requiring insurance companies to cover these services (USDHHS, ACA, 2014a).

Efficiency and Effectiveness

Two other terms are related to microeconomics: efficiency and effectiveness. **Efficiency** refers to producing maximal output, such as a good or service, using a given set of resources (or inputs), such as labor, time, and available money. Efficiency suggests that the inputs are combined and used in such a way that there is no better way to produce the service, or output, and that no other improvements can be made. The word *efficiency* often focuses on time, or speed in performing tasks, and the minimizing of waste, or unused input, during production. Although these notions are true, efficiency depends on tasks as well as processes of producing a good or service and the improvements made (Feldstein, 2012).

Effectiveness, on the other hand, refers to the extent to which a health care service meets a stated goal or objective, or how well a program or service achieves what is intended. For example, the effectiveness of a mass immunization program is related to the level of "herd immunity" developed to reduce the problem that the program was addressing (see Chapter 12). Box 5-2 illustrates the differences between efficiency and effectiveness (Feldstein, 2012).

Macroeconomics

Microeconomics focuses on the individual or an organization, whereas **macroeconomic theory** focuses on the "big picture"—the total, or aggregate, of all individuals and organizations (e.g., behaviors such as growth, expansion, or decline of an aggregate). In macroeconomics, the aggregate is usually a country or nation. Factors such as levels of income, employment, general price levels, and rate of economic growth are important. This aggregate approach reflects, for example, the contribution of all organizations and groups within health care, or all industry within the United States, including health care, on the nation's economic outlook.

When the media refer to “the economy,” the phrase is typically used as a macroeconomic term to describe the wealth and financial performance of the nation as an aggregate. Health care contributes to the economy through goods and services produced and employment opportunities.

The primary focuses of macroeconomics are the **business cycle** and economic growth. Business expands and contracts in cycles. These cycles are influenced by a number of factors, such as political changes (a new president is elected), policy changes (new legislation is implemented, such as the Patient Protection and Affordable Health Care Act of 2010), knowledge and technology advances (a new vaccine to treat H1N1/H5N1 is placed on the market), or simply the belief by a recognized business leader that the cycle is or should be shifting (e.g., when the head of the Federal Reserve Board changes interest rates).

The **human capital** approach is a measure of macroeconomic theory (Goodwin et al, 2014). In this approach improving human qualities, such as health, are a focus for developing and spending money on goods and services because health is valued; it increases productivity, enhances the income-earning ability of people, and improves the economy. Therefore, there is a positive rate of return on the “investment in human capital.”

The individual, population, community, and nation all benefit. If the population is healthy, premature morbidity and mortality are reduced, chronic disease and disability are reduced, and economic losses to the nation are reduced. As an example, more people can work and be productive because they are healthy. The employing company makes more money because people are more productive. More taxes are paid into the local, state, and national economy, and more money is spent by individuals because they are productive, earning money, and taking advantage of the goods and services offered in their community.

Measures of Economic Growth

Economic growth reflects an increase in the output of a nation. Two common measures of economic growth are the **gross national product** (GNP) and the **gross domestic product** (GDP). GNP is the total market value of all goods and services produced in an economy during a period of time (e.g., quarterly or annually). GDP is the total market value of the output of labor and property located in the United States (Strawser, 2014). GDP reflects only the national U.S. output, whereas GNP reflects national output plus income earned by U.S. businesses or citizens, whether within the United States or internationally. This discussion focuses on GDP, because U.S. health care spending reports are based on GDP (NCHS, 2010).

Nurses face microeconomic and macroeconomic issues every day. For example, they are influenced by microeconomics when referring clients for services, informing clients and others of the cost of services, assessing community need for a particular service, evaluating client access to services, and determining health provider and agency response to client needs. Nurses who work with aggregates of individuals and communities are faced with macroeconomic issues, such as health policies that make the development of new programs possible; local, state, and federal budgets that support certain programs; and the total effect that services will have on improving the health of the

community and reducing the poverty level of the population. In short, knowledge about health economics can enhance a nurse’s ability to understand and argue a position for meeting population health needs.

Economic Analysis Tools

The primary methods used to assess the economics of an intervention are **cost-benefit analysis** (CBA), **cost-effectiveness analysis** (CEA), and **cost-utility analysis** (CUA). CBA is considered the best of these methods. In simple form, CBA involves the listing of all costs and benefits that are expected to occur from an intervention during a prescribed time. Costs and benefits are adjusted for time and inflation. If the total benefits are greater than the total costs, the intervention has a *net positive value* (NPV). Future or continued funding is given to the intervention with the highest NPV. This technique provides a way to estimate overall program and social benefits in terms of net costs. A good example of using CBA would be the cost of an influenza vaccine mass immunization program in a community. If most people in the community are vaccinated and the rate of influenza is low or decreased from past years or in relation to the national average, the benefits are many. Citizens can work, play, go to school, participate in other community activities, and, again, be productive. The community is healthy. These are but a few of the benefits of this program.

CBA requires that all costs and benefits be known and quantifiable in dollars; herein lies the major problem with its use. Although it is fairly easy to estimate the direct dollar costs of a health care program, it is often very difficult to quantify the nondollar benefits and indirect costs. For example, benefits and costs could come in the form of increased income and expenses, which are fairly easy to measure. More difficult to measure are benefits such as improved community welfare resulting from a particular program, and the costs to the community that would result if the program did not exist. The value of *potential lives* lost because of lack of access to health care services is one example. The potential for a great number of lives lost from H1N1 resulted in the development of programs and monies invested with pharmaceutical companies in an attempt to reduce the risk of lives lost should the United States experience an epidemic from this disease risk. Although benefits could only be assumed from the cost investment, it was determined that the investment was essential (CDC, 2009).

CEA expresses the net direct and indirect costs and cost savings in terms of a defined health outcome. The total net costs are calculated and divided by the number of health outcomes. Although the data required for CEA are the same as for CBA, CEA does not require that a dollar value be put on the outcome (e.g., on an outcome such as quality of life). CEA is best used when comparing two or more strategies or interventions that have the same health outcome in the population. Both CEA and CBA are useful to nurses as they conduct community needs analyses and develop, propose, implement, and evaluate programs to meet community health needs. In both cases, the cost of a particular program or intervention is examined relative to the money spent and outcomes achieved. Using the same example of the mass immunization program, a comparison of

the overall outcomes of the client visit to the clinic for vaccination in one community versus the mass immunization program at the community center in another community could be done. Outcomes could be the percentage of the population vaccinated by each method and the rate of influenza in each community. In this process, if the higher cost program results in lower rates of illness then that program would be considered the most effective.

An objective commonly used when CEA is performed in health care is improvement in **quality of adjusted life-years** (QALYs) for clients. QALYs are the sum of years of life multiplied by the quality of life in each of those years. The QALY assigns a value, ranging between 0 (death) and 1 (perfect health), to reflect quality of life during a given period of years (Lindemark et al, 2014). In conducting a CEA, the cost of a program or an intervention is compared with real or expected improvements in clients' quality of life. The **How To Box** lists the steps involved in conducting a CEA. The QALY is often used in malpractice suits to award money to clients who have been injured by health care.

HOW TO Do a Cost-Effectiveness Analysis (CEA)

In a cost-effectiveness analysis (CEA), the outcome of the service option is measured in a natural, nonmonetary unit such as years of life gained, therapeutic successes such as reducing the numbers of influenza cases in a community, or lives saved. Results are expressed as the net cost required to produce one or each of the outcomes. The cost to outcome is expressed as a ratio of cost per unit of outcome, where the numerator is a monetary value corresponding to the net expenditure of resources and the denominator is the net improvement in health expressed in nonmonetary terms. The steps for performing a simplified CEA are as follows:

1. Establish a program or service goals and objectives.
2. Consider all possible alternatives to achieve the goal or objectives, which could mean comparing two different programs that are attempting to achieve the same outcome.
3. Measure net effects to reflect a change in health status or health outcome.
4. Analyze costs for each alternative or program for reducing the cases of influenza in a community, such as a mass immunization clinic for a total community population or having individuals choose to go to their private provider for the vaccine.
5. Combine CEA results with other types of information such as past results of a similar program in a different year and the change in influenza cases in the community for the year of the comparison of programs, not included in the CEA, to make the most appropriate therapeutic or policy decision.

Depending on the program or intervention goals, the most effective means of providing a service is not necessarily the least costly, particularly in the short run. This is particularly true in public health, where the cost-effectiveness of a preventive service may not be known until sometime in the future. For example, the total cost savings of a community no-smoking program might be difficult to project 10 years into the future. After 10 years, the number of lung cancer cases or deaths that have occurred can be compared with those in the 10 years before the program, and the cost-effectiveness of the no-smoking

program can be shown. [Trust for America's Health \(2013a,b\)](#), along with a number of other agencies, is publishing reports that are beginning to show positive results and cost savings from prevention programs.

FACTORS AFFECTING RESOURCE ALLOCATION IN HEALTH CARE

The distribution of health care is affected largely by the way in which health care is financed in the United States. Third-party coverage, whether public or private, greatly affects the distribution of health care. Also, socioeconomic status affects health care consumption, because it has determined the ability to purchase insurance or to pay directly out-of-pocket. A description of the effects of barriers to health care access and the effects of **health care rationing** on the distribution of health care follow. Although the barriers are still issues, it remains to be determined how the health care reform of 2010 will change the barriers to access and distribution. One solution proposed is the Health Insurance Marketplace ([Patient Protection and Affordable Care Act, 2010](#)).

The Uninsured

In 1996, 68% of the total U.S. population had private health insurance. An additional 15% received insurance through public programs, and 17%, or 37 million, were uninsured. In 2008 the number of uninsured persons had increased to 47 million. By 2012 the number had grown to 48 million citizens (DeNavas-Walt et al, 2013). The typical uninsured person is a member of the workforce or a dependent of this worker. Uninsured workers are likely to be in low-paying jobs, part-time or temporary jobs, or jobs at small businesses ([Kaiser Family Foundation, 2012a](#)). These uninsured workers have not been able to afford to purchase health insurance, or their employers may not have offered health insurance as a benefit. Others who are typically uninsured are young adults (especially young men), minorities, persons less than 65 years of age in good or fair health, and the poor or near poor. These individuals may have been unable to afford insurance, may lack access to job-based coverage, or, because of their age or good health status, may not perceive the need for insurance. Because of the eligibility requirements for Medicaid, the near poor are actually more likely to be uninsured than the poor.

Socioeconomic status is inversely related to mortality and morbidity for almost every disease. Poor Americans with an income below the poverty level have a mortality rate nearly several times greater than that of middle-income Americans, even after accounting for age, sex, race, education, and risky health behaviors (e.g., smoking, drinking, overeating, and lack of exercise) ([Robert Wood Johnson Foundation, 2009 and 2013](#)). Historically, the link between poor health and socioeconomic status resulted from poor housing, malnutrition, inadequate sanitation, and hazardous occupations. Today, explanations include the cumulative effects of a number of characteristics that explain the concept of poverty. These characteristics include low educational levels, unemployment or low occupational status (blue-collar or unskilled laborer), low

wages, being a child or an older person over the age of 65 years, or being a member of a minority group (NCHS, 2012).

Access to Health Services

Access to health services is a public health issue (USDHHS, 2010). Medicaid is intended to improve access to health care for the poor. Although persons with Medicaid have improved access compared with the uninsured, Medicaid recipients have been only about half as likely to obtain needed health services (e.g., medical-surgical care, dental care, prescription drugs, and eyeglasses) as the privately insured. Specifically, the poorest Americans have Medicaid insurance, yet they also have the worst health (Kaiser Family Foundation, 2013).

The primary reasons for delay, difficulty, or failure to access care included inability to afford health care and a variety of insurance-related reasons, including the insurer not approving, covering, or paying for care; the client having preexisting conditions; and physicians refusing to accept the insurance plan. Other barriers include lack of transportation, physical barriers, communication problems, child care needs, lack of time or information, or refusal of services by providers. In addition, lack of after-hours care, long office waits, and long travel distance are cited as access barriers. Community characteristics also contribute to individuals' ability to access care. For example, the limited prevalence of managed care and the limited number of **safety net providers**, as well as the wealth and size of the community, affect accessibility.

Because reimbursement for services provided to Medicaid recipients has been low, physicians are discouraged from serving this population. Thus, people on Medicaid frequently have not had a primary care provider and may have relied on the emergency department for primary care services. Although physicians can respond to monetary incentives in client selection, emergency departments are required by law to evaluate every client regardless of ability to pay. Emergency department copayments are modest and are frequently waived if the client is unable to pay. Thus, low out-of-pocket costs have provided incentives for Medicaid clients and the uninsured to use emergency departments for primary care services.

With the ACA, some of the issues and barriers that have previously existed may disappear. This depends on whether Congress continues attempts to repeal all or part of PL 111-148 or change some of the mandates in the law. By 2014 Medicaid recipients may benefit from the law in its current structure as follows: (1) Medicaid will expand to include all non-Medicare-eligible persons under age 65 with incomes up to 133% of federal poverty level, (2) all Medicaid-eligible persons will be guaranteed a benchmark benefit package, and (3) states will be given the option to develop a basic health plan for uninsured individuals who do not qualify for the Medicaid program, at 133% to 200% of the poverty level. At present, all states provide Medicaid and CHIP (Children's Health Insurance Program) health care coverage for some individuals, families and children, pregnant women, the elderly with certain incomes, and people with disabilities. Some states cover all adults below certain income levels. Because coverage differs by state, one must seek information about the specific state of interest. Some states are

expanding Medicaid coverage whereas others continue with prior coverage plans (USDHHS, ACA, 2014a). However, all persons must have some form of insurance coverage or they will be charged a fee.

Poverty level income is adjusted annually for each state by the federal government to indicate how much money an individual or families may earn to qualify for subsidies such as food stamps, Medicaid, and CHIP. In 2014 the federal poverty level for an individual was \$11,670; for a family of four the poverty level was \$23,850. If, for example, an individual's income was 133% of the poverty level, then that individual earned no more than \$15,521.10 (USDHHS, 2014b).

Rationing Health Care

Rationing health care in any form implies reduced access to care and potential decreases in acceptable quality of services offered. For example, a health provider's refusal to accept Medicare or Medicaid clients is a form of rationing. As with access to care, rationing health care is a public health issue. Where care is not provided, the public health system and nurses must ensure that essential clinical services are available. Managed care was thought to offer the possibility of more appropriate health care access and better-organized care to meet basic health care needs of the total population. A shift in the general approach to health care from a reactionary, acute-care orientation toward a proactive, primary prevention orientation has been necessary for some time to achieve not only a more cost-effective but also a more equitable health care system in the United States.

The ACA, while providing coverage to more people, will not do away with rationing because the new law provides for a five-tiered plan (bronze, silver, gold, platinum, and catastrophic) and by creating state-based American Health Benefit Exchanges. Persons at differing levels of poverty will have reductions in out-of-pocket expenses based on income up to 400% of the poverty level and may receive tax credits and subsidies to assist with out-of-pocket expenses (USDHHS, ACA, 2014a).

Healthy People 2020

Healthy People 2020 goals are examples of strategies to provide better health care access for all people. The **Levels of Prevention Box** shows the levels of economic prevention strategies.

LEVELS OF PREVENTION

Economic Prevention Strategies

Primary Prevention

Work with legislators and insurance companies to support Affordable Care Act coverage for health promotion to reduce the risk of disease.

Secondary Prevention

Encourage clients who are pregnant to participate in prenatal care and WIC (Women, Infants, and Children) to increase the number of healthy babies and reduce the costs related to preterm baby care.

Tertiary Prevention

Participate in home visits to mothers who are at risk for neglecting babies to reduce the costs related to abuse.

PRIMARY PREVENTION

Society's investment in the health care system has been based on the premise that more health services will result in better health, but non-health care factors also have an effect. Of the major factors that affect health—personal biology and behavior (or lifestyle), environmental factors and policies (including physical, social, health, cultural, and economic environments), social networks, living and working conditions, and the health care system—medical services are said to have the least effect. Behavior and lifestyle have been shown to have the greatest effect, with the environment and biology accounting for the greatest effect on the development of all illnesses (NCHS, 2012).

Despite the significant impact of behavior and environment on health, estimates indicate that 97% of health care dollars are spent on secondary and tertiary care. Such a reactionary, secondary/tertiary care system results in high-cost, high-technology, and disease-specific care and is consistent with the U.S. system's traditional emphasis on "sickness care." A more proactive investment in disease prevention and health promotion targeted at improving health behaviors, lifestyle, and the environment has the potential to improve the health status of populations, thereby improving quality of life while reducing health care costs.

The USDHHS has argued that a higher value should be placed on primary prevention. The goal of this approach is to preserve and maximize *human capital* by providing health promotion and social practices that result in less disease. An emphasis on primary prevention may reduce dollars spent and increase quality of life. As data are made available about the effects of the emphasis of the ACA on primary prevention and primary care, then dollars spent and increased quality of life may be evaluated.

The return on investment in primary prevention through gains in human capital has not been acknowledged in the past, unfortunately. As a consequence, large investments in primary prevention and public health care have not been made. Reasons given for this lack of emphasis on prevention in clinical practice and lack of financial investment in prevention include the following:

- Provider uncertainty about which clients should receive services and at what intervals
- Lack of information about preventive services
- Negative attitudes about the importance of preventive care
- Lack of time for delivery of preventive services
- Delayed or absent feedback regarding success of preventive measures
- Less reimbursement for these services than curative services
- Lack of organization to deliver preventive services
- Lack of use of services by the poor and elderly
- More out-of-pocket expenses for the poor and those who lack health insurance

A focus on prevention could mean reducing the need for and use of medical, dental, hospital, and health provider services. Under **fee-for-service** payment arrangements, this would mean that the health care system, the largest employer in the United States, would be reduced in size and would become less

profitable. However, with the increasing costs of health care and consumer demand and the changes in financing mechanisms, there is a new trend toward financing more preventive care services as is reflected in the ACA coverage for these services.

Today, third-party payers will be covering preventive services, recognizing that the growth of the health care system can no longer be supported. Under capitated health plans, health care providers stand to make money by keeping clients healthy and reducing health care use. Through combining client interests with financial interests of the health care industry, primary prevention and public health can be raised to the status and priority of acute care and chronic care. Despite difficulties, methods for determining prevention effectiveness, such as CEAs and CBAs, are becoming standard and used more widely. Two agendas for preventive services have been published that promote the preventive agenda:

- The U.S. Preventive Services Task Force, *Guide to Clinical Preventive Services* (Agency for Healthcare Research and Quality [AHRQ], 2014) for clinicians in primary care that outlines the regular screening and risk factors to look for at various ages
- The *Community Preventive Services Task Force* (2014), which emphasizes population-level interventions to promote primary prevention

Regardless of the method, prevention-effectiveness analyses (PEAs) are outcome oriented. This area of research seeks to link interventions with health outcomes and economic outcomes, and to reveal the tradeoffs between the two. In theory, support for increasing national investment in primary prevention is sound and long-standing. Since the public health movement of the mid-nineteenth century, public health officials, epidemiologists, and nurses have been working to advance the agenda of primary prevention to the forefront of the health care industry. Today, these efforts continue across a number of disciplines and in both the public and the private sectors, and through the efforts for health care reform (*Healthy People 2020 Box*).

HEALTHY PEOPLE 2020

Objectives Related to Access to Care

- AHS-1: Increase the proportion of persons with health insurance.
- AHS-2: (Developmental) Increase the proportion of insured persons with coverage for clinical preventive services.
- AHS-6: Reduce the proportion of individuals that experience difficulties or delays in obtaining necessary medical care, dental care, or prescription medicines.

AHS, Access to Health Services.

THE CONTEXT OF THE U.S. HEALTH CARE SYSTEM

The U.S. health care system is a diverse collection of industries that are involved directly or indirectly in providing health care services. The major players in the industry are the health professionals who provide health care services, pharmacy and

equipment suppliers, insurers (public/government and private), managed care plans (health maintenance organizations, preferred provider organizations), and other groups, such as educational institutions, consulting and research firms, professional associations, and trade unions (see [Chapter 3](#)). Today, the health care industry is large, and its characteristics and operations differ between rural and urban geographic areas.

In the twenty-first century, health policy and national politics reflect the importance of health care delivery in the general economy. Conflicts arise between competing special-interest groups that have different goals and objectives when it comes to the producing and consuming of health services. To some degree this is caused by federal and state policy changes about how health services are financed (public and private).

[Figure 5-2](#) illustrates the four basic components that make up the framework of health services delivery: service needs and intensity, facilities, technology, and labor. **Intensity** is the extent of use of technologies, supplies, and health care services by or for the client. Intensity includes and is a partial measure of the use of technology ([NCHS, 2012](#)). **Medical technology** refers to the set of techniques, drugs, equipment, and procedures used by health care professionals in delivering medical care to individuals. It also includes information technology and the system within which such care is delivered ([NCHS, 2012](#)).

Health care systems have developed in four phases from the 1800s through 2000. These developmental stages correspond to different economic conditions. Developmentally, the four components of the health services delivery framework have changed over time, reflecting macrolevel, or societal, changes in morbidity and mortality, national health policy, and economics ([Figure 5-3](#)).

First Phase

The first developmental stage (1800 to 1900) was characterized by epidemics of infectious diseases, such as cholera, typhoid,

smallpox, influenza, malaria, and yellow fever. Health concerns of the time related to social and public health issues, including contaminated food and water supplies, inadequate sewage disposal, and poor housing conditions ([Shi and Singh, 2011](#)). Family and friends provided most health care in the home. Hospitals were few in number and suffered from overcrowding, disease, and unsanitary conditions. Sick persons who were cared for in hospitals often died as a result of these conditions. Most people avoided being cared for in a hospital unless there was no alternative. In this first developmental phase, health care was

FIG 5-2 Components of health services development.

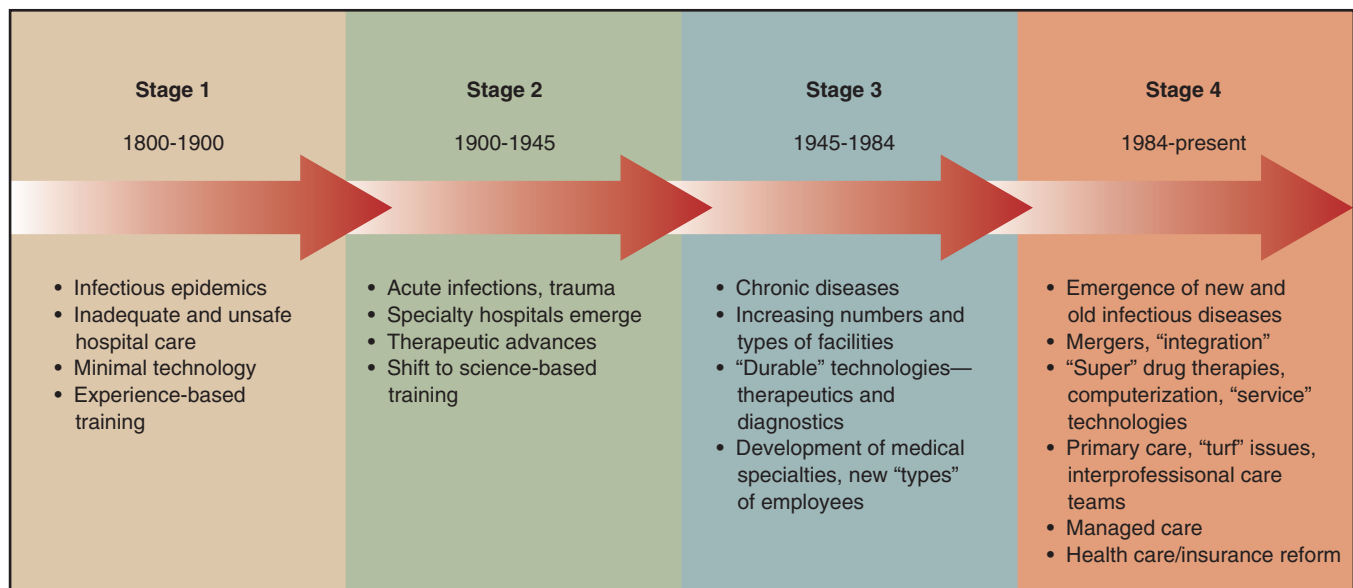

FIG 5-3 Developmental framework for health service needs and intensity, facilities, technology, and labor.

paid for by individuals who could afford it, through bartering with physicians or through charity from individuals or organizations. The first county health departments were established in 1908.

Technology to aid in disease control was very basic and practical but in keeping with the knowledge of the time. The physician's "black bag" contained the few medicines and tools available for treatment. The economics of health care was influenced by the types of health care providers and the number of practitioners, and the labor force then was composed mostly of physicians and nurses who attained their skills through apprenticeships, or on-the-job training. Nurses in the United States were predominantly female, and education was linked to religious orders that expected service, dedication, and charity (Kovner et al, 2011). The focus of nursing was primarily to support physicians and assist clients with activities of daily living.

Second Phase

The second developmental stage (1900 to 1945) of U.S. health care delivery was focused on the control of acute infectious diseases. Environmental conditions influencing health began to improve, with major advances in water purity, sanitary sewage disposal, milk and water quality, and urban housing quality. The health problems of this era were no longer mass epidemics but individual acute infections or traumatic episodes (Shi and Singh, 2011).

Hospitals and health departments experienced rapid growth during the late 1800s and early 1900s as technological advances in science were made (Kovner et al, 2011). In addition to private and charitable financing of health care, city, county, and state governments were beginning to contribute by providing services for poor persons, state mental institutions, and other specialty hospitals, such as tuberculosis hospitals. Public health departments were emphasizing case finding and quarantine. Although health care was paid for primarily by individuals, the Social Security Act of 1935 signaled the federal government's increasing interest in addressing social welfare problems.

Clinical medicine entered its golden age during this period. Major technological advances in surgery and childbirth and the identification of disease processes, such as the cause of pernicious anemia, increased the ability to diagnose and treat diseases. The first serological tests used as a tool for diagnosis and control of infectious diseases were developed in 1910 to detect syphilis and gonorrhea (Shi and Singh, 2011). The first virus isolation techniques were also developed to filter yellow fever virus, for example. The discovery and development of pharmacological agents, such as insulin in 1922 for control of diabetes, sulfa drugs in 1932 for treatment of infectious diseases, and antibiotics such as penicillin in the 1940s, eradicated certain infectious diseases, increased treatment options, and decreased morbidity and mortality (Shi and Singh, 2011).

Advances in technology and knowledge shifted physician education away from apprenticeships to scientifically based college education, which occurred as a result of the Flexner Report in 1910. It was the beginning of medical education as it is today. Nurses were trained primarily in hospital schools of

nursing, with an emphasis on following and executing physicians' orders. Nurses in training were unmarried and under the age of 30. They provided the bulk of care in hospitals (Kovner et al, 2011). Public health nurses, who tracked infectious diseases and implemented quarantine procedures, worked more collegially with physicians (Kovner et al, 2011). In this period the university-based nursing programs were established to accommodate the expanding practice base of nursing. Client education became a nursing function early in the development of the health care delivery system.

Third Phase

The third developmental stage (1945 to 1984) included a shift away from acute infectious health problems of previous stages toward chronic health problems such as heart disease, cancer, and stroke. These illnesses resulted from increasing wealth and lifestyle changes in the United States. To meet society's needs, the number and types of facilities expanded to include, for example, hospital clinics and long-term care facilities. The Joint Commission on Accreditation of Hospitals, established in 1951 and later renamed The Joint Commission on Accreditation of Healthcare Organizations (and now called The Joint Commission [TJC]), focused on the safety and protection of the public and the delivery of quality care.

Changes in the overall health of American society also shifted the focus of technology, research, and development. Major technological advances included developments in the realms of chemotherapeutic agents; immunizations; anesthesia; electrolyte and cardiopulmonary physiology; diagnostic laboratories with complex modalities such as computerized tomography; organ and tissue transplants; radiation therapy; laser surgery; and specialty units for critical care, coronary care, and intensive care. The first "test tube baby" was born via in vitro fertilization, and other fertility advances soon emerged. Negative staining techniques for screening viruses via electronic microscope became available in the 1960s (Shi and Singh, 2011).

Health care providers constituted more than 5% of the total U.S. workforce during this period. The three largest health care employers were hospitals, convalescent institutions, and physicians' offices. Between 1970 and 1984 alone, the number of persons employed in the health care industry grew by 90%. The number of personnel employed in the community also increased. The expansion of care delivery into other sites, such as community-based clinics, increased not only the number but also the types of health care employees.

Technological advances brought about increased special training for physicians and nurses, and care was organized around these specialties. The ongoing shortage of nurses throughout the century was being seen in the 1970s and early 1980s. Nursing education expanded from hospital-based diploma and university-based baccalaureate education to include associate degree programs at the entry level. As the diploma schools of nursing began closing in the early- to mid-1980s, the number of baccalaureate and associate degree programs began to increase. Graduate nursing education expanded to include the nurse practitioner (NP) and clinical nurse specialist (CNS) to meet increasing demands for the education of

nurses in a specialty such as public health. The first doctoral programs in nursing were instituted to build the scientific base for nursing and to increase the number of nurse faculty members.

The role of the commercial health insurance industry increased, and a strong link between employment and the providing of health care benefits emerged. Furthermore, the federal government's role expanded through landmark policy-making that would affect health care delivery well into the twenty-first century. Specifically, the passage of Titles XVIII and XIX of the Social Security Act in 1965 created the Medicare and Medicaid programs, respectively. The health care system appeared to have access to unlimited resources for growing and expanding.

Throughout the twentieth century, many public health advances were achieved. The life expectancy of U.S. citizens increased and has been related to public health activities. The most important achievements were in vaccinations, improved motor vehicle safety, safer workplaces, safer and healthier foods, healthier mothers and babies, family planning, fluoride in drinking water, and recognition of tobacco as a health hazard (Shi and Singh, 2011).

Fourth Phase

The fourth developmental stage (1984 to 2015) has been a period of limited resources, with an emphasis on containing costs, restricting growth in the health care industry, and reorganizing care delivery. For example, amendments were made to the Social Security Act in 1983 that created diagnostic-related groups and a prospective system of paying for health care provided to Medicare recipients. The 1997 Balanced Budget Act legislated additional federal changes in Medicare and Medicaid. Private-sector employer concerns about the rising costs of health care for employees and fear of profit losses spurred a major change in the delivery and financing of health care. Managed care systems were developed.

This period included drastic change in the settings and organization of health care delivery. Transforming health care organizations became commonplace, and buzz words of the period were reorganization, reengineering, restructuring, and downsizing. Organization mergers occurred at an increased rate to consolidate care, to save money, and to coordinate care across the continuum (i.e., from “cradle to grave”). Merger discussions focused on *horizontal integration*, which indicated the union of similar agencies (e.g., a merger of hospitals), and *vertical integration* between different types of organizations (e.g., an acute care hospital, long-term care institution, and a home health facility).

Initially these pressures brought about hospital closings and a shifting of care to other settings, such as ambulatory and community-based clinics and specialty diagnostic centers that offer technologies such as magnetic resonance imaging (MRI) and sonography. Rehabilitative, restorative, and palliative care, once delivered in the hospitals, was shifted to other settings, such as subacute care hospitals, specialty rehabilitation hospitals, long-term care institutions, and even individual homes. Although the basis of care delivery was no longer the traditional

acute care hospital, the nature of the care delivered in hospitals changed remarkably, as evidenced by the following:

- Patients admitted to hospitals were more acutely ill.
- Length of stay for patients admitted to hospitals became shorter.
- Care delivery became more intense as a result of the first two items.

The widespread use of computers and the Internet enabled society to become increasingly sophisticated about health. The public's increasing knowledge about health care and awareness of health care advances influenced the demand for health care, such as diagnostic and therapeutic services for treatment. Furthermore, pharmaceutical companies and other technological suppliers actively marketed their products through television, printed advertisements, the Internet, and other sources, so clients rapidly became aware of the new technologies.

Health professionals were increasingly dependent on technology to care for clients. Distance, as a barrier to the diagnosis and treatment of disease, was overcome through the use of telehealth. The insurance industry became the principal buyer of technology for the client. They often made decisions about when and if a certain technology would be used for a client problem. Nurses became dependent on technologies to monitor client progress, make decisions about care, and deliver care in innovative ways.

The shift away from traditional hospital-based care to the community, together with the need to consider new models of care, brought about an increased emphasis on providing primary care, on developing care delivery teams, and on collaborating in practice and education. The substitution of one type of health personnel for another occurred to control care delivery costs. As examples, NPs were replacing physicians as primary care providers, and unlicensed personnel were replacing staff nurses in hospitals and long-term care facilities. These replacements caused much debate, with territorial, or “turf,” battles, for example, between physicians and nurses.

The increase in specialization by health professionals led to changes in certification, qualifications, education, and standards of care in health professions. These factors, in turn, caused an increase in the number and kinds of providers to meet the demands of the health care system. The Bureau of Labor Statistics predicted that health care employment would be among the top eight professional and related industries with significant employment growth through 2020 (Lockard and Wolf, 2012).

In the last part of the twentieth century, molecular tools were developed that provided a means of detecting and characterizing infectious disease pathogens and a new capacity to track the transmission of new threats, such as bioterrorism, and determine new ways to treat them.

Challenges for the Twenty-First Century

In the twenty-first century the emergence of new and the reemergence of old communicable and infectious diseases are occurring as well as larger foodborne disease outbreaks and acts of terrorism. Seven out of ten of all deaths in the United States are related to chronic disease (USDHHS, 2011). One in every two Americans has one or more chronic diseases. There

is some concern that certain chronic diseases may be caused or intensified by infectious disease processes. Often there are complications that occur as a result of infectious disease, such as HIV/AIDS and tuberculosis, which can result in chronic lung disease and certain types of cancer, because of the compromised immune system. Health behaviors and economics related to poverty are also continuing to build the path to acute and chronic health problems (e.g., the global obesity epidemic) (World Health Organization [WHO], 2010). While some people choose to ignore behavioral factors related to obesity, such as physical activity and eating, those with insufficient income choose foods high in fat and sugar because those are the cheaper foods to obtain. The chronic disease burden is concentrated among the poor. Poor people are more vulnerable for several reasons, including increased exposure to risks and decreased access to health services. Chronic diseases can cause poverty in individuals and families and draw them into a downward spiral of worsening disease and poverty.

Investment in chronic disease prevention programs is going to be essential for many low- and middle-income countries struggling to reduce poverty. For the United States, this issue is addressed in the ACA (2010). Health promotion and protection, disease surveillance, emergency preparedness, new laboratory and epidemiologic methods, continued antimicrobial and vaccine development, and environmental health research are continuing challenges for this century. The role of technology has also intensified during this century.

Technology is now defined as the application of science to develop solutions to health problems or issues such as the prevention or delay of onset of diseases or the promotion and monitoring of good health. Examples of technology include medical and surgical procedures (angioplasty, joint replacements, organ transplants), diagnostic tests (laboratory tests, biopsies, imaging), drugs (biological agents, pharmaceuticals, vaccines), medical devices (implantable defibrillators, stents), prosthetics (artificial body parts), and new support systems (electronic health records, e-prescribing, and telemedicine).

The labor force is changing to include radiology oncologists, geneticists, and surgical subspecialists, as well as allied and support professions such as medical sonographers, radiation technologists, and laboratory technicians. These have all been created to support the use of specific types of technology (HealthIT.gov).

The infrastructure necessary to support more complex technologies is also considered to be a part of health care technology. Electronic health records and electronic prescribing are methods for coordinating the increasingly complex array of services provided, as well as allowing for electronic checks of quality to reduce medical errors (e.g., for drug interactions). Because technologies have become a part of standard medical practice, there are concerns about whether they are consistently being used properly and about the quality of the information provided by tests, imaging, and other technological outputs (NCHS, 2010).

In addition to the labor force changes just described, physicians are increasingly moving away from solo practice to group practices, selling primary care practices to hospitals, or working as hospital or corporation employees. The emerging role of

hospital intensivists is growing, with hospitals employing physicians to be in-house and available to patients and to their community physicians to cover nonurgent, urgent, and emergent care while the patient is hospitalized. More nurse practitioners and physician assistants can be found working side by side with the physician in the community and in the hospital as a member of the office, clinic team, or hospital staff. (See QSEN box below about teamwork and collaboration)

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Teamwork and Collaboration

Refers to the ability to function effectively with nursing and interprofessional teams and to foster communication, mutual respect, and shared decision making to provide quality client care.

- **Knowledge:** Identify system barriers and facilitators of effective team functioning
- **Skill:** Participate in designing systems that support effective teamwork
- **Attitudes:** Values the influences of systems solutions in achieving effective functioning

Teamwork and Collaboration Question

As a strategy set forth by the Affordable Care Act, a fund was established to support prevention and wellness activities within states to reduce risks. Among the options for spending the funds was the establishment of programs and processes to reduce the rate of chronic disease.

Monies have been distributed to states to promote prevention and wellness. Find out through your state government how the money is to be used.

The Quad Council PHN competency: community dimensions of practice, indicates that beginning PHN's will collaborate with community partners to promote the health of their clients.

Have PHNs at the state level or locally in your state been involved in collaborations to determine how chronic disease rates might be reduced in your area. If yes, how? If not, can you suggest how they might be? Also the PHN competency that addresses financial management and planning, suggests that PHNs may provide input into the fiscal planning and the narrative component of proposals submitted for external funding.

Determine what the process will be for obtaining local funds for chronic disease and whether PHNs have had or will have input onto the proposals.

Discussions are increasing regarding the integration of public health and primary care and developing the primary health care system (see Chapter 3).

Public health nurses are more involved with population-centered care, assessment of community needs, and the development or implementation of programs that meet the needs of certain populations. There is a move to provide more care to clients in the home, such as the programs to provide care to new mothers and babies who are defined as at-risk. Public health nurses play key roles in developing and implementing plans for bioterrorism and natural disasters in the community (see Chapter 9).

Nursing education is seeing a dramatic change in this century. There is a recommendation to move all advanced practice nursing to the level of the new doctoral program, begun in 2000, titled the Doctorate of Nursing Practice. This has the potential for closing specialist master's programs in nursing.

This means the new BSN graduate, for example, can go into a doctoral program at graduation and become an advanced public health nurse or a nurse practitioner working in the community. The health care industry is one of the largest employers in the United States, and despite the economic downturn in 2008, has continued to grow. In addition, the largest number of employees in the industry are RNs (American Association of Colleges of Nursing, 2010; Lockard and Wolf, 2012).

Along with other changes in health care delivery and health insurance plans, the ACA (2010) has proposed an emphasis on prevention and wellness by establishing the National Prevention, Health Promotion, and Public Health Council to coordinate health promotion and public health activities as well as the creation of a prevention and public health fund to expand and sustain these activities. These activities will assist in the development of a national strategy to improve health, reduce chronic disease rates, and address health disparities.

TRENDS IN HEALTH CARE SPENDING

Much has been written in the popular and scientific literature about the costs of U.S. health care and how society makes decisions about using available and scarce resources. Given that economics in general and health care economics in particular are concerned with resource use and decision making, any discussion of the economics of health care must consider past and current health care spending. The trends shown here reflect public and private decisions about health care and health care delivery in the past. Past spending reflects past decision making; likewise, past decisions reflect the values and beliefs held by society and policymakers that undergird policymaking at any given point in time.

According to the Centers for Medicare and Medicaid Services (CMS) (formerly the Health Care Financing Administration), national health expenditures reached \$2.5 trillion in 2011. This is compared with the \$600 billion in health care dollars that were spent in 1990 (Centers for Medicare and Medicaid Services [CMS], 2012a). The CMS predicts total U.S. health spending in 2019 will be \$4.5 trillion. Health spending has outpaced increases in the gross domestic product, accounting for 17.3% of the GDP by 2009 rising to 17.8% in 2012 and projected to increase to 19.3% of the GDP in 2019. The percent GDP can be translated into dollars per 100 spent out of pocket. In 2009 \$17.30 of every \$100 was spent for health care. It also means that in 2009 approximately \$8100 was spent on health care for every person in the U.S. population. In 2019 it is projected that out-of-pocket costs will be approximately \$20 for every \$100 spent. The effect of this economic growth represents a large increase in contrast to the approximately 13% GDP spent between 1992 and 2001. The GDP was at 17.8% in 2012 (CMS, 2012a). It is projected that with the implementation of the ACA costs will actually decline.

Figure 5-4 shows a breakdown of the distribution in health care expenses for 2011, and Table 5-1 shows the growth in U.S. health care expenditures between 1960 and 2019 (NCHS, 2012). During fiscal year 2012-2013, the amount spent for public health activities ranged from \$7.63 per person in

FIG 5-4 Distribution of U.S. health care expenditures, 2011. (From National Center for Health Statistics: *Health, United States, 2012, with Special Feature on Emergency Care*. Hyattsville, MD, 2013, U.S. Government Printing Office. Updated tables retrieved December 2014 from <http://www.cdc.gov/nchs/hus/contents2012.htm#113>)

TABLE 5-1 Health Care Expenditures: 1960-2019*

Calendar Year	Total Health Expenditures (in billions of dollars)	Total Health Expenditures per Capita per Person (in billions of dollars)	Percentage of Gross Domestic Product
1960	26.7	143	5.1
1970	73.1	348	7.0
1980	245.8	1,067	8.8
1990	696.0	2,738	12.0
2000	1,309.9	4,560	13.3
2009	2,472.2	8,047	17.3
2010	2,563.6	8,402.3	17.9
2011*	2,695.0	8,660.5	17.9
2021*	4,482.7	14,102.6	19.6

*Projected expenditures.

Arizona to \$144.99 per person in Hawaii (Trust from America's Health, 2014).

The largest portions of health care expenses were for hospital care and physician services, respectively, in 2011 (NCHS, 2012). Only a small fraction of total health care dollars was spent on home health, public health, and research and construction in 2011. The trends over time indicate that this has been an ongoing pattern of spending.

FACTORS INFLUENCING HEALTH CARE COSTS

Health economists, providers, payers, and politicians have explored a variety of explanations for the rapid rate of increase in health expenses as compared with population growth. That individuals have, over time, consumed more health care is not an adequate explanation. The following factors are frequently cited as having caused the increases in total and per capita health care spending since 1960: inflation, changes in population demographics, and technology and intensity of services (NCHS, 2012).

Demographics Affecting Health Care

A major demographic change underway in the United States is the aging of the population. Population changes are also affected by illnesses such as acquired immunodeficiency syndrome, and by chemical dependency epidemics. These changes have implications for providers' health services, and they affect the overall costs of health care. Because the majority of older adults and other special populations receive services through publicly funded programs, the growing health needs among these populations have great impact on costs, payments, and providers associated with Medicaid and Medicare programs. As the population ages and the baby boom generation ages and retires, federal expenses for Social Security have increased (Congressional Budget Office [CBO], 2010). At 78 million strong, the oldest of the baby boomers—born between 1946 and 1964—are already making unsustainable demands on federal entitlement programs such as Medicare and Medicaid (see Chapter 3 for further discussion).

In its *Long-Term Outlook for Medicare, Medicaid and Total Health Care Spending*, the Congressional Budget Office (CBO) reports that spending for those programs was projected to account for 3% each of GDP in 2011 (CMS, 2012a).

By 2035, in the absence of change, spending for Medicare alone (which is more likely to be impacted by aging baby boomers) will have more than doubled to 8%, and by 2080 it will have grown to 15% unless changes as recommended by the ACA (2010) are effective.

The aging population is expected to affect health services more than any other demographic factor:

- In 1950 more than 50% of the U.S. population was under 30 years of age.
- In 1994, 50% of the population was 34 years of age or older.
- In 1990 individuals 65 and older comprised 12% of the population.
- In 2013 they comprised 14% of the population.
- One in 7 citizens in 2013 was 65 and older compared to 1 in 5 in 1990.

By 2050 they are estimated to comprise up to 20% of the population. In addition, the number of individuals 85 and older is expected to double between 1990 and 2050 because the population is living longer, healthier lives (U.S. Census Bureau, 2014).

Although many older adults are independent and active, they are likely to experience multiple chronic and degenerative conditions that may become disabling. They are admitted to hospitals more often than the general population, and their average length of stay is more than 3 days longer than the overall average. They visit physicians more often and make up a larger percentage of nursing home residents than the general population (NCHS, 2012).

Life expectancy, at an average of 78.7 years, and health status have been increasing in the United States. However, older adults continue to consume a large portion of financial resources. Health care providers are concerned about the growth in the older adult population because public funding sources, such as Medicare, have not been increasing their reimbursement rates sufficiently to cover inflation, and thus providers have been collecting a smaller amount for visits by older adult clients each year.

The aging of the population also spurs concerns about funding their health care because of changes in the proportion of employed individuals to fully retired individuals. Persons in the workforce pay the majority of income taxes and all Social Security payroll taxes. The funding base for Medicare decreases as the population ages, as retirement rates increase, and as the numbers in the workforce decrease. As a result, some policymakers believe that Medicare and system reforms could ensure adequate financing and delivery of health care services to an aging population (PL 111-148, 2010).

Health policy reform options being considered include increased age limits to become eligible for Medicare, **means testing** (i.e., determining a lack of financial resources) for Medicare eligibility, increased coverage for long-term care insurance, increased incentives for prevention, and less expensive and more efficient delivery arrangements and care settings (e.g., managed care arrangements). One example of a policy change to reduce the Medicare program burden was the prescription plan (Medicare D) that was passed by Congress in 2005 and became effective in January 2006. This plan, although complicated, required most Medicare recipients to provide a copayment for prescription medications. Although controversial, the plan is thought to provide a positive impact for the elderly who could not afford to pay for their prescriptions, while reducing the cost burden for those who had to pay full price for prescriptions.

The ACA promises to close the “donut hole” by 2020 while providing a 50% discount when the Medicare recipients purchase medications covered on the brand name list, until 2020 (ACA and Medicare, 2014). The **donut hole** is the point at which a prescription D recipient has met the limit that the health insurance policy will pay for prescriptions in a given year and the requirement that the recipient will then be responsible for paying full price for all medicines until the end of the year covered by the health insurance.

Technology and Intensity

The introduction of new technology enhances the delivery of care, but it also has the potential to increase the costs of care. As new and more complex technology is introduced into the system, the cost is typically high. However, clients often demand access to the technology, and providers want to use it. In an effort to keep health care costs down, however, payers have attempted to restrict the use of certain technologies. For example, the drug Viagra, developed for the treatment of impotence by Pfizer Pharmaceuticals, is a controversial technological advance that, as soon as it was available to the public, was in high demand and prescribed by providers. Initially, use was restricted by payers because of cost. The adoption of new

technology demands investment in personnel, equipment, and facilities. Furthermore, new technology adds to administrative costs, especially if the federal government provides financial coverage for the service or is involved in regulating the technology. Table 5-2 outlines federal policy that has impacted technology and the cost of health care over time.

Chronic Illness

Chronic illness is a factor that is showing its impact on health care spending. Chronic disease accounted for 70% of deaths in the United States (USDHHS, 2011) and accounted for 75% of all health care spending in 2013 (USDHHS 2014c). Using Medical Expenditure Panel Survey (MEPS) data, chronic medical conditions are identified by those costing the most, the

TABLE 5-2 Federal Regulations Contributing to Health Care Technology/Cost Controls

Year	Federal Regulation
1906	Prescription drug regulation: Food, Drug, and Cosmetic Act, now the U.S. Food and Drug Administration (FDA)
1935	Social Security Act (PL 74-271): Provides grants-in-aid to states for maternal and child care, aid to crippled children, and aid to the blind and aged
1938	Food, Drug, and Cosmetic Act (PL 75-540): Establishes federal FDA protection for drug safety and protection for misbranded goods, drugs, cosmetics
1946	Hill-Burton Act (PL 79-725): Enacts Hospital Survey and Construction Act providing national direct support for community hospitals; establishes rudimentary standards for construction and planning; establishes community service obligation
1954	Hill-Burton Act amended (PL 83-482): Expands scope of program for nursing homes, rehabilitation facilities, chronic disease hospitals, and diagnostic or treatment centers
1963	Community Mental Health and Mental Retardation Center Construction Act (PL 88-164)
1965	Medicare Title 18; Medicaid Title 19 (PL 89-97): Amendments to Social Security Act provide Medicare and Medicaid to support health care services for certain groups
1966	Comprehensive Health Planning Act (PL 89-749): For health services, personnel, and facilities in federal/state/local partnerships
1971	President Nixon introduces concept of HMOs as the cornerstone of his administration's national health insurance proposal
1972	Social Security Act Amendments (PL 92-603): Extend coverage to include new treatment technologies for end-stage renal disease; provide for professional standards review organizations to review appropriateness of hospital care for Medicare/Medicaid recipients
1973	HMO Act (PL 93-222): Provides assistance and expansion for HMOs
1975	National Health Planning and Resources Development Act (PL 93-641): Designates local health system areas and establishes a national certificate-of-need (CON) program to limit major health care expansion at local and state levels
1978	Medicare End-Stage Renal Disease Amendment PL 95-292: Provides payment for home dialysis and kidney transplantation Health Services Research, Health Statistics, and Health Care Technology Act PL 95-623 establishes national council on health care technology to develop standards for use
1981	Omnibus Budget Reconciliation Act of 1981 (PL 97-351): Consolidates 26 health programs into 4 block grants (preventives, health services, primary care, and maternal and child health)
1982	Tax Equity and Fiscal Responsibilities Act (PL 97-248): Seeks to control costs by limiting hospital costs per discharge adjusted to hospital case mix
1983	Amended Social Security Act (PL 98-21): Establishes new Medicare hospital prospective payment system based on diagnosis-related groups (DRGs)
1986	1974 Health Planning and Resource Development Act (PL 93-641): was amended and moves certificate of need program to states
1989	Omnibus Reconciliation Act of 1989 (PL 101-239): Creates physician resource-based fee schedule to be implemented by 1992, with emphasis on high-tech specialties of surgery; creates Agency for Healthcare Policy and Research to research effectiveness of medical and nursing services, interventions, and technologies
1990	Ryan White CARE Act (PL 101-381): Authorizes formula-based and competitive supplemental grants to cities and states for HIV-related outpatient medical services Safe Medical Devices Act (PL 101-629): Gives FDA authority to regulate medical devices and diagnostic products
1993	Omnibus Budget Reconciliation Act (OBRA 93) (PL 103-66): Cuts Medicare funding and ends ROE payments to skilled nursing facilities; provides support for immunizations for Medicaid children
1996	Health Insurance Portability and Accountability Act: Protects health insurance coverage for laid-off or displaced workers
1997	Balanced Budget Act of 1997: Creates a new program for states to offer health insurance to children in low-income and uninsured families
1998	Balanced Budget Act of 1997 (PL 105-33): Authorizes third-party reimbursement for Medicare Part B services for NPs and CNSs
2003	Medicaid Nursing Incentive Act (HR 2295): Expands direct reimbursement to all NPs and CNSs and recognizes specialized services offered by advanced practice registered nurses such as primary care case management, pain management, and mental health services
2006	Medicare Part D: Provides a plan for prescription payments
2010	Patient Protection and Affordable Care Act passed and signed into law on March 23, 2010
2012	The Affordable Care Act provides for \$18 million to expand health information technology to 37 health center networks

number of bed days, work-loss days, and activity impairments. The most chronic medical condition was stroke.

FINANCING OF HEALTH CARE

Against the backdrop of today's chronic conditions, it must be appreciated that health care financing has evolved through the twentieth and into the twenty-first century from a system supported primarily by consumers to a system financed by third-party payers (public and private). From 1980 to 2011, the percentage of third-party public insurance payments increased slightly while the percentage of out-of-pocket payments had declined. Combined state and federal governments paid the most in 2011 (CDC, 2014c).

Public Support

The U.S. federal government became involved in health care financing for population groups early in its history. In 1798 the federal government created the Marine Hospital Service to provide medical care for sick and disabled sailors, and to protect the nation's borders against the importing of disease through seaports. The Marine Hospital Service is considered the first national health insurance plan in the United States (see Health Care Reform, Chapter 3). The National Health Board was established in 1879 and was later renamed the U.S. Public Health Service (PHS). Within the PHS, the federal government developed a public health liaison with state and local health departments for the purpose of controlling communicable diseases and improving sanitation. Additional health programs were also developed to meet obligations to federal workers and their families within the PHS, the Department of Defense, and the Veterans Administration (VA) (see Chapter 8).

Medicare and **Medicaid**, two federal programs administered by the CMS, account for the majority of public health care

spending. Table 5-3 compares these programs. The CMS is the federal regulatory agency within the U.S. Department of Health and Human Services (USDHHS) that is responsible for overseeing and monitoring Medicare and Medicaid spending. This agency routinely collects and reports actual health care use and spending and projects future spending trends. Through these programs, the federal government purchases health care services for population groups through independent health care systems, such as managed care organizations, private practice physicians, and hospitals.

Medicare

The Medicare program, established in Title XVIII of the Social Security Act of 1965, provides hospital insurance and medical insurance to persons aged 65 and older, to permanently disabled persons, and to persons with end-stage renal disease—altogether approximately 46 million people in 2013 (CMS, 2014). Medicare has two parts: Part A (hospital insurance) covers hospital care, home care, hospice care, and skilled nursing care (limited); Part B (noninstitutional care insurance) covers “medically necessary” services such as health care provider services, outpatient care, home health, and other medical services such as diagnostic services, and physiotherapy. In 1999 a program called Medicare Advantage was added to the program (Part C). This is an option that can be chosen for additional coverage. This option includes both Part A and B services. The Part C plans are coordinated care plans that include health maintenance organizations (HMOs), private fee-for-service plans, and medical savings accounts (MSAs). Part C provides for all health care coverage costs after a high deductible (CMS, 2014).

Medicare Part A is primarily financed by a federal payroll tax that is paid by employers and employees. The proceeds from this tax go to the Hospital Insurance Trust Fund, which is managed by the CMS. If a person did not have federal payroll

TABLE 5-3 Comparison of Medicare and Medicaid Program Features

Feature	Medicare	Medicaid
Where to obtain information	Local Social Security Administration office	State welfare office
Recipients	Client is 65 years or older, is disabled, or has permanent kidney failure	Specified low-income and needy, children, aged, blind, and/or disabled; those eligible to receive federally assisted income
Type of program	Insurance	Insurance
Government affiliation	Federal	Joint federal/state
Availability	All states	All states
Financing of hospital insurance	Medicare Trust Fund, mandatory payroll deduction, recipient deductibles, trust fund interest	Federal and state governments
Financing of medical insurance	Recipient premium payments; general revenue, U.S. Treasury	Federal and state governments
Types of coverage	Part A. Inpatient and outpatient hospital services, skilled nursing facilities (SNFs), limited nursing home care, home health services and hospice Part B. Prevention and screening services Part D. Prescription drugs from a formulary	Inpatient and outpatient hospital services; nursing facility services: home health, physician services, rural health clinic services, community health center services; laboratory and x-rays; family planning; advanced practice nurse services, free-standing birth center services; medical care transportation; tobacco cessation counseling for pregnant women, vaccines for children; many optional services are available by state's choice

From U.S. Department of Health and Human Services, Centers for Medicare and Medicaid Services: *Medicare and You, and Medicaid Benefits*, Baltimore, MD, 2015, USDHHS.

deductions, Part A can be obtained by paying a monthly premium. Part A coverage is available to all persons who are eligible to receive Medicare, with older adults comprising the majority of these individuals. There is concern about the future of the Medicare Trust Fund, because projected expenses may be more than the trust fund resources. Payments to hospitals for covered services have been and continue to be higher than fund growth. Thus Medicare reimbursement policy has been changing in an attempt to control increasing hospital costs. Part A requires a deductible from recipients for the first 60 days of services with a reduced deductible for 61 to 90 days of service. The deductible has increased as daily hospital costs have increased. For skilled nursing facility (SNF) care, persons pay nothing for the first 20 days and a cost per day for days 21 through 100. After 100 days, persons must pay the total cost for care (CMS, 2013a). The person pays zero for hospice care and home health.

The medical insurance package, Part B, is a supplemental (voluntary) program that is available to all Medicare-eligible persons for a monthly premium (\$99.90 minimum in 2012) (CMS, 2012a). The vast majority of Medicare-covered persons elect this coverage. Part B provides coverage for services other than hospital (physician care, outpatient hospital care, outpatient physical therapy, mental health, and home health care) that are not covered by Part A, such as laboratory services, ambulance transportation, prostheses, equipment, and some supplies. After a deductible, up to 80% of reasonable charges are paid for medical and other services. For mental health services, 55% of the costs are paid. Part B resembles the major medical insurance coverage of private insurance carriers. Figure 5-5 shows the total expenses of the Medicare program from 1966 to 2012.

Since the passing of the Medicare amendments to the Social Security Act in 1965, the cost of Medicare has increased dramatically. Hospital care continues to be the major factor

contributing to Medicare costs. However, because of the shorter hospital stays, home health and nursing home costs have increased dramatically. As a result of rising health costs, Congress passed a law in 1983 that radically changed Medicare's method of payment for hospital services. In 1983 federal legislation (PL 98-21) mandated an end to cost-plus reimbursement by Medicare and instituted a 3-year transition to a **prospective payment system** (PPS) for inpatient hospital services (HCFA, 1998). The purpose of the new hospital payment scheme was to shift the cost incentives away from the providing of more care and toward more efficient services. The basis for prospective reimbursement is the 468 **diagnosis-related groups** (DRGs) (See **Evidence-Based Practice Box**). Also, the Balanced Budget Act of 1997 determined that payments to Medicare SNFs would be made on the basis of the PPS, effective July 1, 1998 (HCFA 1998). The PPS payment rates cover SNF services, including routine, ancillary, and capital-related costs (CMS, 2013b). In 2001 CMS developed a PPS for DRGs for home health with Health Insurance Prospective Payment System (HIPPS) codes.

EVIDENCE-BASED PRACTICE

This retrospective study examined the incidence, costs, and factors associated with potentially avoidable hospitalizations (PAH) in dually eligible Medicare and Medicaid beneficiaries. This population was selected due to their complex clinical needs and high costs of care. Potentially avoidable hospitalizations were defined by an expert panel that identified conditions and associated Diagnostic Related Groups (DRGs) which can often be prevented or safely and effectively managed in a skilled nursing facility or home- and community-based services. Seventy-eight percent of the PAH were responsible from five conditions: pneumonia, congestive heart failure, urinary tract infections, dehydration, and chronic obstructive pulmonary disease. The total costs of these hospitalizations were \$3 billion for Medicare beneficiaries and \$463 million for Medicaid beneficiaries. A sensitivity analysis found that between 77,000 and 260,000 hospitalizations and between \$625 million and \$1.9 billion in expenditures could be avoided each year in this population.

Nurse Use

Community health nursing initiatives, such as health education and case management, could significantly reduce the amount of hospital admissions in this population. Such interventions could greatly reduce the negative health effects and quality of life for this population, as well as reduce the high health care costs for this group.

From Walsh EG, Wiener JM, Haber S, et al: Potentially avoidable hospitalizations of dually eligible Medicare and Medicaid beneficiaries from nursing facility and home- and community-based services waiver program. *J Am Geriatr Soc* 60:821–829, 2012.

FIG 5-5 Medicare expenditures for selected years from 1966 to 2012. In 2009 the average amount spent for services for Medicare beneficiaries was approximately \$8000 (Kaiser Family Foundation, 2012b). The average out-of-pocket spending is skewed to those beneficiaries who are older or have declining health. Approximately one in four Medicare beneficiaries spends 30% or more of their income on out-of-pocket health expenses (Kaiser Family Foundation, 2012b). This is because of the limits in Medicare coverage, including certain preventive care, and the limited number of physicians and agencies who accept

Medicare and Medicaid payment. Older adults who do not have supplemental insurance must cover the difference between the Medicare payment and the additional costs for services.

Medicaid

The Medicaid program, Title XIX of the Social Security Act of 1965, provides financial assistance to states and counties to pay for medical services for poor older adults, the blind, the disabled, and families with dependent children. The Medicaid program is jointly sponsored and financed with matching funds from the federal and state governments. In 2013, 55 million people were enrolled in Medicaid (Kaiser Family Foundation, 2014). Medicaid expenditures from 1966 to 2012 are shown in Figure 5-6. Since the beginning of Medicaid, full payment has been provided for five types of services (NCHS, 2012):

- Inpatient and outpatient hospital care
- Laboratory and radiology services
- Physician services
- Skilled nursing care at home or in a nursing home for people more than 21 years of age
- Early Periodic Screening, Diagnosis, and Treatment (EPSDT) programs for those less than 21 years of age

The 1972 Social Security amendments added family planning to the list of full-pay services. States can choose to add prescriptions, dental services, eyeglasses, intermediate care facilities, and coverage for the medically indigent as program options. By law, the medically indigent are required to pay a monthly premium.

Any state participating in the Medicaid program is required to provide the six basic services to persons who are below state poverty income levels. Optional programs are provided at the discretion of each state. In 1989 changes in Medicaid required

states to provide care for children less than 6 years of age and to pregnant women under 133% of the poverty level. For example, if the poverty level were \$12,000, a pregnant woman could have a household income as high as \$16,000 and still be eligible to receive care under Medicaid. These changes also provided for pediatric and family nurse practitioner reimbursement.

In the 1990s states were allowed to petition the federal government for a waiver. If the waiver was approved, the states could use their Medicaid monies for programs other than the six basic services. The first waiver to be approved was given to Oregon for their health care reform plan. Other states have received waivers to develop Medicaid managed care programs for special populations. The 2010 health care reform plan provides for new approaches to offering Medicaid services and incentives for states to offer Medicaid services rather than through the waiver option as described previously (PL 111-148, 2010).

The major expense categories for the Medicaid program have historically been skilled and intermediate nursing home care and inpatient hospital care. When combined, these two categories account today for 3% of all costs to the program (NCHS, 2012).

Public Health

Most public government agencies operate on an annual budget, and they plan for costs by estimating salaries, expenses, and costs of services for a year. Public health agencies, such as health departments and WIC (Women, Infants, and Children) programs, receive primary funding from taxes, with additional money for select goods and services through private third-party payers. Selected public health programs receive reimbursement for services as follows: through grants given by the federal

FIG 5-6 Medicaid expenditures for selected years from 1987 to 2012. (From Centers for Medicare & Medicaid Services: *National Health Expenditure Accounts: National Health Expenditure Data: Historical*. 2012. government to states for prenatal and child health; through Medicare and Medicaid for home health, nursing homes, and WIC and EPSDT programs; and through collecting of fees on a sliding scale for select client services, such as immunizations. (Trust for America's Health, 2014).

In 2011 only 3% of all health care–related federal funds was expended for federal health programs such as WIC, versus 97% for other types of health and illness care (such as hospital and physician services). In addition to this 3% allotment, public health funds also come through states and territorial health agencies. State and local governments contributed 16% to public and general assistance, maternal and child health, public health activities, and other related services in 2010 (NCHS, 2013).

Other Public Support

The federal government finances health services for retired military persons and dependents through TRICARE, the VA, and the Indian Health Service (IHS). These programs are very important in providing needed health care services to these populations (see Chapter 8).

The Affordable Care Act: Public Health Support

The ACA provides for prevention and public health funds with emphasis on chronic disease. Funds are provided to states to implement these provisions. See Table 5-4 for more detail. Also check the state of interest to see what that state is doing to implement this provision in ACA.

Private Support

Private health care payer sources include insurance, employers, managed care, and individuals. Although insurance and consumers have been prominent health care payment sources for some time, the role of employers, managed care, and consumers became increasingly prominent and powerful during the first decade of the twenty-first century, particularly as concerns grew about the use and changing nature of health insurance.

Evolution of Health Insurance

Insurance for health care was first offered for the private sector in 1847 by a commercial insurance company. The purpose of the insurance was to provide security and protection when health care services were needed by individuals. The idea behind insurance was that it provided security, guaranteeing (within certain limits) monies to pay for health care services to offset potential financial losses from unexpected illness or injury related to accidents, catastrophic communicable diseases (such as smallpox and scarlet fever), and recurring (but unexpected) chronic illnesses.

A comprehensive study in the 1920s by the Committee on the Costs of Medical Care showed that a small portion of the population was paying most of the costs of medical care for the majority of the people. The Depression of the 1930s, rising medical costs, and the need to spread financial risk across communities spurred the development of the third-party payment system. The system began as a major industry in the 1930s with the Blue Cross system, which initially provided prepayment for hospital care. In 1939 Blue Shield created plans to provide physician payment. The Blue Cross plans began as tax-free, nonprofit organizations established under special enabling legislation in various states.

In the 1940s and 1950s, hospital and medical-surgical coverage increased. Employee group coverage appeared, and profit-making commercial insurance underwriters began offering health insurance packages with competitive premiums. The commercial insurance companies could offer lower premium rates because of the methods used to set rates. Insurance and premium setting, in general, are based on the notion of risk pooling (i.e., insurance companies were willing to risk the unlikely event that all or even a large portion of individuals covered under a plan would need payment for health services at any given time). Blue Cross used a *community rate*, establishing a similar premium rate for all subscribers regardless of illness potential. In contrast, the commercial companies used

an *experience rate*, in which the premium was based on an estimate of the illness *risk* or the number of claims to be made by the subscriber (Hicks, 2012).

Premium competition, the offering of health insurance as a fringe benefit, and the use of health insurance as a negotiable collective bargaining item led to an increase in covered benefits, first-dollar coverage for medical care expenses, and increased employer-paid premiums. In turn, these factors pushed up insurance premium costs and health care costs and enabled insurance plans to cover high-cost segments of the population (the aged, poor, or disabled) because of the number of low-risk enrollees.

The health needs of high-risk populations led to the passage of Medicare and Medicaid legislation. These and other national health programs targeted health care coverage for specific population groups. Because these programs directed additional money into the health care system to subsidize care, there were financial incentives to encourage the providing of services (i.e., the more services that were ordered, the greater the amount of money that would be received). Other incentives were related to the use of services by clients (i.e., the more available the payment was for services that might otherwise have gone unused, the more services that were requested).

Greater increases in health insurance premiums have occurred as a result of pressure from employers, consumers, and policymakers. Driving forces behind this pressure are quality of care, client dissatisfaction, clients' rights, and the concern that these areas are being compromised in the managed care system. Furthermore, the initial cost savings from managed care may have occurred already, and costs will have to be increased to simply maintain coverage, not to mention providing new services and technologies. Although managed care changed the structure of financing and delivery of care, it was soon recognized that managed care was not the solution to the health care system's problems (Shi and Singh, 2011).

Employers

Since the beginning of Blue Cross and Blue Shield, health insurance has been tied to employment and the business sector. This tie was strengthened during World War II to compensate, attract, and retain employees. Since that time, employers have played the major role in determining health insurance benefits. However, with the economic downturn in 2008, employers began to reduce their health insurance benefits or return the cost of insurance. It is of interest that if a client has health insurance, the payment to the provider is less than the payment made by the client who does not have health insurance.

In 2005 approximately 70% of the population under 65 years of age had private health insurance, most of which was obtained through the workplace (NCHS, 2005). In 2009 the percentage had decreased to about 60% (Kaiser Family Foundation, 2009). In 2005, 87% of employers paid 50% to 100% of the insurance premium (Kaiser Family Foundation, 2005). In 2009 employees paid a minimum of 26% to 36% of the health insurance premium with the employee's share of a family premium doubling in cost since 2000. For employees of small firms, the percentage of payment increased for all premiums (Kaiser

Family Foundation, 2009). This substantial contribution to health care by the private business sector gave the employer considerable health care buying power in making policy about what services insurance would cover. Most older Americans were covered by Medicare; low-income children can now be covered by the Children's Health Insurance Program (CHIP) if enrolled by parents or guardians; and as previously described, some low-income adults were covered by Medicaid.

Before the growth of insurance (i.e., before 1930 and the beginning of Blue Cross), the health care consumer had more influence over health care costs because payment was out of pocket. Consumers made decisions about how they would spend their money, making certain tradeoffs—for example, about the type of health care they were willing to buy and how much they would pay. Entering the system was restricted in large part to those who could afford to pay for care, or to those few who could find care financed through charitable and philanthropic organizations. With the beginning of the insurance (or **third-party payer**) system, health care costs were set by payers, and they determined the type of care or service that would be offered and its price. This began to change somewhat in the 1980s with the increased use of managed care.

As the cost of health insurance has increased, some employers, in an effort to bypass the costs established by insurers, have found it less costly to self-insure. The employer does this by contracting directly with providers to obtain health care services for employees rather than going through health insurance companies. Some large businesses directly employ on-site providers for care delivery or offer on-site wellness programs. These programs within the private sector offer opportunities for nurses to provide wellness programs and health assessments to screen and monitor employees and their families. This move to self-insure resulted in savings to companies and reduced overall sick-care costs (Kovner et al, 2011).

In a truly competitive market, the consumer buys goods and services at will, knowing the costs and expected value of services bought and choosing the provider of those services. In the health system where a third party pays for the services, this transaction has less meaning. The third party makes decisions about the level and type of care that will be purchased for clients and determines how payment will be made. The service provider and client have no influence on how services will be reimbursed. However, the consumer may select the payer/plan and indeed may influence the system through political channels.

The average monthly cost for private health insurance has increased greatly through the years. Premiums reflect a shift of the health care cost burden from employers to employees as the percentage of employer contributions to health care declines. The decrease in employer contribution to health insurance premiums parallels the economic downturn of 2008, the move away from traditional insurance plans, and the move toward managed care plans or self-insurance plans by both small and large employers or toward dropping health insurance as a benefit. In 2008, 2 million people lost employer health insurance coverage (Kaiser Family Foundation, 2012a).

From an economic point of view, the shift in responsibility for the cost of health insurance is not bad. In theory, this shift

makes consumers more knowledgeable about (sensitive to) the price of health services. This means that they have more information for health care decision making and may consider price in making the decision to access types of health care services. Satisfaction with the quality of service rests with the person buying the insurance and receiving health care. As with employers, employees may choose health insurance voluntarily. Therefore three factors—the shifting of responsibility for health insurance premiums to employees, the changing demographics of the workforce in general, and the loss of employment due to the economic downturn—have resulted in a decline in employee enrollment in health insurance plans. Employees are choosing to use their resources to meet basic needs and are assuming the risks of having an illness for which they may have to pay. A minor health problem can lead to major medical debt for someone without health insurance (Kaiser Family Foundation, 2013). PL 111-148 includes a mandate for all citizens and legal residents to have qualifying health coverage. Employers will be required to offer coverage also, except for employers with fewer than 50 employees. These two requirements were to be in effect by 2014 unless repealed by Congress.

Given that access to health insurance is tied to employment, there was growing concern in the late 1980s and early 1990s about the employment layoffs and downsizing occurring in private business. Those who lost their jobs lost their ability to pay for health insurance and to qualify to purchase insurance privately. The Health Insurance Portability and Accountability Act of 1996 (HIPAA) was enacted to protect health insurance coverage for workers and families after a job change or loss (Health Care Financing Administration [HCFA], 1999; Nichols and Blumberg, 1998). Although this has increased the number of people who have access to health insurance and health care, there are claims that individual premiums are high, that insurance companies have lost their ability to pool risks, and that HIPAA is just one more federal control mechanism undermining competitive market influences.

Individuals

In 2011, individuals paid only approximately 14% of total health expenditures out of pocket (NCHS, 2014). However, these figures do not reflect the amount of money the consumer pays in taxes to finance government-supported programs such as Medicare and Medicaid, insurance premiums, and money paid for supplemental insurance to cover the gaps in a primary health insurance policy or Medicare.

Managed Care Arrangements

Managed care is the term used for a variety of health care arrangements that integrate the financing and the delivery of health care. Managed care offers an array of services to purchasers, such as employers, Medicaid, or Medicare, for a set fee. These are called *risk-based plans*. This fee, in turn, is used to pay providers through preset arrangements for services delivered to individuals who are covered (NCHS, 2012). The concept of managed care is based on the notion that the use of costly care could be reduced if consumers had access to care and services that would prevent illness through consumer education and

health maintenance. Therefore, managed care uses disease prevention, health promotion, wellness, and consumer education (Kovner et al, 2011). In addition to risk-based plans, wherein the managed care organization accepts a set fee to cover all costs of care for the enrollee, there are cost-based plans. An example of such a managed care organization is the primary care case management (PCCM) organization often used by Medicaid programs. These PCCMs are composed of a variety of health care providers contracted with states to locate, coordinate, and monitor covered primary care and other services on a per client case management fee payment. Whereas HMOs assume risks for the costs of care, the PCCMs do not (NCHS, 2010).

Although they seem relatively new to many clients of care, HMOs have actually been around since the 1940s. The Health Maintenance Organization Act was enacted in 1972, and since that time, the number of individuals receiving care through HMOs and other types of managed care organizations has increased considerably. Managed care is based, in part, on the principles of managed competition. Managed competition was introduced in health care in the late 1980s and early 1990s to address the increasing costs of health care and to introduce quality into the forefront of discussions. **Managed competition** simply means that clients make decisions and choose the health care services they want on the basis of the quality or reputation of the service. To make decisions, they use knowledge and information about health care problems, care, and providers, and they look at the costs of care. However, health care is a complex market and not one in which information about health care, health problems, and the costs of care are easy to get. With the passing of the ACA(2010), Accountable Care Organizations are being introduced as a new approach to managing care.

Medical Savings Accounts

Another insurance reform discussion at the political level concerns medical savings accounts (MSAs). These are also referred to as health savings accounts. MSAs are touted as a way of turning health care decision-making control over to the individuals receiving care. MSAs are tax-exempt accounts available to individuals who work for small companies, usually established through a bank or insurance company, that enable the individuals to save money for future medical needs and expenses (Internal Revenue Service [IRS], 2012). Money is contributed to an MSA by the employer, and the initial money put into an MSA does not come out of taxable income. Also, interest earned in MSAs is tax free, and unused MSA money can be held in the account from year to year until the money is used. MSAs, in theory, would allow individuals to make cost/quality tradeoffs and would require that individuals become knowledgeable about health care, become involved in health care decision making, and take responsibility for the decisions made. Providers, in turn, must be willing to provide and disclose information to individuals and give up control of health care decision making. The HIPAA and MSAs are examples of health insurance reform efforts, and these efforts will very likely remain in the forefront of political discussions for some time to come, especially with the health care reform discussions.

HEALTH CARE PAYMENT SYSTEMS

Several methods have been used by public and private sources to pay health care providers for health care services. These include retrospective and prospective reimbursement for paying health care organizations, and fee-for-service and capitation for paying health care practitioners (Kovner et al, 2011).

Paying Health Care Organizations

Retrospective reimbursement is the traditional reimbursement method, whereby fees for the delivery of health care services in an organization are set after services are delivered (Kovner et al, 2011). In this scenario, reimbursement is based on either organization costs or charges. The cost method reimburses organizations on the basis of cost per unit of service (e.g., home health visit, patient-day) for treatment and care. Costs include all or a percentage of added, allowable costs. Allowable costs are negotiated between the payer and provider and include items such as depreciation of building, equipment, and administrative costs (e.g., administrative salaries, utilities, and office supplies) (Kovner et al, 2011). For example, the unit of service in home health is the visit, and the agreed-on price is a set amount of money that the home health agency will be paid for a home visit in the region of the United States in which the home care agency is located.

The *charge method* reimburses organizations on the basis of the price set by the organization for delivering a service (Kovner et al, 2011). In this case, the organization determines a charge for providing a particular service, provides the service to a client, and submits a bill to the payer; the payer in turn provides payment for the bill. With this method, the charge may be greater than the actual cost to the agency to deliver the service. When the charge method is used, the client often has to pay the difference between what is paid and what is charged.

Prospective reimbursement, or payment, is a more recent method of paying an organization, whereby the third-party payer establishes the amount of money that will be paid for the delivery of a particular service before offering the services to the client (Kovner et al, 2011). Since the establishment of prospective payment in Medicare in 1983, private insurance has followed by requiring preapprovals before clients can receive certain services, such as hospital admission or mammograms more than once a year (Kovner et al, 2011). Under this payment scheme, the third-party payer reimburses an organization on the basis of the payer's prediction of the cost to deliver a particular service; these predictions vary by case mix (i.e., different types of clients, with different types, levels, and intensities of health problems), the client's diagnosis, and geographic location. This process is used in the DRG system of the hospital (Kovner et al, 2011).

Similarly, ambulatory care services received by Medicare recipients are classified into ambulatory payment classes (APCs), which reflect the type of ambulatory clinical services received and resources required (CMS, 2012b). Prospective

payment to skilled nursing facilities is also adjusted for case mix and geographic variations (CMS, 2012c).

Positive and negative incentives are built into these reimbursement schemes. The retrospective method of payment encourages organizations to inflate prices in one area to offset agency losses in another. These losses can result from providing service to nonpaying clients or from providing care to clients covered under plans that do not cover the total costs of delivering a service (Kovner et al, 2011). The major disadvantage of this system is that little regard is given to the costs involved. This practice of charging a payer at a higher rate to cover losses in providing care is referred to as *cost-shifting*.

Prospective cost reimbursement encourages agencies to stay within budget limits and adds an incentive for providing less service to contain or reduce costs. If an organization provides care to a particular patient or group of patients and keeps the costs of delivering the service lower than the amount of reimbursement, the provider keeps the difference; however, if the provider's costs exceed the reimbursement, the provider must assume the risk and pay the difference. The major disadvantage of this method is that organizations tend to overemphasize controlling costs and sometimes compromise quality of care.

A growth in contracting, or competitive bidding, for health care services, intended to create incentives for providers to compete on price, has occurred as managed care has increased in health care markets. For example, contracting has been used by states to provide Medicaid services to eligible persons. Hospitals and other health care providers that do not have a contract with the state to provide services are not eligible to receive Medicaid payments for client care. Managed care organizations also use this approach to negotiate with health care organizations, such as hospitals, for coverage of services to be provided to covered enrollees, often called *covered lives*.

Paying Health Care Practitioners

The traditional method of paying health care practitioners is known as fee for service (Kovner et al, 2011) and is like the retrospective method just described. The practitioner determines the costs of providing a service, delivers the service to a client, and submits a bill for the delivered service to a third-party payer; the payer then pays the bill. This method is based on usual, customary, and reasonable (UCR) charges for specific services in a given geographic region, determined by periodic regional evaluations of physician charges across specialties (Kovner et al, 2011). Historically, Medicare, Medicaid, and private insurance companies have used this method of reimbursing physicians.

A major effort to regulate and control the costs of physician fees was introduced in 1990 in the Omnibus Reconciliation Act. After a study by the Physician Payment Review Commission established by Congress, the *resource-based relative value scale* (RBRVS) was established. The RBRVS method reimburses physicians for specific services provided and the amount of resources required to deliver the service. Resources are defined broadly and include not only the costs of providing the service, but also the training that is required to provide a particular service and

the time required to perform certain procedures, including client diagnosis and treatment. The RBRVS method of reimbursement, adopted by Medicare in 1991, acknowledges the breadth and depth of knowledge required by primary care physicians in the community to provide services aimed at prevention, health promotion, teaching, and counseling.

Capitation is similar to prospective reimbursement for health care organizations. Specifically, third-party payers determine the amount that practitioners will be paid for a unit of care, such as a client visit, before the delivery of the service, thereby placing a limit on the amount of reimbursement received per patient (Kovner et al, 2011). In contrast to a fee-for-service arrangement, where the practitioner determines both the services that will be provided to clients and the charges for those services, practitioners being paid through capitation are given the rate they will be paid for a client's care, regardless of specific services provided. Therefore, for example, physicians and nurse practitioners are aware in advance of the payment they will receive to perform a routine, uncomplicated physical examination or a more complex, detailed physical examination, diagnosis, and treatment (Kovner et al, 2011).

In capitated arrangements, physicians and other practitioners are paid a set amount to provide care to a given client or group of clients for a set period of time and amount of money. This arrangement, typically used by managed care organizations, is one whereby the practitioner contracts with the managed care organization to provide health care services to plan members for a preset and negotiated fee. The agreed-on fee is negotiated between the practitioner and the managed care organization before the delivery of services and is set at a discounted rate, and the practitioner and managed care organization come to a legal agreement, or contract, for the delivery and payment of services. The managed care organization pays the predetermined fee to the practitioner, often before the delivery of services, to provide care to plan members for a set period (Kovner et al, 2011).

Reimbursement for Nursing Services

Historically, practitioners eligible to receive reimbursement for health care services included physicians only. However, nurses

who function in certain capacities, such as NPs, CNSs, and midwives, also provide primary care to clients and receive reimbursement for their services. Being recognized as primary care providers and eligible to receive reimbursement has not been an easy achievement. There are currently more than 250 nurse-managed clinics in the United States providing population-based preventive services, primary care, or specific wellness programs. Most are receiving financial support through Medicare, Medicaid, contracts, gifts, grants, and private donations.

Hospital nursing care costs have traditionally been included as part of the overall patient room charge and reimbursed as such. Other agencies, such as home health care agencies, include nursing care costs with administrative costs, supplies, and equipment costs. Nursing organizations, such as the American Nurses Association (ANA), have long advocated that nursing care should become a separate budget item in all organizations so that cost studies can show the efficiency and effectiveness of the nursing profession.

Spurred by efforts to control the costs of medical care, effective January 1, 1998, NPs and CNSs were granted third-party reimbursement for Medicare Part B services only, under Public Law 105-33 (ANA, 1999). This new law set reimbursement for NPs and CNSs at 85% of physician rates for the same service, an extension of previous legislation that allowed the same reimbursement rate to NPs and CNSs practicing in rural areas (Buppert, 1999). This law was passed after years of work in this area, including research documenting NP and CNS contributions to health care delivery and client outcomes and after active lobbying efforts by professional nursing organizations. Reimbursement for these nurses has not changed to any extent since the 1990s.

In addition, data about the cost-to-benefit ratio, efficiency, and effectiveness of nursing care in general have been collected. Today, more than 250 nurse-managed clinics provide health care services to individuals in the United States who might not otherwise have access to health care, such as older adults, the homeless, and schoolchildren. All of these events have moved the discipline toward more autonomy in nursing practice and are serving as a means for evaluating and documenting nurses' contributions to health care delivery (Esperat et al, 2012).

LINKING CONTENT TO PRACTICE

The balance of interest within society and health care will continue to shift toward a focus on quality, safety, and elimination of health disparities through public and private sector partnerships. Health care system concerns of the twenty-first century are expected to focus on examining the quality of health care relative to the costs of care delivered, reduction in disparities, access to care, and health care reform. These changes will result from continued efforts of both the public and private sectors to reform the U.S. health care system. The current era of health care delivery will be noted as a time of vast changes in all sectors of health care delivery.

Nurses must plan for future changes in health care financing by becoming aware of the costs of nursing services, identifying aspects of care where cost

savings can be safely achieved, and developing knowledge on how nursing practice affects and is affected by the principles of economics. Nursing must continue to focus on improving the overall health of the nation, defining its contribution to the health of the nation, deriving the value of nursing care, and ensuring its economic viability within the health care marketplace. Nurses must effect changes in the health care system by providing leadership in developing new models of care delivery that provide effective, high-quality care and by assuming a greater role in evaluating client care and nurse performance. It is through their leadership that nurses will contribute to improved decision making about allocating scarce health care resources, and promoting primary prevention as an answer to improve many of the current population level health outcomes.

PRACTICE APPLICATION

Connie, a nursing student, has identified a caseload of five families in a chronic disease program offered by the local public health department. She is interested in assessing the costs of care to her clients and to the agency. Connie approaches the public health nurse administrator and asks the following questions:

A. How is the agency reimbursed for chronic disease management? Has the Affordable Care Act changed the way reimbursement occurs?

- B.** Does the client have a responsibility for paying for services?
- C.** Are nursing care costs known?
- D.** Are services rationed to clients? On what basis?
- E.** What effect will the chronic disease management program have on the community population?

Answers can be found on the Evolve site.

KEY POINTS

- From 1800 to 2000, the U.S. health care delivery system experienced four developmental stages, with different emphases on health care economics. With the twenty-first century, the health care delivery system has changed the focus of the fourth developmental stage.
- Four basic components provide the framework for the development of delivery of health care services: service needs and intensity, facilities, technology, and labor (workforce).
- Three major factors have been associated with the growth of the health care delivery system: price inflation, changes in population demographics, and technology and service intensity.
- Chronic disease is becoming a major health factor affecting health care spending, with one in two Americans experiencing at least one chronic disease.
- Health care financing has evolved through the twentieth century from a system financed primarily by the consumer to a system financed primarily by third-party payers. In the twenty-first century, the consumer is being asked to pay more.
- To solve the problems of rising health care costs, the Affordable Care Act has been passed; this act also includes some form of rationing.
- Excessive and inefficient use of goods and services in health care delivery has been viewed as the major cause of rising health care costs.
- Economics is concerned with use of resources, including money, to fulfill society's needs and wants.
- Health economics is concerned with the problems of producing services and programs and distributing them to clients.
- The goal of public health economics is maximal benefits from services of public health providers, leading to health and wellness of the population.
- The goal of public health is to provide the most good for the most people.
- Nurses need to understand basic economic principles to avoid contributing to rising health care costs.
- The GNP reflects the market value of goods and services produced by the United States.
- The GDP reflects the market value of the output of labor and property located in the United States.
- Microeconomic theory shows how supply and demand can be used in health care.
- Macroeconomic theory helps one look at national and community issues that affect health care.
- Social issues, economic issues, and communicable disease epidemics mark the problems of the twenty-first century.
- Medicare and Medicaid are two government-funded programs that help meet the needs of high-risk populations in the United States.
- A majority of the U.S. population has had health insurance. It is now mandated by law and has a penalty if citizens are not covered.
- The uninsured segment represents millions of people, mostly the working poor, older adults, and children, and those who lost jobs in the economic downturn of 2008.
- Poverty has a detrimental effect on health.
- Health care rationing has always been a part of the U.S. health care system and will continue to be with health care reform.
- Nurses are cost-effective providers and must be an integral part of health care delivery.
- *Healthy People 2020* is a document that has established U.S. health objectives.
- Human life is valued in health economics, as is money. An emphasis on changing lifestyles and preventive care will reduce the unnecessary years of life lost to early and preventable death.

CLINICAL DECISION-MAKING ACTIVITIES

1. Define the following terms in your own words: economics, health economics, public health economics, public health finance, gross national product, gross domestic product, consumer price index, and human capital. How do these terms relate to your work as a nurse?
2. Compare the advantages and disadvantages of applying economics to public health care issues. Be specific.
3. Compare and contrast efficiency and effectiveness of a public health program. What factors make these difficult to control?

CLINICAL DECISION-MAKING ACTIVITIES—cont'd

4. Apply the concepts of supply and demand to an example from population health. Be precise in your answer.
5. Review Chapter 6. Debate in class the ethical implications of the goal of rationing. Focus your debate on the implications for nursing practice. What are some of the complexities of this question?
6. Invite a public health nurse administrator to meet with your class or clinical conference group. Ask how inflation, changes in population, and technology have changed the public health care delivery system and nursing practice. How could we check for ourselves to find the answers?

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Describe a brief history of the ethics of nursing practice.
2. Analyze ethical decision-making processes.
3. Compare and contrast ethical theories and principles, virtue ethics, caring and the ethic of care, and feminist ethics.
4. Comprehend the ethics inherent in the core functions of public health nursing.
5. Analyze codes of ethics for nursing and for public health.
6. Apply the ethics of advocacy to nursing practice.

KEY TERMS

advocacy, p. 132
 assessment, p. 129
 assurance, p. 130
 beneficence, p. 126
 bioethics, p. 122
 code of ethics, p. 123
 communitarianism, p. 127
 consequentialism, p. 125

deontology, p. 126
 distributive justice, p. 126
 ethical decision making, p. 123
 ethical dilemmas, p. 124
 ethical issues, p. 124
 ethics, p. 125
 feminine ethic, p. 129
 feminist ethics, p. 129

*Special thank you to Dr. Mary Silva who offered valuable guidance for the revision of this chapter.

A special thanks to James Fletcher, Mary Silva, and Jeanne Sorrell for the many contributions to this chapter in previous editions of the text.

CHAPTER OUTLINE

History

Ethical Decision Making

Ethics

- Definition, Theories, Principles
- Virtue Ethics
- Caring and the Ethic of Care
- Feminist Ethics

Ethics and the Core Functions of Population-Centered Nursing Practice

- Assessment

- Policy Development

- Assurance

Nursing Code of Ethics

Public Health Code of Ethics

Advocacy and Ethics

- Codes and Standards of Practice
- Conceptual Framework for Advocacy
- Practical Framework for Advocacy
- Advocacy: Issues That Have Ethical Implications

The role of nurses who practice in the community is to focus on protecting, promoting, preserving, and maintaining health while preventing disease. These goals reflect the ethical principles of promoting good and preventing harm. In addition, nurses struggle with the rights of individuals and families versus the rights of local groups within a community. On the other hand, nurses struggle with the rights of a community or population versus the rights of individuals, families, and local groups within a community. These two types of struggle reflect the tensions among respect for autonomy, rights-based ethical theory, and community-based ethical theory.

Nurses also deal with consequence-based ethical theory, obligation-based ethical theory, and the ethical components of advocacy, justice, health policy, caring, women's moral experiences, and the moral character of health care practitioners. They are guided by codes of ethics and ethical decision-making frameworks. The purpose of this chapter, then, is to make explicit the preceding content as it relates to the ethics inherent in nursing.

HISTORY

Chapter 2 discusses the history of public health nursing. The focus in this chapter is a brief history of nursing and public health ethics and the relationship between them and nursing.

Modern nursing has a rich heritage of ethics and morality, beginning with Florence Nightingale (1820 to 1910). Her values and the moral significance she inculcated into the profession have endured. She saw nursing as a call to service and viewed the moral character of persons entering nursing as important. She also viewed nursing within a broad social context, where

poor people mattered and where soldiers harmed in the Crimean War (1854 to 1856) did not have to endure unhealthy environments. Because of her commitment to poor individuals in communities, as well as her stances on primary prevention and on population-based evidence that healthy environments save soldiers' lives, she is seen as nursing's first enduring moral leader who defined the community as her client.

In 1860, Nightingale established the first nursing program in London. It was hospital based, but the curriculum contained not only care of the sick, but also public health concepts with their inherent ethical tenets. Many of these programs were associated with religious institutions. Students, therefore, often received ethics courses with a slant toward a particular religion's values. Soon thereafter in the United States, the notion of hospital-based nursing programs took hold, but nursing practice in the community was not a part of the curricula.

In the 1960s, two seminal events occurred. First, the American Nurses Association (ANA) recommended that all nursing education should occur in institutions of higher education. As this process slowly took place, ethics, as a course per se, was removed from many schools of nursing, although ethical values remained. Second, because of major advances in science and technology that affected health care, the field of **bioethics** began to emerge and was reflected in nursing curricula. Today, most nursing programs integrate bioethical content into their courses or have separate courses on this topic; some do both. Although some of these courses relate bioethics to community nursing, the emphasis has been primarily on acute care nursing.

Nurses' codes of ethics are important in the history of public health nursing practice. According to the American Nurses Association (ANA), the Nightingale Pledge is generally

considered to be nursing's first **code of ethics** (ANA, 2001). After the Nightingale Pledge, a “suggested” code and a “tentative” code were published in the *American Journal of Nursing* but were not formally adopted. In 1950, the ANA House of Delegates formally adopted the *Code for Professional Nurses*. In 1956, 1960, 1968, 1976, 1985, and 2001 the code was amended or revised. After 5 years of work, the ANA House of Delegates adopted the Code of Ethics for Nurses with Interpretive Statements in 2001 (ANA, 2001). This code was revised in 2015 (ANA, 2015).

Nurses also should be familiar with the first known international code of ethics, developed by the International Council of Nurses (ICN) in 1953 (ICN, 1953). Like the ANA code, the ICN code has undergone various revisions and adoptions. The most recent version of the *ICN Code of Ethics for Nurses* was revised in 2012. This code makes it clear that nurses must respect human rights, including the right to life, to dignity, and to be treated with respect. The *ICN Code of Ethics for Nurses* has four principal elements that outline the standards of conduct. They are as follows: (1) nurses and people; (2) nurses and practice; (3) nurses and the profession; and (4) nurses and co-workers (ICN, 2012, pp. 2-4).

In addition to codes of ethics, the nursing literature and nursing associations have consistently reflected a commitment to ethics, as well as an awareness of nursing's ethical obligations to society. From the 1980s to the present, the number of centers for nursing and health care ethics has increased steadily. The majority of these centers are located in academic settings; however, in 1991 the ANA founded its Center for Ethics and Human Rights. The historical contributions of this center have affected the persistent ethicality of nursing. In 2008, the ANA published *Nursing and Health Care Ethics: A Legacy and a Vision*, which creatively assesses historical contributions of nursing scholars in ethics and explores a vision for the future scholarship of nursing ethics (Pinch and Haddad, 2008). Also in 2008, the ANA published *Guide to the Code of Ethics for Nurses: Interpretation and Application* (Fowler, 2008).

The bioethics movement of the late 1960s influenced not only nursing ethics, but also public health ethics. However, until recently, the relationship between public health and ethics was implicit rather than explicit (Callahan and Jennings, 2002; Petrini, 2010). The publication in 2015 of *Essentials of Public Health Ethics* by Bernheim and colleagues is a major contribution to describing the complex relationship between public health and ethics.

Finally, in 2000, public health professionals, individually and through their associations, initiated the writing of a code of ethics that was supported by the American Public Health Association (APHA). In 2001 the Public Health Code of Ethics was widely disseminated via the APHA website for critique (www.apha.org) and was adopted in 2002 (Olick, 2005). The code presents principles, rules, and ideals to guide public health practice but is not intended to provide a specific action plan for ethical decision making. Our language often programs us to think in terms of opposites, such as right or wrong, so that we think we need to choose one or the other. Often, there are more than two sides to an ethical issue. When we try to understand

BOX 6-1 Key Ethical Terms

Ethics is a branch of philosophy that includes both a body of knowledge about the moral life and a process of reflection for determining what persons ought to do or be regarding this life.

Bioethics is a branch of ethics that applies the knowledge and processes of ethics to the examination of ethical problems in health care.

Moral distress is an uncomfortable state of self in which one is unable to act ethically.

Morality is shared and generational societal norms about what constitutes right or wrong conduct.

Values are beliefs about the worth or importance of what is right or esteemed.

Ethical dilemma is a puzzling moral problem in which a person, group, or community can envision morally justified reasons for both taking and not taking a certain course of action.

Codes of ethics are moral standards that delineate a profession's values, goals, and obligations.

Utilitarianism is an ethical theory based on the weighing of morally significant outcomes or consequences regarding the overall maximizing of good and minimizing of harm for the greatest number of people.

Deontology is an ethical theory that bases moral obligation on duty and claims that actions are obligatory irrespective of the good or harmful consequences that they produce. Because humans are rational, they have absolute value. Therefore, persons should always be treated as ends in themselves and never as mere means.

Principlism is an approach to problem solving in bioethics that uses the principles of respect for autonomy, beneficence, nonmaleficence, and justice as the basis for organization and analysis of ethical issues and dilemmas.

Advocacy is the act of pleading for or supporting a course of action on behalf of a person, group, or community.

the differing values of individuals and groups in a community, we find important points to consider on different sides of an ethical issue and focus not only on what we think is right, but also on what we should *respect* in each perspective of an ethical issue. As Bernheim and colleagues (2015, p. 3) point out, “Public health is an ethical enterprise, resting on moral foundations, yet some public health interventions appear to threaten or compromise other moral norms, such as liberty, privacy, and confidentiality.” As is discussed later in this chapter, advances in social media pose ethical concerns about both privacy and confidentiality. Also, vulnerable or high-risk populations as discussed in Chapter 32 can pose ethical concerns and necessitate careful decision making by nurses. Gjengedal and colleagues (2013) point out that a key to acting ethically with vulnerable populations is to try to understand the clients from their perspective rather than from the perspective of the nurse that may be prejudiced.

Before discussing ethics related to nursing practice in the community, some key ethical terms are defined in Box 6-1. Other ethical terms are defined within the context of the chapter.

ETHICAL DECISION MAKING

Ethical decision making is that component of ethics that focuses on the process of how ethical decisions are made. The process is the thinking that occurs when health care professionals must make decisions about ethical issues and ethical

dilemmas. **Ethical issues** are moral challenges facing a person or a profession. In nursing, one such challenge is how to prepare an adequate and competent workforce for the future. In contrast, **ethical dilemmas** are human dilemmas and puzzling moral problems in which a person, group, or community can envision morally justified reasons for both taking and not taking a certain course of action. One example of an ethical dilemma is how to allocate resources to two equally needy populations when the resources are sufficient to serve only one of the populations. Ethical theories, principles, and decision-making frameworks help us think through these issues and dilemmas. In describing what ethics is, [Bernheim and colleagues](#) concentrate on normative ethics and say that in general terms, “normative ethics involves identifying and justifying moral norms regarding right and wrong, good and bad, and determining the meaning, range and strength of those moral norms for purposes of guiding human action” (2015, p. 4)

Ethical decision-making frameworks use problem-solving processes. They provide guides for making sound ethical decisions that can be morally justified. Many such frameworks exist in the health care literature, and some are presented in this chapter. A caveat, however, is in order. [Weston \(2006, p. 22\)](#) notes that the first requirement of ethics is to think appreciatively and carefully about moral matters. We should not simply obey rules or authorities without thinking for ourselves; thinking for ourselves is both a moral responsibility and a hard-won right.

Keeping the preceding caveat in mind, the following generic ethical decision-making framework is presented:

1. Identify the ethical issues and dilemmas.
2. Place them within a meaningful context.
3. Obtain all relevant facts.
4. Reformulate ethical issues and dilemmas, if needed.
5. Consider appropriate approaches to actions or options (such as utilitarianism, deontology, principlism, virtue ethics, caring and the ethic of care, feminist ethics).
6. Make a decision and take action.
7. Evaluate the decision and the action.

The steps of a generic ethics framework are often nonlinear, and, with the exception of step 5, they do not change substantially. The rationale for each of the seven steps is presented in [Table 6-1](#). The six approaches to actions or options in the ethical decision-making framework (step 5) are outlined throughout the chapter in the How To Boxes.

Two factors affect this ethical decision-making framework: (1) the growing multiculturalism of the American society, and (2) moral distress. First, nurses often deal with ethical issues and dilemmas related to the diverse and at times conflicting values that result from ethnicity. From a moral perspective, what should the nurse do when facing ethnicity conflicts?

[Callahan \(2000\)](#) offers useful insights into these conflicts. He describes four situations in which ethnic diversity can be judged in relationship to cultural standards:

1. Situations that place persons at direct risk of harm, whether psychological or physical
2. Situations in which ethnic cultural standards conflict with professional standards

TABLE 6-1 Rationale for Steps of Ethical Decision-Making Framework

Step	Rationale
1. Identify the ethical issues and dilemmas	Persons cannot make sound ethical decisions if they cannot identify ethical issues and dilemmas
2. Place them within a meaningful context	The historical, legal, sociological, cultural, psychological, economic, political, communal, environmental, and demographic contexts affect the way ethical issues and dilemmas are formulated and justified
3. Obtain all relevant facts	Facts affect the way ethical issues and dilemmas are formulated and justified
4. Reformulate ethical issues and dilemmas if needed	The initial ethical issues and dilemmas may need to be modified or changed on the basis of context and facts
5. Consider appropriate approaches to actions or options	The nature of the ethical issues and dilemmas determines the specific ethical approaches used
6. Make decisions and take action	Professional persons cannot avoid choice and action in applied ethics
7. Evaluate decisions and action	Evaluation determines whether or not the ethical decision-making framework used resulted in morally justified actions related to the ethical issues and dilemmas

3. Situations in which the greater community's values are jeopardized by specific ethnic values
4. Situations in which specific ethnic community customs are annoying but not problematic for the greater community

[Callahan \(2000, p. 43\)](#) discusses how to judge diversity in the four situations. In situation 1, he says that “we in America imposed some standards on ourselves for important moral reasons; and there is no good reason to exempt [ethnic] subgroups from those standards.” For situations 2 and 3, he suggests a thoughtful tolerance but also some degree of moral persuasion (not coercion) for ethnic groups to alter values so that they are more in keeping with what is normative in the American culture. However, Callahan says that “in the absence of grievous harm, there is no clear moral mandate to interfere with those values” (p. 43). Finally, regarding situation 4, he believes in moral tolerance of nonthreatening ethnic traditions, because there is no moral mandate to do otherwise.

Second, because decision making is central to the practice of nursing, and many decisions are difficult to make, it is useful to consider experience of ethical or **moral distress**. Moral or ethical distress occurs when a person is unable to act in a way that he or she thinks is right. You do not feel that you are able to act in a manner consistent with your own values, cultural expectations, and religious beliefs. When this conflict occurs, it can lead to a personal sense of failure in the kind of care you give and to subsequent performance issues and may lead to work and/or career dissatisfaction. However, there are ways to handle moral distress, as by (1) identifying the type(s) of situations that lead to distress; (2) communicating that concern to

your manager and examining ways to work toward addressing the stressor; or (3) seeking support from colleagues. It is often useful to talk with colleagues. You may learn that they have similar concerns or that they have found ways to interrupt the stressful situation(s) (Carlock and Spader, 2007). Understanding both multiculturalism and moral distress aids in making ethical decisions.

Two cases are presented in later sections of the chapter. Examine each using the ethical decision-making processes outlined in the How To Boxes and the codes of ethics provided in the chapter. These cases provide an excellent opportunity to discuss with classmates your personal beliefs about the application of ethical processes and to assess your own thoughts, feelings, and possible actions. The cases deal with what the nurse's response should be when (1) the question arises about whether a parent can adequately care for a young child or the child should be removed from the mother, and (2) a client is not able or willing to take personal responsibility and does not want the nurse to report the situation. The Evidence-Based Practice box provides a summary of a research study that examined conflicting ethical concerns.

EVIDENCE-BASED PRACTICE

Park (2013) developed and evaluated a case-based computer program to teach nursing students to effectively make ethical decisions. She used seven ethical cases chosen from 18 possible cases that were developed by practicing nurses and a six-step Integrated Ethical Decision-Making Model developed by the author. Interviews with the practicing nurses concerned ethical cases they had encountered as well as practical moral issues they had experienced. A total of 251 undergraduate students from three nursing schools used the program in their nursing ethics course. The program used in this study was based on *Principles of Biomedical Ethics* introduced by Beauchamp and Childress (2008). These principles are discussed in the chapter and they include autonomy, nonmaleficence, beneficence, justice, fidelity, veracity, and confidentiality. A goal of the program was for the students to learn to make an ethical decision justifiable in a real setting by applying ethical knowledge and critical thinking. The six steps of the Integrated Ethical Decision-Making Model were as follows: (1) the identification of an ethical program; (2) the collection of additional information to identify the problem and develop solutions; (3) the development of alternatives for analysis and comparison; (4) the selection of the best alternatives and justification; (5) the development of diverse, practical ways to implement ethical decisions and actions; and (6) the evaluation of the effects and development of strategies to prevent a similar occurrence of the problem.

The study demonstrated that a case-based computer approach could successfully replicate real-world ethical case vignettes in a structured decision-making process. The users said the program was helpful to them in ethical decision making.

From Ulrich C, O'Donnell P, Taylor C, et al: Ethical climate, ethics stress, and the job satisfaction of nurse and social workers in the United States, *Soc Sci Med* 65(8):1708–1719, 2007.

ETHICS

Definition, Theories, Principles

Ethics is concerned with a body of knowledge that addresses questions such as the following: How should I behave? What actions should I perform? What kind of person should I be? What are my obligations to myself and to fellow humans? There

are general obligations that humans have as members of society. Among these general obligations are not to harm others, to respect others, to tell the truth, and to keep promises. Sometimes, however, a situation dictates that a person tell a lie or break a promise because the consequences of telling the truth or keeping the promise may bring about more harm than good. For example, as a nurse you have promised a family that you will visit them at a certain time, but your schedule has gone awry because of unexpected circumstances. One of the other families you visit is in a state of crisis—their adolescent child is suicidal—and your nursing intervention is needed. Most nurses would agree that this is not a good time to keep the original promise. You are morally justified in breaking your promise because you fear that more harm than good would be done if the promise were kept.

HOW TO Apply the Utilitarian Ethics Decision Process

1. Determine moral rules that are important to society and that are derived from the principle of utility.*
2. Identify the communities or populations that are affected or most affected by the moral rules.
3. Analyze viable alternatives for each proposed action based on the moral rules.
4. Determine the consequences or outcomes of each viable alternative on the communities or populations most affected by the decision.
5. Select the actions on the basis of the rules that produce the greatest amount of good or the least amount of harm for the communities or populations that are affected by the actions.

(Remember that the utilitarian ethics decision process is one of the approaches in step 5 of the generic ethical decision-making framework.)

*Moral rules of action that produce the greatest good for the greatest number of communities or populations affected by or most affected by the rules.

This example of promise breaking illustrates several things about ethical thinking. First, ethical judgments are concerned with values. The goal of an ethical judgment is to choose that action or state of affairs that is good or is right in the circumstances. Second, ethical judgments generally do not have the certainty of scientific judgments. For example, nurses diagnose an ethical situation on the basis of the best available information and then choose the course of action that seems to provide the best ethical resolution to the situation. In some situations, the decision is based on outcomes or consequences. That approach to ethical decision making is called **consequentialism**. It maintains that the right action is the one that produces the greatest amount of good or the least amount of harm in a given situation. **Utilitarianism** is a well-known consequentialist theory that appeals exclusively to outcomes or consequences in determining which choice to make.

In other situations, nurses touch on options open to fundamental beliefs. In such circumstances, these nurses may conclude that the action is right or wrong in itself, regardless of the amount of good that might come from it. This is the position

known as **deontology**. It is based on the premise that persons should always be treated as ends in themselves and never as mere means to the ends of others. Deontological theory is often called nonconsequentialist. It is a “theory of duty holding that some features of actions other than or in addition to consequences make actions right or wrong” (Beauchamp and Childress, 2013, p. 361).

HOW TO Apply the Deontological Ethics Decision Process

1. Determine the moral rules (e.g., tell the truth) that serve as standards by which individuals can perform their moral obligations.
2. Examine personal motives for proposed actions to ensure that they are based on good intentions in accord with moral rules.
3. Determine whether the proposed actions can be generalized so that all persons in similar situations are treated similarly.
4. Select the action that treats persons as ends in themselves and never as mere means to the ends of others.

(Remember that the deontological ethics decision process is one of the approaches in step 5 of the generic ethical decision-making framework.)

Members of the health professions have specific obligations that exist because of the practices and goals of the profession. These health care obligations have been interpreted in terms of a set of principles in bioethics. The primary principles are **respect for autonomy**, **nonmaleficence**, **beneficence**, and **distributive justice** as shown in Box 6-2. These principles are “general guidelines for the formulation of more specific rules” (Beauchamp and Childress, 2013, p. 13). This approach has been called **principlism**, and is clearly discussed in the seventh edition of *Principles of Biomedical Ethics* by Beauchamp and

Childress (2013). This approach to ethical decision making in health care arose in response to life-and-death decision making in acute care settings, where the question to be resolved tended to concern a single localized issue such as the withdrawing or withholding of treatment (Holstein, 2001). In these circumstances, preserving and respecting a client’s autonomy became the dominant issue. According to Beauchamp and Childress (2013), these four clusters of moral principles are central to the field of biomedical ethics. Principles are more general guides than are rules. Principlism is a “theory about how principles link to and guide practice” (Beauchamp and Childress, 2013, p. 25).

Despite its success as a basis for analysis in bioethics, principlism has come under attack (e.g., Callahan, 2000, 2003; Walker, 2009), and there are grounds for the criticism. First, the principles are said to be too abstract and narrow to serve as guides for action. Second, the principles themselves can conflict in a given situation, and there is no independent basis for resolving the conflict. Third, some persons claim that effective ethical problem solving must be rooted in concrete, individual experiences. Fourth, ethical judgments are alleged to depend more on the judgment of sensitive persons than on the application of abstract principles. The How To Box below can serve as a guide for how to use the principlism ethics decision process.

HOW TO Apply the Principlism Ethics Decision Process

1. Determine the ethical principles (respect for autonomy, nonmaleficence, beneficence, justice) that are relevant to an ethical issue or dilemma.
2. Analyze the relevant principles within a meaningful context of accurate facts and other pertinent circumstances.
3. Act on the principle that provides, within the meaningful context, the strongest guide to action that can be morally justified by the tenets foundational to the principle.

(Remember that the principlism ethics decision process is one of the approaches in step 5 of the general ethical decision-making framework.)

BOX 6-2 Ethical Principles

Respect for autonomy: Based on human dignity and respect for individuals, autonomy requires that individuals be permitted to choose those actions and goals that fulfill their life plans unless those choices result in harm to another.

Nonmaleficence: Nonmaleficence requires that we do no harm. It may be impossible to avoid harm entirely, but this principle requires that health care professionals act according to the standards of due care, always seeking to produce the least amount of harm possible.

Beneficence: This principle is complementary to nonmaleficence and requires that we do good. We are limited by time, place, and talents in the amount of good we can do. We have general obligations to perform those actions that maintain or enhance the dignity of other persons whenever those actions do not place an undue burden on health care providers.

Distributive justice: Distributive justice requires that there be a fair distribution of the benefits and burdens in society based on the needs and contributions of its members. This principle requires that, consistent with the dignity and worth of its members and within the limits imposed by its resources, a society must determine a minimal level of goods and services to be available to its members.*

Modified from Bateman N: *Advocacy Skills for Health and Social Care Professionals*. Philadelphia, PA, 2000, Jessica Kingsley, p 63.

*In public health nursing client may be a person, group, or community.

The dominance of the principle of respect for autonomy has been challenged by critics concerned about decision making in non-acute care settings, where the ethical decision is more likely to be about, for example, long-term care or access to health care for persons of diverse cultures (Callahan and Jennings, 2002; Walker, 2009). Thus, whereas autonomy may be stressed in acute care settings, an overemphasis on autonomy may inhibit ethical decisions in public health. In public health, beneficence and distributive justice are frequently a greater issue than autonomy. For this reason, it is useful to look at other models for ethical decision making, including models that expand the focus of nursing beyond the individual nurse-client relationship to the social environment and systems that impact health care (Bekemeier and Butterfield, 2005).

Utilitarianism and deontology were developed from the Age of Enlightenment’s focus on universals, rationality, and isolated individuals. Each theory maintains that there is a universal first

principle—the principle of utility for utilitarianism and the categorical imperative for deontology—that serves as a rational norm for our behavior and allows us to calculate the rightness or wrongness of each individual action. Both utilitarianism and deontology also follow the lead of classic liberalism in asserting that the individual is the special center of moral concern (Steinbock et al, 2008). Giving priority to individual rights and needs means that these should not be sacrificed for the interests of society (Steinbock et al, 2008). The focus on individual rights leads to complications in the interpretation of distributive or social justice.

Public health ethics rests on a set of general moral considerations. Bernheim and colleagues (2015, p. 21) identify nine moral considerations in public health: (1) producing benefits; (2) avoiding, preventing, and removing harms; (3) producing the maximal balance of benefits over harms and other costs (often called utility); (4) distributing benefits and burdens fairly (distributive justice); (5) respecting autonomous choices and actions, including liberty of actions; (6) protecting privacy and confidentiality; (7) keeping promises and commitments; (8) disclosing information as well as speaking honestly and truthfully (often grouped under transparency); and (9) building trust. These nine moral considerations in public health nursing are easy to apply. **Distributive justice**, or *social justice*, refers to the allocation of benefits and burdens to members of society. Benefits refer to basic needs, including material and social goods, liberties, rights, and entitlements. Wealth, education, and public services are benefits. Burdens include such things as taxes, military service, and the locations of incinerators and power plants. Justice requires that the distribution of benefits and burdens in a society be fair or equal. There is wide agreement that the distribution should be based on what one needs and deserves, but there is considerable disagreement as to what these terms mean. Three primary theories of distributive justice that are defended today include egalitarian, libertarian, and liberal democratic theories.

Egalitarianism is the view that everyone is entitled to equal rights and equal treatment in society. Ideally, each person has an equal share of the goods of society, and it is the role of government to ensure that this happens. The government has the authority to redistribute wealth if necessary to ensure equal treatment. Thus, egalitarians are supportive of welfare rights—that is, the right to receive certain social goods necessary to satisfy basic needs, including adequate food, housing, education, and police and fire protection. The weaknesses of egalitarianism are both practical and theoretical. It would be practically impossible to ensure the equal distribution of goods and services in any moderately complex society. Assuming that such a distribution could be accomplished, it would require a coercive authority to maintain it (Coursin, 2009; Hellsten, 1998). Further, egalitarianism is unable to provide any incentive for each of us to do our best, because there is no promise of our merit being rewarded.

The *libertarian* view of justice holds that the right to private property is the most important right. Libertarians recognize only liberty rights—the right to be left alone to accomplish our goals. Hellsten (1998, p. 822) notes, “The central feature of the

libertarian view on distributive justice is that it is totally individualist. It rejects any idea that societies, states, or collectives of any form can be the bearers of rights or can owe duties.” Libertarians see a limited role for government, namely, the protection of property rights of individual citizens through providing police and fire protection. While they also concede the need for jointly shared, publicly owned facilities such as roads, they reject the idea of welfare rights and view taxes to support the needs of others as coercive taking of their property. Given the libertarian rejection of the priority of the state, however, it is not clear where the right to property originates (Hellsten, 1998).

The work of John Rawls (2001) represents the *liberal democratic* theory. Rawls attempts to develop a theory that values both liberty and equality. He acknowledges that inequities are inevitable in society, but he tries to justify them by establishing a system in which everyone benefits, especially the least advantaged. This is an attempt to address the inequalities that result from birth, natural endowments, and historic circumstances. Imagining what he calls a “veil of ignorance” to keep us unaware of our actual advantages and disadvantages, Rawls would have us choose the basic principles of justice (p. 15). Once impartiality is guaranteed, Rawls (2001, p. 42) maintains that all rational people will choose a system of justice containing the following two basic principles:

Each person has the same indefeasible claim to a fully adequate scheme of equal basic liberties, which scheme is compatible with the same scheme of liberties for all; and social and economic inequalities are to satisfy two conditions: first, they are to be attached to offices and positions open to all under conditions of fair equality of opportunity; and second, they are to be to the greatest benefit of the least advantaged members of society (the difference principle).

As the veil of ignorance and the justice principles indicate, Rawls and other justice theorists all assume the Enlightenment concept of isolated, atomic selves in competition for scarce resources. The significance of justice, then, becomes the assurance of fairness to individuals. Violating the dictates of distributive justice is an offense to the dignity of the collective preferences of autonomous, rational moral agents. The interests of the community may be in conflict with the interests of individuals; yet, confined to the Enlightenment ideal, the needs of society are not directly addressed, nor is society given any priority.

This Enlightenment assumption has been challenged by a number of ethical theories loosely grouped together under the heading **communitarianism**. The dominant themes of communitarianism are that individual rights need to be balanced with social responsibilities; individuals do not live in isolation but are shaped by the values and culture of their communities (Wringer, 2006). Among the theories with a communitarian focus are virtue ethics, caring and the ethic of care, and feminist ethics.

Virtue Ethics

Virtue ethics is one of the oldest ethical theories; it belongs to a tradition dating back to the ancient Greek philosophers Plato and Aristotle. It is not concerned with actions, as utilitarianism

and deontology are, but instead asks: What kind of person should I be? The goal of virtue ethics is to enable persons to flourish as human beings. According to Aristotle, **virtues** are acquired, excellent traits of character that dispose humans to act in accord with their natural good. During the seventeenth and eighteenth centuries, the Greek concept of the good as a principle of explanation went out of favor. In public health nursing the virtue of care, or caring, is central to professional ethics. “The ethics of care emphasizes traits valued in intimate personal relationships such as sympathy, compassion, fidelity and love” (Beauchamp and Childress, 2013, p. 35). Caring refers to the “emotional commitment to, and willingness to act on behalf of, persons with whom one has a significant relationship” (Beauchamp and Childress, 2013, p. 35). Beauchamp and Childress (2013) examine five focal virtues for health professionals. They are (1) compassion, which focuses on the pain, suffering, disability, and misery of another person; (2) discernment, which involves the ability to use sensitive insight, astute judgment, and understanding to make good decisions; (3) trustworthiness, which is essential in health care when clients put themselves in the hands of others; (4) integrity, with a differentiation between moral integrity and professional integrity; and (5) conscientiousness, which is the character trait of acting to achieve what one believes to be the right thing to do given the circumstances. The appeal to virtues results in a significantly different approach to moral decision making in health care (Olson, 2008). In contrast to moral justification via theories or principles, the emphasis is on practical reasoning applied to character development.

HOW TO Apply the Virtue Ethics Decision Process

1. Identify communities that are relevant to the ethical dilemmas or issues.
2. Identify moral considerations that arise from a communal perspective and apply the consideration to specific communities.
3. Identify and apply virtues that facilitate a communal perspective.
4. Modify moral considerations as needed to apply to the specific ethical dilemmas or issues.
5. Seek ethical community support to enhance character development.
6. Evaluate and modify the individual or community character traits that impede communal living.

(Remember that the virtue ethics decision process is one of the approaches in step 5 of the generic ethical decision-making framework.)

Modified from Volbrecht RM: Nursing Ethics: Communities in Dialogue. Upper Saddle River, NJ, 2002, Prentice Hall, p 138.

Caring and the Ethic of Care

Caring in nursing, the ethic of care, and feminist ethics are all interrelated and, historically, all converged between the mid-1980s and early 1990s. Seminal work in caring in nursing was done by nurse-scholars (e.g., Leininger, 1984; Watson, 2007), who wrote about caring as the essence of or the moral ideal of nursing. This conceptualization occurred as a response to the

technological advances in health care science and to the desire of nurses to differentiate nursing practice from medical practice. The discussion of the centrality of caring to nursing is reflected in Eriksson's (2002) work on a caring science theory, which she sees as ethical in its essence. Proponents of caring support its premises; its detractors believe that nursing is not the only essentially caring profession and that caring, when placed within a broader societal context, represents the use of a disempowering concept to identify the essence of nursing. However, most nurses, including those who work in the community, would agree that there is a relationship between caring and ethics or morality.

HOW TO Apply the Care Ethics Decision Process

1. Recognize that caring is a moral imperative.
2. Identify personally lived caring experiences as a basis for relating to self and others.
3. Assume responsibility and obligation to promote and enhance caring in relationships.

(Remember that the care ethics decision process is one of the approaches in step 5 of the generic ethical decision-making framework.)

Carol Gilligan (1982) and Nel Noddings (1984) are often associated with the *ethic of care*. Gilligan (1982) speaks of a personal journey wherein, by listening and talking to people, she began to notice two distinct voices about **morality** and two ways of describing the interpersonal relationships between self and others. Contrary to what has been written about Gilligan and the two distinct voices (i.e., male and female) related to moral judgment, here is what she actually wrote: “The different voice I describe is characterized *not by gender* [italics added] but theme. Its association with women is an empirical observation, and it is primarily through women’s voices that I trace its development. But this association is not absolute, and the contrasts between male and female voices are presented here to highlight a distinction between two modes of thought and to focus [on] a problem of interpretation rather than to represent a generalization about either sex” (Gilligan, 1982, p. 2). Her 1982 book is based on three qualitative studies about conceptions of morality and self and about experiences of conflict and choice. She discovered what she calls the “voice of care” through interviews with girls and women (Beauchamp and Childress, 2013). She identified two modes of moral thinking: an ethic of care and an ethic of rights and justice. Although she did not say that these two modes correlated with gender, she did maintain that men tended to be involved with the ethic of rights and justice whereas women were more likely to affirm an ethic of care centering on responsiveness in “an interconnected network of needs, care, and prevention of harm” (Beauchamp and Childress, 2013, p. 35). From these studies she formulated her basic premises about responsibility, care, and relationships. These premises, in Gilligan’s (1982) own voice, are as follows:

- “Sensitivity to the needs of others and the assumption of responsibility for taking care lead women to attend to voices other than their own” (p. 16).

- “Women not only define themselves in a context of human relationships but also judge themselves in terms of their ability to care” (p. 17).
- “The truths of relationship, however, return in the rediscovery of connection, in the realization that self and other are interdependent and that life, however valuable in itself, can only be sustained by care in relationships” (p. 127).

Noddings’ (1984) personal journey started at a point different from that of Gilligan’s. Noddings noticed that ethics was described in the literature primarily on the basis of principles and logic. The goal for Noddings’ book, therefore, was to express a feminine view that could be accepted or rejected by women or men.

The basic premises of Noddings (1984), in her own voice, are as follows:

- “The essential elements of caring are located in the relation between the one caring and the cared-for” (p. 9).
- “Caring requires me to respond with an act of commitment: I commit myself either to overt action on behalf of the cared-for or I commit myself to thinking about what I might do” (p. 81).
- “We are not ‘justified’—we are obligated—to do what is required to maintain and enhance caring” (p. 95).
- “Caring itself and the ethical ideal that strives to maintain and enhance it guide us in moral decisions and conduct” (p. 105).

What both Gilligan and Noddings have in common has been called a **feminine ethic**, because they believe in the morality of responsibility in relationships that emphasize connection and caring. To them, caring is not a mere nicety but a moral imperative. Nevertheless, a long-term healthy debate has surrounded their premises.

HOW TO Apply the Feminist Ethics Decision Process

1. Identify the social, cultural, legal, political, economic, environmental, and professional contexts that contribute to the identified problem (e.g., underrepresentation of women in clinical trials).
2. Evaluate how the preceding contexts contribute to the oppression of women.
3. Consider how women’s lives are defined by their status in subordinate social groups.
4. Analyze how social practices marginalize women.
5. Plan ways to restructure those social practices that oppress women.
6. Implement the plan.
7. Evaluate the plan and restructure it as needed.

(Remember that the feminist ethics decision process is one of the approaches in step 5 of the generic ethical decision-making framework.)

Modified from Volbrecht RM: Nursing Ethics: Communities in Dialogue. Upper Saddle River, NJ, 2002, Prentice Hall, p 219.

Feminist Ethics

Although feminist ethics finally has entered nursing, for many years, nurses appeared reluctant to embrace feminism and its ethics (Silva, 2008). According to Rogers (2006), the tenets of

feminist ethics are relevant to public health. Rogers notes that a feminist perspective leads us to think critically about connections among gender, disadvantage, and health, as well as the distribution of power in public health processes. Because these issues affect health, feminist perspectives and approaches are important for nursing practice.

What is meant by feminists and feminist ethics? **Feminists** are women and men who hold a worldview advocating economic, social, and political equality for women that is equivalent to that of men. Consequently, feminists reject the devaluing of women and their experiences through systematic oppression based on gender. In analyzing the common good, feminists pay careful attention to power relations that constitute a community, to the rules that regulate it, and to who pays and who benefits from membership in the community (Rogers, 2006). Feminists also can ascribe to the ethic of care.

Feminist ethics encompasses the tenets that women’s thinking and moral experiences are important and should be taken into account in any fully developed moral theory, and that the oppression of women is morally wrong. Study of feminist ethics entails knowledge about and critique of classical ethical theories developed by men as well as ethical theories developed by women. Study of feminist ethics includes knowledge about the social, cultural, political, legal, economic, environmental, and professional contexts that insidiously and overtly oppress women as individuals, or within a family, group, community, or society. Feminists and persons who ascribe to feminist ethics are not passive; they demand social justice and political action, preferably at the societal level and through legislation.

ETHICS AND THE CORE FUNCTIONS OF POPULATION-CENTERED NURSING PRACTICE

The three core functions of public health nursing (i.e., assessment, policy development, and assurance) are discussed in Chapter 1. This discussion, however, did not stress the basic assumption that public health nursing is an ethical endeavor, with moral leadership at its core. Now the links of these three core functions to ethics are described.

Assessment

To review, “**assessment** refers to systematically collecting data on the population, monitoring the population’s health status, and making information available about the health of the community” (see Chapter 1). Three ethical tenets underlie this core function. The first relates to competency related to knowledge development, analysis, and dissemination. An ethical question related to competency is: Are the persons assigned to develop community knowledge adequately prepared to collect data on groups and populations? This question is important because the research, measurement, and analysis techniques used to gather information about groups and populations usually differ from the techniques used to assess individuals. Wrong research techniques can lead to wrong assessments, which in turn may hurt rather than help the intended group or population. A startling example of this is the case of Henrietta Lacks, whose cancerous cervical cells were taken without her or her family’s

knowledge or permission and have now launched a medical revolution and a multimillion-dollar industry as the HeLa cells used in countless medical experiments (Skloot, 2010).

The second ethical tenet relates to virtue ethics or moral character. An ethical question related to moral character is: Do the persons selected to develop, assess, and disseminate community knowledge possess integrity? Beauchamp and Childress (2013) define integrity as the holistic integration of moral character. The importance of this virtue is self-evident: without integrity, the core function of assessment is endangered. Persons with compromised integrity are easy prey for potential or real scientific misconduct. An example of a failure of integrity for nurses would be bias in collecting or reporting based on racism or homophobic grounds.

The third ethical tenet relates to “do no harm.” An ethical question related to “do no harm” is: Is disseminating appropriate information about groups and populations morally necessary and sufficient? The answer to “morally necessary” is yes, but to “morally sufficient,” it is no. The fallacy with dissemination is that there is no built-in accountability that what is disseminated will be read or understood. If not read or understood, harm could come to groups and populations regarding their health status.

Policy Development

To review, “**policy development**” refers to the need to provide leadership in developing policies that support the health of the population, including the use of the scientific knowledge base in making decisions about policy” (see Chapter 1). At least three ethical tenets underlie this core function. First, an important goal of both policy and ethics is to achieve the public good (Silva, 2002). Denhardt and Denhardt (2000), Rogers (2006), and Ruger (2008) among others say that the concept of “the public good” is rooted in citizenship. For example, Denhardt and Denhardt (2000) view citizenship, or what they call “democratic citizenship” (p. 552), as a stance in which citizens play a more substantial role in policy development. For this to occur, citizens must be willing to be both informed about policy, and to do what is in the best interests of the community. The approach is basically one in which the voice of the community is the foundation on which policy is developed, rather than the voice of community and public health administrators.

The second ethical tenet purports that service to others over self is a necessary condition of what is “good” or “right” policy (Silva, 2002). Denhardt and Denhardt (2000) offer three perspectives on this matter:

- *Serve rather than steer.* An increasingly important role of the public servant (e.g., nurses and administrators) is to help citizens articulate and meet their shared interests rather than to attempt to control or steer society in new directions (p. 553).
- *Serve citizens, not customers.* The public interest results from a dialogue about shared values rather than the aggregation of individual self-interests. Therefore, public servants do not merely respond to the demands of “customers” but focus on building relationships of trust and collaboration with and among citizens (p. 555).
- *Value citizenship and public service above entrepreneurship.* The public interest is better advanced by public servants and

citizens committed to making meaningful contributions to society rather than by entrepreneurial managers acting as if public money were their own (p. 556).

Service is at the core of these three perspectives, and service has always been one of the enduring values of nursing.

The third ethical tenet holds that what is ethical is also good policy (Silva, 2002). What is ethical should be the singular foundational pillar on which nursing is based. Moral leadership is critical to policy development because it is the highest human standard and therefore should result in ethical health care policies.

Assurance

To review, “**assurance**” refers to the role of public health in ensuring that essential community-oriented health services are available, which may include providing essential personal health services for those who would otherwise not receive them. Assurance also refers to making sure that a competent public health and personal health care workforce is available” (see Chapter 1). At least two ethical tenets underlie this core function.

The first purports that all persons should receive essential personal health services or, put in terms of justice, “to each person a fair share” or, reworded, “to all groups or populations a fair share.” This is an egalitarian perspective of justice. This perspective does not mean that all persons in a society should share all of society’s benefits equally, but that they should share at least those benefits that are essential. People who see justice as fairness often think that basic health care for all is essential for social justice within a society. The case in Box 6-3 provides an example where the nurse needs to balance the client’s right to autonomy and the principle of distributive justice.

The second ethical tenet purports that providers of public health services be competent and available. Although the Public Health Code of Ethics (Public Health Leadership Society [PHLS], 2002) does not speak directly to workforce availability, it does speak directly to ensuring professional competency of public health employees. In addition to the Public Health Code of Ethics, the *Healthy People 2020* objectives (U.S. Department of Health and Human Services [USDHHS], 2010) addresses competencies and workforce needs; a new objective (HP 2020-6) calls for an increased number of health care professionals certified in geriatrics.

The *Healthy People 2020* objectives address the need for all public health workers not only to have knowledge of public health, but also to have additional competencies as needed to fulfill their job responsibilities. Specific areas of knowledge include information technology, biostatistics, environmental health, cultural and linguistic competence, and genomics. The objectives also address needs of future public health leaders, who must be educated to meet new challenges in health care. Emphasis is also given to the availability and provision of life-long learning opportunities for public health employees.

NURSING CODE OF ETHICS

As noted in the history section of this chapter, the Code of Ethics for Nurses with Interpretive Statements was adopted by

BOX 6-3 Case #1: Autonomy and Distributive Justice

Amelia Lewis, a 31-year-old African American woman with multiple mental health diagnoses, has been monitored in the local mental health system for over 10 years. She is the mother of Tyesha, who is 3 years old. Multiple agencies have monitored Ms. Lewis and her little girl, who live in a sparsely furnished apartment in subsidized housing. A guardian handles all of Ms. Lewis's financial affairs. Ms. Lewis's relationship with the father of Tyesha has deteriorated, and he does not live with her.

Ms. Lewis has issues of trust, and she is often suspicious of the care providers who come to her home. She does rely on some of the professionals with whom she interacts on a weekly or biweekly basis. She is both cognitively delayed and suffers from schizophrenia. Her developmental level places her at a stage at which her own needs are her primary focus, and this is not expected to change; her interaction with Tyesha is perfunctory, involving little outward affection. She is unable to understand that Tyesha is not capable of self-care and that her 3-year-old child will not always obey when Ms. Lewis instructs her to do something. Tyesha's needs, level of functioning, and cognitive development are quickly surpassing her mother's ability to cope. Frustration and misunderstanding ensue when Ms. Lewis thinks that Tyesha does not listen to her, and encouragement and parent education have done little to improve the situation as Tyesha gets older and more assertive. This has made toilet training, provision of an appropriate diet, and other aspects of normal child care problematic.

Many services besides those for mental health are involved to help this family of two cope. There is concern about abuse or neglect of Tyesha due to Ms. Lewis's lack of understanding of how to be a parent. Supplemental Security Income provides monetary support because of her mental disability and they have Medicaid coverage for their health care needs, as well as food stamps and modest financial assistance through Temporary Assistance for Needy Families (TANF). Ms. Lewis cannot currently work and take care of her child due to her mental disability. Before Tyesha's birth, Ms. Lewis held a job and maintained self-care, but the care of Tyesha has precluded her managing employment at this time. Child Protective Services are also monitoring Ms. Lewis's situation to

determine to what extent she can meet the needs of her child. Ms. Lewis attends a local program to complete her General Education Development (GED), which provides child care during the day. Though Ms. Lewis is not expected to complete her GED, this program provides structured time for Tyesha three times a week. The child is considered developmentally normal at this time, and an infant development program monitors her progress on developmental issues. The Child Health Partnership, an agency that addresses the needs of challenged families, provides regular visits, family support, and parenting education, and the GED teachers make regular home visits to check on Ms. Lewis and Tyesha. Ms. Lewis thinks things are going just fine.

The Child Health Partnership nurse is concerned about this family and thinks that some permanent resolution of the situation is inevitable. There is minimal coordination of services and there is no "lead agency" in the family's care. Choose one of the ethical decision processes or one set of code of ethics discussed in the chapter and discuss and debate these questions:

1. Should the nurse involved in the Child Health Partnership program initiate any action to try to coordinate the work of the many agencies involved with this family?
2. Who has a professional responsibility to determine when the mother can no longer cope with the developing child?
3. Whose needs, Ms. Lewis's or Tyesha's, should take precedence?
4. Using one of the ethics decision processes, analyze the role of the nurse in this situation. For example, considering the utilitarian ethics decision process, decide if it is morally right for you to take the child away from the mother? If you do this, what are the implications for the mother, the child, and the community? What would be the possible consequences of removing the child? Of not removing the child? What principles can best guide your decision making? What possible moral dilemmas will you experience?
5. Safety is a core concept of public health nursing. Using two of the six quality and safety competences (patient-centered care and safety) for nurses identified in the *Quality and Safety Education for Nurses (QSEN)* work, develop a plan of action for the nurse who is caring for this family.

Created by Mary E. Gibson, Assistant Professor, School of Nursing, University of Virginia.

the ANA House of Delegates in 2001. The Code was revised in 2015 and consists of nine provisions and the accompanying interpretive statements. The Code provides the following:

- A succinct statement of the ethical values, obligations and duties of every individual who enters the nursing profession
- Serves as the profession's nonnegotiable ethical standard
- Expresses nursing's own understanding of its commitment to society (p. 5)

These purposes are reflected in the nine provisional statements of the code. The Code of Ethics for Nurses and its interpretive statements apply to population-centered nurses, although the emphasis for each type of nursing sometimes varies (for the ANA Code of Ethics for Nurses, see <http://www.nursingworld.org/MainMenuCategories/EthicsStandards/CodeofEthicsforNurses.aspx>).

As previously noted, the American Nurses Association has produced a *Guide to the Code of Ethics for Nurses: Interpretation and Application*, which serves as a companion reader to the 2001 Code of Ethics for Nurses (Fowler, 2008). This reader contains specific applications to nursing practice for each of the code's nine interpretive statements.

Whereas provisions 1 through 3 focus on the recipients of nursing care, provisions 4 through 6 focus on the nurse. This

focus addresses nurses' accountability, competency, and contributions to their employment conditions.

Provisions 7 through 9 focus on the bigger picture of both the nursing profession and national and global health concerns. Regarding the nursing profession, the emphasis is on professional standards, active involvement in nursing, and the integrity of the profession. All nurses have a responsibility to meet these obligations. Regarding national and global health concerns, the emphasis is on social justice and reform. According to the ANA code (2015, p xi), The Code specifies that the patients and clients of nurses can be "individuals, families, communities or populations." The Code also specifies that health is a universal right and this right has economic, political, social and cultural dimensions. Many of the components of the Code support and help to elaborate on the ethical responsibilities related to chapters and content throughout the text such as genomics, social determinants of health, cultural uniqueness and so forth, the [Levels of Prevention box](#) presents actions related to ethics.

PUBLIC HEALTH CODE OF ETHICS

The Public Health Code of Ethics (PHLS, 2002) mentioned in the history section of this chapter consists of a preamble; 12

LEVELS OF PREVENTION

Ethics

Primary Prevention

Use the Code of Ethics for Nurses to guide your nursing practice.

Secondary Prevention

If you are unable to behave in accordance with the Code of Ethics for Nurses (e.g., you speak in a way that does not communicate respect for a client), take steps to correct your behavior. You could explain to the client your error and apologize.

Tertiary Prevention

If you have treated a client or staff member in a way that is inconsistent with ethics practices, seek guidance on other choices you could have made.

principles related to the ethical practice of public health (Box 6-4); 11 values and beliefs that focus on health, community, and action; and a commentary on each of the 12 principles. The preamble asserts the collective and societal nature of public health to keep people healthy. The 12 principles incorporate the ethical tenets of preventing harm; doing no harm; promoting good; respecting both individual and community rights; respecting autonomy, diversity, and confidentiality when possible; ensuring professional competency; manifesting trustworthiness; and promoting advocacy for disenfranchised persons within a community. Examples of values and beliefs include a right to health care resources, the interdependency of humans living in the community, and the importance of knowledge as a basis for action. The Healthy People box cites two new objectives that relate to ethics.

When the Code of Ethics for Nurses and the Public Health Code of Ethics are assessed, some commonalities emerge. These codes provide general ethical principles and approaches that are both enduring and dynamic. They guide nurses and public health personnel in thinking about the underlying ethics of their profession. Although the two codes do not specify

HEALTHY PEOPLE 2020

There are two new objectives outlined in *Healthy People 2020* related to access to health services:

- AHS-1: Increasing the proportion of persons who receive appropriate evidence-based clinical preventive services
- AHS-4: Increasing the proportion of practicing primary care providers, including nurse practitioners.

Both of these objectives relate to access to care and reflect important ethical considerations for nurses.

From U.S. Department of Health and Human Services: *Healthy People 2020*. Retrieved December 2014 from <http://www.healthypeople.gov>.

(nor should they specify) details for every ethical issue, other mechanisms such as standards of practice, ethical decision-making frameworks, and ethics committees help work out the details. Nevertheless, the preceding two codes address most approaches to ethical justification, including traditional and emerging ethical theories and principles, humanist and feminist ethics, virtue ethics, professional-individual and/or community relationships, and advocacy. Many websites provide further information on codes of ethics and other ethical concerns in public health; all can be accessed through the WebLinks section of this book's Evolve website. Some of them are noted in the Additional Resources feature at the beginning of the chapter.

ADVOCACY AND ETHICS

Advocacy is an important concept in nursing that embodies an ethical focus grounded in quality of life. The American Public Health Association (APHA) represents a powerful voice for public health advocacy, focusing on finding ways to involve health care professionals in influencing policies related to protection of all Americans and their communities from preventable, serious health threats and helping to ensure access to health care and eliminating health disparities (APHA, 2014).

BOX 6-4 Principles of the Ethical Practice of Public Health*

1. Public health should address principally the fundamental causes of disease and requirements for health, aiming to prevent adverse health outcomes.
2. Public health should achieve community health in a way that respects the rights of individuals in the community.
3. Public health policies, programs, and priorities should be developed and evaluated through processes that ensure an opportunity for input from community members.
4. Public health should advocate and work for the empowerment of disenfranchised community members, aiming to ensure that the basic resources and conditions necessary for health are accessible to all.
5. Public health should seek the information needed to implement effective policies and programs that protect and promote health.
6. Public health institutions should provide communities with the information they have that is needed for decisions on policies or programs and should obtain the community's consent for their implementation.
7. Public health institutions should act in a timely manner on the information they have, within the resources and the mandate given to them by the public.
8. Public health programs and policies should incorporate a variety of approaches that anticipate and respect diverse values, beliefs, and cultures in the community.
9. Public health programs and policies should be implemented in a manner that most enhances the physical and social environment.
10. Public health institutions should protect the confidentiality of information that can bring harm to an individual or community if made public. Exceptions must be justified on the basis of the high likelihood of significant harm to the individual or others.
11. Public health institutions should ensure the professional competencies of their employees.
12. Public health institutions and their employees should engage in collaborations and affiliations in ways that build the public's trust and the institution's effectiveness.

*A section of the Public Health Code of Ethics is presented.

BOX 6-5 Case #2: Applying Virtue Ethics, Truth Telling, and the Deontological Ethical Decision-Making Process

Because finding affordable housing was difficult, 26-year-old Terry White lived with her 6-month-old son, Tommy, and his father, Billy Smith, in one room of the landlord's own house. Ms. White was morbidly obese and was diagnosed with bipolar disease; Mr. Smith had served time for drug dealing and was out on parole and staying straight. Neither had finished high school. Mr. Smith's past drug use had rendered him unable to do much manual labor because of heart damage, but on occasion he would work in construction to support the family.

Public health nurse Jim Lewis had received a referral on Tommy when he was diagnosed with failure to thrive (FTT) 2 months earlier. Ms. White, who had had two children removed from her custody by Child Protective Services (CPS) in the past, and Mr. Smith seemed to adore their baby, so much so that Ms. White would hold the baby all day long. In the past 2 months, the nurse had taught Ms. White about infant nutrition and gotten her enrolled in the Women, Infants, and Children (WIC) nutrition program; as a result, Tommy had increased his rate of physical growth and was above the 5% level of his growth percentile. Yet he was not meeting his gross motor milestones per Denver Developmental Screening Test II (DDST II) testing. Mr. Lewis thought that Tommy was not allowed to play on the floor enough to progress in sitting, pushing his shoulders up, or crawling. Most of their small room was taken up with the bed and the boxes that stored their belongings. There wasn't really space for "tummy time" or play. When not in the room, the family would take the bus to a discount store and spend the day walking around to get a change of scene.

One week Ms. White told the nurse she was not taking her medications for bipolar disease anymore because they caused her to gain weight. The next week she confided that Mr. Smith had had a "dirty" urine specimen check and would have to return to prison in the near future. The following week Mr. Lewis found

the family living in a run-down motel since their landlord evicted them following a disagreement. Ms. White was agitated and told the nurse that they had only \$100. Mr. Smith was going to have to return to prison that week, and the motel bill was already \$240. Ms. White knew she would be homeless soon without Mr. Smith's support but refused to talk with her social worker about her needs. She asked the nurse not to tell anyone about her situation because she was afraid CPS would take Tommy from her. It was clear to Mr. Lewis that Ms. White might not know what would happen to Tommy after they left this motel.

1. Considering the principle of truth telling, what are Mr. Lewis' professional responsibilities to Ms. White, to Tommy, and to the social worker assigned to this family?
2. Using the generic ethical decision-making framework discussed earlier in the chapter and considering the deontological ethical decision-making process, answer the following questions.
 - A. How should Mr. Lewis respond to Ms. White's request to not tell anyone about their situation?
 - B. What communication, about truth telling, if any, should the nurse initiate with the social worker? With others?
 - C. Consistent with the principle of truth telling, how can the nurse involve Mr. Smith in the ongoing support and involvement with his family?
3. Using virtue ethics, what actions would you take to resolve any moral dilemmas you have about the safety of Tommy in this family situation? If you do not tell anyone about the possible dangers to the child, what moral principles come into play? If you do tell the social worker about the situation and the child is removed from the mother, what moral principles come into play for you?
4. What ethical dilemmas may you experience if you are the nurse in this case? How can you deal effectively with these potential dilemmas?

Created by Deborah C. Conway, Assistant Professor of Nursing, School of Nursing, University of Virginia.

The APHA notes the critical need to shift from a nation focused on treating individual illness to one that also promotes population-based health services that encourage preventive and early intervention practices. Also, the field of genetics has increasingly become an important ethical focus in public health; two new *Healthy People 2020* objectives relate to genomics (G HP2020-1, G HP2020-2). The clinical case in [Box 6-5](#) discusses the application of virtue ethics, truth telling and the deontological ethical decision-making process.

Codes and Standards of Practice

Several codes and standards of practice address advocacy. Four are noted here. Advocacy is addressed in codes of ethics put forth by the ANA (2015) and the Public Health Leadership Society (PHLS, 2002), as well as by the ANA (2013) in Standard 17, Public Health Nursing: Scope & Standards of Practice and the PHLS Skills for the Ethical Practice of Public Health (Thomas, 2004). The American Association of Colleges of Nursing (AACN) has developed a document entitled *Recommended Baccalaureate Competencies and Curricular Guidelines for Public Health Nursing* that added specific public health nursing education competencies to their competencies for baccalaureate education. Several of the competencies include a recommendation to include specific content related to ethics and public health nursing (AACN, 2013).

According to the ANA (2015) Code of Ethics for Nurses, "The nurse promotes, advocates for, and protects the rights, health, and, safety of the patient" (p. 9). The focus of the interpretive statements regarding advocacy is the nurse's responsibility to take action when the client's best interests are jeopardized by questionable practice on the part of any member of the health team, the health care system, or others.

The Public Health Code of Ethics (PHLS, 2002) and the PHLS Skills for the Ethical Practice of Public Health (Thomas, 2004) state that public health should advocate for disenfranchised community members, aiming to ensure that the basic resources necessary for health are accessible to all. The PHLS's code addresses two important issues: that the voice of the community should be heard and that the marginalized or underserved in a community should receive "a decent minimum" (p. 4) of health resources.

According to the *ANA Public Health Nursing: Scope & Standards of Practice* (2013), public health nurses have a moral mandate to establish ethical standards when advocating for health care policy. Specifically, Standard 7 says that public health nurses should practice ethically.

Conceptual Framework for Advocacy

One framework that can be used to define helpful behaviors for advocacy is to contrast social justice and market justice

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

One of the six tenets of Quality and Safety Education for Nurses (QSEN) is patient-centered care (Barton et al, 2009). This chapter has discussed many ways in which an understanding of basic principles of ethics can guide safe and effective nursing practice. Some key aspects of patient-centered care in public health nursing include being certain that the information provided to individuals, families, and communities is accurate and reflects the most current evidence, and that it is presented in a timely fashion. Community health education should take into account the age, gender, and cultural and religious backgrounds of those who receive the information. Giving health information that does not meet these criteria can be unsafe and clearly does not reflect attention to quality nursing care. One of the QSEN competencies related to patient-centered care is as follows: Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs. Specific aspects of patient-centered care related to communication are as follows:

- **Knowledge:** Integrate understanding of multiple dimensions of patient-centered care: information, communication, and education.
- **Skills:** Communicate patient values, preferences, and expressed needs to other members of the health care team.

- **Attitudes:** Respect and encourage individual expression of patient values, preferences, and expressed needs (Barton et al, 2009, p. 315).

Specific aspects of patient-centered care related to the public health dilemma of serving the good of the population versus serving the good of the individual are as follows:

- **Knowledge:** Explore ethical and legal implications of patient-centered care.
- **Skills:** Recognize the boundaries of therapeutic relationships (Barton et al, 2009, p. 315).
- **Attitudes:** Acknowledge the tension that may exist between patient rights and the organizational responsibility for professional ethical care.

Patient-centered ethical activity: Public health is more concerned about the good of the collective group than of the individual. In order to think more closely about quality and safety, debate with a classmate about whether children should be required to have all of the Centers for Disease Control and Prevention vaccines before they can enter school or remain the school. At the present time, some parents are choosing not to give their children all the recommended immunizations because of fear of side effects of the vaccines. To support your argument see <http://www.cdc.gov/vaccines/schedules/index.html> for what is required. See web articles such as www.responsibility-project.libertymutual.com for the parents' point of view.

Park EJ: The development and implications of a case-based computer program to train ethical decision-making. *Nurs Ethics* 20:943–956, 2013.

TABLE 6-2 Contrast of Social Justice and Market Justice as an Advocacy Framework

Market Justice Values	Social Justice Values
Self-determination and self-discipline	Shared responsibility
Individual values and self-interest	Interconnection and cooperation among individuals in a community
Personal efforts key to desired benefits	Community shares responsibility for providing basic benefits
Limited responsibilities for good of the community	Important obligations for the collective good
Limited government intervention	Government involvement is necessary
Voluntary focus on individual moral behavior	Community well-being supersedes individual focus on well-being

Adapted from Dorfman L, Wallack L, Woodruff K: More than a message: framing public health advocacy to change corporate practices. *Health Educ Behav* 32:320–336, 2005.

(Dorfman et al, 2005). As noted earlier in this chapter, it is important to recognize the potential conflict of individuals versus society. With communitarianism, individual rights need to be balanced with social responsibilities. When using a framework that contrasts social justice and market justice, the biggest barrier to achieving social justice is the competing concept of market justice. Market justice is grounded in the assumption that the best way to meet the needs of individuals in a society is to avoid regulations. The focus is on individual, not shared, needs (Table 6-2). A focus on market justice, rather than social justice, influences public dialogue about public health needs. It is important that existing values and beliefs in the society be understood in order to frame the public health message appropriately in terms of social justice values that relate to changes that they seek. Health care professionals must develop media

BOX 6-6 Ethical Principles for Effective Advocacy

1. Act in the client's best interests.
2. Act in accordance with the client's wishes and instructions.
3. Keep the client properly informed.
4. Carry out instructions with diligence and competence.
5. Act impartially and offer frank, independent advice.
6. Maintain client confidentiality.

skills to compete effectively with adversaries in public debate and learn to frame their advocacy initiatives.

Practical Framework for Advocacy

Bateman (2000) takes a practical approach to advocacy. He places the advocate's core skills (i.e., interviewing, assertiveness and force, negotiation, self-management, legal knowledge and research, and litigation) within the context of six ethical principles for effective advocacy, as shown in Box 6-6. His focus is on the individual client, although the focus could also apply to groups and communities.

Regarding the first ethical principle, Bateman (2000) is sensitive to the ethical conflict between clients' best interests and the best interests of groups, communities, or societies but does not elaborate on this conflict. The second ethical principle, which puts the client in charge, works in tandem with the first principle. It goes like this: "This is what I think we can do. What do you want me to do?" (Bateman, 2000, p. 51). Of course, the advocate can refuse the request if self or others may be harmed. By following the third ethical principle, the client is empowered to make knowledgeable decisions. The fourth ethical principle addresses standards of practice. The fifth ethical principle addresses fairness and respect for persons (population-centered

nursing is more collaborative in nature than independent nursing). The last ethical principle, confidentiality, ensures that information will be shared only on a need-to-know basis.

Advocacy: Issues that Have Ethical Implications

Advocacy and Bioterrorism

Before the terrorist attacks in the United States on September 11, 2001, the subject of terrorism was not a major focus in philosophical discussions (*terrorism*, in [Stanford Encyclopedia of Philosophy, 2007](#)). The September 11th attack, however, brought a frightening new awareness of the vulnerability of individuals and groups in our society and the need for advocacy. Although some countries have been forced to live with the knowledge of this type of vulnerability for years, today's reality of global terrorism means that nurses must thoughtfully reflect on and debate ethical issues that arise with the threat, action, and aftermath of terrorism. They also must carefully consider their own responsibilities in terms of moral obligation to respond and make themselves available in a crisis that threatens the well-being of a community.

As noted at the beginning of this chapter, population-centered nursing is concerned with protecting, promoting, preserving, and maintaining health while preventing disease. These goals that address the promotion of good and prevention of harm are intimately related to ethics and bioterrorism. It is often difficult to balance goals for the protection of the public and protection of the individual, as evidenced by an incident in which airport security personnel ordered a 4-year-old disabled child to remove his leg braces to go through a metal detector, even though his mother told the screeners that the child could not walk without the braces ([Rubin, 2010](#)). As a nurse, it is often hard when confronted with terrorism or a disaster to determine whether the needs of one's family or the needs of one's clients predominate. [Silva and Ludwick \(2003\)](#) provide a helpful framework related to the need for advocacy in bioterrorism, using the principles of nonmaleficence, beneficence, and distributive justice. These principles can guide nurses as they learn to speak out against violence and terrorism, work with agencies in the community for short-term and long-term efforts to do good and avoid harm, and participate in policy debates that attempt to determine fair distribution of scarce resources to fight terrorism globally. The ANA Center for Ethics and Human Rights maintains a helpful list of resource information addressing biodefense at <http://www.nursingworld.org/MainMenuCategories/ThePracticeofProfessionalNursing/EthicsStandards/CEHR.aspx>.

Advocacy and Health Care Reform

In the current focus on health care reform, it is critical that nurses advocate for reform that embodies ethical considerations that have been discussed in this chapter. Dr. Mary Wakefield, Administrator of the Health Resources and Services Administration (HRSA), noted that not only should nurses participate in implementing new directions for health care, but that it is important that they help to envision these new directions ([Wakefield, 2008](#)). Nurses can be an important voice in advocating for access to consistent, effective, efficient health care for all in our society. Wakefield says that educating the public can be a unique challenge because clever sound bites and attack ads in the media can lure consumers into thinking that the status quo is the best option. Nurses are an important part of the health care industry and are respected by the public; they can make meaningful contributions toward health care reform through advocating for clients and families. The signing of the 2010 health care bill by President Obama, after many years of controversial attempts at health care reform, provides an excellent opportunity for nurses to advocate for tying health care for all to ethics and social justice.

Ethical Use of Social Media

As the trend for using social media grows in both personal and professional arenas the implications for establishing boundaries for its use by health care professionals also grow. As [Baker \(2013, p. 501\)](#) says, "If the risks (of using social media) are managed well, social media can be a positive force for patient advocacy and education, as well as a resource for evidence-based practice and research." She points out that nurses should practice within defined professional boundaries that center around four key elements: (1) promoting the dignity of the clients, (2) seeking client independence and working for their best interests, (3) abstaining from inappropriate involvement with clients, and (4) refraining from personal gain at the expense of the client. Ethical dilemmas arise when nurses act in ways that are not consistent with their professional boundaries. [Baker \(2013\)](#) points out that it is important to think through ethical concerns that are associated with social networking. This can be especially important when the nurse lives and works in a small community. For example, consider the public health nurse who goes to church with clients, attends the same parent-teacher meetings, and shops at the same stores as they do. Is it appropriate for her to then "friend" these clients on a social media site? [Chapter 19](#) discusses rural health, and the issue of close relationships between nurses and clients is described there.

LINKING CONTENT TO PRACTICE

Throughout this chapter, there has been application of the content related to ethics in public health nursing and the many documents that influence the role of public health nurses. These include the ANA Scope and Standards of Public Health Nursing, the ANA Code of Ethics, the core functions of public health as outlined by the Institute of Medicine, and the *Healthy People 2020* objectives. Ethics is also an integral part of the Core Competencies for Public Health Professionals. Skill 8 in the section on analytic/assessment skills says that a

public health professional uses "ethical principles in the collection, maintenance, use, and dissemination of data and information" and skill 2 under leadership and systems thinking says a professional "incorporates ethical standards of practice as the basis of all interactions with organization, communities, and individuals" ([Council on Linkages between Academic and Public Health Practice, 2010](#)).

PRACTICE APPLICATION

The retiring director of the division of primary care in a state health department had recently hired Ann Green, a 34-year-old nurse with a master's degree in public health, to be director of the division. Ms. Green's work involved the monitoring of millions of dollars of state and federal money as well as the supervising of the funded programs within her division.

Ms. Green received many requests for funding from a particular state agency that served a poor, large district. The poor people of the district primarily consisted of young families with children and homebound older adults with chronic illnesses. Over the past 3 years, the federal government had allocated considerable money to the state agency to subsidize pediatric primary care programs, but no formal evaluation of these programs had occurred.

The director of the state agency was a physician who had been in this position for over 20 years. He was good at obtaining funding for primary care needs in his district, but the statistics related to the pediatric primary care program seemed

implausible—that is, few physical examinations were performed on the children, which had resulted in extra money in the budget. This unspent federal money was being used to supplement home health care services for the indigent homebound older adults in his district. The thinking of the physician was that he was doing good by providing some needed services to both indigent groups in his district. Ms. Green felt moral discomfort because she did not have either the money or the personnel to provide both services. What should she do?

A. What facts are the most relevant in this scenario?

B. What are the ethical issues?

C. How can Ms. Green resolve the issues?

(The preceding case and answers are adapted and paraphrased from a real practice application shared by J.L. Chapin on the inappropriate distribution of primary health care funds [in Silva M, editor: *Ethical Decision Making in Nursing Administration*. Norwalk, CT, 1990, Appleton & Lange].)

Answers can be found on the Evolve site.

KEY POINTS

- Nursing has a rich heritage of ethics and morality, beginning with Florence Nightingale.
- During the late 1960s, the field of bioethics began to emerge and influence nursing.
- Ethical decision making is the component of ethics that focuses on the process of how ethical decisions are made.
- Many different ethical decision-making frameworks exist; however, underlying each of them is the problem-solving process.
- Ethical decision making applies to all approaches to ethics: utilitarianism, deontology, principlism, virtue ethics, caring and the ethic of care, and feminist ethics.
- Cultural diversity makes ethical decision making more challenging.
- Moral distress can lead to a personal sense of failure in providing nursing care and may lead to work and/or career dissatisfaction.
- Classical ethical theories are utilitarianism and deontology.
- Principlism consists of respect for autonomy, nonmaleficence, beneficence, and justice.
- Other approaches to ethics include virtue ethics, caring and the ethic of care, and feminist ethics.
- The core functions of public health nursing (i.e., assessment, policy development, and assurance) are all grounded in ethics.
- *Healthy People 2020* objectives address workforce competencies, training in essential public health services, and continuing education.
- The 2015 Code of Ethics for Nurses contains nine statements that address the moral standards that delineate nursing's values, goals, and obligations.
- The 2002 Public Health Code of Ethics contains 12 statements that address the moral standards that delineate public health's values, goals, and obligations.
- Advocacy is the act of pleading for or supporting a course of action on behalf of a person, group, or community.
- Effective advocacy incorporates ethical principles and concepts.
- The Code of Ethics for Nurses, the Public Health Code of Ethics, Skills for the Ethical Practice of Public Health, and Public Health Nursing: Scope & Standards of Practice all address advocacy.
- Public health advocacy is composed of both products and processes.
- The products of advocacy are decreased morbidity and mortality.
- The processes of public health advocacy include, but are not limited to, identifying problems, collecting data, developing and endorsing regulations and legislation, enforcing policies, and assessing the policy process.
- Advocacy related to bioterrorism, health care reform, and ethical use of social media is important for community and public health nurses.

CLINICAL DECISION-MAKING ACTIVITIES

1. Think about the differences in duties between a nurse working in a critical care facility and a nurse working in a community care or public health setting. How might these differences lead to differences in ethical problems and decision making?
2. Interview a long-retired nurse about the most important ethical issues that this nurse faced when practicing in the community. Next, interview a nurse actively practicing in the community about the most important ethical issues that this nurse is now facing. Compare and contrast the ethical issues in the two interviews and place each within a historical context.
3. In a local or national newspaper, read one or more articles that discuss health care public policy with which you agree or disagree. Compose a letter to the editor analyzing why you agree or disagree with the policy but only after you take into account any of your own biases or vested interests.

Cultural Diversity in the Community

Cynthia E. Degazon, RN, PhD

Dr. Cynthia E. Degazon is professor emerita at Hunter College, City University of New York. She received a BS in nursing from Long Island University, and an MA in Community Health nursing and a PhD from New York University. For 20 years she has prepared undergraduate and graduate nurses to provide culturally competent care to ethnically diverse populations. Dr. Degazon has given many national and international presentations, authored several scholarly publications, and served on the editorial board of the *Journal of Cultural Diversity*.

Bobbie J. Perdue, RN, PhD

Dr. Bobbie Perdue is Professor of Nursing at South Carolina State University in Orangeburg, South Carolina. She is professor emerita at Syracuse University. Her teaching career in nursing spans 43 years and includes the teaching of associate degree, baccalaureate, and master degree nursing students. She received a BSN from Vanderbilt University, an MSN in child-psychiatric mental health nursing from Wayne State University, and a PhD in nursing research and theory development from New York University.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Describe the process for developing cultural competence to meet the health care needs of culturally diverse individuals, communities, and organizations.
2. Describe major facilitators and barriers to providing quality health care for diverse populations.
3. Identify culturally competent nursing interventions to promote positive health outcomes for culturally diverse clients.
4. Evaluate the role of the public health nurse in providing culturally competent nursing care.
5. Use a case scenario to chart the five elements of cultural competence as described by Campinha-Bacote.
6. Use electronic resources to locate current databases about culturally competent practices that reduce health disparities.

Cultural Nursing Assessment

Caring for culturally diverse groups has been a focus of nursing from its beginning. As early as 1893, under the leadership of Lillian Wald, nurses in New York City started public health nursing and provided home care to inner city people, particularly immigrants, who could neither read nor write the English language (Anderson and McFarlane, 2010). Because nurses were not from the same cultural background as the immigrants, they had to deal with the cultural differences between themselves and the persons in their care. Today, the U.S. culture reflects a greater diversity of cultures from all over the world and assuring that individuals from these diverse cultures receive equity in health care is as much a challenge for nurses as it was during Lillian Wald's era. Such assurance is viewed as a moral imperative to reduce health disparities.

Data from the [U.S. Census Bureau \(2010\)](#) showed that (72.4%) of the U.S. population defined themselves as a member of a non-Hispanic white ethnic group followed by African Americans (12.6%), Asian Americans (4.8%), American Indians/Alaskan Natives (0.9%), Native Hawaiian and other Pacific Islanders (0.2%), some other race (6.2%), and two or more races (2.9%). Hispanic origin was considered to be a separate concept from race but accounted for 16.4% of the

population with those predominantly identified as white or as some other race. Data also showed a decrease from the 2000 census when the white population accounted for 75.1%. This pattern of a decreasing white population is attributed to rapidly growing Hispanic populations, a strong increase in the Asian populations, a modest increase in Americans of African descent, and an increase in persons who identify as white in combination with another race.

Culture and language have a significant influence on health, belief systems, health practices, and health outcomes. As social determinants of health, they affect how clients and nurses perceive illness, and causes of and treatment of diseases. They contribute to the behaviors and attitudes that clients have about health care and the providers who care for them. As a result of this diversity, significant differences in beliefs and practices about health and illness have become apparent in health care systems. Nurses who want to incorporate their client's beliefs of health and illness when intervening to promote and maintain wellness face many challenges.

Nurses need to understand the sociocultural views that affect perceptions of an illness, as well as the pathophysiology of the illness. According to the [American Association of Colleges of](#)

[Nursing \(2014\)](#), the nursing workforce is overwhelmingly white (83%): African Americans account for 6%, Asian or Pacific Islanders 6%, Hispanics 3%, American Indian/Alaskan Natives 1%, Native Hawaiian/Pacific Islanders 1%, and 1% “other” nurses. There is also a small cadre of minority students enrolled in nursing schools ([Phillips and Malone, 2014](#)) even though clients are often more satisfied with nursing care when they have an ethnic connection with the provider of that care. Minority clients, in contrast to their white counterparts, are at greater safety risk in health care facilities as measured by the incidence of medical errors, length of hospital stay for a specific illness, and the number of laboratory tests ordered ([Beacham et al, 2009](#); [Smedley et al, 2002](#)).

This chapter provides nurses with strategies to use in providing culturally competent care to diverse clients (individuals, aggregates, families, and communities) who may not share the nurse’s culture. Although the chapter is population-focused, it emphasizes knowledge development in the care of clients from five culturally diverse marginalized groups: African Americans, Asian Americans, Hispanic Americans, Native American/Alaskan Natives, and immigrants.

There is much cultural and ethnic diversity present within and among these marginalized groups; they are consistently identified in the literature as more vulnerable, have less access to health care, receive a poorer quality of health care, have higher rates of chronic illnesses, and shorter life expectancies than Anglo-white groups ([Agency for Healthcare Research & Quality, 2014](#); [Agency for Healthcare Research & Quality, 2012](#)). Many groups other than racial and ethnic groups also differ from the expected norms relative to place of origin, sexual orientation, gender identity, educational background, literacy, income, and language. Individuals who are members of these subcultures are marginalized by the dominant health care culture as well. However, evidence is beginning to show a narrowing of the health gap among these groups for some of the access and quality measures.

CULTURE, RACE, AND ETHNICITY

Culture

Culture is a set of beliefs, values, and assumptions about life that are widely held among a group of people and is transmitted intergenerationally ([Leininger, 2002a](#)). The term *culture* encompasses a broad range of concepts. It is an individual concept, a group phenomenon, and an organizational reality. Culture pervades all aspects of life and of health care. Culture determines how health care information is processed, received, and distributed; how rights and protections are exercised; what is considered to be a health problem; how symptoms and concerns of the problem are expressed; who provides treatment for the problem; and what type of treatment should be given ([Giger, 2012](#); [Purnell and Paulanka, 2012](#); [Spector, 2012](#)). Culture is applicable not only to minority groups, but also to majority groups such as white Americans of European descent (i.e. Irish, Italian, and Russian). Individuals are usually members of more than one culture. Each individual should be viewed as a unique human being with differences that are respected. [Box 7-1](#)

BOX 7-1 Factors Influencing Individual Differences Within Cultural Groups

- Age
- Religion
- Dialect and language spoken
- Gender identity roles
- Socioeconomic background
- Geographic location in the country of origin
- Geographic location in the current country
- History of the subcultural group with which clients identify in their current country of residence
- History of the subcultural group with which clients identify in their country of origin
- Amount of interaction between older and younger generations
- Degree of assimilation in the current country of residence
- Immigration status*
- Conditions under which migration occurred

Except where noted with an asterisk, from [Orque M](#): Orque’s ethnic/cultural system: a framework for ethnic nursing care. In Orque MS, Bloch B, Monrroy LSA, editors: *Ethnic Nursing Care. A Multicultural Approach*. St. Louis, 1983, Mosby.

summarizes factors that may influence individual differences within cultural groups.

In response to the needs of its members and the environment, culture provides tested solutions to life’s problems and guides our thinking, discourse, attitudes, and actions. In the present health care system, nurses have the chief responsibility for translating health information so that clients can understand it and engage in more effective strategies to achieve positive health outcomes. Understanding the beliefs and practices these clients bring to the clinical setting, their responses to health and illness, and the type of health care they expect to receive are important data that nurses should draw on when developing a plan of care for clients.

Individuals learn about their culture during the process of socialization and language development ([Box 7-2](#)). Parents and other family members are the primary sources for the transfer of traditions and teaching explicit and implicit behaviors of the culture. Schools, community, and cultural organizations are secondary sources of socialization. Explicit behaviors are straightforward and do not leave room for misinterpretation of what the person wants to communicate. Implicit behaviors are less exact and include the use of body language to communicate rather than persons saying verbally what is on their mind. An example of an explicit message is “No smoking is permitted” and an implicit message is: “Thank you for not smoking” ([Figures 7-1 and 7-2](#)).

Race

Concepts of race and ethnicity within American society play a strong role in understanding human behavior and health. In everyday language, these two concepts are often used interchangeably. Nurses are expected to understand and appreciate the meaning of each concept as each relates to providing culturally competent health care to persons of diverse cultures.

BOX 7-2 Early Cultural Awareness

Think about the first time you had contact with someone you realized was culturally different from you.

Briefly describe the situation/event. How old were you? What were your feelings? What were your thoughts?

What did your parents and other significant adults say about those who were culturally different from you or your family? What adjectives were used? What attitudes were conveyed?

As you got older, what messages did you receive about minority groups from members of your family, school, recreation facilities, and church?

As an adult, when you hear others talk about culturally different people, what images do they conjure up for you? What knowledge source is evident in the comment of the person? Do the views of the person reinforce or contradict the views that you hold today? Give an example.

What parts of your culture make it difficult to work with clients from different cultural groups?

What parts of your culture facilitate your work with clients from different cultural groups?

From [Randall DE](#): *Culturally Competent HIV Counseling and Education*. McLean, VA, 1994, Maternal and Child Health Clearinghouse.

FIG 7-1 The sign is from a culture that values directness in communication. (© 2012 Photos.com, a division of Getty Images. All rights reserved. Image 91883504.)

Race is a biological variation within population groups based on physical markers derived from genetic ancestry such as skin color, physical features, and hair texture. It is a characteristic that allows for some groups to be separated, treated as superior, and given access to power and other valued resources, while others are treated as inferior and have limited access to power and resources. Race differences include areas of growth and development, skin color, enzymatic differences, susceptibility to disease, and laboratory test findings. Individuals may be of the same race but of different cultures. For example, African Americans, who may have been born in Africa, the Caribbean, North America, or elsewhere, are a heterogeneous group, but they may be considered culturally homogeneous by persons who think of African Americans as one group. Monolithic thinking means that the many cultural differences of individuals from these diverse geographic regions may be overlooked because of the similar racial characteristics ([Degazon, 1994](#)).

FIG 7-2 The sign is from a culture that values indirectness in communication. (© 2012 Photos.com, a division of Getty Images. All rights reserved. Image 122153579.)

Individuals who belong to the Caucasian race also experience this same over-generalization of individuals along racial/ethnic lines.

Ethnicity

Ethnicity, in contrast to race, is the shared feeling of peoplehood among a group of individuals and relates to cultural factors such as nationality, geographic region, culture, ancestry, language, beliefs, and traditions ([Giger, 2012](#)) ([Figure 7-3](#)). These ethnicity and racial patterns have been developed in a socioeconomic context with historical and political underpinnings. They are equally influenced by education, income, and cross-cultural experiences. Race and ethnicity account for much of the health disparities in the United States. Members of an ethnic group are likely to give up aspects of their identity and society when they adopt characteristics of another group's identity. However, when there is a strong ethnic identity, the individual maintains the values, beliefs, behaviors, practices, and ways of thinking of their group. Ethnic disparities in health care are explained largely by differences in English fluency whereas racial disparities in health care are best explained by delayed care due to a lack of knowledge by caregivers about culture and ethnic values, norms and thinking outside of their reference group, lack of insurance, and lack of transportation.

CULTURAL DIVERSITY

Cultural diversity refers to the degrees of variation that is represented among populations based on lifestyle, ethnicity, race, interest, across place, and place of origin across time. It includes other aspects of variation among people, such as social class, gender identity, sexual orientation, physical abilities/disabilities and care beyond multiculturalism. Cultural diversity also refers to the changing populations of the world as it becomes more of a global village. It is about understanding and embracing each other's differences and similarities.

FIG 7-3 In countries around the world, there are distinct differences in people who represent the same cultural group. (Copyright © 2013 Thinkstock. All rights reserved. Image # 117003112).

Cultural Variations among Selected Groups

Each culture has an organizational structure that distinguishes it from others and provides the direction for what members of the cultural group determine is appropriate or inappropriate behavior. The organizational elements of health culture have been described in nursing by Andrews and Boyle (2012), Giger (2012), Leininger (2002b), Purnell and Paulanka (2012), and Spector (2012). As part of the nursing process, nurses are expected to accurately assess a client's health needs based on information about seven primary cultural elements: biological variations, personal space, time, environmental control, social organizations, communication patterns, nutrition, and religion (Table 7-1). Usually, the assessment takes place in the initial nurse–client interview. It is important that nurses use this information to develop a client-centered care plan. Once this information is gathered, the nurse should schedule a second interview with the client to determine ways to individualize culturally congruent care so that it is acceptable to the client.

Biological Variations

Biological variations are the physical, biological, and physiological characteristics that exist between racial groups and distinguish one race from another. These characteristics occur in areas of growth and development, skin color, enzymatic differences, susceptibility to disease, and laboratory test findings (Andrews and Boyle, 2012; Giger, 2012). For example, Western-born neonates are slightly heavier at birth than those born in non-Western cultures. Variations in growth and development may be influenced by environmental conditions such as nutrition, climate, and disease. Mongolian spots are bluish discolorations that are sometimes present on the skin of African American, Asian, Hispanic, and Native American/Alaskan Native babies. These spots may be mistaken for bruises. When nurses encounter situations involving unfamiliar biological variations, they may create embarrassing situations. Consider the following scenario: The school nurse observed a bluish discoloration on the thigh of a Filipino child that she mistook for a bruise. The nurse reported her observation to the child

protective agency in her state. The mother had to disprove the allegation to the agency's social worker before her child could be released into her care. Other common and obvious variations include eye shape, hair texture, adipose tissue, shape of earlobes, thickness of lips, and body configuration. A common enzyme deficiency is glucose-6-phosphate dehydrogenase (G6PD), which is responsible for lactose intolerance in many ethnic groups (Giger, 2012).

The findings that DNA composition for any two humans across race is 99.9% genetically identical and that difference between races occur only in 1 in 1000 people diminishes the ethnocentric debate about the importance of race. Another factor making race less important is the increasing numbers of interracial marriages that result in interracial children whose physical and genetic pool dilute the racial characteristics of their parents. Racial categories originated from a shared genealogy due to geographic isolation. In today's global village, this isolation has been broken down and there are more mixed groups. In the United States, children of biracial parents are usually assigned the race of the mother. The **Levels of Prevention** Box gives examples of cultural strategies for primary, secondary, and tertiary levels of prevention.

LEVELS OF PREVENTION

Hypertension, Stroke, and Heart Disease Related to Cultural Differences

Primary Prevention

Provide health teaching about balanced diet and exercise. Based on the details of the individual's culture, the teaching should include members of the family and identification of culturally appropriate foods and the means for preparing them.

Secondary Prevention

Teach clients and/or family to monitor blood pressure. Teach about diet, keeping in mind the client's cultural preferences. Talk about health beliefs and cultural implications, such as the use of alternative therapies; make sure alternative therapies are compatible with any medications that may be prescribed.

Tertiary Prevention

If blood pressure cannot be controlled by diet and/or exercise, refer the client to a culturally appropriate medical practitioner for medication and supervision; advise the client to engage in a cardiac program that will oversee diet and exercise.

Personal Space

Personal space is the physical distance maintained between individuals during an interaction (Giger, 2012). The amount of space varies among individuals and between cultures. When this space is violated, the nurse or the client may experience discomfort. There are four zones of interpersonal space—intimate space (direct contact to 1.5 feet), personal distance (1.5 to 4 feet), social distance (4 to 12 feet), or public distance (greater than 12 feet)—that may be observed when nurses care for clients. Cultural groups also have spatial preferences. To illustrate, Hispanic cultures tend to be comfortable with less space because individuals like to touch some persons with whom they

TABLE 7-1 Cultural Variations among Selected Groups

	African Americans	Asians	Hispanics	American Indian/ Native Alaskans
Verbal Communication	Asking personal questions of someone that you have met for the first time is seen as improper and intrusive.	High level of respect for others, especially those in positions of authority.	Expression of negative feelings is considered impolite.	Speak in a low tone of voice and expect the listener to be attentive.
Nonverbal Communication	Direct eye contact in conversation is often considered rude.	Direct eye contact with elders and authority figures may be considered disrespectful.	Avoidance of eye contact is usually a sign of attentiveness and respect.	Direct eye contact is often considered disrespectful. Avoidance of eye contact should not be interpreted as inattentiveness or evasiveness.
Touch	Very affectionate and expressive. Touching of one's hair by another is often considered offensive.	It is not customary to shake hands with persons of the opposite sex.	Very affectionate and use hand, face, and body gestures to express self. Touching is often observed between two persons in conversation.	Modesty. A light touch of the person's hand instead of a firm handshake is often used when greeting a person.
Family Organization	Usually have close extended family networks; women play key roles in health care decisions.	Usually have close extended family ties; emphasis may be on family needs rather than individual needs.	Usually have close extended family ties; all members of the family may be involved in health care decisions.	Usually have close extended family; emphasis tends to be on family rather than on individual needs. Decision making may vary among tribes.
Time Perception	Often present oriented.	Often present oriented.	Often present oriented.	Often past oriented
Environmental Control	Harmony of mind, health, body, and spirit with nature.	Balance between the "yin" and "yang" energy forces.	Balance and harmony among mind, body, spirit, and nature.	Harmony of mind, body, spirit, and emotions with nature.
Alternative Healers	"Granny," "root doctor," voodoo priest, and spiritualist.	Acupuncture, acupressure, acumassage, herbalist, moodang.	Curandero, espiritualista, Santero priest, yerbero, faith healers.	Medicine man, shaman.
Self-care Practices	Poultices, herbal medicine, oils, teas, massage, hot baths, and roots.	Hot and cold foods, herbal medicine, teas, soups, cupping, burning, rubbing, pinching.	Hot and cold foods, herbal teas.	Herbs, corn meal, medicine bundle.

are speaking. In the Filipino culture individuals may view touching strangers as inappropriate; therefore, nurses who wish to be culturally appropriate may elect to stand farther away from Filipinos than from Hispanics. On the other hand, clients who are comfortable with closer distances may experience discomfort when nurses stand farther away, interpreting the behavior as rejecting. Nurses should take cues from clients to place themselves in the appropriate spatial zone and avoid misinterpretation of clients' behavior as they handle their spatial needs.

Perception of Time

Perception of time refers to past, present, and future time as well as to the duration of and period between events. Some cultures assign greater or lesser value to events that occur in the past, the

present, or the future. If members of a cultural group tend to be future oriented, they often will delay immediate gratification until future goals are accomplished. For example, some future-oriented persons who value longevity may engage in health promotion activities to moderate their dietary intake and engage in exercise activities to minimize future health risks. In contrast, some present-oriented cultural groups may place greater emphasis on the here and now and view information about their present set of circumstances as more important than what will happen in the future. Other cultures believe that their ancestral lineage determines their current health status. When nurses discuss health promotion and disease prevention strategies with persons who have a present orientation, they should focus on the immediate benefits these clients will gain rather than emphasizing

future outcomes. That is not to say that clients cannot or will not learn about preventing future complications of illness, but nurses need to connect their teaching to the “here and now.” It is important to listen carefully to what the clients say in order to gather information about their time orientation. In cultures that focus on a past orientation (e.g., the Vietnamese culture), individuals may be less concerned about planning ahead and focus more on wishes and memories of their ancestors (Giger, 2012). In a past-oriented culture, time is viewed as being more flexible than in a present-oriented culture. It has less of a fixed point, and individuals may not be offended by being late or early for appointments. Nurses socialized in the Western culture may view time as money and equate punctuality with correctness and being responsible. Working with clients who have a different time perception than the nurse can pose a dilemma for the nurse who wishes to be culturally competent and accountable for helping her client receive adequate health care. Nurses should clarify the clients’ perceptions to avoid misunderstanding; however, nurses should explain the importance of keeping appointments from the Western perspective. For example, the nurse can communicate a willingness to be flexible in scheduling appointments and explain to clients that the time will be set aside, specifically for them. Along with culture, socioeconomic status and religion may influence the client’s perception of time.

Environmental Control

Environmental control refers to the person’s relationship with nature and efforts to plan and direct factors in the environment that affect them. Different cultures can be distinguished on the basis of one of three views of nature and the role of environment in everyday life: (1) nature controls the environment, (2) nature and the environment work in harmony to promote health and wellness, and (3) the environment has mastery over nature. In cultures that perceive individuals as having mastery over the environment, one can expect that a client with the diagnosis of cancer will be willing to engage in a rigorous treatment, include chemotherapy, radiation, and laser therapy to beat the disease. Persons who value harmony with the environment (e.g., African Americans, Asians, and American Indian/Alaskan Natives) may perceive cancer as disharmony with other forces and that medicine can only relieve the symptoms rather than cure the disease. They would look to the mind, body, and spirit connection, for healing comes from within, to find treatments for the malignancy. Naturalistic solutions, such as herbs, acupuncture, and hot and cold treatments would be their treatment of choice to resolve the suffering associated with the cancerous condition. Individuals from cultures that view the environment as dominant over nature (e.g., Hispanics) may believe that they have little or no control over the serious illness for which they have been diagnosed. These individuals are less likely to engage in illness management interventions that are harsh and that they cannot trust to yield a positive health outcome.

Social Organization

Social organization refers to the way in which families are structured to carry out role functions. Members depend on the extended family and kinship networks for emotional, social, and

financial support in times of crises. The significance of kinship in the formation of family relations varies across cultures. Some cultures adopt individuals who are unrelated or remotely related as family members. Some Hispanic and Asian cultures place the needs of the family above those of the individual. In the American Indian/Alaskan Native family, members honor and respect their elders and look to them for leadership, believing that wisdom comes with increasing age. When working with clients who prefer family decision making over individual choice, nurses should be aware that it may be counterproductive to exclude family involvement—particularly mothers and grandmothers—in the health care decision making. At the same time, nurses should advocate for the individual, making sure that when families make decisions, the individual’s needs have been considered.

Communication

Communication is the means by which culture is shared. Both verbal and nonverbal communications are learned in one’s culture. Communication is the most significant problem that presents itself in working with cross-cultural groups. Cross-cultural variations in verbal style can range from pronunciation, word meaning, voice quality, and humor, to nonverbal communication with eye contact, gesture, touch, body posture, facial expression, and silence. In all forms of communication, maintain respect for individuals. Often in cultures where the elderly are held in high esteem, they are addressed in a formal manner. Communicating trust is also important because it facilitates the nurse–client interaction and determines the extent to which the client will share information with the nurse (Morgan et al, 2006).

The following example involving a nurse giving instructions to Asian clients about taking anti-tuberculin drugs illustrates the need to understand cultural communication. The clients responded with a smile and a nod. The nurse interpreted this response to mean that the clients understood the instructions and had accepted the treatment protocol. A week later, when the clients returned for a follow-up visit, the nurse discovered that the medications had not been taken. The nurse knew that acceptance by and avoidance of confrontation or disagreement with those in authority are important behaviors in Asian culture. Interventions were adjusted accordingly: the nurse repeated the medication instructions and gave the clients an opportunity to raise questions and concerns and to repeat the instructions that were given; the nurse also discussed the cultural meaning and treatment of tuberculosis. Other factors influencing communication include forms of address such as the use of first names or surnames, and whether it is polite to wait until a person finishes speaking or to talk over each other.

Nutrition

For many cultures, the preparation and eating of food is a social activity and members of the group come together to celebrate life and comfort with one another. Almost all family rituals, including birth, baptisms, graduations, marriages, retirements, and deaths, include food as part of the ceremony. Many of these practices may have their origin in religious (for example, Muslims avoid pork and foods cooked with alcohol) as well as

cultural (for example, African Americans may have a large meal with family and friends after church on Sunday) traditions. The culture domain of nutrition includes much more than having adequate food to sustain dietary requirements.

Efforts to understand dietary patterns of clients should go beyond relying on membership in a defined group. Knowing the client's nutritional practices enables nurses to develop dietary regimens that do not conflict with their cultural food requirements. Health care teams that prescribe an American diet to a Hispanic or an Asian client whose mealtime and food choices may be different from American food patterns may be negligent. Specific foods have been developed for several subcultures such as Vietnamese, Cuban, Puerto Rican, Navajo, Japanese, and Jewish.

When engaging in mutual goal setting with the client and a nutritionist to change harmful dietary practices, the team might need to consult culturally oriented magazines before prescribing particular food items. A number of popular magazines such as *Essence*, *Ebony*, and *Latina* have created healthier dishes from revised old family recipes for Hispanic and African American families. These dishes are tasty and resemble old traditions, yet they are nutritious. Although the foods may differ culturally, excesses often lead to similar risk factors. [Box 7-3](#) identifies several questions that nurses should ask when conducting a nutritional assessment.

Many of clients' health lifestyle choices are associated with their nutritional practices. As a result, before nurses begin a dietary intervention, they should perform a nutritional assessment to determine food preferences, rituals, and taboos. For many cultures, eating is a social activity and people get together for celebration and to comfort each other. [Table 7-2](#) depicts various food preferences that are present among some cultural groups in American society and the associated risk factors when there is excessive use. Efforts to understand dietary patterns of clients should go beyond relying on membership in a defined group. Knowing the client's nutritional practices makes it possible for nurses to develop treatment regimens that will not conflict with their cultural food practices.

Religion

The expression of spirituality is a component of health and illness coping for most people. The Joint Commission requires

that health professionals conduct a spiritual assessment on individuals. Prayer and religion play a dominant role in protecting health and supporting healing in many cultural traditions. Among all the ethnic groups in the United States, African Americans are most likely to report a formal religious affiliation ([Pew Forum on Religion & Public Life, 2008](#)). Among Hispanics, Roman Catholic and Pentecostal beliefs and practices are prevalent. Hispanics who practice Pentecostal beliefs may engage in prayer and believe in miraculous healing.

Muslims are the most racially diverse group and the second largest and fastest growing religion in the world. In the United States, the majority of Muslims are white (37%), African American (24%), Asian (20%), mixed race (15%), and Latino (4%). Muslims are considered either Sunni or Shia Muslim. Muslims face Mecca (which is northeast) when they pray, and when death is imminent they want their faces turned toward Mecca. Sunni Muslims pray five times a day and Shiite Muslims pray three times a day. Muslims gather for corporate worship on Fridays. Tradition says that Muslims pray on the floor, but during illness they may pray in bed. Exceptions from traditional Muslim practices can sometimes be permitted during

BOX 7-3 Assessment of Dietary Practices and Food Consumption Patterns

1. Does the food have nutritional value based on *My Plate*?
2. What is the social significance of food in the family? Has the family adopted foods from other cultural groups?
3. What foods are most frequently purchased for family consumption? Who decides and from where is the food purchased?
4. What foods, if any, are prohibited for the family?
5. What variables play a significant role in food selection (cost, variability, family rituals, religion, family tradition, celebrations)?
6. How often does the family prepare food at home? Who prepares the food? How is it prepared?
7. How much food is eaten? When is it eaten and with whom?
8. Are fresh fruits and vegetables easily accessible for purchase in the community?
9. What spices do the family use in the preparation of the food? What are the family favorite recipes?
10. What are the characteristics of restaurants and other eating facilities that the family uses outside of the home?

TABLE 7-2 Food Preferences and Associated Risk Factors in Selected Cultural Groups

Cultural Group	Food Preferences	Nutritional Excess	Risk Factors
African Americans	Fried foods, greens, bread, pork, rice, foods with high sodium and starch content	Cholesterol, fat, sodium, carbohydrates, calories	Obesity, coronary heart disease, hypertension, cancer, diabetes, and HIV/AIDS
Asians	Soy sauce, rice, pickled dishes, raw fish, tea, balance between yin (cold) and yang (hot) concepts	Cholesterol, fat, sodium, carbohydrates, calories	Coronary heart disease, liver disease, cancer of the stomach, ulcers
Hispanics	Fried foods, beans and rice, chili, carbonated beverages, high-fat and high-sodium foods	Cholesterol, fat, sodium, carbohydrates, calories	Obesity, coronary heart disease, diabetes
American Indian/ Alaskan Natives	Blue corn meal, beans, squash, game and fish	Carbohydrates, calories	Depression, suicide, diabetes, malnutrition, tuberculosis, infant and maternal mortality

pregnancy, breast feeding, illness, or travel; but the nurse should always ask the client because some Muslims may observe the practices even though they may have received permission for an exception.

Some African Americans practice Muslim traditions although most belong to a Christian faith. Many African Americans find comfort and support in their spiritual beliefs, believe God is responsible for health, and view health professionals as God's instruments for healing. African Americans with Haitian background may practice voodoo in conjunction with a traditional religion.

Most Jews observe the holidays of Rosh Hashanah and Yom Kippur. Many Jews observe Sabbath, which extends from sundown on Friday until sundown on Saturday. Jews of European origin are called Ashkenazi Jews; Middle Easterners and non-European Jews are called Sephardic.

Chinese and other Asian people often practice Eastern religions such as Confucianism, Buddhism, and Taoism (Lai and Sunrood, 2009). Confucianism emphasizes respect for the elderly and people in authority. Practitioners believe that moral conduct and maintaining harmonious relationships are the keys to life. The five most important attributes are benevolence, righteousness, loyalty, filial piety, and virtue. The Buddhist principles embrace three attributes: mercy, thriftiness, and humility. Buddhists believe that people receive good fortune for doing the right thing and misfortune for doing the wrong thing. Taoism embraces selflessness and emotional calm. The most important thing to them is to be in harmony with nature. An important element of health is outdoor exercise for peace of mind and outside air. Part of achieving good health is to adjust the thinking and the body to fit in with the natural rhythm of the universe.

Immigrants and Cultural Diversity

Immigrants to the United States are born in countries or territories external to the United States and migrate to the United States, contributing to its vast diversity. Place of origin for the immigrant is distinguished from nationality, which refers to the place where the individual has or had citizenship. For example, if individuals were born in the Dominican Republic, they may be naturalized citizens, but their ethnicity is likely to be Hispanic with a Dominican place of origin. It is estimated that the U.S. population consists of 39 million (foreign-born) immigrants accounting for 12% of the total population of which 11.7 million have illegal status (Congress of the United States, 2012). **Foreign-born** refers to all residents who were not a U.S. citizen at birth, regardless of their current legal or citizen status or those whose parents were not U.S. citizens. More than two thirds of the foreign-born population lives in or around major metropolitan areas in four states: Nevada, Texas, California, and Arizona (Congress of the United States, 2012). Their employment tends to be associated with the region of the world from which they came. For example, persons from South America may be in construction- or agriculture-related occupations (21%), while persons from Asia tend to be associated with professional or technical occupations (39%). The foreign-born are likely to be poorer (23%) than the U.S.-born population

FIG 7-4 A child from Nepal living in the United States. The child has a black dot on her forehead to protect her from the “evil eye.”

(13.5%); 36% of immigrant-headed households use at least one major welfare program (primarily food assistance and Medicaid) compared to 23% of the U.S.-born population. They comprise 16% of the total adult workforce with more than 54% of the adults in the labor force having completed high school (Camarota, 2012). These immigrants bring with them unique cultural, health care, and religious backgrounds (Figure 7-4).

There are four categories of foreign-born. The first category is **legal immigrants**, also known as **lawful permanent residents**. This group constitutes about 85% of the immigrant population. They are not citizens but are legally allowed to live and work in the United States, usually because they fulfill labor demands or have family ties. Legal immigrants usually have a five-year waiting period living in the United States after receiving “qualified” immigration status before they are eligible to receive entitlements such as Medicaid and CHIP (Camarota, 2012). The second category of foreign-born consists of **refugees** and persons seeking asylum. The Refugee Act of 1980 provided a uniform procedure for refugees (based on the United Nations definition) to be admitted to the United States (U.S. Department of Health and Human Services, 2001). This included refugees from Cuba, Vietnam, Laos, Cambodia, and Russian Jewish refugees. These are people who seek protection in the United States because of fear of persecution (on the basis of race, religion, nationality, political view, or membership in a certain

group) if they were to return to their homeland. Refugees are immediately eligible to receive Temporary Assistance for Needy Families, Supplemental Security Income, and Medicaid. The third category of foreign-born is the **non-immigrants**; these are people admitted to the United States for a limited duration and for a specified purpose. Non-immigrants include students, tourists, temporary workers, business executives, career diplomats, their spouses and children, artists, entertainers, and reporters. The fourth category of foreign-born is **unauthorized immigrants**, or undocumented or illegal aliens. These persons may have crossed a border into the United States illegally, or their legal permission to stay in the United States may have expired. Unauthorized immigrants are eligible to receive emergency medical services, immunizations, treatment for the symptoms of communicable diseases, and access to school lunches only. They are not eligible for federal public benefits through the Affordable Care Act. Between 2007 and 2012, increased apprehensions by the U.S. Border Patrol accounted for a smaller number of persons entering the United States illegally than in the previous decade (Pew Research Center, 2013). A description of the immigrant populations and what benefits they are eligible to receive can be found in *A Description of Immigrant Population: An Update* (Congress of the United States, 2012).

National debate about immigration policy has intensified, particularly about amnesty for illegal aliens, since the events of September 11, 2001. As a result, a variety of immigration laws have been enacted (*Changes in Immigration Law*, 2013). These changes reflect tightened and more restrictive visa procedures as well as greater scrutiny given to all visas and entry documents. The complex issues involved with the foreign-born population and health care accessibility restrict the opportunity for public health nurses to provide culturally competent care to this population.

Misperceptions abound about the economic value of allowing immigrants to enter, or to stay in, the United States. It is estimated that immigrants increase the gross domestic product by 37 billion dollars each year because of their presence in the labor force and contributions in skills, education and capital investments by adding workers to the pool (Immigration Policy Center, 2012). The dilemma for communities, however, is that immigrants typically pay federal taxes yet the services they receive are paid for by the states and localities. Although federal matching funds for Medicaid are not available to the states for immigrants, some states have found compelling public health reasons to use their own funds to cover even undocumented immigrant children, pregnant women with low incomes, disabled persons, and older adults (Camarota, 2012).

There are other health care issues in addition to financial constraints on providing health care for immigrants. Some of these are language barriers; differences in social, religious, and cultural backgrounds between the immigrant and the health care provider; and the use of traditional healing or folk health care practices that may be unfamiliar to U.S. health care providers. Providers may lack knowledge about high-risk diseases in the specific immigrant groups for whom they care. For example, some groups are more at risk for hepatitis B (with its attendant effects on the liver), tuberculosis, intestinal parasites, and visual,

hearing, and dental problems. Many of these conditions are either preventable or treatable if managed correctly. Nurses need to know the major health problems and risk factors that are specific to the immigrant populations for whom they provide care. Nurses need to understand the difficulty of the acculturation process for immigrant families and to treat individuals in the context of the culture from which they come. Often children and adolescents adjust to the new culture more easily than adults. This can lead to a shift in the balance of power between adults and children, contributing to family conflict and at times violence. Inability of elders to acculturate may play a large part in their lack of adherence to health care guidelines. When conducting a health history, nurses should be alert for warning signs of family stress and tension. Remember that older family members can help translate their culture, beliefs, religious practices, dietary habits, support systems, and risk factors for the health care provider. They can also assist with decision making and provide support to enable the person or group seeking care to change behaviors and increase their health promotion practices.

Similarly, understanding the role of the community in the care of immigrants is important. Communities can help clients (and thus providers) with communication, crisis intervention, housing, and emotional and other forms of support. Nurses need to carefully assess the community and learn what strengths, resources, and talents are available.

Nurses need knowledge about the traditional healing practices that immigrants use. Many of these practices have therapeutic value and can be blended with traditional Western medicine (Figure 7-5). The key is to know what practices are being used so the blending can be done knowledgeably. Community members are excellent sources of this information, and nurses working with immigrant populations should use the community assessment, group work, and family techniques described in other chapters to partner with immigrant clients.

Culturally appropriate nursing actions that can be implemented to increase authenticity, accuracy, and approachability when working with immigrant populations include the following:

1. Self-awareness: Recognize the values, beliefs, and practices that comprise your own culture. Nurses, like clients, are influenced by culture, values, and language.
2. Identify the client's preferred or native language. When nurses do not speak or understand the client's language, they must obtain assistance from an **interpreter** to ensure that full and effective communication occurs. Health care institutions must provide clients with an interpreter. The interpreter should have knowledge of the client's culture and medical terminology. Interpreters should be trained, qualified, and hired to ensure that they have met minimum standards to provide accurate and safe interpretation. Using family members, friends, and staff who are not trained as health/medical interpreters can create errors in understanding and communicating, pose grave risks for the client and liability to the health care institution. While both an interpreter and a translator interpret and translate information from one language to another, there are significant differences between the two. A translator is usually

FIG 7-5 Mi-yuk kook (seaweed soup) is a Korean dish eaten by postpartum women to stop bleeding and to cleanse body fluids. It is also eaten every birthday.

associated with translating written documents such as medical records and legal documents; in contrast, the interpreter is associated with verbal communication that focuses on accurate expression of equivalent meanings rather than on word-to-word equivalence.

Many nurses cite linguistic barriers as the largest issue they encounter when trying to provide culturally competent care for linguistically different clients (Starr and Wallace, 2009). Experiences of success that nurses report when working with an interpreter include proper use of interpreters to assure that clients understand health care instructions; provision of linguistically appropriate educational material; ability to communicate in the client's language to provide health care instructions; and ensuring proper use of instructions. Experiences of difficulty include language barriers preventing appropriate communications; lack of available interpreters overall and for specific languages; and lack of appropriate translation by interpreter. Nurses can minimize some of these difficulties by learning basic words and sentences of the most commonly spoken languages in the community and observing client reactions when asking them questions. Also, nurses should provide written material in the client's primary language, so that family members can reinforce information when at home with the client. The **How To** Box provides guidelines for using an interpreter.

3. Learn the health-seeking behaviors of your client and their family members. In asking the client about family members, you might try using a simple genogram, which places family members on a diagram. Ask who the family members are, where they live, and who is missing or deceased. You might also ask them to talk about holiday celebrations: who comes, who is missing, what do they do?

4. Get to know the community where the immigrant client lives. Read about the culture of your clients. Take a course. Volunteer to participate in the acculturation process of the community (e.g., to give talks, hold forums with free-flowing and two-way communication), and learn who the formal and informal resources are.
5. Get to know some of the traditional practices and remedies used by families and communities. Coordinate health teaching seminars with traditional healing courses for the community so you can work with, not against them.
6. Learn how cultural subgroups explain common illnesses or events. In cultures where the body and mind are seen as one entity or in cultures in which there is a high degree of stigma associated with mental illness, people or individuals somatize their feelings of psychological distress. In somatization, psychological distress is experienced as a physical illness.
7. Try to see things from the viewpoint of the client, family, and community and accommodate rather than squash the client's view.
8. Conduct a cultural assessment focusing on what is working, what is not working, and changes that need to be made to accommodate cultural norms and promote positive health behaviors.

HOW TO Guidelines for Selecting and Using an Interpreter

1. The interpreter must interpret everything that is said by all the people in the interaction and inform the public health nurse if the content might be perceived as insensitive or harmful to the dignity of the client.
2. The interpreter conveys the content, the spirit of what is said without omitting or adding.
3. The educational level and the socioeconomic status of the interpreter are important. The nurse should know that the interpreter understands the community's interpretation of the disease and the nurse should understand the community's health care practices around the disease.
4. The nurse needs to evaluate the interpreter's style, approach to clients, and ability to develop a relationship of trust and respect.
5. The gender and/or age of the interpreter may be of concern; in some cultures, women may prefer a female interpreter and men may prefer a male, and older clients may want a more mature interpreter. Avoid using children as interpreters, particularly when the client is an adult.
6. Identify the client's country of origin and language or dialect spoken before selecting the interpreter. For example, Chinese clients speak different dialects depending on the region in which they were born.
7. Observe the client for nonverbal messages such as facial expressions, gestures, and other forms of body language. If the client's responses do not fit with the question, the nurse should check to be sure that the interpreter understood the question.
8. Make phrase charts and picture cards available.
9. Increase accuracy in transmission of information by asking the interpreter to translate the client's own words, and ask the client to repeat the information that was communicated.
10. The interpreter must maintain confidentiality of all information and interactions. At the end of the interview, review the material with the client and the interpreter to ensure that nothing has been missed or misunderstood.

CULTURAL DIVERSITY AND HEALTH DISPARITIES

Disparities in Health

Disparities are used to describe incongruent elements. **Health disparities** are associated with inequity in social structures based on particular characteristics such as ethnicity, race, immigrant status, gender, age, and sexual orientation (Levine et al, 2011). Health disparities stem from characteristics historically linked to discrimination. They are also expressed in differences in morbidity and mortality rates among population groups linked to factors such as race or ethnicity, religion, socioeconomic status, gender, mental health, sexual orientation, place of origin, and residence. Health disparities are monitored annually by various departments within The U.S. Department of Health and Human Services as part of the national goal to achieve health equity for all within the United States (see the **Healthy People 2020** box related to health disparities).

HEALTHY PEOPLE 2020

Goals and Objectives of Healthy People 2020 Related to Cultural Issues

Goal: Eliminate health disparities among different segments of the population as defined by gender, race or ethnicity, education, income, disability, living in rural areas, and sexual orientation.

Selected Objectives

- AHS-1: Increase the proportion of persons with health insurance.
- AHS-2: Increase the proportion of insured persons with clinical preventive services coverage.
- AHS-3: Increase the proportion of persons with a usual primary care provider.
- AHS-6: Increase the proportion of persons who have a specific source of ongoing care.
- AHS-7: Reduce the proportion of individuals who are unable to obtain or delay in obtaining necessary medical care, dental care, or prescription medicine.

Social Determinants of Health

Social determinants of health are the circumstances in which people are born, grow up, live, work, age, and the systems put in place to deal with illness. These circumstances are in turn shaped by a wider set of forces such as economic stability (indicators such as poverty and unemployment), education (indicators such as reading levels, graduation rates, and enrollment in higher education), social and community context (indicators such as family structure and social cohesion), health and health care (indicators such as access to health services and access to primary care), and neighborhood (indicators such as quality of schools and housing, access to healthy foods, and incidences of crime and violence) (Healthy People 2020, 2013).

Marginalization

Marginalization of vulnerable populations occurs when a segment of the population has been excluded from the

mainstream in social, economic, cultural, or political life. Marginalization is brought about by policies, practices, and programs that have relegated these populations to the fringe of society and which prevents them from meaningfully participating in society. Examples of these vulnerable populations include but are not limited to groups excluded due to race/ethnicity, homelessness, immigrants with linguistic challenges, drug abuse, sexual orientation, economics, and gender, which are devalued and not granted certain privileges that are given to others. In some instances, vulnerable populations may be considered an equivalent term for marginalization.

Health Equity

Health equity is concerned with providing social justice in health so that individuals are not disadvantaged from achieving the highest possible standard of health based on membership in a group that has historically been disadvantaged (Braveman, 2014). It is the principle underlying a commitment to reduce and ultimately eliminate disparities in health. Achieving health equity requires giving recognition to social barriers as well as barriers that have their origins in genetics, economics, and lifestyle factors that contribute to inequality of health. Health inequities are avoidable treatment between groups of people. They are reflected in differences in length of life, quality of life, rates of disease and disability, severity of disease, access to treatment among groups of people, and death.

Social Justice

Social justice is concerned with values of impartiality and objectivity at a systems or governmental level and is founded on principles of fairness, equity, respect for self and human dignity, and tolerance. Practicing social justice is acting in accordance with fair treatment regardless of economic status, race, ethnicity, age, citizenship, disability, or sexual orientation.

Health Literacy

The Centers for Disease Control and Prevention (CDC) define **health literacy** as the degree to which an individual has the capacity to obtain, communicate, process, and understand basic health information and services to make appropriate health care decisions. Low health literacy negatively influences understanding of medical information (such as illness condition, treatment plan), obtaining health care services, managing chronic conditions, and use of medication and avoidance of medication errors, and places individuals at a safety risk. Low literacy is more common among the elderly, minority populations, immigrants, individuals with lower socioeconomic status, and the medically underserved. Individuals with low health literacy are adversely affected by low educational skills, cultural barriers to health care, and by nurses who use language that the patient does not understand. Often these individuals may have a different perspective about their illness and what to do about it. The pattern in which they present their illness might be different from the pattern persons with high literacy skills would use to present their illness. When caring for persons with low literacy skills, nurses should ask the client to repeat instructions to assess the client's level of literacy, repeat information as needed,

allow the client time to process the information, use face-to-face communication whenever possible, make the information personally relevant, give reasons for short-term benefits for taking the specific action, and provide sufficient follow-up for each person (CDC, 2009).

Health Disparities and Socioeconomic Status

The relationship between health disparities and **socioeconomic status** is reflected in life expectancy, infant death rates, low birth rates, and many other health measures (Agency for Healthcare Research & Quality, 2013). Members of minority groups may be marginalized, preventing them from enjoying the same opportunities and resources for education, occupation, income earning, and property ownership that the dominant group has, thus relegating them to the fringe of society. Between 2007 and 2011 the poverty rate in the United States was 14.3% (Macartney et al, 2013), but there were differences in poverty rates associated with membership in various racial/ethnic groups. Table 7-3 indicates that there are more white families than minorities below the poverty level. However, the proportion of poor families in a minority group is greater. For example, 11.6% of white families are living in poverty, whereas 25.8% of African Americans, 23.2% of Hispanics, and 27% of American Indian/Alaskan Natives are doing so. Consequently, minority families are disproportionately represented on the lower tiers of the socioeconomic ladder. The mortality rate among individuals from lower socioeconomic status is significantly higher than among those from higher income levels (Cheng and Kindig, 2012).

Poor economic achievement is also a common characteristic found among populations at risk, such as single-parent head of households, the homeless, migrant workers, and refugees. Nurses should be able to distinguish between cultural and socioeconomic issues. Attributing behaviors stemming from socioeconomic deficits to behaviors embedded in cultural origins can result in misinterpretations of the client's motivation to adhere to treatment regimens. Data suggest that when nurses and clients come from the same social class, it is more likely that they operate from the same health belief model, and consequently there is less opportunity for misinterpretation and

communication problems. Nevertheless, research on health disparities has shown that individuals from minority racial and ethnic groups are disproportionately likely to develop severe health problems and to experience lower quality care and poor outcomes in relation to health problems even after controlling for socioeconomic status, insurance status, and age (Agency for Healthcare Research & Quality, 2014; 2013).

There is danger in believing that only individuals in the lower socioeconomic rung use cultural behaviors such as folk (natural and magico-religious) practices. More individuals in Western cultures, including health professionals, are integrating folk practices with the biomedical system to promote, protect, and restore their health. Acceptance of this is reflected in courses being offered in universities, the arrival of newer disciplines in health care such as homeopathic medicine, and more acceptance of traditional medicine (such as acupressure and acupuncture). Nurses can consult and seek guidance from non-Western practitioners to better understand how clients and families integrate cultural concepts with other aspects of client care to meet their clients' total health care needs.

CULTURAL COMPETENT NURSING INTERVENTIONS

Cultural Competence

Transcultural nursing recognizes and appreciates differences in health care values, beliefs, and customs. Transcultural theorists subscribe to the belief that nurses must acquire knowledge, skill, and attitudes in cultural competence and be committed to change to ensure positive outcomes, eliminate health disparities, and increase client satisfaction.

A number of governmental agencies such as the U.S. Department of Health and Human Services, state regulations, and private and quasi-governmental regulators such as The Joint Commission have attempted to address the need for cultural competence through various standards and legislation. For instance, standards of practice for culturally competent nursing care were developed by a task force of the expert panel for Global Nursing and Health of the American Academy of Nursing in concert with members of the Transcultural Nursing Society to help nurses apply these standards universally in the arenas of clinical practice, research, education, and administration (American Academy of Nursing Expert Panel, 2010). The 12 standards address core values inherent in professional nursing practice and include behaviors, attitudes, and skills requisite for cultural competence. These standards are described in Box 7-4.

Both of the accreditation bodies for nursing education, the Accreditation Commission for Education in Nursing (ACEN) and the Commission on Collegiate Nursing Education (CCNE), address the need for cultural competence as essential content in nursing education. State Boards of Nursing are requiring cultural competence education in nursing schools and recent legislation in many states includes requiring cultural competency training for health care providers to receive licensure or relicensure.

Cultural competence entails a combination of culturally congruent behaviors, practice attitudes, and policies that allow nurses to use interpersonal communication, relationship skills,

TABLE 7-3 Poverty Rates by Ethnic Groups

Ethnic Groups	Percent of Total Populations	Percent of Poverty Rate
Non-Hispanic Whites	42.4%	11.6%
Blacks	12.6%	25.8%
Asians	4.8%	11.7%
Hispanics	16.4%	23.2%
American Indian/ Alaskan Natives	.09%	27.0%
Native Hawaiians	0.02%	17.6%

From U.S. Census Bureau: *Income, Poverty, and Health Insurance Coverage in the US: 2010* and Macartney S, Bishaw A, Fontenot K: *Poverty rates for selected detailed race and Hispanic groups by state and place: 2007–2011*.

BOX 7-4 Standards of Practice for Culturally Competent Nursing Care

- Standard 1. Social justice: Nurses use principles of social justice to guide them as they advocate for the patient, family, community, and other health care professionals.
- Standard 2. Critical reflection: Nurses critically reflect on their own values, beliefs, and cultural heritage to determine the influence of these qualities and issues on providing culturally congruent nursing care.
- Standard 3. Knowledge of cultures: Nurses understand the perspectives, traditions, values, practices, and family systems of culturally diverse individuals, families, communities, and populations for whom they care, as well as having knowledge of the complex variables that affect the achievement of health and well-being.
- Standard 4. Culturally competent practice: Nurses use cross-cultural knowledge and culturally sensitive skills when implementing culturally congruent nursing care.
- Standard 5. Cultural competence in health care systems and organizations: Health care organizations provide the structure and resources for nurses to evaluate and meet the cultural and language needs of their culturally diverse clientele.
- Standard 6. Patient advocacy and empowerment: Nurses recognize the impact that health care policies, delivery systems, and resources have on their populations and advocate on the patients' behalf for inclusion of their cultural beliefs and practices in all dimensions of their health care.
- Standard 7. Multicultural workforce: Nurses engage in activities to ensure multicultural workforce health care settings, such as those that strengthen recruitment and retention in hospitals and academic settings.
- Standard 8. Education and training in culturally competent care: Nurses shall have knowledge and skills to ensure that the delivery of patient care is culturally congruent and includes global health care agendas that mandate formal education and clinical training as well as ongoing continuing education for all practicing nurses.
- Standard 9. Cross-cultural communication: Nurses use culturally appropriate verbal and nonverbal communication skills to identify patient's values, beliefs, practices, perceptions, and unique health care needs.
- Standard 10. Cross-cultural leadership: Nurses influence individuals, groups, and systems to achieve positive health outcomes of culturally competent care for diverse populations.
- Standard 11. Policy development: Nurses have the knowledge and skills to work with public and private organizations, professional associations, and communities to develop policies and standards for comprehensive implementation and evaluation of culturally competent care.
- Standard 12. Evidence-based practice and research: Nurses use tested interventions shown to be effective for the culturally diverse populations that they serve. The nurse also engages in research to test the effectiveness of interventions appropriate for specific culturally diverse clients.

Adapted from American Academy of Nursing Expert Panel: *Standards of practice for culturally competent nursing care*, 2010. Available at http://www.tcn.org/files/Standards_of_Practice_for_Culturally_Compt_Nsg_Care-Revised.pdf. Accessed February 25, 2014.

and behavioral flexibility to work effectively in cross-cultural situations. Cultural competence allows nurses to partner with the client to deliver health promotion, disease prevention, and health restoration (Campinha-Bacote, 2011; Leininger, 2002a). Culturally competent nurses respect individuals from different cultures, value diversity, and function effectively when caring for clients from other cultures. Cultural competence reflects a higher level of knowledge than cultural sensitivity, which was

once thought to be all that was needed for nurses to effectively care for their client. In contrast, cultural sensitivity suggests that the nurse has basic knowledge of the client's culture but does not use the information to devise a plan of care that reflects the client's total cultural needs. Nurses should be aware of the social determinants of health in the environment that prevent individuals from achieving good health.

It is generally accepted that culturally competent nursing care is guided by the following principles (American Academy of Nursing Expert Panel, 2010):

1. Care must be client centered, that is, designed for the specific client, family, or community.
2. Care must be based on the uniqueness of the client's culture and incorporate the cultural norms and values of the client in the management of the care plan.
3. Self-empowerment strategies of the client are identified and viewed as strengths to facilitate client decision making and self-care management in health and illness situations.

Cultural competence is also one of the core attributes of public health nurses (Quad Council, 2011). Nurses work toward becoming culturally competent for a number of reasons. First, nurses who come from a culture different from that of the client may not be knowledgeable about the client's culture. Nurses come from a variety of cultural backgrounds and have their own cultural traditions. Each nurse has unique cultural experiences that give meaning and understanding to his or her behavior. Because of differences between the client's cultural system and the nurse's cultural system, when the client and the nurse interact they may have different understandings about the meaning of the health issue and different ideas about what to do to promote and protect health. In these circumstances, nurses who value and practice cultural competence use communication and relational strategies that respect clients' values, expectations, and goals without diminishing the nurses' own values, expectations, and goals. To illustrate, a recent Mexican immigrant who speaks little English goes to a community health center because of a urinary tract infection. The nurse understands that she must use strategies that would allow her to effectively communicate with the client. She also understands that the client has the right to receive effective care that is based upon culturally informed nursing science, to judge whether she has received the care she wanted, and to follow up with appropriate action if she did not receive the expected care. Nurses must be culturally competent to modify nursing interventions that are specific to the needs of cultural and ethnic groups.

Second, care that is not culturally competent may further increase the gap in racial and health disparities between minority and majority populations. Failure to effectively respond to the health care needs and preferences of culturally and linguistically diverse individuals may (1) increase barriers to equitable access to care, (2) inhibit effective communication between the client and the nurse, and (3) create obstacles in gathering assessment data, thus limiting the development and implementation of effective treatment plans.

Third, nurses use culturally competent practice to improve the quality, cost, and safety of care and health outcomes. The health care industry focuses on cost-effectiveness to balance

cost and quality (Agency for Healthcare Research & Quality, 2012). **Quality of care** means that the client has access to health care and that the care is delivered by culturally competent nurses to help clients achieve positive health outcomes. Care that is not focused on the clients' values, expectations, and goals is likely to increase cost and diminish quality. For example, when clients are using both folk medicine and traditional Western medicine and nurses fail to assess and use this information in teaching, the clients may not get the full benefits of the treatment protocol. Positive outcomes, which are indicators of quality, may not be met. When quality is compromised, additional resources that typically increase costs may be needed to achieve the desired health care outcomes.

Fourth, legal regulations and accreditation mandates specify that culturally competent health care must be provided so that health disparities can be reduced and ultimately eliminated. For example, the specific *Healthy People 2020* objectives for persons of different cultures need to be met (USDHHS, 2010). To accomplish these objectives, the client's lifestyle and personal choices must be considered beyond the cursory ways that health care providers have interacted with clients in the past. Clients may present their symptoms vastly differently from the way they are presented in medical and nursing text books; they may present with different threshold for seeking care or expectations about their care. They may have beliefs about the origin and treatment of disease that affect their willingness to adhere to the treatment regimen, and they may have limited English proficiency and low health literacy.

For example, American health care professionals frequently view excessive drinking as a sign of disease and alcoholism as a mental illness. However, in the American Indian/Alaskan Native culture, these signify a disharmony between the individual and the spirit world, and biomedical interventions alone may not be adequate to reduce alcoholism within this culture. American Indians and Alaskan Natives have an alcohol-related death rate that is two times higher than it is in the general population. This is particularly devastating among American Indian males in the 35 to 49 age group, and contributes to a loss of 6.4 more years of potential life compared with those in the general population (CDC, 2008). The national goal is to reduce this disparity. However, many American Indian/Alaskan Natives view alcohol consumption as an acceptable way to participate in family celebrations and tribal ceremonies, and refusal to drink with family may be viewed as a sign of rejection. West (1993, p. 234) suggested that nurses understand the possible ramifications of not having culturally competent staff available to care for the American Indian/Alaskan Native population. She stated, "If the government sends Indians to a health clinic where personnel do not understand the holistic health practices of Indians and where young white people serve as caregivers and authority figures, failure is likely to result." To have successful outcomes, nurses who develop population-based programs to reduce alcohol-related deaths must be willing to respect the cultural uniqueness of Native Americans and to explore individuals' life experiences to find the underlying causes of their behaviors.

Fifth, to gain a competitive edge in the marketplace, the private sector is incorporating culturally competent policies

and care practices for its diverse populations and providers. Insurance companies, health maintenance organizations, and other private health entities have developed initiatives in cultural competence for their providers and engage in cultural competence strategies to improve patient satisfaction and patient care outcomes.

Sixth, in an effort to decrease the risk of liability from malpractice claims and to increase client satisfaction, health care providers and health care organizations are engaging in cultural negotiations. For example, a communication strategy focused on increasing productive health care services for clients was initiated. The strategy utilizes a nurse–client partnership and underscores openness, mutual respect, and flexibility when communicating.

Developing Provider Cultural Competence

Cultural competence is an ongoing life process in which the nurse is challenged to break with the old and engage in new ways of thinking and performing.

Nurses develop cultural competence through the critical reflective use of self-awareness skills, communications skills, relationship-building skills, and intervention skills that promote mutual respect for differences in the use of participatory decision making. In developing cultural competence, nurses may be guided by two principles suggested by Leininger (2002a): (1) maintain a broad objective and open attitude toward individuals and their cultures, and (2) avoid seeing all individuals as alike. Because there are varying degrees of cultural competence, not all nurses will achieve the same level of development concurrently. For example, Starr and Wallace (2009) reported that public health nurses in a southeastern public health department rated themselves higher on cultural thoughts (cultural awareness and sensitivity) than on cultural competence behaviors. Over all, the nurses reported a moderate level of cultural competence that was increased through online and class room courses.

In an early model developed by Orlandi (1992), three stages to developing cultural competence were depicted (culturally incompetent, culturally sensitive, and culturally competent). Table 7-4 shows that each stage has three dimensions—cognitive

TABLE 7-4 The Cultural Competence Framework: Stages of Competence Development

	Culturally Incompetent	Culturally Sensitive	Culturally Competent
Cognitive	Oblivious	Aware	Knowledgeable
Affective	Apathetic	Sympathetic	Committed to change
Psychomotor (skills)	Unskilled	Lacking some skills	Highly skilled
Overall effect	Destructive	Neutral	Constructive

From Orlandi MA: Defining cultural competence: an organizing framework. In Orlandi MA, editor: *Cultural Competence for Evaluators*. Washington, DC, 1992, U.S. Department of Health and Human Services.

(thinking), affective (feeling), and psychomotor (doing)—that have an overall effect on nursing outcomes. The most effective outcomes are knowledgeable, committed to change, and highly skilled. The most destructive outcomes are oblivious, apathetic, and unskilled.

A widely used model to explain the process of cultural competence was created by [Campinha-Bacote \(2011\)](#). The most recent model depicts five elements of cultural competence: (1) cultural awareness, (2) cultural knowledge, (3) cultural skill, (4) cultural encounter, and (5) cultural desire.

Cultural Awareness

Cultural awareness refers to the self-examination and in-depth exploration of one's own biases, stereotypes, and prejudices as they influence behavior toward other cultural groups ([Campinha-Bacote, 2011](#)). Culturally aware nurses are conscious of culture as an influencing factor on differences between themselves and others, and are receptive to learning about the cultural dimensions of diverse clients. They understand the basis for their own behavior and how it helps or hinders the delivery of competent care to persons from cultures other than their own ([American Academy of Nursing Expert Panel, 2010](#)). Culturally aware nurses recognize that health is expressed differently across cultures and that culture influences an individual's responses to health, illness, disease, and death. Culturally competent care can be delivered in a variety of modes consistent with the client's health values. For example, at a community outreach program, a nurse was teaching a racially mixed group the screening protocol for breast and cervical cancer detection. An African American woman in the group refused to give the return demonstration for breast self-examination. When encouraged to do so, she said, "My breasts are much larger than those on the model. Besides, the models are not like me. They are all white." After hearing the client's comments, the nurse realized that she did not take into account the significance of breasts based on ethnicity and culture, the size of the breast, and had made no reference in her talk to the influence of culture or race on screening for breast and cervical cancer.

The nurse then talked with the client, asked for her recommendations, and encouraged her to return the demonstration. The nurse coached the client through the self-examination process while pointing out that regardless of breast size, shape, and color, the technique is the same for feeling the tissue and squeezing the nipple to make certain that there is no discharge. Because this nurse was culturally aware, she neither became angry with herself or the client nor imposed her own values on the client. Rather, she elicited a discussion with the client about her beliefs, attitudes, and feelings about screening for cancer that may have been influenced by her culture. The nurse understood that she had to tailor her teaching material to the needs of diverse client groups. Subsequently, she advocated for her agency to purchase a model of an African American woman's breast to be used in future health education programs with African American women.

If the nurse had not been culturally aware, she might have misunderstood the client's concerns and acted in a defensive manner. Such an interaction would have failed to identify client

assets and barriers and appropriate intervention strategies. A confrontation might have ensued that would not have been helpful to the client or the nurse. Nurses should champion the cause for clients seeking health care to have health care professionals respect their cultural traditions.

Cultural Knowledge

Cultural knowledge refers to the process of searching for and obtaining a sound educational understanding about culturally diverse groups ([Campinha-Bacote, 2011](#)). Emphasis is on learning about the clients' worldview from an emic (native) perspective as it pertains to health beliefs and practices, cultural values, and disease incidence and prevalence. For example, cultural knowledge indicates that Middle Eastern women might not attend prenatal classes without encouragement and support from the nurse ([Meleis, 2005](#)). Attendance at prenatal classes is about the future of the baby while the mother's main focus may be on the present and what is happening in the immediate environment. The nurse's understanding of the client's concept of time would decrease misinterpretation that the mother might undermine efforts to promote a healthy baby, and allows the nurse to select strategies to ensure the client's cooperation in providing the best care for the baby. In contrast, knowledge of Nigerian culture indicates that while women will start prenatal care as soon as pregnancy is confirmed, they view pregnancy and birth as natural events and may not continue to attend prenatal classes throughout the prenatal phase ([Ogbu, 2005](#)). Although the behavior of the women from these two countries may be the same, the rationale for their action is different. [Leininger \(2002a\)](#) points out that nurses who lack cultural knowledge may develop feelings of inadequacy and helplessness because they are often unable to effectively help their clients.

Although it is unrealistic to expect that nurses will have knowledge of all cultures, they should know how and where to obtain information that impacts the individual with whom they have frequent interaction. Missing or inadequate knowledge of the client's culture can contribute to negative situations such as client's inadequate use of health resources. Because cultural competence is a requirement in nursing education, students are now exposed to a variety of individuals who hold membership in cultures that are different from their own. Students therefore have an opportunity to assess gaps in their cultural knowledge about how to care for individuals, families, and communities from diverse groups. Students also learn that clients are a rich source of information about their own culture. The **Evidence-Based Practice** box provides an example of learning how to meet the needs of a cultural group that is different from that of the nurse.

Cultural Skill

Cultural skill is the third element of developing cultural competence. Cultural skill refers to the ability of nurses to effectively integrate cultural awareness and cultural knowledge when conducting a cultural assessment as well as a culturally based physical assessment and to use the data to meet the specific client's needs ([Campinha-Bacote, 2011](#)). Culturally skillful nurses elicit

EVIDENCE-BASED PRACTICE

The purpose of this descriptive correlation designed study was to assess the personal beliefs about the causes and meaning of having diabetes among members of the Lumbee Indian tribe living in rural southeastern North Carolina. The sample consisted of 40 adult men and women. A mixed method approach to consist of qualitative and quantitative data was used to conduct this study.

The participant responses indicated a moderate belief in the efficacy of diabetes treatment, a moderate belief in their ability to understand a coherent model of diabetes, and a low level of emotional distress related to having diabetes. Two major themes emerged from the open-ended questions about the causes of diabetes: (1) genetic predetermination and (2) lifestyle practices. Although participants believed that their prescribed diabetes medications were a necessary part of controlling their illness, several expressed fatigue and “felt worn out” with having to persist with their treatment expectations. Limitations were that the sample only included persons who were seeking health care treatment for diabetes and did not include those who were not scheduled for an appointment at the clinic during the data collection period, or included those who did not have access to health care.

Nurse Use

Nurses should be aware that their Lumbee Indian clients may not always have a high degree of confidence in conventional treatment regimens nor understand the unpredictable course of diabetes. Nurses should work with these clients to provide culturally congruent education using appropriate communication to increase clients’ knowledge about current treatment regimens. Nurses should incorporate culturally specific strategies that will empower clients to take a more active role in their illness management, dispel the attitude that a diagnosis of diabetes is genetically predetermined, link concrete behaviors to disease progression and outcomes, and demonstrate to clients how attainable decreases in blood sugar can reduce the risk of long-term consequences. Such strategies would help eliminate negative perceptions that may interfere with the health care delivery process. The researchers suggested that by using a broad systems approach, nurses will increase the availability of Native American health care providers who can serve as role models for the community as well as become activists for developing community infrastructure to support healthy lifestyles.

From Jacobs A, Kemppainen JK, Taylor JS, et al: Beliefs about diabetes and medication adherence among Lumbee Indians living in rural southeastern North Carolina. *J Transcult Nurs* 25:167–175, 2014.

from clients their perception of the health problem, discuss treatment protocol, negotiate acceptable options, select interventions that incorporate alternative treatment plans, and collaborate with all stakeholders. For example, culturally competent nurses use appropriate touch during conversation and modify the physical distance between themselves and others while meeting mutually agreed upon goals.

Cultural Encounter

Cultural encounter is the fourth element essential to becoming culturally competent. Cultural encounter refers to the process that permits nurses to seek opportunities to directly engage in cross-cultural interactions with clients of diverse cultures to modify existing beliefs about a specific cultural group and possibly avoid stereotyping (Campinha-Bacote, 2011). Culture encounters, a key element in becoming culturally competent, have their roots in the nurse–client interpersonal relationship

that focuses on caring, compassion, presence, caring consciousness, and empathy. There are two types of cultural encounters: direct (face-to-face) and indirect. An example of a direct cultural encounter occurs when nurses learn directly from their Puerto Rican clients about spicy foods that they avoid during periods of breastfeeding. Indirect cultural encounters occur when nurses share these assessment findings with other nurses to help them develop their knowledge to effectively care for other Puerto Rican clients who are breastfeeding. The most important encounters are those in which nurses engage in effective communication, use appropriate language and literacy level, and learn about clients’ life experiences and the significance of these experiences for health (Leininger, 2002a). In some communities, nurses may have few opportunities to work directly with persons of other cultures. Thus, when nurses come in contact with clients who are culturally different from the nurse, they should adapt general cultural concepts to the situation until they are able to learn directly from the clients about their culture. Developing cultural competence also comes from reading about, taking courses on, and discussing different cultures within multicultural settings. Successful cultural encounters embrace. Continuously interact with patients from diverse backgrounds to validate, refine, or modify existing values, beliefs and practices about a cultural group and to develop cultural desire, cultural awareness, cultural skill, and cultural knowledge (Figure 7-6).

Cultural Desire

Cultural desire is the fifth element needed in the process of developing cultural competence. It refers to nurses’ intrinsic motivation to want to engage in the previous four elements necessary to provide culturally competent care (Campinha-Bacote, 2012). It is based on the humanistic value of caring for the individual. Nurses who wish to become culturally competent do so because they want to, rather than because they are directed to do so. They demonstrate a sense of energy and enthusiasm about the possibility of providing culturally competent nursing interventions. Unlike the other elements, cultural desire cannot be directly taught in the classroom or in other educational or work settings. Nurses are more likely to demonstrate cultural desire when the environment at all levels of the organization reflects a philosophy that values cultural competence for all its clients.

Campinha-Bacote (2011) recommends that nurses who want to develop cultural competence should not fear making mistakes, but should internalize and incorporate into their own worldview selected beliefs, values, practices, life-ways, and problem-solving skills of other cultures with which they have the most frequent encounters. Several measures of the cultural competence construct have been reported in the nursing literature: the Interpersonal Process of Care survey (IPC-18, Chart Form: Stewart et al, 2007) and the Cultural Competent Assessment (CCA-25; Doorenbos et al, 2005). The IPC survey consists of two subscales that are used to determine disparities in interpersonal care, predict patient outcomes, and examine outcomes of quality improvement efforts to reduce health care disparities. The CCA consists of two subscales that

FIG 7-6 A Hispanic nursing student interacting with African American men at a nutritional center. To interact in a culturally competent manner, the student needs to have awareness of and knowledge about the differences between her culture and the men's culture and the skill to portray this in her behavior toward them.

examine nurses' cultural diversity experience, cultural awareness and sensitivity, and performance of cultural competence behaviors.

Barriers to Developing Cultural Competence

Nurses fail to provide culturally competent nursing care for a variety of reasons: they may have had minimal opportunity to learn about cross-cultural nursing; their supervisors may encourage them to increase productivity at the expense of quality; or they may be pressured by colleagues who are not knowledgeable about cultural concepts and are offended when others use the concepts. These and similar issues may result in nurses engaging in behaviors such as stereotyping, prejudice and racism, ethnocentrism, cultural imposition, cultural conflict, and culture shock.

Stereotyping

Stereotyping is ascribing certain beliefs and behaviors about a given racial and ethnic group to an individual without assessing for individual differences. Stereotyping blocks the willingness of a person to be open and to learn about specific individuals or groups. When information is not immediately available, nurses may generalize about an individual's group behavioral pattern as a guide until they have had time to observe and assess the client's behavior. This can be a problem, and it may lead to a nurse's unwillingness to incorporate new and specific data about the client. New information may be distorted to fit with preconceived ideas. The generalizing that was a beginning point for understanding the individual becomes a final point. The individual is thus stereotyped on the basis of the group's ascribed behavior.

Stereotypes can be either positive or negative. For example, Asians are often positively stereotyped as the "model" minority

group, leading to an expectation that they will always behave in ways that reinforce the stereotypical notion. Other groups are stereotyped as "industrious and hard working," while some groups are stereotyped as negative and noncompliant. To illustrate, a nurse who believes that young African American women are sexually permissive may label a woman in this group who is complaining of abdominal pain as having symptoms of a sexually transmitted disease. Clients who perceive they are being stereotyped may respond with anger and hostility. This in turn perpetuates the stereotype and creates barriers to health-seeking behavior. To minimize the use of stereotypes, nurses should rely on their ability to conduct good health assessment and engage in culturally competent discussions.

Prejudice

Prejudice is the emotional manifestation of deeply held beliefs (stereotypes) about a group. These beliefs are directed toward a person who is a member of that group, and who is presumed to have the qualities ascribed to the group. Prejudice is not based on reason or experience but rather on negative or favorable preconceived feelings. These feelings are often precursors for discriminatory acts based on prejudging, limited knowledge about, misinformation about, fear of, or limited contact with individuals from that group. Those who are prejudiced wish to deny the individuals, on the basis of race, skin color, ethnicity, or social standing, the opportunity to benefit fully from society's offerings of accessible health care, education, good jobs, and community activities.

Racism

Racism is a form of prejudice that occurs through the exercise of power by individuals and institutions against people who are

judged to be inferior on the basis of intelligence, morals, beauty, inheritance, and self-worth. Individuals are denied certain opportunities (e.g., jobs, housing, education, and health care) typically enjoyed by the larger group because of some characteristic over which they have no control. When racism is acted upon, it results in perceived or actual harm to the individual. Three types of racism exist: individual, institutional, and cultural. Individual racism refers to discriminatory behavior or acts directed toward individuals or groups because of identified characteristics, such as skin color, hair texture, and facial features. Institutional racism refers to discriminatory behavior or acts by an institution, as expressed in policies, priority setting, hiring, and resource allocation practices that are directed toward individuals and groups and restrict their access to opportunities or resources. Institutional racism provides the structure for racism at the individual level to be accepted and condoned. Cultural racism refers to discriminatory behavior or acts directed by the dominant group toward another cultural group. The cultural group is depicted in derogatory or stereotypical ways because of, for example, language or dress. All forms of racism can have individual, as well as community and population, effects.

The Tuskegee Syphilis Study is a well-known example of racism (Gamble, 1997). This study was conducted by the U.S. Public Health Service to observe the effects of syphilis on African American men over a period of 40 years, beginning in 1932. When African American men with syphilis were recruited for the study, they were told that they were being treated for “bad blood,” and treatment for syphilis was withheld intentionally so that the study on the deleterious effect of syphilis could be completed. As a result, hundreds of men lost their lives because of discriminatory policies that promoted substandard health care. The consequence of such racism has contributed to the long-held beliefs by some African Americans that health research might be designed to harm them and that accessible health care for African Americans might be part of a research study, especially government-sponsored programs. In 2005, Dwayne, Isaac, and Laveist reported that a telephone survey revealed that no differences by race existed between African Americans and whites in knowledge about the Tuskegee study. There were significant race differences in medical care that the researchers attributed to broader historical and personal experiences of African Americans. Perceived racism by cultural groups can have physiological and psychological negative health outcomes that include high blood pressure, stroke, engaging in risky behaviors such as smoking and substance abuse, depression, and low self-esteem. Nurses too may be recipients of prejudicial or racist acts (Fielo and Degazon, 1997), but they do not have to accept such behavior from clients. Rather, they should set limits, discuss the behavior with other colleagues when appropriate, and avoid personalizing the behavior.

One way to depict the effects of prejudice and racism is to use a two-dimensional matrix: overt versus covert, and intentional versus unintentional. Locke and Hardaway (1992) depict four types of prejudice and racism that result from this matrix: overt intentional, covert intentional, overt unintentional, and covert unintentional. Overt intentional prejudice or racism

means that the behavior is both apparent and purposeful. The nurse is aware of personal biases and beliefs and integrates them into a plan of action to negatively manage client problems. With overt unintentional, the behavior is apparent but not purposeful, and no harm is intended, although harm may result. Covert intentional means that the behavior is subtle and purposeful but the person tries to avoid being viewed as prejudicial or racist. Covert unintentional means that the person's behavior is neither apparent nor purposeful. The person is unaware of the behavior. Regardless of the type of prejudice or racism, the behavior is harmful to the client. Examples of each type of prejudice and racism are presented in Box 7-5.

Ethnocentrism

Ethnocentrism, or cultural prejudice, is the belief that one's own cultural group determines the standards by which another group's behavior is judged. The implication is that one's own standards are better than and superior to the other person's standards. Ethnocentric nurses favor their own professional values and find unacceptable that which is different from their culture. Their inability to accept different worldviews often leads them to devalue the experiences of others, judge them to be inferior, and treat those who are different from themselves with suspicion or hostility (Andrews and Boyle, 2012).

Ethnoculturalism is in contrast to **cultural blindness**, in which there is an inability to recognize the differences between one's own cultural beliefs, values, and practices and those of another culture. The tendency is to believe that the recognition of racial, ethnic, religious, or gender difference is itself prejudicial and discriminatory. Hence, nurses who state that they treat all clients the same, regardless of cultural orientation, are demonstrating cultural blindness.

Cultural Imposition

Cultural imposition is the belief in one's own superiority, or ethnocentrism, and is the act of imposing one's cultural beliefs, values, and practices on individuals from another culture. Nurses impose their values on clients when they forcefully promote biomedical traditions while ignoring the clients' valuing of non-Western treatments such as acupuncture, herbal therapy, or spiritualistic rituals. A goal for nurses is to develop an approach of **cultural relativism**, whereby they recognize that clients have different approaches to health, and that each culture should be judged on its own merit and not on the nurse's personal beliefs.

Cultural Conflict

Cultural conflict is a perceived threat that may arise from a misunderstanding of expectations when nurses are unable to respond appropriately to another individual's cultural practice because of unfamiliarity with the practice (Andrews and Boyle, 2012). Although cultural conflicts are unavoidable, the nursing goal is to manage conflicts so that they do not affect the delivery of culturally competent nursing care. Knowing how conflict is managed in the particular culture can minimize the conflict. It is important, when resolving the conflict, that all persons involved in the conflict have a way to “save face.”

BOX 7-5 Types of Prejudice and Racist Behaviors

Overt Intentional Prejudice/Racism

Two homeless women, one African American and the other Irish, are clients at the oncology clinic at the free neighborhood health care center. Both of the women have a history of ovarian cancer and are experiencing financial difficulty from time to time due to the cost of medical care associated with the illness. Although the African American client has been homeless longer, both clients have health issues associated with diminished quality of life and functional status related to the length of the illness, the progression of the illness, and the seriousness of the illness. The nurse as case manager referred the Irish client to the social services department to inquire about available resources but did not refer the African American client. The nurse reasoned that minority clients have direct contact with some local and national government programs, know about available resources, and have experience negotiating the social system for themselves and their family. In contrast, the nurse reasoned that because the Irish woman had no prior experience negotiating government programs, she needed to advocate for her client. The nurse did not assess the health-seeking behaviors of either client before coming to these conclusions, stereotyped both women, and intentionally used her informational power to help one client while denying assistance to the other client.

Overt Unintentional Prejudice/Racism

The community health nurse was assigned to make an initial home visit to two clients recently discharged from the hospital with a diagnosis of hypertension. The nurse performed physical assessments on both clients. He developed an extensive culturally relevant teaching plan with the Filipino client that included information on sodium restriction and its effect on kidney functioning, ways to integrate cultural foods into the diet, and support in lifestyle changes. With the Puerto Rican client, the nurse performed a routine physical assessment and did not discuss the client's culturally special dietary requirements. The nurse reasoned that the Puerto Rican client was not capable of understanding such complex information and would most likely seek information from her *curandera* (a folk practitioner) to manage the hypertension. At the end of the visit, the nurse said to this client, "Take care of yourself. See you next time." This nurse did not realize that he had stereotyped the client and that his nursing interventions were

minimal. He believed that he had delivered patient-centered care and the difference in his assessment and implementation approach reflected his understanding of cultural competence theory.

Covert Intentional Prejudice/Racism

A Native American nurse works in a home health agency that serves an ethnically diverse community. The nurse has observed that her assigned clients are always among the poorest and live in the unsafe ZIP code areas of the community. Her nonminority nurse colleagues are not assigned to clients residing in those ZIP codes. In a recent staff meeting, the Native American nurse expressed discomfort about the assignment patterns that she had observed with her nursing supervisors. Upon hearing her observations, the supervisors looked at the nurse in a surprised and skeptical manner and asked her to give a specific example. This is an example of covert racism because the nursing supervisors were aware of the informal policy that they assign minority nurses to clients residing in designated minority neighborhoods. The nursing supervisors were aware of this long-standing practice to assign minority nurses to minority clients and Caucasian nurses to Caucasian clients but would never admit to it. The supervisors thought that the best way for minority clients to be the recipients of culturally competent care was to assign a minority nurse to care for their own.

Covert Unintentional Prejudice/Racism

Ashley is the seven-year-old daughter of a lesbian middle-class couple. The school nurse is frustrated that Ashley's parents refuse to disclose the father and insist on altering the demographic form to include the two mothers as parents. Ashley frequently shows up to the nurse's office with stomach upsets and the nurse attributes the upsets to the parents' sexual orientation. The school nurse has not conducted an in-depth assessment of the child's chief complaint. This is unusual behavior for the school nurse as she has been cited for her thorough assessments of children that have resulted in early diagnosis and treatment of disorders for this age group. This school nurse is unaware that her intolerance for the parents' sexual orientation and family's lifestyle has contributed to her decision to provide a cursory assessment for Ashley.

Culture Shock

Culture shock is the feeling of helplessness, discomfort, and disorientation experienced by an individual attempting to understand or effectively adapt to a cultural group whose beliefs and values are radically different from the individual's culture. When nurses experience culture shock, it may be a normal reaction to a client's beliefs and practices that are not allowed or approved in the nurse's own culture (Andrews and Boyle, 2012). Culture shock is brought on by anxiety that results from losing familiar signs and symbols of social interaction. As nurses change their practice environments and leave the safety of the hospital for community settings, they may experience heightened discomfort and feelings of powerlessness to confront differences between themselves and clients. This is especially true when nurses have little knowledge or exposure to the culture from which the client comes. For example, nurses who are unfamiliar with "cupping" may experience culture shock when Cambodians use this practice to relieve headaches, to reduce stress and sinus tension, or to delay the onset of colds. Being aware of the clients' own cultural beliefs and having knowledge of other cultures may help nurses to be more accepting of cultural differences.

Culturally Competent Nursing Interventions

In culturally competent nursing interventions nurses integrate their professional knowledge with the client's knowledge and practices to maintain, protect, and restore the client's health. Leininger (2002a) developed a nursing intervention framework to increase culturally competent care; this framework suggests three modes of action, based on negotiation between the client and nurse, which guide the nurse to deliver culturally competent care: cultural preservation, cultural accommodation, and cultural repatterning. When these decisions and actions are used with cultural brokering, the nurse is able to provide holistic care for culturally diverse clients (individual, family, or community).

Cultural Preservation

Cultural preservation refers to assistive, supportive, facilitative, or enabling nurse actions and decisions that help the clients of a particular culture to retain and preserve traditional values, so they can maintain, promote, and restore health. For example, acupuncture, an ancient Chinese practice of inserting needles in specific points on the skin through which life energy flows, is used to relieve pain or cure diseases by restoring balance of

yin and yang (Spector, 2012). This practice is being accepted by increasing numbers of Western practitioners as a legitimate treatment for many health problems. Thus, when Western practitioners integrate modalities such as acupuncture in the plan of care to maintain and protect the health of Asian clients who subscribe to the practice, they are providing care that is consistent with the clients' beliefs and values and helping to preserve their culture.

In another example, the nurse helps maintain cultural family values of Ms. Rodriguez, a 73-year-old Filipino woman who was discharged from hospital to home care after surgery for cancer of the large intestine. During the home visit, the nurse discussed with the client and her husband about making a referral to have a home health aide assist with physical care and light house-keeping chores. The family was gracious but seemed hesitant to accept the referral. The nurse knew that in the Filipino family the older daughter is expected to be the caregiver for her mother and father. She asked the couple if they would like to discuss the situation with their daughters. Both the client and her husband seemed pleased with the idea, and the nurse promised to get back to them the next day. When the nurse returned for her visit, Ms. Rodriguez's older daughter was present and told the nurse that she would manage without additional help. The three daughters had made a schedule to take turns caring for their parents. The nurse accepted and supported the family's decision and told them that if they decided at a later time to accept the services of a home health aide, they should call the agency. The nurse then gave the family the telephone number of the agency, and scheduled the next follow-up visit with them.

Cultural Accommodation

Cultural accommodation refers to assistive, supportive, facilitative, or enabling nurse actions and decisions that help clients of a particular culture accept nursing strategies, or negotiate with nurses to achieve satisfying health care outcomes. Nurses may support and facilitate successful use of home burial of placenta alongside interventions from the biomedical health care system. For example, the delivery nurse was very helpful when Ms. Sanchez asked her not to discard a piece of the amniotic sac that was present on her grandbaby's face immediately after birth. Ms. Sanchez asked the nurse to give it to her instead. The grandmother believed that being born with a piece of the amniotic sac on the face was a visible sign that something special was going to happen in the person's life. The grandmother explained that after she dried the piece of the amniotic sac, she would keep it in a safe place. She would also spend extra time protecting the baby to prevent her from being harmed. Although the delivery room nurse was not knowledgeable about this practice, she was assistive and gave the grandmother the piece of the sac as she requested.

Cultural Repatterning

Cultural repatterning refers to assistive, supportive, facilitative, or enabling nurse actions and decisions that help clients of a particular culture to change or modify a cultural practice for new or different health care patterns that are meaningful, satisfying, and beneficial. Successful repatterning is likely to occur

when cultural values and beliefs are respected while at the same time there is a cocreation of interventions with the client to provide for a healthier pattern than before the changes were developed. For example, a culturally competent school nurse who works with Mexican Americans knows of the high incidence of obesity among women 20 years and older. Using this information, she developed a health education program for Mexican teenagers in the local high school. While respecting their cultural traditions, the nurse discussed weight management strategies with the teenagers. The nurse understood the teenagers' cultural issues pertaining to food and knew how to negotiate with them. She discouraged the use of fried foods (such as tortillas), sour cream, and regular cheese and encouraged and demonstrated the use of baked tortillas and salsa as dip and topping. In another example, a nurse discovered during her instructions on diabetes self-management that pregnant Haitian women were visiting an herbalist to obtain teas so they would not have to take insulin. The nurse asked for the names of the herbs in the teas that they were drinking and scheduled a conference with the pharmacist to discuss the specific ingredients in the herbs as well as ways that they might help clients meet their cultural needs. The nurse found out that one of the herbs contributed to high blood pressure, a problem that many of the women were experiencing. She negotiated with the women not to take the tea with the specific herb. The nurse understood the importance of supernatural causes of illness in the Haitian culture and sought cooperation from the herbalist. Another example of cultural repatterning occurs when nurses assist older Chinese clients to use low-sodium soy sauce, rather than soy sauce with high sodium, in their cooking as a means to more effectively manage their hypertension. Similarly, nurses should guide African Americans to eat more broiled and less fried foods.

Culture Brokering

Culture brokering is advocating, mediating, negotiating, and intervening between the client's culture and the biomedical health care culture on behalf of clients. Nurses as culture brokers act as go-betweens or advocates between groups of persons or persons of different cultural backgrounds to reduce conflict or produce change to facilitate client access to health care. As client advocates, nurse brokers are positioned to understand both cultures (the client's culture and the culture of the health care system) and resolve or lessen problems that result when individuals in either culture do not understand the other person's values. To illustrate, migrant workers tend to have high occupational mobility; many are poor and have limited formal education. They may seek health care only when they are ill and cannot work. Nurses who staff mobile health care vans often come in contact with migrant workers and usually take the opportunity to teach these individuals about prevention, health maintenance, environmental sanitation, and nutrition because it may be the only opportunity they will ever have to care for that particular migrant worker. These public health nurses also advocate for the rights of the migrant worker to receive quality health care. In this instance mobile health care nurses who provide manpower for the health mobile care van clinic may

contact the migrant health services for follow-up or referral care for the migrant workers who received health care from the mobile health care van.

LINKING CONTENT TO PRACTICE

As has been discussed throughout the chapter, culturally competent nursing care uses many of the standards, guidelines, and competencies from key nursing and public health documents. For example, the Council on Linkages (Council on Linkages, 2010) has a set of skills related to cultural competency and a set related to communication that are consistent with the information in this chapter. Likewise, the Quad Council further develops and applies the skills of the Council on Linkages related to both cultural competency and communication to public health nursing practice. As an example, the Council on Linkages states that a necessary skill in public health is to consider “the role of cultural, social, and behavioral factors in the accessibility, availability, acceptability and delivery of public health services.” The Quad Council states that “public health nurses should consider the role of cultural, social, and behavioral factors in the accessibility, availability, acceptability and delivery of public health nursing services.” Each of the competencies in the Council on Linkages core competencies is applied directly to public health nursing practice by the Quad Council (2011). Also, the American Academy Expert Panel on Global Nursing and Health (2010) identifies 12 standards that serve as a resource and guide for nurses in practice, administration, education, and research by underscoring cultural competence as a priority of care for the populations that they serve.

Developing Organizational Cultural Competence

Cultural competence barriers extend beyond the individual health care provider. Institutions and agencies can facilitate cultural competence. For example, a number of organizations subscribe to the nine cultural competence strategies that Lie and colleagues (2010) targeted at the institutional level: (1) providing interpreter services, (2) establishing recruitment and retention policies to increase ethnic minority representation, (3) providing training in cultural competence and sensitivity, (4) coordinating with traditional healers in the community, (5) using community health workers, (6) carrying out culturally competent health promotion that incorporates cultural notions of health and well-being, (7) including families and community members in care and decision making, (8) facilitating provider immersion into another culture and administrative and organizational accommodation, such as providing a welcoming environment, and (9) ensuring linguistic appropriateness of materials and information. By incorporating culturally competent behaviors that are embedded in the culture of the organization into the cultural competence framework, institutions have expanded the reach of their resources into the community and are addressing social determinants of health care.

Tripp-Reimer et al (2001) described another organizational cultural competence intervention model. They described four levels of systems interventions: (1) being culturally neutral refers to the standard practice typically developed by whites for whites; (2) being culturally insensitive refers to addressing issues of accessibility of services by using bilingual and bicultural health informational material that incorporates surface-level cultural knowledge, such as dietary preferences into

practice; (3) being culturally innovative refers to the use of cultural symbols and notions of health and well-being to convey health promotion messages, working with established social institutions in the community; and (4) being cultural transformative refers to using principles of social activism and change to unearth power relationships and partnering with communities to alter aspects of the basic social structure. The assertion by these authors that social activism can and should be a part of social competence underscores the commitment that organized nursing has to address social justice issues rooted in larger systems problems of inequality and discrimination. Nurses, as providers, are expected to develop cultural competence to change the dynamic of the nurse–client relationship. As leaders, nurses are expected to use leadership skills to advocate for social justice by promoting community empowerment, liberation, and relief of suffering and human oppression.

Betancourt et al (2003) presented a three-tier cultural competence framework—clinical, organizational, and structural—through which culturally competent strategies can be implemented to reduce health disparities. According to Betancourt, the rationale for these three levels of focus is that all three levels contribute to disparate health outcomes; therefore they must all be addressed to level the playing field and equalize health outcomes. Social cultural barriers to culturally competent care in this model are clinical barriers (poor provider communication, provider stereotyping and discrimination, and misunderstanding of culture perspective on health issues), organizational barriers (the lack of minorities in institutional leadership and the health care workforce), and structural (lack of interpreter services, bureaucratic intake processes, and difficulties accessing specialty care for minorities). Interventions to overcome these barriers are suggested for each level. Structural interventions include improving access to processes within the delivery health care system that includes expanding interpreter services and health teaching; organizational interventions include increasing diversity within the workforce and the health care leadership; and clinical interventions include working to enhance provider knowledge of the relationship between sociocultural factors and health beliefs and behaviors, and equipping providers with tools and skills to manage these factors appropriately.

Institutional level interventions could include agency engagement with the broader community, increased access to care for socioeconomically disadvantaged groups, and selection of interventions that are culturally appropriate. This macro level model provides direction for agencies that want to adopt culturally competent practices as part of their operational procedures and to facilitate provider level culturally competent care. When describing these broad-base interventions, cultural competence becomes an umbrella term to address the many individual level skills, attitudes, and knowledge and organizational level structures, policies, and protocols that come together in a profession, organization, or community to provide effective care to culturally diverse populations.

How well do culturally competent interventions fare in improving positive health outcomes for culturally diverse clients? Many studies demonstrate a beneficial effect on

provider knowledge, provider attitudes, and provider skills. Favorable patient satisfaction measures and improvement in adherence to follow-up among client assignees to intervention group providers have also been reported. Interventions that focus on the avoidance of bias, gender concepts of culture, and client-centeredness demonstrate promise as lasting strategies to decrease health disparities. These strategies include availability and access to assessment of problems in their social and cultural context, selection of culturally and socially acceptable interventions, and increased accountability to recipients of services and their community. Institutional level interventions could include agency engagement with the broader community, increased access to care for socially disadvantaged groups, and selection of interventions that are culturally appropriate. These four macro level modes provide direction to agencies that want to adopt culturally competent practices as part of their operational procedure and to facilitate provider level culturally competent care. When describing these broad-based interventions, cultural competence becomes an umbrella term to address the many individual level competencies, skills, attitudes, and knowledge, and organizational level competencies, structures, policies, and protocols that come together in a profession, organization, or community to provide effective care to culturally diverse populations.

Positive Health Outcomes Associated with Cultural Competence

Nurse clinicians and educators are beginning to understand how to provide critical learning environments and workplaces for students, faculty, and practitioners to apply the concepts of cultural competence in their practice in order to improve the effectiveness of their actions. The majority of nurses continue to believe that they are less confident and inadequately prepared to provide sustained culturally competent care to clients from diverse cultures (Esposito, 2014). It is important to disseminate cultural competence outcomes in nursing through public health and research conferences, staff development programs, continuing education programs, and the student nursing associations.

Sealey et al (2006) examined the cultural competence of nurse educators in Louisiana and found that very few of the nurse educators had formal preparation to teach transcultural nursing and that they felt uncomfortable attempting to do so. A study conducted on community-based nurses' perceptions of cultural competence offers some encouragement (Starr and Wallace, 2009). The study indicated that about 85% of clients participating in the study perceived that nursing care today contains key components of decision making, communication, and interpersonal styles that reflect cultural components, 57% indicated that their communication style was culturally competent, 61% rated their decision-making choices as reflective of cultural competence behaviors, and about 70% said their interpersonal style was indicative of cultural competence behaviors.

Evidence-based cultural competence practice in nursing connecting culturally competent health care goals with the professional values of nursing and patient care outcomes and

satisfaction has been the subject of recent research activity in nursing. The majority of studies of the effectiveness of culturally competent nursing interventions are descriptive. Few studies have employed a randomized clinical trial design. Fisher et al (2007) identified 38 nursing interventions that used some form of culturally oriented interventions to target racial and ethnic disparities. Kulbok et al (2012) cited several examples from the evidence-based nursing literature of public health nursing using the technique of participatory practice, defined as the building of partnerships with community members to assess, plan, analyze data, and implement sustainable health promotion and prevention programs to reach marginalized populations in vulnerable communities. For instance, Andrews et al (2007) used participatory methods to assess an African American population living in an impoverished neighborhood. To gain in-depth insights about the community's assets and needs, the research team involved community advisory board members and community health workers to assist them in conducting a series of community forums and interpreting the data gathered at the forums. Anderson and her research team (2007) were able to identify multilevel factors related to smoking patterns of the community. Thomas et al (2009) worked with a tribal community council to attain culturally sensitive knowledge of the tradition, history, and strength of that community in projects to reduce substance abuse. McQuiston et al (2005) used ethnographic community participatory strategies to set up a nominal group process to obtain important cultural aspects of health when assessing health disparities in a Latino population. Zandee et al (2010) described how public health nursing students used cultural competence principles to better understand the cultural background of the communities in which they were placed. By partnering with community health workers, the students were able to improve their cultural competence.

CULTURAL NURSING ASSESSMENT

A **cultural nursing assessment** is "a systematic identification and documentation of the culture care beliefs, meanings, values, symbols, and practices of individuals or groups within a holistic perspective, which includes the worldview, life experiences, environmental context, ethno history, language, and diverse social structure influences" (Leininger, 2002b, pp. 117-118). A cultural assessment is the basis for providing culturally competent health care and helps to ensure that nurses will understand and respect the client's beliefs, values, and health care practices and take these cultural data into consideration when creating a treatment plan for the client. A cultural assessment should focus on those aspects relevant to the presenting problem, necessary intervention, and participatory education. Nurses use the information gathered to help them identify and understand clients' beliefs and practices about health and illness. By adopting a relativistic approach, nurses avoid judging or evaluating the clients in terms of their own culture.

A nonjudgmental approach toward the client's culture is facilitated through having a skill set that includes understanding, eliciting, listening, explaining, acknowledging, recommending, and negotiating. It is vital that nurses listen to clients'

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

The six quality and safety competencies for nurses that were identified in the Quality and Safety Education for Nurses (QSEN) project are patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics. While each of these is important and pertinent to the nursing actions taken with people from cultural groups other than that of the nurse, perhaps the most significant is that of patient-centered care. The chapter presents many guidelines and principles for aiding nurses in providing culturally competent care. One of the areas in which patient-centered care is lacking occurs when the nurse and the patient are not communicating effectively. The lack of communication may occur when they speak different languages, have different cultural practices and expectations that lead them to hear messages differently or when the persons being served simply do not understand what the nurse is saying and are reluctant to acknowledge this. Nurses must observe for both verbal and nonverbal cues that a message is either understood or not understood. When the latter occurs, the nurse should take action to clarify the message. This may include asking someone from that cultural group to assist or to enlist the aid of an interpreter. See: Issel LM, Bekemeier B: Safe practice of population-focused nursing care: Development of a public health nursing concept, *Nursing Outlook*, 58(5):226-232, 2010.

The following applies the QSEN competency of client-centered interventions that reflect cultural competence.

Targeted Competency: Client-Centered Intervention—Recognize the client or designee as the source of control and full partner in providing compassionate and coordinated interventions based on respect for the client's preferences, values, and needs.

Important aspects of client-centered intervention include:

- **Knowledge:** Describe strategies to empower clients or families in all aspects of the health care process
- **Skills:** Communicate client values, preferences, and expressed needs to other members of the health care team
- **Attitudes:** Willingly support client-centered care for individuals and groups whose values differ from your own.

Client-Centered Care Question

Competence in providing client-centered interventions involves not only effective interviewing of individual clients, but developing an awareness of their context. As a community-based clinician, it is helpful to familiarize yourself with the cultural context of your clients. Learning about community resources can sometimes be helpful in learning about the cultural context. You have just been hired as a visiting nurse in a Hispanic community. What community resources could you explore to assist you in providing effective client-centered care?

Answer

- You might explore community centers. Where are they? How well frequented are the community centers? Which programs are most popular? Which community center programs are health-oriented?
- Are community members very involved with one or more churches? You might familiarize yourself with elements of this faith tradition.
- Are there community elders who are publically recognized as leaders in the community? Can you meet with them to understand how the community has changed and evolved over time?

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

perceptions of their problem and, in turn, that nurses explain to clients their own perceptions of the problem. Nurses and clients should acknowledge and discuss similarities and differences between the two perceptions to develop recommendations and suggestions for management of problems. A variety of tools are available to assist nurses in conducting cultural assessments (Andrews and Boyle, 2012; Leininger, 2002b). The focus of such tools varies, and selection is determined by the dimensions of the culture to be assessed.

During an initial contact with clients, nurses should perform a general cultural assessment to obtain an overview of the clients' characteristics. Nurses ask clients about their ethnic background, language, education, religious affiliation, dietary practices, family relationships, hospital experiences, occupation and socioeconomic status, cultural beliefs, and language. Nurses also want to know about clients' distinctive features, perceptions of the health issue, causation, treatment, anticipated results, and the impact the issue might have on the client. Such basic data help nurses understand the clients from the clients' points of view and recognize their uniqueness, thus avoiding stereotyping. Data for an in-depth cultural assessment should be gathered over a period of time and not restricted to the first encounter with the client. This gives both the client and the nurse time to get to know each other, and it is especially beneficial for the client to see the nurse in a helping relationship. An in-depth cultural assessment should be conducted in two phases: a data collection phase and an organization phase.

The data collection phase consists of three steps:

1. The nurse collects self-identifying data similar to those collected in the brief assessment.
2. The nurse raises a variety of questions that seek information on the client's perception of what brings them to the health care system, the illness, and previous and anticipated treatments.
3. After the nursing diagnosis is made, the nurse identifies cultural factors that may influence the effectiveness of nursing care actions.

In the organization phase, data related to the client's and family's views on optimal treatment choices are routinely examined, and areas of difference between the client's cultural needs and the goals of Western medicine are identified. Nurses may use Leininger's (2002a) three actions (discussed previously in this chapter) to guide them in selecting and discussing culturally appropriate interventions with clients.

The key to a successful cultural assessment lies in nurses being aware of their own culture. The nurse should consider the following suggestions when eliciting cultural information:

- Be sensitive to the cues in the environment and be in tune with the verbal and nonverbal communications before taking action.
- Know about the resources in the community such as schools, churches, hospitals, tribal councils, restaurants, taverns, and bars.
- Know the specific areas to focus on before beginning the cultural assessment.
- Select a strategy for gathering cultural data. Possible strategies include in-depth interviews, informal conversations,

observations of the client's everyday activities or specific events, survey research, and a case method approach to study certain aspects of a client.

- Identify a confidante who will help “bridge the gap” between cultures. Be aware that in some cultures the woman's husband or a close male family friend may be the person from whom the nurse may need to obtain the cultural information.
- Know the appropriate questions to ask without offending the client.
- Interview other nurses or health care professionals who have worked with the specific individual, family, or community to get their input.

- Use a trained interpreter if the client has limited proficiency with English.
- Talk with formal and informal community leaders to gain a comprehensive understanding about significant aspects of community life.
- Be aware that all information has both subjective and objective aspects, and verify and cross-check the information that is collected before acting on it.
- Avoid the pitfalls that may occur when making premature generalizations.
- Be sincere, open, and honest with yourself and the client.

PRACTICE APPLICATION

Mr. Nguyen, a 64-year-old man from rural Vietnam, entered the United States with his family 3 years ago through the refugee program. Mr. Nguyen was a farmer in his homeland, and since his arrival he has been unable to obtain a stable job that would allow him to adequately care for his family. His financial resources are limited, and he has no insurance. He speaks enough English to interact directly with people outside his family and community. His oldest daughter, Aeyoung, is enrolled in a 2-year program to become a registered nurse.

The Nguyen family attends the neighborhood church with other Vietnamese families. Mr. Nguyen has been attending the clinic at the hospital but refuses to discuss with his family, even with Aeyoung, the reason for these visits. Aeyoung became increasingly concerned as she observed her father to have insomnia, retarded motor activity, an inability to concentrate, and weight loss. However, Mr. Nguyen denied that he was not well. Aeyoung decided to discuss her concerns with a nurse, with whom she had developed an attachment, at the church. She invited the nurse to her home for lunch on a Saturday so she could meet her father and validate her impressions.

After several visits with the family, the nurse was able to establish a close enough relationship with Mr. Nguyen so that she could engage him in a discussion of his health. Because of her extensive work with other Vietnamese immigrants, the nurse was familiar with themes of loss and decided to focus her conversation with Mr. Nguyen on his adjustment to the new community living, gains and losses as a result of immigration, and coping strategies. After several discussions with

Mr. Nguyen, he confided in the nurse that he feared that he was dying because he had been diagnosed with cancer of the small intestine. He further revealed that he had not shared the diagnosis with the family because he did not want them to know of his “bad news.” Mr. Nguyen had refused treatment because he knew that people never get better when they have cancer; they always die.

- Which of the following actions best characterize the nurse's willingness to provide culturally competent care to Mr. Nguyen and his family?
 - Discuss with the client his understanding of his diagnosis.
 - Discuss with the client the prognosis for a person diagnosed with cancer of the small intestine in the United States.
 - Discuss with the client the prognosis for a person diagnosed with cancer of the small intestine in Vietnam.
 - Discuss the medical treatment and surgical intervention for cancer of the small intestine.
- The way in which the nurse poses questions to Mr. Nguyen is very important and determines the kind of responses the client gives to the nurse. What types of questions should the nurse pose to Mr. Nguyen to get the best responses from him?
- Which resources should a community health agency have available to assist Mr. Nguyen with his health care concerns?

Answers can be found on the Evolve site.

KEY POINTS

- The U.S. population is becoming increasingly diverse, and nurses and health care organizations need to learn more about the culture of individuals to whom they provide care and the impact of culture on health care.
- Culture is a learned set of behaviors that are widely shared among a group of people and helps guide individuals in problem solving and decision making processes.
- Cultural differences exist among groups and they may be observed in areas such as biological variations, personal

space, perception of time, environmental control, family organization, communication, nutrition, and religion.

- There are individual differences among people within a cultural group.
- Changes in immigration laws and policies have increased migration, contributing to changes in community demographics and challenges for nurses to effectively communicate with their clients and help them understand the basic health information needed to make appropriate health

KEY POINTS—cont'd

- decisions. When nurses do not speak or understand the client's language, interpreters should be available to assist them in communicating with clients.
- In selecting an interpreter, nurses should not only consider the clients' cultural needs but also respect their right to privacy.
 - Members of minority groups are over-represented on the lower tiers of the socioeconomic ladder. Poor economic achievement is also a common characteristic among populations at risk, such as the homeless, migrant workers, and refugees. Nurses should be able to distinguish between culture and socioeconomic class issues and not interpret behavior as having a cultural origin when in fact it is based on socioeconomic class.
 - Clients who are excluded from full participation in the economic, social, and political life of the society may have more complex health issues and more difficulty accessing and receiving services from health care institutions.
 - The social determinants of health are the circumstances in which people are born and grow up, live, work, and age, and the systems put in place to deal with illness. They are shaped by race, economics, education, the family structure, health, and access to health resources.
 - Efforts to understand dietary practices should go beyond relying on the individual having membership in a specific group and include religious requirements.
 - Culturally competent nursing care is designed for a specific client, reflects the nurse's knowledge and the individual's knowledge and practices, and is implemented with care and sensitivity. Such nursing care helps to improve health outcomes and reduce health care costs.
 - Standards of practice have been developed to guide nurses around the world in the areas of clinical practice, research, education, and administration.
 - Culturally competent nurses are empowered to provide equitable nursing care that is focused on meeting the physical, physiological, social, and cultural needs of the client.
 - Culturally competent nurses are aware of their own cultures, use cultural knowledge, have cultural skill, and select culturally appropriate interventions to care for the client holistically. The most important aspect is cultural encounter with the client.
 - Nurses must have the desire or intrinsic motivation to want to provide culturally competent nursing care.
 - Barriers to providing culturally competent care include stereotyping, prejudice and racism, ethnocentrism, cultural imposition, cultural conflict, and culture shock.
 - Culturally competent nurses may select from four modes of interventions when providing care: cultural preservation, cultural accommodation, cultural repatterning, and culture brokering.
 - Organizations, institutions, and professional associations should have policies, procedures, and practices that support a climate in which nurses can deliver culturally competent care to clients whom they serve.
 - Nurses should perform a cultural assessment on every client with whom they interact. Cultural assessments help nurses understand clients' perspectives of health and illness and thereby guide them to implement culturally competent interventions. The needs of clients vary with their age, education, religion, and socioeconomic status.

CLINICAL DECISION-MAKING ACTIVITIES

1. Select a culture that you would like to study. Go to the appropriate websites and gather information about the cultural group. Identify the group's cultural beliefs and practices and health-seeking behaviors. Share what you have obtained from websites and ask the person to evaluate the information. Discuss this information with at least one member of that cultural group. Compare and contrast information obtained from the two sources. Describe how you would use this information in your clinical practice.
2. Discuss how you would interview older clients who are considering giving up their independence and living in a nursing home. Prepare them for the likelihood that their health care providers are likely to be culturally diverse and may not share the same race or ethnicity. How will they engage in communication with the care provider about their health needs, family of origin, and important routine behaviors? How will they share their daily routine, dietary practices, and memories of family and friends?
3. Identify an alternative health care practitioner in the community of your clinical placement where you have been assigned. Prepare six questions and use them as a guide to interview the alternative healer about cultural health beliefs, healing practice, and alternative biomedical explanation of illness systems.
4. Select from one of the standards of practice for culturally competent care (Office of Minority Health, Expert Panel for Global Nursing and Health of the American Academy of Nursing and the Transcultural Nursing Society, the Quad Council, and the Joint Commission) and examine the extent to which the public health agency in your community is in compliance with cultural competence standards as identified by one of these organizations. Report your findings to a culturally competent leader in the organization.
5. On the basis of *Healthy People 2020* objectives, identify an at-risk aggregate in your community. Use the AHRQ website to access information for that year on the progress the community has made toward decreasing a specific health disparity. Work with the public health nurse to evaluate the effectiveness of the plan the community has developed to remedy the disparity.

Public Health Policy

Marcia Stanhope, PhD, RN, FAAN

Dr. Marcia Stanhope is currently an Associate of the Tufts and Associates Search Firm, Chicago, Ill. She is also a consultant for the nursing program at Berea College, Kentucky. She has practiced community and home health nursing, has served as an administrator and consultant in home health, and has been involved in the development of two nurse-managed centers. At one time in her career, she held a public policy fellowship and worked in the office of a U.S. senator. She has taught community health, public health, epidemiology, policy, primary care nursing, and administration courses. Dr. Stanhope formerly directed the Division of Community Health Nursing and Administration and served as Associate Dean of the College of Nursing at the University of Kentucky. She has been responsible for both undergraduate and graduate courses in population-centered nursing. She has also taught at the University of Virginia and the University of Alabama, Birmingham. During her career at the University of Kentucky she was appointed to the Good Samaritan Foundation Chair and Professorship in Community Health Nursing, and was honored with the University Provost's Public Scholar award. Her presentations and publications have been in the areas of home health, community health, and community-focused nursing practice, as well as primary care nursing.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Discuss the structure of the U.S. government and health care roles.
2. Identify the functions of key governmental and quasi-governmental agencies that affect public health systems and nursing, both around the world and in the United States.
3. Differentiate between the primary bodies of law that affect nursing and health care.
4. Define key terms related to policy and politics.
5. State the relationships between nursing practice, health policy, and politics.
6. Develop and implement a plan to communicate with policy makers on a chosen public health issue.

KEY TERMS

advanced practice nurses, p. 182

Agency for Healthcare Research and Quality, p. 174

American Association of Colleges of Nursing, p. 184

The Nurse's Role in the Policy Process

- Legislative Action
- Regulatory Action
- The Process of Regulation
- Nursing Advocacy

Nurses are an important part of the health care system and are greatly affected by governmental and legal systems. Nurses who select the community as their area of practice must be especially aware of the impact of government, law, and health policy on nursing, health, and the communities in which they practice. Insight into how government, law, and political action have changed over time is necessary to understand how the health care system has been shaped by these factors. Also, understanding how these factors have influenced the current and future roles for nurses and the public health system is critical for better health policy for the nation.

Nurses have historically viewed themselves as advocates for the health of the population. It is this heritage that has moved the discipline into the policy and political arenas. To secure a more positive health care system, nurse professionals must develop a working knowledge of government, key governmental and quasi-governmental organizations and agencies, health care law, the policy process, and the political forces that are shaping the future of health care. This knowledge and the motivation to be an agent of change in the discipline and in the community are necessary ingredients for success as a population-centered nurse.

DEFINITIONS

To understand the relationship between health policy, politics, and laws, one must first understand the definitions of the terms. **Policy** is a settled course of action to be followed by a government or institution to obtain a desired end (CDC, 2014). **Public policy** is described as all governmental activities, direct or indirect, that influence the lives of all citizens (Birkland, 2010). **Health policy**, in contrast, is a set course of action to obtain a desired health outcome for an individual, family, group, community, or society (WHO, 2014). Policies are made not only by governments, but also by such institutions as a health department or other health care agency, a family, a community, or a professional organization.

Politics plays a role in the development of such policies. Politics is found in families, professional and employing agencies, and governments. Politics determines who gets what and when and how they get it (Birkland, 2010). Politics is the art of influencing others to accept a specific course of action. Therefore, political activities are used to arrive at a course of action (the policy). **Law** is a system of privileges and processes by which people solve problems based on a set of established rules; it is intended to minimize the use of force (Yourdictionary, 2014). Laws govern the relationships of individuals and organizations to other individuals and to government. Through political action, a policy may become a law, a regulation, a judicial ruling, a decision, or an order.

After a law is established, regulations further define the course of action (policy) to be taken by organizations or individuals in reaching an outcome. Government is the ultimate authority in society and is designated to enforce the policy whether it is related to health, education, economics, social welfare, or any other society issue. The following discussion explains the role of government in health policy.

GOVERNMENTAL ROLE IN U.S. HEALTH CARE

In the United States, the federal and most state and local governments are composed of three branches, each of which has separate and important functions (Truman, 2014). The *executive branch* is composed of the president (or state governor or local mayor) along with the staff and cabinet appointed by this executive, various administrative and regulatory departments, and agencies such as the **U.S. Department of Health and Human Services** (USDHHS). The *legislative branch* (i.e., Congress at the federal level) is made up of two bodies: the Senate and the House of Representatives, whose members are elected by the citizens of particular geographic areas. There is a federal Division of Nursing, a section within the Health Resources and Services Agency (HRSA) of the USDHHS, that refines criteria

for nursing education programs as funded by Congress and affirmed by the President.

The *judicial branch* is composed of a system of federal, state, and local courts guided by the opinions of the Supreme Court. Each of these branches is established by the Constitution, and each plays an important role in the development and implementation of health law and public policy.

The executive branch suggests, administers, and regulates policy. The role of the legislative branch is to identify problems and to propose, debate, pass, and modify laws to address those problems. The judicial branch interprets laws and their meaning, as in its ongoing interpretation of states' rights to define access to reproductive health services to citizens of the states.

One of the first constitutional challenges to a federal law passed by Congress was in the area of health and welfare in 1937, after the 74th Congress had established unemployment compensation and old-age benefits for U.S. citizens ([U.S. Law, 1937a](#)). Although Congress had created other health programs previously, its legal basis for doing so had never been challenged. In *Stewart Machine Co. v. Davis* ([U.S. Law, 1937b](#)), the Supreme Court (judicial branch) reviewed this legislation and determined, through interpretation of the Constitution, that such federal governmental action was within the powers of Congress to promote the general welfare. It was obvious in 2008 and beyond that unemployment benefits are important to the economy and to individuals who lose jobs during a national economic crisis ([BLS, 2010](#)).

Most legal bases for the actions of Congress in health care are found in Article I, Section 8 of the U.S. Constitution, including the following:

1. Provide for the general welfare.
2. Regulate commerce among the states.
3. Raise funds to support the military.
4. Provide spending power.

Through a continuing number and variety of cases and controversies, these Section 8 provisions have been interpreted by the courts to appropriately include a wide variety of federal powers and activities. State power concerning health care is called **police power** ([Legal Information Institute, 2014](#)). This power allows states to act to protect the health, safety, and welfare of their citizens. Such police power must be used fairly, and the state must show that it has a compelling interest in taking actions, especially actions that might infringe on individual rights. Examples of a state using its police powers include requiring immunization of children before being admitted to school and requiring case finding, reporting, treating, and follow-up care of persons with tuberculosis. These activities protect the health, safety, and welfare of state citizens.

Trends and Shifts in Governmental Roles

The government's role in health care at both the state and federal level began gradually. Wars, economic instability, and political differences between parties all shaped the government's role. The first major federal governmental action relating to health was the creation in 1798 of the Public Health Service (PHS). Then in 1890 federal laws were passed to promote the public health of merchant seamen and Native Americans. In 1934

Senator Wagner of New York initiated the first national health insurance bill. The Social Security Act of 1935 was passed to provide assistance to older adults and the unemployed, and it offered survivors' insurance for widows and children. It also provided for child welfare, health department grants, and maternal and child health projects. In 1948 Congress created the National Institutes of Health (NIH), and in 1965 it passed very important health legislation creating Medicare and Medicaid to provide health care service payments for older adults, the disabled, and the categorically poor. These legislative acts by Congress created programs that were implemented by the executive branch. In March 2010, the most recent legislation passed and signed by President Obama to improve the health of the nation and access to care was the health reform law, the Patient Protection and Affordable Care Act ([US LAW, PL 111-148](#)). See [Chapter 3](#) for in-depth information ([Kaiser Family Foundation, 2010a](#)).

The U.S. Department of Health and Human Services (USDHHS) (known first as the Department of Health, Education, and Welfare [DHEW]) was created in 1953. The Health Care Financing Administration (HCFA) was created in 1977 as the key agency within the USDHHS to provide direction for Medicare and Medicaid. In 2002 HCFA was renamed the Center for Medicare and Medicaid Services (CMS). During the 1980s, a major effort of the Reagan administration was to shift federal government activities to the states, including federal programs for health care. The process of shifting the responsibility for planning, delivering, and financing programs from the federal level to the states is called **devolution**. Throughout the 1980s and 1990s, Congress has increasingly funded health programs by giving **block grants** to the states. Devolution processes including block granting should alert professional nurses that state and local policy has grown in importance to the health care arena. With the new health reform law, stimulus grants have been provided to state and local areas to improve health care access ([HRSA, 2010](#)).

The role of government in health care is shaped both by the needs and demands of its citizens and by the citizens' beliefs and values about personal responsibility and self-sufficiency. These beliefs and values often clash with society's sense of responsibility and need for equality for all citizens. A federal example of this ideological debate occurred in the 1990s over health care reform. The Democratic agenda called for a health care system that was universally accessible, with a focus on primary care and prevention. The Republican agenda supported more modest changes within the medical model of the delivery system. This agenda also supported reducing the federal government's role in health care delivery through cuts in Medicare and Medicaid benefits. The Democrats proposed the Health Security Act of 1993, which failed to gain Congress's approval. In an effort to make some incremental health care changes, both the Democrats and the Republicans in Congress passed two new laws. The Health Insurance Portability and Accountability Act (HIPAA) allows working persons to keep their employee group health insurance for up to 16 months after they leave a job ([U.S. Law 107-105, 1996](#)). The State Child Health Improvement Act (SCHIP) of 1997 provides insurance for children and families who cannot otherwise afford health insurance ([U.S. Law, 1997](#)).

With the latest health care reform, numerous debates occurred in the House of Representatives and the Senate until there was agreement that the Senate version of the bill would be passed. On March 30, 2010 President Obama signed into law the Health Care and Education Reconciliation Act of 2010, which made some changes to the comprehensive health reform law and included House amendments to the new law (Kaiser, 2010B). See Chapter 3 for further discussion.

This discussion has focused primarily on trends in and shifts between different levels of government. An additional aspect of governmental action is the relationship between government and individuals. Freedom of individuals must be balanced with governmental powers. After the terrorist attacks on the United States in September (World Trade Center attack) and October (anthrax outbreak) of 2001, much government activity was being conducted in the name of national security.

It is interesting to note that before September 11, 2001, the Congress and President, recognizing that the public health system infrastructure needed help, passed “The Public Health Threats and Emergencies Act” (PL 106-505) in 2000. This law “addresses emerging threats to the public’s health and authorizes the Secretary of HHS to take appropriate response actions during a public health emergency, including investigations, treatment, and prevention” (Katz et al, 2014, p. 133). This legislation is said to have signaled the beginning of renewed interest in public health as the protector for entire communities. In June 2002 the Public Health Security and Bioterrorism Preparedness and Response Act was signed into law (US Law 2002, PL 107-188), with \$3 billion appropriated by Congress, to implement the following antibioterrorism activities:

- Improving public health capacity
- Upgrading of health professionals’ ability to recognize and treat diseases caused by bioterrorism
- Speeding the development of new vaccines and other countermeasures
- Improving water and food supply protection
- Tracking and regulating the use of dangerous pathogens within the United States (Katz et al, 2014)

Yet there is considerable debate on just how much governmental intervention is necessary and effective and how much will be tolerated by citizens. For example, in 2010 approximately 49% of citizens were against the new health care reform acts, and the Republicans were seen as being obstructionists. In 2014, 50% of citizens were for government intervention and 50% against (Debate.org, 2013).

Government Health Care Functions

Federal, state, and local governments carry out five health care functions, which fall into the general categories of direct services, financing, information, policy setting, and public protection.

Direct Services

Federal, state, and local governments provide direct health services to certain individuals and groups. For example, the federal government provides health care to members and dependents of the military, certain veterans, and federal prisoners. State and local governments employ nurses to deliver a variety of services

to individuals and families, frequently on the basis of factors such as financial need or the need for a particular service, such as hypertension or tuberculosis screening, immunizations for children and older adults, and primary care for inmates in local jails or state prisons. The Evidence-Based Practice box presents a study that examined the use of a state health insurance program.

EVIDENCE-BASED PRACTICE

The purpose of this study was to examine the changes in access to care, use of services, and quality of care among children enrolled in Child Health Plus (CHPlus), a state health insurance program for low-income children that became a model for the State Child Health Insurance Program (SCHIP). A before-and-after design was used to evaluate the health care experience of children the year before and the year after enrollment in the state health insurance program. The study consisted of 2126 children from New York State, ranging from birth to 12.99 years of age. Results indicated that the state health insurance program for low-income children was associated with improved access, use, and quality of care. The development and implementation of SCHIP was an outcome of the soaring costs of health care and the fact that there were 11 million uninsured children in the United States at the time of the study. It was the largest public investment in child health in 30 years.

Nurse Use

This study supports the value of health policy and the need to evaluate the effectiveness of policy in accomplishing the purposes of the policy.

From U.S. Department of Health and Human Services: Healthy People 2010: understanding and improving health, ed 2, Washington, DC, 2000, U.S. Government Printing Office.

Financing

Governments pay for some health care services; the 2011 percentage of the bill paid by the government was about 46.3%, and this is projected to increase to 47.6% by the year 2015. The government also pays for training some health personnel and for biomedical and health care research (NCHS, 2014). Support in these areas has greatly affected both consumers and health care providers. Federal governments finance the direct care of clients through the Medicare, Medicaid, Social Security, and SCHIP programs. State governments contribute to the costs of Medicaid and SCHIP programs. Many nurses have been educated with government funds through grants and loans, and schools of nursing in the past have been built and equipped using federal funds. Governments also have financially supported other health care providers, such as physicians, most significantly through the program of Graduate Medical Education funds.

The federal government invests in research and new program demonstration projects, with NIH receiving a large portion of the monies. The National Institute of Nursing Research (NINR) is a part of the NIH and, as such, provides a substantial sum of money to the discipline of nursing for the purpose of developing the knowledge base of nursing and promoting nursing services in health care (NINR, 2014).

Information

All branches and levels of government collect, analyze, and disseminate data about health care and health status of the citizens.

TABLE 8-1 International and National Sources of Data on the Health Status of the U.S. Population

An example is the annual report *Health: United States, 2013*, compiled each year by the USDHHS (NCHS, 2014). Collecting vital statistics, including mortality and morbidity data, gathering of census data, and conducting health care status surveys are all government activities. Table 8-1 lists examples of available federal and international data sources on the health status of populations in the United States and around the world. These sources are available on the Internet and in the governmental documents' section of most large libraries. This information is especially important because it can help nurses understand the major health problems in the United States and those in their own states and local communities.

Policy Setting

Policy setting is a chief governmental function. Governments at all levels and within all branches make policy decisions about health care. These health policy decisions have broad implications for financial expenses, resource use, delivery system change, and innovation in the health care field. One law that has played a very important role in the development of public health policy, public health nursing, and social welfare policy in the United States is the Sheppard-Towner Act of 1921 (USDHHS, HRSA, 2010).

The Sheppard-Towner Act made nurses available to provide health services for women and children, including well-child and child-development services; provided adequate hospital services and facilities for women and children; and provided grants-in-aid for establishing maternal-child welfare programs. The act helped set precedents and patterns for the growth of modern-day public health policy. It defined the role of the federal government in creating standards to be followed by states in conducting categorical programs such as the Women, Infants, and Children (WIC) and Early Periodic Screening and Developmental Testing (EPSDT) programs. The act also defined the position of the consumer in influencing, formulating, and shaping public policy; the government's role in research; a system for collecting national health statistics; and the integrating of health and social services. This act established the importance of prenatal care, anticipatory guidance, client education, and nurse-client conferences, all of which are viewed today as essential nursing responsibilities.

Public Protection

The U.S. Constitution gives the federal government the authority to provide for the protection of the public's health. This function is carried out in numerous venues, such as by regulating air and water quality and protecting the borders from the influx of diseases by controlling food, drugs, and animal transportation, to name a few. The Supreme Court interprets and makes decisions related to public health, such as affirming a woman's rights to reproductive privacy (*Roe v. Wade*), requiring vaccinations, and setting conditions for states to receive public funds for highway construction/repair by requiring a minimum drinking age.

HEALTHY PEOPLE 2020: AN EXAMPLE OF NATIONAL HEALTH POLICY GUIDANCE

In 1979 the surgeon general issued a report that began a 30-year focus on promoting health and preventing disease for all Americans (DHEW, 1979). In 1989, *Healthy People 2000* became a national effort with many stakeholders representing the perspectives of government, state, and local agencies; advocacy groups; academia; and health organizations (USDHHS, 1991).

Throughout the 1990s states used *Healthy People 2000* objectives to identify emerging public health issues. The success of this national program was accomplished and measured through state and local efforts. The *Healthy People 2010* document focused on a vision of healthy people living in healthy communities. *Healthy People 2020* has four overarching goals, which can be found in the Healthy People 2020 box; this box compares the goals of *Healthy People* documents from 2000 to 2020.

ORGANIZATIONS AND AGENCIES THAT INFLUENCE HEALTH

International Organizations

In June 1945, following World War II, many national governments joined together to create the United Nations (UN). By charter, the aims and goals of the UN deal with human rights,

HEALTHY PEOPLE 2020

A Comparison of the Goals of Healthy People 2000, Healthy People 2010, and Healthy People 2020

Healthy People 2000	Healthy People 2010	Healthy People 2020
Increase the years of healthy life for Americans	Increase quality and years of healthy life	Attaining high quality, longer lives free of preventable disease, disability, injury, and premature death
Reduce health disparities among Americans	Eliminate health disparities	Achieving health equity, eliminating disparities, and improving the health of all groups
Achieve access to preventive services for all Americans		Creating social and physical environments that promote good health for all
		Promoting quality of life, healthy development, and healthy behaviors across all life stages

From U.S. Department of Health and Human Services: Leading indicators. In *Healthy People 2000, 2010, & 2020*, Washington, DC, 1989, 1999, 2010, U.S. Government Printing Office.

world peace, international security, and the promotion of economic and social advancement of all the world's peoples. The UN, headquartered in New York City, is made up of six principal divisions, several subgroups, and many specialized agencies and autonomous organizations. With the approval and support of the UN Commission on the Status of Women, five world conferences on women have been held. At these conferences, the health of women and children and their rights to personal, educational, and economic security as well as initiatives to achieve these goals at the country level were debated and explored, and policies were formulated (United Nations, 1975, 1980, 1985, 1995, 2000). The work of the UN and the world conferences continues with agendas to include the development of human beings, eradication of poverty, protection of human rights, investment in health, education, training, trade, economic growth, and a continued emphasis on women (United Nations, 2014).

One of the special autonomous organizations growing out of the UN is the **World Health Organization** (WHO). Established in 1946, WHO relates to the UN through the Economic and Social Council to achieve its goal to attain the highest possible level of health for all persons. "Health for All" is the creed of the WHO. Headquartered in Geneva, Switzerland, the WHO has six regional offices. The office for the Americas is located in Washington, DC, and is known as the Pan American Health Organization (PAHO).

The WHO provides services worldwide to promote health, it cooperates with member countries in promoting their health efforts, and it coordinates the collaborating efforts between countries and the disseminating of biomedical research. Its services, which benefit all countries, include a day-to-day information service on the occurrence of internationally important diseases; the publishing of the international list of causes of disease, injury, and death; monitoring of adverse reactions to

drugs; and establishing of world standards for antibiotics and vaccines. Assistance available to individual countries includes support for national programs to fight disease, to train health workers, and to strengthen the delivery of health services. The World Health Assembly (WHA) is the WHO's policy-making body, and it meets annually. The WHA's health policy work provides policy options for many countries of the world in their development of in-country initiatives and priorities; however, although WHA policy statements are important everywhere, they are guides and not law. The WHA's most recent policy statement on nursing and midwifery was released in 2013, and the current worldwide shortage of professional nurses is now on the WHO agenda and is being addressed by country (WHA, 2011; WHO, 2010; WHO, 2013).

The World Health Report, first published in 1995, is WHO's leading publication. Each year the report combines an expert assessment of global health, including statistics relating to all countries, with a focus on a specific subject. The main purpose of the report is to provide countries, donor agencies, international organizations, and others with the information they need to help them make policy and funding decisions. In the 2010 report, the WHO mapped out what countries can do to modify their financing systems so they can move more quickly toward this goal—universal coverage—and sustain the gains that have been achieved. The report builds on new research and lessons learned from country experience. It provides an action agenda for countries at all stages of development and proposes ways that the international community can better support efforts in low-income countries to achieve universal coverage and improve health outcomes (WHO, 2010).

The presence of nursing in international health is increasing. Besides offering direct health services in every country in the world, nurses serve as consultants, educators, and program planners and evaluators. Nurses focus their work on a variety of public health issues, including the health care workforce and education, environment, sanitation, infectious diseases, wellness promotion, maternal and child health, and primary care. Dr. Naeema Al-Gasseer of Bahrain has served as the scientist for nursing and midwifery at the WHO; Marla Salmon, former dean of nursing at The University of Washington, chaired a Global Advisory Group on Nursing and Midwifery; and Linda Tarr Whelan served as the U.S. Ambassador to the UN Commission on the Status of Women. Virginia Trotter Betts, past president of the **American Nurses Association** (ANA), served as a U.S. delegate to both the WHA and the Fourth World Conference on Women in Beijing in 1995, where she participated on the negotiating team of the conference to develop a platform on the health of women across the life span. Many U.S. nurse leaders, such as Dr. Carolyn Williams, current author in this book, have been WHO consultants.

Federal Health Agencies

Laws passed by Congress may be assigned to any administrative agency within the executive branch of government for implementing, supervising, regulating, and enforcing. Congress decides which agency will monitor specific laws. For example, most health care legislation is delegated to the USDHHS. However, legislation concerning the environment would most

likely be implemented and monitored by the Environmental Protection Agency (EPA), and that concerning occupational health by the **Occupational Safety and Health Administration** (OSHA) in the U.S. Department of Labor.

U.S. Department of Health and Human Services

The USDHHS is the agency most heavily involved with the health and welfare of U.S. citizens. It touches more lives than any other federal agency. The following agencies have been selected for their relevance to this chapter.

Health Resources and Services Administration. The Health Resources and Services Administration (HRSA) has been a long-standing contributor to the improved health status of Americans through the programs of services and health professions education that it funds. The HRSA contains the Bureau of Health Professions (BHP), which includes the Division of Nursing as well as the Divisions of Medicine, Dentistry, and Allied Health Professions. The Division of Nursing is the key federal focus for nursing education and practice, and it provides national leadership to ensure an adequate supply and distribution of qualified nursing personnel to meet the health needs of the nation.

At the 122nd meeting of the Division of Nursing's National Advisory Council for Nursing Education and Practice (NACNEP), the participants discussed the role of public health nurses in participating in primary care in their communities. The speaker indicated several factors that need to be in place to support the public health nurse role:

- Baccalaureate standard for entry into practice
- Ongoing stable funding for health departments
- Competitive salaries commensurate with responsibilities
- Interventions grounded in and responsive to community needs
- Consideration of health determinants
- Experience in health promotion and prevention
- Long-term trusting relationships in the community (i.e., with clients)
- Established network of community partners
- Commitment to social justice and eliminating health disparities

In the council's twelfth report to Congress (USDHHS, 2013a) the council recommended further investment by the government in public health nursing, arguing the need based on system changes and the Affordable Care Act implementation, greater need to connect public health and care delivery with front-line public health nurses, plus the economic benefits of supporting this investment. Through the input of the NACNEP, the Division of Nursing sets policy for nursing nationally.

Centers for Disease Control and Prevention. The Centers for Disease Control and Prevention (CDC) serve as the national focus for developing and applying disease prevention and control, environmental health, and health promotion and education activities designed to improve the health of the people of the United States. The mission of the CDC is to protect America from health, safety and security threats, both foreign and in the United States. Whether diseases start at home or abroad, are chronic or acute, curable or preventable, human error or deliberate attack, CDC fights disease and supports communities and citizens to do the same. As such CDC increases

the health security of our nation (CDC, 2014A) The CDC seeks to accomplish its mission by working with partners throughout the nation and the world in the following ways:

- To provide health security
- To detect and investigate health threats
- To tackle the biggest health problems causing death and disability
- To conduct research that will enhance prevention
- To promote healthy and safe behaviors, communities, and environments
- To develop leaders and train the public health workforce, including disease detectives
- To develop and advocate sound public health policies
- To implement prevention strategies
- To promote healthy behaviors
- To foster safe and healthful environments
- To provide leadership and training

The outbreak of summer 2014 is an example of how the CDC fulfills its mission. The Shiga toxin-producing *Escherichia coli* outbreak linked to raw clover sprouts affected six states and 19 people, and 44% were hospitalized. Idaho was the state that was most likely the source of the outbreak. The CDC regularly collects data about foodborne illnesses through the National Notifiable Disease Surveillance System on a weekly basis through the CDC MMWR weekly report from states. Because of the recognized increase in cases, states were asked to report aggregate numbers of cases twice a week along with foodborne-related hospitalizations and complications. The CDC implemented an investigation to track the cases and worked with state and local health departments to perform the following:

- Detect the possible outbreak
- Define and find cases
- Generate hypotheses about the likely source
- Test the hypothesis
- Find the point of contamination
- Control the outbreak from further spread
- Decide when the outbreak is over.

By August 2014, there had been about 19 cases beginning in June 2014. In 3 months there were cases in 6 states. [Figure 8-1](#) presents a CDC map indicating cases per state (CDC, MMWR Dispatch, 2014b). The six states involved were California (1), Idaho (3), Michigan (1), Montana (2), Utah (1), and Washington (11). By August 2014 CDC determined the outbreak to be over. Although few people were involved in this outbreak, the outcome could have been deadly to the persons who ate the sprouts. While the Ebola virus of West Africa continues to spread, the CDC is monitoring the effects of the virus as part of their global monitoring system. CDC has information and training materials ready for those who may need to use the materials (CDC, 2014c). The CDC has taken an active role in the recent outbreak of measles as a result of exposure to the virus at Disneyland in California. This outbreak resulted in 140 people from seven states being infected. On 1/23/2015, the CDC issued a health advisory to all public health and health care facilities nationwide (Zipprich et al, 2015).

National Institutes of Health. Founded in 1887, NIH today is one of the world's foremost biomedical research centers, and the federal focus point for biomedical research in the United States.

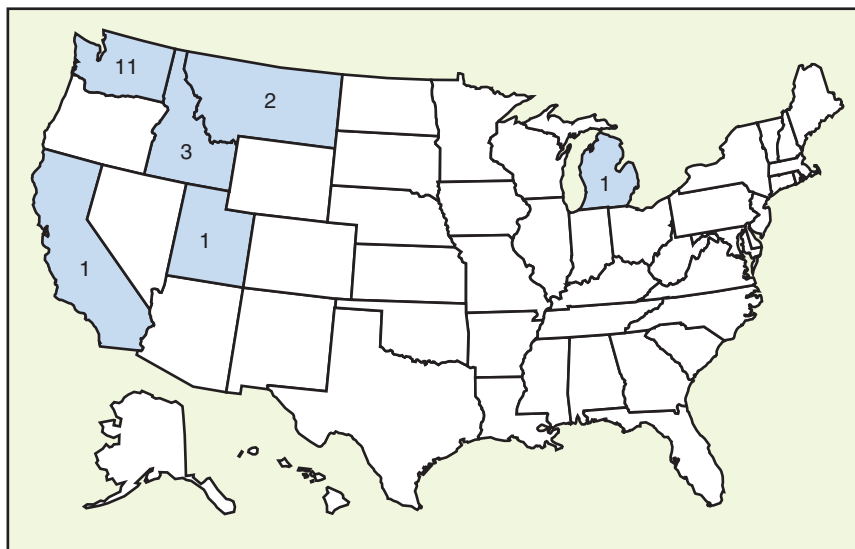

FIG 8-1 The number of reported *Escherichia coli* cases linked to multistate outbreak, by state—United States, May to August, 2014 (From Centers for Disease Control and Prevention: *Epidemiology of Escherichia coli outbreak, United States*, Atlanta, 2014 USDHHS.)

The NIH is composed of 27 separate institutes and centers. The goal of NIH research is to acquire new knowledge to help prevent, detect, diagnose, and treat disease and disability, from the rarest genetic disorder to the common cold. The NIH mission is to uncover new knowledge that will lead to better health for everyone. The NIH works toward that mission by conducting research in its own laboratories; supporting the research of nonfederal scientists in universities, medical schools, hospitals, and research institutions throughout the country and abroad; helping in the training of research investigators; and fostering communication of medical and health sciences' information (NIH, 2010a).

In late 1985 Congress overrode a presidential veto, allowing the creation of the National Center for Nursing Research within the NIH. In 1993 the Center became one of the divisions of the NIH and was renamed the **National Institute of Nursing Research** (NINR). The research and research-related training activities previously supported by the Division of Nursing were transferred to the new Institute. The NINR is the focal point of the nation's nursing research activities. It promotes the growth and quality of research in nursing and client care, provides important leadership, expands the pool of experienced nurse researchers, and serves as a point of interaction with other bases of health care research. The mission of NINR is to promote and improve the health of individuals, families, communities, and populations.

NINR supports and conducts clinical and basic research and research training on health and illness across the life span. The research focus encompasses health promotion and disease prevention, quality of life, health disparities, and end of life. NINR seeks to extend nursing science by integrating the biological and behavioral sciences, using new technologies to research questions, improving research methods, and developing the scientists of the future (NINR, 2011).

Agency for Healthcare Research and Quality. The **Agency for Healthcare Research and Quality** (AHRQ) is the lead

federal agency charged with improving the quality, safety, efficiency, and effectiveness of health care for all Americans. As one of 12 agencies within the USDHHS, AHRQ supports health services research that will improve the quality of health care and promote evidence-based decision making. AHRQ is committed to improving care safety and quality by developing successful partnerships and generating the knowledge and tools required for long-term improvement. The goal of AHRQ research is to promote measurable improvements in health care in America. The outcomes are gauged in terms of improved quality of life and client outcomes, lives saved, and value gained for what we spend (AHRQ, 2014a).

By examining what works and what does not work in health care, the AHRQ fulfills its missions of translating research findings into better client care and providing consumers, policy makers, and other health care leaders with information needed to make critical health care decisions. In 1999, Congress, through legislation, specifically directed AHRQ to focus on measuring and improving health care quality; promoting client safety and reducing medical errors; advancing the use of information technology for coordinating client care and conducting quality and outcomes research; and seeking to eliminate disparities in health care delivery for the priority populations of low-income groups, minorities, women, children, older adults, and individuals with special health care needs.

The AHRQ published protocols for care of clients with a variety of health problems. These protocols became the standards of health care delivery. The agency continues to maintain a clinical practice guidelines clearinghouse for use by clinicians and others. In addition, the AHRQ had a project called "Put Prevention into Practice" to promote the use of standardized protocols for primary care delivery for clients across the age span (see Schedule of Clinical Preventive Services in AHRQ, 2014b). Today there is a program titled The Practice-Based Research Network that rapidly develops and assesses methods

and tools to ensure that new scientific evidence is incorporated into real-world practice settings (AHRQ, 2014c).

Centers for Medicare and Medicaid Services. One of the most powerful agencies within the USDHHS is the CMS, which administers Medicare and Medicaid accounts and guided payment policy and delivery rules for services for 100 million people in 2014 (CMS, 2014). In addition to providing health insurance, CMS also performs a number of quality-focused health care or health-related activities, including regulating of laboratory testing, developing coverage policies, and improving quality of care. CMS maintains oversight of the surveying and certifying of nursing homes and continuing care providers (including home health agencies, intermediate care facilities for the developmentally disabled, and hospitals). It makes available to beneficiaries, providers, researchers, and state surveyors information about these activities and nursing home quality.

Federal Non-Health Agencies

Although the USDHHS has primary responsibility for federal health functions, several other departments of the executive branch carry out important health functions for the nation. Among these are the Defense, Labor, Agriculture, and Justice Departments.

Department of Defense

The Department of Defense delivers health care to members of the military, to their dependents and survivors, to National Guard and reserve members, and to retired members and their families. The assistant secretary of defense for health affairs administers a variety of health care plans for service personnel: TriCare Prime (a managed care arrangement) and an option for fee-for-service plans called TriCare Standard as well as TriCare Extra with many other options available. In each branch of the uniformed services, nurses of high military rank are part of the administration of these health services (U.S. Department of Defense, 2014).

Department of Labor

The Department of Labor houses OSHA, which imposes workplace requirements on industries. These requirements shape the functions of nurses and the types of health services provided to workers in the workplace. A record-keeping system required by OSHA greatly affects health records in the workplace. Each state has an agency similar to OSHA that also monitors and inspects industries, as well as the health services delivered to them by nurses.

Needlestick injuries and other sharps-related injuries that result in occupational bloodborne pathogen exposure continue to be an important public health concern, especially to health care workers. In response to this serious situation, Congress passed the Needle Stick Safety and Prevention Act, which became law on November 6, 2000. To meet the requirements of this act, OSHA revised its Bloodborne Pathogen Standard to become effective on April 18, 2002. This act clarified the responsibility of employers to select safer needle devices as they become available and to involve employees in identifying and choosing the devices. The updated standard also required employers to maintain a log of injuries from contaminated sharps (OSHA, 2008; 2011; OSHA, 2013).

Department of Agriculture

The Department of Agriculture houses the Food and Nutrition Service, which oversees a variety of food assistance activities. This service collaborates with state and local government welfare agencies to provide food stamps to needy persons to increase their food purchasing power. Other programs include school breakfast and lunch programs, WIC, and grants to states for nutrition education and training. In 2013, WIC provided support for 53% of all infants born in the United States. Although these programs have been successful, the increasing use of the process of giving federal block grants to states (rather than implementing national programs) may threaten the effectiveness of these programs because of differences in how decisions are made at the state level on how to spend money on nutrition (USDA, 2013).

Department of Justice

Health services to federal prisoners are administered within the Department of Justice. The Federal Bureau of Prisons is responsible for the custody and care of approximately 214,000 federal offenders (Bureau of Federal Prisons, 2014). The Medical and Services Division of the Bureau of Prisons includes medical, psychiatric, dental, and health support services with community standards in a correctional environment. Health promotion is emphasized through counseling during examinations, education about effects of medications, infectious disease prevention and education, and chronic care clinics for conditions such as cardiovascular disease, diabetes, and hypertension. The Bureau also provides forensic services to the courts, including a range of evaluative mental health studies outlined in federal statutes. Health care for prisoners is highly regulated because of a series of court decisions on inmates' rights.

State and Local Health Departments

Depending on funding, public commitment and interest, and access to other resources, programs offered by state and local health departments vary greatly. Many state and local health officials report that employees in public health agencies lack skills in the core sciences of public health, and that this has hindered their effectiveness. The lack of specialized education and skill is a significant barrier to population-based preventive care and the delivery of quality health care to the public. Public health workforce specialists report that the number of retirees expected in this decade will result in a major shortage of public health workers, including nurses. More often than at other levels of government, nurses at the local level provide direct services. Some nurses deliver special or selected services, such as follow-up of contacts in cases of tuberculosis or venereal disease or providing child immunization clinics. Other nurses have a more generalized practice, delivering services to families in certain geographic areas (PHE, 2010; University of Michigan Center of Excellence in Public Health Workforce Studies, 2013).

At the local and state levels, coordinating health efforts between health departments and other county or city departments is essential. Gaps in community coordination are showing up in glaring ways as states and communities scramble to

address bioterrorism preparedness since September 11, 2001, and since such natural disasters as Hurricane Katrina. The United States had 220,000 people lose their homes in 2013 due to extreme storms and tornadoes in Oklahoma and another 100,000 from flooding in Colorado. Health departments are on the front line in such occurrences (see [Chapter 46](#)).

IMPACT OF GOVERNMENT HEALTH FUNCTIONS AND STRUCTURES ON NURSING

The variety and range of functions of governmental agencies have had a major impact on the practice of nursing. Funding, in particular, has shaped roles and tasks of population-centered nurses. The designation of money for specific needs, or **categorical funding**, has led to special and more narrowly focused nursing roles. Examples are in emergency preparedness, school nursing, and family planning. Funds assigned to antibioterrorism cannot be used to support unrelated communicable disease programs or family planning.

The events of September 11, 2001, have had the public and the profession of nursing concerned about the ability of the present public health system and its workforce to deal with bioterrorism, especially outbreaks of deadly and serious communicable diseases. For example, smallpox vaccinations were stopped in 1972, but immunity lasts for only 10 years; although there have been no reported cases since the early 1970s, almost no one in the United States retains their immunity. Thus, the population is vulnerable to a smallpox outbreak, and smallpox could be used as a weapon of bioterrorism. Two laboratories in the world retain a small amount of the smallpox virus. Because of these potential threats, the U.S. government has begun to increase production of the vaccine ([NIH, 2010b](#)). Few public health professionals are knowledgeable of the symptoms, treatment, or mode of transmission of this disease. Most health professionals, including registered nurses (RNs), who currently work in the United States, have never seen a case of anthrax, smallpox, or plague—the three major biological weapons of concern in the world today. A few have now seen the effects of the Ebola virus. The USDHHS and the federal **Office of Homeland Security** have provided funds to address this serious threat to the people of the United States.

One of the first things being done is the rebuilding of the crumbling public health infrastructures of each state to provide surveillance, intervention, and communication in the face of future bioterrorism events and natural disasters. On December 19, 2006, President George W. Bush signed the Pandemic and All-Hazards Preparedness Act (PAHPA), which was intended to improve the organization, direction, and utility of preparedness efforts. PAHPA centralizes federal responsibilities, requires state-based accountability, proposes new national surveillance methods, addresses surge capacity, and facilitates the development of vaccines and other scarce resources ([Morhard and Franco, 2013](#)). On March 13, 2013, President Barack Obama signed the Pandemic and All-Hazards Preparedness Reauthorization Act into law. The 2013 law reauthorizes funding for public health and medical preparedness programs that enable communities to build systems to support people in need during and after disasters ([USDHHS, 2013B](#)).

THE LAW AND HEALTH CARE

The United States is a nation of laws, which are subject to the U.S. Constitution. The law is a system of privileges and processes by which people solve problems on the basis of a set of established rules. It is intended to minimize the use of force. Laws govern the relationships of individuals and organizations to other individuals and to government. After a law is established, regulations further define the course of actions to be taken by the government, organizations, or individuals in reaching an agreed-on outcome. Government and its laws are the ultimate authority in society and are designed to enforce official policy whether it is related to health, education, economics, social welfare, or any other society issue. The number and types of laws influencing health care are ever increasing. Definitions of law ([Catholic University of America, 2010](#)) include the following:

- A rule established by authority, society, or custom
- The body of rules governing the affairs of people, communities, states, corporations, and nations
- A set of rules or customs governing a discrete field or activity (e.g., criminal law, contract law)

These definitions reflect the close relationship of law to the community and to society's customs and beliefs.

The law has had a major impact on nursing practice. Although nursing emerged from individual voluntary activities, society passed laws to give formality to public health and, through legal mandates (i.e., laws), positions and functions for nurses in community settings were created. These functions in many instances carry the force of law. For example, if the nurse discovers a person with smallpox, the law directs the nurse and others in the public health community to take specific actions. In another example, in a mumps outbreak, a nurse and other health professionals are required to report mumps cases. This reporting requirement helps with locating and treating cases so cases can be treated or isolated as they occur to prevent further spreading of disease. Three types of laws in the United States have particular importance.

Constitutional Law

Constitutional law derives from federal and state constitutions. It provides overall guidance for selected practice situations. For example, on what basis can the state *require* quarantine or isolation of individuals with tuberculosis? The U.S. Constitution specifies the explicit and limited functions of the federal government. All other powers and functions are left to the individual states. The major constitutional power of the states relating to population-centered nursing practice is the state's right to intervene in a reasonable manner to protect the health, safety, and welfare of its citizens. The state has *police power* to act through its public health system, but it has limits. First, it must be a "reasonable" exercise of power. Second, if the power interferes or infringes on individual rights, the state must demonstrate that there is a "compelling state interest" in exercising its power. Isolating an individual or separating someone from a community because that person has a communicable disease has been deemed an appropriate exercise of state powers. The

state can isolate an individual even though it infringes on individual rights (such as freedom and autonomy), under the following conditions (Lee et al, 2012):

- There is a compelling state interest in preventing an epidemic.
- The isolation is necessary to protect the health, safety, and welfare of individuals in the community or the public as a whole.
- The isolation is done in a reasonable manner.

The legal and medical communities along with AIDS (acquired immunodeficiency syndrome) activists rejected (and made the case) that the social quarantine of individuals with AIDS was unnecessary. Thus, individual freedom and autonomy of the individual come before “compelling state interest” unless science warrants another conclusion (Swendiman and Elsea, 2010).

Legislation and Regulation

Legislation is law that comes from the legislative branches of federal, state, or local government. This is referred to as Statute Law because it becomes coded in the statutes of a government (Birkland, 2010). Much legislation has an effect on nursing. **Regulations** are specific statements of law related to defining or implanting individual pieces of legislation or statute law. For example, state legislatures enact laws (statutes) establishing **boards of nursing** and defining terms such as *registered nurse* and *nursing practice*. Every state has a board of nursing. The board may be found either in the department of licensing boards of the health department or in an administrative agency of the governor’s office. Created by legislation known as a state **nurse practice act**, the board of nursing is made up of nurses and consumers. The functions of this board are described in the nurse practice act of each state and generally include licensing and examination of RNs and licensed practical nurses; licensing and/or certification of advanced practice nurses; approval of schools of nursing in the state; revocation, suspension, or denying of licenses; and writing of regulations about nursing practice and education.

The state boards of nursing operationalize, implement, and enforce the statutory law by writing explicit statements (rules) on what it means to be an RN, and on the nurse’s rights and responsibilities in delegating work to others and in meeting continuing education requirements.

All nurses employed in community settings are subject to legislation and regulations. For example, home health care nurses employed by private agencies must deliver care according to federal Medicare or state Medicaid legislation and regulations, so the agency can be reimbursed for those services. Private and public health care services rendered by nurses are subject to many governmental regulations for quality of care, standards of documentation, and confidentiality of client records and communications. All state health departments have a public health practice reference that governs the practice of nurses and others, and state public health laws that define the essential public health services that must be offered in the state as well as the optional services that may also be offered.

Judicial and Common Law

Both **judicial law** and common law have great impact on nursing. Judicial law is based on court or jury decisions. The opinions of the courts are referred to as *case law* (Birkland, 2010). The court uses other types of laws to make its decisions, including previous court decisions or cases. Precedent is one principle of common law. This means that judges are bound by previous decisions unless they are convinced that the older law is no longer relevant or valid. This process is called *distinguishing*, and it usually involves a demonstration of how the current situation in dispute differs from the previously decided situation. Other principles of common law such as justice, fairness, respect for individual’s autonomy, and self-determination are part of a court’s rationale and the basis upon which to make a decision.

LAWS SPECIFIC TO NURSING PRACTICE

Despite the broad nature and varied roles of nurses in practice, two legal arenas are most applicable to nurse practice situations. The first is the statutory authority for the profession and its scope of practice, and the second is professional negligence or malpractice.

Scope of Practice

The issue of scope of practice involves defining nursing, setting its credentials, and then distinguishing between the practices of nurses, physicians, and other health care providers. The issue is especially important to nurses in community settings, who have traditionally practiced with much autonomy.

Health care practitioners are subject to the laws of the state in which they practice, and they can practice only with a license. The states’ nurse practice acts differ somewhat, but they are the most important statutory laws affecting nurses. The nurse practice act of each state accomplishes at least four functions: defining the practice of professional nursing, identifying the scope of nursing practice, setting educational qualifications and other requirements for licensure, and determining the legal titles nurses may use to identify themselves. The usual and customary practice of nursing can be determined through a variety of sources, including the following:

- Content of nursing educational programs, both general and special
- Experience of other practicing nurses (peers)
- Statements and standards of nursing professional organizations
- Policies and procedures of agencies employing nurses
- Needs and interests of the community
- Updated literature, including research, books, texts, and journals
- Internet sites if it can be determined that the site is a professional source of information

All of these sources can describe, determine, and refine the scope of practice of a professional nurse. Every nurse should know and follow closely any proposed changes in the practice acts of nursing, medicine, pharmacy, and other related

professions. The nurse should always examine all legislation, rules, and regulations related to nursing practice. For example, a review of the pharmacy act will let the nurse know whether to question the right to dispense medications in a family planning clinic in a local health department. Defining the scope of practice forces one to clarify independent, interdependent, and dependent nursing functions.

Just as practice acts vary by state, so do the evolving issues and tensions of scopes of practice among the health professions. In past years, several state legislatures (working closely with the National Council of State Boards of Nursing) embarked on a legislative effort to develop the Interstate Nurse Licensure Compact. The compact allows mutual recognition of generalist nursing licensure across state lines in the compact states. By 2014, 24 states had adopted the compact (NCSBN, 2014).

Professional Negligence

Professional negligence, or *malpractice*, is defined as an act (or a failure to act) that leads to injury of a client. To recover money damages in a malpractice action, the client must prove all of the following:

1. That the nurse owed a duty to the client or was responsible for the client's care
2. That the duty to act the way a reasonable, prudent nurse would act in the same circumstances was not fulfilled
3. That the failure to act reasonably under the circumstances led to the alleged injuries
4. That the injuries provided the basis for a monetary claim from the nurse as compensation for the injury

Reported cases involving negligence and population-centered nurses are rare. However, the following is an example:

Home Nurse Fails to Properly Supervise Bottle Feeding of Child With Tracheal Tube for Oxygen—Death—\$4.5 Million Verdict

The plaintiff, a child, age sixteen months, suffered insufficiency of her lungs and required a continuous supply of oxygen via a tracheal tube. She required constant supervision by a home health nurse.

In January 2008, during the day a bottle of formula was given by the nurse. The formula entered the tracheal tube and lungs. After several minutes the nurse observed that the child had stopped breathing and began cardiopulmonary resuscitation. The child did not survive. It was determined that the child had suffered asphyxiation due to ingestion of vomited material.

The plaintiff claimed that the child had choked and gagged throughout the nurse's resuscitation attempts and that CPR was not the correct method of resuscitating the child. The plaintiff claimed that the tracheal tube should have been cleared or changed.

The case was initially brought against the defendant nurse's employer, the home care agency, and the hospital which had provided the tracheal tube. The claims against the hospital were discontinued and the matter proceeded to trial against the home care agency. The defendant did not contest liability.

According to a published account a \$4.5 million verdict was returned for the child's pain and suffering. A defense motion to set aside the verdict was pending.

An integral part of all negligence actions is the question of who should be sued. When a nurse is employed and functioning within the scope of employment, the employer is responsible for the nurse's negligent actions. This is referred to as the doctrine of *respondeat superior*. By directing a nurse to carry out a particular function, the employer becomes responsible for negligence, along with the individual nurse. Because employers are usually better able to pay for the injuries suffered by clients, they are sued more often than the nurses themselves, although an increasing number of judgments include the professional nurse by name as a co-defendant. In some instances, if the agency is found liable, the agency may in turn sue the nurse for negligence. At least, the nurse often loses the job.

Thus, it is imperative that all nurses engaged in clinical practice carry their own professional liability insurance. Nurses may have personal immunity for particular practice areas, such as giving immunizations. In some states, the legislature has granted personal immunity to nurses employed by public agencies to cover all aspects of their practice under the legal theory of *sovereign immunity* (Cherry and Jacobs, 2013).

Nursing students need to be aware that the same laws and rules that govern the professional nurse govern them. Students are expected to meet the same standard of care as that met by any licensed nurse practicing under the same or similar circumstances. Students are expected to be able to perform all tasks and make clinical decisions on the basis of the knowledge they have gained or been offered, according to their progress in their educational programs and along with adequate educational supervision.

LEGAL ISSUES AFFECTING HEALTH CARE PRACTICES

Specific legal issues of nursing vary depending on the setting where care is delivered, the clinical arena, and the nurse's functional role. The law, including legislation and judicial opinions, significantly affects each of the following areas of nursing practice. Nurses responsible for setting and implementing program priorities need to identify and monitor laws related to each special area of practice.

School and Family Health

Nurses employed by health departments or boards of education may deliver school and family health nursing. School health legislation establishes a minimum of services that must be provided to children in public and private schools. For example, most states require that children be immunized against certain communicable diseases before entering school. Children must

have had a physical examination by that time, and most states require at least one physical at a later time in their schooling. Legislation also specifies when and what type of health screening will be conducted in schools (e.g., vision and hearing testing). These requirements are found in statutory laws of states. Some states are now requiring a simple dental examination in schools for the purpose of referring children to a dental health professional if needed.

Statutes addressing child abuse and neglect make a large impact on nursing practice within schools and families. Most states require nurses to notify police and/or a social service agency of any situation in which they suspect a child is being abused or neglected. This is one instance in which the law mandates that a health professional breach client confidentiality to protect someone who may be in a helpless or vulnerable position. There is *civil immunity* for such reporting, and the nurse may be called as a witness in a court hearing of the case.

Occupational health is another special area of practice that has specific legal requirements as a result of state and federal statutes. Of special concern are the state workers' compensation statutes, which provide the legal foundation for claims of workers injured on the job. Access to records, confidentiality, and the use of standing orders are legal issues that have great practice significance to nurses employed in industries.

Home Care and Hospice

Home care and hospice services rendered by nurses are shaped through state statutes and have specific nursing requirements for **licensure** and certification. Compliance with these laws is directly linked to the method of payment for the services. For example, a service must be licensed and certified to obtain payment for services through Medicare. Federal regulations implementing Medicare/Medicaid have an enormous effect on much of nursing practice, including how nurses record details of their visits, record time spent in care activities, and document client care and the client's status and progress.

In addition, many states have passed laws requiring nurses to report elder abuse to the proper authorities, as is done with children and youth. Laws affecting home care and hospice services have focused on such issues as the right to death with dignity, rights of residents of long-term facilities and home health clients, definitions of death, and the use of living wills and advance directives. The legal and ethical dimensions of nursing practice are particularly important. Individual rights, such as the right to refuse treatment, and nursing responsibilities, such as the legal duty to render reasonable and prudent care, may appear to be in conflict in delivering home and hospice services. Much case discussion (sometimes including outside ethics consultation) may be needed to resolve such conflicts.

Correctional Health

Correctional health nursing practice is significantly shaped by federal and state laws and regulations and by recent Supreme Court decisions. The laws and decisions primarily relate to the type and amount of services that must be provided for incarcerated individuals. For example, physical examinations are

required for all prisoners after they are sentenced. Regulations specify basic levels of care that must be provided for prisoners, and access to care during illness is a particular focus. Court decisions requiring adequate health services are based on constitutional law. If minimal services are not provided, it is a violation of a prisoner's right to freedom from cruel and unusual punishment. Such decisions provide a framework that strongly influences the setting of nursing priorities. For example, providing care to the sick would take priority over wellness or health education classes.

THE NURSE'S ROLE IN THE POLICY PROCESS

The number and types of laws influencing health care are increasing. Because of this, nurses need to be involved in the policy process and understand the importance of involvement of nursing to the clients they serve.

For nurses to effectively care for their client populations and their communities in the complex U.S. health care system, professional advocacy for logical health policy that considers equality is essential. Professional nurses working in the community know all too well about the health care problems they and their clients encounter daily, and it is through policy and political activism that both big-picture and long-term solutions can be developed.

Although the term *policy* may sound rather lofty, health policy is quite simply the process of turning health problems into workable action solutions. Health policy is developed on the three-legged stool of *access*, *cost*, and *quality*. The policy process, which is very familiar to professional nurses, includes the following:

- Statement of a health care problem
- Statement of policy options to address the health problem
- Adoption of a particular policy option
- Implementation of the policy product (e.g., a service)
- Evaluation of the policy's intended and unintended consequences in solving the original health problem

Thus the policy process is very similar to the nursing process, but the focus is on the level of the larger society and the adoption strategies require political action. For most professional nurses, action in the policy arena comes most easily and naturally through participation in nursing organizations such as the ANA at the state level or the Association of Community Health Nursing Educators (ACHNE) or the Association of State and Territorial Directors of Nursing (ASTDN) at the national or state level, and in certain specialty organizations like the American Association of Specialty Nursing Organizations.

Legislative Action

It is often helpful to review the legislative and political processes that may have been a part of high school education. It becomes important material to remember as a professional career is embarked upon.

The people within geographic jurisdictions elect their legislative representatives and senators. An important part of the legislative process is the work of the **legislative staff**. These

individuals do the legwork, research, paperwork, and other activities that move policy ideas into bills and then into law. In addition to the individual legislator's office, the congressional committee staffs are also important. They are usually experts in the content of the work of a committee, such as a health and welfare committee. Frequently, developing a working relationship with key legislative staffers can be as important to achieving a policy objective as the relationship with the policy maker (i.e., the legislator).

The legislative process begins with ideas (policy options) that are developed into bills. After a bill is drafted, it is introduced to the legislature, given a number, read, and assigned to a committee. Hearings, testimony, lobbying, education, research, and informal discussions follow. If the bill is passed from the legislative committee, the entire House of Representatives hears the bill, amends it as necessary, and votes on it. A majority vote moves the bill to Senate where it is read and amended, and then a vote is taken. [Figure 8-2](#) shows the necessary formal process of the legislative pathway.

Nurses can be involved in the legislative process at any point. Many professional nursing associations have legislative committees made up of volunteers, governmental relations staff professionals, and sometimes political action committees (PACs), all engaged in efforts to monitor, analyze, and shape health policy.

Common methods of influencing health policy outcomes include face-to-face encounters, personal letters, mailgrams, electronic mail, telephone calls, testimony, petitions, reports, position papers, fact sheets, letters to the editor, news releases, speeches, coalition building, demonstrations, and lawsuits. Depending on the issue, any of these can be effective. Although most business, including politics and the policy agendas, are dependent upon the Internet today for instant communication and quick response, all of these methods continue to be of great importance in influencing policy agendas. For example, if a face-to-face encounter is used with a legislator or a staffer, these persons can put a "face on the policy" agenda, and the reality that the policy affects real persons is an important consideration when the legislator or staff pushes the policy agenda forward. Guidelines on communication are provided in the [How To](#) box. Tips on communication and visiting legislators and their staffs, as well as general tips on political action, are presented in [Boxes 8-1, 8-2, and 8-3](#). Political activities in which nurses can and should be involved include a wide variety of activities such as being informed voters (a must!), participating in a political party, registering others to vote, getting out the vote, fundraising for candidates, building networks or communication links for issues (e.g., a phone tree or Internet distribution list), and participating in organizations to ensure their effective involvement in health policy and politics.

BOX 8-1 Tips for Visits with Legislators

- Face-to-face visits are viewed as the most effective.
- Call ahead and ask how much time the staff or legislator is able to give you.
- When you arrive, ask if the appointment time is the same or if a scheduled vote on the House/Senate floor is going to need the legislator's attention.
- Engage in small talk at the beginning of the conversation only if the staff or legislator has time.
- Structure time so that the issue can be briefly presented. The visit will probably be 15 minutes or less.
- Allow an opportunity for the staff or Congress member to seek clarity or ask questions.
- Offer to provide additional information or find answers to questions asked.
- Do not assume that the legislator or the legislator's staff is well informed on the issue.
- Leave a one- or two-page fact sheet on the issue.
- Numbers count. If the views you express are shared by a local nurses' organization or by nurses employed at a health care facility, let the legislator know.
- Invite Congress members and their staffs to conferences or meetings of nurses' organizations, or to tour nursing facilities to meet others interested in the same policy issues.
- If appropriate, invite the media and let the legislator know.
- Follow up with a letter of thanks to both the legislator and the staffer.

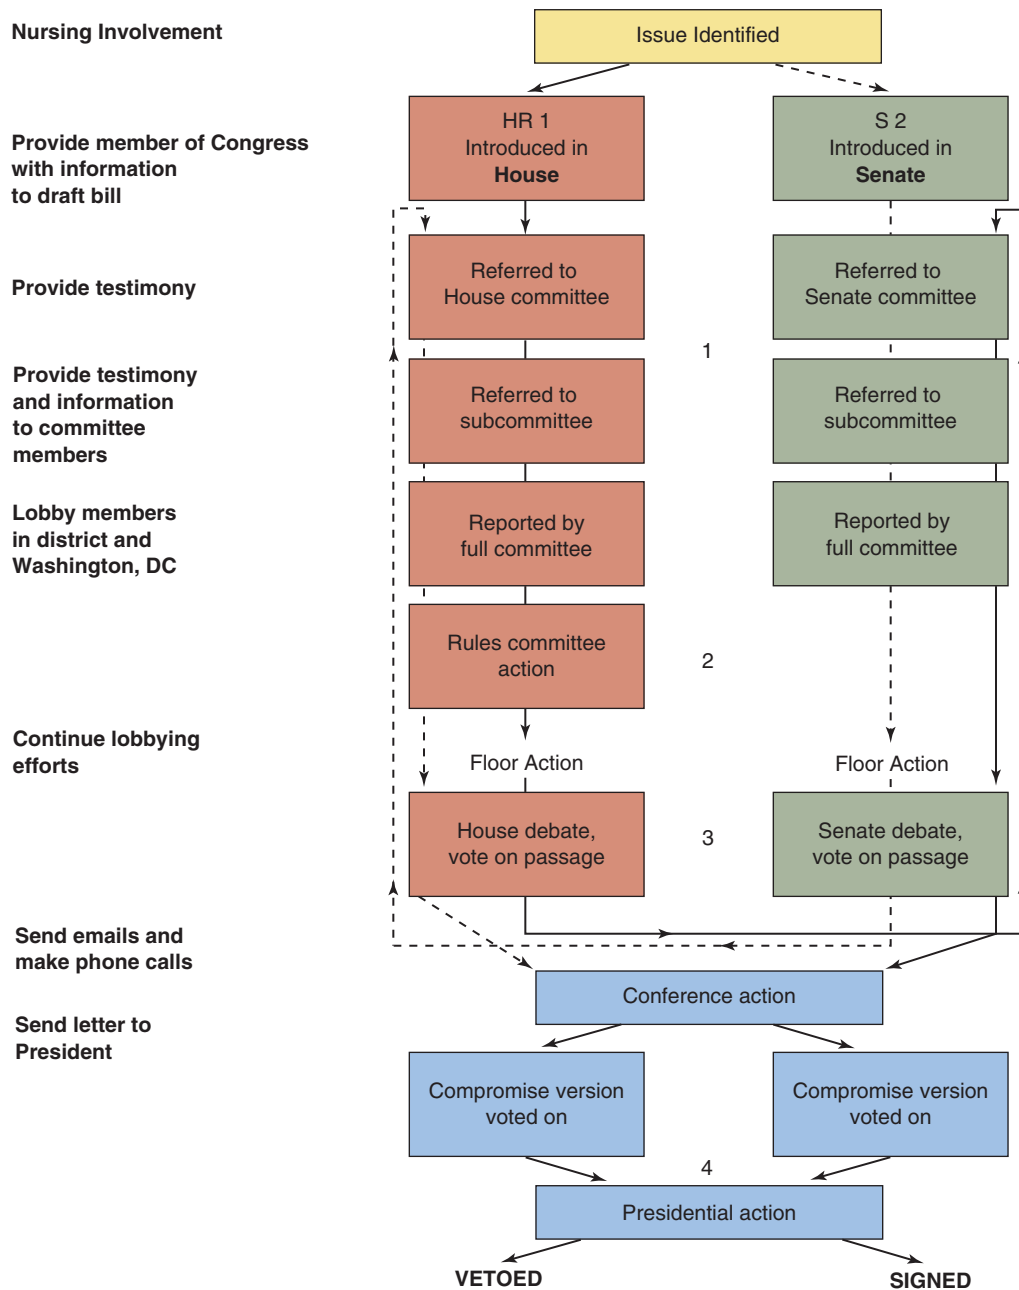

Modified from Mason D et al: *Policy and politics in government*, ed 5, St Louis, 2007, Elsevier.

BOX 8-2 Tips for Written Communication with Legislators

- Communicate in writing to express opinions.
 - Identify yourself as a nurse.
 - Acknowledge the Congress member's work as positive or negative, but be courteous.
 - Follow up on meetings or phone calls with a letter or e-mail.
 - Share knowledge about a particular problem.
 - Recommend policy solutions so the legislator or staff will know why you are writing.
 - The letter should be typed, a maximum of two pages, and focused on one or two issues at most.
 - The purpose of the letter should be stated at the beginning.
 - Present clear and compelling rationales for your concern or position on an issue.
 - If the purpose of the letter is to express disappointment regarding a stance on an issue or a vote that has been cast, the letter should be as positive as possible.
 - Write letters thanking a Congress member for taking a particular position on an issue.
 - A letter to the editor of the local newspaper or a nursing newsletter praising a legislator's position (with a copy forwarded to the legislator) is welcome publicity, especially during an election year.
 - If you visited with the legislator or a staffer, review the major points covered in person and answer any questions that were raised during conversation.
 - Have personal business cards and include them with letters.
 - Address written correspondence as follows (the same general format applies to state and local officials):
- | | |
|---------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| U.S. Senator
Honorable Jane Doe
United States Senate
Washington, DC 20510
Dear Senator Doe: | U.S. Representative
Honorable Jane Doe
House of Representatives
Washington, DC 20515
Dear Representative Doe: |
|---------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|

Modified from Mason D et al: *Policy and politics in government*, ed 5, St Louis, 2007, Elsevier.

The Federal Level

- ¹ A bill goes to full committee first, then to special subcommittees for hearings, debate, revisions, and approval. The same process occurs when it goes to full committee. It either dies in committee or proceeds to the next step.
- ² Only the House has a Rules Committee to set the "rule" for floor action and conditions for debate and amendments. In the Senate, the leadership schedules action.
- ³ The bill is debated, amended, and passed or defeated. If passed, it goes to the other chamber and follows the same path.
- If each chamber passes a similar bill, both versions go to conference.
- ⁴ The President may sign the bill into law, allow it to become law without his signature, or veto it and return it to Congress. To override the veto, both houses must approve the bill by a two-thirds majority vote.

FIG 8-2 How a bill becomes a law. (From Mason DJ, Leavitt JK, Chaffee MW: *Policy and politics in nursing and health care*, ed 6, St Louis, 2011, Elsevier.)

BOX 8-3 Tips for Action

- Become informed.
- Become acquainted with elected officials.
- Become involved in the state nurses' association.
- Build communication and leadership skills.
- Increase your knowledge about a range of professional issues.
- Expand and strengthen your professional network.
- Build relationships within the profession and with representatives of public and private sector organizations with an interest in health care.
- Be aware of what is taking place in health care beyond the environment and the practice in which you work.
- Communicate with legislators regularly and share expertise and perspective on issues related to health care and nursing.
- Offer your expertise to assist in developing new legislation, modifying existing legislation or regulations.
- Identify yourself as a nurse with associated education and expertise.
- Let people know that nurses are capable of functioning in many different roles and making substantial contributions.
- Be confident.
- Do not burn bridges.
- Be friendly.
- Lend a hand to other nurses. It benefits all of us.
- Find an experienced mentor to work with you if you are new to the policy arena.
- Volunteer, seek appointments, or participate in elections in campaigns.
- Explore opportunities for involvement through internships, fellowships, and volunteer work at all levels (local, state, and national).

Modified from Mason D, Keavitt JK, Chaffee MW: Policy and politics in government, ed 5, St Louis, 2007, Elsevier.

HOW TO Be an Effective Communicator

- Use simple communications that will be readily understood.
- Choose language that clearly conveys information to individuals of diverse cultures, different ages, and different educational backgrounds.
- Target oral or written communication to the issue and omit jargon unique to medicine and nursing.
- State your expertise on the issue first.
- Briefly describe your education and experience.
- Identify the relevance of the issue beyond nursing.
- Provide information regarding the impact of the issue on the legislator's constituents.
- Present accurate, credible data.
- Do not oversell or give inaccurate information about the problem.
- Present information in an organized, thorough, concise form that is based on factual data (when available).
- Give examples.

The direct reimbursement of **advanced practice nurses** (APNs) in the Medicare program is one example of how nurses can use their influence. The inclusion of amendments to Medicare that authorized APN reimbursement regardless of specialty or client location in the Balanced Budget Act of 1997 required the sustained efforts of the ANA and other national nursing organizations over a long period (Nursing World, 2000; USDHHS, CMS, 2011). During that time, individual nurses provided testimony to Congress and to MEDPAC (the physicians' political action committee) on the importance of direct reimbursement to APNs. Many APNs worked closely and vigorously with their congressional representatives to lobby for this Medicare amendment. Even more wrote letters and provided position papers and fact sheets to help legislators understand the value of APNs. Although the process took more than 10 years to achieve fully, APN reimbursement in Medicare became a reality. Both the nursing profession and Medicare beneficiaries will benefit from the enhanced access of Medicare clients to APNs.

The ANA was likewise a strong supporter of the Patient Safety Act of 1997 (ANA, 1997). This law requires health care agencies to make public some information on nurse staff levels,

staff mix, and outcomes, and it requires the USDHHS to review and approve all health care acquisitions and mergers. All of these requirements are to determine any long-term effect on the health and safety of clients, communities, and staff.

On the state legislative level, all 50 states have passed title protection for APNs; this was achieved by individual nurses, state nurses associations, and various nursing specialty groups participating in the legislative process with the 50 state legislators. Title protection means that only certain nurses who meet state criteria can call themselves *advanced practice nurses*.

Regulatory Action

The regulatory process, although it may not be as visible a process as legislation, can also be used to shape laws and dramatically affect health policy. This process should be on the radar screen of professional nurses who wish to successfully participate in policy activity.

At each level of government, the executive branch can and, in most cases, must prepare regulations for implementing policy for new laws and new programs. These regulations are detailed, and they establish, fix, and control standards and criteria for carrying out certain laws. Figure 8-3 shows the steps in the typical process of writing regulations. When the legislature passes a law and delegates its oversight to an agency, it gives that agency the power to make regulations. Because regulations flow from legislation, they have the force of law.

The Process of Regulation

After a law is passed, the appropriate executive department begins the process of regulation by studying the topic or issue. Advisory groups or special task forces are sometimes formed to provide the content for the regulations. Nurses can influence these regulations by writing letters to the regulatory agency in charge or by speaking at open public hearings. Many letters are now accepted by Internet.

After rewriting, the proposed regulations are put into final draft form and printed in the legally required publication (e.g., at the federal level, the *Federal Register*). Similar registers exist in most states, where regulations from state executive

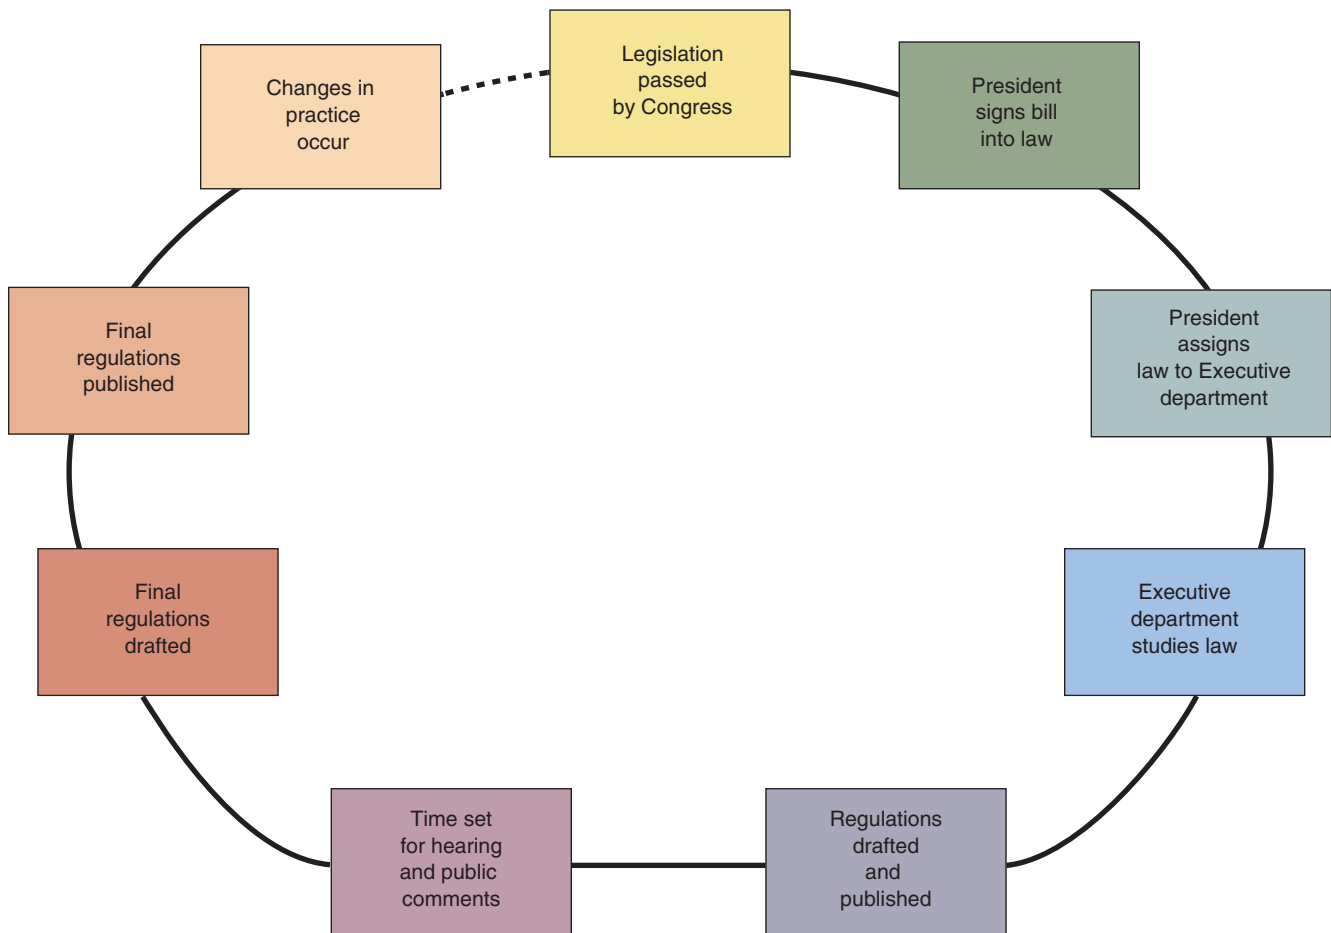

FIG 8-3 The process of writing regulations.

departments, including state health departments, are published. Public comment is called for in written form or oral presentation within a given period.

Revisions made to proposed regulations are based on public comment and public hearing. Depending on the amount and content of the public reaction, final regulations are prepared or more study of the area and issues is conducted. Final published regulations carry the force of law. When regulations become effective, health care practice is changed to conform to the new regulations. Monitoring administrative regulations is essential for the professional nurse, who can influence regulations by attending the hearings, providing comments, testifying, and engaging in lobbying aimed at individuals involved in the writing of the regulations. Concrete written suggestions for revision submitted to these individuals are frequently persuasive and must be acknowledged by government in publishing the final rules. An excellent example of how nurses must continue to influence health policy outcomes, even after positive legislation has passed, occurred after the passage of the Balanced Budget Act of 1997 (PL 105-33, 1997). The HCFA began to implement the BBA '97 through the publication of draft regulations seeking to define APN practice and Medicare reimbursement. The nursing community responded vigorously with negative opinions about the initial restrictive definitions and requirement. Their reactions were effective and reshaped the

final regulations to recognize the state definitions for APN practice autonomy.

Final regulations, published in a *Code of Regulations* (both federal and state), usually lead to changes in practice. For example, Medicare regulations setting standards for nursing homes and home health are incorporated into these agencies' manuals. In the case of APN reimbursement, some Medicare fiscal intermediaries have had difficulty in recognizing APNs as appropriate providers, but professional nursing organization advocates have forcefully addressed these implementation barriers.

Nursing Advocacy

Advocacy begins with the art of influencing others (politics) to adopt a specific course of action (policy) to solve a societal problem. This is accomplished by building relationships with the appropriate policy makers—the individuals or groups that determine a specific course of action to be followed by a government or institution to achieve a desired end (policy outcome). Relationships for effective advocacy can be built in a number of ways.

In January 2006, Medicare Part D—the prescription drug benefits policy—became effective. Public health professionals need to continue to assist many vulnerable persons to understand the value of enrolling in Part D, to educate them on how to use the benefits, and to ensure that the populations who are

“dually” enrolled in both Medicare and Medicaid are registered. Coordinating efforts between civic, religious, and health care agencies to provide health education is a necessity.

A letter or visit to the district, state, or national office of a legislator to discuss a particular policy or health care issue can be interesting, educational, and effective. Contributions of money, labor, expertise, or influence may also be welcomed by the policy makers involved in setting a course of action to obtain a desired health outcome for an individual, a family, a group, a community, or society (health policy). In addition, one may develop a grassroots network of community and professional friends with a mutual interest in health policy advocacy. The network may be able to promote health policy initiatives for the community. During the Obama presidential campaign, many advocacy networks were established via the Internet and monies were solicited using this process.

Many special-interest groups in health care have the potential, desire, and resources to influence the health policy process. A tremendous advantage that nursing has in advocating for issues and in influencing policy makers is the force of its numbers, since nursing is the largest of the health professions. However, nursing must organize its numbers in such a way that each nurse joins with others to speak with one voice. The greatest effect will be had when all nurses make similar demands for policy outcomes.

During 2002, the nursing profession spoke clearly, distinctly, and together on a serious problem for the health arena and for the profession: the nursing shortage. Health care facilities and employers were having ever-increasing difficulty finding experienced nurses to employ. In addition, the need for RNs was predicted to balloon in the next 20 years because of the aging of the U.S. population, technological advances, and economic factors. Demand for RNs was anticipated to increase by 22% by the year 2008. This increased demand for professional nurses, coupled with the expected retirement of a rapidly aging nursing workforce, placed a tremendous stress on the health care system.

The workforce shortage resulted from a complex set of factors such as fewer young people entering the profession, declining nursing school enrollment, the aging of the current nurse workforce, and uncomfortable working conditions in which nurses felt pressured to “do more with less.” On December 4, 2009, the *BLS (2009)* reported that the health care sector of the economy was continuing to grow, despite significant job losses in nearly all major industries. During the same time period a shortage of registered nurses was projected to spread across the country between 2009 and 2030 (*AJMQ, 2012*).

The *American Association of Colleges of Nursing (AACN)* remained concerned about the shortage of RNs and worked with schools, policy makers, other organizations, and the media to bring attention to this health care crisis. AACN worked to enact legislation, identify strategies, and form collaborations to address the nursing shortage (*AACN, 2010*). However, in June 2011 it was reported that employers and staffing agencies posted more than 121,000 new job ads for Registered Nurses in May, up 46% from May 2010 (*AACN, 2014*).

Advocacy by expert and committed health professionals can bring about positive change for the profession, the community,

and the clients that nurses serve. Keeping up to date on issues within government, professional organizations, law, and public policy is vitally important. Informed activism directed toward a professional role, image, and value for professional nurses, and toward a health care system in the United States that provides high quality and affordable universal access to health care, should be a life-long commitment for all professional nurses.

LINKING CONTENT TO PRACTICE

An example of how the policy process works follows, involving a nursing organization and individual members. Whether you are a member of a group as described below, or working on your own to influence health policy, the steps described here apply.

Over a 15-month time frame, the American Nurses Association was involved in advocating for health care reform. During the presidential campaign, candidates were educated about the nursing profession and ANA's *Agenda for Health System Reform*. ANA and its members participated in national media interviews and local media events. The message was that the association and its members believed that health care is a basic right. ANA collaborated with the nursing community to outline the profession's priorities as proposals were developed in Congress. Testimony was given before three key congressional committees. ANA representatives met with White House and congressional health care reform staff, and took part in two presidential press conferences at the White House.

As reported by ANA, thousands of nurses joined ANA's health care reform team, sending letters to representatives of Congress, sharing their stories, and meeting with members of Congress. They also participated in rallies and events.

For more information on ANA's health care reform work, visit <http://www.naction.org/toolkit>.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

- **Targeted competency:** Quality improvement
- **Knowledge:** Describe strategies for learning about the outcomes of care in the public setting
- **Skills:** Seek information about outcomes of care for populations served in care settings
- **Attitudes:** Appreciate that continuous quality improvement is an essential part of the daily work of all professionals

QI Question

The Quad Council competency of policy development and program planning skills indicates that the beginning PHN collects information that will inform policy decisions. Also the PHN describes the legislative policy development process and identifies outcomes of current health policy relevant to PHN practice. The 2014 outbreak of the Ebola virus in the United States brought quick recognition that there was a need for improvement in policies related to infectious disease control. What were the indicators that the infection control policies in place were not sufficient to prevent the spread of disease? Describe the CQI data collection processes that determined the need for policy change. What role did nurses and organized nursing play in improving the infection control policy and guidelines nationally? What has been the outcome of the new policy and how were populations affected both locally and nationally?

PRACTICE APPLICATION

Larry was in his final rotation in the Bachelor of Science in nursing program at State University. He was anxious to complete his final nursing course, because upon graduation he would begin a position as a staff nurse specializing in school health at the local health department. His wife was expecting their first child, and she had been receiving prenatal care at the health department.

Larry was aware that a few years ago the federal government had, by law, provided block grants to states for primary care, maternal–child health programs, and other health care needs of states. He had read the *Federal Register* and knew that the regulations for these grants had been written through USDHHS departments. He was aware that these regulations did not require states to fund specific programs.

Larry read in the local newspaper that the health department was closing its prenatal clinic at the end of the month. When

his state had received its block grant, it decided to spend the money for programs other than prenatal care. Larry found that a 3-year study in his own state showed improved pregnancy outcomes as a result of prenatal care. The results were further improved when the care was delivered by population-centered nurses. After Larry's daughter was born, he read in the *Federal Register* that states could apply for federal stimulus funds and receive a grant for home visiting services to support mothers and new babies.

Larry was concerned that, as a student, he would have little influence on how such grant dollars would be spent. However, he decided to call his classmates together to plan a course of action.

What would such an action plan include?

Answers can be found on the Evolve site.

KEY POINTS

- The legal basis for most congressional action in health care can be found in Article I, Section 8, of the U.S. Constitution.
- The five major health care functions of the federal government are direct service, financing, information, policy setting, and public protection.
- The goal of the World Health Organization is the attainment by all people of the highest possible level of health.
- Many federal agencies are involved in government health care functions. The agency most directly involved with the health and welfare of Americans is the U.S. Department of Health and Human Services (USDHHS).
- Most state and local governments have activities that affect nursing practice.
- The variety and range of functions of governmental agencies have had a major impact on nursing. Funding, in particular, has shaped the role and tasks of nurses.
- The private sector (of which nurses are a part) can influence legislation in many ways, especially through the process of writing regulations.
- The number and types of laws influencing health care are increasing. Because of this, involvement in the political process is important to nurses.
- Professional negligence and the scope of practice are two legal aspects particularly relevant to nursing practice.
- Nurses must consider the legal implications of their own practice in each clinical encounter.
- The federal and most state governments are composed of three branches: the executive, the legislative, and the judicial.
- Each branch of government plays a significant role in health policy.
- The U.S. Public Health Service was created in 1798.
- The first national health insurance legislation was challenged in the Supreme Court in 1937.
- *Health: United States* (NCHS, 2013) is an important source of data about the nation's health care problems.
- In 1921 the Sheppard-Towner Act was passed, and it had an important influence on child health programs and population-centered nursing practice.
- The Division of Nursing, the National Institute of Nursing Research, and the Agency for Healthcare Policy and Research are governmental agencies important to nursing.
- Nurses, through state and local health departments, function as consultants, policy advocates, population level and direct care providers, researchers, teachers, supervisors, and program managers.
- The state governments are responsible for regulating nursing practice within the state.
- Federal and state social welfare programs have been developed to provide monetary benefits to the poor, older adults, the disabled, and the unemployed.
- Social welfare programs affect nursing practice. These programs improve the quality of life for special populations, thus making the nurse's job easier in assisting the client with health needs.
- The nurse's scope of practice is defined by legislation and by standards of practice within a specialty.

CLINICAL DECISION—MAKING ACTIVITIES

1. Conduct an interview with a local health officer. Ask for information from a 10-year period. Try to see trends in population size, health needs and corresponding roles, and activities of government that were implemented to meet these changes. What were some of the problems you identified?
2. Examine a current health department budget and compare it with a budget from previous years. Has there been any impact on health care because of changes in government spending (especially before and after the passing of the Patient Protection and Affordable Care Act)? Give an example.
3. Locate your state register or other documents, such as newspapers, that publish proposed regulations. Select one set of proposed regulations and critique them. Submit your opinion in writing as public comment, or attend the hearing and testify on the regulations. Be sure to submit something in writing. Evaluate your participation by stating what you learned and whether the proposed regulations were changed in your favor.
4. Find and review your state nurse practice act and define your scope of practice. Give examples of your practice boundaries.
5. Contact your local public health agency to discuss the state's official powers in regulating epidemics, such as the measles outbreak in Orange County, California, (HCA, 2014) and anthrax exposures related to bioterrorism.
6. Explore the state's right to protect the health, safety, and welfare of its citizens.
7. Ask about the conflict between the state's rights and individual rights and how such issues are resolved.
8. Ask about the standards of care that apply to this issue and how it is decided which services offered to clients should be mandatory and which should be voluntary.
9. Explore how the role of public health differs in these epidemics compared with the past epidemics of smallpox and tuberculosis. Be specific.

Conceptual and Scientific Frameworks Applied to Population-Centered Nursing Practice

In recent years many foundations, organizations and associations have developed important documents that discuss the importance of public health nursing and that define the essential competencies for public health nursing practice. Because of the emerging public health threats in the United States and many other countries it has been important to focus on the essential role of public health nursing in dealing effectively with these threats. Specifically, there has been a reemergence of communicable diseases, and other diseases previously limited in scope have now become more virulent. At the same time, there has been an increased incidence of drug-resistant organisms. Also, environmental hazards that affect the water, land, air, and food that animals and people eat and drink and the locations where people live have increased. As will be discussed in other sections of the book, chronic diseases consume an increasing portion of health care expenditures, and many of these diseases are associated with lifestyle choices.

Many factors influence behavior and subsequently health. Edberg (2015) says that “ecological models integrate the various influences on health behavior, including interpersonal, organizational, community and public policy factors, to name a few” (p.12). Public health nursing incorporates an ecological approach as it responds to the needs of families, communities, and populations. Public health nurses are in an ideal position to identify risk factors as well as protective factors for the populations they serve.

Documents that can guide and assist public health nurses in developing strategies to serve their populations include the “Scope and Standards of Public Health Nursing” revised in 2013 by the American Nurses Association. This document provides a framework for the practice of public health nursing that builds on the current information about the influences on practice and the issues facing public health nurses. Similarly, in 2013, the American Association of Colleges of Nursing developed a supplement to the “Essentials of Baccalaureate Education for Professional Nursing Practice” entitled “Public Health: Recommended Baccalaureate Competencies and Curricular Guidelines for Public Health Nursing.” Another useful document that is cited in many chapters in the text is “Core Competences for Public Health Professionals” which was developed by the Council on Linkages Between Academia and Public Health Practice and revised in 2014. In 2011 the Quad Council of Public Health Nursing developed a companion document for the Core Competences for Public Health Professionals that aligns the work of the Council on Linkages directly with public health nursing. Also, the Institute

of Medicine developed “For the Public’s Health: Investing in a Healthier Future” in 2012 which provides considerable information about population-based prevention efforts designed to improve the health of Americans.

The chapters in Part Three support the tenants of these documents and provide information about how to use conceptual

models, epidemiology, genomics, environmental health, infectious and communicable diseases, principles of education, and how evidence helps to organize population-centered nursing practice to meet the core functions of public health. Each chapter provides readers with tools that can be used to influence population-centered nursing practice.

Population-Based Public Health Nursing Practice: The Intervention Wheel

Linda Olson Keller, DNP, CPH, APHN-BC, RN, FAAN

Linda Olson Keller is a Clinical Associate Professor at the University of Minnesota School of Nursing. Her research focuses on evidence-based public health nursing practice and the infrastructure of the public health nursing workforce. She spent 20 years of her career in the Office of Public Health Practice at the Minnesota Department of Health. Dr. Olson Keller is certified in Public Health, board certified as an Advanced Public Health Nurse, and is a Fellow of the American Academy of Nursing. She is a frequent national speaker and consultant on public health leadership and practice.

Sue Strohschein, MS, RN/PHN, APRN, BC

Sue Strohschein's public health nursing career spans more than 40 years and includes practice in both local and state health departments in Minnesota. She was a generalized public health nurse consultant for the Minnesota Department of Health for 25 years. Since 2008 she has been with the University of Minnesota School of Nursing as a senior research fellow.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Identify the components of the Intervention Wheel.
2. Describe the assumptions underlying the Intervention Wheel.
3. Define the wedges and interventions of the Intervention Wheel.
4. Differentiate among three levels of practice (community, systems, and individual/family).
5. Apply the nursing process at three levels of practice.

CHAPTER OUTLINE**The Intervention Wheel Origins and Evolution****Assumptions Underlying the Intervention Wheel**

- Assumption 1: Defining Public Health Nursing Practice
- Assumption 2: Public Health Nursing Practice Focuses on Populations
- Assumption 3: Public Health Nursing Practice Considers the Determinants of Health
- Assumption 4: Public Health Nursing Practice Is Guided by Priorities Identified Through an Assessment of Community Health
- Assumption 5: Public Health Nursing Practice Emphasizes Prevention
- Assumption 6: Public Health Nurses Intervene at All Levels of Practice
- Assumption 7: Public Health Nursing Practice Uses the Nursing Process at All Levels of Practice
- Assumption 8: Public Health Nursing Practice Uses a Common Set of Interventions Regardless of Practice Setting
- Assumption 9: Public Health Nursing Practice Contributes to the Achievement of the 10 Essential Services
- Assumption 10: Public Health Nursing Practice Is Grounded in a Set of Values and Beliefs

Using the Intervention Wheel in Public Health Nursing Practice**Components of the Model**

- Component 1: The Model Is Population Based
- Component 2: The Model Encompasses Three Levels of Practice
- Component 3: The Model Identifies and Defines 17 Public Health Interventions

Adoption of the Intervention Wheel in Practice, Education, and Management

Healthy People 2020

Applying the Nursing Process in Public Health Nursing Practice**Applying the Process at the Individual/Family Level**

- Community Assessment
- Public Health Nursing Process: Assessment of a Family
- Public Health Nursing Process: Diagnosis
- Public Health Nursing Process: Planning (Including Selection of Interventions)
- Public Health Nursing Process: Implementation
- Public Health Nursing Process: Evaluation

Applying the Public Health Nursing Process at the Community Level of Practice Scenario

- Community Assessment (Public Health Nursing Process: Assessment)
- Community Diagnosis (Public Health Nursing Process: Diagnosis)
- Community Action Plan (Public Health Nursing Process: Planning, Including Selection of Interventions)
- Community Implementation Plan (Public Health Nursing Process: Implementation)
- Community Evaluation (Public Health Nursing Process: Evaluation)

Applying the Public Health Nursing Process to a Systems Level of Practice Scenario

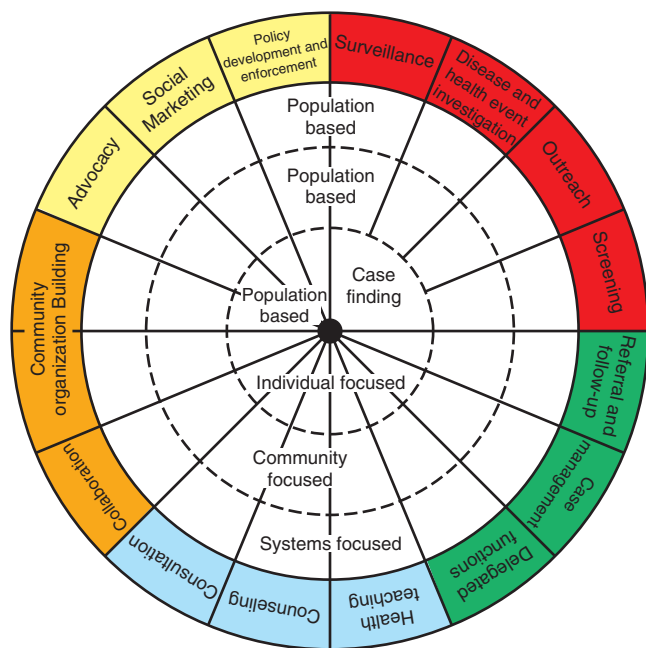

- Public Health Nursing Process: Assessment
- Public Health Nursing Process: Diagnosis
- Public Health Nursing Process: Planning (Including Selection of Interventions)
- Public Health Nursing Process: Implementation
- Public Health Nursing Process: Evaluation

In these times of change, the public health system is constantly challenged to keep focused on the health of populations. The Intervention Wheel is a conceptual framework that has proved to be a useful model in defining population-based practice and explaining how it contributes to improving population health.

The Intervention Wheel provides a graphic illustration of population-based public health practice (Keller et al, 1998, 2004a,b). It was previously introduced as the Public Health Intervention Model and was known nationally as the “Minnesota Model”; it is now often simply referred to as the “Wheel.” The Wheel depicts how public health improves population

health through interventions with communities, the individuals and families that comprise communities, and the systems that impact the health of communities (Figure 9-1). The Wheel was derived from the practice of public health nurses (PHNs) and intended to support their work. It gives PHNs a means to describe the full scope and breadth of their practice.

This chapter applies the Intervention Wheel framework to public health nursing practice. However, it is important to note that other public health members of the interprofessional team such as nutritionists, health educators, planners, physicians, and epidemiologists also use these interventions.

The Intervention Wheel is composed of three distinct elements of equal importance:

- First, the model is population based.
- Second, the model encompasses three levels of practice (community, systems, individual/family).
- Third, the model identifies and defines 17 public health interventions.

Each intervention and level of practice contributes to improving population health.

FIG 9-1 The Intervention Wheel components. (Used with permission from Keller LO, Strohschein S, Lia-Hoagberg B, et al: Population-based public health interventions: practice-based and evidence-supported, part I. *Public Health Nurs* 21:453–468, 2004.)

THE INTERVENTION WHEEL ORIGINS AND EVOLUTION

The original version of the Wheel resulted from a grounded theory process carried out by PHN consultants at the Minnesota Department of Health in the mid-1990s. This was a period of relentless change and considerable uncertainty for Minnesota's public health nursing community. Debates about health care reform and its impact on the role of local public health departments created confusion about the contributions of public health nursing to population-level health improvement. In response to the uncertainty, the consultant group presented a series of workshops across the state highlighting the core functions of public health nursing practice (see [Chapter 1](#) for a description of these core functions). A workshop activity required participants to describe the actions they undertook to

carry out their work. The consultant group analyzed 200 practice scenarios developed at the workshops that ranged from home care and school health to home visiting and correctional health. In the final analysis, 17 actions common to the work of PHNs regardless of their practice setting were identified. The analysis also demonstrated that most of these interventions were implemented at three levels: (1) with individuals, either singly or in groups, and with families; (2) with communities as a whole; and (3) with systems that impact the health of communities. A wheel-shaped graphic was developed to illustrate the set of interventions and the **levels of practice** (see [Figure 9-1](#)).

The interventions were subjected to an extensive review of supporting evidence in the literature through a grant from the federal Division of Nursing awarded to the Minnesota Department of Health in the 1990s. In 1999 the PHN consultant group at the Minnesota Department of Health designed and implemented a systematic process identifying more than 600 items from supporting evidence in the literature. These items were rated for their quality and relevancy by a group of graduate nursing students. The resulting subset of 221 items was further analyzed by two expert panels. One panel was composed of public health nursing educators and expert practitioners from five states (Iowa, Minnesota, North Dakota, South Dakota, and Wisconsin). The other panel was a similarly composed national panel. The result was a slightly modified set of 17 interventions. [Figure 9-2](#) graphically illustrates the systematic critique. Each intervention was defined at multiple levels of practice; each was accompanied by a set of basic steps for applying the framework and recommendations for best practices.

Adoption of the model was rapid and worldwide. Since its first publication in 1998, the Intervention Wheel has been incorporated into the public/community health coursework of numerous undergraduate and graduate curricula. The Wheel serves as a model for practice in many state and local health departments and has been presented in Mexico, Norway, Poland, Hungary, Namibia, Kazakhstan, and Japan. It has served as an organizing framework for inquiry for topics ranging from honors theses examining residents' perceptions regarding environmental hazards in their community ([Kariuki, 2012](#)) to nursing curriculum reviews ([Schoneman et al, 2014](#)) to building breast cancer screening coalitions ([Depke and Onitilo, 2011](#)). The Wheel's strength comes from the common language it affords PHNs to discuss their work ([Keller et al, 1998](#)).

ASSUMPTIONS UNDERLYING THE INTERVENTION WHEEL

As with all conceptual frameworks and models, assumptions are made that help to explain the model or framework. The Intervention Wheel framework is based on 10 assumptions.

Assumption 1: Defining Public Health Nursing Practice

Public health nursing is defined as “the practice of promoting and protecting the health of populations using knowledge from nursing, social, and public health sciences” ([APHA, 2013, p. 2](#)).

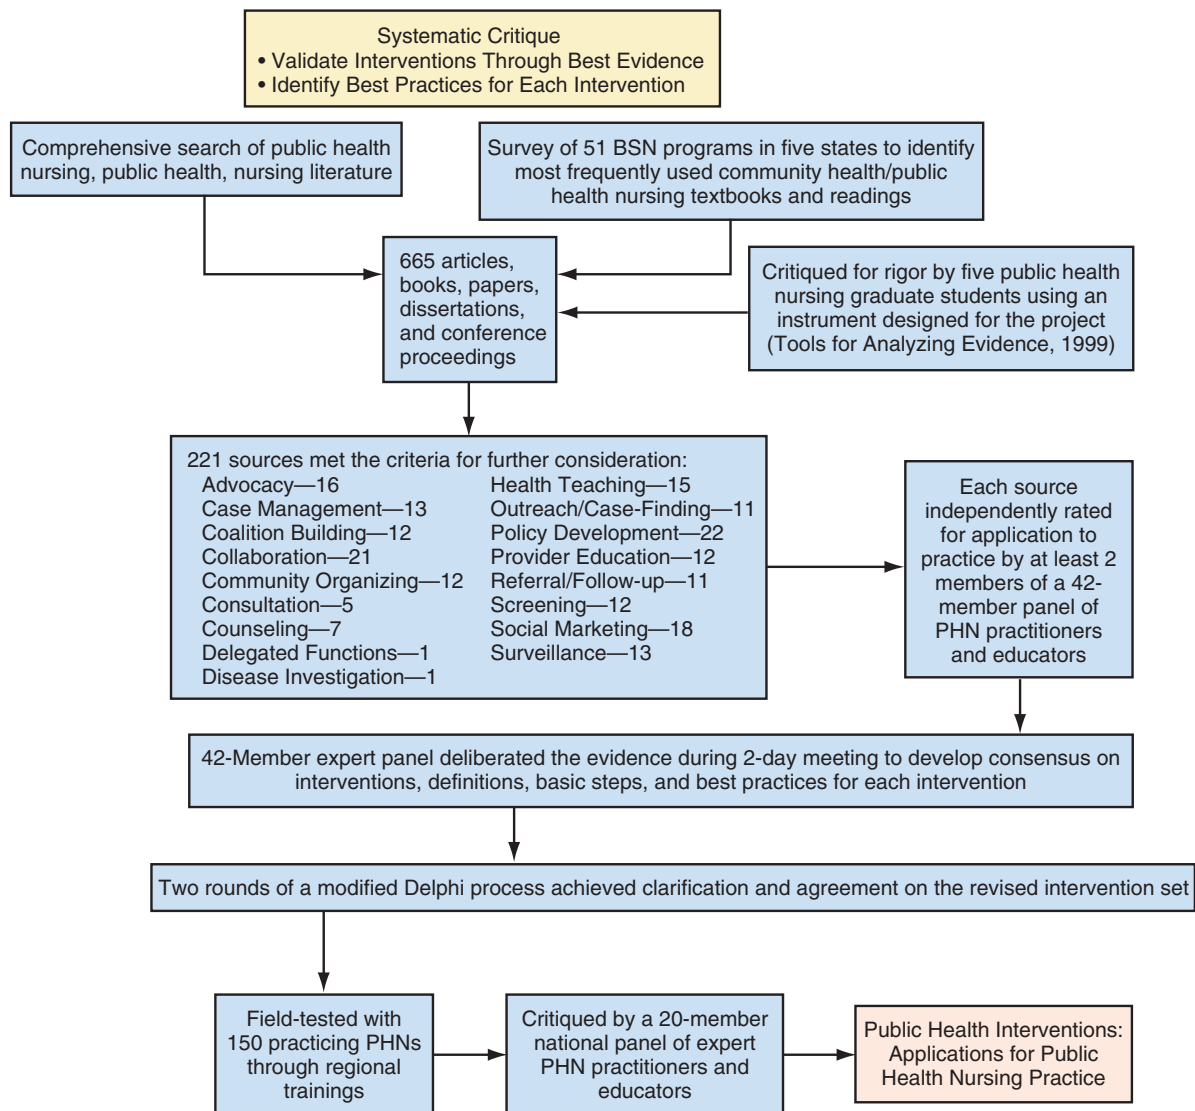

FIG 9-2 Development of a conceptual framework using an evidence-based process. (Used with permission from Keller LO, Strohschein S, Lia-Hoagberg B, et al: Population-based public health interventions: practice-based and evidence-supported, part I. *Public Health Nurs* 21:459, 2004.)

The title “public health nurse” designates a registered nurse with educational preparation in both public health and nursing. The primary focus of **public health nursing** is to promote health and prevent disease for entire population groups. This is done by working with individuals, families, communities, and/or systems.

Assumption 2: Public Health Nursing Practice Focuses on Populations

The focus on populations as opposed to individuals is a key characteristic that differentiates public health nursing from other areas of nursing practice. A **population** is a collection of individuals who have one or more personal or environmental characteristics in common (Williams and Highriter, 1978). Populations may be understood as two categories. A **population at risk** is a population with a common identified risk factor or risk exposure that poses a threat to health. For example, all

adults who are overweight and hypertensive constitute a population at risk for cardiovascular disease. All under-immunized or un-immunized children are a population at risk for contracting vaccine-preventable diseases. A **population of interest** is a population that is essentially healthy but that could improve factors that promote or protect health. For instance, healthy adolescents are a population of interest that could benefit from social competency training. All first-time parents of newborns are a population of interest that could benefit from a public health nursing home visit. Populations are not limited to only individuals who seek services or individuals who are poor or otherwise vulnerable.

Assumption 3: Public Health Nursing Practice Considers the Determinants of Health

Health inequities are defined as health status inequalities that society deems to be avoidable or unnecessary (Bleich, Jarlenski,

Bell, and LaVeist, 2012). Significant health disparities related to race, gender, age, and socioeconomic status exist within the United States. The CDC's (2013) *Health Disparities and Inequalities Report—United States, 2013* provides the following examples:

- In 2008, the U.S. rate of infant deaths per 1000 live births was 6.61 for all races; across races and ethnicities the rates varied. For infants born to white women the rate was 5.52; for black and African American women, 12.67; for Asian or Pacific Islander women, 4.51; for American Indian or Alaskan Native women, 8.42, for Hispanic women, 5.59 (Table 1, pp 172).
- Infant mortality rates also differed based on the geographic location of the mother. The rates were generally higher in the Southern and Midwestern regions. The infant mortality rates were highest in DC (11.97 per 1000 live birth) and Mississippi (10.16 per live birth) and lowest in Massachusetts and Utah (both at 4.94 per 1000 live births) (Table 2, pp 173).
- Disparities in life expectancy exist between gender and race. In 2008, the life expectancy at birth for men in the United States was 75.6 years; yet for U.S. women, the life expectancy at birth was 80.6 (Table 1, p. 89). Furthermore, the life expectancy at birth for black populations in the U.S. was 74.0 years, compared to 78.5 years for white populations (Table 1, p. 89).

What are the factors driving these differences? Factors that influence health status across the life cycle are known as the **determinants of health**. They include income, education, employment, social support, biology and genetics, physical environment, housing, transportation, and personal health practices.

Resolving health inequities and addressing the determinants of health are key distinguishing characteristics of public health nursing. For example, historically, Lillian Wald's Henry Street Settlement House offered numerous social programs, including drama and theater productions, vocational training for boys and girls, three kindergartens, summer camps for children, two large scholarship funds, study rooms staffed with people to help children with their homework, playgrounds for children, a neighborhood library, and classes in carpentry, sewing, art, diction, music, and dance. The following photo shows the settlement house's backyard playground.

In a recent interpretive qualitative study of PHNs' practice in Nova Scotia, researchers found that PHNs routinely implemented "ecosocial surveillance functions" that focused on monitoring changes in social determinants of health. The researchers observed that PHNs "...monitored both bottom-up changes in individual, family, and community determinants of health, and top-down vertical changes or policy directives in the larger system" (Meagher-Stewart et al, 2009, p 557).

Assumption 4: Public Health Nursing Practice Is Guided by Priorities Identified Through an Assessment of Community Health

In the context of the Intervention Wheel, a **community** is defined as "a group of people who share common culture, values and/or interests, based on social identity and/or territory,

From Jewish Women's Archive: This day in history, March 10, 1893, Resource information for backyard of a Henry Street branch. Available at <http://www.jwa.org/archive/jsp/gresInfo.jsp?resID=297>. Accessed December 11, 2010.

and who have some means of recognizing, and (inter)acting upon, these commonalities" (Gregory et al, 2009, p. 103).

Assessing the health status of the populations that comprise the community requires ongoing collection and analysis of relevant quantitative and qualitative data. Community assessment includes a comprehensive assessment of the determinants of health. Data analysis identifies deviations from expected or acceptable rates of disease, injury, death, or disability as well as risk and protective factors. Community assessment generally results in a lengthy list of community problems and issues. However, communities rarely possess sufficient resources to address the entire list. This gap between needs and resources necessitates a systematic priority-setting process. Although data analysis provides direction for priority setting, the community's beliefs, attitudes, and opinions as well as the community's readiness for change must be assessed (Keller et al, 2002). PHNs, with their extensive knowledge about the communities in which they work, provide important information and insights during the priority-setting process.

Assumption 5: Public Health Nursing Practice Emphasizes Prevention

Prevention is "anticipatory action taken to prevent the occurrence of an event or to minimize its effect after it has occurred" (Turnock, 2011). Prevention is customarily described as a continuum moving from primary to **tertiary prevention** (Leavell and Clark, 1965; Shi and Johnson, 2013; Turnock, 2011). The **Levels of Prevention** box provides definitions and examples of the levels of prevention.

A hallmark of public health nursing practice is a focus on health promotion and disease prevention, emphasizing **primary prevention** whenever possible. Although not every event is preventable, every event has a preventable component.

Assumption 6: Public Health Nurses Intervene at All Levels of Practice

To improve population health, the work of PHNs is often carried out sequentially and/or simultaneously at three levels of prevention (see Figure 9-2).

LEVELS OF PREVENTION

Examples of Interventions Applied to Definition of Prevention

Primary Prevention

Primary prevention promotes health and protects against threats to health. It keeps problems from occurring in the first place. It promotes resiliency and protective factors or reduces susceptibility and exposure to risk factors. Primary prevention is implemented before a problem develops. It targets essentially well populations. Immunizing against a vaccine-preventable disease is an example of reducing susceptibility; building developmental assets in young persons to promote health is an example of promoting resiliency and protective factors.

Secondary Prevention

Secondary prevention detects and treats problems in their early stages. It keeps problems from causing serious or long-term effects or from affecting others. It identifies risk or hazards and modifies, removes, or treats them before a problem becomes more serious. Secondary prevention is implemented after a problem has begun, but before signs and symptoms appear. It targets populations that have risk factors in common. Programs that screen populations for hypertension, obesity, hyperglycemia, hypercholesterolemia, and other chronic disease risk factors are examples of secondary prevention.

Tertiary Prevention

Tertiary prevention limits further negative effects from a problem. It keeps existing problems from getting worse. It alleviates the effects of disease and injury and restores individuals to their optimal level of functioning. Tertiary prevention is implemented after a disease or injury has occurred. It targets populations who have experienced disease or injury. Provision of directly observed therapy (DOT) to clients with active tuberculosis to ensure compliance with a medication regimen is an example of tertiary prevention.

Data from Keller LO, Strohschein S, Lia-Hoagberg B, et al: Population-based public health nursing interventions: a model from practice. *Public Health Nurs* 15(3):207-15, 1998.

Community-level practice changes community norms, community attitudes, community awareness, community practices, and community behaviors. It is directed toward entire populations within the community or occasionally toward populations at risk or populations of interest. An example of community-level practice is a social marketing campaign to promote a community norm that serving alcohol to under-aged youth at high school graduation parties is unacceptable. This is a community-level primary prevention strategy.

Systems-level practice changes organizations, policies, laws, and power structures within communities. The focus is on the systems that impact health, not directly on individuals and communities. Conducting compliance checks to ensure that bars and liquor stores do not serve minors or sell to individuals who supply alcohol to minors is an example of a systems-level secondary prevention strategy practice.

Individual-level practice changes knowledge, attitudes, beliefs, practices, and behaviors of individuals. This practice level is directed at individuals, alone or as part of a family, class, or group. Even though families, classes, and groups are comprised of more than one individual, the focus is still on

individual change. Teaching effective refusal skills to groups of adolescents is an example of individual secondary prevention strategy level of practice.

Assumption 7: Public Health Nursing Practice Uses the Nursing Process at All Levels of Practice

Although the components of the nursing process (assessment, diagnosis, planning, implementation, and evaluation) are integral to all nursing practice, PHNs must customize the process to the three levels of practice. Table 9-1 outlines the nursing process at the community, systems, and individual/family levels of practice.

Assumption 8: Public Health Nursing Practice Uses a Common Set of Interventions Regardless of Practice Setting

Interventions are “actions taken on behalf of communities, systems, individuals, and families to improve or protect health status” (ANA, 2010). The Intervention Wheel encompasses 17 interventions: surveillance, disease and other health investigation, outreach, screening, case finding, referral and follow-up, case management, delegated functions, health teaching, consultation, counseling, collaboration, coalition building, community organizing, advocacy, social marketing, and policy development and enforcement.

The interventions are grouped with related interventions; these **wedges** are color coordinated to make them more recognizable (Figure 9-3, A). For instance, the five interventions in the **red wedge** are frequently implemented in conjunction with one another. Surveillance is often paired with disease and health event investigation, even though either can be implemented independently. Screening frequently follows either surveillance or disease and health event investigation and is often preceded by outreach activities in order to maximize the number of those at risk who actually get screened. Most often, screening leads to case finding, but this intervention can also be carried out independently.

The green wedge consists of referral and follow-up, case management, and delegated functions—three interventions that, in practice, are often implemented together (Figure 9-3, B).

Similarly, health teaching, counseling, and consultation—the blue wedge—are more similar than they are different; health teaching and counseling are especially often paired (Figure 9-3, C).

The interventions in the orange wedge—collaboration, coalition building, and community organizing—although distinct, are grouped together because they are all types of collective action and are most often carried out at systems or community levels of practice (Figure 9-3, D).

Similarly, advocacy, social marketing, and policy development and enforcement—the yellow wedge—are often interrelated when implemented (Figure 9-3, E). In fact, advocacy is often viewed as a precursor to policy development; social marketing is seen by some as a method of carrying out advocacy.

The interventions on the right side of the Wheel (i.e., the red, green, and blue wedges) are most commonly used by PHNs who focus their work more on individuals, families, classes, and

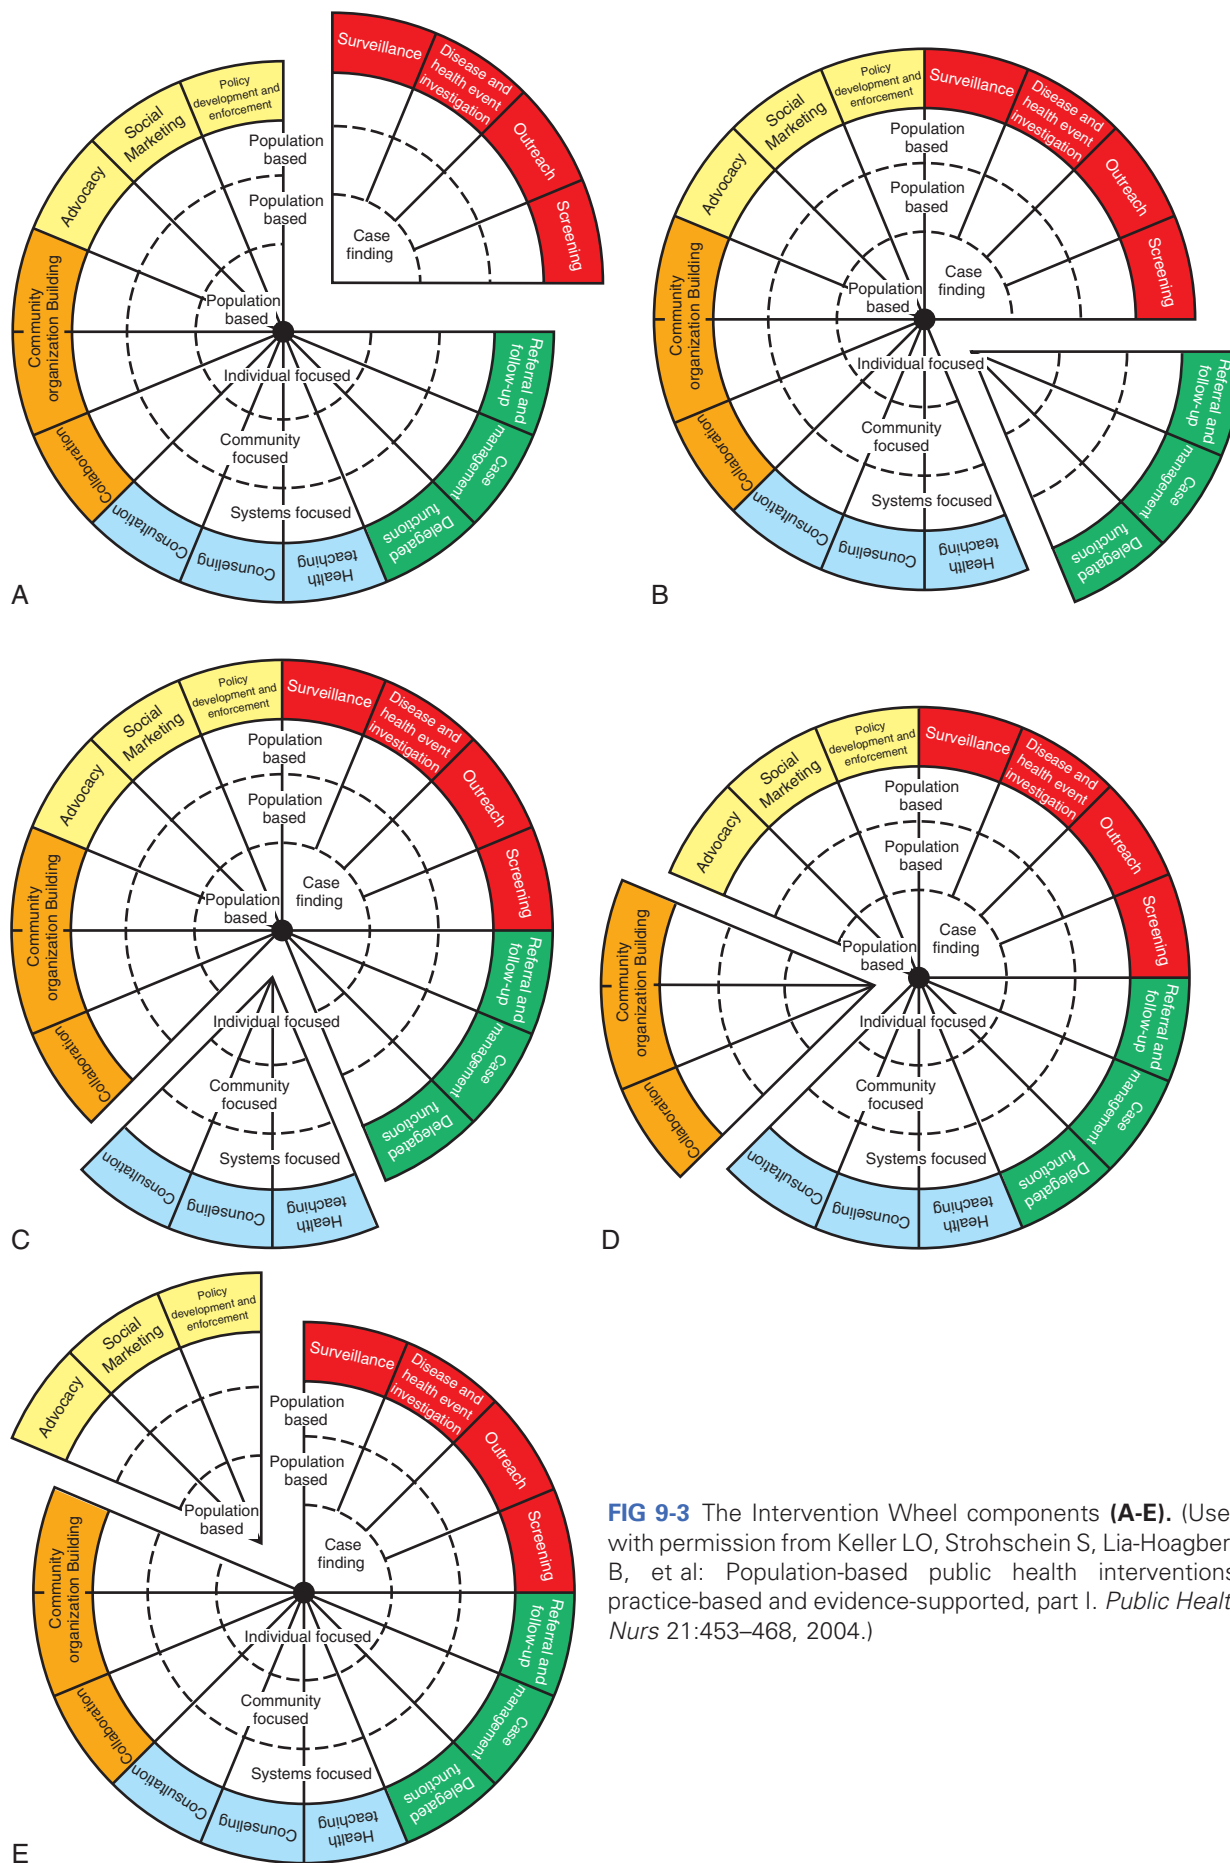

FIG 9-3 The Intervention Wheel components (A-E). (Used with permission from Keller LO, Strohschein S, Lia-Hoagberg B, et al: Population-based public health interventions: practice-based and evidence-supported, part I. *Public Health Nurs* 21:453–468, 2004.)

TABLE 9-1 Public Health Nursing Process

Public Health Nursing Process	Systems Level	Community Level	Individual/Family Level
Recruit additional partners.	Recruit additional partners (local, regional, state, national) from systems that are key to impacting and/or who have an interest in the health issue/problem.	Recruit community organizations, services, and citizens who are part of the community intervention that have an interest in this health issue/problem.	
Identify population of interest.	Identify those systems for which change is desired.	Identify the population of interest at risk for the problem.	Identify new and current clients in caseload who are at risk for the priority problem.
Establish relationship.	Begin/continue establishing relationship with system partners.	Begin/continue establishing relationship with community partners and population of interest.	Begin/continue establishing relationship with the family.
Assess priority.	Assess the impact and interrelationships of the various systems on the development and extent of the health issue/problem.	Assess the health issue/problem (demographics, health determinants, past and current efforts). Identify the particular strengths, health risks, and health influences of the population of interest	Identify the particular strengths, health risks, social supports, and other factors influencing the health of the family and each family member.
Elicit perceptions.	Develop a common consensus among system partners of the health issue/problem and the desired changes.	Elicit the population of interest's perception of their strengths, problems, and health influences.	Elicit family's perception of their strengths, problems, and other factors influencing their health.
Set goals.	In conjunction with system partners, develop system goals to be achieved.	In conjunction with the population of interest, negotiate and come to agreement on community-focused goals.	In conjunction with the family, negotiate and come to agreement on meaningful, achievable, measurable goals.
Select health status indicators.	Based on systems goals, select meaningful, measurable health status indicators that will be used to measure success.	Based on the refined community goal/problem, select meaningful, measurable health status indicators that will be used to measure success.	Select meaningful, measurable health status indicators that will be used to measure success.
Select interventions.	Select system-level interventions considering evidence of effectiveness, political support, acceptability to community, cost-effectiveness, legality, ethics, greatest potential for successful outcome, nonduplicative, levels of prevention.	Select community-level interventions considering evidence of effectiveness, acceptability to community, cost-effectiveness, legality, ethics, nonduplicative, greatest potential for successful outcome.	Select interventions considering evidence of effectiveness, acceptability to family, cost-effectiveness, legality, ethics, greatest potential for successful outcome.
Select intermediate outcome indicators.	Determine measurable, meaningful intermediate outcome indicators.	Determine measurable and meaningful intermediate outcome indicators.	Determine measurable, meaningful intermediate outcome indicators.
Determine strategy frequency and intensity.	Using best practices, determine intensity, sequencing, frequency of interventions considering urgency, political will, resources.	Using best practices, determine intensity, sequencing, frequency of interventions.	Using best practices, determine intensity, sequencing, frequency of interventions.
Determine evaluation methods.	Determine evaluation methods for measuring process, intermediate, and outcome indicators.	Determine evaluation methods for measuring process, intermediate, and outcome indicators.	Determine evaluation methods for measuring process, intermediate, and outcome indicators.
Implement the interventions.	Implement the interventions.	Implement the interventions.	Implement the interventions.
Regularly reassess interventions.	Regularly reassess the system's response to the interventions and modify plan as indicated.	Reassess the population of interest's response to the interventions on an ongoing basis and modify plan as indicated.	Reassess and modify plan at each contact as necessary.
Adjust interventions.	Adjust the frequency and intensity of the interventions according to the needs and resources of the community.	Adjust the frequency and intensity of the interventions accordingly.	Adjust the frequency and intensity of the interventions according to the needs and resources of the family.
Provide feedback.	Provide feedback to system's representatives.	Provide feedback to the population of interest and informal and formal organizational representatives.	Provide regular feedback to family on progress (or lack thereof) of client goals.
Collect evaluation.	Regularly and systematically collect evaluation information.	Regularly and systematically collect evaluation information.	Regularly and systematically collect evaluation information.
Compare results to plan.	Compare actual results with planned indicators.	Compare actual results with planned indicators.	Compare actual results with planned indicators.

TABLE 9-1 Public Health Nursing Process—cont'd

Public Health Nursing Process	Systems Level	Community Level	Individual/Family Level
Identify differences.	Identify and analyze differences in those systems that achieved outcomes compared with those that did not.	Identify and analyze differences in those in the population of interest who achieved outcomes compared with those who did not.	Identify and analyze differences in services received by families who achieved outcomes compared with those who did not.
Apply results to practice.	Apply results to identify needed systems changes. Depending on readiness of the system to accept the results, present results to decision makers and the general population.	Apply results to modify community interventions. Present results to community for policy considerations as appropriate.	Report results to supervisor and other service providers as appropriate. Apply results to personal practice and agency for policy considerations as appropriate.

groups and to a lesser extent on work with systems and communities. The orange and yellow wedges, on the other hand, are more commonly used by PHNs who focus their work on effecting systems and communities. However, a PHN may use any or all of the interventions. No single PHN is expected to perform every intervention at all three levels of practice. From a management perspective, however, it is useful to ensure that a public health workforce has the capacity to implement all 17 interventions at all three practice levels.

Assumption 9: Public Health Nursing Practice Contributes to the Achievement of the 10 Essential Services

Implementing the interventions ultimately contributes to the achievement of the 10 essential public health services (see Chapter 1). The 10 essential public health services describe *what* the public health system does to protect and promote the health of the public. Interventions are the means through which public health practitioners implement the 10 essential services. Interventions are the *how* of public health practice (Public Health Functions Steering Committee, 1995).

Assumption 10: Public Health Nursing Practice Is Grounded in a Set of Values and Beliefs

The Cornerstones of Public Health Nursing (Box 9-1) were developed as a companion document to the Intervention Wheel. The Wheel defines the “what and how” of public health nursing practice; the Cornerstones define the “why.” The Cornerstones synthesize foundational values and beliefs from both public health and nursing. They inspire, guide, direct, and challenge public health nursing practice (Keller, Strohschein, and Schaffer, 2010).

USING THE INTERVENTION WHEEL IN PUBLIC HEALTH NURSING PRACTICE

The Wheel is a conceptual model. It was conceived as a common language or catalog of general actions used by PHNs across all practice settings. When those actions are placed within the context of a set of associated assumptions or relations among

BOX 9-1 Cornerstones of Public Health Nursing

Public Health Nursing Practice

- Focuses on the health of entire populations
- Reflects community priorities and needs
- Establishes caring relationships with the communities, families, individuals, and systems that comprise the populations PHNs serve
- Is grounded in social justice, compassion, sensitivity to diversity, and respect for the worth of all people, especially the vulnerable
- Encompasses the mental, physical, emotional, social, spiritual, and environmental aspects of health
- Promotes health through strategies driven by epidemiologic evidence
- Collaborates with community resources to achieve those strategies, but can and will work alone if necessary
- Derives its authority for independent action from the Nurse Practice Act

Cornerstones from Public Health

Population-based/focused
Grounded in social justice
Focus on greater good
Focus on health promotion and disease prevention
Does what others cannot or will not
Driven by the science of epidemiology
Organizes community resources

Cornerstones from Nursing

Relationship-based
Grounded in an ethic of caring
Sensitivity to diversity
Holistic focus
Respect for the worth of all
Independent practice
Long-term commitment to the community

concepts, the Intervention Wheel serves as a conceptual model for public health nursing practice (Fawcett and DeSanto-Madeya, 2013). It creates a structure for identifying and documenting interventions performed by PHNs and captures the nature of their work. The Intervention Wheel provides a framework, a way of thinking about public health nursing practice. The *Public Health Nursing: Scope and Standards of Practice* includes the Intervention Wheel as one of several public health nursing frameworks used in practice today (ANA, 2013).

COMPONENTS OF THE MODEL

As depicted in Figure 9-1, the model has three components: a population basis, three levels of practice, and 17 interventions.

Component 1: The Model Is Population Based

The upper portion of the Intervention Wheel clearly illustrates that all levels of practice (community, systems, and individual/family) are population based. Public health nursing practice is population focused. It identifies populations of interest or populations at risk through an assessment of community health status and an assignment of priorities. Services to individuals and families are population based only if they meet the following criteria: (1) Individuals receive services because they are members of an identified population, and (2) services to individuals clearly contribute to improving the overall health status of the identified population.

The population of Sherburne County (Minnesota) increased almost 175% in 25 years (Minnesota Departments of Education, Health, Human Services, and Public Safety, 2013). The numerous new housing developments characterized urban sprawl, which has been implicated in the current obesity epidemic in both children and adults (Ferdinand et al, 2012; Renalds, Smith, and Hale, 2010). The local health department staff was concerned about the prevalence of obesity in its population. Data from the U.S. Department of Agriculture's Food Environment Atlas website showed that 25.7% of the population's adults were considered obese in 2012 (USDA, 2014).

A 2013 state student health survey documented that 16% of ninth-grade girls and 26% of ninth-grade boys in the county were overweight or obese. In this same age group, 26% of girls and 21% of boys reported they had been active less than 60 minutes daily for two days or less of the previous seven days. It was clear that Sherburne County had an obesity problem (Minnesota Departments of Education, Health, Human Services, and Public Safety, 2013).

Reversing this trend required reducing barriers to exercise. Health department staff recognized the impact of urban sprawl on their built environment (Renalds, Smith, and Hale, 2010), or the "collective availability of sidewalks, parks, trails, recreational facilities, traffic safety, and other neighborhood characteristics that promote recreational physical activity as well as active transport to work, school, or errands" (Ferdinand et al, 2012).

One of the first factors they considered was the walkability of their communities, or the extent to which planned transportation networks and public spaces accommodate walking and other forms of physical exercise. Walkability includes: (1) continuous and well-maintained sidewalks, (2) easy access, path directness, and street network connectivity, (3) crossing safety, (4) absence of heavy and high-speed traffic, (5) pedestrian buffering from traffic, (6) land-use density and diversity, (7) street trees and landscaping, (8) visual interest and sense of place, and (9) security (Lo, 2009; Walkability Checklist).

With these data, the public health staff engaged community members to determine the next steps to improve their community walkability. The department asked undergraduate nursing students who were in their public health nursing clinical program to design, implement, and evaluate a walkability project. The students walked over 100 miles and rated the walkability of three different Sherburne County communities. The students analyzed the results and presented recommendations

for improvements to the city councils of the three communities. The findings were used by two of the three communities to secure funding for improvements to their community's walkability (Zoller, 2010).

Component 2: The Model Encompasses Three Levels of Practice

Public health nursing practice intervenes with communities, the individuals and families that comprise communities, and the systems that impact the health of communities. Interventions at each level of practice contribute to the overall goal of improving population health. The work of PHNs is accomplished at all levels. No one level of practice is more important than another; in fact, many public health priorities are addressed simultaneously at all three levels.

One public health priority that almost every PHN will encounter is the potential for the occurrence of vaccine-preventable disease because of delayed or missing immunizations. A recent task analysis of 60 PHNs from 29 states revealed that 93% of all PHNs participated in immunization activities (Keller, 2008). This held true regardless of the PHN's work setting (e.g., home, clinic, school, correctional facility, childcare center) or the population focus (e.g., maternal-child health, elderly chronic disease management, refugee health, disease prevention and control).

Vaccine-preventable diseases, or diseases that may be prevented through recommended immunizations, include diphtheria, pertussis, tetanus, polio, mumps, measles, rubella, hepatitis A, hepatitis B, varicella, meningitis, *Haemophilus influenzae* type b (Hib), pneumococcal pneumonia, rotavirus, human papillomavirus (HPV), herpes zoster, and seasonal influenza (CDC, 2012).

This section illustrates strategies for reducing the occurrence of vaccine-preventable diseases at all three levels of practice. These are only selected examples of strategies to improve immunization rates; it is not an inclusive list.

Community Level of Practice

The goal of community-level practice is to increase the knowledge and attitude of the entire community about the importance of immunization and the consequences of not being immunized. These strategies will lead to an increase in the percentage of people who obtain recommended immunizations for themselves and their children.

At the community level, PHNs work with health educators on public awareness campaigns. They perform outreach at schools, senior centers, county fairs, community festivals, and neighborhood laundromats.

PHNs conduct or coordinate audits of immunization records of all children in schools and childcare centers to identify children who are under-immunized. The PHNs refer them to their medical providers or administer the immunizations through health department clinics.

When a confirmed case of a vaccine-preventable disease occurs, PHNs work with epidemiologists to identify and locate everyone exposed to the index case. PHNs assess the immunization status of people who were exposed and ensure appropriate treatment.

In the event of an outbreak in the community, all PHNs have a role and ethical responsibility to take part in mass dispensing clinics. Mass dispensing clinics disperse immunizations or medications to specific populations at risk. For example, clinics may be held in response to an epidemic of mumps, a case of hepatitis A attributable to a foodborne exposure in a restaurant, or an influenza pandemic in the general population.

Systems Level of Practice

The goal of systems-level practice is to change the laws, policies, and practices that influence immunization rates, such as promoting population-based immunization registries and improving clinic and provider practices.

PHNs work with schools, clinics, health plans, and parents to develop population-based immunization registries. Registries, known officially by the Centers for Disease Control and Prevention (CDC) as “Immunization Information Systems,” combine immunization information from different sources into a single electronic record. A registry provides official immunization records for schools, daycare centers, health departments, and clinics. Registries track immunizations and remind families when an immunization is due or has been missed.

PHNs conduct audits of records in clinics that participate in the federal vaccine program. PHNs ascertain if a clinic is following recommended immunization standards for vaccine handling and storage, documentation, and adherence to best practices. PHNs also provide feedback and guidance to clinicians and office staff for quality improvement.

PHNs also work with health care providers in the community to ensure that providers accurately report vaccine-preventable diseases as legally required by state statute.

Individual/Family Level of Practice

The goal of individual/family-level strategies is to identify individuals who are not appropriately immunized, identify the barriers to immunization, and ensure that the individual’s immunizations are brought up to date.

At the individual level of practice, PHNs conduct health department immunization clinics. Unlike mass dispensing clinics, immunization clinics are generally available to anyone who needs an immunization and do not target a specific population. These clinics often provide an important service to individuals without access to affordable health care.

PHNs use the registry to identify children with delayed or missing immunizations. They contact families by phone or through a home visit. The PHNs assess for barriers and consult with the family to develop a plan to obtain immunizations either through a medical clinic or from a health department clinic. The PHN follows up at a later date to ensure that the child was actually immunized.

PHNs routinely assess the immunization status for clients in all public health programs, such as well-child clinics, family planning clinics, maternal–child health home visits, or case management of elderly and disabled populations, and they ensure that immunizations are up to date.

BOX 9-2 Screening

A school nurse was approached by the school’s health and physical education staff who expressed interest in implementing a BMI screening program for children in 4th through 8th grades. Their plan was to do height, weight, and BMI measurements during gym class and requested that the school nurse do the follow-up with the parents of children found to be overweight or obese and encourage that these children be seen by their family health care provider. Although aware that prevalence of obesity in that age group was growing, she was also aware that most local health care providers believed that “chunkiness” in the middle years was a natural occurrence for children. She was also aware that a cardinal rule of screening is that it is unethical to screen if effective treatment and other resources for follow-up do not exist.

In 2008 the U.S. Task Force on Community Preventive Services found insufficient evidence to recommend school-based programs to prevent or reduce obesity. In addition, the American Academy of Pediatrics expressed caution to schools when considering implementing such a program (AAP, 2010). Based on this knowledge, the school nurse suggested to the health and physical education staff that together they find other means of addressing the issue.

Component 3: The Model Identifies and Defines 17 Public Health Interventions

The Intervention Wheel encompasses 17 interventions: surveillance, disease and other health investigation, outreach, screening, case finding, referral and follow-up, case management, delegated functions, health teaching, consultation, counseling, collaboration, coalition building, community organizing, advocacy, social marketing, and policy development and enforcement.

All interventions, except case finding, coalition building, and community organizing, are applicable at all three levels of practice. Community organizing and coalition building cannot occur at the individual level. Case finding is the individual level of surveillance, disease and other health event investigation, outreach, and screening. Altogether, a PHN selects from among 43 different intervention-level actions.

Table 9-2 provides examples of the intervention at the three levels of practice for each of the 17 interventions.

- **Surveillance** describes and monitors health events through ongoing and systematic collection, analysis, and interpretation of health data for the purpose of planning, implementing, and evaluating public health interventions, and disseminating this data to those who need to know to prevent and control outbreaks (adapted from *Morbidity and Mortality Weekly Review*, 2012).
- **Disease and other health event investigation** systematically gathers and analyzes data regarding threats to the health of populations, ascertains the source of the threat, identifies cases and others at risk, and determines control measures.
- **Outreach** locates populations of interest or populations at risk and provides information about the nature of the concern, what can be done about it, and how services can be obtained.
- **Screening** identifies individuals with unrecognized health risk factors or asymptomatic disease conditions in populations (Box 9-2).

Text continued on p. 206

TABLE 9-2 Examples of 17 Interventions at Three Levels of Practice

Interventions	Systems	Community	Individual
Surveillance	PHNs participated in dead bird reporting (i.e., making “dead bird calls”). People were asked to report the sighting of dead birds to a health department as part of surveillance activities for the West Nile virus. PHNs collected dead birds found in atypical places, such as the middle of a backyard or on a hiking trail. Birds were tested until a positive was found in the county.	PHNs implemented a program that tracked the growth and development of all newborns in the county. Parents were mailed questionnaires at regular intervals that they completed and returned to the public health office. PHNs screened the questionnaires for potential problems or delays and contacted the families by phone or home visits to determine if further action was indicated.	Surveillance at the Individual Level is CASE FINDING (see Case Finding Intervention).
Disease and other health event investigation	During a flood, the PHNs spent part of the day doing “rounds” among the rows of people living in a large emergency shelter set up in a gymnasium. The PHNs were concerned about the stresses that this population experienced, so they assessed for withdrawal, depression, and inability to cope. The PHNs observed that the children were not coping well. They questioned parents and heard stories about night terrors and atypical behavior. In response, the PHNs requested child mental health counselors from the Emergency Response Team. They also worked with parents in the shelter to set up a “toddler corner” where children could play and act like children. Parents took turns staffing the corner.	A PHN worked with a Catholic church that served a parish with a rapidly growing Hispanic population to connect mothers and children with community resources. The priest mentioned that he was seeing an unusual number of stillbirths among his parishioners. His comment led the PHN into a series of questions and investigation. The PHN discovered that the church allowed its kitchen facilities to store foods brought from Mexico. Suspecting a possible foodborne contaminant, the PHN took samples to the health department lab for testing. A supply of queso blanco fresco obtained from the church’s refrigerator was found to be contaminated with <i>Listeria</i> . After an outreach and education campaign within the parish and the community, the rate of stillbirths decreased.	Disease and other health event investigation at the Individual Level is CASE FINDING (see Case Finding Intervention).
Outreach	Prior to launching a universally offered home visiting program for newborns, focus group interviews revealed the best strategies to encourage participation were as follows: <ul style="list-style-type: none"> • Send letters or postcards announcing the program to pregnant women • Make hospital visits to moms after delivery • Include photos of visitors on business cards and brochures • Be recommended by trusted individuals, such as physicians, nurses, and other new mothers • Have program staff visit Lamaze and other childbirth education programs, and early childhood development classes 	PHNs were part of a coalition that received a grant to do community education on depression to an elderly Hmong population. Many Hmong elders were isolated but did not view depression as a disease. The PHNs tailored an outreach event to the Hmong population during a community market. Even though the program targeted persons over 50, people were allowed to determine their own eligibility. That is, if they “felt old,” they qualified. Second, since it was considered unlikely that the elders would come to the booth, the coalition members talked with elders in more casual settings, approaching elders sitting under shade trees or at their market booth. All the interviews were conducted in the Hmong language.	Outreach at the Individual Level is CASE FINDING (see Case Finding Intervention).

Continued

TABLE 9-2 Examples of 17 Interventions at Three Levels of Practice—cont'd

Interventions	Systems	Community	Individual
Screening	Vision screening is a core PHN activity with the school-aged population. PHNs worked with a community group to determine why school children who failed vision screening and were referred did not receive the recommended follow-up. Issues included the expense of eye-care services and glasses, lack of convenient appointment times with eye-care specialists, and whether parents valued eye care. The PHNs participated in a task force that facilitated an agreement among eye-care providers to schedule evening and weekend appointments, arranged support from the Lions International Service Club toward the purchase of eyewear, and communicated the need for follow-up to parents at parent-teacher conferences.	PHNs collaborated with a high school on a prevention program to address physical inactivity and unhealthy dietary behaviors. The PHNs conducted health screenings that gave each student a “snapshot” of his or her health (height, weight, BMI, blood pressure, total cholesterol, HDL). Students received a report of their nutritional and physical activity levels with information about how to begin building lifestyle changes. One hundred ninety-two students from five schools were screened and 71 were referred (37% referral rate). Upon completion of the educational components, students who were rescreened had a total cholesterol decrease of 219 points.	Screening at the Individual Level is CASE FINDING (see Case Finding Intervention).
Case finding	Does not apply at this practice level	Does not apply at this practice level	A state’s newborn blood screening program detected an infant with a possible case of congenital hypothyroidism. The information was sent to the infant’s medical provider, who was expected to contact the family. The mother of the infant was a single Hispanic woman who did not speak English and did not respond to the clinic’s numerous calls. The provider referred the situation to a PHN for assistance in locating the mother. After talking with contacts in the Hispanic community, the PHN located friends of the young mother who confirmed she had returned to Mexico with the infant. They did not know how to contact her but agreed to alert those within the Hispanic community of the seriousness of the baby’s problem. About 2 months later the mother did return, sought the PHN’s assistance, and received care for the baby.
Referral and follow-up	PHNs providing health services to inmates in a county jail noticed that individuals with mental health issues, chronic health concerns, chemical dependency issues, or homelessness frequently returned to jail. Few of these issues were typically addressed prior the inmates’ release. The PHNs initiated RAPP (Release Advance Planning Program), a voluntary “discharge planning” process through which referrals and other arrangements with community resources could be made prior to the inmates returning to the community. Recidivism rates decreased by 57% by the third year of the program’s operation.	PHNs often serve as community resource directories. PHNs are known by community members for their extensive knowledge of whom or where to call for a variety of problems or issues. For example, PHNs in a rural health department responded to calls ranging from rats to cockroaches to bedbugs, from septic tank failures to peeling paint, and from air quality to blue-green algae. The PHNs often followed up with community members to ensure that their issues were resolved.	A PHN received a referral on a mentally ill young man from a small town. He needed regular injections to prevent rehospitalization. When the PHN was unable to locate this client at home, she found him at his regular “hangout”—the local bar—where he drank only soda pop. While creatively maintaining confidentiality, the PHN worked with the bartender in this establishment to set up regular appointment times for the client.

Case management	Public health nurses representing 10 county health departments, medical clinics, a large health plan company, and the state health department worked together to provide coordinated prenatal care to improve birth outcomes. The group created an integrated prenatal care system that promoted early prenatal care, improved nutrition, and linked women to services in the communities.	PHNs provided case management for all frail elderly and disabled persons at risk for institutionalization but deemed eligible for community placement. Case management maintained this vulnerable population in their homes or community and ensured that their needs were met within the allotted amount of money that would otherwise be spent on hospitalization or nursing home care.	A local physician reported a highly contagious active infectious tuberculosis (TB) case that was determined to be multidrug resistant. The client did not speak English. The PHN coordinated his care with the physician, the state health department's TB unit, the CDC, and a home health agency. Neither the hospital outpatient department nor any home health agency would agree to treat this client in their facility or make home visits. <i>(Continued under delegated functions below.)</i>
Delegated functions	In a county of 120,000 residents, PHNs from the local health department led a coalition of hospitals, clinics, schools, and emergency managers in designing and implementing a community-wide mass immunization plan to administer influenza vaccine. The design included the establishment of administration protocols approved by the health department's medical advisor. The health department also served as the central distribution point for all vaccines available within the county.	PHNs administered immunizations at "drive-thru" flu clinics held in a county highway garage. Residents received their assessment and flu shots in their vehicles. This unique access increased the numbers of immunizations received by elderly and disabled residents, particularly those with limited mobility. The drive-thru clinic also reduced the exposure potential to infectious diseases that was inherent in regular clinic waiting rooms.	<i>(See above case management.)</i> In addition to doing daily direct observed therapy (DOT), the PHN was the only health care provider who would do weekly lab draws, daily IV therapy, and biweekly dressing changes for the first 7 months of treatment. Without PHN involvement, this client would have likely succumbed to TB. The client completed a full 18 months of therapy and recovered.
Health teaching	PHNs worked with the epidemiologist in their health department to develop "best practice" guidelines for pediculosis (lice) treatment from the perspectives of the scientific literature and the practice community. Recommendations included both suffocating and chemical agents. Clinics, schools, and pharmacists used the new guidelines. The public health department created an internal standardized pediculosis response procedure, and the county's social services department developed a new policy for school truancy issues related to pediculosis.	Several rural counties launched a program to help youth incorporate a healthy diet and exercise into their lives. A health fair was held in conjunction with parent-teacher conferences. Committees composed of youth and adults planned activities such as "Dance 'n' Dips," a dance followed by a dip at the city pool. Members of a church began offering evening exercise classes. A small town sponsored the "Run, Walk 'n' Roll" that was open to runners, walkers, strollers, and wheelchairs. The "Toilet Paper" document, a monthly nutrition and health tip sheet designed to resemble toilet paper, was displayed in 152 bathrooms, next to the toilet paper dispensers. The tips were popular; PHNs reported that people came up to them on the street to discuss the tips. PHNs reported seeing changes in community attitudes.	A PHN works with pregnant and parenting teens at an alternative high school program that provides educational options for teens whose lives did not fit the traditional school day. The program included teens from a variety of cultures and backgrounds. The program had an onsite childcare center; students were able to visit their child during the school day. The PHNs taught weekly prenatal classes in conjunction with life skills and child development classes. PHNs also worked with each student to look at family planning options. Their "Pregnancy Free Club" provided each student private time with a PHN to look at barriers that prevented the student from effectively using birth control. The program had a repeat adolescent pregnancy rate significantly lower than the national average, declining from a baseline of 25% to a mean of 4.7% over 9 years of the program.
Counseling	PHNs partnered with a community family center to promote prenatal attachment for families who were isolated, who had experienced previous pregnancy loss, or who had other attachment issues. The project promoted attachment to the baby through the use of doulas, guided videotaping, nutrition counseling, and relaxation through music and imagery.	In response to multiple deaths within an American Indian community, PHNs in a tribal health department worked with the community to design and implement a culturally appropriate grief and loss program. Interventions included drumming activities for youth, traditional healers, and peer counselors.	A PHN led monthly support groups for family members and volunteers providing in-home care to individuals with Alzheimer's disease. The PHN provided one-to-one caregiver coaching to those needing additional support.

Continued

TABLE 9-2 Examples of 17 Interventions at Three Levels of Practice—cont'd

Interventions	Systems	Community	Individual
Consultation	After hearing about the risk for serious infectious disease for children in daycare, PHN daycare consultants from eight local health departments developed a curriculum on handwashing for children. They obtained a grant to develop a video in several languages and widely distributed the handwashing materials.	PHNs providing postpartum home visits to new mothers noted that women employed by a certain large company often gave up breastfeeding upon returning to work. Reasons included lack of private space to express milk and nonresponsive supervisors. The PHNs approached the company's human resources director and presented a business case for breastfeeding. After several meetings the company agreed to revamp its policies on breastfeeding in the workplace and requested PHNs' assistance in providing training.	The older sister of an elderly bachelor farmer died. The sister had kept house and cooked for her brother for their entire adult lives. Upon her death, he was unable to live independently. Neighbors concerned for his well-being convinced him to talk with a PHN/social worker team to explore his preferences and determine the best options for a living situation that respected his need for self-determination. He eventually moved into an assisted living facility that met his needs.
Collaboration	PHNs changed the way they had traditionally related to the 26 medical clinics in their community. They visited each clinic quarterly to provide information about change in vaccine policy and improving the reporting of notifiable diseases as required by law. They also answered questions, promoted disease prevention programs, and resolved problems together, such as vaccine shortages. This relationship benefited the public health department and the medical clinics.	Everyone is a bully, is being bullied, or is a bystander. School nurses worked with a community action team to develop community assets—caring, encouraging environment for youth and valuing of youth by adults. Through strategies such as a mentoring program for at-risk elementary school students and a revitalized orientation program for ninth graders entering high school, the incidence of bullying behavior was reduced.	Over a period of years, a PHN was able to establish a trusting relationship with a Haitian client with HIV. Through her transactions with this client, the PHN came to understand her own values differently and honored the client's spiritual values and practices.
Coalition building	PHNs were part of a coalition that formed to address the exploding bedbug issue in the community. The coalition was a response to requests from local housing providers for assistance. Coalition members included PHNs along with property owners and managers, commercial pest management operators, university entomologists, and the local housing authority. They provided education about the eradication and prevention of bedbug infestations, cost implications, and potential litigation issues to local apartment managers, fraternity house operators, and housing officials.	A student health survey revealed a greater than expected number of overweight or obese children in a school district. A coalition of school nurses, educators, and health care providers concerned about childhood obesity developed a school-based program for elementary students. As a result of the work of this coalition, parents received a report card about their child's BMI. Parents also received educational materials that offered tips for healthy living and a directory of physical activity options. A follow-up evaluation revealed that parents who received a report card were more likely to have initiated dietary changes or a physical activity plan than parents who had not.	Coalition building is not implemented at the individual level of practice.
Community organizing	A local newspaper reported that a statewide student health survey revealed their school district had one of the highest teen alcohol-use rates in the state. Numerous letters to the editors questioned why the community was not doing anything about the problem and demanded community action. In response, a PHN from the public health department partnered with other community groups and organizations to develop a plan to address alcohol use in the community. The plan included enforcing existing laws, such as enforcing "not a drop" laws with minors and developing social media messages for adolescents that emphasized "Not everyone drinks..."	In response to a public safety meeting where 750 angry residents showed up to complain about what they saw as the deterioration of their community, a city health department dispersed a team of PHNs to develop "social capital." The PHNs facilitated the development of social connections, relationships, and trust in a community that had experienced an influx of mainly poor, minority renters. Their goal was to ensure that neighbors know and care about each other enough to run next door to borrow a cup of sugar or offer to help the elderly woman down the block. PHNs helped organize exercise classes, a farmer's market, community gardens, and neighborhood dinners, which were free with the only requirement that diners eat next to somebody they did not know.	Community organizing is not implemented at the individual level of practice.

Advocacy	<p>A worker at a large meat packing plant that employed over 1000 people speaking 12 languages was diagnosed with active infectious tuberculosis (TB). Initially the plant managers were more concerned about losing production than being exposed. The PHNs worked with the managers to convince them that exposure to TB was a serious problem and that they could cooperate with public health without decreasing production. Although the managers would not mandate testing, they did allow PHNs to offer free Mantoux tests during work time on all three shifts to any employee who wanted to be tested. Over 700 employees were tested, with over 70 positives. Many of the employees with positive Mantoux tests lacked access to health care. The PHNs negotiated reduced clinic fees and secured community grant funds to pay for x-rays and prescribed treatment for infected persons who were uninsured and without resources. (See <i>individual advocacy example</i>.)</p>	<p>A visiting nurse agency (VNA) served many families with small children living at or below poverty level. Many were homeless, experiencing mental health issues, alcohol or drug abuse, or domestic violence. Club 100 was a voluntary organization of community women and men associated with the VNA. It is a program that reaches out into the community to ask people of means to help care for people who have very little. It paired men and women with VNA nurses and their at-risk family clientele. The volunteers of Club 100 were divided into teams that worked with a PHN. The PHN selected clients who would benefit from the program and presented the client's case to the team on a quarterly basis. The club provided "gifts" such as high chairs, strollers, diapers, books, toys, and tools to support family self-sufficiency and improved the lives of these men, women and children.</p>	<p>A PHN received a referral on a 9-month-old boy with a recent diagnosis of meningitis resulting from active TB. The child's parents were a young Hispanic couple who did not speak English. The child's mother was pregnant and stayed at home with her two small children. The family had no telephone and neither parent had a driver's license. The entire family reacted positively to the Mantoux tests that the PHN administered. At this point, the PHN arranged an appointment at the local clinic for the entire family, complete with transportation and interpreters. The father was found to have active infectious TB. He was ordered not to return to his job at the meat packing plant and consequently lost his health insurance. The PHN assisted the family in applying for medical assistance and other services for which they were eligible. (<i>The fact that a meat packing plant employee had infectious TB required this PHN to intervene at the systems level—see systems advocacy example.</i>)</p>
Social marketing	<p>A partnership of health departments, managed care organizations, pharmaceutical companies, health care insurers, and others sought to decrease unnecessary antimicrobial use and reduce the spread of antimicrobial resistance. "Moxie Cillin" and "Annie Biotic" were mascots that appeared on pamphlets, posters, stickers, and in person. They urged discontinuation of inappropriate requesting of antibiotics by parents and unnecessary prescribing of antibiotics by health care providers.</p>	<p>A PHN working in a small rural county was assigned to work on a Fetal Alcohol Syndrome prevention grant in partnership with the local hospital. The PHN coordinated the grant activities, which included mass media efforts such as billboards, radio spots read by local celebrities, and newspaper articles. Multiple posters were placed in every bar in the community, and local bartenders were engaged as partners in the effort to reduce alcohol use among pregnant women. After 2 years, the project documented an increase in community awareness, which is the first step in changing the community norm regarding alcohol use among pregnant women.</p>	<p>PHNs routinely conducted home safety checks with pregnant and parenting families to prevent childhood injuries. As incentives, they distributed safety kits that included items to child-proof a home, such as cupboard safety locks, outlet covers, door knob safety covers, and drawer latches. While having a PHN checking contents in cupboards and water temperatures may have felt intrusive to some families, the kits increased the number of families who were receptive to home safety checks.</p>
Policy development and enforcement	<p>Local health department PHNs and health educators partnered with law enforcement to establish ordinances prohibiting the sale of tobacco to under-age youth. Part of the initiative included recruiting and training youth to conduct compliance checks, in which under-age youth attempted to purchase cigarettes in retail stores. PHNs also created an electronic compliance tracking system that was eventually used by the entire state.</p>	<p>A PHN investigated a public health complaint about a fly problem originating from the manure pit of a farm that housed millions of chickens. Garbed in protective equipment, the intrepid PHN crawled under the chicken cages that dumped into the manure pits and found masses of maggots. After determining that the situation constituted a public health nuisance, the PHN successfully worked with the business owners to find a solution that involved the drying of manure to prevent the maggots from surviving.</p>	<p>A PHN received a referral regarding the safety of an 80-year-old woman living alone on a littered farm site. The woman lived with 18 cats in a house without heat that was ankle-deep with cans, clothes, and cat feces. The PHN initiated a vulnerable adult evaluation that resulted in a "not sufficiently vulnerable" finding under state statute. Through repeated contacts, the PHN was able to establish a trusting relationship; the woman accepted a referral for care to a physician. However, she was not successful in changing the woman's living situation.</p>

BOX 9-3 Health Teaching

- Health teaching communicates facts, ideas, and skills that change knowledge, attitudes, values, beliefs, behaviors, practices, and skills of individuals, families, systems, and/or communities.
- Knowledge is familiarity, awareness, or understanding gained through experience or study.
- Attitude is a relatively constant feeling, predisposition, or set of beliefs directed toward an object, person, or situation, usually in judgment of something as good or bad, positive or negative.
- Value is a core guide to action.
- Belief is a statement or sense, declared or implied, intellectually and/or emotionally accepted as true by a person or group.
- Behavior is an action that has a specific frequency, duration, and purpose, whether conscious or unconscious.
- Practice is the act or process of doing something or the habitual or customary performance of an action.
- Skill is proficiency, facility, or dexterity that is acquired or developed through training or experience.

- **Case finding** locates individuals and families with identified risk factors and connects them with resources.
- **Referral and follow-up** assists individuals, families, groups, organizations, and/or communities to identify and access necessary resources in order to prevent or resolve problems or concerns.
- **Case management** optimizes self-care capabilities of individuals and families and the capacity of systems and communities to coordinate and provide services.
- **Delegated functions** are direct care tasks a registered professional nurse carries out under the authority of a health care practitioner as allowed by law. Delegated functions also include any direct care tasks a registered professional nurse entrusts to other appropriate personnel to perform.
- **Health teaching** communicates facts, ideas, and skills that change knowledge, attitudes, values, beliefs, behaviors, and practices of individuals, families, systems, and/or communities (Box 9-3).
- **Counseling** establishes an interpersonal relationship with a community, system, family, or individual intended to increase or enhance their capacity for self-care and coping. Counseling engages the community, system, family, or individual at an emotional level.
- **Consultation** seeks information and generates optional solutions to perceived problems or issues through interactive problem solving with a community, system, family, or individual. The community, system, family, or individual selects and acts on the option best meeting the circumstances.
- **Collaboration** commits two or more persons or organizations to achieve a common goal through enhancing the capacity of one or more of the members to promote and protect health (Freshman et al, 2010; Henneman et al, 1995).
- **Coalition building** promotes and develops alliances among organizations or constituencies for a common purpose. It builds linkages, solves problems, and/or enhances local leadership to address health concerns.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted competency: Client-centered care

Knowledge: Integrate understanding of multiple dimensions of client-centered care including communication, information, and education.

Skills: Communicate values, preferences, and expressed needs to all members of the team

Attitudes: Values seeing health care situation through the client's health

Question: The Quad Council competency, community dimensions of practice, supports the application of the Intervention Wheel's PHN intervention of community organizing. The Quad Council suggests beginning PHN's participate effectively in activities that facilitate community involvement.

A statewide behavioral risk survey was conducted by the state health department. The survey shows that in your community there is still a high rate of smoking among the population. What types of activities could be planned to identify common goals among the population and the health care system? How could you participate? What might your role be in resource mobilization and development of strategies to be implemented for reaching goals?

- **Community organizing** helps community groups to identify common problems or goals, mobilize resources, and develop and implement strategies for reaching the goals they collectively have set (Bezboruah, 2013; Minkler, 2012).
- **Advocacy** pleads someone's cause or acts on someone's behalf, with a focus on developing the capacity of the community, system, individual, or family to plead their own cause or act on their own behalf.
- **Social marketing** uses commercial marketing principles and technologies for programs designed to influence the knowledge, attitudes, values, beliefs, behaviors, and practices of the population of interest.
- **Policy development** places health issues on decision makers' agendas, acquires a plan of resolution, and determines needed resources. Policy development results in laws, rules, regulations, ordinances, and policies.
- **Policy enforcement** compels others to comply with the laws, rules, regulations, ordinances, and policies created in conjunction with policy development.

In addition to the definition and examples, each intervention has basic steps for implementation at each of the three levels (i.e., community, systems, and individual/family) as well as a listing of best practices for each intervention. The basic steps are intended as a guide for the novice public health nurse or the experienced public health nurse wishing to review his/her effectiveness. Box 9-4 describes the basic steps of the counseling intervention.

The best practices are provided as a resource for PHNs seeking excellence in implementing the interventions. They were constructed by a panel of expert public health nursing educators and practitioners after a thorough analysis of the literature. Many practices of public health nursing are either not researched or, if they are researched, not published. The process used to develop this model considered this limitation and met the challenge with the use of expert practitioners

BOX 9-4 Basic Steps for the Intervention of Counseling*

Working alone or with others, PHNs:

1. Meet the “client”—the individual, family, system, or community.
2. Establish rapport by listening and attending to what the client is saying and how it is said.[†]
3. Explore the issues.
4. Gain the client’s perception of the nature and cause of the identified problem or issue and what needs to change.[‡]
5. Identify priorities.
6. Gain the client’s perspective on the urgency or importance of the issues; negotiate the order in which they will be addressed.
7. Establish the emotional context.
8. Explore, with the client, emotional responses to the problem or issue.
9. Identify alternative solutions.
10. Establish, with the client, different ways to achieve the desired outcomes and anticipate what would have to change in order for this to happen.
11. Agree on a contract.
12. Negotiate, with the client, a plan for the nature, frequency, timing, and end point of the interactions.
13. Support the individual, family, system, or community through the change.
14. Provide reinforcement and continuing motivation to complete the change process.
15. Bring closure when the PHN and client mutually agree that the desired outcomes are achieved.

*Complete version available at <http://www.health.state.mn.us/divs/cfh/ophp/resources/docs/phinterventionsmanual2001.pdf>.

[†]Modified from Burnard P: Counseling: a guide to practice in nursing, Oxford, England, 1992, Butterworth-Heinemann.

[‡]Understanding the client’s cultural or ethnic context is important to perception. For further information, please see Sue DW: Counseling the Culturally Diverse: Theory and Practice, ed. 6, New Jersey, 2013, Wiley.

and educators. The best practices are a combination of research and other evidence from the literature and/or the collective wisdom of experts. Box 9-5 outlines an example of a set of best practices for the intervention of referral and follow-up, some supported by evidence and others supported by practice expertise.

ADOPTION OF THE INTERVENTION WHEEL IN PRACTICE, EDUCATION, AND MANAGEMENT

The speed at which the Intervention Wheel was adopted may be attributed to the balance between its practice base and its evidence-based support. The Intervention Wheel has led to numerous innovations in practice and education since it was first published in 1998 (Keller et al, 2004a). Further dissemination of the model has occurred through the hundreds of graduate and undergraduate schools of nursing that use the Intervention Wheel as a framework for teaching public health nursing.

The Intervention Wheel has been widely adopted as a framework for public health nursing practice:

- In 2007, the American Nurses Association officially recognized the Intervention Wheel as a framework in the Public

BOX 9-5 Best Practices for the Intervention of Referral and Follow-up**Best Practice**

Successful implementation is increased when the:

- PHN respects the client’s right to refuse a referral.
- PHN develops referrals that are timely, merited, practical, tailored to the client, client controlled, and coordinated.
- Client is an active participant in the process and the PHN involves family members as appropriate.
- PHN establishes a relationship based on trust, respect, caring, and listening.
- PHN allows for client dependency in the client–PHN relationship until the client’s self-care capacity sufficiently develops.
- PHN develops comprehensive, seamless, client-sensitive resources that routinely monitor their own systems for barriers.

Health Nursing Scope and Standards of Practice (ANA, 2007, 2012).

- The Los Angeles County Department of Health Services used the Intervention Wheel in their initiative to reinvigorate public health nursing practice—orientation, practice standards, documentation, recruitment, and retention—for their 500 public health nurse generalists and specialists (LACDHS, 2002; Avilla and Smith, 2003; Smith and Bazini-Barakat, 2003).
- The Massachusetts Association of Public Health Nurses used the Intervention Wheel as the framework for their state “Leadership Guide and Resource Manual” (Massachusetts Association of Public Health Nurses, 2009).
- PHNs in the Shiprock Service Unit of the Indian Health Service use the Wheel in their practice and adapted it to reflect the Navajo culture. The Navajo Intervention Wheel (Figure 9-4) is presented as a Navajo basket and uses the traditional colors of the Navajo nation.
- From 2001 to 2005, the Intervention Wheel served as the framework for a Division of Nursing grant that successfully brought together education and practice communities to collaboratively redesign the public health nursing student’s clinical experience. Several of these collaboratives remain viable and active.

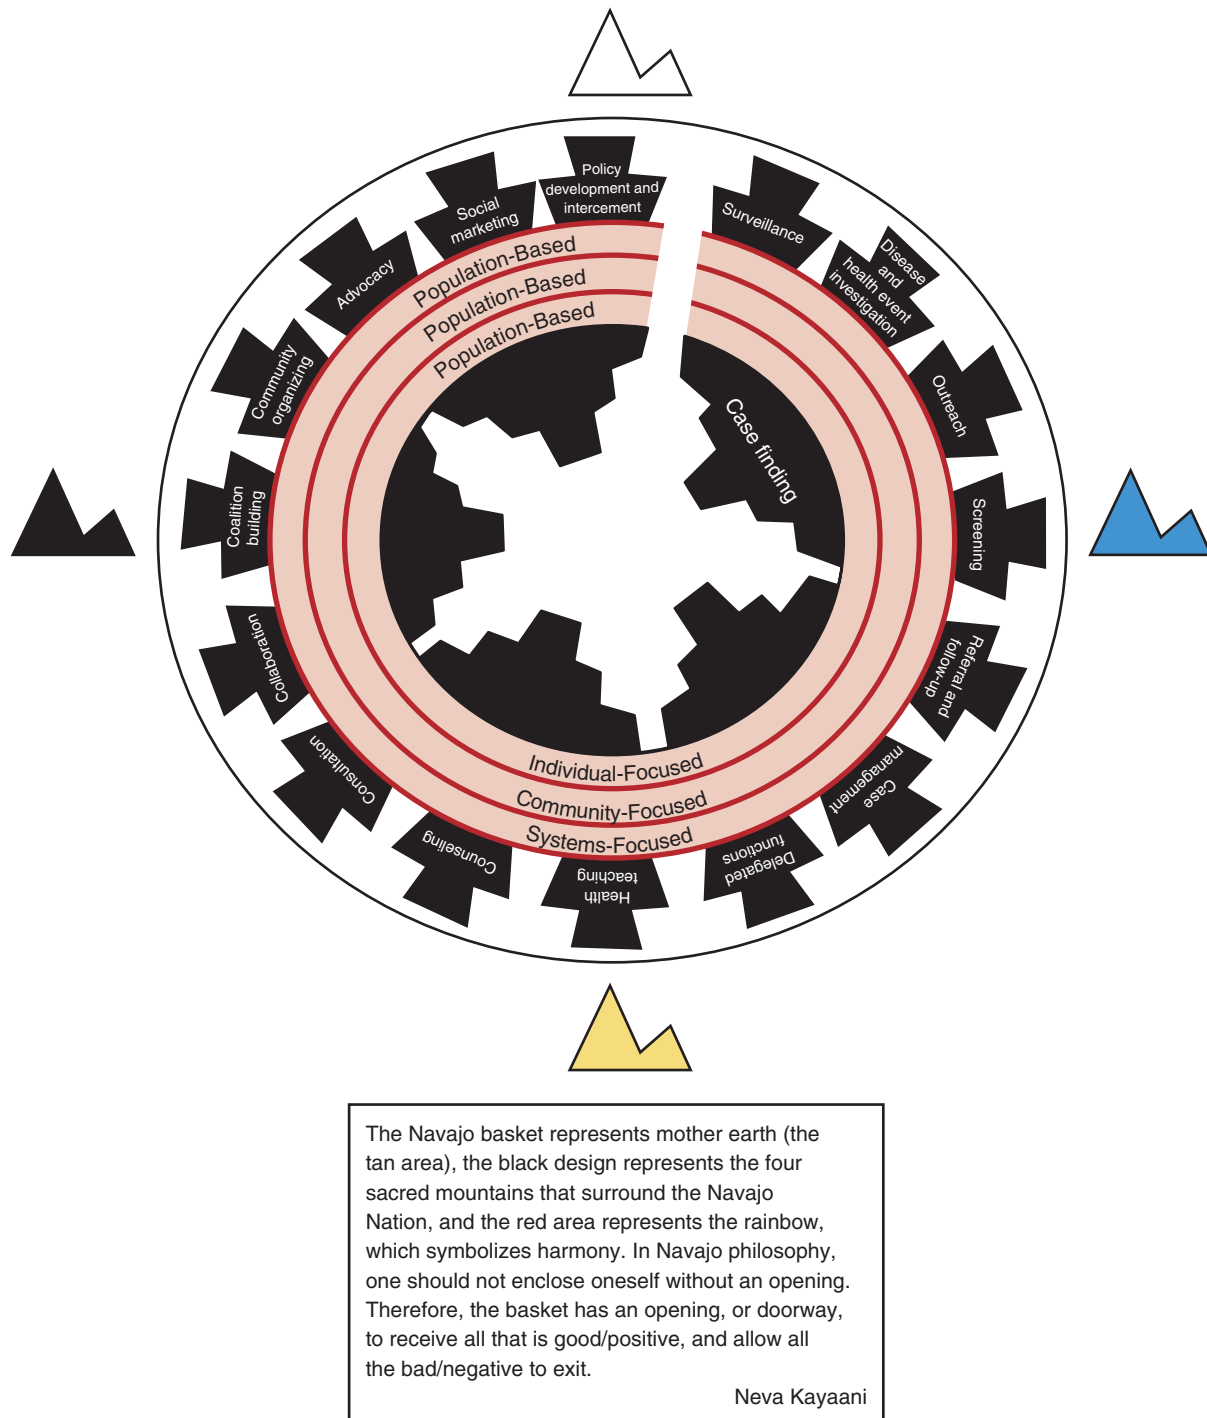

FIG 9-4 Navajo Wheel. (Courtesy Shiprock Service Unit, Shiprock, NM, Indian Health Service.)

- PHN consultants at the Wisconsin Department of Health used the Intervention Wheel to differentiate levels of nursing practice in local health departments related to educational preparation and to outline the role of the associate degree and diploma nurse in public health. (Although the baccalaureate degree is the accepted standard for entry to public health nursing practice, shortages of baccalaureate prepared nurses sometimes result in health departments employing associate degree and diploma nurses.)
- PHNs at the St. Paul-Ramsey County (MN) Department of Health used the Intervention Wheel to illustrate the activities of their refugee health program. Their display ([Figure 9-5](#)) identified the most common interventions implemented with the refugee population and illustrated each intervention with a photograph.

EVIDENCE-BASED PRACTICE BOX

Nursing informatics is relatively new for many public health departments in the United States. Community health nurses typically use the Omaha System to document their practice; however, this system is used by various disciplines working in public health. The Omaha System taxonomy is the conceptual framework for the Automated Community Health Information System (ACHIS), which is the longstanding electronic data system used to document nursing practice in community nursing centers. However, researchers identified a gap in the Omaha System and ACHIS in that both were better at capturing individual-level interventions than community- and system-level interventions. Therefore, researchers in this study incorporated interventions from the Intervention Wheel into the existing electronic record system in hopes that community- and system-level activities could be documented better. Nine Wheel interventions were added to the ACHIS: "Policy Development," "Social Marketing," "Advocacy," "Community Organizing," "Coalition Building," "Collaboration," "Consultation," "Screening," and "Outreach." The newly expanded system was piloted by two community/public health nurses and the data indicated the system was successful in capturing a broad scope of the nurses' practice. The researchers documented their methodology so that other administrators in public health may replicate the adaptation of the electronic health record for community nursing practice.

Nurse Use

By having a systematic data collection method, better evaluation of processes and outcomes of public health nursing and other public health professionals would be possible. Such data would also aid in providing evidence-based decision support for public health practice that could be used for quality improvement, funding proposals, and policy decisions.

Baisch MJ: A systematic method to document population-level nursing interventions in an electronic health system. *Public Health Nursing* 29(4):352–360, 2012.

The Wheel provides a meaningful frame of reference and common language for staff to communicate about the nature of their work and is used in orientation programs in several states.

- The Alaskan Public Health Nurse Leadership Academy uses the Intervention Wheel to familiarize new staff with population-based practice (<http://www.hss.state.ak.us/dph/nursing/PFDs/Troshynski-Academy.pdf>).
- Several universities have developed online applications of the Intervention Wheel, including the Virginia Commonwealth University (<http://www.people.vcu.edu/~elmiles/interventions/>) and the University of Minnesota School of Public Health (<http://www.sph.umn.edu/ce/tools/wheel.asp>). The concepts of the model have also been used internationally. The Intervention Wheel was used in public health nursing projects in New Zealand and Ireland. The Institute of Primary Health & Ambulatory Care in the Townsville Health Service District, Queensland Health in Australia used the Intervention Wheel to develop a set of competencies (<http://www.health.qld.gov.au/townsville/Clinicians/default.asp>).

The significance of the contributions of the Intervention Wheel has been recognized by the nursing community. The authors of the Intervention Wheel received Sigma Theta Tau International and National Pinnacle Awards for Research Dissemination and a Creative Achievement Award from the American Public Health Association, Section of Public Health Nursing.

HEALTHY PEOPLE 2020

The objectives chosen to be highlighted in this chapter show how many of the interventions from the Wheel are applied in the *Healthy People 2020* document. It further indicates how appropriate these interventions are to improving the health of individuals, populations, and communities, thus improving the health of the nation.

APPLYING THE NURSING PROCESS IN PUBLIC HEALTH NURSING PRACTICE

PHNs use the nursing process at all levels of practice. PHNs must customize the components of the nursing process (assessment, diagnosis, planning, implementation, evaluation) to the three levels of practice. See [Table 9-2](#) for an outline of the nursing process at the community, systems, and individual/family levels of practice.

APPLYING THE PROCESS AT THE INDIVIDUAL/FAMILY LEVEL

Community Assessment

During a health department's community assessment process, information on the health status of children was obtained from the following:

- Staff public health nurses who worked with families in clinics, schools, and homes
- Community partners who worked with families, including health care providers, mental health workers, social workers, and school personnel

HEALTHY PEOPLE 2020

Healthy People 2020 identifies action steps for 38 health priorities that the United States must take to achieve better population health by the year 2020. The 500 recommended objectives offer numerous opportunities for public health nurses to contribute through implementing interventions at any or all of the levels. Here are a few examples:

- AH-8: Adolescent Health Objective: *Increase the proportion of adolescents who have had a wellness check-up in the past 12 months.* PHNs who provide well-child screening services in school settings or local health departments will need well-designed outreach interventions to convince teens that even healthy kids can benefit from check-ups. This will require consulting with parents and groups of teens themselves to identify what “benefits” would attract them and incorporating them into the outreach design. PHNs will also need to collaborate with other health care providers in the community to ensure that diagnostic and treatment services are available for teens who require additional services.
- DH-7: Disability and Secondary Conditions Objective: *Reduce the proportion of older adults with disabilities who use inappropriate medications.* The case management that PHNs provide to elderly or disabled populations in their communities includes an assessment of clients’ medications to ensure compliance with the regimen prescribed by health care providers under delegated functions.
- ECBP-10: Education and Community-Based Programs Objective: *Increase the number of community-based organizations providing population-based primary prevention services in the following areas: injury, violence, mental illness, tobacco use, substance abuse, unintended pregnancy, chronic disease programs, nutrition, and physical activity.* PHNs may convene coalitions to

address an issue or serve as facilitators or participants of coalitions already organized. For instance, PHNs with expertise in substance use prevention might offer health teaching and consultation to a coalition organized to find ways to reduce substance use during pregnancy. It could also mean the establishment of a new screening and referral system among providers to identify early pregnant women and their partners struggling with drug or alcohol use and link with resources for treatment.

- EH-8.1: Environmental Health Objective: *Eliminate elevated blood lead levels in children.* PHNs providing services to families with young children assess (surveillance) the living conditions for lead. Housing constructed prior to 1978, the year lead-based paint for residential use was banned, is particularly suspect. Depending on the community’s housing and lead-abatement codes, PHNs may provide health teaching and counseling to the families regarding the dangers of lead exposure to small children or provide advocacy on their behalf with housing authorities.
- MICH-18: Maternal Infant and Child Health Objective: *Decrease postpartum relapse of smoking among women who quit smoking during pregnancy.* A recent systematic review of the literature on effective strategies to prevent postpartum smoking relapse concluded that PHNs would more likely be effective in assisting new mothers to resist returning to smoking and exposing their child to second-hand smoke if they: (1) consistently used the U.S. Preventive Services Task Forces “5 A’s” when counseling with smokers, (2) tailored health teaching regarding the dangers of second-hand smoke to the client’s specific situation, (3) empowered the mother and family members to adopt a smoke-free home smoking policy, and (4) advocated for the importance of partners also quitting (Ashford et al, 2009).

From Ashford K, Hahn E, Hall L, et al: Postpartum smoking relapse and secondhand smoke, *Public Health Rep* 124:515-526, 2009.

- Preschool screening program data on the number of young children with developmental delays and problems for the past 5 years
- Data from the county social services department on the number of substantiated child maltreatment and neglect cases for the past 5 years

PHNs participated in the community meeting that prioritized the long list of issues identified in the community assessment. One of the top community priorities that emerged was the following: *Decreasing numbers of children at risk for delayed development, injury, and disease because of inadequate parenting by parents experiencing mental health problems.*

The community health plan developed a goal to decrease the number of children with delayed development, injury, and disease attributable to inadequate parenting. The local health department, with the support of community partners, decided they would address this priority through a home visiting strategy. Home visiting enhances a child’s environment and increases the capacity of parents to behave appropriately. Although parental mental health problems are a major source of stress for children, this vulnerability can be tempered through support from others and a caring environment.

Home visiting to families is an example of practice at the individual level because the interventions are delivered to families with the goal of changing parental knowledge, attitudes, practices, and behaviors.

Public Health Nursing Process: Assessment of a Family

A PHN received a referral on Tyler, age 3. He was the only child of Ashley, a 19-year-old single mother with severe depression. Ashley lived in an old rented house in the small town where she grew up. She had a boyfriend who was not Tyler’s biological father. Ashley survived on limited public assistance and occasional help from her mom.

The PHN assessed the resilience, assets, and protective factors as well as the problems, deficits, and health risks of this family. The PHN also tried to elicit Ashley’s perception of her situation, which was difficult because of her depressed state. This step is important because often a client’s perception of their problems or strengths may not align with the PHN’s professional assessment.

All public health nursing practice is relationship based, regardless of level of practice. An established trust relationship increases the likelihood of a successful outcome. One of the PHN’s main priorities was to establish a trusting relationship with Ashley. This was difficult because Ashley was seldom out of bed when the PHN arrived, but the PHN persisted and eventually developed the relationship.

Public Health Nursing Process: Diagnosis

- *Diagnosis:* Increased risk for delayed development, injury, and disease because of inadequate parenting by a primary parent experiencing depression

- *Population at risk:* Young children who are being parented by a primary parent who is experiencing mental health problems
- *Prevention level:* Secondary prevention, because the families have an identified risk

Public Health Nursing Process: Planning (Including Selection of Interventions)

Based on the assessment of this family, the PHN negotiated with Ashley to establish meaningful, measurable, achievable **intermediate goals**. In families experiencing mental illness (actually, in most families), behavior change occurs in very small steps. For this family, client goals included the following outcomes:

- Ashley will get out of bed at least 3 days in the week.
- Tyler will be dressed when the PHN arrives.
- Tyler will get to the bus on time 3 days in a row.
- The clutter will be cleaned off the steps.
- Ashley will call to make a doctor's appointment for Tyler's well-child check.
- Ashley will use "time outs" instead of spanking.
- Ashley will read a story to Tyler twice a week. (Intermediate indicators at the individual level of practice are changes in an individual's knowledge, attitudes, motivation, beliefs, values, skills, practices, and behavior that lead to desired changes in health status.)

The PHN also selected meaningful, measurable **outcome health status indicators** to measure the impact of the interventions on population health. Examples include no signs or reports of child maltreatment; child regularly attends preschool; child receives well-child examinations according to recommended schedule; child's immunizations are up to date; the family seeks medical care for acute illness as needed and does not seek medical care inappropriately; and child falls within normal limits on developmental tests.

The PHN selected the interventions, which included collaboration, case management, health teaching, delegated functions, and referral and follow-up. In selecting these interventions, the PHN considered evidence of effectiveness, political support, acceptability to the family, cost-effectiveness, legality, ethics, greatest potential for successful outcome, and level of prevention.

Public Health Nursing Process: Implementation

The PHN determined the sequence and frequency of her home visits based on her assessment of each family. Some families received home visits once a week, some twice a week, and others twice a month. The PHN visited this family weekly in the beginning and then spaced the home visits farther apart. She used the following interventions.

Collaboration

The PHN identified and involved as many alternative caregivers in Tyler's care as possible, including Tyler's biological father, aunt and uncle, and grandparents as well as Ashley's boyfriend.

Case Management

The PHN arranged childcare services and coordinated transportation for Tyler to spend significant portions of his day outside of the home.

Health Teaching

The PHN provided information on child growth and development, nutrition, immunizations, safety, medical and dental care, and discipline to Ashley and the alternative caregivers.

Delegated Functions (Public Health Nurse to Paraprofessional)

The PHN placed a family health aide in the home to provide role modeling for Ashley. As part of this intervention, the PHN monitored and supervised the aide.

Referral and Follow-up

Based on the assessment, the PHN referred Ashley to community resources and services that included early childhood services, legal aid, food stamps, mental health counselors, and transportation.

Public Health Nursing Process: Evaluation

The PHN reassessed and modified her plan at each home visit. She provided regular feedback to Ashley and the other caregivers on their progress. The PHN documented her results and compared them with the selected indicators. After 6 months of home visits, Ashley got out of bed most days of the week but rarely got dressed. Ashley was more successful in getting Tyler to the bus and to preschool. The family health aide helped Ashley clean the clutter off the steps. Ashley scheduled a doctor's appointment for Tyler's well-child visit but failed to get him to the appointment. Ashley was successful in learning to substitute "time outs" for spanking, with the help of the family aide. Tyler exhibited no signs of child maltreatment. He attended preschool regularly. Tyler was still behind on his immunizations because of the missed appointment. All of Tyler's developmental tests were within normal limits.

The PHN reported her results to her supervisor during their regular supervisory meetings. The PHN also talked with other PHNs who worked with similar families about common issues and best practices, and applied what she had learned to her practice.

APPLYING THE PUBLIC HEALTH NURSING PROCESS AT THE COMMUNITY LEVEL OF PRACTICE SCENARIO

Note: At the community level of practice, the community assessment, program planning, and evaluation process is the public health nursing process.

Community Assessment (Public Health Nursing Process: Assessment)

Childhood obesity is a rapidly growing community problem. An increasing number of children ages 2 to 11 are considered overweight, as defined by a body mass index (BMI) at or above the 95th percentile (based on CDC Growth Charts; [Ogden et al, 2010](#)). The 2011-2012 National Health and Nutrition Examination Survey data estimated that 9.5% of boys and 7.2% of girls aged 2 to 5 were obese in the United

States. Among children aged 6 to 11 years, the percentages were 16.4% for boys and 19.1% for girls (CDC, 2014). Childhood obesity and hyperplasia of adipose cells are linked to obesity later in life.

A health department recognized the well-established association between overweight and obesity in childhood and the development of both continuing overweight/obesity as adults and a host of chronic diseases (CDC, 2010). In response, the public health nursing director of a health department convened a childhood obesity prevention summit. Over 80 participants representing area health care providers, schools, child care, and governmental and community-based health organizations met for an entire day to discuss the problem and frame solutions.

Community Diagnosis (Public Health Nursing Process: Diagnosis)

The percentage of children aged 2 to 11 who are overweight or obese is unacceptable and threatens the future health status of the community.

- *Population of interest:* Children aged 2 to 11
- *Level of prevention:* Primary prevention

Community Action Plan (Public Health Nursing Process: Planning, Including Selection of Interventions)

At the conclusion of the summit, each organization represented committed to promoting healthy eating and physical activity habits for all residents, with an emphasis on parents of young children. The health department recognized that a substantial portion of a child's caloric intake occurs at child care.

Based on its assessment of the community, the health department initiated a 24-week evidence-based program that promotes the consumption of fruits and vegetables by young children through intervention with licensed home childcare providers. "LANA the Iguana" (Learning About Nutrition Through Activities) encourages eating eight targeted fruits and vegetables: broccoli, sweet red pepper, cherry tomatoes, apricots, sugar snap peas, kiwi, sweet potatoes, and strawberries (Figure 9-6). These fruits and vegetables were featured in activities throughout the program related to menu changes, classroom activities, and family involvement.

Menu Changes

Home childcare providers increased opportunities for children to eat more fruits and vegetables by serving the targeted fruits and vegetables on the menu, alternating four for one week and four the next. Fruits and vegetables were served as the morning and afternoon snack every day.

Classroom Activities

Home childcare providers increased children's preference for and knowledge of fruits and vegetables by featuring one of the targeted fruits and vegetables each week throughout the program. During that week, the featured fruit or vegetable was

FIG 9-6 LANA the Iguana. (Used with permission from Minnesota Department of Health, Center for Health Promotion.)

the focus of tasting and cooking activities as well as the topic of stories and games.

Family Involvement

Home childcare providers gave families information about the program and activities to do at home. These included quick and easy kid-tested recipes and take-home fruit/vegetable tasting kits.

The PHNs selected their interventions, which included consultation, health teaching, social marketing, collaboration, and surveillance. In selecting these interventions, the PHNs considered evidence of effectiveness, acceptability to community, cost-effectiveness, legality, ethics, and greatest potential for successful outcome.

Community Implementation Plan (Public Health Nursing Process: Implementation)

1. *Social marketing:* LANA the Iguana was a social marketing program. It incorporated a range of age-appropriate social marketing techniques including iguana puppets and storybooks, recipe cards, and activities. The PHNs promoted retention by providing home childcare providers with incentives, including two grocery store gift cards and plastic fruit/vegetable toys for the children. They worked with librarians to place LANA the Iguana kits (comprised of iguana puppets, activities, and storybooks) in the local library for parents to check out. PHNs also donned the LANA the Iguana costume to implement the curriculum directly to children as well as train the home childcare providers and parents.
2. *Health teaching:* The PHNs trained the home childcare providers on the LANA curriculum to ensure fidelity to the program.
3. *Consultation:* The public health nurses consulted with home childcare providers about the program on a regular and ongoing basis.
4. *Collaboration:* PHNs collaborated with health educators to develop and distribute LANA materials, including a curricu-

lum guide, recipe books, storybooks, parent newsletters, and LANA the Iguana puppets. They also collaborated with public health nursing students to collect program evaluation data.

5. *Surveillance*: The PHNs collected data on the consumption of fruits and vegetables in the home childcare setting.

Community Evaluation (Public Health Nursing Process: Evaluation)

Follow-up surveys with the county's 75 licensed home childcare providers, who served about 500 children, found that 67% of children were more or much more likely to eat fruits and 78% were more likely to eat vegetables; 92% of children were more likely to try new foods; and 76% of providers offered fruits and vegetables more often at snack time (Dakota County, 2010). Establishing healthy eating habits among young children will lead to reduced levels of obesity.

APPLYING THE PUBLIC HEALTH NURSING PROCESS TO A SYSTEMS LEVEL OF PRACTICE SCENARIO

Health departments conduct assessments of community health status, a core function of public health, on an ongoing basis. The identification of some community problems emerges out of practice, rather than through a formal community assessment. This scenario is such an example.

Public Health Nursing Process: Assessment

For several years, PHNs had been very concerned about the poor living conditions in an apartment complex in which many of their clients lived. The walls were moldy, the carpet was unclean and deteriorated, and closet doors had fallen off their runners and struck children living in the apartment. The PHNs were suspect of the required cash payments that the manager required for repairs, extra security deposits, and increased rent after the birth of a baby.

Many of the tenants were undocumented Latinos and tried not to create problems. Most could not speak or read English well, and often signed lease agreements without taking note of damage or existing problems in the apartment and were therefore blamed for them. In addition, the manager blamed the tenants for the mold on the walls, implying that their cooking created too much humidity. Citing these "problems," the manager often gave bad references for the tenants, which made it difficult for them to move.

Over the years, the PHNs had diligently worked with their clients to correct these problems, but with little success. When the PHNs met with the manager to discuss the issues, he became angry. As a result, the manager had the PHNs' cars towed whenever he saw them in the parking lot. The PHNs also had sought help from city officials, but the officials had no legal recourse to remedy the situation.

Finally, several events occurred that spurred the PHNs to action. One of the PHNs found a nonfunctioning smoke detector in an apartment during a home safety check. The family

reported that the apartment manager had dismantled the smoke detector and left it that way. At the same time, another PHN was working with a family that was trying to move to a new, safer, cleaner apartment. The family had found a new apartment but could not move because the manager gave them a bad (although false) reference. The family no longer had a lease, but the manager said they could not move. The PHNs realized that there were many complex legal issues related to the living conditions of their clients.

Public Health Nursing Process: Diagnosis

- *Diagnosis*: Families at risk of illness and injury because of hazardous housing and abuse of legal rights
- *Population at risk*: Families living in hazardous housing in an apartment complex
- *Prevention level*: Secondary, because families are at risk for injury and illness

Public Health Nursing Process: Planning (Including Selection of Interventions)

At the systems level of practice, the goal is to change policies, laws, and structures. The PHNs' goals were to enforce the tenants' legal rights and improve the living conditions in the apartment complex. Their plan was to seek advice from a housing advocate service and connect their clients with legal counsel. Before they could pursue this plan, the PHNs consulted with their supervisor. Their supervisor supported their decision but also had to clear the plan with the health department director and the city manager.

The PHNs selected their interventions, which included consultation, referral and follow-up, advocacy, policy development, and surveillance. In selecting these interventions, the PHNs considered evidence of effectiveness, political support, acceptability to the family, cost-effectiveness, legality, ethics, greatest potential for a successful outcome, non-duplication, and level of prevention.

Public Health Nursing Process: Implementation

The PHNs worked with the tenants and the housing advocacy service to implement the following interventions.

Consultation

The PHNs consulted with attorneys at a housing advocate service.

Referral and Follow-up

The attorneys informed the PHNs that they needed to hear directly from the tenants in order to proceed. The PHNs set up a meeting time between the tenants and the attorneys from the housing advocate service.

Advocacy

The PHNs arranged for their public health interpreter to go door to door with an advocate from the housing service to invite tenants to the meeting. They also arranged for the interpreter to attend the meeting to interpret each family's concerns. The PHNs strongly encouraged all of the tenants to attend.

Policy Development

The public health nurses worked with the attorneys from the housing advocate service to develop the meeting agenda.

Surveillance

The PHNs continued to conduct ongoing monitoring of living conditions in the apartment complex.

Public Health Nursing Process: Evaluation

Many of the tenants attended the meeting. As a result of the meeting, the attorney chose to have the rent paid to the court and put in escrow until a legal determination could be

made. During this process the apartment owner became aware of these issues and dismissed the manager, who was discovered to have been acting fraudulently. A new manager was employed who worked to improve the living conditions of the apartments.

LINKING CONTENT TO PRACTICE

The discussions of the application of the nursing process to a variety of clients beginning on [page 209](#) and [Tables 9-1](#) and [9-2](#) provide numerous examples of how the content in this chapter is applied in practice. Please review these for examples of how you may apply this model in your practice.

PRACTICE APPLICATION

Outreach locates populations of interest or populations at risk and provides information about the nature of the concern, what can be done about it, and how services can be obtained. Outreach activities may be directed at whole communities, at targeted populations within those communities, and/or at systems that impact the community's health. Outreach success is determined by the proportion of those considered at risk that receive the information and act on it.

The chance of a 20-year-old woman developing breast cancer within the next 10 years is 1 in 1681. At age 30, a woman's chance of developing breast cancer within the next 10 years is 1 in 232; at age 40, it is 1 in 69; at age 50, it is 1 in 42; at age 60, it is 1 in 29; and at age 70, it is 1 in 27 ([Susan G. Komen Foundation, 2013](#)).

A health system decided to offer free mammograms in recognition of National Breast Cancer Month. They sponsored a

mobile mammography van at a large shopping mall every Saturday in October. The van offered mammograms to everyone, regardless of age. The health system advertised the service by placing windshield flyers on all the cars in the shopping mall parking lot. The van provided 180 mammograms, mostly to women in their 30s who had health insurance that covered preventive services.

1. What is the population most at risk of breast cancer?
2. Did the mammograms in the parking lot reach this population?
3. What types of outreach would public health nurses conduct to reach the population at risk?

Answers can be found on the Evolve site.

KEY POINTS

- In these times of change, the public health system is constantly challenged to keep focused on the health of populations.
- The Intervention Wheel is a conceptual framework that has proved to be a useful model in defining population-based practice and explaining how it contributes to improving population health.
- The Wheel depicts how public health improves population health through interventions with communities, the individuals and families that comprise communities, and the systems that impact the health of communities.
- The Wheel serves as a model for practice in many state and local health departments.
- The Wheel is based on 10 assumptions.
- The Intervention Wheel encompasses 17 interventions.
- Other public health members of the interprofessional team such as nutritionists, health educators, planners, physicians, and epidemiologists also use these interventions.
- Implementing the interventions ultimately contributes to the achievement of the 10 essential public health services.
- The *Cornerstones of Public Health Nursing* was developed as a companion document to the Intervention Wheel.
- The original version of the Wheel resulted from a grounded theory process carried out by public health nurse consultants at the Minnesota Department of Health in the mid-1990s.
- The interventions were subjected to an extensive review of supporting evidence in the literature.
- The Wheel is a conceptual model. It was conceived as a common language or catalog of general actions used by public health nurses across all practice settings.
- The Intervention Wheel serves as a conceptual model for public health nursing practice and creates a structure for identifying and documenting interventions performed by public health nurses and captures the nature of their work.
- The Wheel has three main components: a population basis, three levels of practice, and 17 interventions.

KEY POINTS—cont'd

- The Wheel has led to numerous innovations in practice and education since the original Intervention Wheel was first published in 1998.
- Public health nurses in the Shiprock Service Unit of the Indian Health Service adapted the Intervention Wheel to reflect the Navajo culture.
- Numerous graduate and undergraduate schools of nursing throughout the United States have adopted the Intervention Wheel as a framework for teaching public health nursing practice.

CLINICAL DECISION-MAKING ACTIVITIES

1. Describe the three components of the Intervention Wheel. How do the components relate to each other? Explain how you can apply them to your clinical practice.
2. Go to [Chapter 1](#) and reread the definitions of the core functions of public health practice and look at the 10 essential services. How does the Wheel address the core functions? How does it relate to the 10 essential services?
3. Go to the Wheel website: www.health.state.mn.us/divs/cfh/ophp/resources/docs/wheel.pdf. Choose one of the 17 interventions to explore. Read about the recommended strategies to use when intervening with a client. Explain the level of practice and how you can apply the intervention. Give a concrete example.

Environmental Health

Barbara Sattler, RN, DrPH, FAAN

Dr. Barbara Sattler has a diploma in nursing from Pilgrim State Psychiatric Center School of Nursing, a BS in political science from the University of Baltimore, and the MPH and DrPH from the Johns Hopkins University. She is a Professor at the University of San Francisco. She is a founding member of the Alliance of Nurses for Healthy Environments (www.enviRN.org), a national network of nurses who are addressing the integration of environmental health into our nursing education, practice, research, and policy/advocacy efforts. She has been working in the area of environmental health and nursing for three decades and has been involved in issues associated with air, water, food, and products, as well as climate change and energy policies as they relate to human health.

- [Appendix F.3](#): Comprehensive Occupational and Environmental Health History

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Explain the relationship between the environment and human health and disease.
2. Understand the key disciplines that inform nurses' work in environmental health.
3. Apply the nursing process to the practice of environmental health.
4. Describe legislative and regulatory policies that have influenced the impact of the environment on health and disease patterns in communities.
5. Explain and compare the environmental health roles and skills for nurses practicing in public health, as well as those practicing in practice settings.
6. Incorporate environmental principles into practice.

Roles for Nurses in Environmental Health

“Environmental health comprises those aspects of human health, including quality of life, that are determined by physical, chemical, biological, social, and psychosocial factors in the environment. It also refers to the theory and practice of assessing, correcting, controlling, and preventing those factors in the environment that can potentially affect adversely the health of present and future generations.”

United Nations University, 1993 (UNU)

An estimated 24% of the global burden of disease and 23% of all deaths can be attributed to environmental factors (WHO, 2015). As nurses there are a number of ways in which we can define our environment. Our homes, schools, workplaces, and communities are the environments in which most of us can be found at any given time. Each location holds potential health risks. As nurses, who are among the most trusted conveyors of information to the public, it is our responsibility to understand as much as possible about these risks—how to assess them, how to eliminate or reduce them, how to communicate and educate about them, and how to advocate for policies that support healthy environments.

We can also divide and examine the environment from the perspective of the media in which environmental degradation takes place: air, water, soil, and food. And a third approach would be to divide environmental exposures into categories: biological, chemical, and radiological. In this chapter we will look at the environment as comprehensively as possible and consider the roles that nurses can have in assessing and addressing environmental health.

Environmental exposures are rarely limited to one location or to one source. For example, the broad category of pesticides includes the insecticides we may use in our homes, the herbicides we may use in our gardens, the pesticide residues on fruits and vegetables, and our antimicrobial soaps. Each of these

forms of pesticides comes with a potential health risk. If you have children and regularly use pesticides in your home, you increase their risk of contracting leukemia. The more you use insecticides, the greater the risk of leukemia (Metayer et al, 2013; Wigle et al, 2009; Turner et al, 2010; Brown, 2004). The childhood risk for leukemia increases if the mother was exposed to pesticides, including occupational exposures (Bailey et al, 2014). Many playing fields where children compete in sports are regularly sprayed with pesticides (Gilden et al, 2012).

In May 2010, the President's Cancer Panel proclaimed that the contribution environmental carcinogens have made to the burden of cancer in the United States has been grossly underestimated. In addition to the main focus on chemical carcinogens, the panel noted the importance of radiation sources—ionizing and nonionizing. In a letter to President Obama, they wrote: “The Panel urges you most strongly to use the power of your office to remove the carcinogens and other toxins from our food, water, and air that needlessly increase our health care costs, cripple our Nation's productivity and devastate American lives” (President's Cancer Panel, 2010). With this call came a range of recommendations for reducing the risk of cancer, both through individual choices and through national policy. The recommendations for individuals are found in Resource 10.A on the Evolve resources website.

Cancer is not the only health endpoint of environmental exposures. An estimated 52 million homes in the United States contain some lead-based paint that is associated with risks for premature births, learning disabilities in children, hypertension in adults, and many other health problems. Lead poisoning is a completely preventable disease (Figure 10-1). Of the top 20 environmental pollutants that were reported to the Environmental Protection Agency (EPA), nearly three fourths were known or suspected neurotoxins. Thirty million Americans drink water that exceeds one or more of the EPA's safe drinking

FIG 10-1 Although lead is no longer allowed in house paint, over 34 million homes in the United States have lead-based paint U.S. Department of Housing and Urban Development (US DHUD, 2011). Pregnant women and parents who live in homes built before 1978 should be encouraged to have their homes tested for lead-based paint dust. (From State of Hawaii Department of Public Health. Available at <http://hawaii.gov/health/environmental/noise/asbestoslead/images2/child.jpg>. Accessed December 15, 2010.)

water standards, and 50% of Americans live in an area that exceeds current national ambient air quality standards. When these standards are exceeded, there is an increased risk to the public for a wide range of health effects.

Although food labeling includes nutrition information, there is no requirement to label whether pesticides are used in the food production; whether nontherapeutic antibiotics were given to the livestock, poultry, or farmed fish; the presence of genetically modified organisms (GMOs) in a product; or whether recombinant bovine growth hormone (rBGH) was given to the dairy cows. Nurses have declared that the “right to know” about potentially hazardous exposures is one of the basic principles of environmental health (see [Box 10-1](#)). Nurses have a range of potential public health responsibilities in protecting the public from exposures and environmental health risks (ANA 2007).

A range of influences including genetics, socioeconomic status, and environmental exposures impact environmental health. In evaluating environmental exposures in a home, nurses’ assessments can begin with a set of questions: What exposures can you identify in your own home? Do you use pesticides? Does your home have lead-based paint? (The age of a home is a good proxy for identifying the presence of

BOX 10-1 American Nurses Association’s Principles of Environmental Health for Nursing Practice

The ANA calls for all nurses to understand basic environmental health concepts, invokes the Precautionary Principle, recognizes the multidisciplinary nature of environmental health, and promotes and supports nurses’ roles in developing and maintaining environmentally healthy workplaces for themselves and their patients. Principles include knowledge about environmental health and its effect on nursing practice, the Precautionary Principle, nurses’ rights to work in a safe workplace and use materials, products, technology, and practices that reflect an evidence-based approach. Other principles relate to quality assessment of the environment, interdisciplinary work in environmental health, involvement in research, and support of nurses who advocate for a safe environment (ANA, 2007).

From American Nurses Association. Principles of environmental health for nursing practice, Silver Spring, MD, 2007.

lead-based paint because it is most likely found in homes built before 1978, when the use of lead was banned in household paint.) Is the paint chipping or peeling? Are any of your appliances or heat sources producing unhealthy levels of carbon monoxide? Have you checked your home for radon, the second largest cause of lung cancer in the United States? How about your workplace? Do you eat fish on a regular basis? (Some fish can have unhealthy levels of mercury.) A more comprehensive home assessment tool can be found in the Resources.

LINKING CONTENT TO PRACTICE

The [Council on Linkages Between Academic and Public Health Practice, 2010](#) is a key document that guides practice in both nursing and public health. Specifically, the core competencies of the Council on Linkages includes, within the domain of public health science skills, a competency that says practitioners will apply “the basic public health sciences (including, but not limited to, environmental health sciences, health services administration, and social and behavioral health sciences) to public health policies and programs.” The [Quad Council of Public Health Nursing Organizations \(2011\)](#) further applies this competency specifically to public health nursing practice by adding that these skills are applied to public health nursing practice, policies, and programs. In 2007, the ANA adopted 10 principles of environmental health. Although all 10 are essential, three are highlighted here. Nurses should know about environmental health concepts, participate in assessing the quality of the environment in which they practice, and live and use the Precautionary Principle (which is discussed later in the chapter) to guide their work. A third principle points out that healthy environments are sustained through multidisciplinary collaboration, which is a key concept discussed throughout the chapter.

In 2010, the American Nurses Association (ANA) established an environmental health standard within the Scope and Standards of Professional Practice that define the profession of nursing. This means that all nurses are now expected to have knowledge of and skills associated with environmental health.

Underpinning many of these organizational decisions to include environmental health in nursing were the recommendations made in the report *Nursing, Health and Environment* (Pope, Snyder, and Mood, 1995) from the Institute of Medicine (IOM) of the National Academy of Science, which recommended that all nurses have a basic understanding of environmental health principles and integrate these principles into our practice, education, advocacy, policies, and research. In this chapter, we will explore the basic competencies recommended by the IOM. [Box 10-2](#) presents the competencies.

BOX 10-2 General Environmental Health Competencies for Nurses Recommended by the Institute of Medicine in *Nursing, Health and the Environment*

Basic Knowledge and Concepts

All nurses should understand the scientific principles and underpinnings of the relationship between individuals or populations and the environment (including the work environment). This understanding includes the basic mechanism and pathways of exposure to environmental health hazards, basic prevention and control strategies, the interprofessional nature of effective interventions, and the role of research.

Assessment and Referral

All nurses should be able to successfully complete an environmental health history, recognize potential environmental hazards and sentinel illnesses, and make appropriate referrals for conditions with probable environmental causes. An essential component is the ability to access and provide information to clients and communities and to locate referral sources.

Advocacy, Ethics, and Risk Communication

All nurses should be able to demonstrate knowledge of the role of advocacy (case and class), ethics, and risk communication in client care and community intervention with respect to the potential adverse effects of the environment on health.

Legislation and Regulation

All nurses should understand the policy framework and major pieces of legislation and regulations related to environmental health.

From Pope AM, Snyder MA, Mood LH, editors: *Nursing, health, and environment*, Washington, DC, 1995, Institute of Medicine, National Academy Press.

HEALTHY PEOPLE 2020 OBJECTIVES FOR ENVIRONMENTAL HEALTH

Environmental health is one of the priority areas of the *Healthy People 2020* objectives. The federal government has long recognized the importance of the relationship between environmental risks and the underlying factors contributing to diseases. Selected examples of the *Healthy People 2020* environmental health objectives are outlined in the following [Healthy People 2020 box](#) (U.S. Department of Health and Human Services, *Healthy People 2020*, 2010).

HEALTHY PEOPLE 2020

Examples of Objectives Related to Environmental Health

- EH-8.1: Eliminate elevated blood lead levels in children.
- EH-9: Minimize the risks to human health and the environment posed by hazardous sites.
- EH-10: Reduce pesticide exposures that result in visits to the health care facility.
- EH-11: Reduce the amount of toxic pollutants released into the environment.
- EH-13: Reduce indoor allergen levels.
- EH-18: Decrease the number of U.S. homes that are found to have lead-based paint or related hazards.

From U.S. Department of Health and Human Services: *Healthy People 2020*. Available at <http://www.healthypeople.gov/2020/topicsobjectives2020/default.aspx>. Accessed January 1, 2011.

HISTORICAL CONTEXT

Historically, nurses and physicians have been taught little about the environment and environmental threats to health. In the IOM report mentioned previously, quotes from Florence Nightingale are used extensively, not only because she is a recognized symbol of nursing (i.e., the lady with the lamp), but also because of the central focus of environment in her practice and writings. She promoted the use of clean water and safe sanitary conditions and connected these elements to disease prevention. Early in the twentieth century, Lillian Wald, who coined the name “public health nurses,” spent her life improving the environment of the Henry Street neighborhood and encouraging her broad network of influential contacts to make changes in the physical environment, as well as social conditions that had direct health impacts. As modern day nurses are rediscovering environmental health, they are reintegrating many of the observations and skills that were practiced by early nurse pioneers.

There are still many communities like the ones that Lillian Wald served. Poverty is highly associated with health disparities and is also associated with disproportionately higher environmental exposure, which compounds the health disparities. Poverty is linked to living in substandard housing, living closer to hazardous waste sites, working in more hazardous jobs, having poorer nutrition, and having less access to quality health care (particularly preventative services). The term *environmental justice* refers to the disproportionate environmental exposures that poor people and people of color experience in the United States and elsewhere, including lead paint dust exposure, the presence of pests (resulting in increased use of pesticides), and the use of supplemental heating sources that may cause dangerous carbon monoxide exposure. These combined circumstances multiply the risk for health disparities.

It is important to note how we began to understand the relationship between environmental chemical exposures and their potential for harm. There are several ways in which we have historically made such discoveries:

- When humans present with signs and symptoms that can be connected to a specific chemical exposure. This may occur with acute pesticide poisoning or carbon monoxide poisoning. It often occurs when workers are occupationally exposed. In such instances, the temporal and geographic relationships to the exposures and health effects help to identify health hazards in the environment (e.g., the diagnosis of mesothelioma from asbestos exposure).
- When large accidental releases of chemicals occur in a community that contaminate air, water, soil, or food, resulting in health effects. Such events show us how toxic chemicals are to humans and animals. For example, in the Love Canal incident outside of Buffalo, NY, an entire community was affected by hazardous chemicals that were dumped on the land where a housing development was built.
- In rare instances, when human environmental (and occupational) epidemiologic studies have been performed. Through such studies, we have learned about the toxic effects of chemicals.

However, the most common way in which the relationships between chemical exposures and health risks are identified is when toxicologists study the effects of chemicals on animals and then use models to estimate what the effects might be on humans. This estimation process is called *extrapolation*. More than 84,000 man-made (synthetic) chemical compounds have been developed and introduced to our environment since World War II, and we are most often reliant on the data that are created in animal studies to warn us about their potential toxicity to humans. For many of these chemicals, no toxicity data are available. Surprisingly, there is no current requirement for original toxicological research to be completed when a product or process is being brought to market.

We live in a radically different environment compared to a century ago. In addition to man-made pollutants contaminating our air, water, and food, many of the same pollutants are now also found in our bodies (including breast milk). In 2001, the Centers for Disease Control and Prevention began **biomonitoring**—the testing of human fluids and tissues for the presence of potentially toxic chemicals, as part of its National Health and Nutrition Exam Study. For instance, most Americans carry pesticides, solvents, heavy metals and other potentially toxic chemicals in their bodies. In 2005, an Environmental Working Group tested the umbilical cord blood of newborn babies and found that they also contained a similar range of potentially harmful chemicals (EWG, 2005). Each of these potentially hazardous substances creates a health risk. Nurses need to understand the environmental exposures and the health effects that may be associated with chemicals in order to develop assessment tools, implement hazard reduction programs, and advocate for safe and healthy chemical policies. For example, when a woman is pregnant for the first time, this is an ideal time for a nurse to help her assess and reduce or eliminate preventable environmental health risks in her home and workplace. A good environmental health history can help uncover a number of exposures from the products she may use, the ways in which she addresses pests in her home and garden, to the way in which she may set up a new nursery room.

In the Resource Section under chemical policies, there are a number of links to organizations that track federal and state legislation on chemical issues.

ENVIRONMENTAL HEALTH SCIENCES

Toxicology

Toxicology is the basic science that contributes to our understanding of health effects associated with chemical exposures. Historically, it was referred to as the “study of poisons.” Its corollary in health care is pharmacology, which studies the human health effects, both desirable and undesirable, associated with drugs. In toxicology, only the negative effects of chemical exposures are studied. However, the key principles of pharmacology and toxicology are the same. Just as the dose of a drug makes the difference in its efficacy and its toxicity, the quantity of an air or water pollutant to which we may be exposed can determine whether or not (and the extent to which) we experience a risk of a health effect. In addition, the timing

of the exposure—over the human life span—can make a difference. For example, during embryonic and fetal development, exposure to toxic chemicals can create immediate harm or create a critical pathway for future disease. Very young children, whose systems are still immature, are also more vulnerable to exposures. In *Harm's Way*, an online report by Physicians for Social Responsibility (with associated training materials) describes the neurological damage that several common chemicals can cause to developing children (Schettler et al, 2000). Just as is true of medications, the same dose that one would give an adult will have a much greater effect on a child and certainly on a fetus. As we age our liver and renal functions slow, thereby creating opportunities for toxic chemicals to accumulate, and thus creating higher risks for harm.

Both drugs and pollutants can enter the body from a variety of routes. Most drugs are given orally and absorbed by the gastrointestinal (GI) tract. Water- and food-associated pollutants, including pesticides and heavy metals, enter the body via the digestive tract. Some drugs are administered as inhalants, and some pollutants in the air (including indoor air) enter the body via the lungs. Some drugs are applied topically. In work settings, employees can receive dermal exposures from toxic chemicals when they immerse their unprotected hands in chemical solutions, especially solvents. Pollution can enter our bodies via the lungs (inhalation), GI tract (ingestion), skin, and even the mucous membranes (dermal absorption). Most chemicals cross the placental barrier and can affect the fetus, just as most chemicals cross the blood–brain barrier. In addition to direct damage to cells, tissues, organs and organ systems, there can be changes to the DNA from chemical exposures that can change gene expression, which in turn can predict disease. This latter effect is the focus of a relatively new field of biological study: **epigenetics**. Scientists now understand that there are many variables that predict disease outcomes, including environmental exposures.

In the same way that we consider age, weight, other drugs taken, and underlying health status of a client when we administer drugs, we must consider that these same factors can affect an individual's response to environmental exposures. For example, children are much more vulnerable to virtually all pollutants. People who are immunosuppressed (people with HIV/AIDS or those on immunosuppressant drugs like steroids or anti-cancer medications) are especially at risk for foodborne and waterborne pathogens. Because our communities are comprised of people of different ages and different health statuses, their vulnerabilities to the effects of pollution will also vary. When assessing a community's environmental health status, be sure to review the general health status of the community and to identify members who may have higher risk factors.

Chemicals that are similar are often grouped into categories or “families” so that it is possible to understand the actions and risks associated with those groupings. Examples are metals and metallic compounds (e.g., arsenic, cadmium, chromium, lead, mercury), hydrocarbons (e.g., benzene, toluene, ketones, formaldehyde, trichloroethylene), irritant gases (e.g., ammonia, hydrochloric acid, sulfur dioxide, chlorine), chemical asphyxiants (e.g., carbon monoxide, hydrogen sulfide, cyanides), and

pesticides (e.g., organophosphates, carbamates, chlorinated hydrocarbons). Although some common health risks exist within these families of chemicals, the possible health risks for each chemical should be evaluated individually when a potential human exposure exists. The best source of peer-reviewed information for this is the National Library of Medicine (NLM). The NLM has a set of databases that are focused on toxicology and environmental health called TOXNET. You will find the link to several of these helpful informational programs and databases in the Referral Resources.

Epidemiology

Whereas toxicology is the science that studies the poisonous effects of chemicals, **epidemiology** is the science that helps us understand the strength of the association between exposures and health effects. Epidemiology is often used for occupationally related illnesses but has been used less often to study environmentally related diseases. It is difficult to characterize and/or distinguish among the many exposures that we all experience, and it can be challenging to find control groups when the environmental exposure of concern is in the air, water, or food.

Epidemiologic studies have helped us to understand the association between learning disabilities and exposure to lead-based paint dust, asthma exacerbation and air pollution (Smargiassi et al, 2014; Habre et al, 2014), and GI disease and waterborne *Cryptosporidia* (Yoder et al, 2012). Environmental surveillance, such as childhood lead registries, provides data with which to track and analyze incidence and prevalence of health outcomes. The results of such analyses can help to target scarce public health resources. Scientists are now approaching epidemiology at the molecular level, looking at gene/environment interactions.

As described in Chapter 12, three major concepts—agent, host, and environment—form the classic **epidemiologic triangle**. (See Figure 12-2, A in Chapter 12.) This simple model belies the often-complex relationships between **agent**, which may include chemical mixtures (i.e., more than one agent); **host**, which may refer to a community with people of multiple ages, genders, ethnicities, cultures, and disease states; and **environment**, which may include dynamic factors such as air, water, soil, and food, as well as temperature, humidity, and wind. Limitations of environmental epidemiologic data include reliance on occupational health studies to characterize certain toxic exposures. The occupational health studies were performed on healthy adult workers whose biological systems were different from those of neonates, pregnant women, children, people who are immunosuppressed, and the elderly. Nevertheless, nurses can review epidemiologic studies regarding exposures of concern to their communities and use epidemiologic techniques to assess environmental risks in communities.

Geographic Information Systems

Another research tool for environmental health studies is **geographic information systems** (GIS), a methodology that requires the coding of data so that it is related spatially to a place on Earth. By layering geographically related data, maps can be created to note where the data may be related. For instance, by

taking a data set that geographically notes where children under 10 years of age live and overlaying another data set that notes geographical areas designated by the age of housing stock, a public health nurse could see where there are the largest number of children who live in areas with older housing stock. With this information, the nurse could target a lead surveillance and educational program. Nurse researcher Mona Choi used GIS to study the relationship between air pollution and emergency visits for cardiovascular and pulmonary diagnosis. Community-based maps that are created using GIS technologies are helpful in educating community members and local policy makers. The maps can provide useful graphic depictions of public health problems.

Environmental health requires a combination of tried and tested nursing tools mixed with new tools, such as GIS, and the recognition that many disciplines may be involved in the identification and the resolution of environmental health issues.

Nurse scientists Wade Hill and Patricia Butterfield (2006) developed a model for environmental risk interventions, which can be provided by public health nurses, that improves children's health by addressing home-related sources such as lead paint, contaminated drinking water, and environmental tobacco smoke, among others. These risks can cause health effects ranging from minor learning deficiencies to serious and life-threatening diseases such as cancer. Many of the environmental risks children encountered were prevented or reduced by taking practical and affordable steps. Butterfield developed an environmental justice framework by which to consider environmental exposures in rural areas (Butterfield & Postma, 2009).

Multidisciplinary Approaches

In addition to toxicology and epidemiology, there are a number of earth sciences to help us understand how pollutants travel in air, water, and soil. Geologists, meteorologists, physicists, and chemists all contribute information to help explain how and when humans may be exposed to hazardous chemicals, radiation (e.g., radon), and biological contaminants. Key public health professionals include food safety specialists, sanitarians, radiation specialists, and industrial hygienists.

The nature of environmental health demands a multidisciplinary approach to assess and reduce/eliminate environmental health risks. For instance, to assess and address a lead-based paint poisoning case we might include a housing inspector with expertise in lead-based paint or a sanitarian to assess the lead-associated health risks in the home; clinical specialists to manage the client's health needs; laboratories to assess the blood lead levels, as well as lead levels in the paint and house dust and drinking water; and then lead-based paint remediation specialists to reduce the lead-based paint risk in the home.

We might also add a health educator and outreach worker to educate the family and encourage compliance with environmental health behaviors and clinical treatments. And finally, we may need to work with public health lawyers to address non-compliant landlords. Such combined approaches could potentially involve the local health department, the state department of environmental protection, the housing department, a primary and tertiary care setting, public or private sector labs, and the

legal system. The nurse's responsibility is to understand the roles of each respective agency and organization, know the public health laws (particularly as they pertain to lead-based paint poisoning in their communities), and work with the community to coordinate services to meet their needs. The nurse also might set up a blood lead screening program through the local health department, educate local health providers to encourage them to systematically test children for lead poisoning, and/or work with advocacy organizations to improve the condition of local housing stock. Note that although lead-based paint is no longer in use in the United States, it is still widely used in developing countries.

OSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality client care.

Knowledge: Describe scopes of practice and roles of health care team members.

Skills: Assume the role of team member or leader based on the situation.

Attitudes: Value the perspectives and expertise of all health team members.

Safety Question: One of the objectives of *Healthy People 2020* related to environmental health is "Reduce pesticide exposures that result in visits to a health care facility" (ED 8-10). The public health nurse, who is working on a project to help mothers learn parenting skills, visits a new mother who lives and works on a large farm. When the nurse drives into the farm on her way to the housing where workers live, she sees that the fields are being sprayed with pesticides from a truck and that two young children are riding in the back of the truck. What action should she take?

Answer: At the individual level, she should talk with the owner or manager of the farm and remind him or her of the toxicity of pesticides and the danger to those who are in the vicinity of the spraying. She should recommend that he or she not allow anyone to ride in the open portion of the vehicle and that the driver should leave the window closed and wear a mask to protect his or her nose and mouth.

Systems level: She should identify areas where the workers on the farms congregate, such as churches, social halls, and so forth. Then she should ask if she could provide an educational program on the dangers of coming into contact with pesticides. She could distribute pamphlets about this hazard in local venues where both farm managers and workers will be able to access them. What else might the nurse do?

CLIMATE CHANGE

According to the World Health Organization, "climate change is a significant and emerging threat to public health, and changes the way we must look at protecting vulnerable populations" (WHO, 2014b). The 2014 report of the Intergovernmental Program on Climate Change, a WHO-related group of scientists, concludes that "climate change will act mainly, at least until the middle of this century, by exacerbating health problems that already exist, and the largest risks will apply in populations that are currently most affected by climate-related diseases" (IPCC, 2014). In the United States we are already seeing some of the earlier climate change predictions materialize: long-term warming trends, extreme weather conditions, as well as

disruption in water supplies, agriculture, ecosystems, and coastal communities.

There are two concurrent categories of roles for nurses: mitigation and response. There is still much we can do to mitigate the steep upward slope that we are now observing for temperatures, CO₂ levels, desertification, and sea water levels. Working at the individual, community, institutional (school, hospital, etc.), and governmental levels, there is much work to be done to ensure energy-conserving policies and practices, rational transportation practices, and changes in our consumption patterns.

Regarding response preparation, public health nurses must lead the development of contingencies for long-term, high-heat weather conditions, as well as increased storm activities (that include more severe storm patterns), more extensive fires in areas prone to fires, and the associated disaster preparedness. For more on disaster preparedness, see [Chapter 23](#) on nurses' roles in disaster management. Nurses should also be prepared for threats to food security from shifting weather patterns that may deter/eliminate food production and for acute shifts of populations as they migrate away from low-lying, coastal regions or other areas acutely affected by storm or fire damage. These shifts are likely to create climate change–related refugee migrations.

The oil spill in the Gulf of Mexico was the largest in history and caused devastating damage. It is expected that its effects on birds, fish, and other sea animals, as well as the environment, will continue for many more years. Since fish populations were affected, many fishermen lost their jobs and the livelihood that they knew ([Gulf Oil Spill, n.d.](#)). This type of ecosystem destruction and economic disruption will be typical if we do not address climate change and our associated need to reduce/eliminate our reliance on fossil fuels (gas, oil, coal). It is important to explore the science underpinning climate change, consider the human and ecological health threats, and reflect on nurses emerging roles as climate change unfold.

ENVIRONMENTAL HEALTH ASSESSMENTS

There are a number of ways to assess environmental health risks in a community. For example, risks can be assessed by medium: air, water, soil, or food. Or exposures could be listed according to urban, rural, or suburban settings, with many exposures being common to all three settings. Nurses may also divide the environment into functional locations such as home, school, workplace, and community. Each of these locations will have unique environmental exposures, as well as overlapping exposures. For instance, ethylene oxide, the toxic gas that is used in the sterilizing equipment in hospitals, is typically found only in a workplace. However, pesticides might be found in any of the four areas. When assessing environments, be sure to determine if an exposure is in the air, water, soil, and/or food and whether it is a chemical, biological, or radiological exposure.

Information Sources

The NLM has developed some of the most useful, comprehensive, and reliable sources of environmental health information.

The NLM's website for ToxTown (<http://toxtown.nlm.nih.gov/>) is one of the best places to start when developing environmental assessment skills. Within ToxTown, there is a Household Products page where nurses can research common products such as those for personal care, cleaning, pet care, lawn care, and others to see the potential health risks that may be associated with them. Also, chemicals can be researched by brand or chemical name or by Chemical Abstract System number. (The NLM website can be accessed at www.nlm.nih.gov; at the website, search for the environmental assessment section.)

Also within ToxTown, you can search for general environmental health risks in the “city,” “town,” and “farm,” or even go to a “US–Mexico Border Community.” While in the virtual “city” you can visit a hair salon, hospital, or funeral home to see what kinds of environmental health risks are posed in such places. ToxTown brings together governmental and well-vetted nongovernmental sources for a rich web resource in which to learn about environmental health.

Another database that is specific to personal care products, which includes over 68,000 products that can be searched by brand name and specific product descriptors, is the Skin Deep database (<http://www.ewg.org/skindeep/>). The Safe Cosmetics website, which links to the Skin Deep database, additionally provides information on better protecting your health by selecting products that have simpler ingredients and fewer synthetic chemicals. For example, the site points out that even top-selling brands of natural and organic products may have some toxic components. Specifically, they say that some top-selling herbal shampoos contain 1,4-dioxane, a synthetic chemical carcinogen. They also comment on the number of lipsticks that they found to contain lead. Note that in both the NLM and the Safe Cosmetics databases, the information is predicated on what the manufacturers place on the label as ingredients (Figure 10-2). If the manufacturer claims that a component is a “trade secret,” it will not appear on the label. Rarely are the chemicals that make up a “fragrance” listed on the label; instead, it is likely to only read “fragrance” on the label. And finally (and this is especially true with pesticides), the label may merely say “inerts”

FIG 10-2 Some of the chemicals in our personal care products can be hazardous to our health. You can look up the chemicals in your products and learn about the potential health risks by going to the SkinDeep database: <http://www.ewg.org/skindeep/>. (Photo from the U.S. Food and Drug Administration. Available at <http://www.fda.gov/Cosmetics/default.htm?vvsessionid=1724ec6bbda343c6b7d0e092db6c2f30>.)

without any further information about their chemical identity. Thus, it is sometimes impossible to make a true assessment about the health risks based on the information provided by the manufacturer.

One of the ANA Environmental Health Principles is the tenet of the “Right to Know,” which recommends the need for access to all information necessary to make informed decisions and protect our health. There are still a number of ways in which full disclosure of chemical exposure is lacking in terms of air and water pollution, food contents, and product ingredients. Nurses, both individually and through their professional organizations, can advocate for increasing access to information through “right to know,” labeling, and other legislative and regulatory efforts.

APPLYING THE NURSING PROCESS TO ENVIRONMENTAL HEALTH

If you suspect that a client's health problem is being influenced by environmental factors, follow the nursing process and note the environmental aspects of the problem in every step of the process:

1. *Assessment.* Use your observational skills (e.g., windshield surveys); interview community members; ask your individual clients; and ask the families of your clients. Review web-based data on existing exposures, such as air and water pollution monitoring data, drinking water testing, and contaminated soil. Relate the disease and the environmental factors in the diagnosis.
2. *Planning.* Look at community policy and laws as methods to facilitate the care needs for the client; include environmental health personnel in planning.
3. *Intervention.* Coordinate medical, nursing, and public health actions to meet the client's needs. Ensure that the affected person or family is referred for appropriate clinical care.
4. *Evaluation.* Examine criteria that include the immediate and long-term responses of the client as well as the recidivism of the problem for the client.

Individual Environmental Exposure History

When working with individuals, it is important to include environmental health risks as part of a client's history. Ask certain questions to assess exposures that may occur in all of the settings in which they spend time. A helpful mnemonic was developed to assist health professionals in remembering the areas of concern when taking an environmental history: “I PREPARE.” The mnemonic (see Box 10-3) can be used when interviewing an individual client or when assessing a family or it can be adapted for use with a group of community members.

Community-wide Environmental Health Assessment Tools

Nurses have developed several exposure assessment tools, including forms for pregnant women, home and school assessments, community-wide assessments, and assessment tools for hospital-related exposures. The web links on the Evolve site for this book include several examples of environmental assessment tools.

BOX 10-3 The “I PREPARE” Mnemonic from the Agency for Toxic Substances and Disease Registry

Investigate Potential Exposures

Present Work

Residence

Environmental Concerns

Past Work

Activities

Referrals and Resources

Educate

Do an Exposure History to:

Identify current or past exposures.

Reduce or eliminate current exposures.

Reduce adverse health effects.

Taking an Exposure History: Questions to Consider

I—Investigate Potential Exposures

Investigate potential exposures by asking:

Have you ever felt sick after coming in contact with a chemical, such as a pesticide or other substances?

Do you have any symptoms that improve when you are away from your home or work?

P—Present Work

At your present work:

Are you exposed to solvents, dusts, fumes, radiation, pesticides, or other chemicals?

Are you exposed to loud noise?

Do you know where to find material safety data sheets for chemicals with which you work?

Do you wear personal protective equipment?

Are work clothes worn home?

Do coworkers have similar health problems?

R—Residence

When was your residence built?

What type of heating do you have?

Have you recently remodeled your home?

What chemicals are stored on your property?

Where is the source of your drinking water?

E—Environmental Concerns

Are there environmental concerns in your neighborhood (i.e., air, water, soil)?

What types of industries or farms are near your home?

Do you live near a hazardous waste site or landfill?

P—Past Work

What are your past work experiences?

What job did you have for the longest period of time? Have you ever been in the military, worked on a farm, or done volunteer or seasonal work?

A—Activities

What activities and hobbies do you and your family pursue?

Do you burn, solder, or melt any products?

Do you garden, fish, or hunt?

Do you eat what you catch or grow?

Do you use pesticides?

Do you engage in any alternative healing or cultural practices?

R—Referrals and Resources

Use these key referrals and resources:

Environmental Protection Agency (www.epa.gov)

National Library of Medicine—TOXNET Programs (www.nlm.nih.gov)

Agency for Toxic Substances and Disease Registry (www.atsdr.cdc.gov)

Association of Occupational and Environmental Clinics (www.aoc.org)

Occupational Safety and Health Administration (www.osha.gov)

EnvRN website (www.enviRN.umaryland.edu)

Local Health Department, Environmental Agency, Poison Control Center

E—Educate (A Checklist)

Are materials available to educate the client?

Are alternatives available to minimize the risk of exposure?

Have prevention strategies been discussed?

What is the plan for follow-up?

Prepared by Grace Paranzino, RN, MPH, for the Agency for Toxic Substances and Disease Registry. For more information, contact ATSDR at 1-888-42-ATSDR or visit ATSDR's website at <http://www.atsdr.cdc.gov>.

A windshield survey is a helpful first step in understanding the potential environmental health risks in a community. If the community is urban, the age and condition of the housing stock and potential trash problems (and the associated pest problems) can be determined easily by driving around the neighborhood. Note proximity to factories, dump sites, major transportation routes, and other sources of pollution. In rural communities, note if and when there are aerial and other types of pesticide and herbicide spraying, if people rely on wood-burning stoves, if there are industrial-type agricultural practices, and/or if there are contaminated waterways. Using ToxTown can really help with identifying health risks associated with the observations from a windshield survey.

You may not be able to “see” the pollution that is in your community, but the U.S. Environmental Protection Agency's website, EnviroFACTS, can help identify air, water, and soil pollution in your area by entering your ZIP code. Nurses are often surprised to find out what is being released into their neighborhood's water and air.

The Right to Know section of this chapter contains a description of the types of information that are available to the public about air and water pollutants, drinking water quality, and other environmental sources or exposures. Armed with this information, a nurse can create a significant environmental health map of a community. In addition, [Appendix F.3](#) presents an example of an occupational and environmental assessment.

While we observe environmental health risks in our communities, it is equally important for us to identify the positive environmental contributors to our communities. Settings that connect people to nature—parks, green spaces, and beaches—are incredible assets to communities. The term *nature-deficit disorder* was coined by author Richard Louv in his book *Last Child in the Woods* to describe what happens to young people who become disconnected from the natural world. Louv links this lack of nature to some of the most disturbing childhood trends, such as the rises in obesity, attention disorders, and depression ([Louv, 2005](#)). Policy makers, educators, and children's health advocates are considering their roles in addressing

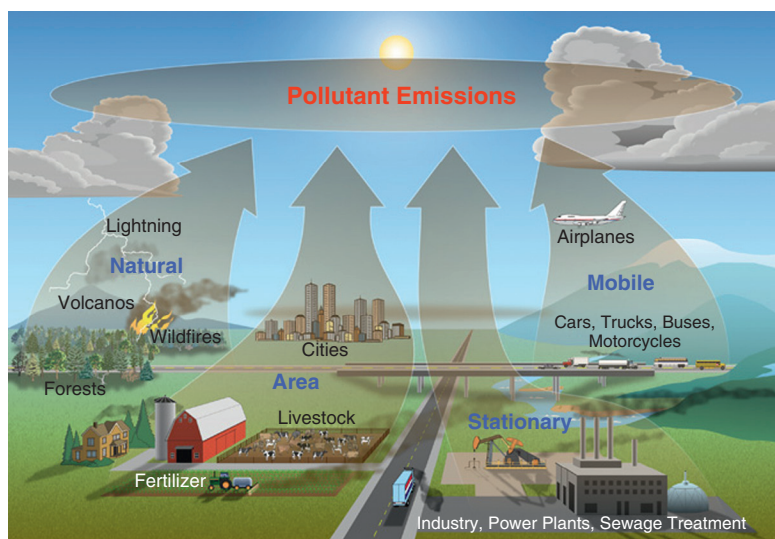

FIG 10-3 Air pollution comes from a wide range of sources. EPA’s EnviroFACTS site allows you to check the air and other pollutants in your ZIP code. <http://www.epa.gov/enviro/>. (Figure from the National Park Service, Sources of Air Pollution. Retrieved March 16, 2014 from <http://www2.nature.nps.gov/air/aqbasics/sources.cfm>.)

this issue. The National Park Service works to bring more people to parks—local, state, and national.

Man-made “green” spaces such as community gardens, streetscapes, bike paths, and water features can positively contribute to a community’s health and sense of well-being. Recent attention has been paid to the importance of “walkable communities,” access to nature, and other concerns included in discussions about “Smart Growth” or “Sustainable Communities.”

Some new suburban developments are designing space for agriculture in the form of Community Sustainable Agriculture (CSA), a model of local agriculture in which community members purchase shares in the spring and receive fruits and vegetables as they are harvested. Also in this model, community members have the option to volunteer on the farm. This creative new community design addresses a number of public health issues—obesity, depression/social isolation, poor nutrition—by getting people outside and moving, creating opportunities for building supportive relationships, and providing fresh produce.

ENVIRONMENTAL EXPOSURE BY MEDIA

Many of the environmental protection regulations are based on the “medium” in which pollutants are carried—air, water, and soil. Additionally, chemical, biological, and radiological hazards can be found in food and consumer products. For air, water, and soil, the U.S. EPA and its state-level equivalents are the primary regulatory agencies. However, the EPA also regulates pesticides used in agriculture. The U.S. Department of Agriculture focuses substantially on pathogens in our food supply.

Air

Air pollution is a significant contributor to human health problems, and a sign that regulatory efforts are not completely

BOX 10-4 U.S. EPA Criteria Air Pollutants—National Ambient Air Quality Standards (NAAQS)

Ozone (ground level)	Particulate matter
Sulfur dioxide	Carbon monoxide
Nitrogen dioxide	Lead

effective. Nurses can have a role in addressing both the health problems and the policies affecting the exposures. Air pollution is divided into two major categories: point source and non-point source (see Figure 10-3). **Point sources** are individual, identifiable sources such as smokestacks. They are sometimes referred to as fixed sites. **Non-point sources** come from more diffuse exposures. For instance, the largest non-point source of air pollution is from mobile sources such as cars and trucks, which are the greatest single source of air pollution in the United States. The Clean Air Act regulates air pollution from point and non-point sources. Box 10-4 presents a list of the air pollutants that comprise the “criteria pollutants”—a set of pollutants that the EPA uses to gauge the overall air quality. The burning of fossil fuel (e.g., diesel fuel, industrial boilers, and coal-fired power plants) and waste incineration are two other major contributors. Health effects associated with air pollution include asthma and other respiratory diseases, cardiovascular diseases (including cardiac disorders and hypertension), cancer, immunological effects, and reproductive health problems including birth defects, infant death, and neurological problems. For children with asthma the additional insult of living near a fixed source of pollution can create additional health risks (Smargiassi et al, 2014).

The single greatest source of mercury in our air is coal-fired power plants. Many people do not know that a pea-sized amount of mercury is sufficient to contaminate a 25-acre lake

and make its fish unfit to eat. Mercury, like lead, is an element and it persists in our fresh waterways and oceans from which we continue to get our fish. We cannot readily take these elements out once they have been released into the environment; our job is to focus on policies that prevent them from being released.

Indoor air quality (IAQ) is a growing public health concern in office buildings, schools, and homes and is reflected in the alarming rise in asthma incidence in the United States, particularly among children. The EPA and the American Lung Association both provide excellent materials on IAQ. The EPA has a free kit called *IAQ: Tools for Schools*, which includes a video and a number of helpful materials for people interested in improving the air quality in a school building.

Radon, a naturally occurring radioactive element that is found in the earth's crust and can seep into basements and into groundwater, is the second leading cause of lung cancer in the United States, second only to smoking. To learn more about this important environmental exposure, read more in the Resource Section. Other major culprits contributing to poor indoor air are carbon monoxide, formaldehyde, dusts, molds, pests and pets, pesticides, cleaning and personal care products (particularly aerosols), lead, and of course environmental tobacco smoke.

Because environmental health implies a relationship between the environment and our health, we must assess both the environmental exposures and the human health status within a community. Health status is assessed by using local, state, and national health data or by collecting our own data, or a combination of the two. As we learn more about the exposures in our communities and their known or suspected health effects, we can target the health statistics we wish to review or collect.

Water

Water is necessary for all life forms. Human bodies consist of 70% water. Only 2.5% of the water on this planet is fresh water; the rest is salt water. Much of the fresh water is in the polar icecaps, whereas groundwater makes up most of what remains, leaving only 0.01% in lakes, creeks, streams, rivers, and rainfalls. People's lives are inextricably tied to safe and adequate water. Water is necessary for the production of food. In the United States, all public water suppliers must test their water in accordance with the EPA's safe drinking water standards and they must summarize the results of their testing annually and make them available to their customers—those who pay water bills. The technical term for these reports is Consumer Confidence Reports (CCR). Nurses can request these summaries from the water suppliers that serve their communities. Private wells are not regulated and need not be tested except when they are first drilled. Nurses should encourage people with private wells to have them tested annually, especially in agricultural areas where pesticides are applied.

Pollution discharges into water bodies from industries and from wastewater treatment systems can contribute to the *degradation* of water quality. An additional source of pollution in our waters is pharmaceuticals used for humans and animals. The U.S. Geological Service has found antibiotics, codeine,

17 β -estradiol (an estrogen replacement hormone), and acetaminophen (Tylenol), as well as a variety of endocrine disrupting chemicals, in measurable quantities in U.S. streams and rivers.

Water quality is also affected by non-point sources of pollution, such as storm water runoff from paved roads and parking lots, erosion from clear-cut tracts of land for timbering and mining, and runoff from chemicals added to soils such as pesticides and fertilizers. Soil erosion is another huge public health threat in the making as it is decreasing the amount of soil that can sustain agriculture and the global food supply. Eighty percent (80%) of the world's forests are gone, which is contributing to massive erosion of farmable soil and deterring the flow of and healthy biotic life in creeks and rivers.

Land and Soil

Current and past land use can affect a community's health. Local governments dictate land use through zoning laws. For instance, zoning decisions can determine if a community will have a hazardous waste site built in its neighborhood or whether the land can be used only for residential purposes (housing). Historically, communities in which poor people and people of color live have been more likely to have undesirable and unhealthy industries, railway lines, and hazardous waste sites. In many communities, prior use of the land has left a legacy of unhealthy contaminants. There are two designations for lands that may be contaminated: Superfund sites (highly contaminated sites, with associated health threats that are designated by the EPA) and Brownfield sites (land that has been used previously *and* which is now slated for redevelopment). Public health nurses can play an important role with both Superfund and Brownfield sites related to the health assessment. Funds are available through both the Superfund and Brownfield laws to engage the community and to do health assessments.

Food

Many health risks are associated with food and food production. In recent years, we have seen foodborne illnesses associated with *Salmonella* and *Escherichia coli* H:0157:H7 in chicken, eggs, and meats. Good food preparation practices, such as proper washing and using adequate cooking temperatures and time, can prevent foodborne illnesses associated with most pathogens. Local health departments are responsible for monitoring food establishments (restaurants, food trucks, etc.) in the community, and the U.S. Department of Agriculture is responsible for oversight of meat, poultry, fish, and produce production.

However, there are also environmental health risks posed by the presence of pesticide residues in our food; the use of recombinant bovine growth hormone (rBGH), which is given to many dairy cows; the administration of antibiotics to beef cattle, pigs, and chickens at nontherapeutic doses that are given to promote growth; and the use of genetically modified organisms (GMOs) for genetically engineered crops. In the Resources Section, there are a number of websites through which you can find out more information about food-related public health issues.

When assessing a community's environmental health risks, a nurse must consider air, water, soil, and food. It is important

that nurses understand the term “organic” regarding food labeling. If a food is labeled “Certified Organic” this is a meaningful term that has a legal USDA definition. The legal definition stands for foods that have been produced without the use of pesticides, genetically modified organisms (GMOs), or unnecessary (nontherapeutic) use of antibiotics. If a food is merely labeled “organic,” the consumer does not have the same guarantee for what chemicals or farming practices have been used. When purchasing foods directly from farmers through farm stands or farmers’ markets, consumers can directly ask about the chemicals and farm practices.

RIGHT TO KNOW

Several environmental statutes give the public the **right to know** about the hazardous chemicals in the environment. Under one of the “right to know” laws, health professionals and community members can easily access key information by ZIP code regarding major sources of pollution that are being emitted into the air or water in their community. The EPA has an Envirofacts section on its website that provides several sources of exposure data by ZIP code (<http://www.epa.gov/enviro/>).

Nurses can access drinking water **consumer confidence reports**, sometimes referred to as “right to know” reports, to determine what pollutants have been found in the drinking water. If the drinking water poses an immediate health threat, the water provider must send emergency warnings out to the community via the local newspapers, radios, and television. If there is a biological hazard (microbial) in the water, the health notice may suggest boiling the water or not drinking it at all. If the hazard is chemical, boiling the water may not be helpful because that may simply concentrate the chemical. A federal law, the Freedom of Information Act, allows citizens to request many kinds of public documents, including information about environmental permits and inspections of facilities in your communities.

Employees have the right to know about the hazardous chemicals with which they work through the federal Hazard Communication Standard, which is under the purview of the Occupational Safety and Health Administration (OSHA). This standard requires employers (including hospitals) to maintain a list of all of the potentially hazardous chemicals that are used on site. Each of these chemicals should have an associated chemical information sheet known as a material safety data sheet (MSDS), which is written by the chemical manufacturer. These MSDSs are to be made available to any employee or his or her representative (e.g., a union) and should provide information about the chemicals that constitute the product, the health risks, and any special guidance on safe use or handling (e.g., requirements for protective gloves or respiratory protection). For more extensive information on workplace health and safety, see <http://www.osha.gov>.

RISK ASSESSMENT

Currently, the EPA uses a process referred to as “risk assessment” when they develop health-based standards. The term **risk**

assessment refers to a process to determine the probability of a health threat associated with an exposure. The following illustration of a chemical exposure demonstrates the four phases to a risk assessment:

1. Determining if a chemical is known to be associated with negative health effects (in animals or humans). For this, we rely on toxicological and/or epidemiologic data. (Remember, the available toxicological data will probably be based on animal studies and these studies estimate the potential effects on humans, whereas the results of human epidemiologic studies will be for human health effects.)
2. Determining whether the chemical has been released into the environment—into the air, water, soil, or food. This is accomplished by testing for the presence of the suspected chemical in the various media (air, water, soil, food). Environmental professionals such as air and water pollution scientists, environmental engineers, meteorologists, and others might be involved in this activity. When doing a risk assessment, it is important to note if there are multiple sources of the chemical in question. For example, is lead found in the drinking water, the ambient air, *and* in the paint within the houses of a given community?
3. Estimating how much and by which route of entry the chemical might enter the human body—inhale, ingest, dermally, or in utero exposure. This estimate can be based on a one-time exposure, a short-term exposure, or a projected lifetime exposure. (When federal standards are created for air, water, and other pollutants, they are based on an estimation of a lifetime exposure. However, in workplace settings the chemical exposure standards are based on an average exposure during a typical 8-hour work shift or set for a maximum exposure level that should not be exceeded.)
4. Characterizing the risk assessment process and taking into account all three of the previous steps. Is the chemical toxic? What is the source and amount of the exposure? What is the route and duration of the exposure for humans? The final synthesis attempts to predict the potential for harm based on the estimated exposure.

All science is subject to interpretation, and so is risk assessment. The reason that environmental laws are so often contentious is because there are economic interests at stake and not just public or ecological health concerns. In translating the risk assessment results for the purposes of policy development and recommendation for risk reduction activities, there are often several interpretations of each of the risk assessment steps that then result in differing recommendations for health-based standards. There are also areas of scientific uncertainty that contribute to variations in assessment of risk. It is critical to have public health voices in the debates. The American Public Health Association is actively engaged on major policy debates through the Environment Section.

VULNERABLE POPULATIONS

Many of the social determinants of health contribute to the risk levels associated with environmental exposures. Poor people who live in low-income communities are more often housed in

substandard housing (with attendant risks of chipping and peeling paint, pests, and unsafe neighborhoods), live closer to pollution sources, are employed in more dangerous occupations, and have less access to healthy food options. In addition, vulnerability is variable through the human life cycle. The embryo and fetus are the most vulnerable to chemical exposures because of the rapid growth of cells and the development of tissues, organs, and organ systems. Following is a section on children's special vulnerabilities. The very young and the very old also are vulnerable because their body systems are either still developing or are less efficient, respectively. For more information about the special vulnerabilities of the elderly, see the EPA's dedicated information site on older Americans (www.epa.gov/aging/) and look at their report "Growing Smarter/Living Healthier: A Guide to Smart Growth and Active Aging" (<http://www.epa.gov/aging/docs/growing-smarter-living-healthier.pdf>). For more information on the effects of perinatal exposures, the University of California San Francisco has a Program on Reproduction and Environment that provides informational webinars, factsheets, the latest research and policy/advocacy information available at <http://www.prhe.ucsf.edu>.

Children's Environmental Health

Consider some of the current childhood health statistics with which environmental factors are associated: approximately 9% of American children suffer from asthma, with higher rates in black children (CDC, 2012). About 20% of the world's children and adolescents suffer from a mental health problem (WHO, n.d.), and this statistic is mirrored in the United States (DHHS, 2005). The CDC monitoring system for autism spectrum disorders reports that the prevalence of autism among 8-year-olds in the United States is 1 in every 68 children (CDC, 2014a). The global prevalence of autism has increased twentyfold to thirtyfold since the earliest epidemiologic studies were conducted in the late 1960s and early 1970s. And millions of homes in the United States continue to have chipping and peeling lead-based paint.

Developmental disorders and attention deficit hyperactivity disorder (ADHD) collectively are estimated to affect 17% of school-age children (AHRQ, 2002; Anney et al, 2006). Child obesity has doubled and adolescent obesity has more than quadrupled in the last 30 years (CDC, 2014b). From 1975 to 2010 the incidence rates for 4 cancer types, acute lymphocytic leukemia, non-Hodgkin lymphoma, acute myeloid leukemia, and testicular germ cell tumors, increased in children (ACS, 2014). The most common cancers among children ages 0 through 14 are acute lymphocytic leukemia, brain and CNS, neuroblastoma, and non-Hodgkin lymphoma (ACS, 2014, p. 25). "All cancers involve the malfunction of genes that control cell growth and division. Only a small proportion of cancers are strongly hereditary..." (ACS, 2014, p. 1). According to the American Cancer Society (ACS), about 5% of all cancers are strongly associated with heredity (ACS, 2010). The rest occur from environmental exposures, lifestyle choices (diet, smoking, etc.), and other factors during our lifetimes.

Over the past 25 years there has been great improvement in the 5-year survival rate of major childhood cancers. The 5-year

survival rate for children for all cancer sites improved from 58% for those diagnosed between 1975 and 1977 to 81% for children diagnosed between 1999 and 2007 (Jemal et al, 2010). The list of possible causes of children's cancers includes the following: genetic abnormalities, ultraviolet and ionizing radiation, electromagnetic fields, viral infections, certain medications, food additives, tobacco, alcohol, and industrial and agricultural chemicals (Ross and Olshan, 2004; Bassil et al, 2007). Clearly, the environment is playing an important role.

EVIDENCE-BASED PRACTICE

Gilden et al examined the use of pesticides on athletic fields where children play sports. This cross-sectional descriptive study used a survey to assess playing field maintenance practices related to the use of pesticides on the field. The authors gave the survey to 33 field managers in order to assess maintenance practices. Their data were analyzed using descriptive statistics and generalized estimating equations.

They found that 65.3% of the managers said they applied pesticides, primarily herbicides, to the fields. They also found that managers of urban and suburban fields were less likely to apply pesticides than were managers of rural fields. The use of pesticides presents many health hazards, and the results of this study demonstrated that children who engage in sports activities on athletic fields are exposed to health hazards.

- Nurse Use: Nurses can inform people such as school officials, coaches, and field managers of the dangers of using pesticides on athletic fields.

Gilden R, Friedmann E, Sattler B, et al: Potential health effects related to pesticide use on athletic fields. *Public Health Nursing* 29(3):198-207, May/June 2012.

Children are not just little adults. They are different in many ways, particularly with regard to their exposures and responses to the environment. As nurses, we know that infants and young children breathe more rapidly than adults, and this increase in respiratory rate translates to a proportionately greater exposure to air pollutants. While infants' lungs are developing they are particularly susceptible to environmental **toxics**. Although full function of the lungs is attained at approximately age 6, changes continue to occur in the lungs through adolescence (Dietert et al, 2000). Children are short and, as such, their breathing zones are lower than adults, causing them to have closer contact to the chemical and biological agents that accumulate on floors and carpeting. Children of color and poor children in America are disproportionately affected by a range of environmental health threats, including lead, air pollution, pesticides, incinerator emissions, and exposures from hazardous waste sites (Suk and Davis, 2008; Landrigan et al, 2010).

In clinical settings, there is little that can be done to address a child's body burden of toxic chemicals; however, the nursing community as a profession has a weighty obligation to understand the science and risks associated with environmental pollutants and to engage in the political and economic decisions regulating the environment that have a profound effect on human health, especially the health of our children. This engagement occurs in policy-making arenas including legislative, regulatory, and international treaties. Nurses have increasingly become involved in the policy arena. The Alliance of Nurses for Healthy Environments is actively engaging nurses in

state and federal chemical policies and energy policies (including fracking) as they relate to health, and policies related to sustainable foods.

Children's bodies also operate differently. Some of the protective mechanisms that are well developed in adults, like the blood–brain barrier, are immature in young children, thereby increasing their vulnerability to the effects of toxic chemicals. And finally, the kidneys of young children are less effective at filtering out undesirable toxic chemicals, and these chemicals then continue to circulate and accumulate.

Infants and young children drink more fluids per body weight than adults, thus increasing the dose of contaminants found in their drinking water, milk (hormones and antibiotics), and juices (particularly pesticides). If an adult were to drink a proportionate amount of water to an infant, the adult would have to drink about 50 glasses of water a day. Children also eat more per body weight, eat different proportions of food, and absorb food differently than adults (EPA, 2013). How many adults could eat the same amount of raisins pound-for-pound as the average 2-year-old? Children consume much greater quantities of fruits and fruit juices than adults, once again adding exposure to doses of pesticide residues. The average 1-year-old drinks 21 times more apple juice, 11 times more grape juice, and nearly 5 times more orange juice per unit of body weight than the average adult (Rawn et al, 2004). The Food Quality Protection Act (FQPA) was passed to specifically address the consumption patterns and special vulnerabilities of children (Box 10-5).

BOX 10-5 Provisions Under the Food Quality Protection Act Regarding Pesticide Exposure to Children from Multiple Sources

New provisions under the Food Quality Protection Act of 1996 related to protection of infants and children:

Health-based standard: A new standard of a reasonable certainty of “no harm” that prohibits taking into account economic considerations when children are at risk.

Additional margin of safety: Requires that the EPA use an additional 10-fold margin of safety when there are adequate data to assess prenatal and postnatal development risks.

Account for children's diet: Requires the use of age-appropriate estimates of dietary consumption in establishing allowable levels of pesticides on food to account for children's unique dietary patterns.

Account for all exposures: In establishing acceptable levels of a pesticide on food, the EPA must account for exposures that may occur through other routes, such as drinking water and residential application of the pesticide.

Cumulative impact: The EPA must consider the cumulative impact of all pesticides that may share a common mechanism of action.

Tolerance reassessments: All existing pesticide food standards must be reassessed over a 10-year period to ensure that they meet the new standards to protect children.

Endocrine disruption testing: The EPA must screen and test all pesticides and pesticide ingredients for estrogen effects and other endocrine disruptor activity.

Registration renewal: Establishes a 15-year renewal process for all pesticides to ensure that they have up-to-date science evaluations over time.

From Environmental Protection Agency: Food Quality Protection Act of 1996. Available at <http://www.epa.gov/pesticides/regulation/laws/fqpa/>. Accessed December 15, 2010.

Toxic chemicals can have different effects depending on the timing of exposure. During fetal development, there are periods of exquisite sensitivity to the effects of toxic chemicals. During such times, even extraordinarily small exposures can prevent or change a process that may permanently affect normal development. The brain undergoes rapid structural and functional changes during late pregnancy and in the neonatal period. Therefore, it is extremely important to safeguard women's environments when they are pregnant (Table 10-1).

Alarming, 27 states have issued mercury contamination advisories for fish in every lake and river within their state's borders (EPA, 2009). According to the EPA, more than 1 million women in the United States of childbearing age eat sufficient amounts of mercury-contaminated fish to risk damaging brain development of their children. Nurses in all settings need to understand the implications that the fish advisories have for their clients and communities, and the contribution that the health sector has in creating this health risk, while at the same time counseling on the positive contribution of fish to a nutritionally balanced diet.

About 84,000 chemicals are used in commerce in the United States (EPA, 2014). Almost all are man-made; 15,000 of them are produced annually in quantities greater than 10,000 lb and 2800 of them are produced in quantities greater than 1 million pounds per year (Goldman and Koduru, 2000). Of the 2,800, only 7% have been tested for developmental effects and only 43% have been tested for any human health effects.

Companies are not required to divulge the results of their private testing. A full battery of neurotoxicity tests is not required even for pesticides that may be sprayed in nurseries and labor and delivery areas, not to mention in homes. To make things even more complicated, risks from multiple chemical exposures are rarely considered when regulations are drafted. Such an omission ignores the reality that both children and adults are exposed to many toxic chemicals, often concurrently. The only exception to this rule is in the case of regulations regarding pesticides that are used on food (Figure 10-4). This exception was created by the 1996 FQPA, in which Congress acknowledged that children eat foods that may be contaminated by more than one pesticide residue. See Box 10-5 for the provisions under the FQPA.

PRECAUTIONARY PRINCIPLE

With thousands of chemical compounds now creating a chemical soup in our air and water (and in our bodies, in our breast milk), it is increasingly difficult to prove specific hypotheses regarding the relationship of exposure to a singular chemical and disease outcome in humans. It has been suggested that we adopt a precautionary approach when research and other indicators demonstrate a possible toxic relationship between a chemical and health. Box 10-6 presents the *Wingspread Statement on the Precautionary Principle*. This precautionary approach calls for action to reduce potentially toxic exposure to humans in light of data or other indicators, rather than delaying until more “conclusive” studies are performed. We will never have the perfect studies. Nurses, who are trained in disease

TABLE 10-1 Workplace Hazards to Women of Reproductive Age*

Agent	Observed Effects	Potentially Exposed Workers
Cancer treatment drugs (e.g., methotrexate)	Infertility, miscarriage, birth defects, low birth weight	Health care workers, pharmacists
Organic solvents (e.g., toluene, xylene, formaldehyde)	Miscarriage	Health care workers, laboratory workers, print shop and manufacturing employees
Lead	Infertility, miscarriage, low birth weight, developmental disorders	Battery makers, solderers, welders, bridge repainters, firing range workers, home remodelers
Strenuous physical labor (e.g., prolonged standing, shift/night work)	Miscarriage, preterm delivery	Many types of workers
Cytomegalovirus	Birth defects, low birth weight, developmental disorders	Health care workers, workers who have contact with infants and children
Parvovirus B19	Miscarriage	Health care workers, workers who have contact with infants and children
Rubella	Birth defects, low birth weight	Health care workers, workers in who have contact with infants and children
Toxoplasmosis	Miscarriage, birth defects, developmental disorders	Animal care workers, veterinarians
Varicella zoster	Birth defects, low birth weight	Health care workers, workers who have contact with infants and children

*This list is not complete. Information about these hazards is constantly being revised. Readers should not assume that a substance is safe if it is missing from this list.

Source: National Institute for Occupational Safety and Health (www.cdc.gov/niosh/99-104.html)

FIG 10-4 Aerial application of agricultural pesticides makes it very difficult to control exposures. The chemicals get tracked into homes in farming communities. (Copyright © 2011 Photos.com, a division of Getty Images. All rights reserved. Photo #87531230.)

prevention, appreciate and should advocate for a precautionary approach when it may prevent injuries or illnesses. The ANA has adopted the **precautionary principle** as the basic tenet on which to guide its environmental advocacy work.

The bottom line is that life depends on the environment, and what humans do collectively can affect this vital resource for present and future generations. A central concept in Native American cultures is that humans are stewards, not proprietors, of the environment. Native Americans make the “Rule of Seven” central to all environmental decisions: What will be the effect

on the seventh generation? A quote ([Myths-Dreams-Symbols, 2006](#)) attributed to Chief Seattle, a nineteenth-century Native American, illustrates the need to think more holistically when we consider environmental impacts: “Whatever befalls the earth befalls the sons of the earth. Man did not weave the web of life; he is merely a strand in it. Whatever he does to the web, he does to himself.” McDonough suggests that, as we make policies, plans, and designs, we ask ourselves how these decision are evidence that “we love all the children of all the species for all times” ([Huff interview with McDonough, 2013](#)).

Mary O’Brien, in her book *Making Better Environmental Decisions: An Alternative to Risk Assessments*, notes that we are repeatedly given a very short list of risk reduction choices, and that the public is not effectively engaged in the decision-making process. She suggests that a broader range of options would allow us to see the possibilities for further reducing (or even eliminating) risks and that the process should be much more democratic in nature. O’Brien suggests the best approach to making effective environmental decisions is to use information, emotion, and a sense of relationship to others concurrently. By “others” she means other species, cultures, and generations (O’Brien, 2000). Her method is consistent with a nursing approach. Using her approach will require that nurses more actively engage in environmental health—assessing environmental health risks, developing risk reduction strategies, and supporting policies that embrace the precautionary principle and care for all of the children of all of the species for all times.

ENVIRONMENTAL HEALTH RISK REDUCTION

Prevention is a core goal in every public health intervention. Preventing problems is less costly whether the cost is measured in resources consumed or in human health effects. Policies, as well as practices, can promote primary prevention. After we have assessed the environmental risks in our communities, we

BOX 10-6 Wingspread Statement on the Precautionary Principle

In 1998 an international group of health and public health professionals, scientists, government officials, lawyers, grassroots activists, and labor activists met at a conference center called “Wingspread” in Wisconsin to define the “precautionary principle.” The group issued the following consensus statement:

The release and use of toxic substances, the exploitation of resources, and physical alterations of the environment have had substantial unintended consequences affecting human health and the environment. Some of these concerns are high rates of learning deficiencies, asthma, cancer, birth defects and species extinctions, along with global climate change, stratospheric ozone depletion and worldwide contamination with toxic substances and nuclear materials.

We believe existing environmental regulations and other decisions, particularly those based on risk assessment, have failed to protect adequately human health and the environment the larger system of which humans are but a part.

We believe there is compelling evidence that damage to humans and the worldwide environment is of such magnitude and seriousness that new principles for conducting human activities are necessary.

While we realize that human activities may involve hazards, people must proceed more carefully than has been the case in recent history. Corporations, government entities, organizations, communities, scientists and other individuals must adopt a precautionary approach to all human endeavors.

Therefore, it is necessary to implement the Precautionary Principle: When an activity raises threats of harm to human health or the environment, precautionary measures should be taken even if some cause and effect relationships are not fully established scientifically. In this context the proponent of an activity, rather than the public, should bear the burden of proof.

The process of applying the Precautionary Principle must be open, informed and democratic and must include potentially affected parties. It must also involve an examination of the full range of alternatives, including no action.

Wingspread Statement on the Precautionary Principle, Racine WI, 1998. Available at <http://www.gdrc.org/u-gov/precaution-3.html>. Retrieved March 12, 2015.

can apply the basic principles of disease prevention when planning intervention strategies. For lead exposure, remediating a home with lead-based paint to make it lead safe applies the primary prevention strategy of removing the exposure (at least from that specific source of lead) (Figure 10-5). Even good lead poisoning surveillance will not prevent lead exposure, but may help with early detection of rising blood lead levels. Such surveillance is a secondary prevention strategy. Finally, when a symptomatic child is seen, it is important to have a health care system readily available in which specialists familiar with lead poisoning will provide swift medical interventions to reduce blood lead levels, thus reducing the risk of further harm. This is a tertiary prevention response. Box 10-7 presents examples of risk reduction strategies for nurses in the health care setting.

Industrial Hygiene Hierarchy of Controls

For workplace exposures, industrial hygienists have developed a “hierarchy of control” for avoiding or minimizing employee

FIG 10-5 Lead can be found in many places in a home. Nurses should help families learn about these sources and take actions to remove any lead-based paint using certified professionals. Good hygiene is key to reducing lead dust exposure, especially given that urban soot will often have lead from the legacy of lead used in gasoline for many decades. (From U.S. Environmental Protection Agency. Available at <http://www.epa.gov/lead/pubs/leadpdf.pdf>. Accessed December 29, 2010.)

exposures to potentially hazardous chemicals. Industrial hygienists are public health professionals who specialize in workplace exposures to hazards—physical, chemical, and biological—that create the conditions for health risks (Box 10-8 presents the **industrial hygiene hierarchy of controls**). Once it is established that a human health threat exists, develop a plan of action—a way of eliminating or managing (reducing) the risk. **Risk management** should be informed by the risk assessment process and involves the selection and implementation of a strategy to eliminate or reduce risks.

Box 10-9 lists the 3 Rs for reducing environmental pollution.

Nursing interventions to reduce environmental health risks can take many forms. Education is one example of a nursing intervention. By working with a wide array of community

BOX 10-7 Risk Reduction: Every Nurse's Role

In the health care setting (hospital, clinic, home health), we have many opportunities to make environmentally friendly and healthy choices:

- Shift to electronic records, thus avoiding the use of paper. When paper is a must, use products that are made from recycled ingredients
- Recycle: paper, glass, cans, plastic, small batteries, blue wrap, electronic equipment
- Work with suppliers to get products with minimum packaging and the safest ingredients possible: "environmentally preferable purchasing"
- Promote the use of green cleaners
- Go fragrance free by using fragrance-free products in the hospital and creating a policy that requires employees to use fragrance-free personal care products (shampoos, creams, etc.)
- Turn off lights AND computers AND patient monitoring equipment when rooms are not being used
- Report leaky sinks, toilets, and other plumbing sources
- Promote the purchase of local, sustainably grown foods (with a preference for organic, no use of GMOs, no use of unnecessary antibiotics, and no pesticides)
- Start a hospital/clinic/health department garden
- Start a Green Team, or join the existing one in your institution
- Create community while doing these activities and build relationships—it makes the whole process more meaningful and fun!

BOX 10-8 Industrial Hygiene Hierarchy of Controls

Eliminate unnecessary toxic chemicals.

Substitute less hazardous or nonhazardous substances (e.g., using water-based vs. solvent-based products).

Isolate the hazardous chemicals from human exposure (e.g., use closed systems).

Apply engineering controls (e.g., ventilation systems, including exhaust hoods).

Reduce the exposures through **administrative controls** (e.g., rotating employees in areas with high exposures).

Use **personal protective equipment** (e.g., gloves, respirators, protective clothing).

*In addition, education is a critical tool in the hierarchy of controls. Modified from Levy B, Wegman D: Occupational health: recognizing and preventing work-related disease and injury, ed 4, Philadelphia, 2000, Lippincott Williams & Wilkins.

BOX 10-9 The 3 Rs for Reducing Environmental Pollution

The "3 Rs" adage of the environmentalist community—*reduce*, *reuse*, and *recycle*—helps us consider ways to decrease our personal impact on the environment, and thereby decrease environmental health risks. These concepts can apply to our health care settings, as well as our homes. By recycling, we prevent the need to extract more resources from the earth to manufacture products. By recycling, we also prevent products from unnecessary landfilling or incineration. Choosing reusable products, versus single-use devices and products, similarly prevents the need for manufacturing more products and decreases the waste stream. Reducing our waste stream can also be accomplished generally by a reduction in consumption (buying less "stuff," as well as by reducing unnecessary packaging and other nonessential goods). The "Story of Stuff" (www.thestoryofstuff.org) provides an excellent overview of the "cradle to grave" travels of products and the full range of their human and ecological impacts.

members, nurses can help a community understand the relationship between harmful environmental exposures and human health and guide the community toward risk reduction on the basis of both individual behavior changes, as well as community-wide approaches. In communities in which radon is likely to be a naturally occurring exposure, nurses can educate the community about the health risks, methods to measure radon levels in a home, and how to address unhealthy radon levels.

Nurses work with individuals, families, and communities in all three levels of prevention. For example, in Planned Parenthood Clinics in the United States, as a form of primary prevention, clinicians ask clients about possible environmental health risks in their everyday lives and then direct them to safer products and healthier behaviors to decrease potentially toxic exposures. Secondary prevention takes place when pediatric clinics include lead screening as part of their protocols. By doing so they are apt to find children with elevated blood lead levels, which then allow them to act to decrease the child's environmental lead exposures. This form of secondary prevention does not actually prevent the exposure but calls for action based on evidence of exposure. If a child has a seriously high blood lead level, the child would be admitted to the hospital for chelation therapy which is a process used to decrease the body's burden of lead.

LEVELS OF PREVENTION

Example Applied to Lead-Based Paint Exposure

Primary Prevention

Eliminate lead-based paint and lead-based paint dust from the home.

Secondary Prevention

Provide blood lead testing of children in communities with older housing stock.

Tertiary Prevention

When a child presents with extremely elevated blood lead levels, make sure the child is being cared for by a health professional who is familiar with clinical interventions to reduce blood lead levels using clinical (chelating medications) interventions, **while concurrently assuring that the child returns to a lead-safe place.**

The clinical intervention is tertiary prevention. It neither prevents the exposure, nor focuses on decreasing the exposure, but rather focuses on decreasing the potential health sequela associated with elevated lead levels.

Risk Communication

Risk communication is both an area of practice and a skill that is a composite of two separate words: "risk" and "communication." *Risk* is a familiar term in nursing practice. It is understood in the health context when we counsel patients about the risks of pregnancy, communicable disease (especially sexually transmitted disease), unintentional injury, and risk associated with personal choices (e.g., smoking, alcohol consumption, and diet). Risk assessment in environmental health focuses on characterizing the hazard (the "source"), its physical and chemical properties, its toxicity, and the potential exposure pathways—mode of transmission, **route of exposure**, receptor population, and dose. In their seminal work on risk communication,

BOX 10-10 Definitions of Risk

Risk has traditionally been defined by the following equation:

$$\text{Risk} = \text{magnitude} \times \text{probability}$$

There is a growing body of literature from practitioners and researchers who have studied the human reaction to risk—real and perceived. Sandman et al (1991) were the first to examine the “outrage” factor that can influence the way in which we perceive risk, particularly to environmental risks.

$$\text{Risk} = \text{hazard} + \text{outrage}$$

Addressing only the hazard is doing only half of the necessary work; addressing the response (outrage) is equally important.

From Sandman PM, Chess C, Hane BJ: Improving dialogue with communities, New Brunswick, NJ, 1991, Rutgers University.

BOX 10-11 Outrage Factors: Characteristics of Risk That Contribute to the Public’s Feeling of Outrage

Safer = Less Outrage	Less Safe = More Outrage
12 Principal Outrage Components	
Voluntary	Involuntary (coerced)
Natural	Industrial (artificial)
Familiar	Exotic
Not memorable	Memorable
Not dreaded	Dreaded
Chronic	Catastrophic
Knowable (detectable)	Unknowable (undetectable)
Individually controlled	Controlled by others
Fair	Unfair
Morally irrelevant	Morally relevant
Trustworthy sources	Untrustworthy sources
Responsive process	Unresponsive process

Sandman, Chess, and Hane (1991) noted that risk has traditionally been formulated as magnitude (the size, severity, extent of area, or population affected) multiplied by the probability (how likely exposure or damage is to occur) (Box 10-10). For example, an environmental risk assessment of a contaminated site would involve a calculation of the dose that might be received through all routes of exposure, the toxicity of the chemical, the size and vulnerability (age, health) of the population potentially exposed (resident, future resident, transient), and the likelihood of exposure. Sandman et al (1991) also noted that the reaction to things that scare people and the things that kill people are often not related to the actual hazard. They have gone further to probe what is behind those differences and identified a list of “outrage factors” to explain people’s responses to risk (Box 10-11). They maintain that the outrage is just as predictable and open to intervention as the science of addressing the hazard.

“Communication” of risk involves understanding the outrage factors relevant to the risk being addressed so they can be incorporated in the message—the information—either to create action to ensure safety or prevent harm or to reduce unnecessary fear. An example of raising outrage to produce action can be seen in the shift from emphasis on smokers (voluntary) to

victims of passive smoking (involuntary) to stimulate public policy that limits or bans smoking in public places. When the emphasis on risk went from a voluntary choice of smokers to an involuntary exposure of nonsmokers, the outrage level of the nonsmoking public became high enough to result in legislation guaranteeing smoke-free public spaces (e.g., public buildings, airplanes, and restaurants).

On the other hand, outrage decreases when people receive information on the situation from a trusted source, and physicians and nurses are often cited in surveys as trusted sources of information on environmental risks (Kaiser Foundation, 2013). The public trust is a compelling incentive to match professional knowledge and skills to a community’s expectations. The outrage factor can also be a driving force in building credibility and trustworthiness in every person whose work involves interacting with the public.

Risk communication includes all the principles of good communication in general. It is a combination of the following:

- *The right information:* Accurate, relevant, in a language that audiences can understand. A good risk assessment is essential information for shaping the message.
- *To the right people:* Those affected and those who are worried but may not be affected. Information on the community is essential: geographic boundaries, who lives there (i.e., demographics), how they obtain information (e.g., flyers or newspapers, radio, television, word of mouth), where they congregate (e.g., school, church, community center), and who within the community can help plan the communication.
- *At the right time:* For timely action or to allay fear.

GOVERNMENTAL ENVIRONMENTAL PROTECTION

The government has a variety of tools to address environmental exposures. In addition to passing legislation, creating and enforcing standards and regulations, deciding how land should be used, providing permits, and supporting research, the government is actively engaged in educating the public. Many federal agencies are involved in environmental health regulation, such as the EPA, the FDA, and the Department of Agriculture. The Department of Health and Human Services (DHHS) has two major research institutes, the National Institute of Environmental Health Science (NIEHS) and the National Institute of Occupational Safety and Health (NIOSH). Within DHHS is the CDC (which includes the National Center for Environmental Health [NCEH] that is responsible for tracking environmental health trends, recommending clinical and public health practices, and also engaging in research). Every state has an agency responsible for environmental quality. At the city or county level, the local health department most often manages environmental health issues. However, environmental protection issues are typically directed by the state using both federal and state laws. Box 10-12 lists key environmental protection laws.

Potentially harmful pollution that cannot be prevented must be controlled. An important step in the process of controlling pollution is permitting, a process by which the government

BOX 10-12 Environmental Laws**National Environmental Policy Act (NEPA)**

The NEPA established the Environmental Protection Agency (EPA) and a national policy for the environment and provides for the establishment of a Council on Environmental Policy. All policies, regulations, and public laws shall be interpreted and administered in accordance with the policies set forth in this act.

Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA)

FIFRA provides federal control of pesticide distribution, sale, and use. The EPA was given the authority to study the consequences of pesticide usage and requires users such as farmers and utility companies to register when using pesticides. Later amendments to the law required applicators to take certification examinations, registration of all pesticides used in the United States, and proper labeling of pesticides that, if in accordance with specifications, will cause no harm to the environment (summary from [FIFRA, 1972](#)).

Clean Water Act (CWA)

The CWA sets basic structure for regulating pollutants to U.S. waters. The law gave the EPA the authority to set effluent standards on an industry basis and continued the requirements to set water quality standards for all contaminants in surface water. The 1977 amendments focused on toxic pollutants. In 1987 the CWA was reauthorized, and again focused on toxic pollutants, authorized citizen suit provisions, and funded sewage treatment plants.

Clean Air Act (CAA)

The Clean Air Act regulates air emissions from aerial, stationary, and mobile sources. The EPA was authorized to establish National Ambient Air Quality Standards (NAAQS) to protect public health and the environment. The goal was to set and achieve the NAAQS by 1975. The law was amended in 1977 when many areas of the country failed to meet the standards. The 1990 amendments to the Clean Air Act intended to meet unaddressed or insufficiently addressed problems such as acid rain, ground level ozone, stratospheric ozone depletion, and air toxics. Also in the 1990 reauthorization was a mandate for Chemical Risk Management Plans. This mandate requires industry to identify “worst case scenarios” regarding the hazardous chemicals that they transport, use, or discard (summary from [Clean Air Act, 1970](#)).

Occupational Safety and Health Act (OSHA)

The OSHA was passed to ensure worker and workplace safety. The goal was to make sure employers provide an employment place free of hazards to health and safety such as chemicals, excessive noise, mechanical dangers, heat or cold extremes, or unsanitary conditions. To establish standards for the workplace, the Act also created NIOSH (National Institute for Occupational Safety and Health) as the research institution for OSHA.

Safe Drinking Water Act (SDWA)

The SDWA was established to protect the quality of drinking water in the United States. The Act authorized the EPA to establish safe standards of purity and required all owners or operators of public water systems to comply with primary (health-related) standards.

Resource Conservation and Recovery Act (RCRA)

The RCRA gave the EPA the authority to control the generation, transportation, treatment, storage, and disposal of hazardous waste. The RCRA also proposed a framework to manage nonhazardous waste. The 1984 Federal Hazardous and Solid Waste Amendments to this Act required phasing out land disposal of hazardous waste. The 1986 amendments enabled the EPA to address problems from underground tanks storing petroleum and other hazardous substances.

Toxic Substances Control Act (TSCA)

The TSCA gives the EPA the ability to track the 75,000 industrial chemicals currently produced in or imported into the United States. The EPA can require

reporting or testing of chemicals that may pose environmental health risks and can ban the manufacture and import of those chemicals that pose an unreasonable risk. TSCA supplements the Clean Air Act and the Toxic Release Inventory.

Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA or Superfund)

This law created a tax on the chemical and petroleum industries and provided broad federal authority to respond directly to releases or threatened releases of hazardous substances that may endanger public health or the environment.

Superfund Amendments and Reauthorization Act (SARA)

SARA amended the Comprehensive Environmental Response, Compensation, and Liability Act with several changes and additions. These changes included increased size of the trust fund; encouragement of greater citizen participation in decision making on how sites should be cleaned up; increased state involvement in every phase of the Superfund program; increased focus on human health problems related to hazardous waste sites; new enforcement authorities and settlement tools; emphasis on the importance of permanent remedies and innovative treatment technologies in clean-up of hazardous waste sites; and Superfund actions to consider standards in other federal and state regulations. (Under Superfund legislation, the Federal Agency for Toxic Substances and Disease Registry was established.)

Emergency Planning and Community Right to Know Act (EPCRA)

The EPCRA, also known as Title III of SARA, was enacted to help local communities protect public health safety and the environment from chemical hazards. Each state was required to appoint a State Emergency Response Commission that was required to divide their state into Emergency Planning Districts and establish a Local Emergency Planning Committee (LEPC) for each district.

National Environmental Education Act

The National Environmental Education Act created a new and better coordinated environmental education emphasis at the EPA. It created the National Environmental Education and Training Foundation.

Pollution Prevention Act (PPA)

The PPA focused industry, government, and public attention on reduction of the amount of pollution through cost-effective changes in production, operation, and use of raw materials. Pollution prevention also includes other practices that increase efficient use of energy, water, and other water resources, such as recycling, source reduction, and sustainable agriculture.

Food Quality Protection Act (FQPA)

The FQPA amended the Federal Insecticide, Fungicide, and Rodenticide Act and the Federal Food, Drug, and Cosmetic Act. The Act changed the way the EPA regulates pesticides. The requirements included a new safety standard of reasonable certainty of no harm to be applied to all pesticides used on foods.

Chemical Safety Information, Site Security, and Fuels Regulatory Act (Amendment to Section 112 of Clean Air Act)

This act removed from coverage by the Risk Management Plan (RMP) any flammable fuel when used as fuel or held for sale as fuel by a retail facility (flammable fuels used as a feedstock or held for sale as a fuel at a wholesale facility are still covered). This Act required certain facilities to have in place a risk management program and submit a summary of that program, called a Risk Management Plan (RMP) to the EPA. The law has two distinct parts that pertain to: flammable fuels and public access to Off-Site Consequence Analysis (OCA) data. OCA is “worst-case scenario” data.

places limits on the amount of pollution emitted into the air or water. A **permit** is a legally binding document.

Environmental standards may describe a permitted level of emissions, a maximum contaminant level (MCL), an action level for environmental clean-up, or a risk-based calculation; environmental standards are required to address health risks. It is the responsibility of potential polluters to operate within the regulations and standards. Compliance and enforcement are the next building blocks in controlling pollution. **Compliance** refers to the processes for ensuring that permit/standard/regulatory requirements are met. Clean-up or remediation of environmental damage is another control step. Public information and involvement processes, such as citizen advisory panels or community forums, are integral to the development of standards, on-going **monitoring**, and remediation.

POLICY AND ADVOCACY

There are almost 3 million nurses in the United States today—approximately 1 in every 100 Americans is a registered nurse! Nurses can and should be a strong voice for a healthy environment. As informed citizens, nurses can take a variety of actions to protect the environmental health of families, clients, and communities. Nurses are perceived as trusted messengers and as reliable sources of environmental health information and as such, have a responsibility to be informed and take action in the best interest of public health. Often, legislators are called to vote on environmental legislation without a sound understanding of how the legislation may affect public health. Nurses can serve as a resource for state and federal legislators and their staff. Although every nurse may not be an expert in all aspects of environmental health, every nurse does have a basic education in human health and has a sufficient understanding of who may be most vulnerable to environmental insult. Nurses' thoughts about the potential impacts of new laws on the health of individuals and communities are valuable to legislators and other policy makers, as well as the public.

Grounded in science and using sound risk communication skills, nurses become the most credible sources of information at community gatherings, formal governmental hearings, and professional nursing forums. Nurses work as advocates for environmental justice so that all members of the community have a right to live and work in an environment that is healthy and safe (Mood, 2002). Public health nurses also volunteer to serve on state, local, or federal commissions, and they know about zoning and permit laws that regulate the impact of industry and land use on the community. Many nurse legislators began their careers by advocating for the rights of others. Nurses must read, listen, and ask questions. Then, as informed citizens, they will be leaders, fostering community action to address environmental health threats.

In 2008 the Alliance of Nurses for Healthy Environments was created to coalesce individual nurses and nursing organizations around issues associated with the environmental exposures and human health. This organization addresses the integration of environmental health into nursing education, practice (including greening the health care sector), research, and advocacy.

Environmental Justice and Environmental Health Disparities

Some diseases differentially affect different populations. Certain environmental health risks disproportionately affect poor people and people of color in the United States. If you are a poor person of color, you are more likely to live near a hazardous waste site or an incinerator, and more likely to have children who are lead poisoned. You are also more likely to have children with asthma, which has a strong association with environmental exposures. Campaigns to improve the unequal burden of environmental risks in communities of color and in poor communities are striving to achieve **environmental justice** or environmental equity.

In 1993 the Environmental Justice Act was passed, and in 1994 Executive Order 12898, "Federal Actions to Address Environmental Justice in Minority Populations," was signed. This Act and the subsequent actions created policies to more comprehensively reduce the incidence of environmental *injustice* by mandating that every federal agency act in a manner to address and prevent illnesses and injuries. Nursing interventions and involvement in environmental health policies can have a significant effect on the health disparities experienced by our most challenged communities.

Environmental Health Threats from the Health Care Industry: New Opportunities for Advocacy

Many choices in the health care setting affect environmental health. Nurses often lead in reducing the use of mercury-containing products in hospitals. The use of mercury-containing thermometers and sphygmomanometers leads to a risk of breakage, which releases a highly toxic substance into the workplace. Further, when a hospital uses incineration to dispose of their waste, the mercury-containing products will create significant releases of mercury into the air, thus contaminating communities. This airborne mercury will be present in raindrops; when the airborne mercury lands on water bodies (e.g., lakes, rivers, or oceans), it is converted by the microorganisms in the water to methylmercury, which is highly toxic to humans. The **methylmercury** is then **bioaccumulated** in the fish: as larger fish eat smaller fish, the body burden of methylmercury increases significantly.

Many synthetic chemicals that contaminate the environment are referred to as **persistent bioaccumulative toxins** (PBTs) or **persistent organic pollutants** (POPs). These are chemicals that do not break down in air, water, or soil, or in the plant, animal, and human bodies to which they may be passed. Ultimately, since humans are at the top of the food chain, these chemicals may come to reside in our bodies. For instance, lead, which should not be found in the human body, can be found in the long bones of almost any human in the world because of its ubiquitous use and presence in our environment.

Dioxin, another pollutant that contaminates our communities, is created, in part, by the health care industry. Dioxins are created when we manufacture or burn (incinerate) products that contain chlorine, such as bleached white paper or polyvinyl chloride (PVC) plastics. When dioxins are released into the

environment, they are consumed by agricultural animals (e.g., beef and dairy cows, hogs, and poultry) and fish, where they are stored in fat cells as they work their way up the food chain. This phenomenon has resulted in dioxin deposition in breast tissue and been found in both cow and human milk. Virtually all women now have dioxin in their breast tissue. Dioxin, an endocrine-disrupting chemical and a strong carcinogen, is associated with several neurodevelopmental problems including learning disabilities and is now in every human's body. The solution to this problem is to stop releasing dioxins into the environment. In the health care setting, one way to eliminate the creation and release of dioxins is to stop using products like PVC plastics and selecting safer alternatives by employing environmentally preferable purchasing policies and practices.

An international campaign called Health Care Without Harm is working to reduce and eliminate mercury and PVC plastic in the health care industry, as well as the elimination of incineration of medical waste. The ANA was a founding member of the Health Care Without Harm campaign, and nurses have taken many leadership roles in the activities in the United States and around the world. The Health Care Without Harm website (<http://www.noharm.org>) provides outstanding information on greening hospitals and resources about pollution prevention in the health care sector.

REFERRAL RESOURCES

There is no one source of information about environmental health nor is there a single resource to which a public health nurse can refer an individual or community should an environmentally related problem be suspected. As mentioned earlier, the NLM's ToxTown is a great starting place, and it allows the interested browser to dig deeply into environmental health content. TOXNET has an amalgamation of important databases and environmental health literature and additional peer-reviewed environmental health literature. The EPA is another rich source of information (www.epa.gov). Use of the Internet

makes information widely accessible, but finding an actual person to assist you or the communities you serve may not be as easy. One starting point may be the environmental epidemiology unit or toxicology unit of the state health department or department of environmental quality. The Association of Occupational and Environmental Clinics (AOEC) (<http://www.aoec.org>) is a national network of specialty clinics and individual practitioners available for consultation and sometimes for provision of educational programs for health professionals. Through AOEC, you can also find the Pediatric Environmental Health Specialty Units; there are 10 throughout the country. These specialty units were specifically established to provide consultation on environmental health issues. Another local or state resource may be environmental health experts in nursing or medical schools or schools of public health.

Local resources include local health and environmental protection agencies; poison control centers; agricultural extension offices; and occupational and environmental departments in schools of medicine, nursing, and public health. Some local and state agencies have developed topical directories to assist in accessing the appropriate staff for specific questions. Many of the resources have websites that allow ready access through the Internet and can be located by using any of the popular search methods. Box 10-13 presents an extensive list of environmental health agency resources.

The most active advocates for environmental health policies are grassroots organizations, the big environmentalist organizations, and environmental justice organizations. To learn more about who these organizations are, see the Resource Section under nongovernmental organizations.

ROLES FOR NURSES IN ENVIRONMENTAL HEALTH

Nurses can be involved in many environmental health roles, in full-time work, as an adjunct to existing roles, and as informed citizens. Nurses who are passionate about this issue can develop

BOX 10-13 Information and Guidance Sources for Referrals

research expertise, sit on commissions, write articles, and take national leadership roles. All nurses can include environmental exposures in their history taking; consider the environmental impacts of the products they select for their clinics, hospitals, schools, and other settings; promote recycling and reuse of products; and promote environmentally preferable purchasing. Each type and level of engagement is important. The following are some ways in which nurses can get involved both professionally and as informed citizens:

- *Community involvement/public participation.* Organizing, facilitating, and moderating; making public notices effective and public forums accessible; welcoming input. Making information exchange understandable and problem solving acceptable to culturally diverse communities are valuable assets a nurse contributes. Skills in community organizing and mobilizing can be essential for a community to have a meaningful voice in decisions that affect them.
- *Individual and population risk assessment.* Using nursing assessment skills to detect potential and actual exposure pathways and outcomes for clients cared for in the acute, chronic, and healthy communities of practice.
- *Risk communication.* Interpreting, applying principles to practice. Nurses may serve as skilled risk communicators

within agencies, working for industries or working as independent practitioners. Amendments to the Clean Air Act require major industrial sources of air emissions to have risk management plans and to inform their neighbors of specifics of the risks and plans ([Clean Air Act, 1996](#)).

- *Epidemiologic investigations.* Nurses need to have the skills to respond in scientifically sound and humanely sensitive ways to community concerns about cancer, birth defects, and stillbirths when citizens fear environmental causation.
- *Policy development.* Proposing, informing, and monitoring action from agencies, communities, and organization perspectives.

The assimilation of the concepts of environmental health into a nurse's daily practice gives new life to traditional public health values of prevention, community building, and social justice. [Box 10-14](#) presents the work of three nurses currently working in environmental health.

As nurses learn more about the environment, opportunities for integration into their practice, education programs, research, advocacy, and policy work will become evident and will evolve. Opportunities abound for those pioneering spirits within the nursing profession who are dedicated to creating healthier environments for their clients and communities.

BOX 10-14 Examples of Three Modern-Day Environmental Health Nursing Pioneers

In Baltimore, MD, **Dr. Claudia Smith** (a nurse who is on the faculty at the University of Maryland) directed a project in which nurses worked with community members to address a variety of health problems associated with poor housing conditions. For this project, which was funded by the U.S. Department of Housing and Urban Development, Dr. Smith hired and trained community members to assess and reduce unhealthy conditions caused by lead-based paint, high levels of carbon monoxide, and asthma triggers (e.g., dust mites, pet dander, and pests); she taught community members about safer choices for pest control using the least toxic approach to pest management by using an integrated pest management approach.

After **Denise Choiniere**, a graduate student in community health who was working in the cardiac care unit (CCU) at the University of Maryland Medical Center, learned about the health effects associated with heavy metals, she was very uncomfortable with simply throwing away the batteries that were used in the many small devices, such as Holter monitors. Instead, she developed a battery recycling program for the CCU and the telemetry unit. She then discovered that her hospital purchased 97,000 small batteries every year. Each of these small batteries contains a heavy metal—mercury, lithium, cadmium, or lead. She was the driving force in developing a hospital-wide, small battery recycling program. This activity created a whole new career trajectory for Ms. Choiniere, who was recently appointed to the executive position of Sustainability Coordinator for the whole hospital. She has since addressed green cleaning products, promoted the recycling of “blue wrap” used in the operating rooms, and organized a farmers’ market that meets weekly in front of the hospital, thus bringing locally grown and sustainably farmed products to hospital employees and the surrounding community. She then was given oversight for all of the 650-bed hospital’s purchases.

Dr. Robyn Gilden is a nursing faculty member who worked for 5 years with communities that knew or suspected that they were living near a hazardous waste site. She learned about the many laws and agencies involved in hazardous waste site assessments and clean-ups. Hazardous wastes can affect soil, water,

and air. Sources of contamination may come from old, unlined landfills; uncontrolled dump sites; spills or discharges from industry; leaking underground storage tanks (like gasoline tanks); or runoff from fields. The Agency for Toxic Substances and Disease Registry (ATSDR), a federal agency responsible for documenting the health hazards associated with environmental exposures, maintains a listing of the most problematic contaminants found at polluted sites. They include a wide range of highly toxic chemicals including arsenic, lead, mercury, vinyl chloride, benzene, polychlorinated biphenyls (PCBs), and cadmium. These toxic chemicals top the list because they are the most commonly found contaminants and pose a significant threat to human health based on routes of exposure and level of toxicity. Dr. Gilden learned about the resources that are available for the best and most current toxicological information. The National Library of Medicine’s TOXNET and ATSDR’s websites, including their ToxFaq’s, are some of the best sources of navigable information.

In working with communities, Dr. Gilden met with government officials, including mayors of small towns, as well as concerned parents, people from local governments, health departments, educational institutions, businesses, developers, bankers, realtors, and other community members. She has also learned about the many statutes that cover hazardous waste sites, such as the Superfund legislation (which covers the most polluted waste sites) and Brownfields legislation (which covers contaminated sites where economic development is involved). Both these pieces of legislation mandate community involvement, which is where Dr. Gilden’s community health and risk communication skills are used. Regardless of who is responsible for or in charge of a contaminated site, the nurse understands that the community must be an active and equal participant. It is the community members who will be impacted by decisions and have to live with the results of clean-up and redevelopment. As is true of most nurses, Dr. Gilden quickly became a trusted person to the community members.

When she discovered the “Pesticide Warning” signs on the playing fields where her children played sports, this launched Dr. Gilden into a new area of research and advocacy regarding children’s exposures.

PRACTICE APPLICATION

Following are two case scenarios related to exposure pathways. The first involves lead poisoning and the second, fracking-related concerns.

At the county health department, a 3-year-old boy named Billy presents with gastric upset and behavioral changes. These symptoms have persisted for several weeks. During your history taking, you discover that Billy's parents have been renovating their old home. A parent in Billy's daycare center suggested that Billy's symptoms might be associated with lead, so Billy's parents have brought him in to the clinic.

You relay this information to the primary care practitioner who, in turn, orders a blood lead level, which comes back at 45 mcg/dL. This is a very high value.

You research lead poisoning and discover that there are many potential health effects of lead exposure and that children are at greatest risk because their bodies, especially their nervous systems, are still developing. You also find that chronic lead poisoning may lead to long-term effects, such as developmental delays and impaired learning ability.

You let the health professional know about the lead poisoning specialists in the nearby children's hospital. On further investigation, you find that Billy's home was built before 1950 and is still under renovation. Billy should not return to the home. At this point, the sanitarian from the local health department tests the dust in the home and finds high lead levels. Because of Billy's age and associated behaviors, such as

hand-to-mouth activities, you determine that the lead dust in the home is the probable exposure. However, you must also consider multiple sources of exposure.

1. What other sources of exposure might exist?
2. What would you include in an assessment of this situation?
3. What prevention strategies would you use to resolve this issue? At the individual level? At the population level?

Mrs. Bell calls the local health department to report that her drinking water, from their private well, is discolored and that her son has been experiencing headaches and nose bleeds. You talk with Dan, the health department's environmental health professional (sanitarian) who tells you that there is new "fracking" activity on the east side of your rural county, where Mrs. Bell and her family live, and that this may be the reason for the water discoloration and the child's symptoms. You look up "fracking" and discover that the word is shorthand for hydraulic fracturing, a new technique for extracting natural gas that is fraught with community and health concerns. (For more information on fracking, see the Resource Section.) Dan and you agree to make a site visit to the Bell's farm.

1. What will you be looking for on your visit?
2. How can you help the Bells, if any of their issues seem to be associated with the nearby fracking site?
3. What other experts are available to you and the Bells?

Answers can be found on the Evolve site.

KEY POINTS

- Nurses need to be informed professionals and advocates for citizens in their community regarding environmental health issues.
- Models describing the determinants of health acknowledge the role of the environment in health and disease.
- Climate change is creating profound risks to human health globally and in the United States.
- For most chemicals in our homes, work, schools, and communities, no research has been completed to determine whether or not they will cause health effects.
- Prevention activities include education, reduction/elimination of exposures, waste minimization, energy policies, and land use planning.
- Pollution control activities include use of technologies; environmental permitting; environmental standards, monitoring, compliance, and enforcement; and clean-up and remediation.
- Each nursing assessment should include questions and observations concerning potential and existing environmental exposures.
- Useful environmental exposure data are difficult to acquire. Those data that exist can be used to aid in the assessment, diagnosis, intervention, and evaluation of environmentally related health problems.
- Both case advocacy and class advocacy are important skills for nurses in environmental health practice.
- Risk communication is a critical skill and must acknowledge the outrage factor experienced by communities with environmental hazards.
- Federal, state, and local laws and regulations, as well as international treaties, exist to protect the health of people from environmental hazards.
- Environmental health practice engages multiple disciplines, and nurses are important members of the environmental health team.
- Environmental health practice includes principles of health promotion, disease prevention, and health protection.
- *Healthy People 2020* objectives address both targets for the reduction of risk factors and diseases related to environmental causes.

CLINICAL DECISION-MAKING ACTIVITIES

1. Explain why the source of drinking water is important to investigate in the assessment of an unusually high number of infertility cases in a community; in increased lead levels in children from a certain school; and in an outbreak of a gastrointestinal epidemic in an agricultural community.
2. Discuss the use of the epidemiologic triangle in explaining the determinants of health.
3. Discover if your jurisdiction has a law or regulation for the disclosure of lead-based paint or radon levels for personal property as part of the act of sale for real estate. If your community does not, investigate with the government officials of the community the reasons for the lack of a disclosure requirement.

Genomics in Public Health Nursing*

Elke Jones Zschaebitz, DNP, FNP-BC

Elke Jones Zschaebitz is a nurse practitioner who has worked in the fields of school health, pediatrics, and women's health, as well as in a telehealth practice in primary care. She received her BSN from Villanova University, her MSN-FNP from Midwestern State University in Wichita Falls Texas, and her DNP from Duquesne University in Pittsburgh, Pennsylvania. She currently is employed at the University of Virginia Student Health Center in Charlottesville, VA, and is part-time faculty for the Family Nurse Practitioner program at Georgetown University.

Jeanette Lancaster, PhD, RN, FAAN

Dr. Lancaster is Professor and Dean Emerita of Nursing at the University of Virginia. She has edited this book with Dr. Marcia Stanhope through its previous eight editions.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Define key terms related to genetics and genomics.
2. Discuss the history of genomics and its integration into public health nursing.
3. Describe the relationship between genomics, genetics, and nursing.
4. Explain the core competencies related to genomics that nurses and selected other public health professionals should integrate into their practice.
5. Describe at least three potential implications of persons knowing their genetic information on clients, families, and communities.

KEY TERMS

DNA, p. 245

epigenetics, p. 253

family health history, p. 251

genes, p. 245

genome, p. 243

genomics, p. 243

genetics, p. 243

genetic susceptibility, p. 254

Human Genome Project, p. 244

multifactorial diseases, p. 253

mutations, p. 245

pedigree, p. 251

—See Glossary for definitions

*Special thanks are given to Gia Mudd-Martin, RN, MPH, PhD, Assistant Professor, College of Nursing, University of Kentucky for reviewing the manuscript, providing public health nursing input, and providing two of the case examples for the 8th edition of the chapter.

CHAPTER OUTLINE

The Human Genome and Its Transforming Effect on Public Health

A Brief History of the Science

DNA and Its Relationship to Genomics and Genetics

The Challenges of Genetic and DNA Testing

Current Issues in Genomics and Genetics

Ethical and Legal Considerations

Personalized Health Care

Genomic Competencies for the Public Health Workforce

Incorporating Genomics and Genetics into Public Health Nursing Practice

Professional Practice Domain: Nursing Assessment:

Applying/Integrating Genetic and Genomic Knowledge
Identification

Referral

Provision of Education, Care, and Support

Application and Practice: Mapping out a Pedigree The Future

“Mapping the human genome is the outstanding achievement not only of our lifetime but in human history. This code is the essence of mankind, and as long as humans exist, this code is going to be important and will be used.”

**T. Michael Dexter, Director of
Wellcome Trust and contributor to the
Sanger Center for the Human Genome Project**

THE HUMAN GENOME AND ITS TRANSFORMING EFFECT ON PUBLIC HEALTH

The mapping of the human **genome** was a strategic inflection point in the history of health care that created a massive shift in how all health professionals provide care and how public health is approached. The understanding of the fundamental role genetics and genomics play in shaping the practice of public health nurses in the twenty-first century is in its early stages, although the rate of new knowledge is incredible. This chapter discusses the history of the field of genetics and genomics, what we know about genetics and genomics now, their impact on current nursing practice, and the prospects for significant changes in how nursing care is delivered. Clearly, nursing is being dramatically altered by new discoveries in molecular genetics. Examples of the effect on nursing include: (1) how nursing students are educated, (2) how nurses collect and use health histories, (3) how nurses learn and apply innovative biotechnology, (4) the role genetics and genomics will continue to play in traditional nursing arenas such as prevention and health education, (5) the administration of innovative and evolving therapies, (6) the role epigenetics has in current research of disease, and (7) in ongoing public health debates including the moral, ethical, legal, and social issues around this powerful new field of knowledge.

It is important to recognize that the fields of genetics and genomics are continuously evolving, extremely complex, and involve personal health and ethical dilemmas surrounding the emergence of personal DNA discoveries. They have enormous implications for the detection, prevention, and treatment of human disease, not to mention educational and economic development. Learning about genomics and genetics opens many new possibilities, such as in the prevention and treatment

of human maladies ranging from cancer to cystic fibrosis and from autism to Alzheimer’s disease. To understand the effects of this knowledge in public health and in nursing, it is important to pull key snapshots from this highly detailed landscape in order to begin to describe this new territory that nursing practice occupies. This chapter provides a general overview of the history of the development of this new science and briefly discusses the current state of the science of genetics and genomics in relation to the role of the nurse and the future implications for care of individuals, families, and populations. What is clear is that every nurse needs to become knowledgeable and to keep current with ongoing discoveries regarding genetics and genomics and their effects on populations.

In this chapter, the term **genetics** refers to the study of the function and effect of single genes that are inherited by children from their parents. **Genomics** is the study of all of a person’s genes, including their interaction with one another as well as the interaction of a person’s genes with the environment. Genomics examines the molecular mechanisms and the interplay of genetic and environmental, and of cultural and psychosocial, factors in disease. Genomics deals with the functions and interactions of all genes in an organism and is the study of the total DNA structure (Perry, 2011).

A BRIEF HISTORY OF THE SCIENCE

It is important to understand the evolution of genetic and genomic knowledge. The concept of this hereditary information began with agriculture in the eighteenth century by Gregor Mendel, an Austrian monk who is usually considered to be the father of genetics. At about the same time, Charles Darwin expounded on the theories of evolution, and Darwin’s cousin, Francis Galton, performed family studies using twins in an effort to understand the influence of heredity on various human characteristics.

A major breakthrough occurred on February 28, 1953, in Cambridge, England, when James Watson and Francis Crick announced that they had figured out the structure of deoxyribonucleic acid (DNA), and that this double-helix structure could unzip to make copies of itself—thus confirming that DNA carries life’s hereditary information, or the secret to life (McKusick, 2007). H.J. Muller later demonstrated the genetic

consequences of ionizing radiation on the fruit fly, and the theoretical basis of population genetics was developed by three prominent individuals: Ronald Fisher, J.B.S. Haldane, and Sewall Wright. Genetic diseases and their mode of inherited anomalies such as phenylketonuria, sickle cell disease, Huntington's disease, and cystic fibrosis were established. In the same decade that Watson and Crick discovered DNA, the correct specification of the number of human chromosomes was determined. Because of this 1956 discovery, one of the new findings in genetics included the discovery in 1959 that Down syndrome is caused by an extra copy of chromosome 21. The scientific revolution was underway.

To date, the **Human Genome Project** (HGP), an international research project funded by the U.S. Congress in 1988 and completed in 2003, has mapped all of the approximately 25,000 genes in human DNA. This enormous project reflects the work of scientists from 20 research centers in six countries: China, France, Germany, Japan, the United Kingdom, and the United States (**National Institutes of Health, 2014**). The stated goals of the HGP were *determining* the sequences of the 3 billion chemical base pairs that make up human DNA; *storing* this information in databases; *improving* tools for data analysis; *transferring* related technologies to the private sector; and *addressing* the ethical, legal, and social issues (ELSI) that may arise. The director of the Project was Francis Collins, MD. Dr. Collins and his team developed a conceptual vision for their work that had three overarching themes:

1. Genomes to biology to look at how the study of genomics would affect the future understanding of biology.
2. Genomes to health to help explain the underlying mechanisms for human health and disease including the gene-gene, gene-environment, and their interactions.
3. Genomes to society to provide the foundation for research to improve the use and interpretation of genetic and genomic information and technologies (**Collins et al, 2003**).

Interestingly, two key findings from early work to sequence the human genome were that all humans are 99.9% identical at the DNA level and nearly 25,000 genes make up the human genome (**Perry, 2011**). Most of the 0.1% of genetic variations are found within and not among populations. These findings have implications for public health with its emphasis on population health. Francis Collins, who directed the HGP, compared the project to a book that had many different uses. He said, "It's a history book: a narrative of the journal of our species through time. It's a shop manual, with an incredibly detailed blueprint for building every human cell. And it's a transformative book of medicine, with insights that will give healthcare providers immense new powers to treat, prevent, and cure disease" (**Collins, 2006**, p. 1).

Many implications for health care have emerged from this project, including ethical and moral dilemmas that continue to be challenging. As health information advances, genomics has influenced the availability of genetic tests. Clinical tests and home testing kits such as 23andMe, a direct-to-consumer personal genome service, are giving individuals and families information regarding ancestry. See www.23andme.com/ for more information on this test. Many of these tests have implications

for families, and it is important for nurses to help individuals and communities understand the purpose, limitations, potential benefits, and potential risks of a test before submitting samples for analysis. The controversies surrounding the information derived from tests, particularly home testing, include the trust and decision making individuals might make depending on the information derived. The Food and Drug Administration has urged the medical community to focus on educating health care providers and patients about the benefits—and limitations—of genetic testing (**Szoka, 2013**). The issues of genetic screening and prophylactic treatments alone are staggering and will require the full resources of the nursing profession to find answers. The following case illustrates many of the complex issues in genetics and genomics.

WHAT DO YOU THINK? Case Example: Screening for Breast or Ovarian Cancer Risk

During an initial visit to the High Risk Breast and Ovarian Cancer Clinic, a 37-year-old, Ms. Brown, a Medicaid patient referred to this specialty clinic from a primary care provider, reports that she had found a mass during a self-breast examination in 2006. She subsequently had the mass inspected by a clinician and underwent a mammogram, which showed a suspicious finding. A breast core-biopsy was performed and the pathology report indicated that she had atypical ductal hyperplasia. Ms. Brown then had a breast lumpectomy, and the lump was benign. In 1996, she had a total abdominal hysterectomy and bilateral salpingo-oophorectomy for endometriosis. Ms. Brown briefly took hormone replacement therapy but stopped in 2006 when the breast mass was identified. She began Evista therapy as a breast cancer reduction measure, but after 6 months she stopped the medication because of the side effects. Ms. Brown reports that she is not entirely opposed to considering using Evista again. Her family history indicated that a paternal grandmother likely had a type of "female cancer." This grandmother died in her middle 30s to early 40s. There were also three cousins on the paternal side of the family who had unilateral breast cancer when they were in their 30s and 40s.

On the maternal side of the family, her grandmother was diagnosed with breast cancer when she was in her 40s. She is alive and doing well at age 72. One of the grandmother's sisters had lymphoma and died in her late 60s. A maternal great-aunt who was a sister to her maternal grandfather, not maternal grandmother, died in her 70s of ovarian cancer. A sister to her maternal great-aunt (another maternal great-aunt) died in her 70s or 80s of a primary brain cancer.

Reflect on the following questions and see what implications they have for nursing action and for public health concerns:

1. What are some possible issues that could arise if Ms. Brown has a positive test? What legal and ethical issues would you consider? What considerations would you take into account if she has a teenage daughter?
2. What effect would the client's literacy level have on how you would handle this case?
3. What if Ms. Brown's Medicaid insurance would not pay for this costly test?
4. If you were caring for a family with multiple family members who obtain genetic testing and some members are found to be genetic mutation carriers while others are not, what would you anticipate might occur in relation to family dynamics? What actions might you take? Consider the referrals you might make.

Over 232,340 women in 2013 were diagnosed with new cases of invasive breast cancer, as well as an estimated 64,640 cases of in situ breast cancer (American Cancer Society, 2013). Epidemiologic studies have established that family history is an important risk factor for both breast and ovarian cancer. “After gender and age, a positive family history of breast cancer is the strongest known predictive risk factor for breast cancer” (NCI, 2014, p. 2). It is important for the nurse to take a brief family pedigree as done above to identify inherited risk factors. If Ms. Brown were to have had a BRCA1 or BRCA2 mutation, many more implications for decision making would arise, including prophylactic surgery for prevention of breast and/or ovarian cancer. In addition, men with a BRCA1 mutation are at increased risk to develop prostate cancer or colorectal cancer. Men who have the BRCA2 mutation are at risk for male breast cancer and pancreatic cancer. For women, both BRCA1 and BRCA2 mutation carriers have the greatest risk for breast and ovarian cancer. It is important when interpreting genetic information to be sensitive to the many issues involved, including emotional, socioeconomic, lifestyle, and environmental issues that may affect the onset of disease (Calzone et al, 2010).

“Life is a delicate balance based on a fragile harmony: moving only a little nitrogenous base, the whole structure will collapse. This is why every living organism, even the tiniest, is so important for science: it is an unrepeatable opportunity to study the diversity and the uniqueness of nature.”

L. Figarai quote from the European Society of Human Genetics

DNA AND ITS RELATIONSHIP TO GENOMICS AND GENETICS

At the core of the issues related to genetics and genomics is deoxyribonucleic acid (DNA). The structure of DNA is a nucleic acid that contains the genetic instructions used in the development and functioning of all known living organisms and some viruses. DNA is the chemical inside the nucleus of a cell that has the genetic instructions for making living organisms. DNA can be compared to long-term storage or a blueprint or code to construct other components of cells such as proteins and ribonucleic acid (RNA) molecules. The DNA segments that carry the genetic information are called genes. Within cells, DNA is organized into long structures called chromosomes. These chromosomes are duplicated before cells divide, in a process called DNA replication. DNA is comprised of four bases: adenine (A), guanine (G), cytosine (C), and thymine (T). Genes are comprised of specific sequences of these bases.

Alterations in the usual sequence of bases that form a gene or changes in DNA or chromosomal structures are called **mutations**. A large number of agents are known to cause mutations (Jorde et al, 2010). These mutations, which are attributed to known environmental causes, can be contrasted with spontaneous mutations, which arise naturally during the process of DNA replication. Approximately 3 billion DNA base pairs must be replicated in each cell division, and considering the large number of mutagens to which we are exposed, DNA replication is fascinatingly accurate (Jorde et al, 2010). A key reason for this accuracy is a mechanism called DNA repair, which occurs in all

normal cells of higher organisms. It is estimated that repair mechanisms correct at least 99.9% of initial errors.

Hundreds of chemicals are now known to be mutagenic in laboratory animals. Among these are nitrogen mustard, vinyl chloride, alkylating agents, formaldehyde, sodium nitrite, and saccharin. In addition, ionizing radiation, such as those produced by x-rays and from nuclear fallout, can promote chemical reactions that change DNA bases or break the bonds of double-stranded DNA.

How does an understanding of DNA and the science of genetics relate to public health nursing? In essence, this brief history of the field of genetics shows that human disease comes from the collision between genetic variations and environmental factors. As knowledge has evolved with the mapping of the human genome, our understanding of this interaction continues to advance. This has increased knowledge about disease prevention and new methodologies for the practice of public health. We are learning to integrate more effectively our understanding of biological determinism within a social context affecting the delivery of health care.

Most hereditary cancer syndromes are inherited in an autosomal dominant pattern with variable expression and incomplete penetrance, which means:

- Genes exist as pairs.
- A gene pair member can occur as either the normal, unaltered form or as a mutation.
- A mutation in one member of the pair is associated with an increased risk to develop certain types of cancer. If a person has a mutation in a hereditary cancer syndrome-related gene, she or he has both a normal form and an altered form of that gene in each of the cells.
- Both men and women carry, pass on to children, and inherit these mutations.
- For mutation carriers, the hereditary cancer syndrome can be mild or more severe.
- Whether or not cancer ever develops, the site at which it develops, or the seriousness of the cancer can vary among different people with the same mutation, even within the same family.

(See <http://www.cancer.gov/cancertopics/factsheet/Risk/BRCA.>)

The Challenges of Genetic and DNA Testing

Tests are now available to evaluate for more than 1600 genetic disorders ranging from single-gene disorders, such as cystic fibrosis, to more complex disorders, such as diabetes (CDC, 2013). As will be discussed in a later section of the chapter, taking a family history is a useful place to begin when considering a genetic connection and prior to the onset of testing.

DNA testing was first used in the late 1970s; today, the indications for a DNA test have expanded to include predicting the development of genetic disorders, screening populations, confirming clinical diagnoses, prenatal testing, and DNA testing to develop and apply individualized medical treatment. The next few years will see an explosion in the number of DNA tests driven by information generated from the HGP. Improved technology will make DNA testing more accessible. These advances in genetics/genomics will necessitate that nurses continue to

learn about this area of science in order to respond effectively to the challenges of this new knowledge.

An example of this challenge is that of genetic testing for mutations associated with hereditary disease. The best way to identify whether there is a mutation in a family where a hereditary disease is suspected is to test the person who displays the most evidence of being a mutation carrier. This is usually a relative who has had a cancer that occurs typically as part of the hereditary cancer syndrome (e.g., breast or ovarian) that is suspected in the family.

The previous example could present a difficulty because family members who have had cancer may not agree to being tested for genetic mutations. This refusal presents challenges to the person who desires information that might affect decision making and his or her health. An additional ethical challenge encountered involves individuals without an insurance carrier that reimburses for genetic testing, or who may have a high deductible in the insurance policy. Some individuals also think that testing will decrease the quality of their life and make them anxious about the future if they were to discover they have a mutation. Other people fear a positive test result may lead to feelings of guilt about passing along a disease to children and grandchildren.

Case Example 1

K.N. is a 42-year-old mother with three daughters, ages 16, 18, and 22. She has an extensive family history of ovarian cancer. Because of her family history, K.N. is regularly screened per current treatment guidelines. K.N.'s mother, who was diagnosed with ovarian cancer at age 55, underwent genetic testing and was discovered to be a carrier of the *BRCA2* gene mutation predisposing to breast and ovarian cancer. Despite undergoing frequent screening, several of K.N.'s aunts have died of ovarian cancer at an early age. K.N.'s husband wants her to be tested for the *BRCA2* gene and, if positive, has encouraged her to undergo a prophylactic salpingo-oophorectomy. K.N. is concerned that a positive genetic test may result in loss of insurance coverage. She is also concerned that this will have a negative psychological impact on her children.

Joan Akins is a public health nurse at the county health department serving the area where K.N. resides. Ms. Akins has recently conducted a cancer awareness campaign that included public health education on hereditary cancer syndromes. K.N. contacts Ms. Akins to request advice on whether to undergo genetic testing. Ms. Akins actively listens to K.N.'s concerns and provides general information on genetic testing and the implications of the test results for K.N. and for her children. She also discusses the newly enacted Genetic Information Nondiscrimination Act (GINA) legislation that protects the public from genetic discrimination by employers and insurers. Ms. Akins encourages K.N. to talk with her gynecologist about her concerns and to make an appointment for genetic counseling, providing names and contact information for local genetic counselors who specialize in cancer genetics.

As mentioned, genetic testing decisions are personal and complex and can be controversial, leading to dissonance in families. It is important for public health nurses to respect

individuals' and family members' decision-making processes. They must, at the same time, be well informed about genetic testing to provide accurate education to members of the public in order to support appropriate decision making.

Also, current methods of testing do not detect all of the mutations that can occur in some diseases, including hereditary cancer syndrome–related genes. If a mutation is detected during DNA testing, this would not confirm an absolute risk for cancer, but rather would indicate that a person is at increased risk to develop the cancers that are part of the particular hereditary cancer syndrome and may need high-risk management. Such a finding has implications for family members who might have inherited the same mutation, enabling them to undergo DNA testing specific to the identified mutation. Such focused testing is more accurate and cost-effective than testing for multiple potential mutations (NCI, 2014). In contrast, if DNA testing in a cancer-affected relative is negative, this does not indicate family members are not at risk. There might be a mutation in a different hereditary cancer syndrome gene than those tested. It is important to remember that many mutations associated with cancer susceptibility and familial syndromes have yet to be identified.

For these reasons, family history must also be considered. However, caution is needed in interpreting family history for several reasons: an inherited syndrome may not be evident for someone with a small family; not everyone is informed of their family's history of disease; death of a family member may be unrelated to cancer, such as early accidental death; or members may have been adopted and this may not be known to others in the family. Finally, because most cancers are not hereditary, family history should be accompanied by assessment of shared familial environments.

Case Example 2

Sickle cell anemia is an autosomal recessive disease in which a gene mutation results in the production of structurally abnormal hemoglobin called hemoglobin S. Gene carriers have one normal form of the hemoglobin gene and one mutation, a condition called sickle cell trait. The highest rates of disease are among African Americans, with sickle cell anemia affecting approximately 1 in 500 African Americans and 8% of the population being carriers (anemia, sickle, [National Center for Biotechnology Information \[n.d.\]](http://www.ncbi.nlm.nih.gov/books/NBK22238); see <http://www.ncbi.nlm.nih.gov/books/NBK22238>).

Marge Covington is a public health nurse employed by a nonprofit, community-based organization that provides health care education and outreach services to members of the African American community in a large metropolitan area. The rate of sickle cell anemia among members of the community is higher than the national average. In response, Ms. Covington has implemented a program with the projected outcome to reduce disease rates among African Americans in the community. The program objectives are to (1) increase awareness of the disease in the community and (2) increase rates of carrier testing to support informed decision making regarding childbearing. To meet these objectives, Ms. Covington has initiated monthly educational sessions on sickle cell anemia and sickle cell trait at

community centers throughout the area. She has also collaborated with a local hospital system to provide free biannual genetic counseling sessions with optional carrier screening at community health clinics.

Continuing education is important for public health nurses during this time of rapid integration of new genetic tests into health care practice. Only through ongoing education will public health nurses have the basis from which to appropriately educate the public regarding genetic testing. In addition, recognition of the role of gene–environment interactions in susceptibility to cancer and many other diseases underscores the importance of assessing risk from an environmental perspective. Public health nurses offer this perspective as part of the larger interprofessional team needed to address the complex issues involved in genetic testing.

CURRENT ISSUES IN GENOMICS AND GENETICS

“Translating the knowledge we are gaining from gene discoveries into practical clinical and public health applications will be critical for realizing the potential of personalized health care and improving the health of the nation.”

**Muin J. Khoury, MD, PhD, Director,
CDC Office of Public Health Genomics**

Many issues are involved in the growing field of genetics/genomics. Selected issues are discussed in this section. Individuals are learning the importance of having a family medical history. Some health care providers are unclear about how to accurately interpret the family history of a client who has had the initiative to collect it. Moreover, many clients are reluctant to disclose this family history for fear that it will affect their health insurance status or eligibility despite current laws in place designed to protect these clients.

Helping patients and families navigate through the disclosure process and uncovering their personal and family health history and understanding specific genetic tests is an important role for public health nurses. In addition, if patients are willing to make lifestyle changes or health decisions, the appropriate psychosocial support and education can be provided to clients and their families. Nurses play an important role in answering questions and assisting in challenges these clients and families face with making decisions when there is any suspicion of increased risk for genetically based diseases. To make things more confusing, companies market their tests and advertise directly to the public. This type of marketing has implications for nurses and other health care providers who need to provide the appropriate counseling about the implications and indications for such testing. For example, marketing on the Internet complicates client decision making since it can provide consumers with easy access to genetic tests without involving a health care professional in the testing process. Even the clinically available genetic tests, which may provide legitimate test results, are difficult to interpret without genetic counseling. Currently, the Centers for Disease Control and Prevention (CDC), the Centers for Medicare Services (CMS), and the

Federal Drug Administration (FDA) have oversight of genetic tests and products, whereas the Federal Trade Commission (FTC) has oversight of the advertising of these tests and products. The National Institutes of Health (NIH), Health Resources and Services Administration (HRSA), and Agency for Healthcare Research and Quality (AHRQ) support research related to genetic tests and products (CDC, 2014).

Keeping current with the changes in this scientific field with many complex systems in place is a challenging task. The National Human Genome Research Institute of the National Institutes of Health (NIH) provides reliable, up-to-date genetics and genomics information related to patient management, curricular resources, new National Institutes of Health and NHGRI research activities, and ethical, legal and social issues. Additionally, the Centers for Disease Control and Prevention (CDC) provides a “Genomics & Health Impact Update” periodically on their website for public use (NIH, 2014; CDC 2014).

Helping patients and families understand genetic predisposition to disease versus normal population risk and the impact of lifestyle and environment on health is another role for public health nurses. According to the CDC (2014), genomics plays a role in nine of the ten leading causes of death in the United States, most notably chronic diseases such as cancer and heart disease. There are multifactorial influences acting together to influence disease risk, physiological and mental health conditions, pathogenic DNA, and the therapies used to treat disease (Perry, 2011). For example, “common congenital malformations, such as cleft lip and palate and neural tube defects, result from multifactorial inheritance, a combination of genetic and environmental factors” (Perry, 2011, p. 147). Box 11-1 presents examples of multifactorial diseases, or those caused by gene and environment interaction.

The issue of multifactorial interactions that lead to disease is becoming increasingly recognized in occupational health. According to the CDC, advances in technology in the last few decades have increased our knowledge of the role that genetics plays in occupational diseases. In occupational health, one of the key issues relates to genetic changes that are acquired during a lifetime as a result of exposures and the interaction between genes and environmental factors. However, the use of genetic information in occupational safety and health research and

BOX 11-1 Examples of Multifactorial Disorders

Autism (strong genetic basis)	Multiple sclerosis
Neural tube disorders	Asthma
Cleft lip, palette	Allergies
Congenital heart disease	Autoimmune disorders
Coronary artery disease	Bipolar disorder
Type I diabetes	Schizophrenia
Type II diabetes	Kidney stones
Breast cancer	Gallstones
Colon cancer	Obesity
Lung cancer	Peptic ulcer disease
Rheumatic heart disease	Gout
Alcoholism	

practice presents both potential benefits and concerns and raises medical, ethical, legal, and social issues that are emerging in policy and procedure and have an impact on society and individuals (CDC, 2010).

Ethical and Legal Considerations

Discoveries in genetics, including those associated with the HGP, present complicated ethical issues for consumers, providers, and health care policy makers. All humans have a right to be concerned about genetic science and its effect on their well-being. Therefore, in the face of this biotechnological revolution, nurses need to carefully review the ethical and legal implications of genetic science.

The Code of Ethics developed by both the International Council of Nurses and the American Nurses Association emphasize the responsibility of nurses to work with other health care professionals to meet the social and health care needs of the public. They include in this mandate the right that people have to seek and receive genomic health care that is nondiscriminatory, confidential, and private and that enables patients to make informed decisions (ICN, 2012; ANA, 2001). Similarly, the International Society of Nurses in Genetics (ISONG, 1998) advocates for nurses at both the basic and advanced practice levels to be able to deliver genetic nursing care. ISONG further postulates that the genetic nurse at the basic level of preparation identifies genetic risk factors, provides nursing interventions, makes referrals, and provides health promotion education.

Logan Karns, a certified genetics counselor working in the prenatal genetics department at the University of Virginia Health System, describes many ethical dilemmas as medical science moves forward: “Our technological advances have always outpaced our ethical thinking about the consequences of what we’re doing. We need to have a measured thoughtfulness about everything.” She describes genetic knowledge as unique: “a window from the past and a glimpse into the future” (Karns, 2010).

With the advancement of technology and science, the use of personal genetic information has been a source of controversy. In the past, private health information and genetic data had been available for agencies and resulted in genetic discrimination and a denial of health insurance coverage for individuals and families.

On November 21, 2009, the Genetic Information Nondiscrimination Act (GINA) took effect through an act of the U.S. Congress. It was designed to prohibit the improper use of genetic information in health insurance and employment. This act prevents group health plans and health insurers from denying coverage to a healthy individual or charging higher premiums based solely on genetic predisposition to disease. This legislation also prohibits employers from using individuals’ genetic information when making hiring, firing, job placement, or promotion decisions.

GINA does the following: (1) prohibits employers from discriminating against an employee based on genetic information, (2) places broad restrictions on an employer’s deliberate acquisition of genetic information, (3) mandates confidentiality for genetic information that employers lawfully collect, (4) strictly

limits disclosure of such information, and (5) prohibits retaliation against employees who complain about genetic discrimination (USDHHS, 2009).

In accordance with GINA, genetic information is defined as information about the following:

- An individual’s genetic tests (including genetic tests done as part of a research study)
- Genetic tests of an individual’s family members (defined as dependents and up to and including fourth-degree relatives)
- Genetic tests of any fetus of an individual or family member who is a pregnant woman, and genetic tests of any embryo legally held by an individual or family member using assisted reproductive technology
- The manifestation of a disease or disorder in an individual’s family members (family history)
- Any request for, or receipt of, genetic services or participation in clinical research that includes genetic services (genetic testing, counseling, or education) by an individual or an individual’s family members (USDHHS, 2010).

PERSONALIZED HEALTH CARE

The importance of genetic developments to public health nursing practice is underscored by initiatives between the private sector and the public sector to improve population health through the use of genetic and genomic information. These included the initial goals for the Personalized Health Care Initiative instituted by the U.S. Department of Health and Human Services. Now policy makers and scientists agree that there are many factors involved in bringing new genomic technologies into the marketplace, and consideration of these factors is influencing the direction of DHHS. Ensuring that new technologies are accessible is of particular concern. Policies and practices for large genomic databases still need to be developed (National Cancer Institute, 2014). See the box on [Quality and Safety Education for Nurses](#).

Despite the need for ongoing policy and practice development, however, continual integration of genetics into public health remains the objective for *Healthy People 2020*. Screening and genetic testing for specific groups of individuals remain as the standard of practice while other routine screenings or tests are questioned for their impact on morbidity and mortality. Women with certain high-risk family health history patterns for breast and ovarian cancer, for example, could benefit from receiving genetic counseling to learn about genetic testing for *BRCA1* and *BRCA2* mutations. Surgery for women with these gene mutations could reduce the risk of breast and ovarian cancer by 85% or more.

The Evaluation of Genomic Applications in Practice and Prevention Working Group (EGAPP) supports the development of a systematic process for assessing the available evidence regarding the validity and utility of rapidly emerging genetic tests for clinical practice. This independent, multidisciplinary panel prioritizes and selects tests, reviews CDC-commissioned evidence reports and other contextual factors, highlights critical knowledge gaps, and provides guidance on appropriate use of

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Client-Centered Care

Recognize the client or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for the client's preferences, values, and needs.

Important aspects of client-centered care include:

- **Knowledge:** Describe strategies to empower patients or families in all aspects of the health care process
- **Skills:** Assess level of patient's decisional conflict and provide access to resources
- **Attitudes:** Appreciate shared decision making with empowered patients and families, even when conflicts occur

Client-Centered Care Question

As the study of genomics becomes more integrated in health care through the rapid growth of personalized medicine, public health nurses may be required to provide the rationale behind the value of population-based health initiatives. The following client-centered scenario speaks to this tension.

You are providing home care to a healthy newborn baby and mother. The baby is three weeks old and this is your first visit. Part of your education for the mother is to review the newborn's vaccination schedule. Upon review of the baby's next needed vaccinations, the mother states that she is interested in the baby's care being based on the baby's genetics, that she wants her baby to receive personalized medicine. The mother states that she has read an article about individualized approaches to vaccines. "What is recommended for the whole population might not be good for my baby."

- What probing questions might you ask to further understand this mother's position?
- How do you address this mother's concern about the lack of individual consideration in population-based vaccination recommendations?
- What information about personalized medicine will be helpful to this mother?
- What information about vaccines and vaccination schedules will be helpful to this mother?
- What Internet resources do you share with her, to address her questions and concerns?
- What conversation will you be ready to have in your second home visit with this mother?

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver, College of Nursing.

HEALTHY PEOPLE 2020

The objectives for *Healthy People 2020* include two new objectives that relate to genomics:

- G-2: (Developmental) Increase the proportion of persons with newly diagnosed colorectal cancer who receive genetic testing to identify Lynch syndrome (or familial colorectal cancer syndromes).
- G-1: Increase the proportion of women with a family history of breast and/or ovarian cancer who receive genetic counseling.

genetic tests in specific clinical scenarios. Currently, EGAPP finds sufficient evidence to recommend offering genetic testing for Lynch syndrome, sometimes referred to as Hereditary Nonpolyposis Colorectal Cancer, or HNPCC, to individuals with newly diagnosed colorectal cancer to reduce morbidity and mortality in relatives (EGAPP, 2013).

GENOMIC COMPETENCIES FOR THE PUBLIC HEALTH WORKFORCE

Public health professionals should know about genetics and how to apply current information to the health of individuals, families, and communities. Several significant health care professional groups have developed competencies for members of their workforces that include knowledge of genetics and genomics. The development of such competencies has grown considerably since the mapping of all human genes in the HGP. The CDC (2001) developed "Genomic Competencies for the Public Health Workforce" in 2001. See www.cdc.gov/genomics/translation/competencies. The CDC's contention is that all public health workers need to be aware of the advances in the science of genomics and incorporate the appropriate competencies into their work. They developed seven sets of competencies that related to the work of the individual public health worker. The competencies discussed here are those designed for all public health professionals and are to be used in educational and training programs for public health professionals. According to the CDC (2010), a public health worker should be able to perform the following:

- Demonstrate basic knowledge of the role genomics plays in the development of disease
- Identify limits of his or her genomic expertise
- Make appropriate referrals to those with more genomic expertise

The CDC goes on to list eight specific competencies for public health professionals. They are not listed here because they are consistent with more recently developed competencies that are specific to nursing. The public health competencies can be found online at <http://www.cdc.gov/genomics/public>.

Similar to the set of competencies developed by the CDC are those developed by the National Coalition of Health Professional Education in Genetics (NCHPEG) to be included in all health professional education (NCHPEG, 2007). These competencies, entitled "Core Competencies in Genetics for Health Professionals," recommend that at a minimum health care professionals should be able to do the following:

1. Examine their competence of practice regularly to identify areas of strength and areas where professional development related to genetics and genomics would be helpful.
2. Understand that health-related genetic information can have social and psychological implications for individuals and families.
3. Know how and when to make a referral to a genetics professional.

NCHPEG goes on to group their competencies into the following areas: knowledge, skills, and attitudes. Their competencies are congruent with those developed by the CDC and the ones that will be discussed in more depth in the following section that pertain specifically to nursing. NCHPEG has also developed core principles in genetics related to (1) biological variation, (2) cell biology, (3) classical (Mendelian) genetics, (4) molecular genetics, (5) development, and (6) new genetic technology (NCHPEG, 2009).

It is well established that new health technologies driven by the knowledge of human genetics can improve the safety, quality, and effectiveness of health care for every client in the United States (USDHHS, 2007) (myhealthcare.com). This perspective on health care is proactive, focused on wellness by managing gene-based information to understand each individual's requirements for the maintenance of his or her health, prevention of disease, and therapy tailored to each individual's genetic uniqueness. An approach to health care that is inclusive of a genetic profile of each individual enables nurses and other health care professionals to design care highly customized to match individual needs. A continuing approach to health care, built on the knowledge of continual scientific discovery of the health applications from genetics and genomics can help improve health outcomes for individuals and families. An incorporated knowledge of environment, health-related behaviors, culture, values, and the impact of social conditions such as poverty will provide additional arms of assessment when caring for patients. Genetic science emphasizes a fundamental public health nursing issue: the importance of understanding both biological predisposition to disease and the impact of behavior and social conditions on overall community health and well-being.

INCORPORATING GENOMICS AND GENETICS INTO PUBLIC HEALTH NURSING PRACTICE

Public health nursing has long been concerned with environmental or social determinants of health and disease and has only recently become engaged in genomic variations within populations. The advances brought about by genomics, however, are dynamically changing our perceptions, as advancing knowledge enables health promotion and disease prevention programs to be specifically directed at susceptible individuals and families, or at subgroups of the population, based on their unique genomic risk profile. Personalized health care based on a broad cultural and social context, a core value of public health nursing, will continue to be more predictive and preventive in nature. The public is beginning to expect that all nurses will use emerging genetic information and technology in their practice, in research, and in all forms of health education.

Nurses began applying genetic concepts to their practice in the 1970s. Some of these early nurses worked as genetic clinical coordinators and provided genetic counseling to persons with genetic diseases or who had risk factors for such disorders (Williams, 2002). The scope of the work for nurses in the field of genetics changed in the early 1990s when the *BRCA1* gene for familial breast cancer was mapped and cloned. This moved the scope of practice from diagnosis and management to that of risk identification (Williams, 2002).

In 2000 the Health Resources and Services Administration (HRSA) convened an expert panel that described the importance of integrating genetics content into nursing curricula. Not much action occurred in this regard for several years. In 2004, the National Human Genome Research Institute (NHGRI) and the National Cancer Institute (NCI) collaborated to develop a genetic and genomic training program for the U.S. nursing

workforce. Their work led to the development of the genomic competencies discussed later in this section (Jenkins and Calzone, 2007).

An advisory group developed a set of competencies in 2006 that were revised in 2008 to incorporate outcome indicators (Consensus Panel on Genetic/Genomic Nursing Competencies, 2009). These essential competencies apply to all registered nurses.

Professional Practice Domain: Nursing Assessment: Applying/Integrating Genetic and Genomic Knowledge

The registered nurse:

- Demonstrates an understanding of the relationship of genetics and genomics to health, prevention, screening, diagnostics, prognostics, selection of treatment, and monitoring of treatment effectiveness
- Demonstrates ability to elicit a minimum of three-generation family health history
- Constructs a pedigree from collected family history information using standardized symbols and terminology
- Collects personal, health, and developmental histories that consider genetic, environmental, and genomic influences and risks
- Critically analyzes the history and physical assessment findings for genetic, environmental, and genomic influences and risk factors
- Assesses clients' knowledge, perceptions, and responses to genetic and genomic information
- Develops a plan of care that incorporates genetic and genomic assessment information

Identification

The registered nurse:

- Identifies clients who may benefit from specific genetic and genomic information and/or services based on assessment data
- Identifies credible, accurate, appropriate, and current genetic and genomic information, resources, services, and/or technologies specific to given clients
- Identifies ethical, ethnic/ancestral, cultural, religious, legal, fiscal, and societal issues related to genetic and genomic information and technologies
- Defines issues that undermine the rights of all clients for autonomous, informed genetic- and genomic-related decision making and voluntary action

Referral

The registered nurse:

- Facilitates referral for specialized genetic and genomic services for clients as needed.

Provision of Education, Care, and Support

The registered nurse:

- Provides clients with interpretation of selective genetic and genomic information or services

- Provides clients with credible, accurate, appropriate, and current genetic and genomic information, resources, services, and/or technologies that facilitate decision making
- Uses health promotion/disease prevention practices that:
 - Consider genetic and genomic influences on personal and environmental risk factors
 - Incorporate knowledge of genetic and/or genomic risk factors (e.g., a client with a genetic predisposition for high cholesterol who can benefit from a change in lifestyle that will decrease the likelihood that the genetic risk will be expressed)
- Uses genetic- and genomic-based interventions and information to improve clients' outcomes
- Collaborates with health care providers in providing genetic and genomic health care
- Collaborates with insurance providers/payers to facilitate reimbursement for genetic and genomic health care services
- Performs interventions/treatments appropriate to clients' genetic and genomic health care needs
- Evaluates impact and effectiveness of genetic and genomic technology, information, interventions, and treatments on clients' outcome ([Consensus Panel on Genetic/Genomic Nursing Competencies, 2009](#)).

HOW TO Help Families Complete a Health History

1. Inform the family that a **family health history** is a written or graphic record of diseases or health conditions present in their biological family.
2. Encourage the family to develop a three-generation history of biological relatives, their age of diagnosis of a chronic disease, and the age and cause of death of any deceased family members.
3. Explain to the family that this type of history is a useful tool to help them know about their health risks and to prevent disease in themselves and their close relatives.
4. Tell the family that the health history is not a one-time document, but rather one that should be updated periodically.
5. Suggest that the family consider using the CDC online tool "My Family Health Portrait" to collect and organize their family health history. The tool is available free at <https://familyhistory.hhs.gov/fhh-web/home.action> in both English and Spanish.

APPLICATION AND PRACTICE: MAPPING OUT A PEDIGREE

A **pedigree** is a drawing of a family tree used by medical professionals and genetic counselors to assess families and try to spot patterns or indications that may be helpful in diagnosing or managing an individual's health. The pedigree symbols are used globally (see example from the National Society of Genetic Counselors).

Step One: Talk to the client and/or family and ask questions, and collect all information to include: biological parents, brothers and sisters including half-siblings, children, grandparents, aunts and uncles, cousins, nieces and nephews, and include the family giving the history.

Step Two: Draw a basic outline of the family tree using pedigree symbols (see Symbols used in [Figure 11-1](#)).

Step Three: Next to each family member's name, write down everything you know about his or her health and medical history. You can also ask family members if you are uncertain. If a family member is adopted, you can possibly collect information on either or both the adopted and birth families.

Include the following information: 1) age or date of birth; 2) age or date of death and cause of death for family members who have passed away; 3) medical conditions and how old the person was when diagnosed with the condition; 4) where each side of the family comes from originally and pertinent cultural heritage (e.g., England, Iceland, Mexico, Ashkenazi or Eastern European Jewish) (see [Figure 11-2](#)).

LINKING CONTENT TO PRACTICE

In addition to the organizations previously discussed who state that all nurses and public health professionals should have some level of competence in genetics and genomics, there is broader endorsement of this competency in terms of basic public health and public health nursing skills. Specifically, the Quad Council Competencies, which build on those of the Council of Linkages of the Public Health Foundation, state in Domain 36, under Public Health Sciences Skills, that nurses define, assess, and utilize the understanding of the health status of populations, determinants of health and illness, factors contributing to health promotion and disease prevention, and factors influencing the use of health services. This group also points out in Domain #8, Leadership and Systems Thinking Skills, that nurses should be able to utilize ethical standards of public health nursing practice as the basis of all interactions with organizations, communities, and individuals ([Quad Council, 2011](#)). This recommended skill would directly pertain to nursing practice that incorporates genetic and genomic competencies.

Although the public health nurse will not always use each of these competencies, the ones used will depend on the nature of the role of the nurse. Nurses work at all three levels (individual, family, and community) in providing care, services, and referrals as well as advocating for policy changes and for laws that protect the right to health. Nurses also promote assurance for access to care including genetic screening, privacy of health information, and certainty that no discrimination will be allowed.

The NCHPEG has developed a tool called "genetic red flags" that provides quick tips for risk assessment related to genetics. These tips can serve as a guide to help nurses provide careful and consistent assessments. The "genetic red flags" developed by the National Coalition of Health Professional Education in Genetics provide an excellent tool to determine if an individual or family might be at risk. The group says that the primary red flag for most common diseases is a large number of affected relatives who are closely related. Some of the red flags include the following:

1. Family history of multiple affected family members with the same or related disorders, which may or may not follow an identifiable pattern in the family
2. Onset at an earlier age than expected. Condition occurrence in the gender that is least expected to have it
3. Disease occurrence in the absence of known risk factors

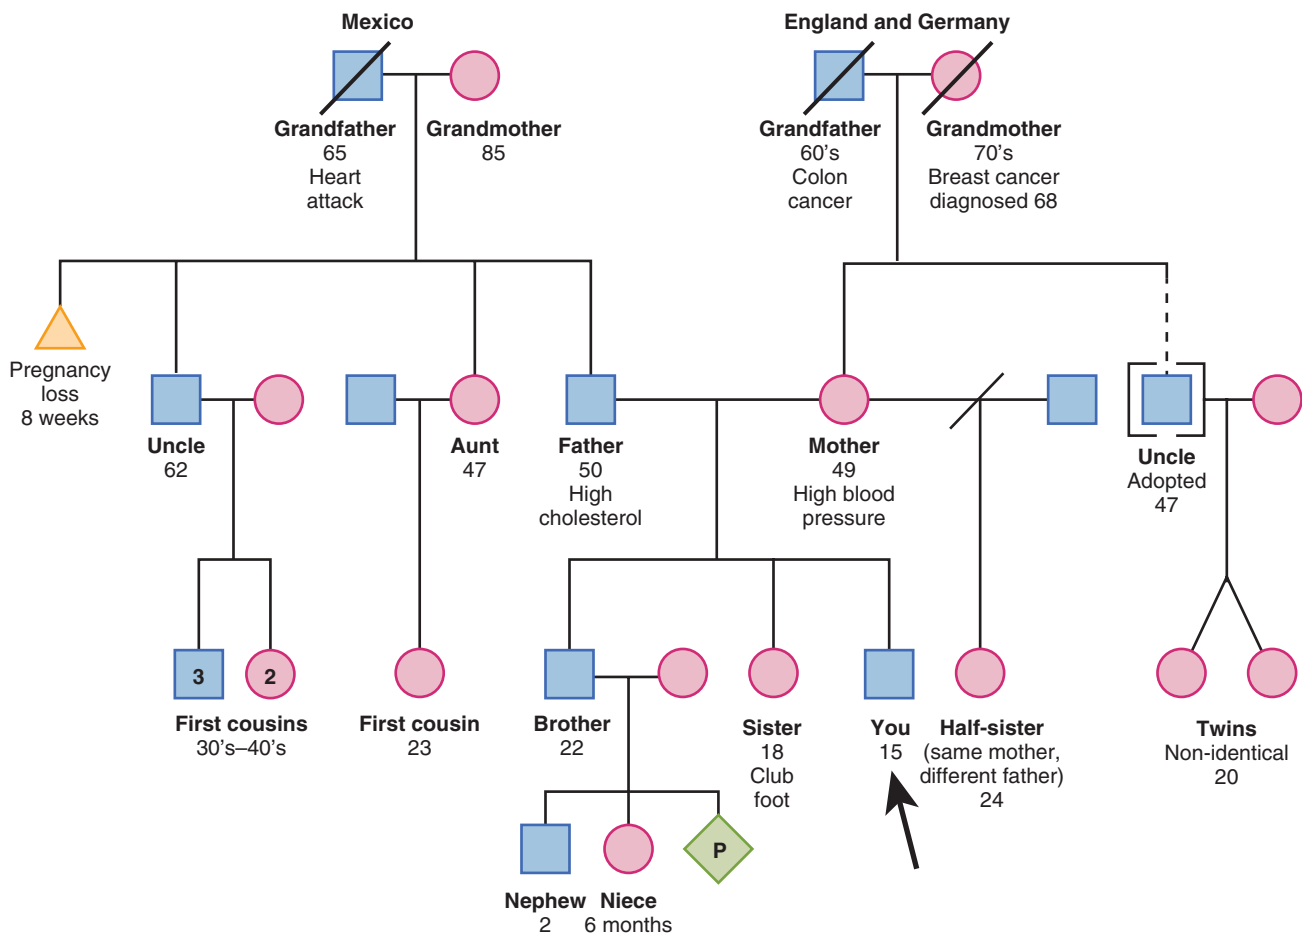

FIG 11-2 An example of a family pedigree for four generations. National Society of Genetic Counselors (2014), <http://nsgc.org/p/cm/ld/fid=143>.

EVIDENCE-BASED PRACTICE

The term **epigenetics** refers to heritable changes in gene expression that do not involve changes to the underlying DNA sequence: a change in phenotype without a change in genotype. Epigenetic approaches in research examine complex, **multifactorial diseases** (e.g., cancer, pain, cardiovascular disease) as well as other health conditions and therapies such as pregnancy, childbirth, and immunotherapy that have an environmental component associated with the condition. Research in epigenetics can also include previous cohorts of populations in order to identify environmental factors affecting disease states and that impact one generation to the next. Epigenetic inheritance is an unconventional finding. It goes against the idea that inheritance happens only through the DNA code that passes from parent to offspring. It proposes that a parent's experiences, in the form of epigenetic tags, can be passed down to future generations.

Epigenetic changes are regular and natural and can be influenced by several factors including age, the environment/lifestyle, and physical state. Many diseases and conditions that affect a population have a genetic/genomic element that is influenced by these factors. Epigenetic-related diseases have the following characteristics: 1) a heritability that cannot be fully explained by genetic inheritance patterns found in testing; 2) evidence of the influence of imprinting (e.g., maternal diet, or other in utero exposure to toxins, pathogens, or drugs), which could influence the development of the disease in the offspring even into adulthood; and 3) increase in prevalence of these changes with aging.

Environmental factors on epigenetic changes can be examined using large cohort studies. Epigenetic studies, for example, have examined the impact of famine during the perigestational period to determine the impact on offspring of individuals who have experienced these extreme conditions. One particular study has demonstrated that children born during the period of the Dutch famine from 1944-1945 have increased rates of coronary heart disease and obesity after maternal exposure to famine during early pregnancy compared to those not exposed to famine. In other studies, DNA changes in insulin factors were also found to be associated with exposure to famine (Lumey, Stein & Susser, 2011; Jirtle and Skinner, 2007).

Nurse Use

The authors provided an overview of how epigenetic research relates to nursing practice, and they make recommendations and provide online epigenetic resources that will be useful for future nursing research. They also provide an overview of major epigenetic students in nursing including those specific to childbirth, preeclampsia, metabolic syndrome, immunotherapy cancer, and pain.

4. Ethnic predisposition to certain genetic disorders
5. Close biological relationship existing between parents (Genetics in Primary Care, 2014)

THE FUTURE

At a time of rapid discoveries in genetics and epigenetics, nurses need to be current with the ongoing discoveries and new literature surrounding these discoveries in order to help clients make

LEVELS OF PREVENTION

Applying the Three Levels of Prevention to Genetics and Genomics

Primary Prevention

Since family members share genes, behaviors, lifestyles, and environments with one another that may influence their health, help people complete a family health history.

Secondary Prevention

When you review the health history, observe for any diseases that may have a genetic basis; if found, immediately refer the person or family to the appropriate health care provider. The goal of screening is to detect or define risk in low-risk groups and identify those people who should have diagnostic testing.

Tertiary Prevention

If a genetic link to an early or a probable disease is found, guide the family in changing any behaviors in order to minimize the effect of the disease.

effective decisions. Knowing which populations have genetic risk for various diseases will lead nursing science to develop and apply public health interventions that will improve health outcomes and community well-being as well as reduce costs. Nurses will increasingly provide guidance on policy discussions affecting health and decisions to ensure confidentiality, provide protection against discrimination based on genetic information, and regulate commercialized genetics products and services.

As the American Academy of Nursing (AAN) has asserted, public health nurses must be well positioned to incorporate evolving knowledge into practice. For people to benefit from widespread genetic and genomic discoveries, nurses must be competent to obtain comprehensive family histories, identify family members at risk for developing a genomic-influenced condition and genomic-influenced drug reactions, help people make informed decisions about and understand the results of their genetic and genomic tests and therapies, and refer at-risk people to appropriate health care professionals and agencies for specialized care (AAN, 2009).

“Nurses have always been ahead of their time in their focus on prevention and health promotion. As we move toward a more balanced health system with more focus and support for health promotion and disease prevention, the role of nurses will be more significant than ever before.”

David Satcher, MD, director, Satcher Health Leadership Institute, Morehouse School of Medicine, and former U.S. surgeon general

Nurses bring a bio-behavioral perspective that includes an emphasis on prevention and health promotion for individuals, families, and communities. This enables nurses to bring considerable expertise to policy-making groups who are working in the area of genetics/genomics (Calzone et al, 2010).

PRACTICE APPLICATION

T.S., a 4-year-old with hemophilia B, is attending his Head Start program this fall. His mother brought all of his medical supplies and needles so that staff could start an emergency IV infusion if the need arose. The possibility of needing to start an IV concerned the staff who were teachers, not health care workers. The mother was also anxious about her son being away from home and attending preschool for the first time. As the public health nurse who is responsible for providing health care for Head Start programs in your community, how do you manage the health care for this child while also ensuring safety and making sure that adequate plans are in place for this facility?

A. Let T.S.'s mother know that she needs a note from T.S.'s physician before he can bring any medications to the facility.

B. Notify all of the student's parents/guardians of T.S.'s condition in order to set the guidelines and prevent possible bleeds. The children at the center should be aware of the condition, and the parents also need to educate their children to ensure extra precaution around T.S.

C. Organize a meeting between staff, educators, and parents of T.S. to educate about hemophilia. The aim is to educate key people to ensure T.S.'s safety while at Head Start.

Answers can be found on the Evolve site.

KEY POINTS

- Genetics is the study of the function and effect of single genes that are inherited by children from their parents. Genomics is the study of individual genes in order to understand the interplay of genetic, environmental, cultural, and psychosocial factors in disease.
- DNA is a nucleic acid that contains genetic information called genes.
- Genetic mutations can be caused by the environment or can be spontaneous and arise naturally during the process of DNA replication.
- Human disease comes from the collision between genetic variations and environmental factors.
- Genetic testing decisions are personal and complex and can be controversial, leading to challenging situations in families.
- The Genetic Information Nondiscrimination Act (GINA) of 2008 was designed to prohibit the improper use of genetic information in health insurance and employment.
- The use of genomics and how it relates to drug treatment will enable personalized health care and medicine to be tailored to each person's needs; health, therefore, can be predictive and preventive in nature.
- According to the International Society of Nurses in Genetics (ISONG), the genetic nurse carries out the responsibility for

identifying genetic risk factors, providing nursing interventions, making referrals, and providing health promotion education. The advanced practice nurse can provide genetic counseling or refer to a genetic counselor and act as case manager for a person with or at risk for a disease that arises from a **genetic susceptibility**.

- Nurses can promote assurance for access to care, including genetic screening, the privacy of health information, and certainty that no discrimination will be allowed in treatment or screening for disease.
- The field of genetics/genomics is growing rapidly and will require nurses to continue to learn and to be aware of advances in research in this area.
- Genomics affects individuals, families, and communities.
- Epigenetics is the study of heritable changes in gene activity that are *not* caused by changes in the DNA sequence; it also can be used to describe the study of stable, long-term alterations in the transcriptional potential of a cell that are not necessarily heritable. Unlike simple genetics based on changes to the DNA sequence (the genotype), the changes in gene expression or cellular phenotype of epigenetics have other causes.

CLINICAL DECISION-MAKING ACTIVITIES

1. Choose a disorder that has a genetic basis. Look at three sites on the Internet to see what information is available for clients, families, and health professionals. Then evaluate the sites according to the following criteria:
 - Who wrote the information on the site? Is it written by a health professional? Is it sponsored by a government organization that is a reliable source of health information such as the CDC? Is it peer reviewed?
 - Is the information written at the literacy level that a client could understand?
 - How would you improve the usefulness of these three sites based on the clients, families, and communities with whom you work?

2. Since public health nurses often identify groups within a community who are considered high risk for illness and then provide care to them as individuals, or to their families or in groups, choose a group in your community. Then develop a plan of care including appropriate referrals to other agencies and a comprehensive plan for follow-up.
3. Identify parent support groups in your community and inquire about attending a meeting.

Epidemiology

Swann Arp Adams, MS, PhD

Dr. Swann Arp Adams has over 17 years of experience in clinical epidemiology. She holds a PhD in epidemiology and an MS in biomedical sciences. Dr. Adams has previous experience in a variety of research fields including physical activity, bone marrow transplantation, diabetes, breast cancer, and cancer disparities. She is the Associate Director of the Cancer Prevention and Control Program and is an associate professor with a joint appointment in the College of Nursing and the Department of Epidemiology and Biostatistics at the University of South Carolina. Her current research work focuses on reducing the burden of cancer disparities experienced by African Americans. Past honors include the Doctoral Achievement Award (2004) and the Gerry Sue Arnold Alumni Award (2008) from the Arnold School of Public Health of the University of South Carolina.

DeAnne K. Hilfinger Messias, PhD, RN, FAAN

Dr. DeAnne K. Hilfinger Messias is an international community health nurse, educator, and researcher. She spent more than two decades in Brazil, where she directed a primary health care project on the lower Amazon, taught women's health and community health nursing, and organized women's health initiatives among poor urban populations. Her research and scholarship focuses on women's work and health, immigrant women's health, language access, and community empowerment. She is currently involved in a community-based intervention trial of a promotora-delivered physical activity intervention among low-income Latinas. Dr. Messias was a fellow with the International Center for Health Leadership Development at the School of Public Health, University of Illinois at Chicago (2002–2004) and a Fulbright Senior Scholar in Global/Public Health at the Federal University of Goiás, Brazil (2005). She is a professor and director of the PhD Program in the University of South Carolina College of Nursing, with a joint appointment in the Women's and Gender Studies Program.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Define epidemiology and describe its essential elements and approach.
2. Describe current and historical contexts of the development of the field of epidemiology.
3. Identify key elements of the epidemiologic triangle and the ecological model and describe the interactions among these elements in both models.
4. Explain the relationship of the natural history of disease to the three levels of prevention and to the design and implementation of community interventions.
5. Interpret basic epidemiologic measures of morbidity (disease) and mortality (death).
6. Discuss descriptive epidemiologic parameters of person, place, and time.
7. Describe the key features of common epidemiologic study designs.
8. Describe essential characteristics and methods of evaluating a screening program.
9. Identify the most common sources of bias in epidemiologic studies.
10. Evaluate epidemiologic research and apply findings to nursing practice.
11. Discuss the role of the nurse in epidemiologic surveillance and primary, secondary, and tertiary prevention.

The authors would like to acknowledge the contribution of Robert E. McKeown, PhD, FACE, who contributed to this chapter for previous editions.

Applications of Epidemiology in Nursing

Community-oriented Epidemiology
 Popular Epidemiology

Epidemiology is considered the basic science of public health. Like public health nursing, epidemiology is a complex and continually evolving field with a common focus: the optimal health for all members of all communities, local and global. Nurses use epidemiologic frameworks, methods, and data to better understand factors that contribute to health and disease; to develop health promotion and disease prevention interventions and

measures; to identify the presence of infectious agents in individuals and groups; to design, implement, and evaluate community health programs; and to develop and evaluate public health policies. Since nurses care for individuals and families, it is important that they consider the broader context in which these individuals live and the complex interplay of social and environmental factors that affect individual and collective

well-being. Basic knowledge of epidemiology is essential to the practice of nursing across all settings and populations.

DEFINITIONS OF HEALTH AND PUBLIC HEALTH

Health is the core concept in nursing and epidemiology. In 1978 the World Health Organization (WHO) affirmed that “health, which is a state of complete physical, mental and social well-being, and not merely the absence of disease or infirmity, is a fundamental human right and the attainment of the highest possible level of health is a most important world-wide social goal” (WHO, 1978, p. 1). As defined by the American Nurses Association (ANA), “Nursing is the protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations” (ANA, 2012). This definition reflects the WHO goal and coincides with epidemiologic principles. A holistic approach to health, including the incorporation of epidemiologic principles, is particularly appropriate for nurses. Nurses incorporate concepts of health into their nursing practice on a daily basis.

Public health has been described as a system and social enterprise; a profession; a collection of methods, knowledge, and techniques; governmental health services, especially medical care for the poor and underserved; and the health status of the public (Turnock, 2011). In the early twentieth century, C.E.A. Winslow defined public health as “the science and art of preventing disease, prolonging life and promoting physical health and efficiency through organized community effort.” The Institute of Medicine (IOM) report *The Future of Public Health* drew upon Winslow’s definition in stating the mission of public health is to fulfill “society’s interest in assuring conditions in which people can be healthy” (IOM, 1988, p. 40). This mission statement clearly indicates a societal interest in the health of all its members. More specifically, the mission of the public health enterprise is to *ensure conditions* that promote health and well-being. From both public health and nursing perspectives, *health* encompasses much more than the presence or absence of a physical disease or disability; it involves optimal functioning across a broad range of systems—physiological, somatic, psychological, social, and environmental. The authors of the 1988 IOM report caution that this broad view of health and the role of public health professionals and agencies forces “practitioners to make difficult choices about where to focus their energies and raises the possibility that public health could be so broadly defined so as to lose distinctive meaning” (IOM, 1988, p. 40). Nurses are especially well suited to address this concern because of their holistic view of health and broad, interprofessional approach to intervention.

The practice of public health nursing is based on definitions of health and public health that go beyond a narrow biomedical model of individual health. Ensuring the public’s health includes delivery of specific services to individuals, but also includes the establishment and implementation of public policies and programs. Public health and public health nursing activities focus on community prevention, disease control, and personal and

community health services. The IOM report *The Future of the Public’s Health in the 21st Century* (IOM, 2002) highlights the importance of intersectoral collaborations to accomplish the mission of public health. There is further emphasis on an ecological approach to research and practice (discussed later). Interprofessional collaboration between nurses and other health professionals, including epidemiologists, is critical to efforts to create and sustain the conditions necessary for health promotion, health maintenance, and overall improvements in public health (Baldwin, 2007).

HEALTHY PEOPLE 2020

Examples of New Epidemiologic Objectives Included in Healthy People 2020

- AH-2: Increase the percentage of adolescents who participate in extracurricular and out-of-school activities.
- AOCBC-4: Reduce the proportion of adults with doctor-diagnosed arthritis who find it “very difficult” to perform specific joint-related activities.
- C-9: Reduce invasive colorectal cancer.
- D-16: Increase prevention behaviors in persons at high risk for diabetes with prediabetes.
- FS-5: Increase the proportion of consumers who follow key food safety practices.
- HAI-2: Reduce invasive methicillin-resistant *Staphylococcus aureus* (MRSA) infections.

DEFINITIONS AND DESCRIPTIONS OF EPIDEMIOLOGY

Epidemiology has been defined as “the study of the occurrence and distribution of health-related states or events in specified populations, including the study of the determinants influencing such states, and the application of this knowledge to control the health problems” (Porta, 2008, p. 81). The word *epidemiology* comes from the Greek words *epi* (upon), *demos* (people), and *logos* (thought), and it originally referred to the spread of diseases of infectious origin. In the past century the definition and scope of epidemiology have broadened and now include the examination of the occurrence of chronic diseases, such as cancer and cardiovascular disease; mental health and health-related events, such as accidents, injuries, and violence; occupational and environmental exposures and their effects; and positive health states.

Epidemiologists investigate the **distribution** or patterns of health events in populations to characterize health outcomes in terms of *what*, *who*, *where*, *when*, *how*, and *why*: What is the outcome? Who is affected? Where are they? When do events occur? This focus is called **descriptive epidemiology**, because it seeks to describe the occurrence of a disease in terms of person, place, and time (Koepsell and Weiss, 2003). The *how* and *why*, or **determinants** of health events, are those factors, exposures, characteristics, behaviors, and contexts that determine (or influence) the patterns: How does it occur? Why are some affected more than others? Determinants may be individual, relational or social, communal, or environmental. This

focus on investigation of causes and associations is called **analytic epidemiology**, in reference to the goal of understanding the etiology (or origins and causal factors) of disease; the broad consideration of many levels of potential determinants is called the *ecological approach* (IOM, 2002). The results of these investigations are used to guide or evaluate policies and programs that improve the health of the community. The differentiation between *descriptive* and *analytic* epidemiologic studies is not clear-cut: analytic studies rely on descriptive comparisons, and descriptive comparisons shed light on determinants.

LINKING CONTENT TO PRACTICE

It is important that nurses understand the relationship between population health concepts and clinical practice. Within the field of epidemiology, the definition of *population* is not necessarily confined to large groups of people, such as the population of the United States. Population health concepts also apply to other types of groups, such as the collective group of clients at one clinical practice site. In this case, the clinical epidemiologic application of population health concepts is evident in questions such as: What are the factors that contribute to the health and illness issues among clients I see in my clinic? Why do some of my clients fare better than others with the same disease conditions? Are there alternative clinical practices that might positively impact the health of my clients? All of these very clinical questions incorporate epidemiologic concepts of describing the *burden of disease* in a population, identifying and understanding *determinants of health*, and examining possible *root causes* of health outcomes. Two important nursing documents recently highlighted ways in which epidemiologic knowledge and skills are essential to nursing practice. The [Council on Linkages Between Academia and Public Health Practice \(2014\)](#) outlined essential analytic/assessment and public health science skills, and The Quad Council of Public Health Nursing Competencies (Swider et al, 2013) provided details and examples of ways to implement these skill sets in nursing practice.

The first step in the epidemiologic process is to answer the “what” question by defining a health outcome. The case definition usually refers to cases of disease, but also may include instances of injuries, accidents, or even wellness (Koepsell and Weiss, 2003). Epidemiology has played an important role in the refinement of the case definition for acquired immunodeficiency syndrome (AIDS) and other emerging infectious diseases and in the development of more precise diagnostic criteria for psychiatric disorders. Epidemiologic methods are used to quantify the frequency of occurrence and characterize both the case group and the population from which they come. The aim is to describe the distribution (i.e., determine who has the disease and where and when the disease occurs) and to search for factors that explain the pattern or risk of occurrence (i.e., answer the questions of why and how the disease occurs).

An **epidemic** occurs when the rate of disease, injury, or other condition exceeds the usual (endemic) level of that condition. There is no specific threshold of incidence that indicates the existence of an epidemic. Because of the virtual eradication of smallpox globally, any occurrence of smallpox could be considered an epidemic. In contrast, given the high rates of ischemic heart disease in the United States, an increase of many cases would be needed before an epidemic was noted; some would

argue the current high rates compared with earlier periods already indicate an epidemic. The rising rates of obesity in the United States have led the Centers for Disease Control and Prevention (CDC) to consider adult obesity as an epidemic (CDC, 2012). Recent epidemiologic data show that 35.7% of U.S. adults 20 years of age and older—more than 78 million people—are obese. Approximately 19% of the population ages 6 to 12 and 17% of those 12 to 19 years old are considered overweight (Ogden et al, 2012). Obesity contributes to increased risk for heart disease, hypertension, diabetes, arthritis-related disabilities, and certain cancers.

Epidemiology builds on and draws from other disciplines and methods, including clinical medicine and laboratory sciences, social sciences, quantitative methods (especially biostatistics), and public health policy, among others. Epidemiology differs from clinical medicine, which focuses on the diagnosis and treatment of disease in individuals. Epidemiology is the study of populations in order to (1) monitor the health of the population, (2) understand the determinants of health and disease in communities, and (3) investigate and evaluate interventions to prevent disease and maintain health. Effective nursing practice bridges the disciplines of clinical medicine and epidemiology, incorporating a focus on both individual and collective strategies. Nurses working in the community provide clinical services to individuals as they also tend to the broader context in which these individuals live and the complex interplay of social and environmental factors that affect their well-being. Nurses apply epidemiologic methods in their daily practice, as they note trends in specific illnesses (e.g., sexually transmitted infections) or conditions (e.g., accidents) and in designing, implementing, and evaluating community health programs. The AIDS epidemic was first identified because clinicians, using basic epidemiology methods, realized that much higher numbers of *Pneumocystis jirovecii* (*carinii pneumonia*) were being diagnosed than had ever been seen previously.

HISTORICAL PERSPECTIVES

The roots of epidemiology have been traced to ancient Greece (Merrill and Timmreck, 2006). In the fourth century BC, Hippocrates maintained that to understand health and disease in a community, one should look to geographic and climatic factors, the seasons of the year, the food and water consumed, and the habits and behaviors of the people. Yet modern epidemiology did not emerge until the nineteenth century and it was only in the twentieth century that the field developed as a discipline with a distinctive identity (Susser, 1985).

Two refinements in research methods in the eighteenth and nineteenth centuries were critical for the formation of epidemiologic methods: (1) use of a comparison group, and (2) the development of quantitative techniques (numerical measurements, or counts). One of the most famous studies using a comparison group is the pivotal mid-nineteenth-century investigation of cholera by John Snow, who is often credited with being the “father of epidemiology” (Merrill and Timmreck, 2006). By mapping cases that clustered around a single public water pump in one London cholera outbreak, Snow

demonstrated a connection between water supply and cholera. He later observed that cholera rates were higher among households supplied by water companies whose water intakes were downstream from the city than among households whose water came from further upstream, where it was subject to less contamination (Table 12-1). Snow realized that his investigation was an example of what epidemiologists call a *natural experiment* and his findings added credibility to his argument that foul water was the vehicle for transmission of the agent that caused cholera (Gordis, 2013; Koepsell and Weiss, 2003).

Development and application of epidemiologic methods in the twentieth century were stimulated by dramatic changes in society and population dynamics (the combined effects of birth rates, death rates, life expectancy, and patterns of illness and causes of death) (McKeown, 2009). Contributing factors included improved nutrition, new vaccines, better sanitation, the advent of antibiotics and chemotherapies, and declining infant and child mortality and birth rates. Societal changes also

resulted from large-scale events including the Great Depression and World War II, followed by a rising standard of living for many but continued deep poverty for others. These changes led to increasing longevity and significant shifts in the age distribution of the population, resulting in increases in age-related diseases, such as coronary heart disease (CHD), stroke, cancer, and senile dementia (Susser, 1985; IOM, 2002). However, disparities remain among population subgroups in life expectancy and risk of many acute and chronic diseases. Figure 12-1 shows the 10 leading causes of death in the United States in 1900, 1950, and 2010, with the percentage of all deaths attributed to each cause. The top three causes of death have not changed since 1950, whereas the composition of the remaining seven leading causes *has* changed.

With the increase in chronic disease, epidemiologists realized the necessity of looking beyond single agents (e.g., the infectious agent that causes cholera) toward a multifactorial etiology (i.e., many factors or combinations and levels of factors contributing to disease, such as the complex set of factors that cause cardiovascular disease), referred to as an *ecologic model* (IOM, 2002). Researchers and practitioners also recognized the contribution of behavioral and environmental causes to some chronic conditions formerly considered to be degenerative diseases of aging. This understanding prompted new thinking about the possibility of preventing or delaying the onset of certain chronic diseases (Susser, 1985). In addition, the development of genetic and molecular techniques (such as genetic markers for increased risk of breast cancer and sophisticated tests for antibodies to infectious agents or for other biological markers of exposures to environmental toxins, such as lead or pesticides) has increased the ability to identify and classify persons in terms of exposures or inherent susceptibility to disease.

BASIC CONCEPTS IN EPIDEMIOLOGY

Measures of Morbidity and Mortality

Proportions, Rates, and Risk

The distribution of health states and events is an important focus of epidemiology. Because people differ in their probability or risk of disease, a primary concern is the identification of how they differ. Today, epidemiologists use tools such as geographic information systems (GISs) to study health-related events to identify disease distribution patterns, similar to John Snow's mapping of cholera cases in London in the nineteenth century. However, mapping cases is limited in what it can reveal. A higher number of cases may simply be the result of a larger population with more people who are potential cases, or of a longer period of observation. Any description of disease patterns should take into account the size of the population at risk for the disease. That is, we should look not only at the numerator (the number of cases), but also at the denominator (the number of people in the population at risk) and at the length of time the population was observed. For example, 50 cases of influenza in a month might be viewed as a serious epidemic in a population of 250 but would indicate a low rate in a population of 250,000. On the other hand, even in a small population, one might observe 50 cases over a period of several years. Using rates and proportions instead of simple counts of cases takes the size of the population at risk into account (Koepsell and Weiss, 2003). How time is considered differs according to the measure being used.

Epidemiologic studies rely on proportions and rates. A **proportion** is a type of ratio in which the denominator includes the numerator. For example, in 2006 there were 2,426,264 deaths recorded in the United States, of which 631,636 were reported as caused by heart disease; so the proportion of deaths attributable to heart disease in 2006 was $631,636/2,426,264 = 0.260$, or 26.0%. Because the numerator must be included in the denominator, proportions can range from 0 to 1. Proportions are often multiplied by 100 and expressed as a percent, literally meaning per 100. In public health statistics, however, if the proportion is very small, we use a larger multiplier to avoid small fractions; thus the proportion may be expressed as a number per 1000 or per 100,000.

A **rate** is a measure of the frequency of a health event in "a defined population, usually in a specified period of time" (Porta, 2008, p. 207). A rate is a ratio, but it is not a proportion because the denominator is a function of both the population size and the dimension of time, whereas the numerator is the number of events (Rothman, 2012; Koepsell and Weiss, 2003; Gordis, 2013). Furthermore, depending on the units of time and the frequency of events, a rate may exceed 1. As its name suggests, a rate is a measure of how rapidly something is happening: how rapidly a disease is developing in a population or how rapidly people are dying. Conceptually, a rate is the instantaneous change in a continuous process. Notice the use of the words *event* and *happening*. Rates deal with change over time, as individuals move from one state of being to another (e.g., from well to ill, alive to dead, or ill to cured). In observing a population over time to observe such changes in status, we typically exclude

from the population being followed those persons who have already experienced the event.

Using the same health event of death from heart disease detailed previously, we can also compute a rate. To calculate the death rate, the denominator will be the number of individuals in the population *during the year in which the deaths occurred*, rather than total number of deaths. For example, in 2006, the U.S. population estimate was 299,398,484. Since rates are commonly expressed per 100,000 or per 1000, we will divide this total population figure by 100,000, to get 2993.98484. The resulting calculation of the rate of death from heart disease in the United States in 2006 would be $631,636/2993.98484 = 211$ per 100,000.

Risk refers to the probability that an event will occur within a specified time period. A population at risk is the population of persons for whom there is some finite probability (even if small) of that event. For example, although the risk of breast cancer in men is small, a few men do develop breast cancer and therefore could be considered part of the population at risk. There are some outcomes for which certain people would never be at risk (e.g., men cannot be at risk of ovarian cancer, nor can women be at risk of testicular cancer). A high-risk population, on the other hand, would include those persons who, because of exposure, lifestyle, family history, social or environmental context, or other factors, are at greater risk for disease than the population at large. Although anyone may be susceptible to HIV infection, the degree of susceptibility does vary. Everyone in the population is at risk for HIV and AIDS, but persons who have multiple sexual partners without adequate protection or who use intravenous drugs are in the high-risk population for HIV infection. However, others who do not fit these categories may unknowingly be at high risk. An example is women who consider themselves to be in monogamous relationships but are unaware that their partners have sexual relations with other women or men. As proportions, risk estimates have no dimensions, but they are a function of the length of time of observation. Given a continuous rate, increasing time will mean that a larger proportion of the population will eventually become ill.

Epidemiologists and other health professionals are interested in measures of morbidity, especially incidence proportions, incidence rates, and prevalence proportions (Gordis, 2013). These measures provide information about the risk of disease, the rate of disease development, and the levels of existing disease in a population, respectively.

HOW TO Quantify a Health Problem in the Community

Planning for resources and personnel often requires quantifying the level of a problem in a community. For example, to know how different districts compare in the rates of very-low-birth-weight (VLBW) infants, one would calculate the prevalence of VLBW births in each district:

1. Determine the number of live births in each district from birth certificate data obtained from the vital records division of the health department.
2. Use the birth weight information from the birth certificate data to determine the number of infants born weighing less than 1500 g in each district.

3. Calculate the prevalence of VLBW births by district as the number of infants weighing less than 1500 g at birth divided by the total number of live births.
4. If the number of VLBW births in each district is small, use several recent years of data to obtain a more stable estimate.

Measures of Incidence

Measures of incidence reflect the number of *new* cases or events in a population at risk during a specified time. An **incidence rate** quantifies the rate of development of new cases in a population at risk, whereas an **incidence proportion** indicates the proportion of the population at risk who experience the event over some period of time, for example, the proportion of the population who develop influenza during a given year (Rothman, 2012). The population at risk is considered to be persons without the event or outcome of interest but who are at risk of experiencing it. Note that existing (or prevalent) cases are excluded from the population at risk for this definition, since they already have the condition and are no longer at risk of developing it. The incidence proportion is also referred to as the **cumulative incidence rate** (and erroneously simply as the incidence rate) because it reflects the cumulative effect of the incidence rate over the time period, whether it is a month, a year, or several years. A constant incidence rate operating over a period of time results in an increasing proportion of the population who are affected, that is, the incidence rate may stay constant while the cumulative incidence rate increases with time because the pool of people who have the disease is becoming larger. An incidence proportion can be interpreted as an estimate of risk of disease in that population over that period. An example of this might be the incidence proportion for cancer. Using statistics published for a 5-year period of time, one could calculate that 20 of 200 individuals were newly diagnosed with cancer (hypothetical example). The incidence proportion would then be $20/200 = 0.10$ or 10%. This could be interpreted that over a 5-year period of time, the risk of cancer in the population was 10%. The risk of disease is a function of both the rate of new disease development and the length of time the population is at risk. The interpretation can be for an individual (i.e., the probability that the person will become ill) or for a population (i.e., the proportion of a population expected to become ill over the specified period). For further examples of these calculations as it relates to mortality, see Table 12-2.

Another common risk measure used by both the science and general community is relative risk. Essentially, the relative risk compares the incidence of disease in an “exposed” population to the incidence of disease in an “unexposed” population. In this way, the relative risk is based on the calculations that are performed for the cumulative incidence rate. As an example, one could conceptualize the exposure as “taking hormone replacement therapy” and the outcome as breast cancer. In this case, we would identify a group of women who would be of an age to take hormone replacement therapy. Next, we would categorize these women into two groups—those women not taking hormone replacement therapy and those who are taking hormone replacement. Within these two groups, then we would

calculate the *cumulative incidence rate* for each group. The *relative risk* would then be expressed as the cumulative incidence rate of breast cancer among women taking hormone replacement therapy divided by the cumulative incidence rate of breast cancer among those *not* taking hormone replacement therapy.

Because the relative risk is based upon a ratio, the actual value can range anywhere from >0 to infinity (theoretically). When the cumulative incidence rates are exactly equal, the relative risk is 1.00. This is often termed the “null value,” indicating that the exposure of interest has no effect on the outcome of interest. This is the statistic most often cited in media releases about scientific studies. Using the hormone replacement therapy and breast cancer example, a research study that indicated a relative risk of 1.75 can be interpreted to indicate that the risk of developing breast cancer among those women taking hormone replacement therapy is 75% times the risk of developing breast cancer among women not taking hormone replacement therapy. This is also the statistic that the nurses can use to estimate the probability of disease among their patients. This concept will be discussed in more detail later in this chapter in the section on cohort studies.

HOW TO Use Epidemiologic Concepts in Nursing

Epidemiologic concepts and data are used in ongoing assessments of both community and individual health problems. An initial component of a community health assessment is the collection of incidence, morbidity, and mortality rates for specific diseases. Health service data, such as immunization rates, causes of hospitalization, and emergency department visits, are also obtained. Additional areas for community assessment are outlined in the How To box on page 264. Individual health problems should incorporate evaluations of health risk based on lifestyle patterns along with the standard history and clinical examinations.

Prevalence Proportion

The **prevalence proportion** is a measure of existing disease in a population at a particular time (i.e., the number of existing cases divided by the current population). We can also calculate the prevalence of a specific risk factor or exposure. When used alone, the term *prevalence* typically refers to the *prevalence proportion*, although the term is sometimes used to refer to the count of existing cases (i.e., the numerator of the prevalence proportion). For example, consider the following data from a breast cancer screening program that had reached 8000. Among these 8000 women, if 35 had previously been diagnosed with breast cancer and an additional 20 cases of breast cancer were identified as a result of the screening program, the prevalence proportion of current and past breast cancer events in this population would be 55 out of 8000, expressed as a rate of 687.5 per 100,000.

It is important to note that a prevalence proportion is not an estimate of the risk of developing disease. The prevalence proportion is a function of both the rate at which new cases of the disease develop and how long these cases remain in the population. To illustrate this point, consider the prevalence of

TABLE 12-2 Common Mortality Rates

Rate/Ratio	Definition and Example
Crude mortality rate	Usually an annual rate that represents the proportion of a population who die from any cause during the period, using the midyear population as the denominator Example: In 2006 there were 2,426,264 deaths in a total population of 299,398,484, or 810.4 per 100,000: $\frac{2,426,264}{299,398,484} = 810.4 \text{ per } 100,000$
Age-specific rate	Number of deaths among persons of given age group per midyear population of that age group Example: 2006 age-specific mortality rate for 20- to 24-year-olds: $\frac{21,148}{21,111,240} = 100.2 \text{ per } 100,000$
Cause-specific rate	Number of deaths from a specific cause per midyear population Example: 2006 cause-specific rate for accidents: $\frac{121,599 \text{ deaths from accidents}}{299,398,484 \text{ midyear population}} = 40.6 \text{ per } 100,000$
Case-fatality rate	Number of deaths from a specific disease in a given period divided by number of persons diagnosed with that disease Example: If 87 of every 100 persons diagnosed with lung cancer die within 5 years, the 5-year case fatality rate is 87%. The 5-year survival rate is 13%.
Proportionate mortality ratio	Number of deaths from a specific disease per total number of deaths in the same period Example: In 2006 there were 631,636 deaths from diseases of the heart, and 2,426,264 deaths from all causes: $\frac{631,636}{2,426,264} = 0.26 \text{ or } 26 \text{ of all deaths in } 2006 \text{ were attributable to heart disease}$
Infant mortality rate	Number of infant deaths before 1 year of age in a year per number of live births in the same year Example: In 2006 there were 28,527 infant deaths and 4,265,555 live births: $\frac{28,527}{4,265,555} = 668.79 \text{ per } 100,000 \text{ live births or } 6.69 \text{ per } 1000 \text{ live births}$
Neonatal mortality rate	Number of infant deaths under 28 days of age in a year per number of live births in the same year Example: In 2006 there were 18,989 neonatal deaths and 4,265,555 live births: $\frac{18,989}{4,265,555} = 445.17 \text{ per } 100,000 \text{ or } 4.45 \text{ per } 1000 \text{ live births}$
Postneonatal mortality rate	Number of infant deaths from 28 days to 1 year in a year per number of live births in the same year Example: In 2006 there were 9538 postneonatal deaths and 4,265,555 live births: $\frac{9538}{4,265,555} = 223.61 \text{ per } 100,000 \text{ or } 2.24 \text{ per } 1000 \text{ live births}$

Deaths: Leading causes for 2010. *Natl Vital Stat Rep* 62(6), Hyattsville, MD, 2013, National Center for Health Statistics; Martin JA, Hamilton BE, Sutton PD, et al: Births: Final data for 2006. *Natl Vital Stat Rep* 57(7), Hyattsville, MD, 2009, National Center for Health Statistics.

prostate cancer. The number of people with prostate cancer at any given time reflects both the number of new cases diagnosed at that specific point in time and the number of previously diagnosed men currently living with the diagnosis of prostate cancer. The duration of a specific disease is affected by both case fatality and cure. For example, a disease with a short duration (e.g., an intestinal virus) may not have a high prevalence proportion, even if the rate of new cases is high, because cases do not accumulate (see Point Epidemic later in this chapter). A disease with a long course (e.g., Crohn's disease) will have a higher prevalence proportion than a rapidly fatal disease that has the same rate of new cases.

Comparing Prevalence and Incidence

The prevalence proportion measures existing cases of disease and is affected by factors that influence risk (incidence) and by factors that influence survival or recovery (duration). Prevalence proportions are useful in planning health care services because they indicate the level of disease existing in the

population and therefore the size of the population in need of services. However, prevalence measures are less useful when we are looking for factors related to disease etiology. Because prevalence proportions reflect duration in addition to the risk of getting the disease, it is difficult to sort out what factors are related to risk and what factors are related to survival or recovery.

For example, the 5-year survival rate for breast cancer is about 85%, but the 5-year survival rate for lung cancer in women is only about 15%. Even if the incidence rates of breast and lung cancer were the same in women (and they are not), the prevalence proportions would differ because, on average, women live longer after a diagnosis of breast cancer than do women diagnosed with lung cancer. In other words, the duration of breast cancer is longer.

The measures of choice in studying disease etiology are incidence rates and incidence proportions, because incidence is affected only by factors related to the risk of developing disease and not to survival or cure. At the level of a local health

department, epidemiologists and nurses would rely on both incidence and prevalence data in planning services focused on the prevention and control of tuberculosis (TB). They would examine the existing level of TB within the community (prevalence) to plan services and direct prevention and control measures, and they would take into consideration the rate of new TB cases (incidence) to study risk factors and evaluate the effectiveness of prevention and control programs.

HOW TO Assess Health Problems in a Community

1. Examine local epidemiologic data (e.g., incidence, morbidity, and mortality rates) to identify major health problems.
2. Examine local health services data to identify major causes of hospitalizations and emergency department visits. Consult with key community leaders (e.g., political, religious, business, educational, health, and cultural leaders) about their perceptions of identified community health problems.
3. Mobilize community groups to elicit discussions and identify perceived health priorities within the community (e.g., focus groups, neighborhood forums, or community-wide forums).
4. Analyze community environmental health hazards and pollutants (e.g., water, sewage, air, toxic waste).
5. Examine indicators of community knowledge and practices of preventive health behaviors (e.g., use of infant car seats, safe playgrounds, lighted streets, seat belt use, designated driver programs).
6. Identify cultural priorities and beliefs about health among different social, cultural, racial, or national origin groups.
7. Assess community members' interpretations of and degrees of trust in federal, state, and local assistance programs.
8. Engage community members in conducting surveys to assess specific health problems.

****For Further Note:** This process is very similar to the intake/assessment process that all nurses are familiar with such as obtaining medical and family history (analogous to #1 and #2 above), identifying health concerns of the patient (analogous to #3 and #5 above), perform clinical exam (analogous to #4 above), and evaluate patient knowledge, beliefs, and personal risk (analogous to #5-#8).

Attack Rate

Another measure of morbidity, often used in infectious disease investigations, is the **attack rate**. This form of incidence proportion is defined as the proportion of persons who are exposed to an agent and develop the disease. Attack rates are often specific to an exposure; food-specific attack rates, for example, are the proportion of persons becoming ill after eating a specific food item.

Mortality Rates

Mortality rates are key epidemiologic indicators of interest to nurses (Table 12-2). Although measures of mortality reflect serious health problems and changing patterns of disease, they are limited in their usefulness. Mortality rates are informative only for fatal diseases and do not provide direct information about either the level of existing disease in the population or the risk of contracting any particular disease. Also, it is not uncommon for a person who has one disease (e.g., prostate cancer) to die from a different cause (e.g., stroke).

Note that many commonly used mortality rates in Table 12-2 are in fact proportions, not true rates (Rothman, 2012; Gordis, 2013). Because the population changes during the course of a year, we typically take an estimate of the population at midyear as the denominator for annual rates, because the midyear population approximates the amount of person-time contributed by the population during a given year. Using the approximation noted previously for small rates when the period of observation is a single unit of time, the annual mortality rate is an estimate of the risk of death in a given population for that year. These rates are multiplied by a scaling factor (usually 100,000) to avoid small fractions. The result is then expressed as the number of deaths per 100,000 persons. Although a crude mortality rate is calculated easily and represents the actual death rate for the total population, it has certain limitations. It does not reveal specific causes of death, which change in relative importance over time (see Figure 12-1). Also, it is affected by the age distribution of the population because older people are at much greater risk of death than younger people. For example, in 2005 the U.S. crude mortality rate for African Americans was 749.4 per 100,000, compared with a rate of 873.7 per 100,000 for white Americans, even though the mortality rate was higher for African Americans than for whites in every age group up to age 85 (Heron, 2010).

Mortality rates are also calculated for specific groups (e.g., age-, sex-, or race-specific rates). In these instances, the number of deaths occurring in the specified group is divided by the population at risk, now restricted to the number of persons in that group. This rate may be interpreted as the risk of death for persons in the specified group during the period of observation.

The cause-specific mortality rate is an estimate of the risk of death from some specific disease in a population. It is the number of deaths from a specific cause divided by the total population at risk, usually multiplied by 100,000. Two related measures should be distinguished from the cause-specific mortality rate. The **case fatality rate (CFR)** is usually a proportion: the proportion of persons diagnosed with a particular disorder (i.e., cases) that die within a specified period of time. The CFR may be interpreted as an estimate of the risk of death within that period for a person newly diagnosed with the disease (e.g., the proportion of persons with breast cancer who die within 5 years). Because the CFR is the proportion of diagnosed persons who die within the period, 1 minus the CFR yields the survival rate. For example, if the 5-year CFR for lung cancer is 86%, then the 5-year survival rate is only 14% (Remington et al, 2010). Persons diagnosed with a particular disease often want to know the probability of survival. These rates provide an estimate of that probability.

The second measure to be distinguished from the cause-specific mortality rate is the **proportionate mortality ratio (PMR)**—the proportion of all deaths that are attributable to a specific cause. The denominator is not the population at risk of death but the total number of deaths in the population; therefore, the PMR is not a rate nor does it estimate the risk of death. The magnitude of the PMR is a function of both the number of deaths from the cause of interest and the number of deaths

from other causes. If deaths from certain causes decline over time, the PMR for deaths from other causes that remain fairly constant (in absolute numbers) may increase. For example, motor vehicle accidents accounted for 3.3 deaths per 100,000 persons 5 to 14 years of age in the United States in 2006, which is 21.8% of all deaths in this age group (the PMR). By comparison, motor vehicle accidents caused 22.3 deaths per 100,000 persons 75 to 84 years of age in 2006, which was less than 0.5% of all deaths in this older age group (Heron, 2010). This demonstrates that, although the risk of death from a motor vehicle accident was almost 6.8 times greater in the older group (based on the rates), such accidents accounted for a far greater proportion of all deaths in the younger group (based on the PMR). The reason is that there is a much greater risk of death from other causes in the older group.

Measures of infant mortality are used around the world as an indicator of overall health and availability of health care services. The most common measure, the infant mortality rate (IMR), is the number of deaths to infants in the first year of life divided by the total number of live births. Because the risk of death declines rather dramatically during the first year of life, neonatal and postneonatal mortality rates are also of interest (see Table 12-2). To effectively plan and evaluate community health interventions, nurses need to be able to understand and interpret these key epidemiologic indicators. One of the benefits of epidemiologic studies is that the results may demonstrate which disease prevention and control interventions are more useful and effective.

Epidemiologic Triangle, Web of Causality, and the Ecologic Model

Epidemiologists understand that disease results from complex relationships among causal agents, susceptible persons, and environmental factors. These three elements—**agent**, **host**, and **environment**—are traditionally referred to as the **epidemiologic triangle** (Figure 12-2, A). This model was originally developed as a way of identifying causative factors, transmission, and risk related to infectious diseases. Changes in one of the elements of the triangle can influence the occurrence of disease by increasing or decreasing a person's risk for disease. As illustrated in Figure 12-2, B, specific characteristics of agent and host, as well as the interactions between agent and host, are influenced by the environmental context in which they exist, and may in turn influence the environment. Examples of these three components are listed in Box 12-1.

Although the interactions of host, environment, and agent are clearly key elements in disease causation, causal relationships are often more complex than implied by the concept of the epidemiologic triangle. The concept of a **web of causality** reflects the more complex interrelationships among the numerous factors interacting, sometimes in subtle ways, to increase (or decrease) risk of disease. Furthermore, associations are sometimes mutual, with lines of causality going in both directions. More recently, some epidemiologic researchers have advocated a new paradigm that goes beyond the two-dimensional causal web to consider multiple levels of factors that affect health and disease (Krieger, 1994; Macintyre and Ellaway, 2000).

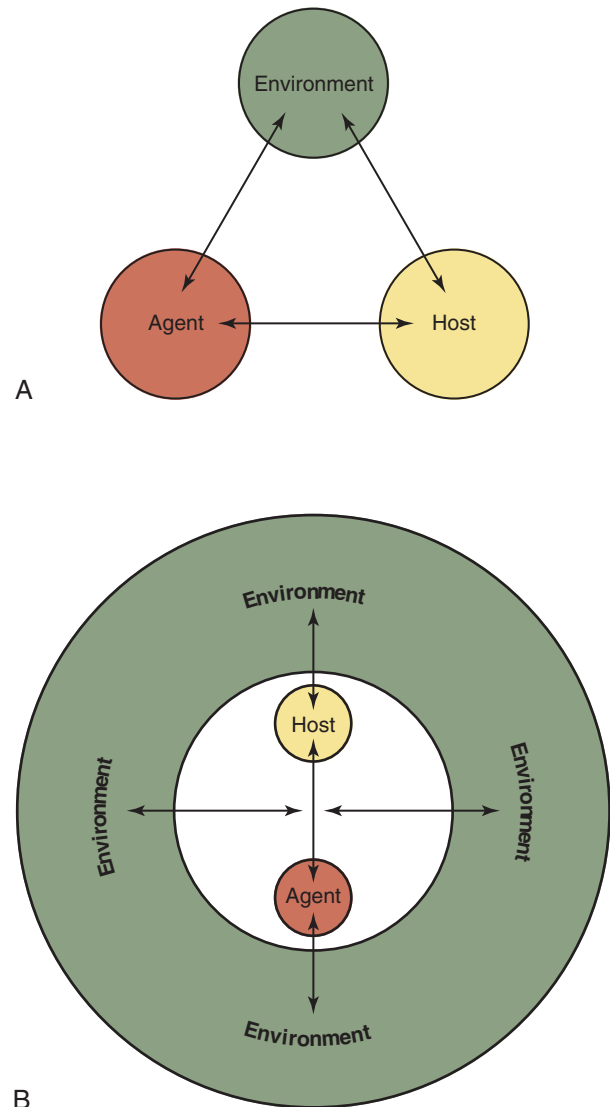

FIG 12-2 Two models of the agent-host-environment interaction (the epidemiologic triangle).

BOX 12-1 Examples of Agent, Host, and Environmental Factors in the Epidemiologic Triangle

Agent

Infectious agents (e.g., bacteria, viruses, fungi, parasites)
Chemical agents (e.g., heavy metals, toxic chemicals, pesticides)
Physical agents (e.g., radiation, heat, cold, machinery)

Host

Genetic susceptibility
Immutable characteristics (e.g., age, sex)
Acquired characteristics (e.g., immunological status)
Lifestyle factors (e.g., diet and exercise)

Environment

Climate (e.g., temperature, rainfall)
Plant and animal life (e.g., agents or reservoirs or habitats for agents)
Human population distribution (e.g., crowding, social support)
Socioeconomic factors (e.g., education, resources, access to care)
Working conditions (e.g., levels of stress, noise, satisfaction)

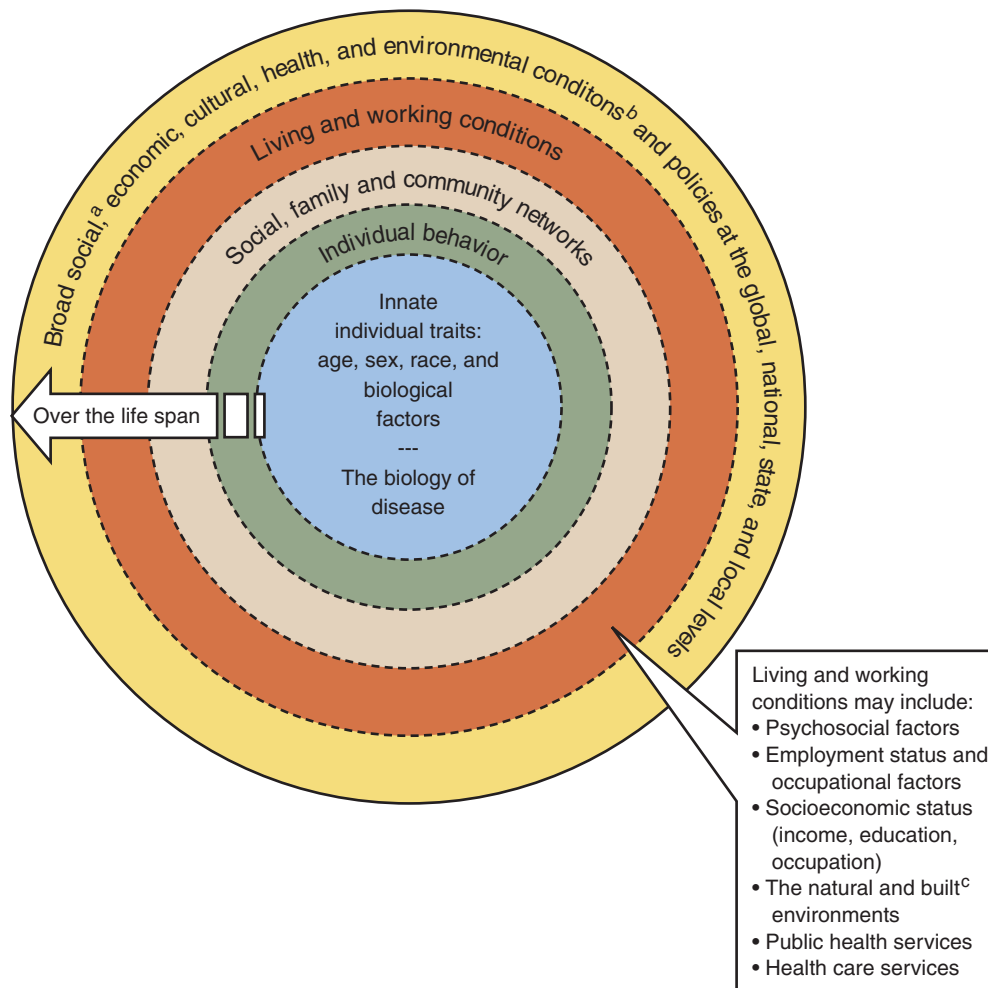

FIG 12-3 Determinants of population health. This is a guide to thinking about the determinants of population health. (Reprinted with permission from *The Future of the Public's Health in the 21st Century*, Copyright 2002 by the National Academy of Sciences, courtesy of the National Academies Press, Washington, DC). ^a Social conditions include, but are not limited to: economic inequality, urbanization, mobility, cultural values, attitudes and policies related to discrimination and intolerance on the basis of race, gender, and other differences. ^b Other conditions at the national level might include major sociopolitical shifts, such as recession, war, major environmental disasters, and governmental collapse. ^c The built environment includes transportation, water and sanitation, housing, and other dimensions of urban planning.

Krieger (1994) has suggested that in addition to research on the relationships within the web, we need to look for “the spider”—that is, focus on those larger factors and contexts that influence or create the causal web itself.

With this shift in the scientific thinking, practitioners and researchers are thinking more broadly about the multiple underlying determinants of health. There is increasing recognition of the widespread and profound influence of external factors on the health of individuals, communities, and populations. This is consistent with the ecologic model for population health illustrated in Figure 12-3. This approach expands epidemiologic studies both upward to broader contexts (such as neighborhood characteristics and social context) and downward to the genetic and molecular level. Of course the relative impact of the various factors depicted in this figure is not fixed, and would vary across different populations, contexts, and

settings. However, the model does provide a useful guide for considering the potential relative impact for intervention across various sectors.

Like the web of causality model, the ecologic model recognizes multiple determinants of health and treats them as inter-related and acting synergistically (or antagonistically), rather than as a list of discrete factors. The ecologic model spans a broader spectrum of systems and etiological factors than the more traditional web of causality model and it encompasses determinants at many levels: biological, mental, behavioral, social, and environmental factors, including policy, culture, and economic environments. Another way of thinking of this is that the ecologic model moves from a two-dimensional perspective to a multidimensional perspective. Nurses have a significant role in shaping the health of the population and need to be mindful of the many environmental factors that may contribute

to health behaviors and health outcomes. In addressing health behavior change, nurses often focus on patient education (within the domain of “health behaviors” in [Figure 12-3](#)). However, lack of attention to other environmental and social issues (i.e., lack of transportation, lack of adequate childcare arrangements, financial constraints, inadequate housing) may mean that the patient is unable to access or respond appropriately to the health education efforts.

Social Epidemiology

A renewed interest in social epidemiology is attributed in part to the recognition of persistent social inequalities in health. **Social epidemiology** is the branch of epidemiology that studies the social distribution and social determinants of health and disease ([Berkman and Kawachi, 2000](#); [Krieger, 2000](#); [Kawachi and Berkman, 2003](#)). Social epidemiologists focus on the roles and mechanisms of specific social phenomena (e.g., socioeconomic stratification, social networks and support, discrimination, work and employment demands) in the production of health and disease states. Social epidemiologists examine social inequalities and data related to neighborhoods, communities, employment, and family conditions to analyze health issues and design appropriate and feasible public health interventions. Public health professionals are concerned with relationships between social conditions and patterns of health and disease in individuals, families, groups, and populations.

The complex factors that influence or lead to social inequalities in health are being increasingly examined or “rediscovered” through the lens of epidemiology. [Berkman and Kawachi \(2000\)](#) identified several key concepts within the subfield of social epidemiology. These include a population perspective ([IOM, 2002](#)), the social context of behavior, contextual and multilevel analysis ([Sampson et al, 1997](#); [Diez-Roux, 2002](#)), a developmental and life-course perspective, and general susceptibility to disease. The aim of social epidemiology is to identify ways in which the structure of society influences the public’s health, through the interactions of social context, environmental factors, biological mechanisms, and the timing and accumulation of risk, as represented by the ecologic model and the life-span perspective. Social epidemiologists have called for further research to examine the impact of extra-individual factors (institutions, communities, macroeconomic conditions, and economic and social policy) on exposure to resources ([Lynch and Kaplan, 2000](#)).

Levels of Preventive Interventions

The goal of epidemiology is to identify and understand the causal factors and mechanisms of disease, disability, and injuries so that effective interventions can be implemented to prevent the occurrence of these adverse processes before they begin or before they progress. The **natural history of disease** is the course of the disease process from onset to resolution ([Porta, 2008](#)). The three levels of prevention provide a framework commonly used in public health practice (see the Levels of Prevention box later in the chapter). As practicing epidemiologists, nurses working in the community are involved in primary, sec-

ondary, and tertiary prevention of communicable and noncommunicable diseases.

Primary Prevention

In their daily practice, nurses are often involved in activities related to all three **levels of prevention** (see [Levels of Prevention](#) box). Primary prevention refers to interventions aimed at preventing the occurrence of disease, injury, or disability. Interventions at this level of prevention are aimed at individuals and groups who are susceptible to disease but have no discernible pathology (i.e., they are in a state of prepathogenesis). This first level of prevention includes broad efforts such as health promotion, environmental protection, and specific protection. Health promotion includes nutrition education and counseling and the promotion of physical activity. Environmental protection ranges from basic sanitation and food safety, to home and workplace safety plans, to air quality control. Examples of specific protection against disease or injury include immunizations, proper use of seat belts and infants’ car seats, preconception folic acid supplementation to prevent neural tube defects, fluoridation of water supplies to prevent dental caries, and actions taken to reduce human exposure to agents that may cause cancer. Primary prevention occurs in homes, in community settings, and at the primary level of health care (e.g., in public health clinics, physicians’ offices, community health centers, and rural health clinics).

LEVELS OF PREVENTION

Examples Related to Cardiovascular Disease

Primary Prevention

Counsel clients about low-fat diet and regular physical exercise.

Secondary Prevention

Implement blood pressure and cholesterol screening; give treadmill stress test.

Tertiary Prevention

Provide cardiac rehabilitation, medication, surgery.

Examples of nurses’ involvement in primary prevention include health education and promotion programs, such as nutrition education and counseling, sex education, and family planning services. Primary prevention efforts focus on both the general population and on specific vulnerable groups (e.g., the homeless, HIV-positive persons, certain immigrant groups) to improve the general health status and to reduce the incidence of specific diseases such as TB. An example of a primary prevention intervention is the provision of health education and training for daycare workers regarding health and hygiene issues, such as proper hand hygiene, diapering, and food preparation and storage. Immunizations are another example of primary prevention. In terms of environmental protection, nurses work proactively to develop and advocate for policies and legislation that lead to prevention of environmental hazards. They can also provide consultation to industries, local governments, and

groups of concerned citizens as well as public education for a wide range of preventable environmental health problems.

Secondary Prevention

Secondary prevention encompasses interventions designed to increase the probability that a person with a disease will have that condition diagnosed at a stage when treatment is likely to result in cure. Health screenings are the mainstay of secondary prevention. Early and periodic screenings are critical for diseases for which there are few specific primary prevention strategies, such as breast cancer. (Screening programs are discussed in more detail later in the chapter.) As noted above, primary prevention is a major focus of health education. However, nurses often use health education interventions when caring for individuals with a diagnosed health problem with the aim of preventing further complications or exacerbations. For example, at the individual and family level, teaching the asthmatic child to recognize and avoid exposure to potential asthma triggers and helping the family implement specific protection strategies, such as replacing carpets, keeping air systems clean and free of mold, and avoiding contact with household pets and second-hand smoke could be considered secondary prevention.

Interventions at the secondary level of prevention may occur in community settings as well as within primary and secondary levels of health care services. Oral rehydration therapy (ORT) for infant diarrheal disease is an excellent example of secondary prevention in the community. Particularly in developing countries, when safe water can be made available, ORT is a low-cost and effective way to treat infant diarrheal disease. When mothers identify the early signs of infant dehydration and administer a homemade ORT solution of water, sugar, and salt, they are putting secondary prevention into practice. When taking a health history with clients, nurses can integrate secondary prevention into practice by asking about family history of cancer, heart disease, diabetes, and mental illness, and then providing follow-up education about appropriate screening procedures.

Other examples of secondary prevention interventions include screening tests to detect breast cancer (i.e., mammography), cervical cancer (i.e., Pap tests), colon cancer (i.e., colonoscopy), prenatal screening of pregnant women to detect gestational diabetes, routine tuberculin testing of specific groups (e.g., health care providers, childcare workers), and identification and screening of persons who have had contact with an individual known to have TB. In all these examples, the aim of secondary prevention is to identify the presence of a disease or condition at an early stage and begin necessary treatment early to increase the likelihood of cure or to prevent further complications.

Tertiary Prevention

Tertiary prevention includes interventions aimed at disability limitation and rehabilitation from disease, injury, or disability. Tertiary prevention interventions occur most often at secondary and tertiary levels of care (e.g., specialized clinics, hospitals, rehabilitation centers) but may also occur in community and primary care settings. Medical treatment, physical and occupational therapy, and rehabilitation are interventions characterized as tertiary prevention. With the emergence of new drug-resistant strains of TB, nurses now face the challenge of designing and implementing programs to increase long-term compliance and provide aftercare for clients in a variety of community settings. An example of tertiary prevention is a public health nurse providing directly observed therapy (DOT) to individuals diagnosed with active TB.

An Intervention Spectrum

The standard classification of preventive measures in public health is composed of the primary, secondary, and tertiary levels of prevention. However, this standard classification has been revised and refined for application to diverse settings and health issues. In the field of cancer, this potential for intervention has been conceptualized across the entire continuum of care (Figure 12-4). As cancer is a disease which, for most anatomical sites,

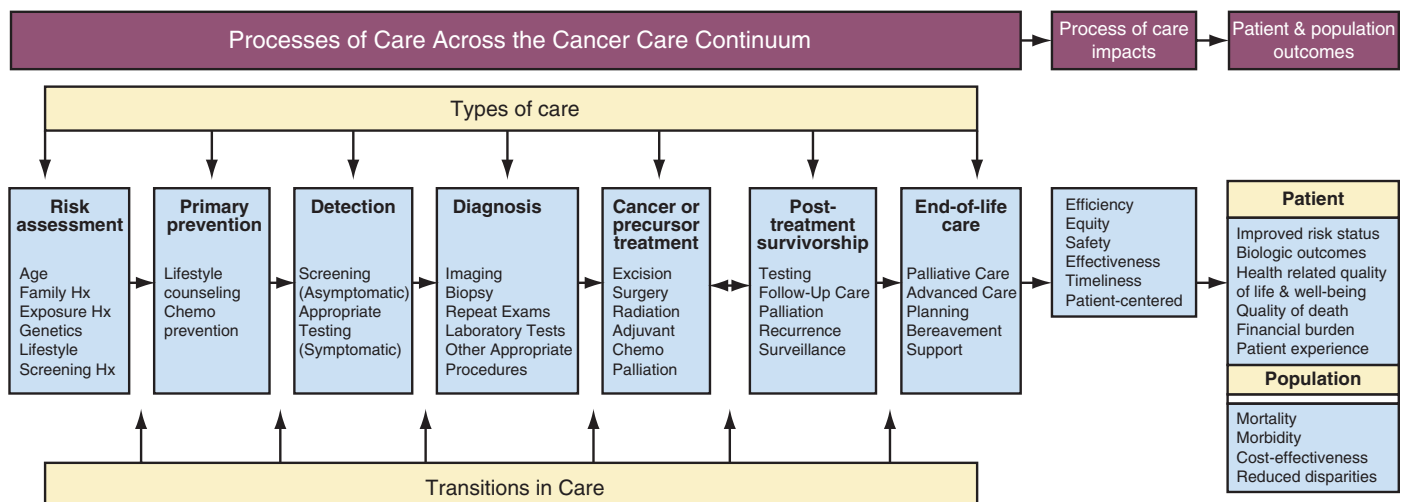

FIG 12-4 Multilevel interventions in health care across the cancer care continuum. (Taplin SH, Price RA, Edwards HM, et al: Introduction: Understanding and Influencing Multilevel Factors Across the Cancer Care Continuum. *J Natl Cancer Inst Monogr* (44): 2–10, 2012. Oxford University Press.)

has a relatively long period of development, this creates a longer timeline for potential intervention by the researcher or health practitioner. For example, family history of breast cancer is known to be a strong risk factor among specific subgroups of women. Knowing this, the nurse can advocate for genetic testing (first intervention) and also (regardless of the test result) promote healthy lifestyle choices when counseling patients (second intervention). In patients diagnosed with hormone positive breast cancer, the nurse can counsel and facilitate treatment adherence for the woman to her hormonal therapy (third intervention point). Other interventions would include facilitating communication with patients and their families in order to expedite the treatment trajectory from the point of diagnosis to the scheduled surgery (fourth intervention point). Clearly, nurses have critical roles in prevention at all points across the intervention spectrum.

SCREENING

Screening, a key component of many secondary prevention interventions, involves the testing of groups of individuals who are at risk for a certain condition but are as yet asymptomatic. The purpose is to classify these individuals with respect to the likelihood of having the disease. From a clinical perspective, the aim of screening is early detection and treatment when these result in a more favorable prognosis. From a public health perspective, the objective is to sort out efficiently and effectively those who probably have the disease from those who probably do not, again to detect early cases for treatment or begin public health prevention and control programs. A screening test is *not* a diagnostic test. Effective screening programs must have built-in referral mechanisms for subsequent diagnostic evaluation for those who screen positive, to determine if they actually have the disease and need treatment, and there must be effective protocols in place for referral to accessible and appropriate follow-up care and treatment. If there is no effective treatment, or if the individuals or groups targeted for screening experience considerable barriers in accessing appropriate treatment, the justification of the screening program must be assessed ethically as well as epidemiologically (Childress et al, 2002).

As public health advocates, nurses are responsible for planning and implementing screening and prevention programs targeted to the at-risk populations. Nurses working in schools, worksites, primary care facilities, and public health agencies may work together to target at-risk populations on the basis of occupational and environmental risks. Successful screening programs have several characteristics that depend on the tests and on the population screened (Box 12-2). In planning screening programs for a specific population (e.g., school, workplace, community), nurses need to take into consideration various factors. These include the characteristics of the health problem, the screening tests available, and the population (Harkness, 1995). Screening is recommended for health problems that have a high prevalence, are relatively serious, can be detected in early states, and for which effective treatment is available. The population should be easily identifiable and assessable, amenable to screening, and willing and able to seek treatment or follow-up

BOX 12-2 Characteristics of a Successful Screening Program

1. *Valid (accurate)*: A high probability of correct classification of persons tested
2. *Reliable (precise)*: Results consistent from place to place, time to time, and person to person
3. *Capable of large group administration*:
 - a. Fast in both the administration of the test and the procurement of results
 - b. Inexpensive in both personnel required and materials and procedures used
4. *Innocuous*: Few, if any, side effects; minimally invasive test
5. *High yield*: Able to detect enough new cases to warrant the effort and expense (yield defined as the amount of previously unrecognized disease that is diagnosed and treated as a result of screening)
6. *Ethical and effective*: Meets the desired public health goal with health benefits that outweigh any moral or ethical infringements.

procedures. Criteria for evaluating the suitability of screening tests include cost-effectiveness, ease and safety of administration, availability of treatment, ethics of administration or widespread implementation, sensitivity, specificity, validity, and reliability (Gordis, 2013; McKeown and Learner, 2009).

Screening procedures exist for a wide range of health conditions, including cancer (e.g., breast, cervical, testicular, colon, rectal, and skin), diabetes, hypertension, TB, lead poisoning, hearing loss, and sexually transmitted diseases (e.g., gonorrhea, chlamydia, syphilis). Nurses must keep abreast of recommended screening guidelines, which are regularly reviewed and revised on the basis of epidemiologic research results. For example, the latest **U.S. Preventive Services Task Force guidelines (USPSTF, 2008)** strongly recommend routine screening for lipid disorders in men 35 years and older and women 45 years and older. Screening for younger adults (men ages 20 to 35 and women ages 20 to 45) is recommended when any of the following risk factors are present: diabetes, family history of cardiovascular disease before age 50 in men or age 60 in women, family history suggestive of familial hyperlipidemia, or multiple coronary heart disease risk factors (e.g., tobacco use, hypertension). The Task Force also noted that all clients, regardless of lipid levels, should be offered counseling about the benefits of a diet low in saturated fat and high in fruits and vegetables, regular physical activity, avoidance of tobacco, and maintenance of healthy weight.

The rationale for the current lipid screening guidelines is as follows. The clearest benefit of lipid screening is identifying individuals whose near-term risk of coronary heart disease is sufficiently high to justify drug therapy or other intensive lifestyle interventions to lower cholesterol levels. Screening men older than age 35 years and women older than age 45 years will identify nearly all individuals whose risk of coronary heart disease is as high as that of the subjects in the existing primary prevention trials. Younger people typically have a substantially lower risk, unless they have other important risk factors for coronary heart disease or familial hyperlipidemia. The primary goal of screening younger people is to promote lifestyle

changes, which may provide long-term benefits later in life. The average effect of diet interventions is small, and screening is not needed to advise young adults about the benefits of a healthy diet and regular exercise because this advice is considered useful for all age groups. Although universal screening may detect some clients with familial hyperlipidemia earlier than selective screening, it has yet to be determined if universal screening would lead to significant reductions in coronary events (USPSTF, 2008).

Reliability and Validity

Reliability

The precision, or **reliability**, of the measure (i.e., its consistency or repeatability) and its **validity** or accuracy (i.e., whether it really measures what we think it is measuring, and how exact the measurement is) are important considerations for any measurement. For example, suppose you are planning to conduct a blood pressure screening in a community setting. You will probably be taking blood pressure measurements on a large number of people and then following up with repeated measures for individuals identified as having higher levels of blood pressure. If the sphygmomanometer used for the blood pressure screening varies in its measurement so that it does not record a similar reading for the same person twice in a row, it lacks precision (or reliability). The instrument would be unreliable even if the overall mean of repeated measurements was close to the true overall mean for the persons measured. The problem would be that the readings would not be reliable for any individual, which is what a screening program requires. On the other hand, suppose the readings are reliably reproducible, but, unknown to you, they tend to be about 10 mm Hg too high. This instrument is producing precise readings, but the uncorrected (or uncalibrated) instrument lacks accuracy (or validity). In short, a measure can be *consistent* without producing *valid* results.

Three major sources of error can affect the reliability of measurement:

- Variation inherent in the trait being measured (e.g., blood pressure changes with time of day, activity, level of stress, and other factors)
- Observer variation, which can be divided into intra-observer reliability (the level of consistency by the same observer) and inter-observer reliability (the level of consistency from one observer to another)
- Inconsistency in the instrument, which includes the internal consistency of the instrument (e.g., whether all items in a questionnaire measure the same thing) and the stability (or test-retest reliability) of the instrument over time

Validity: Sensitivity and Specificity

Validity in a screening test is measured by sensitivity and specificity. **Sensitivity** quantifies how accurately the test identifies those *with* the condition or trait. In other words, sensitivity represents the proportion of persons with the disease whom the test correctly identifies as positive (true positives). High sensitivity is needed when early treatment is important and when identification of every case is important.

Specificity indicates how accurately the test identifies those *without* the condition or trait—in other words, the proportion of persons whom the test correctly identifies as negative for the disease (true negatives). High specificity is needed when rescreening is impractical and when reduction of false positives is important. The sensitivity and specificity of a test are determined by comparing the results from the screening test with results from a definitive diagnostic procedure (sometimes called the gold standard). For example, the Pap smear is used frequently to screen for cervical dysplasia and carcinoma. The definitive diagnosis of cervical cancer requires a biopsy with histologic confirmation of malignant cells.

The ideal for a screening test is 100% sensitivity and 100% specificity. That is, the test is positive for 100% of those who actually have the disease, and it is negative for all those who do not have the disease. In practice, sensitivity and specificity are often inversely related. That is, if the test results are such that one can choose some point beyond which a person is considered positive (a “cutpoint”), as in a blood pressure reading to screen for hypertension or a serum glucose reading to screen for diabetes, then moving that critical point to improve the sensitivity of the test will result in a decrease in specificity. In other words, an improvement in specificity can be made only at the expense of sensitivity. Table 12-3 shows how to calculate sensitivity and specificity. Some authors refer to a false-positive rate, which is 1 minus the specificity, and a false-negative rate, or 1 minus the sensitivity. These “rates” are simply the proportions of subjects incorrectly labeled as *nondiseased* and *diseased*, respectively.

A third measure associated with sensitivity and specificity is the predictive value of the test. The **positive predictive value** (also called predictive value positive) is the proportion of persons with a positive test who actually have the disease, interpreted as the probability that an individual with a positive test has the disease. The **negative predictive value** (or predictive value negative) is the proportion of persons with a negative test who are actually disease free. Although sensitivity and specificity are relatively independent of the prevalence of disease, predictive values are affected by the level of disease in the screened population and by the sensitivity and specificity of the test. When the prevalence is very low, the positive predictive value will be low, even with tests that are sensitive and specific. In

TABLE 12-3 Classification of Subjects According to True Disease State and Screening Test Results for Calculation of Indices of Validity

Result of Screening Test	Disease	No Disease
Positive	True positive (TP)	False positive (FP)
Negative	False negative (FN)	True negative (TN)

Sensitivity = $TP/(TP + FN)$; specificity = $TN/(TN + FP)$; false-negative “rate” = $1 - \text{sensitivity} = FN/(FN + TP)$; false-positive “rate” = $1 - \text{specificity} = FP/(TN + FP)$; positive predictive value = $TP/(TP + FP)$; often multiplied by 100 and expressed as a percentage.

addition, lower specificity produces lower positive predictive values because of the increase in the proportion of false-positive results.

In setting cut points, it is necessary to consider the potential human and economic costs of missing true cases by lowering the sensitivity versus the cost of falsely classifying noncases by lowering the specificity. In making such decisions, factors to be considered include the importance of capturing all cases, the likelihood that the population will be rescreened, the interval between screenings relative to the rate of disease development, and the prevalence of the disease. A low prevalence typically requires a test with high specificity; otherwise, the screening will produce too many false positives in the largely nondiseased population. On the other hand, a disease with a high prevalence usually requires high sensitivity; otherwise, too many of the real cases will be missed by the screening (false negatives).

Two or more tests can be combined, in series or in parallel, to enhance sensitivity or specificity. In series testing, the final result is considered positive only if all tests in the series were positive, and it is considered negative if any test was negative. For example, if a blood sample were screened for HIV, a positive enzyme-linked immunosorbent assay (ELISA) might be followed up with a Western blot, and the sample would be considered positive only if both tests were positive. Series testing enhances specificity, producing fewer false positives, but sensitivity will be lower. In series testing, sequence is important; a very sensitive test is often used first to pick up all cases including false positives, and then a second, very specific test is used to eliminate the false positives. In parallel testing, the final result is considered positive if *any* test was positive and negative only if all tests were negative. To return to the example of a blood sample being tested for HIV, a blood bank might consider a sample positive if a positive result was found on either the ELISA or the Western blot. Parallel testing enhances sensitivity, leaving fewer false negatives, but specificity will be lower.

SURVEILLANCE

Surveillance involves the systematic collection, analysis, and interpretation of data related to the occurrence of disease and the health status of a given population. Surveillance systems are often classified as either active or passive (Teutsch and Churchill, 2010). Passive surveillance is the more common form used by most local and state health departments. Health care providers in the community report cases of notifiable diseases to public health authorities through the use of standardized reports. Passive surveillance is relatively inexpensive but is limited by variability and incompleteness in provider reporting practices. Active surveillance is the purposeful, ongoing search for new cases of disease by public health personnel, through personal or telephone contacts or the review of laboratory reports or hospital or clinic records. Because active surveillance is costly, its use is often limited to brief periods for specific purposes as in the emergence of a newly identified disease, a particularly severe disease, or the reemergence of a previously eradicated disease. In situations that do not require ongoing active surveillance, or

where it may not be feasible to maintain a surveillance system across larger geographic areas, sentinel surveillance systems may be instituted. Representative populations may be selected and sentinel providers identified to provide information on specific diseases or conditions. Nurses engage in surveillance activities as they monitor the health status of individuals, families, and groups in their care. They use surveillance data to assess and prioritize the health needs of populations, design public health and clinical services to address those needs, and evaluate the effectiveness of public health programs.

BASIC METHODS IN EPIDEMIOLOGY

Sources of Data

One of the first issues to address in any epidemiologic study is how to obtain the data (Koepsell and Weiss, 2003; Gordis, 2013). Three major categories of data sources are commonly used in epidemiologic investigations:

1. Routinely collected data, such as census data, vital records (birth and death certificates), and surveillance data as carried out by the CDC.
2. Data collected for other purposes but useful for epidemiologic research, such as medical, health department, and insurance records.
3. Original data collected for specific epidemiologic studies.

The first two types of data are often referred to as *secondary data*, and the third type is commonly considered *primary data*.

Routinely Collected Data

Vital records are the primary source of birth and mortality statistics. Although registration of births and deaths is mandated in most countries, thus providing one of the most complete sources of health-related data, the quality of specific information varies. For example, on birth certificates, sex and date of birth are fairly reliable, whereas gestational age, level of prenatal care, and smoking habits of the mother during pregnancy are less reliable. On death certificates, the quality of the cause of death information varies over time and from place to place, depending on diagnostic capabilities and custom. Vital records, readily available in most areas, are inexpensive and convenient and allow study of long-term trends. Mortality data, however, are informative only for fatal diseases or events.

Since 1790, the U.S. Census has been conducted every 10 years. The U.S. Census provides population data, including demographic distribution (e.g., age, race, sex), geographic distribution, and additional information about economic status, housing, and education. Census data are used as denominators for various rates. The American Community Survey is an ongoing survey also conducted by the U.S. Census Bureau. Data from these surveys provide important information on the status of the population and for public health planning and evaluation activities.

Data Collected for Other Purposes

Hospital, physician, health department, laboratory, and insurance records provide information on morbidity, as do surveillance systems, such as cancer registries and health department

reporting systems, which solicit reports of all cases of a particular disease within a geographic region. Other information, such as occupational exposures, may be available from employer records. School and employment attendance and absenteeism records are another potential source of data that may be used in epidemiologic investigations.

Epidemiologic Data

The National Center for Health Statistics sponsors periodic health surveys and examinations in carefully drawn samples of the U.S. population. Examples are the National Health and Nutrition Examination Survey (NHANES), the National Health Interview Survey (NHIS), and several National Health Care Surveys including the National Hospital Discharge Survey (NHDS), the National Ambulatory Medical Care Survey (NAMCS), and the National Nursing Home Survey (NNHS). The CDC also conducts or contracts for surveys such as the Youth Risk Behavior Survey (YRBS), the Pregnancy Risk Assessment Monitoring System (PRAMS), and the Behavioral Risk Factor Surveillance System (BRFSS). These surveys provide information on the health status and behaviors of the population. For many studies, however, the only way to obtain the needed information is to collect the required data in a study specifically designed to investigate a particular question. The design of such studies is discussed later.

With the technological advances available through GIS, the use of cartographic data for epidemiologic studies is becoming more widespread. For example, GIS systems are now an integral component of malaria vector control in Mexico and Central America (Najera-Aguilar et al, 2005). Local health professionals and authorities who survey their communities to identify mosquito breeding sites now use global positioning system (GPS) and GIS technology to display and analyze their data. The resulting GIS maps are graphic illustrations of their communities, including buildings, streets, rivers, mosquito breeding sites, and dwellings where individuals with malaria live. These maps allow the calculation of preventive treatments for dwellings located inside various radiuses, from 50 to 250 meters, around the houses with malaria cases. The standardization and integration of cartographic data collection in countries with endemic malaria are part of coordinated international efforts to strengthen malaria control. GIS technology has been used to examine other health issues, such as access to prenatal care. McLafferty and Grady (2005) compared levels of geographic access to prenatal clinics among immigrant groups in Brooklyn, New York. They used kernel estimation—a technique to depict the density of points (in this case, prenatal clinics) as a spatially continuous variable that can be represented as a smooth contour map. Then, using birth record data for the year 2000, which included the mother's country of birth, they compared clinic density levels among different immigrant groups. The authors noted the usefulness of these methods for public health departments in exploring demographic transitions and developing health service networks that are responsive to immigrant populations. GIS technology can be applied in a variety of situations, such as mapping the distribution of health exposures or outcomes, linking data with geo-coded addresses of individuals to

sources of potentially toxic exposures, and mapping water quality measures in sensitive ecosystems.

Rate Adjustment

Rates, which are of central importance in epidemiologic studies, can be misleading when compared across different populations. For example, the risk of death increases rather dramatically after 40 years of age; therefore, a higher crude death rate is expected in a population of older people compared with a population of younger people (Rothman, 2012; Koepsell and Weiss, 2003; Gordis, 2013). Because the direct comparison of the overall mortality rate in an area with a large population of older adults to the mortality rate in an area with a much younger population would be misleading, there are methods that adjust for such differences in populations. Age adjustment is based on the assumption that a population's overall mortality rate is a function of the age distribution of the population and the age-specific mortality rates. Rates for any outcome can be adjusted by the methods described here, but we focus our discussion on age adjustment of death rates because it is most common. As noted previously: as the population ages, the risk of death increases.

Age adjustment can be performed by direct or indirect methods. Both methods require a *standard population*, which can be an external population, such as the U.S. population for a given year; a combined population of the groups under study; or some other standard chosen for relevance or convenience. A direct age-adjusted rate applies the age-specific death rates from the study population to the age distribution of the standard population. The result is the (hypothetical) death rate of the study population if it had the same age distribution as the standard population.

The indirect method, as the name suggests, is more complicated. The age-specific death rates of the standard population applied to the study population's age distribution produce an index rate that is used with the crude rates of both the study and standard populations to produce the final indirect adjusted rate, which is also hypothetical. The indirect method may be required when the age-specific death rates for the study population are unknown or unstable (e.g., based on relatively small numbers). Often, instead of an indirect adjusted rate, a standardized mortality ratio (SMR) is calculated. This is the number of observed deaths in the study population divided by the number of deaths expected on the basis of the age-specific rates in the standard population and the age distribution of the study population (Szklo and Nieto, 2012; Gordis, 2013).

Although this discussion has focused on age adjustment, the process can be used to adjust for any factor that might vary from one population to another. For example, to compare infant mortality rates across populations with different birth weight distributions, these methods may be used to produce birth weight-adjusted infant mortality rates. Note that all adjusted rates are fictitious rates. They may resemble crude rates if the distribution of the study sample is similar to the distribution of the standard population. The magnitude of adjusted rates depends on the standard population used. The choice of a different standard would produce a different adjusted

rate. The change from the 1940 U.S. population to the 2000 U.S. population as the standard for age-adjusted rates from the NCHS demonstrates the difference a change in standard population can make (Anderson and Rosenberg, 1998; Sorlie et al, 1999).

Comparison Groups

The use of comparison groups is at the heart of the epidemiologic approach. Incidence or prevalence measures in groups that differ in some important characteristic must be compared to gain clues about which factors influence the distribution of disease (i.e., disease determinants or risk factors). Observing the rate of disease only among persons exposed to a suspected risk factor will not show clearly that the exposure is associated with increased risk until the rate observed in the exposed group is compared with the rate in a group of comparable unexposed persons. To illustrate, one might investigate the effect of smoking during pregnancy on the rate of birth of low-birth-weight infants by calculating the rate of low-birth-weight infants born to women who smoked during their pregnancy. However, the hypothesis that smoking during pregnancy is a risk factor for low birth weight is supported only when the low-birth-weight rate among smoking women is compared with the (lower) rate of low-birth-weight infants born to nonsmoking women.

The ideal approach would be to compare one group of people who all have a certain characteristic, exposure, or behavior, with a group of people *exactly* like them except that they all *lack* that characteristic, exposure, or behavior. In the absence of that ideal, researchers either randomize people to exposure or treatment groups in experimental studies, or they select comparison groups that are comparable in observational studies. Advances in statistical techniques now make it possible to control for differences between groups, but these advanced techniques are effective only in reducing the bias that results from confounding by variables we have measured.

DESCRIPTIVE EPIDEMIOLOGY

Descriptive epidemiology describes the distribution of disease, death, and other health outcomes in the population according to person, place, and time, providing a picture of how things are or have been—the who, where, and when of disease patterns. Analytic epidemiology, on the other hand, searches for the determinants of the patterns observed—the how and why. That is, epidemiologic concepts and methods are used to identify what factors, characteristics, exposures, or behaviors might account for differences in the observed patterns of disease occurrence. Descriptive and analytic studies are observational, meaning the investigator observes events as they are or have been and does not intervene to change anything or introduce a new factor. Experimental or intervention studies, however, include interventions to test preventive or treatment measures, techniques, materials, policies, or drugs.

Person

Personal characteristics of interest in epidemiology include race, ethnicity, sex, age, education, occupation, income (and

related socioeconomic status), and marital status. As noted previously, the most important predictor of overall mortality is age. The mortality curve by age drops sharply during and after the first year of life to a low point in childhood, then it begins to increase through adolescence and young adulthood, and after that it increases sharply (exponentially) through middle and older ages (Gordis, 2013).

There are also substantial differences in mortality and morbidity rates by sex. Female infants have a lower mortality rate than comparable male infants, and the survival advantage continues throughout life (Xu, Kochanek, and Tejada-Vera, 2009). However, patterns for specific diseases vary. For example, women have lower rates of CHD until menopause, after which the gap narrows. For rheumatoid arthritis, the prevalence among women is greater than among men (Remington, Brownson, and Wegner, 2010).

Although the concept of race as a variable for public health research has come under scrutiny (CDC, 1993; Fullilove, 1998), there are clear differences in morbidity and mortality rates by race in the United States (USDHHS, 2000; NCHS, 2009). According to the Office of Minority Health (OMH, 1999), racial and ethnic minority groups are among the fastest-growing populations in the United States, yet they have poorer health and remain chronically underserved by the health care system. Data in the OMH report *Elimination of Racial and Ethnic Disparities in Health* highlighted some of the significant health disparities within the leading categories of death in the United States. For example, in 2007 the overall infant mortality rate (IMR) was 6.8 deaths per 1000 live births, but the IMR among African Americans was 12.9 per 1000 live births (Xu, Kochanek, and Tejada-Vera, 2009), and the gap has been widening in recent years. Racial and ethnic health disparities have been observed in a wide range of diseases and health behaviors, from infant mortality to diabetes, heart disease, cancer, and HIV. Although there has been some progress toward meeting the goal of eliminating racial/ethnic disparities, with improvement in rates for most health status indicators across all racial/ethnic groups, the improvements have not been uniform across groups and “substantial differences among racial/ethnic groups persist” (Keppel, Percy, and Wagener, 2002). Among Native Americans and Native Alaskans, several health indicators actually worsened from 1990 to 1998. The IMR declined in all groups, but it remains 2.3 times higher for infants born to non-Hispanic African American mothers than for those born to white non-Hispanic mothers. Similarly, the overall age-adjusted mortality rate was 22% higher in the African American population than in the white population in 2006, and it was higher for 10 of the 15 leading causes of death (Heron, 2010). Although individual characteristics such as race, gender, and immigration status are of interest to epidemiologists, there has been increasing focus on social, economic, and cultural contexts and processes underlying racial and ethnic inequalities in health, such as discrimination (Krieger, 2000; Fuller et al, 2005).

Place

When considering the distribution of a disease, geographic patterns come to mind: Does the rate of disease differ from place

to place (e.g., with local environment)? If geography had no effect on disease occurrence, random geographic patterns might be seen, but that is often not the case. For example, at high altitudes there is lower oxygen surface tension, which might result in smaller babies. Other diseases reflect distinctive geographic patterns. For example, Lyme disease is transmitted from animal reservoirs to humans by a tick vector. Thus, the disease is more likely to be found in areas where there are animals carrying the disease, a large tick population for transmission to humans, and contact between the human population and the tick vectors (Heymann, 2014).

The influence of place on disease may certainly be related to geographic variations in the chemical, physical, or biological environment. However, variations by place also may result from differences in population densities, or in customary patterns of behavior and lifestyle, or in other personal characteristics. For example, geographic variations might occur because of high concentrations of a religious, cultural, or ethnic group who practice certain health-related behaviors. The high rates of stroke found in the southeastern United States are likely to be the result of a number of social, economic, cultural, and personal factors that have little to do with geographic features per se. Recent epidemiologic research has also focused on neighborhood-level variables, such as unemployment and crime rate, social cohesion, educational levels, racial segregation, and access to important services (Cohen et al, 2000; Caughy, O'Campo, and Patterson, 2001; Bradman et al, 2005; Fuller et al, 2005; McLafferty and Grady, 2005). For example, recent research on adolescent injection drug users (IDUs) found that African American IDUs from neighborhoods with large percentages of minority residents and low adult educational levels were more likely to initiate injection use during adolescence than white IDUs from neighborhoods with low percentages of minority residents and high adult education levels. Nurses need to pay attention to this wide range of community-level variables as they assess the health of communities.

Time

Time is the third component of descriptive epidemiology. In relation to time, epidemiologists ask these questions: Is there an increase or decrease in the frequency of the disease over time? Are other temporal (and spatial) patterns evident? Temporal patterns of interest to epidemiologists include secular trends, point epidemic, cyclical patterns, and event-related clusters.

Secular Trends

Long-term patterns of morbidity or mortality rates (i.e., over years or decades) are called **secular trends**. Secular trends may reflect changes in social behavior or health practices. For example, the increased lung cancer mortality rates among men and women in recent years reflect a delayed effect of increased smoking in prior years. Similarly, the decline in cervical cancer deaths is primarily attributable to widespread screening with the Pap test (Remington, Brownson, and Wegner, 2010). Some secular trends may result from increased diagnostic capability or changes in survival (or case fatality) rather than in incidence. For example, case fatality from breast cancer has decreased

in recent years although the incidence of breast cancer has increased. Some, although not all, of the increased incidence is a result of improved diagnostic capability. These two trends result in a breast cancer mortality curve that is flatter than the incidence curve (Remington et al, 2010). Mortality data alone do not accurately reflect the true situation. For example, changes in case definition or revisions in the coding of a disease according to the International Classification of Diseases (ICD) can produce an artificial change in mortality rates.

Point Epidemic

One temporal and spatial pattern of disease distribution is the **point epidemic**. This time-and-space-related pattern is important in infectious disease investigations and is a significant indicator for toxic exposures in environmental epidemiology. A point epidemic is most clearly seen when the frequency of cases is plotted against time. The sharp peak characteristic of such graphs indicates a concentration of cases in some short interval of time. The peak often indicates the response of the population to a common source of infection or contamination to which they were all simultaneously exposed. Knowledge of the incubation or latency period (the time between exposure and development of signs and symptoms) for the specific disease entity can help to determine the probable time of exposure. A common example of a point epidemic is an outbreak of gastrointestinal illness from a foodborne pathogen. Nurses who are alert to a sudden increase in the number of cases of a disease can chart the outbreak, determine the probable time of exposure, and, by careful investigation, isolate the probable source of the agent.

Cyclical Patterns

In addition to secular trends and point epidemics, there are also cyclical time patterns of disease. One common type of cyclical variation is the seasonal fluctuation seen in a number of infectious illnesses. Seasonal changes may be influenced by changes in the agent itself, changes in population densities or behaviors of animal reservoirs or vectors, or changes in human behavior that result in changing exposures (e.g., being outdoors in warmer weather and indoors in colder months). There may also be artificial seasons created by calendar events (e.g., holidays and tax-filing deadlines) that may be associated with patterns of stress-related illness. Patterns of accidents and injuries may also be seasonal, reflecting differing employment and recreational patterns. Some disease cycles, such as influenza, have patterns of smaller epidemics every few years, depending on strain, with major pandemics occurring at longer intervals (Heymann, 2014). Workers in public health can prepare to meet increased demands on resources by paying careful attention to these cyclical patterns.

Event-Related Clusters

A fourth type of temporal pattern is nonsimultaneous event-related clusters. These are patterns in which time is not measured from fixed dates on the calendar but from the point of some exposure or event, presumably experienced in common by affected persons, although not occurring at the same time.

An example would be vaccine reactions in an ongoing immunization program. If vaccinations are given on a regular basis, one might see nonspecific symptoms (e.g., fever, headaches, and rashes) fairly consistently over perhaps a year, making identification of a cluster related to the vaccinations difficult. If, however, the time of vaccination is artificially set as zero for each client, and the number of clients with symptoms is plotted against the time since time zero, the reactions are likely to show up as a peak at some period after the immunization.

ANALYTIC EPIDEMIOLOGY

Descriptive epidemiology deals with the distribution of health outcomes, whereas analytic epidemiology seeks to discover the determinants of outcomes, or the how and the why (i.e., the factors that influence observed patterns of health and disease

and increase or decrease the risk of adverse outcomes). This section deals with analytic study designs and the related measures of association derived from them. [Table 12-4](#) summarizes the advantages and disadvantages of each design.

Cohort Studies

The **cohort study** is the standard for observational epidemiologic studies, coming closest to the ideal of a natural experiment ([Rothman, 2012](#)). In epidemiology, the term *cohort* is used to describe a group of persons who are born at about the same time. In analytic studies, a cohort refers to a group of persons (generally sharing some characteristic of interest) enrolled in a study and followed over a period of time to observe some health outcome ([Porta, 2008](#)). Because they enable us to observe the development of new cases of disease, cohort study designs allow calculation of incidence rates and therefore estimates of disease

TABLE 12-4 Comparison of Major Epidemiologic Study Designs

Study Design	Advantages	Disadvantages
Ecologic	Quick, easy, and inexpensive first study Uses readily available existing data May prompt further investigation or suggest other/new hypotheses May provide information about contextual factors not accounted for by individual characteristics	Ecologic fallacy: associations observed may not hold true for individuals Problems in interpreting temporal sequence (cause and effect) More difficult to control for confounding and “mixed” models (ecological and individual data); more complex statistically
Cross-sectional	Gives general description of scope of problem; provides prevalence estimates Often based on population (or community) sample, not just those who sought care Useful in health service evaluation and planning Data obtained at once; less expensive and quicker than cohort because no follow-up Baseline for prospective study or to identify cases and controls for case-control study	No calculation of risk; prevalence, not incidence Temporal sequence unclear Not good for rare disease or rare exposure unless large sample size or stratified sampling Selective survival can be major source of selection bias; surviving subjects may differ from those who are not included (e.g., death, institutionalization) Selective recall or lack of past exposure information can create bias
Case-control (retrospective, case comparison)	Less expensive than cohort; smaller sample required Quicker than cohort; no follow-up Can investigate more than one exposure Best design for rare diseases If well designed, can be important tool for etiological investigation Best suited to disease with relatively clear onset (timing of onset can be established so that incident cases can be included)	Greater susceptibility than cohort studies to various types of bias (selective survival, recall bias, selection bias on choice of both cases and controls) Information on other risk factors may not be available, resulting in confounding Antecedent-consequence (temporal sequence) not as certain as in cohort Not well suited to rare exposures Gives only an indirect estimate of risk Limited to a single outcome because of sampling on disease status
Prospective cohort (concurrent cohort, longitudinal, follow-up)	Best estimate of disease incidence Best estimate of risk Fewer problems with selective survival and selective recall Temporal sequence more clearly established Broader range of options for exposure assessment	Expensive in time and money More difficult organizationally Not good for rare diseases Attrition of participants can bias estimate Latency period may be very long; may miss cases May be difficult to examine several exposures
Retrospective cohort (nonconcurrent cohort)	Combines advantages of both prospective cohort and case-control Shorter time (even if follow-up into future) than prospective cohort Less expensive than prospective cohort because reliant on existing data Temporal sequence may be clearer than case-control	Shares some disadvantages with both prospective cohort and case-control Subject to attrition (loss to follow-up) Relies on existing records that may result in misclassification of both exposure and outcome May have to rely on surrogate measure of exposure (e.g., job title) and vital records information on cause of death

	CHD	CHD	
Physically active	48 a	952 b	1000
Sedentary	120 c	880 d	1000

FIG 12-5 Cohort study.

risk. Cohort studies may be prospective or retrospective (Rothman, 2012; Szklo and Nieto, 2012; Gordis, 2013).

Prospective Cohort Studies

In a prospective cohort study (also called a longitudinal or follow-up study), subjects determined to be free of the outcome under investigation are classified on the basis of the exposure of interest at the beginning of the follow-up period. The different exposure groups constitute the comparison groups for the study. The subjects are then followed for some period of time to determine the occurrence of disease in each group. The question is the following: “Do persons with the factor (or exposure) of interest develop (or avoid) the outcome more frequently than those without the factor (or exposure)?”

For example, one might recruit a cohort of subjects classified as physically active (“exposed”) or sedentary (“not exposed”). One might further quantify the amount of the “exposure” if there is sufficient information. These subjects would then be followed over time to determine the development of CHD. This study design avoids the problem of selective survival that sometimes affects other study designs (Figure 12-5). Because persons initially without the disease are followed over time, this design allows estimation of both incidence rates and incidence proportions. The cohort study can also estimate the relative risk of acquiring disease for those who are exposed compared with those who are unexposed (or less exposed). This ratio of incidence proportions is called the risk ratio (or relative risk), and a ratio incidence rate is called the rate ratio. For example, if the risk of CHD in smokers is twice as high as the risk among nonsmokers, the risk ratio would be 2. If a factor is unrelated to the risk of a disease, the risk ratio will be close to 1. A value less than 1 may suggest a protective association. For example, the risk of CHD is lower among those who are physically active than among sedentary persons, so the risk ratio for the association between physical activity and CHD should be less than 1.

Suppose 1000 physically active and 1000 sedentary middle-aged men and women enroll in a prospective cohort study. All are free of CHD at enrollment. Over a 5-year follow-up period, regular examinations detect CHD in 120 of the sedentary men and women, and in 48 of the active men and women. Assuming no other deaths or losses to follow-up, the data could be presented as shown in Figure 12-5.

The incidence proportion of CHD in the active group is $a/(a + b)$, or $48/1000$, and the incidence of CHD in the sedentary group is $c/(c + d)$, or $120/1000$. The risk ratio is as follows:

$$\left(\frac{48}{1000} \right) \div \left(\frac{120}{1000} \right) = 0.4$$

Because physical activity is protective for CHD, the risk ratio is less than 1. The interpretation for this hypothetical example is that, over a 5-year period, the risk of CHD in persons who are physically active is about 0.4 as great as the risk among sedentary persons. If the risk was greater for those exposed, the risk ratio would be greater than 1. For example, if the risk ratio of CHD for overweight persons compared with normal weight is 3.5, it would be interpreted to mean that the risk of CHD among overweight persons is 3.5 times the risk of those with normal weight. The null value indicating no association is 1, because the incidence proportion and thus the risk would be equal in the two groups if there were no association. This same statistic can also be expressed (and indeed is more commonly used in the media) as a percentage increase or decrease in risk. For a relative risk of 0.40, it also can be expressed as “a 60% decreased risk ($1.0 - 0.4 = 60\%$ reduction from 1.0)”. Likewise, a relative risk of 1.4 could be expressed as a “40% increase in risk.”

Because subjects are enrolled before onset of disease, using the cohort design allows us to study more than one outcome, calculate incidence rates and proportions, estimate risk, and establish the temporal sequence of exposure and outcome with greater clarity and certainty. Use of the cohort design also may avoid many of the problems of the other study designs with selective survival or exposure misclassification (discussed later). On the other hand, large samples are often necessary to ensure that enough cases are observed to provide enough statistical power to detect meaningful differences between groups. This is complicated by the long period required for some diseases to develop (the latency period). In addition, the number of subjects required to observe sufficient cases makes longitudinal studies unsuitable for very rare diseases unless they are part of a larger study of a number of outcomes.

Retrospective Cohort Studies

Retrospective cohort studies combine some of the advantages and some of the disadvantages of both case-control studies and prospective cohort studies. In these studies, the epidemiologist relies on existing records, such as employment, insurance, or hospital records, to define a cohort, whose members are classified according to exposure status at some time in the past. The cohort is followed over time using the records to determine if the outcome occurred. Retrospective cohort (also called historical cohort) studies may be conducted entirely using past records or may include current assessment or additional follow-up time after study initiation. The obvious advantage of this approach is the time savings, because one does not have to wait for new cases of disease to develop. The disadvantages are largely related to the reliance on existing historical records. Retrospective cohort studies are frequently used in occupational epidemiol-

ogy where industrial records are available to investigate work-related exposures and health outcomes.

Case-control Studies

The **case-control design** can be viewed against the background of an underlying cohort. The design uses a sample from the cohort rather than following the entire cohort over time. Because it uses only samples of cases and non-cases, it is a more efficient design, although it is subject to certain types of bias (Rothman, 2012). In the **case-control study**, participants are enrolled because they are known to have the outcome of interest (cases) or they are known *not* to have the outcome of interest (controls). Case-control status is verified using a clear case definition and some previously determined method or protocol (e.g., by an examination, laboratory test, or medical chart review). Information is then collected on the exposures or characteristics of interest, frequently from existing sources, subject interview, or questionnaire (Schlesselman, 1982; Rothman, 2012; Szklo and Nieto, 2012). The question in a case-control study is the following: “Do persons with the outcome of interest (cases) have the exposure characteristic (or a history of the exposure) more frequently than those without the outcome (controls)?”

Suppose a research group wanted to study risk factors for suicide attempts among adolescents. They were able to enroll 100 adolescents who had attempted suicide, and they selected 200 adolescents from the same community with no history of suicide attempt. One of the factors they wanted to investigate is a history of substance abuse. Through a questionnaire and other medical records, they determine that 68 of the 100 adolescents who had attempted suicide had a history of substance abuse, whereas 36 of the 200 adolescents with no suicide attempt had such a history. The information could be presented as shown in Figure 12-6. The odds of a positive history of substance abuse among adolescents who attempt suicide is a/c , or $68/32$, whereas the odds of substance abuse among controls (no suicide attempts) is b/d , or $36/164$. The odds ratio (equivalent to ad/bc) is as follows:

$$\frac{(68 \times 164)}{(36 \times 32)} = 9.68$$

	Suicide attempt	No attempt
History of substance abuse	68 a	36 b
No history of substance abuse	32 c	164 d
	100	200

FIG 12-6 Case-control study.

This would be interpreted to mean that the odds of a history of substance abuse are about 10 times greater among adolescents who have attempted suicide than among adolescents who have not attempted suicide. Note that, as with the risk ratio, an odds ratio of 1 is indicative of no association (i.e., the odds of exposure are similar for cases and controls). An odds ratio less than 1 suggests a protective association (cases are less likely to have been exposed than controls).

Given the way subjects are selected for a case-control study, neither incidence nor prevalence measures can be calculated directly. However, if newly diagnosed cases are enrolled as they are found, and if case ascertainment is fairly complete and the source population well defined, an estimate of incidence may be obtained. In a case-control study, an odds ratio tells how much more or less likely the exposure is to be found among cases than among controls. The odds of exposure among cases (a/c in Figure 12-6) are compared with the odds of exposure among controls (b/d in Figure 12-6). Under certain conditions, the ratio of these two odds provides an estimate of the risk ratio or rate ratio.

Because the number of cases is known or actively sought out, case-control studies do not demand large samples or the long follow-up time that is often required for prospective cohort studies. Thus many of the influential cancer studies are of the case-control design.

Case-control studies are, however, prone to a number of biases (see further discussion under “Bias” later in this chapter). Because these studies begin with existing cases, differential survival can produce biased results. The use of recently diagnosed, or “incident,” cases may reduce this bias. Also, exposure information is obtained from subject recall or past records, and there may be errors in exposure assessment or misclassification. Because participants are selected precisely because they do or do not have a specific health outcome, case-control studies are limited to a single outcome, although they may investigate a number of potential risk factors.

Cross-sectional Studies

The **cross-sectional study** provides a snapshot, or cross-section, of a population or group (Gordis, 2013). Information is collected on current health status, personal characteristics, and potential risk factors or exposures all at once. The cross-sectional study is characterized by the simultaneous collection of information necessary for the classification of exposure and outcome status, although there may be historical information collected (e.g., on past diet or history of radiation exposure). Surveys are one common type of data collection for cross-sectional studies. They may be administered in person, over the phone, by mail, or, increasingly, on websites or through personal electronic devices. Each form of administration has its advantages and disadvantages, as does the use of surveys for epidemiologic studies, but a complete discussion of survey methodology is beyond the scope of this chapter.

Cross-sectional studies are sometimes called prevalence studies because they provide the frequency of existing cases of a disease in a population. One way cross-sectional studies

evaluate the association of a factor with a health problem is by comparing the prevalence of the disease in those who have the factor (or exposure) with the prevalence in the unexposed. The ratio of the two prevalence proportions indicates an association between the factor and the outcome. If the prevalence of CHD in smokers was twice as high as the prevalence among non-smokers, the prevalence ratio would be 2. If a factor is unrelated to the prevalence of a disease, the prevalence ratio will be close to 1. A value less than 1 may suggest a protective association. For example, the prevalence of CHD is lower among those who are physically active than among sedentary persons, so the prevalence ratio for the association between physical activity and CHD should be less than 1. Prevalence ratios require caution in interpretation because the prevalence measure is affected by cure, survival, and migration and does not estimate the risk of getting the disease.

Cross-sectional studies are subject to bias resulting from selective survival (i.e., people who have survived to be in the study may be different from people diagnosed about the same time who have died and are not available for inclusion). Suppose that physical activity not only reduced the risk of CHD but also markedly improved survival among those with CHD. Sedentary persons with CHD would then have higher fatality rates than physically active persons who did develop CHD. One might observe higher rates of physical activity in a group of persons surviving with CHD than in a general population without CHD, both because of the survival advantage of those who previously were active and because of increased participation of other survivors in cardiac rehabilitation programs. It could erroneously appear that physical activity was a risk factor for CHD.

Ecologic Studies

An epidemiologic study that is a bridge between descriptive epidemiology and analytic epidemiology is the **ecologic study**. The descriptive component involves examining variations in disease rates by person, place, or time. The analytic component lies in the effort to determine if there is a relationship between disease rates and variations in rates for possible risk (or protective) factors. The identifying characteristic of ecologic studies is that only aggregate data, such as population rates, are used rather than data on individuals' exposures, characteristics, and outcomes. For example, information on per capita cigarette consumption might be examined in relation to lung cancer mortality rates in several countries, in several groups of people, or in the same population at different times. Other examples include comparisons of rates of breastfeeding and breast cancer, average dietary fat content and rates of CHD, or unemployment rates and levels of psychiatric disorders.

Ecologic studies are attractive because they often make use of existing, readily available rates and are therefore quick and inexpensive to conduct. They are subject, however, to **ecologic fallacy** (i.e., associations observed at the group level may not hold true for the individuals who make up the groups, or associations that actually exist may be masked in the grouped data). This may be the result of other factors operating in these

populations for which the ecological correlations do not account. For that reason, ecologic studies may be suggestive but require confirmation in studies using individual data (Koepsell and Weiss, 2003; Gordis, 2013). However, it has been shown that ecologic data can add important information to analyses even when individual-level data are available (Lynch et al, 1998; Diez-Roux, 2002). Uncertainty concerning the temporal sequence of events is a disadvantage that ecologic studies share with cross-sectional study designs. For example, in the study of unemployment rates and psychiatric disorders, it is unclear whether unemployed persons are at higher risk for psychiatric problems or whether persons with existing psychiatric problems are more likely to be unemployed. Although determining whether one event precedes or succeeds another may seem at first to be a simple matter, in practice it may be difficult to confirm.

EXPERIMENTAL STUDIES

The study designs discussed so far are called *observational studies* because the investigator observes the association between exposures and outcomes as they exist but does not intervene to alter the presence or level of any exposure or behavior. Studies in which the investigator initiates some treatment or intervention that may influence the risk or course of disease are called *intervention*, or *experimental*, studies. Such studies test whether interventions are effective in preventing disease or improving health. Like observational studies, experimental studies generally use comparison (or control) groups, but unlike observational studies, they are subject to the consequences of randomly allocating persons to a particular intervention group and determining the type or level of the "exposure" (the treatment or intervention). Intervention studies are of two general types: clinical trials and community trials.

Clinical Trials

In clinical trials, the research issue is generally the efficacy of a medical treatment for disease, such as a new drug or an existing drug used in a new or different way, a surgical technique, or another treatment. The preferred method of subject allocation in clinical trials is randomization (i.e., assigning treatments to clients so that all possible treatment assignments have a predetermined probability but neither subject nor investigator determines the actual assignment of any participant). Randomization avoids the bias that may result if subjects self-select into one group or the other or if the investigator or clinician chooses subjects for each group. A second aspect of treatment allocation is the use of masking, or "blinding," treatment assignments. The optimal design for most situations is the double-blind study in which neither the subject nor the investigator knows who is receiving which treatment. The aim of blinding is to reduce the bias from overestimating therapeutic benefit for the experimental treatment when it is known who is receiving it.

Clinical trials are generally thought to provide the best evidence of causality because of the assignment of treatment and

the greater control over other factors that could influence outcome. Like cohort studies, clinical trials are prospective in direction and provide the clearest evidence of temporal sequence. However, clinical trials are generally conducted in a contrived situation, under controlled conditions, and with select client populations. That means that the treatment may be less effective when it is applied under more realistic clinical or community conditions in a more diverse client population. There are also ethical considerations in experimental studies that go beyond those that apply to observational studies. Also, clinical trials tend to be costly in time, personnel, facilities, and other factors.

Community Trials

Community trials are similar to clinical trials in that an investigator determines the exposure or intervention, but in this case the issue is often health promotion and disease prevention rather than treatment of existing disease. The intervention is usually undertaken on a large scale, with the unit of treatment allocation being a community, region, or group rather than individuals. Although a pharmaceutical product may be involved in a community trial (e.g., fluoridation of water or mass immunizations), community trials often involve educational, programmatic, or policy interventions. An example of community intervention is providing exercise programs and facilities and increasing the availability of healthy, fresh foods to study the effect on diabetes rates.

Although community trials provide the best means of testing whether changes in knowledge or behavior, policy, programs, or other mass interventions are effective, they are not without problems. For many interventions, it may take years for the effectiveness of the intervention to be evident. In the meantime, other factors may also influence the outcome, either positively (making the intervention look more effective than it really is) or negatively (making the intervention look less effective than it really is). Comparable community populations without similar interventions for comparative analysis are often difficult to determine. Even when comparable comparison communities are available, especially when the intervention is intended to improve knowledge or change behavior, it is difficult and unethical to prevent the control communities from making use of generally available information. Exposure to this information, however, may have the effect of making control communities more like the intervention communities. Also, because community trials are often undertaken on a large scale and over long periods, they can be expensive, requiring large staff, complicated logistics, and extensive communication resources. Although the randomized trial is often considered the “gold standard” of medical and public health research, because of the limitations noted above, there is clearly a need for other types of research designs to complement randomized control trials (Victoria, Habicht, and Bryce, 2004).

CAUSALITY

In a previous section, we introduced the concept of the *web of causation*. This is a useful analogy in considering causal agents

at a population level and how these multiple factors are related to each other. This next section will focus on causality within the context of the individual study or series of studies (as with a body of evidence). This is quite different from the web analogy that was used previously because it only focuses on the relationship between a single exposure and outcome measure. It may be useful to think of the web of causation as those factors that play out at the macroscopic level, in contrast to focusing efforts to identify and prove causality at a microscopic level.

Statistical Associations

One of the first steps in assessing the relationship of some factor with a health outcome is determining whether a statistical association exists. If the probability of disease seems unaffected by the presence or level of the factor, no association is apparent. If, on the other hand, the probability of disease does vary according to whether the factor is present, there is a statistical association. The earlier discussion of null values is pertinent at this point. When an observed measure of association (such as a risk ratio) does not differ from the null value, it may not be assumed that there is an association between the factor and the outcome under investigation.

In many studies, a great deal of emphasis is placed on tests of statistical significance. This is a judgment that the observed results are or are not likely to be attributable to chance at some predetermined level of probability (usually 0.05). However, many epidemiologists contend that much more information is provided by an estimate of the association (the ratio or difference in rates or risks) and a confidence interval that indicates the precision of the estimate (Rothman, 2012). Note that statistical significance is determined by sample size, the amount of difference between groups, and the variance in the estimates.

Bias

Although statistical testing and estimation are critical, it is important to remember that statistical testing and interval estimation generally assume that deviations from the true value are the result of chance. However, estimates may appear to be greater or less than they really are because of **bias**, a systematic error resulting from the study design, execution, or confounding. For example, if there were a gumball machine with colors randomly mixed and three red ones in a row came out, that would be a result of chance. If, however, the person loading the gumball machine had poured in a bag of red ones first, then green ones, and then yellow, it would not be surprising to get three red ones in a row because of the way the machine was loaded. In epidemiologic studies, results are sometimes biased because of the way the study was “loaded” (i.e., the way the study was designed, subjects were selected, information was collected, or subjects were classified). Three generally recognized categories are selection, classification, and confounding bias (Rothman, 2012).

Bias attributable to the way subjects enter a study is called selection bias. It has to do with selection procedures and the population from which subjects are drawn. It may involve

self-selection factors as well. For example, are teenagers who agree to complete a questionnaire on alcohol, tobacco, and other drug use representative of the total teenage population?

Bias attributable to misclassification of subjects once they are in the study is information, or classification (or misclassification), bias. It is related to how information is collected, including the information that subjects supply or how subjects are classified.

Bias resulting from the relationship of the outcome and study factor with some third factor not accounted for is called confounding. For example, there is a well-known association between maternal smoking during pregnancy and low-birth-weight babies. There is also an association between alcohol consumption and smoking that is not attributable to chance nor is it causal (i.e., drinking alcohol does not cause a person to smoke, nor does smoking cause a person to drink alcohol). If one were to investigate the association of alcohol consumption and low birth weight, smoking would be a confounder because it is related to both alcohol consumption and low birth weight. Failure to account for smoking in the analysis would bias the observed association between alcohol use and low birth weight. In practice, one can often identify potentially confounding variables and adjust for them in analysis.

Assessing for Causality

The existence of a statistical association does not necessarily mean that there is a causal relationship or that causality is present (Susser, 1973). As noted previously, the observed association may be a random event (caused by chance) or may be attributable to bias from confounding or from flaws in the study design or execution. Statistical associations, although necessary to an argument for causality, are not sufficient proof. Some epidemiologists refer to *criteria for causality*, a term originally established to evaluate the link between an infectious agent and a disease but revised and elaborated to also apply to other outcomes. Although various lists of criteria have been proposed, the seven criteria listed in Box 12-3 are fairly commonly cited (Gordis, 2013; Koepsell and Weiss, 2003). Some have questioned the use of lists of criteria as misleading, especially because only temporal sequence is necessary, and none of the others really is a criterion (Rothman, 2012). Although no single epidemiologic study can satisfy all criteria, public health practitioners rely on the accumulation of evidence and the strength of individual studies to provide a basis for effective public health interventions and policies.

APPLICATIONS OF EPIDEMIOLOGY IN NURSING

Both knowledge and practical application of epidemiology are essential competencies for nurses (Gebbie and Hwang, 2000). Nurses incorporate epidemiology into their practices and take on a variety of epidemiologic roles. Nurses in diverse settings are involved in the collection, reporting, analysis, interpretation, and communication of epidemiologic data as part of their daily practice. As nurses care for persons with communicable diseases, they are implementing epidemiologic practices as they

BOX 12-3 Criteria for Causality

1. *Strength of association*: A strong association between a potential risk factor and an outcome supports a causal hypothesis (e.g., a relative risk of 7 provides stronger evidence of a causal association than a relative risk of 1.5).
2. *Consistency of findings*: Repeated findings of an association with different study designs and in different populations strengthen causal inference.
3. *Biological plausibility*: Demonstration of a physiological mechanism by which the risk factor acts to cause disease enhances the causal hypothesis. Conversely, an association that does not initially seem biologically defensible may later be discovered to be so.
4. *Demonstration of correct temporal sequence*: For a risk factor to cause an outcome, it must precede the onset of the outcome. (See Prospective Cohort Studies and Table 12-4.)
5. *Dose-response relationship*: The risk of developing an outcome should increase with increasing exposure (either in duration or in quantity) to the risk factor of interest. For example, studies have shown that the more a woman smokes during pregnancy, the greater the risk of delivering a low-birth-weight infant.
6. *Specificity of the association*: The presence of a one-to-one relationship between an agent and a disease (i.e., the idea that a disease is caused by only one agent and that agent results in only one disease lends support to a causal hypothesis, but its absence does not rule out causality). This criterion is cultivated from the infectious disease model, where it is more often, although not always, satisfied and is less applicable in chronic diseases.
7. *Experimental evidence*: Experimental designs provide the strongest epidemiologic evidence for causal associations, but they are not feasible or ethical to conduct for many risk factor-disease associations.

identify, report, treat, and provide follow-up on cases and contacts of TB, gonorrhea, and gastroenteritis. School nurses also function as epidemiologists, collecting data on the incidence and prevalence of accidents, injuries, and illnesses in the school population. They are also key players in the detection and control of local epidemics, such as outbreaks of lice. As described earlier in this chapter, nurses across practice settings are actively involved in activities related to primary, secondary, and tertiary prevention (see [Levels of Prevention](#) box).

Some nursing job descriptions are specifically based in epidemiologic practice. These include hospital infection control nurses, nurse epidemiologists, and nurse environmental risk communicators employed by local health departments. Nurses are key members of local fetal and infant mortality review boards, which examine cases of newborn deaths for identifiable risk factors and quality of care measures. Members of these review boards may include public health and maternal child nurses as well as representatives from hospital labor and delivery and neonatal intensive care units.

Nursing documentation on client charts and records is an important source of data for epidemiologic reviews. Client demographics and health histories are often collected or verified by nurses. As nurses collect and document client information, they might not be thinking about the epidemiologic connection. However, the reliability and validity of such data can be a key factor in the quality of future epidemiologic studies. An

excellent resource for the application of epidemiologic concepts and methods in practice settings can be found in [Brownson and Petitti \(2006\)](#).

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency: Informatics—Use Information and Technology to Communicate, Manage Knowledge, Mitigate Error, and Support Decision Making

Important aspects of informatics include:

- **Knowledge:** Identify essential information that must be available in a common database to support client care.
- **Skills:** Use information management tools to monitor outcomes of care processes.
- **Attitudes:** Value nurses' involvement in design, selection, implementation and evaluation of information technologies to support client care.

Informatics Question: Determine If a Health Problem Exists in the Community

Nurses are involved in the surveillance and monitoring of health phenomena. Planning for resources and personnel often requires quantifying the level of a problem in the community. For example, to know how different districts compare in the rates of very-low-birth-weight infants, you would calculate the prevalence of very-low-birth-weight infants in each district:

1. Determine the number of live births in each district from birth certificate data obtained from the vital records division of the health department.
2. Use the birth weight information from the birth certificate data to determine the number of infants born weighing less than 1500 grams in each district.
3. Calculate the prevalence of very-low-birth-weight births by district as the number of infants weighing less than 1500 grams at birth divided by the total number of live births.
4. If the number of very-low-birth-weight births in each district is small, use several years of data to obtain a more stable estimate.

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

Community-oriented Epidemiology

Nurses are often involved in environmental health issues, where they play important roles not only as epidemiologists, but also as community liaisons ([Mood, 2000](#)). Nurses serve as important professional contacts and liaisons for people in the community who are actively investigating or concerned about the health and illness issue, such as an increase in the number of cases of cancer, asthma, or traffic accidents. The role of community liaison involves observation, data collection, consultation, and interpretation. By talking and listening to community members around their kitchen tables, at local gathering places, or at community meetings, nurses gather information from the citizens' perspectives. They can also interpret scientific information for lay persons. The liaison role also involves consultation with public health and environmental professionals and participation in environmental inspections and investigations.

Lillian Mood is a public health nurse with more than 20 years of experience in South Carolina working with communities to detect and explain the causes of illness and disability. In

describing her involvement with specific communities, Mood noted that the contact often began with a telephone call of concern about a planned or existing industrial facility or a first-hand observation of illness, expressed in lay terms as “too many cases of cancer,” “several people have had miscarriages,” or “more respiratory problems.” The citizen’s reasoning behind these observations is that “If I am seeing more health problems in my community, I ask what they have in common. The common factor may be where we live. So it must be the air or the water.” This is basic epidemiologic thinking, not irrational fear. Citizens try to make sense of what they are seeing, and they want professional help to unravel the pattern of illness” ([Mood, 2000](#), p 24).

Popular Epidemiology

In health departments and hospitals, nurses frequently work with other professionals who have training in epidemiology. However, in the community they may encounter citizens engaged in the practice of popular epidemiology ([Brown and Ferguson, 1995](#); [Brown and Masterson-Allen, 1994](#)). **Popular epidemiology** is a form of epidemiology in which lay people gather scientific data as well as mobilize knowledge and resources of experts to understand the occurrence and distribution of a disease or injury. Popular epidemiology is more than just adding public participation to traditional epidemiology; it also includes an emphasis on social structural factors as a component of disease etiology, as well as the involvement of social movements, political and judicial approaches to remedies, and challenges to basic assumptions of traditional epidemiology, risk assessment, and public health regulation ([Brown and Ferguson, 1995](#), p. 149). Popular epidemiology considers the physiological, psychological, and social effects of environmental hazards and attempts to show how racial, class, and gender differences are evident in the health effects of environmental toxic exposure. In contrast, many standard environmental health assessments are not designed to understand local cultures, traditions, or ethnic backgrounds ([DiChiro, 1997](#)). This lack of cultural competency can render assessment tools ineffective in terms of the ability to identify potential routes of toxic exposure.

Toxic waste activists are often women living in the community who have first-hand contact with toxic hazards and therefore have experiences and access to data that would otherwise be inaccessible to scientists ([Brown and Ferguson, 1995](#)). Community toxic waste activists engage in a process of linking traditional scientific practices with more narrative approaches. Their health surveys often make use of sampling techniques, laboratory testing, and mapping of suspected pollutants together with experiential narratives of the effects of toxic pollutants on the body and on their local environments ([DiChiro, 1997](#)). The information gathered can be used by community activists and health professionals to lobby for health services; advocate for policy development at local, state, and federal levels; establish preventive programs; educate medical professionals about environmental illness; and work with other agencies and community groups to reduce or eliminate toxic exposures.

EVIDENCE-BASED PRACTICE

The Epidemiologic Basis for Community Health Interventions

Queso fresco, a popular Latin American fresh cheese often made from raw milk, has been implicated as a source of *Salmonella typhimurium* definitive type (DT) 104 in the United States. From 1992 to 1996, the annual incidence of *S. typhimurium* DT104 infections in Yakima County, Washington, increased from 5.4 to 29.7 cases per 100,000 population, making it one of the highest rates in the country. Between January and May 1997, 89 cases of *S. typhimurium* were reported in the county, of which 54 were culture-confirmed as DT104, a strain that is resistant to five major antibiotics. The median age of infected persons was 4 years, and 90% of the clients had Spanish surnames. A case-control investigation conducted by the CDC indicated that the most probable source of the outbreak was raw-milk *queso fresco*. The CDC investigation also indicated that street vendors were the most frequent source (70%) of *queso fresco* among those who developed the illness.

In response to the outbreak, a multiagency intervention was initiated with the goal of reducing the incidence of *S. typhimurium* infections resulting from consumption of raw-milk *queso fresco* while maintaining the traditional, nutritious food in the local Hispanic diet. A pasteurized-milk *queso fresco* recipe developed by a local Hispanic woman was modified by dairy scientists at Washington State University to inhibit undesirable microbial growth, increase shelf life, and improve ease of preparation. The new recipe was tested by local Hispanic persons and adjusted until flavor and texture were satisfactory.

A preintervention survey was conducted to gather background information for use in planning the multipronged intervention, which featured safe-cheese workshops introducing the new pasteurized-milk recipe, a mass media campaign about the risk of raw-milk cheese, and newsletter articles warning dairy farmers about the risks of

selling or giving away raw milk. The safe-cheese workshops were conducted by older Hispanic women (*abuelas*, or grandmothers), who were recruited from the community and trained to make the new *queso fresco* recipe from pasteurized milk. Following the training, each *abuela* educator signed a contract indicating her willingness to teach at least 15 additional members of the community how to safely make *queso fresco* with pasteurized milk. They followed through on their commitment, which included returning surveys completed by the women they taught.

The incidence of *S. typhimurium* infection in Yakima County decreased rapidly to below pre-1992 levels after the multilevel intervention was initiated. Between June and December 1997, only 16 cases were reported, of which 2 were associated with consumption of *queso fresco*; in 1998 there were 18 reported cases, none of which were associated with *queso fresco*. Postintervention surveys of Hispanic area residents who did not participate in the workshops indicated that consumption of *queso fresco* did not decrease as a result of the intervention (Bell, et al 1999).

Nurse Use

The *Abuela Project* is an example of a successful combination of applied epidemiology and community-based, culturally appropriate public health interventions. This activity clearly falls within the scope of good public health nursing. To be successful in seeing correlations, nurses must be vigilant, have inquiring minds, and be able to make associations between events and characteristics (e.g., the associations between how and by whom the cheese was being made, and by whom it was being eaten).

From Bell RA, Hillers VN, Thomas TA: The Abuela project: safe cheese workshops to reduce the incidence of *Salmonella typhimurium* from consumption of raw-milk fresh cheese, *Am J Public Health* 89:1421-1424, 1999.

PRACTICE APPLICATION

You are a nurse providing health screenings at a health fair at a local community center. Mr. Greer, a 32-year-old African American man, stops by your station and requests that you check his blood pressure. His blood pressure measurement is 135/85 mm Hg. In conducting a brief health history, you learn that Mr. Greer is single, works part time at a convenience store, often eats at fast-food establishments, and has been a smoker since age 17. His father died of a heart attack at age 48; his mother has diabetes. He does not have health insurance at this time. Which of the following would be your best choice in providing Mr. Greer recommendations related to his need for lipid disorder screening, based on the U.S. Preventive Services Task Force guidelines?

A. Do not discuss lipid screening with Mr. Greer, because he is under 35 years of age and routine screening is not recommended.

B. Suggest that Mr. Greer stop smoking and make modifications in his diet to reduce his consumption of saturated fats. Guide him to the information on local community-based resources for tobacco cessation and healthy diet programs at the health fair.

C. Discuss with Mr. Greer his increased risk for heart disease, based on his family history and status as a smoker. Provide a referral for Mr. Greer for a lipid screening, including measurement of total cholesterol and high-density lipoprotein cholesterol (HDL-C), being offered by the local hospital at the health fair.

Answers can be found on the Evolve site.

KEY POINTS

- Epidemiology is the study of the distribution and determinants of health-related events in human populations and the application of this knowledge to improving the health of communities.
- Epidemiology is a multidisciplinary enterprise that recognizes the complex interrelationships of factors that influence disease and health at both the individual level and the community level; it provides the basic tools for the study of health and disease in communities.
- Epidemiologic methods are used to describe health and disease phenomena and to investigate the factors that promote health or influence the risk or distribution of disease. This knowledge can be useful in planning and evaluating programs, policies, and services, as well as in clinical decision making.
- Epidemiologic models explain the interrelationships between agent, host, and environment (the epidemiologic triangle) and the interactions of multilevel factors, exposures, and characteristics (causal web) affecting risk of disease.

KEY POINTS—cont'd

- A key concept in epidemiology is that of the levels of prevention, based on the stages in the natural history of disease.
- Primary prevention involves interventions to reduce the incidence of disease by promoting health and preventing disease processes from developing.
- Secondary prevention includes programs (such as screening) designed to detect disease in the early stages, before signs and symptoms are clinically evident, to intervene with early diagnosis and treatment.
- Tertiary prevention provides treatments and other interventions directed toward persons with clinically apparent disease, with the aim of lessening the course of disease, reducing disability, or rehabilitating.
- Epidemiologic methods are also used in the planning and design of community health promotion (primary prevention) strategies and screening (secondary prevention) activities, and in the evaluation of the effectiveness of these interventions.
- Basic epidemiologic methods include the use of existing data sources to study health outcomes and related factors and the use of comparison groups to assess the association between exposures or characteristics and health outcomes.
- Epidemiologists rely on rates and proportions to quantify levels of morbidity and mortality. Prevalence proportions provide a picture of the level of existing cases in a population at a given time. Incidence rates and proportions measure the rate of new case development in a population and provide an estimate of the risk of disease.
- Descriptive epidemiologic studies provide information on the distribution of disease and health states according to personal characteristics, geographic region, and time. This knowledge enables practitioners to target programs and allocate resources more effectively and provides a basis for further study.
- Analytic epidemiologic studies investigate associations between exposures or characteristics and health or disease outcomes, with a goal of understanding the etiology of disease. Analytic studies provide the foundation for understanding disease causality and for developing effective intervention strategies aimed at primary, secondary, and tertiary prevention.

CLINICAL DECISION-MAKING ACTIVITIES

1. Interview a local public health nurse or other public health professional from the local health department.
 - A. Ask about the current public health priorities and how those priorities were determined.
 - B. Describe the type of epidemiologic data used in determining local public health priorities.
2. Identify a current health issue in your local community (e.g., childhood lead poisoning, diabetes, HIV/AIDS).
 - A. Describe primary, secondary, and tertiary prevention interventions related to this health issue.
 - B. How could nurses improve the effectiveness of their prevention activities related to this health issue?
3. Look at a recent issue of the *Final Mortality Statistics* from the National Center for Health Statistics, or the most recent issue of *Health: United States*. Examine the trends in cause-specific mortality and choose one or two of the leading causes of death.
 - A. On the basis of current epidemiologic evidence, explain the factors that have contributed to the following: the observed trend in mortality rates for this disease; the changes in survival; the changes in incidence.
 - B. Are the changes the result of better (or worse) primary, secondary, or tertiary prevention? Are there modifiable factors, such as health behaviors, that lend themselves to better prevention efforts? What would they be?
4. Identify existing inequalities among the counties in your state, using infant mortality data.
 - A. Describe the distribution of infant mortality in your state (by county), using rate ratio and population attributable risk data.
 - B. Compare the infant mortality rates in your state with national and international data.
 - C. Compare the characteristics of the counties (e.g., urban, rural, racial/ethnic distribution, economic indicators, distribution of health care facilities) with the highest and lowest infant mortality rates.
 - D. Identify local, state, and national initiatives that are addressing infant mortality.
5. Examine the leading causes of infant death in the United States.
 - A. What differences in intervention approaches are suggested by the various causes of death?
 - B. How would you design an epidemiologic study to examine risk factors for specific causes of neonatal and postneonatal death? What types of epidemiologic measures would be useful? What study design(s) would be appropriate?
 - C. How would you use the information from your study to develop an intervention program and to define the target population for your intervention?
6. Find a report of an epidemiologic study in one of the major public health, nursing, or epidemiology journals. How do the findings of this study, if valid, affect your nursing practice? How do you incorporate the results of epidemiologic research into your nursing practice?

Infectious Disease Prevention and Control

Francisco S. Sy, MD, PhD

Dr. Francisco S. Sy is the Director of the Division of Extramural Activities and Scientific Programs at the National Center on Minority Health and Health Disparities (NCMHD) at the National Institutes of Health (NIH) in Bethesda, MD. Before joining NIH, he served as a Senior Health Scientist in the Division of HIV/AIDS Prevention (DHAP), National Center for HIV, STD and TB Prevention (NCHSTP), at the Centers for Disease Control and Prevention (CDC) in Atlanta, GA. Dr. Sy was a tenured professor at the University of South Carolina (USC) School of Public Health in Columbia, SC, where he taught infectious disease epidemiology for 15 years. Dr. Sy has written several book chapters and scientific articles on various infectious and tropical diseases, HIV disease epidemiology, prevention, and program evaluation. He is the editor of the *AIDS Education and Prevention: An Interprofessional Journal* since its inception in 1988. Dr. Sy earned his Doctor of Public Health (DrPH) degree in Immunology and Infectious Diseases from Johns Hopkins University in 1984, Master of Science in Tropical Public Health from Harvard University in 1981 and Doctor of Medicine degree from the University of the Philippines in 1975.

Susan C. Long-Marin, DVM, MPH

Susan C. Long-Marin developed an interest in infectious disease and public health while serving as a Peace Corps Volunteer in the Philippines in the 1970s. Training in veterinary medicine further increased her respect for the ingeniousness of microbes and the importance of primary prevention. Today she manages the epidemiology program of a county health department in Charlotte, NC, which serves a growing and rapidly changing population from a variety of racial, ethnic, and national backgrounds. Dr. Long-Marin earned her Doctor of Veterinary Medicine degree from Virginia Tech and her Master of Public Health in Epidemiology degree from the University of South Carolina.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Discuss the current impact and threats of infectious diseases on society.
2. Explain how the elements of the epidemiologic triangle interact to cause infectious diseases.
3. Provide examples of infectious disease control interventions at the three levels of public health prevention.
4. Explain the multisystem approach to control of communicable diseases.
5. Discuss the factors contributing to newly emerging or re-emerging infectious diseases.
6. Define the bloodborne pathogen reduction strategy and universal precautions.

KEY TERMS

Parasitic Diseases

- Intestinal Parasitic Infections

- Parasitic Opportunistic Infections

- Control and Prevention of Parasitic Infections

Health Care-Associated Infections

- Universal Precautions

The topic of infectious diseases includes the discussion of a wide and complex variety of organisms; the pathology they may cause; and their diagnosis, treatment, prevention, and control. This chapter presents an overview of the **communicable diseases** that nurses encounter most often. Diseases are grouped according to descriptive category (by mode of transmission or means of prevention) rather than by individual organism (e.g., *Escherichia coli*) or taxonomic group (e.g., viral, parasitic). Detailed discussion of sexually transmitted diseases, human immunodeficiency virus (HIV), acquired immunodeficiency syndrome (AIDS/HIV stage III), viral hepatitis, and

tuberculosis (TB) is provided in [Chapter 14](#). Although not all infectious diseases are directly communicable from person to person, the terms *infectious disease* and *communicable disease* are used interchangeably throughout this chapter.

HISTORICAL AND CURRENT PERSPECTIVES

In the United States at the beginning of the twentieth century, infectious diseases were the leading cause of death. By 2000 improvements in nutrition and sanitation, the discovery of antibiotics, and the development of vaccines had put an end to

infectious disease epidemics like diphtheria and typhoid fever that once ravaged entire populations. In 1900 respiratory and diarrheal diseases were major killers. For example, tuberculosis (TB) led to over 11% of all deaths in the United States and was the second leading cause of death; in 2010, 536 deaths or 0.02% were attributed to this once frequently fatal disease (CDC, 2012a). As individuals live longer, chronic diseases—heart disease, cancer, and stroke—have replaced infectious diseases as the leading causes of death.

Infectious diseases, however, have not vanished, and they remain a continuing cause for concern. They remain the leading cause of death for children and adolescents worldwide and the second-leading cause overall, killing an estimated 8 million people a year (WHO, 2013). In the United States, the downward trend in mortality from infectious diseases seen since 1900—with the exception of the 1918 influenza pandemic—reversed itself in the 1980s, with the emergence of new entities such as HIV disease and the increasing development of antibiotic resistance. Respiratory diseases in the form of pneumonias and influenza remain among the 10 leading causes of death, and new strains such as novel influenza A H1N1 and avian influenza A H5N1 test our disease control abilities and consume resources. Previously unknown causal connections between infectious organisms and chronic diseases have been recognized, such as *Helicobacter pylori* and peptic ulcer disease, and human papillomaviruses (HPVs) and cervical cancer. Also, in the twenty-first century, infectious diseases have become a means of terrorism, as illustrated by the anthrax letters of 2001.

New killers emerge and old familiar diseases take on different, more virulent characteristics. Consider the following developments from the past 30 years. HIV disease reminds us of plagues from the past and challenges our ability to control and contain infection like no other disease in recent history. Because drugs have been developed to slow the progression but there is still neither vaccine nor cure, this initially infectious disease is now a chronic condition as well. Legionnaires' disease and toxic shock syndrome, unknown at mid-twentieth century, have become part of the common vocabulary. The identification of infectious agents causing Lyme disease and ehrlichiosis provided two new tickborne diseases to worry about. And, in the summer of 1993 in the southwestern United States, healthy young adults were stricken with a mysterious and unknown but often fatal respiratory disease that is now known as hantavirus pulmonary syndrome. The summer of 1994 brought public attention to a severe, invasive strain of *Streptococcus pyogenes* group A, referred to by the press as the “flesh-eating” bacteria.

In the 1990s the transmission of infectious disease through the food supply became a newsworthy concern when the consumption of improperly cooked hamburgers and unpasteurized apple juice contaminated with a highly toxic strain of *E. coli* (*E. coli* 0157:H7) caused illness and death in children across the country. In 1996 multiple states reported outbreaks of diarrheal disease traced to imported fresh berries; the implicated organism in these outbreaks, *Cyclospora cayentanensis* (a coccidian parasite), was first diagnosed in humans in 1977. Also in 1996, the fear that “mad cow disease” (bovine spongiform encephalopathy [BSE]) could be transferred to humans through beef

consumption led to the slaughter of thousands of British cattle and a ban on the international sale of British beef. Initially seen only in Europe and Japan as well as Great Britain, the first case of BSE was diagnosed in the United States in 2003. Variant Creutzfeldt-Jakob disease (vCJD), which attacks the brain with fatal results, is the human disease hypothesized but not yet proven to result from eating beef infected with the transmissible agent causing BSE; only three acquired cases of vCJD have been seen in the United States, but these individuals were born outside of and resided in the country for only a short period (CDC, 2013a).

In 1997 vancomycin-resistant *Staphylococcus aureus* (VRSA) was first reported; previously, vancomycin had been considered the only effective antibiotic against methicillin-resistant *S. aureus* (MRSA). Although MRSA is still largely a health care-associated infection, community-associated disease is becoming more common with outbreaks frequently associated with school athletic programs and prison populations. Also in 1997, the first reported outbreak of avian flu affecting humans occurred in Hong Kong. Lack of subsequent reports suggested an isolated incident, but in 2004 avian influenza A H5N1 again emerged in Southeast Asia with resulting human cases. This virus has now infected avian populations in Asia, Europe, the Near East, and North Africa, and it continues to cause sporadic human cases, especially in Southeast Asia and Egypt. Human cases are determined to spread largely through direct contact with infected poultry or infected surfaces, with human to human transmission largely ineffective and only a few rare cases thought to have occurred. In 1999 the first Western Hemisphere activity of West Nile virus (WNV), a mosquito-transmitted illness that can affect livestock, birds, and humans, occurred in New York City. By 2002 WNV, thought to be carried by infected birds and possibly mosquitoes in cargo containers, had spread across the United States as far west as California and was reported in Canada and Central America as well.

The viral hemorrhagic fevers (HF) Ebola and Marburg, unknown to most people 30 years ago, have become the premise of movies and novels, and recently the cause of widespread international concern. While earlier reported Ebola virus outbreaks largely occurred in Central Africa and were limited and quickly contained, an outbreak of Ebola virus that began in the spring of 2014 in Guinea, West Africa resisted containment and in spite of international assistance, spread rapidly through neighboring Liberia and Sierra Leone. A small number of cases also occurred in several other West African countries but were contained. An air traveler brought a case to the United States resulting in the infection of two nurses who cared for him. Health care workers returning from work in West Africa were diagnosed, one in the United States and one in Great Britain, and a nurse in Spain was also infected caring for a patient who had been transported from the Ebola-infected region of Africa. By January 2015, this on going epidemic had resulted in over 21,700 reported cases in nine countries (the majority in Guinea, Liberia and Sierra Leone) and almost 8,650 reported deaths. In response to the imported and health care-transmitted cases, infectious disease policies and procedures within hospitals were modified, and screening and surveillance tactics were

introduced at airports around the world for passengers arriving from West Africa (CDC, 2015a).

Although caused by different viruses within the *Filoviridae* family, Ebola and Marburg hemorrhagic fevers (HF) have similar clinical presentations. The reservoir host of Ebola viruses remains unknown but there is an association with non-human primates, and evidence is also beginning to point toward a bat reservoir (CDC, 2014a). Marburg HF virus had been reported only five times since its recognition in 1967 before a major outbreak in Angola occurred during 2004 and 2005, affecting more than 350 people with a fatality rate of close to 90%. Since then, a much smaller outbreak occurred in Uganda in 2007 among gold miners and another in Uganda in 2012 affecting 15 people. The reservoir host of Marburg virus is the African fruit bat, *Rousettus aegyptiacus* (CDC, 2014b).

Severe acute respiratory syndrome (SARS) was first recognized in China in February 2003 and, as if in a bestselling thriller, this newly emerging infectious disease quickly achieved pandemic proportions. By the summer of 2003, major outbreaks had occurred in Hong Kong, Taiwan, Vietnam, Singapore, and Canada. Three months after the first official news of SARS, over 8000 cases with more than 700 deaths had been reported to the World Health Organization (WHO) from 28 countries. Played out on television in pictures of people wearing facemasks for protection, the rapid spread of a previously unknown disease with an initially unknown cause and no definitive treatment contributed to the creation of a perception of risk of infection far greater than actually existed. Frightened Americans canceled trips to China and Hong Kong and avoided people who had recently returned from Asia. Then, as suddenly as it began, the pandemic subsided. SARS was found to be caused by a new strain of coronavirus, but since 2003, only a few cases, largely associated with laboratory workers, have been reported. A large number of individuals infected by SARS could be traced back to unrecognized cases in hospitals, suggesting that prompt identification and isolation of symptomatic people is the key to interrupting transmission. No new cases of SARS have been reported since 2004. Global efforts continue to clarify the epidemiology of this disease as well as develop a reliable diagnostic test and vaccine. In 2012, SARS coronavirus was officially declared a select agent—a bacterium, virus, or toxin that has the potential to pose a severe threat to public health and safety. Additional information on SARS can be obtained at the CDC SARS website (<http://www.cdc.gov/sars/>).

In the first decade of the twenty-first century, foodborne infections again have made headlines as *E. coli*-infected spinach sickened and killed individuals across the United States. In 2008, tomatoes were blamed for a nationwide outbreak of salmonellosis but were ruled innocent when the green chilies that accompanied them in salsa were found to be the actual culprit. Salmonella made the news as contaminated peanut butter forced recalls across the United States, sickened hundreds, and resulted in several deaths, and again in 2012 when contaminated cantaloupes resulted in 261 reported illnesses and 3 deaths across 24 states. Even chocolate chip cookie dough was not safe; a national recall in 2009 followed the discovery that people had been sickened after eating raw dough contaminated by *E. coli*.

Perhaps the most publicized infectious disease event of 2009 was the advent of a new strain of flu, novel influenza A H1N1. First reported from Mexico and rapidly acquired by travelers to that country, H1N1 spread quickly across the world, causing the WHO to declare a pandemic and stimulate the race for a vaccine. While H1N1 did not become the major killer it was feared to, it did disproportionately result in hospitalizations and deaths in younger and middle-aged adults. H1N1 did not disappear and has been included in the seasonal vaccine since 2009. During the 2013-2014 flu season in the United States, H1N1 once more became the predominant circulating strain, and once more hit hardest the young and middle-aged.

The year 2012 brought the first reports of another novel coronavirus that, like SARS, results in acute respiratory distress with a high mortality rate. Middle Eastern Respiratory Syndrome Coronavirus or MERS-CoV has only been seen in individuals living in or who have traveled to countries in the Arabian Peninsula. It seems to spread by close contact and many of the cases have been in health care workers. The reservoir is unknown but there appears to be an association with camels. The first cases of MERS-CoV in the United States were reported in 2014 in individuals who had traveled from Saudi Arabia. Read more about MERS at <http://www.cdc.gov/coronavirus/mers/index.html>.

Worldwide, infectious diseases are the leading killer of children and young adults and are responsible for almost half of all deaths in developing countries. Of these infectious disease deaths, 90% result from six causes: acute respiratory infections, diarrheal diseases, malaria, and measles among children; and TB and HIV infection among adults. TB alone is estimated to kill a million people a year and malaria another 625,000 (WHO, 2013). The CDC in its *Ounce of Prevention* campaign notes that in the United States as many as 160,000 people die per year with infectious diseases as an underlying cause. The economic burden of infectious diseases is staggering. Foodborne illnesses alone are estimated to cost \$77.7 billion annually in the United States (Scharff, 2012). The CDC estimates the costs to the U.S. health care system of almost 19 million new STD infections each year to be as much as \$15.9 billion annually (USDHHS, 2014). In 2013, the annual cost for five of the most significant health care-associated infections was estimated at \$9.8 billion (Zimlichman et al, 2013).

Because of the morbidity, mortality, and associated cost of infectious diseases, the national health promotion and disease prevention goals outlined in *Healthy People 2020* list a number of objectives for reducing the incidence of these illnesses in a variety of the sections, including Immunization & Infectious disease. Objectives for reducing salmonellosis and other foodborne infections are found in the section on Food Safety, an objective for reducing malaria cases reported in the United States may be seen under Global Health, there is a section on sexually transmitted diseases, and there are objectives related to health care-associated infections (see the *Healthy People 2020* box for examples). Although infectious diseases are not currently the leading causes of death in the United States, they continue to present varied, multiple, and complex challenges to all health care providers. Nurses must know about these diseases

to effectively participate in diagnosis, treatment, prevention, and control.

HEALTHY PEOPLE 2020

Selected Objectives Related to Infectious Diseases

- IID-1: Reduce, eliminate, or maintain elimination of cases of vaccine-preventable diseases.
- IID-12: Increase the percentage of children and adults who are vaccinated against seasonal influenza.
- FS-1: Reduce infections caused by key pathogens transmitted commonly through food.
- HAI-2 Reduce invasive health care-associated methicillin-resistant *Staphylococcus aureus* (MRSA) infections.

From U.S. Department of Health and Human Services: *Healthy People 2020: The Road Ahead*. 2009, USDHHS. Available at <http://www.healthypeople.gov/HP2020/>. Accessed January 26, 2010.

TRANSMISSION OF COMMUNICABLE DISEASES

Agent, Host, and Environment

The transmission of communicable diseases depends on the successful interaction of the infectious **agent**, the **host**, and the **environment**. These three factors make up the **epidemiologic triangle** (Figure 13-1), as discussed in Chapter 12. Changes in the characteristics of any of the factors may result in disease transmission. Consider the following examples. Antibiotic therapy not only may eliminate a specific pathologic agent, but also alter the balance of normally occurring organisms in the body. As a result, one of these agents overruns another and disease, such as a yeast infection, occurs. HIV performs its deadly work not by directly poisoning the host but by destroying the host's immune reaction to other disease-producing agents. Individuals living in the temperate climate of the United

FIGURE 13-1 The epidemiologic triangle of a disease (Redrawn from Gordis L: *Epidemiology*, ed 5, Philadelphia, 2005, Saunders.)

States do not normally contract malaria at home, but they may become infected if they change their environment by traveling to a climate where malaria-carrying mosquitoes thrive. As these examples illustrate, the balance among agent, host, and environment is often precarious and may be unintentionally disrupted. At present, the potential results of such disturbance require attention as advances in science and technology, destruction of natural habitats, explosive population growth, political instability, and a worldwide transportation network combine to alter the balance among the environment, people, and the agents that produce disease.

Agent Factor

Four major categories of agents cause most infections and infectious disease: bacteria (e.g., *Salmonella* and *E. coli*), fungi (e.g., *Aspergillus* spp. and *Candida* spp.), parasites (e.g., helminthes and protozoa), and viruses (e.g., hepatitis A and B and HIV). Less commonly seen is the prion, a transmissible agent that causes abnormal folding of normal cellular prion proteins in the brain, resulting in a family of rare progressive neurodegenerative disorders that affect both humans and animals. Variant Creutzfeldt-Jakob disease and kuru are examples of prion diseases. The individual agent may be described by its ability to cause disease and by the nature and the severity of the disease. *Infectivity*, *pathogenicity*, *virulence*, *toxicity*, *invasiveness*, and *antigenicity*, terms commonly used to characterize infectious agents, are defined in Box 13-1.

Host Factor

A human or animal host can harbor an infectious agent. The characteristics of the host that may influence the spread of disease are host resistance, immunity, herd immunity, and infectiousness of the host. **Resistance** is the ability of the host to withstand infection, and it may involve natural or acquired immunity.

Natural immunity refers to species-determined, innate resistance to an infectious agent. For example, opossums rarely contract rabies. **Acquired immunity** is the resistance acquired by a host as a result of previous natural exposure to an infectious agent. Having measles once protects against future infection. Acquired immunity may be induced by active or passive immunization. **Active immunization** refers to the immunization of an individual by administration of an antigen (infectious agent or vaccine) and is usually characterized by the presence of an antibody produced by the individual host.

BOX 13-1 Six Characteristics of an Infectious Agent

- **Infectivity:** The ability to enter and multiply in the host
- **Pathogenicity:** The ability to produce a specific clinical reaction after infection occurs
- **Virulence:** The ability to produce a severe pathological reaction
- **Toxicity:** The ability to produce a poisonous reaction
- **Invasiveness:** The ability to penetrate and spread throughout a tissue
- **Antigenicity:** The ability to stimulate an immunological response

Vaccinating children against childhood diseases is an example of inducing active immunity. **Passive immunization** refers to immunization through the transfer of a specific antibody from an immunized individual to a nonimmunized individual, such as the transfer of antibody from mother to infant or by administration of an antibody-containing preparation (immunoglobulin or antiserum). Passive immunity from immunoglobulin is almost immediate but short lived. It is often induced as a stopgap measure until active immunity has time to develop after vaccination. Examples of commonly used immunoglobulins include those for hepatitis A, rabies, and tetanus.

Herd immunity refers to the immunity of a group or community. It is the resistance of a group of people to invasion and spread of an infectious agent. Herd immunity is based on the resistance of a high proportion of individual members of a group to infection. It is the basis for increasing immunization coverage for vaccine-preventable diseases. Through studies, experts determine what percent coverage (e.g., >90%) of a specified group of people (e.g., children entering school) by a specified vaccine (e.g., one dose of measles vaccine) is necessary to ensure adequate protection for the entire community against a given disease and target immunization campaigns and initiatives to meet that goal. The higher the immunization coverage, the greater the herd immunity.

Infectiousness is a measure of the potential ability of an infected host to transmit the infection to other hosts. It reflects the relative ease with which the infectious agent is transmitted to others. Individuals with measles are extremely infectious; the virus spreads readily on airborne droplets. A person with Lyme disease cannot spread the disease to other people (although the infected tick can).

Environment Factor

The environment refers to everything that is external to the human host, including physical, biological, social, and cultural factors. These environmental factors facilitate the transmission of an infectious agent from an infected host to other susceptible hosts. Reduction in communicable disease risk can be achieved by altering these environmental factors. Using mosquito nets and repellants to avoid bug bites, installing sewage systems to prevent fecal contamination of water supplies, and washing utensils after contact with raw meat to reduce bacterial contamination are all examples of altering the environment to prevent disease.

Modes of Transmission

Infectious diseases can be transmitted horizontally or vertically. **Vertical transmission** is the passing of the infection from parent to offspring via sperm, placenta, milk, or contact in the vaginal canal at birth. Examples of vertical transmission are transplacental transmission of HIV and syphilis. **Horizontal transmission** is the person-to-person spread of infection through one or more of the following four routes: direct/indirect contact, common vehicle, airborne, or vector borne. Most sexually transmitted infections are spread by direct sexual contact. Enterobiasis, or pinworm infection, can be acquired through direct contact or indirect contact with contaminated

objects such as toys, clothing, and bedding. **Common vehicle** refers to transportation of the infectious agent from an infected host to a susceptible host via food, water, milk, blood, serum, saliva, or plasma. Hepatitis A can be transmitted through contaminated food and water, and hepatitis B through contaminated blood. Legionellosis and TB are both spread via contaminated droplets in the air. **Vectors** are arthropods such as ticks and mosquitoes or other invertebrates such as snails that transmit the infectious agent by biting or depositing the infective material near the host. Vectors may be necessary to the life cycle of the organism (e.g., mosquitoes and malaria) or may act as mechanical transmitters (e.g., flies and food).

Disease Development

Exposure to an infectious agent does not always lead to an infection. Similarly, infection does not always lead to disease. Infection depends on the infective dose, the infectivity of the infectious agent and the immunocompetence of the host. It is important to differentiate infection and disease, as clearly illustrated by the HIV disease epidemic. **Infection** refers to the entry, development, and multiplication of the infectious agent in the susceptible host. **Disease** is one of the possible outcomes of infection and it may indicate a physiological dysfunction or pathologic reaction. An individual who tests positive for HIV is infected, but if that person shows no clinical signs, the individual is not diseased. Similarly, if an individual tests positive for HIV and also exhibits clinical signs consistent with AIDS (HIV stage III), that individual is both infected and diseased.

Incubation period and communicable period are not synonymous. The **incubation period** is the time interval between invasion by an infectious agent and the first appearance of signs and symptoms of the disease. The incubation periods of infectious diseases vary from between 2 and 4 hours for staphylococcal food poisoning to between 10 and 15 years for AIDS (HIV stage III). The **communicable period** is the interval during which an infectious agent may be transferred directly or indirectly from an infected person to another person. The period of communicability for influenza is 3 to 5 days after the clinical onset of symptoms. Hepatitis B–infected persons are infectious many weeks before the onset of the first symptoms and remain infective during the acute phase and chronic carrier state, which may persist for life.

Disease Spectrum

Persons with infectious diseases may exhibit a broad spectrum of disease that ranges from subclinical infection to severe and fatal disease. Those with subclinical or inapparent infections are important from the public health point of view because they are a source of infection but may not be receiving care like those with clinical disease. They should be targeted for early diagnosis and treatment. Those with clinical disease may exhibit localized or systemic symptoms and mild to severe illness. The final outcome of a disease may be recovery, death, or something in between, including a carrier state, complications requiring extended hospital stay, or disability requiring rehabilitation.

At the community level, the disease may occur in endemic, epidemic, or pandemic proportion. **Endemic** refers to the

constant presence of a disease within a geographic area or a population. Pertussis is endemic in the United States. **Epidemic** refers to the occurrence of disease in a community or region in excess of normal expectancy. Although people tend to associate large numbers with epidemics, even one case can be termed epidemic if the disease is considered previously eliminated from that area. For example, one case of polio, a disease considered eliminated from the United States, would be considered epidemic. **Pandemic** refers to an epidemic occurring worldwide and affecting large populations. HIV disease is both epidemic and pandemic, as the number of cases continues to grow across various regions of the world as well as in the United States. SARS and novel influenza A H1N1 are both emerging infectious diseases and responsible for recent pandemics.

SURVEILLANCE OF COMMUNICABLE DISEASES

During the first half of the twentieth century, the weekly publication of national morbidity statistics by the U.S. Surgeon General's Office was accompanied by the statement, "No health department, state or local, can effectively prevent or control disease without knowledge of when, where, and under what conditions cases are occurring" (CDC, 1996). **Surveillance** gathers the "who, when, where, and what"; these elements are then used to answer "why." A good surveillance system systematically collects, organizes, and analyzes current, accurate, and complete data for a defined disease condition. The resulting information is promptly released to those who need it for effective planning, implementation, and evaluation of disease prevention and control programs.

Elements of Surveillance

Infectious disease surveillance incorporates and analyzes data from a variety of sources. Box 13-2 lists 10 commonly used data elements.

Surveillance for Agents of Bioterrorism

Since September 11, 2001, increased emphasis has been placed on surveillance for any disease that might be associated with the intentional release of a biological agent. The concern is that, because of the interval between exposure and disease, a covert release may go unrecognized and without response for some time if the resulting outbreak closely resembles a naturally

occurring one. Health care providers are asked to be alert to (1) temporal or geographic clustering of illnesses (people who attended the same public gathering or visited the same location), especially those with clinical signs that resemble an infectious disease outbreak—previously healthy people with unexplained fever accompanied by sepsis, pneumonia, rash, or flaccid paralysis, and (2) an unusual age distribution for a common disease (e.g., chickenpox-like disease in adults without a child source case).

Because of the heightened concern about possible bioterrorist attacks, various sorts of syndromic surveillance systems have been developed by public health agencies across the country. These systems incorporate factors such as the previously mentioned temporal and geographic clustering and unusual age distributions with groups of disease symptoms or syndromes (e.g., flaccid paralysis, respiratory signs, skin rashes, gastrointestinal symptoms) with the goal of detecting early signs of diseases that could result from a bioterrorism-related attack. Syndromic surveillance systems may include tracking emergency department visits sorted by syndrome symptoms as well as other indicators of illness including school absenteeism and sales of selected over-the-counter medications. Early on, CDC developed EARS (Early Aberration Reporting System), a surveillance tool available at no charge and used by various public health officials across the country and abroad. Work continues to enhance and strengthen these tools. Although more active infectious disease surveillance is being encouraged because of the potential for bioterrorism, the positive benefit is increased surveillance for other communicable diseases as well. Such heightened surveillance can just as easily warn of a community salmonellosis or influenza outbreak. Although the benefit of syndromic surveillance as a warning system has not been proved, it has been valuable in tracking disease outbreaks such as the 2009 H1N1 pandemic. (For additional information on preparedness surveillance, see the CDC website at <http://www.bt.cdc.gov/episurv/>.)

Nurses are frequently involved at different levels of the surveillance system. They play important roles in collecting data, making diagnoses, investigating and reporting cases, and providing information to the general public. Examples of possible activities include investigating sources and contacts in outbreaks of pertussis in school settings or shigellosis in daycare; performing TB testing and contact tracing; collecting and reporting information pertaining to notifiable communicable diseases; performing infection control in hospitals; and providing morbidity and mortality statistics to those who request them, including the media, the public, service planners, and grant writers.

List of Reportable Diseases

"A notifiable disease is one for which regular, frequent, and timely information regarding individual cases is considered necessary for the prevention and control of the disease" (CDC, 2013b). Requirements for disease reporting in the United States are mandated by state rather than federal law and, as such, vary slightly from state to state. State health departments, on a voluntary basis, report cases of selected diseases to the CDC through the National Notifiable Diseases Surveillance System (NNDSS). State public health officials collaborate with the CDC

BOX 13-2 Ten Basic Data Elements of Surveillance

1. Mortality registration

*AIDS has been reclassified as HIV stage III.

to determine which diseases should be nationally notifiable. The list of nationally notifiable diseases may be revised as new diseases emerge or disease incidence declines. The 69 diseases designated as notifiable at the national level and reported in 2014 are listed in **Box 13-3**. The NNDSS data are collated and published weekly in the *Morbidity and Mortality Weekly Report* (MMWR). Final reports are published annually in the *Summary of Notifiable Diseases*. (Learn more about the NNDSS at the CDC website at <http://wwwn.cdc.gov/nndss/default.aspx>. A brief history of the reporting of nationally notifiable infectious diseases in the United States is available at <http://wwwn.cdc.gov/nndss/script/history.aspx>.)

EMERGING INFECTIOUS DISEASES

Emergence Factors

Emerging infectious diseases are those in which the incidence has actually increased in the past several decades or has the potential to increase in the near future. These emerging diseases

may include new or known infectious diseases. Consider the following selected examples. Identified only in 1976 when sporadic outbreaks occurred in Sudan and Zaire, Ebola virus is a mysterious killer with a frightening mortality rate that sometimes reaches 90%, has no known treatment, and has no recognized reservoir in nature. It appears to be transmitted through direct contact with bodily secretions and as such can be contained once cases are identified. Why outbreaks occur is not understood, although index cases have been associated with the handling of wild primates and evidence is increasing for a bat reservoir. Ebola and its fellow virus Marburg are examples of new viruses that may appear as civilization intrudes farther and farther into previously uninhabited natural environments, changing the landscape and disturbing ecological balances that may have existed unaltered for hundreds of years. (Read more about the viral hemorrhagic viruses Ebola and Marburg at the CDC's viral special pathogens website: <http://www.cdc.gov/nceid/dhcpp/vsp/index.html>.) See also [World Health Organization, 2014a](#).

Hantavirus pulmonary syndrome was first detected in 1993 in the Four Corners area of Arizona and New Mexico, when young, previously healthy Native Americans fell ill with a mysterious and deadly respiratory disease. The illness was soon discovered to be a variant of, but to exhibit different pathology from, a rodent-borne virus previously known only in Europe and Asia. Transmission is thought to occur through aerosolization of rodent excrement. One explanation for the outbreak in the Southwest is that an unseasonably mild winter led to an unusual increase in the rodent population; more people than usual were exposed to a virus that had until that point gone unrecognized in this country. Infection in Native Americans first brought attention to hantavirus pulmonary syndrome because of a cluster of cases in a small geographic area, but no evidence suggests that any ethnic group is particularly susceptible to this disease. Hantavirus pulmonary syndrome has now been diagnosed in sites across the United States. The best protection against this virus seems to be avoiding rodent-infested environments.

Not only is HIV disease relatively new but the resultant immunocompromise gave rise to previously rare opportunistic infections such as cryptosporidiosis, toxoplasmosis, and *Pneumocystis* pneumonia (PCP). HIV may have existed in isolated parts of sub-Saharan Africa for years and emerged, only recently, into the rest of the world as the result of a combination of factors, including new roads, increased commerce, and prostitution.

Escherichia coli 0157:H7 and other shiga toxin–producing *E. coli* show a more virulent nature than strains of the past. TB is another familiar face turned newly aggressive. After years of decline, it has resurged as a result of infection resulting from HIV disease and the development of multidrug resistance. New influenza viruses like A H1N1 and A H5N1 challenge scientists to rapidly develop vaccines to protect a world population with little or no immunity.

West Nile Virus (WNV), a mosquito-borne seasonal disease, was first identified in Uganda in 1937 and first detected in the United States in 1999. How WNV arrived in the United States may never be known, but the answer most likely involves infected birds or mosquitoes. Because the virus was new in this country and the outbreak of 2002 caused numerous deaths, WNV garnered a great deal of media attention. However, for the majority of people, infection with WNV results in no clinical signs (about 80%) or only mild flu-like symptoms. In a small percentage of individuals, approximately 1 of 150 cases, a more severe, potentially fatal neuroinvasive form may develop, which may leave permanent neurologic deficits for those who survive. The incidence of neuroinvasive disease increases with age, with the highest rates in those 70 years and older. After first appearing in New York City in 1999, the virus spent several years quietly spreading up and down the East Coast without remarkable morbidity or mortality. This situation changed abruptly in the summer of 2002 when it began moving across the country, accompanied by significant avian, equine, and human mortality. WNV has now been reported in every state except Hawaii and Alaska and is the most common arbovirus (virus carried by arthropods) disease in the country. The CDC estimates that

during its introduction into the United States, between 1999 and 2008, WNV led to almost 30,000 confirmed and probable cases and over 1000 deaths. The number of reported cases varies widely per year. These periodic outbreaks appear to result from a complex interaction of multiple factors, including weather: hot, dry summers followed by rain, which influences mosquito breeding sites and population growth. Because the ecology of WNV is not fully understood, the future pattern and nature of the virus in the United States is uncertain. Until a human vaccine is developed (a vaccine for horses does exist), preventing human infection is dependent on mosquito control and preventing mosquito bites. Rarely, WNV has been transmitted through blood transfusions, in utero exposure, and possibly breastfeeding (CDC, 2010a). (Learn more about WNV and view maps of recent activity at the CDC website: <http://www.cdc.gov/ncidod/dvbid/westnile/index.html>.)

Other examples of emerging pathogens newly recognized in the past 30 years include viruses (Australian bat lyssavirus and Hendra or equine morbilli virus); bacteria (*Bartonella henselae*, *Ehrlichiae*, and *Borrelia burgdorferi*); and parasites (*Babesia microti* and *Acanthamoeba*). *B. henselae* causes cat scratch fever. *Ehrlichiae*, *B. burgdorferi* (causes Lyme disease), and *B. microti* are all transmitted by ticks.

As shown in Table 13-1 several factors, operating singly or in combination, can influence the emergence of these diseases (Table 13-1) (CDC, 1994). Except for microbial adaptation and changes made by the infectious agent, such as those likely in the emergence of *E. coli* 0157:H7, most of the emergence factors are consequences of activities and behavior of the human hosts, and of environmental changes such as deforestation,

TABLE 13-1 Factors that Can Influence the Emergence of New Infectious Diseases

Categories	Specific Examples
Societal events	Economic impoverishment, war or civil conflict, population growth and migration, urban decay
Health care	New medical devices, organ or tissue transplantation, drugs causing immunosuppression, widespread use of antibiotics
Food production	Globalization of food supplies, changes in food processing and packaging
Human behavior	Sexual behavior, drug use, travel, diet, outdoor recreation, use of childcare facilities
Environmental	Deforestation/reforestation, changes in water ecosystems, flood/drought, famine, global changes (e.g., warming)
Public health	Curtailment or reduction in prevention programs, inadequate communicable disease infrastructure surveillance, lack of trained personnel (epidemiologists, laboratory scientists, vector and rodent control specialists)
Microbial adaptation	Changes in virulence and toxin production, development of drug resistance, microbes as co-factors in chronic diseases

From Centers for Disease Control and Prevention: *Addressing emerging infectious disease threats: a prevention strategy for the U.S.*, Atlanta, 1994, CDC.

urbanization, and industrialization. The rise in households with two working parents has increased the number of children in daycare and with this shift has come an increase in diarrheal diseases such as shigellosis. Changing sexual behavior and illegal drug use influence the spread of HIV disease as well as other sexually transmitted infections. Before the use of large air-conditioning systems with cooling towers, legionellosis was virtually unknown. Modern transportation systems closely and quickly connect regions of the world that for centuries had little contact. Insects and animals as well as humans may carry disease between continents on ships and planes. Immigrants, both legal and undocumented, as well as travelers, bring with them a variety of known and potentially unknown diseases.

Examples of Emerging Infectious Diseases

Selected emerging infectious diseases, including a brief description of the diseases and symptoms they cause, their modes of transmission, and causes of emergence, are listed in Table 13-2. Progress in addressing emerging infectious disease as well as current findings and topics can be found in the CDC journal *Emerging Infectious Diseases*. (The journal is published monthly and is available online at <http://www.cdc.gov/ncidod/EID/about/about.html>) (Figure 13-2).

PREVENTION AND CONTROL OF INFECTIOUS DISEASES

Planning to Address Infectious Disease

In 2011, the CDC published *A CDC Framework for Preventing Infectious Disease: Sustaining the Essentials and Innovating for the Future*, a plan for preventing and controlling infectious threats through a “strengthened, adaptable, and multi-purpose U.S. public health system.” Reflecting technological advances of the past decade, the plan places a heavy emphasis on the role of technology in surveillance, detection, and control. Three elements for action are identified: (1) Strengthen public health fundamentals, including infectious disease surveillance, laboratory detection, and epidemiologic investigation; (2) Identify and implement high-impact public health interventions to reduce infectious diseases; and (3) Develop and advance policies to prevent, detect, and control infectious diseases. It also discusses linkages between infectious and chronic disease; lists a timeline of disease threats, emerging pathogens, and unusual health events worldwide from 2000–2011; and identifies infectious disease issues of special concern: (1) antimicrobial resistance, (2) chronic viral hepatitis, (3) food safety, (4) health care–associated infections, (5) HIV/AIDS,

TABLE 13-2 Examples of Emerging Infectious Diseases

Infectious Agent	Diseases/Symptoms	Mode of Transmission	Causes of Emergence
<i>Borrelia burgdorferi</i>	Lyme disease: rash, fever, arthritis, neurologic and cardiac abnormalities	Bite of infective Ixodes tick	Increase in deer and human populations in wooded areas
<i>Cryptosporidium</i>	Cryptosporidiosis; infection of epithelial cells in gastrointestinal and respiratory tracts	Fecal–oral, person-to-person, waterborne	Development near watershed areas; immunosuppression
Ebola-Marburg viruses	Fulminant, high mortality, hemorrhagic fever	Direct contact with infected blood, organs, secretions, and semen	Unknown, likely human invasion of virus ecological niche
<i>Escherichia coli</i> O157:H7	Hemorrhagic colitis; thrombocytopenia; hemolytic uremic syndrome	Ingestion of contaminated food, especially undercooked beef and raw milk	Likely caused by a new pathogen
Hantavirus	Hemorrhagic fever with renal syndrome; pulmonary syndrome	Inhalation of aerosolized rodent urine and feces	Human invasion of virus ecological niche
Human immunodeficiency virus (HIV-1)	HIV infection; AIDS (HIV stage III); severe immune dysfunction, opportunistic infections	Sexual contact with or exposure to blood or tissues of infected persons; perinatal	Urbanization; lifestyle changes; drug use; international travel; transfusions; transplant
Human papillomavirus (HPV)	Skin and mucous membrane lesions (warts); strongly linked to cancer of the cervix and penis	Direct sexual contact, contact with contaminated surfaces	Newly recognized; changes in sexual lifestyle
Influenza A H1N1 virus (novel, pandemic)	Influenza: fever, cough, headache, myalgia, prostration, possibly GI signs	Person-to-person, airborne (droplet), and contact (direct and indirect)	Antigenic shift
Influenza A H5N1 virus (novel, avian)	Influenza: fever, cough, headache, myalgia, prostration	Direct contact with infected poultry or birds; limited person-to-person transmission	Antigenic shift
<i>Legionella pneumophila</i>	Legionnaires’ disease: malaise, myalgia, fever, headache, respiratory illness	Air cooling systems, water supplies	Recognition in an epidemic situation
<i>Pneumocystis jiroveci</i>	Acute pneumonia	Unknown; possibly airborne or reactivation of latent infection	Immunosuppression
SARS	Severe and acute pneumonia	Person-to-person, airborne (droplet) and direct and indirect contact with respiratory secretions and other bodily fluid	Unknown; newly recognized coronavirus; possible animal transmission into Chinese population
West Nile virus	No clinical signs to mild flu-like symptoms to fatal neuroinvasive disease	Bite of infected mosquitoes; infected birds serve as reservoirs	International travel and commerce

Based on information from Heymann DL, editor: *Control of communicable diseases manual*, ed 20, Washington, DC, 2014, American Public Health Association; Fauci AS, Touchette NA, Folkers GK: Emerging infectious diseases: a 10-year perspective from the National Institute of Allergy and Infectious Diseases, *Emerg Infect Dis* 11(4):519–525, 2005.

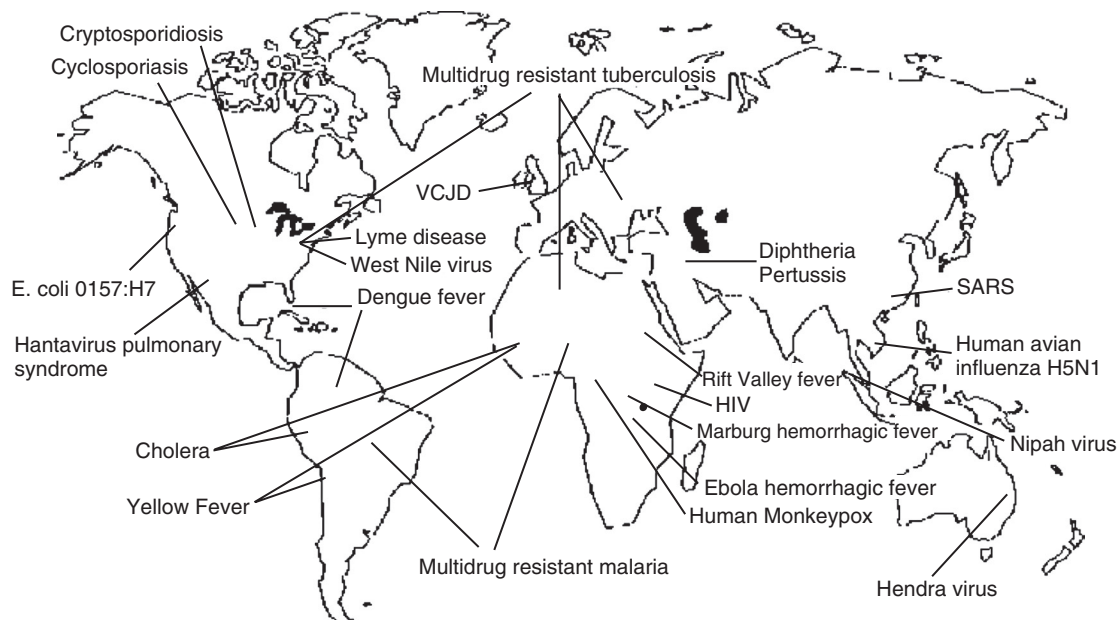

FIGURE 13-2 Examples of recent emerging and reemerging infectious diseases. (Based on Institute of Medicine: *Microbial threats to health: emergence, detection, and response*. Washington, DC, 2003, National Academy Press.)

(6) respiratory infections, (7) safe water, and (8) zoonotic and vectorborne diseases (CDC, 2011a). (This plan may be viewed at <http://www.cdc.gov/oid/docs/ID-Framework.pdf>.)

Prevention and Control Programs

Infectious disease can be prevented and controlled. The goal of prevention and control programs is to reduce the prevalence of a disease to a level at which it no longer poses a major public health problem. In some cases, diseases may even be eliminated or eradicated. The goal of **elimination** is to remove a disease from a large geographic area such as a country or region of the world. **Eradication** is removing a disease worldwide by ending all transmission of infection through the complete extermination of the infectious agent. WHO officially declared the global eradication of smallpox on May 8, 1980 (Evans, 1985). After the successful eradication of smallpox, the eradication of other communicable diseases became a realistic challenge, and in 1987 WHO adopted resolutions for eradication of paralytic poliomyelitis and dracunculiasis (Guinea worm infection) from the world by the year 2000.

These eradication goals were not reached in 2000, but substantial progress has been made. When the resolution was made in 1987 for the eradication of Guinea worm disease, there were an estimated 3.5 million cases a year in 20 countries in Asia and Africa and 120 million people were at risk for the disease. In 2013, only 148 cases were reported worldwide, making the goal of global eradication appear within reach (CDC, 2013c). Read more about Guinea worm disease eradication at <http://www.cdc.gov/parasites/guineaworm/>.

With the Global Polio Eradication Initiative, the World Health Organization (WHO) partnered with national governments, Rotary International, the CDC, and UNICEF in what has been called the world's largest public health initiative. Since

1988, over 2 billion children around the world have been immunized against polio through the cooperation of more than 200 countries and 20 million volunteers, supported by an international investment of over \$3 billion. At the end of 2008, WHO reviewed the progress of the initiative with two independent outside agencies and concluded that the remaining technical and operational challenges to eradication could be overcome in each of the polio-endemic countries by ensuring the political commitment of all polio-affected countries to attain the highest possible coverage and enhancing routine vaccination and surveillance (CDC, 2009a).

As a result of the Global Polio Eradication Initiative launch in 1988, the number of polio-endemic countries has decreased from 125 to 3 (Afghanistan, Nigeria, and Pakistan); 4 of the 6 regions of the World Health Organization (WHO) are certified polio free—the Americas, Europe, South East Asia, and the Western Pacific; and the number of worldwide polio cases has fallen from an estimated 350,000 to 407 in 2013, a decrease of more than 99% in reported cases. However, importation of cases resulting from the ease of worldwide travel or breakdowns in coverage in a neighboring country continues to lead to outbreaks in nonendemic countries. Between January and May of 2014, 77 cases of wild polio were reported from 8 countries: Afghanistan, Cameroon, Equatorial Guinea, Ethiopia, Iraq, Nigeria, Pakistan, and Syria. Such outbreaks point to the necessity of maintaining mass vaccination campaigns in polio-free countries to protect against cases imported from endemic areas. Challenges to maintaining coverage include political instability and sporadic violence, cultural beliefs about immunization, religious fears, and distrust of immunization. With the potential for eradication so close, in May of 2014, the WHO declared the recent international spread of wild poliovirus a public health emergency of international concern and issued Temporary

Recommendations under the International Health Regulations (2005) to prevent further spread of the disease (CDC, 2014c). (Read more about global polio eradication efforts at <http://www.polioeradication.org/>.)

Primary, Secondary, and Tertiary Prevention

There are three levels of prevention in public health: primary, secondary, and tertiary. In prevention and control of infectious disease, primary prevention seeks to reduce the incidence of disease by preventing occurrence, and this effort is often assisted by the government. Many interventions at the primary level, such as federally supplied vaccines and “no shots, no school” immunization laws, are population based because of public health mandates. Nurses deliver childhood immunizations in public and community health settings, check immunization records in daycare facilities, and monitor immunization records in schools.

The goal of secondary prevention is to prevent the spread of infection and/or disease once it occurs. Activities center on rapid identification of potential contacts to a reported case. Contacts may be (1) identified as new cases and treated, or (2) determined to be possibly exposed but not diseased and appropriately treated with prophylaxis. Public health disease control laws also assist in secondary prevention because they require investigation and prevention measures for individuals affected by a communicable disease report or outbreak. These laws can extend to the entire community if the exposure potential is deemed great enough, as could happen with an outbreak of smallpox or epidemic influenza. Nurses perform much of the communicable disease surveillance and control work in this country.

Although many infections are acute, with either recovery or death occurring in the short term, some exhibit chronic courses (AIDS/HIV stage III) or disabling sequelae (leprosy/Hansen’s disease). Tertiary prevention works to reduce complications and disabilities through treatment and rehabilitation. The Levels of Prevention box has examples of communicable disease prevention and control interventions at the three levels of prevention.

Role of Nurses in Prevention

Prevention is at the center of public health, and nurses perform much of this work. Examples include immunizations for vaccine-preventable disease, especially childhood immunization and the monitoring of immunization status in clinic, daycare, school, and home settings. Nurses work in communicable disease surveillance and control, teach and monitor bloodborne pathogen control, and advise on prevention of vector borne diseases. They teach methods for responsible sexual behavior, screen for sexually transmitted infection, and provide HIV disease counseling and testing. They screen for TB, identify TB contacts, and deliver directly observed TB treatment in the community.

Multisystem Approach to Control

Communicable diseases represent an imbalance in the harmonious relationship between the human host and the

LEVELS OF PREVENTION

Examples of Infectious Disease Interventions

Primary Prevention

To prevent the occurrence of disease:

- Responsible sexual behavior
- Malaria chemoprophylaxis
- Tetanus boosters, flu shots
- Rabies pre-exposure immunization
- Safe food-handling practices in the home
- Repellants for preventing vector borne disease
- Following childhood immunizations recommendations, and “no shots, no school” laws
- Regulated and inspected municipal water supplies
- Bloodborne pathogen regulations
- Restaurant inspections
- Federal regulations protecting American cattle from exposure to bovine spongiform encephalopathy (BSE)

Secondary Prevention

To prevent the spread of disease:

- Immunoglobulin after hepatitis A exposure
- Immunization and chemoprophylaxis as appropriate in meningococcal outbreak
- Rabies postexposure immunization
- Tuberculosis screening for health care workers
- Sexually transmitted disease (STD) partner notification
- Human immunodeficiency virus (HIV) testing and treatment
- Quarantine

Tertiary Prevention

To reduce complications and disabilities through treatment and rehabilitation:

- *Pneumocystis pneumonia* (PCP) chemoprophylaxis for people with AIDS/HIV stage III
- Regular inspection of hands and feet as well as protective footwear and gloves to avoid trauma and infection for leprosy clients who have lost sensation in those areas

environment. This state of imbalance provides the infectious agent an opportunity to cause illness and death in the human population. Given the many factors that can disrupt the agent-host-environment relationship, a multisystem approach to control of communicable diseases as shown in Table 13-3 must be developed (Wenzel, 1998).

AGENTS OF BIOTERRORISM

September 11, 2001, made real the specter of terrorism on American soil. The anthrax attacks that followed further highlighted the possibilities for the intentional release of a biological agent, or bioterrorism. The CDC suggests that the agents most likely to be used in a bioterrorist attack are those having the potential for both high mortality and easy dissemination—factors most likely to result in major public panic and social disruption. Six infectious agents are considered of highest concern: anthrax (*Bacillus anthracis*), plague (*Yersinia pestis*), smallpox (variola major), botulism (*Clostridium botulinum*), tularemia (*Francisella tularensis*), and selected hemorrhagic viruses (filoviruses such as Ebola and Marburg; arenaviruses

TABLE 13-3 A Multisystem Approach to Communicable Disease Control

Goal	Example
Improve host resistance to infectious agents and other environmental hazards	Hygiene, nutrition, and physical fitness; increased immunization coverage; provision of drugs for prevention and treatment; stress control and improved mental health
Improve safety of the environment	Sanitation, clean water and air; proper cooking and storage of food; control of vectors and animal reservoir hosts
Improve public health systems	Increased access to health care; appropriate health education; improved surveillance systems
Facilitate social and political change to ensure better health for all people	Individual, organizational, and community action; legislation

Modified from Wenzel RP: Control of communicable diseases: overview. In Wallace RB, editor: *Public health and preventive medicine*, ed. 15, 2008, New York.

such as Lassa fever, Junin virus, and related viruses). The CDC urges health care providers to be familiar with the epidemiology of these diseases as well as illness patterns possibly indicating an unusual infectious disease outbreak associated with the intentional release of a biological agent. (More information on recognition of illness associated with the intentional release of a biological agent as well as possible agents may be found at the CDC Emergency Preparedness and Response website: <http://www.bt.cdc.gov>.)

Anthrax

Until the fall of 2001, anthrax was more commonly a concern of veterinarians and military strategists than the general public. After September 11th, the news of deaths caused by letters deliberately contaminated with anthrax and transmitted through the postal service profoundly changed our view of this infectious disease. Anthrax is an acute disease caused by the spore-forming bacterium *B. anthracis*. It is thought that anthrax may have caused the biblical fifth and sixth plagues of Exodus as well as the Black Bane of Europe in the 1600s. In 1881 anthrax became the first bacterial disease for which immunization was available. More commonly seen in cattle, sheep, and goats, anthrax in modern times has rarely and sporadically affected humans, usually through the handling or consumption of infected animal products (Cieslak and Eitzen, 1999).

Anthrax is a clever organism that perpetuates itself by forming spores. When animals dying from anthrax suffer terminal hemorrhage and infected blood comes into contact with the air, the bacillus organism sporulates. These spores are highly resistant to disinfection and environmental destruction and may remain in contaminated soil for many years. In the United States, anthrax zones are said to follow the cattle drive trails of the 1800s. Sometimes referred to as wool handler's disease, anthrax has commonly posed the greatest risk to people who work directly with dying animals, such as veterinarians, or those

who handle infected animal products such as hair, wool, and bone or bone meal or products made from these materials such as rugs and drums. Products made from infected materials may transmit this disease around the world. Person-to-person transmission is rare (Heymann, 2014).

Anthrax disease may manifest in one of three syndromes: cutaneous, gastrointestinal, and respiratory or inhalational. Cutaneous anthrax, the form most commonly seen, occurs when spores come in contact with abraded skin surfaces. Itching is followed in 2 to 6 days by the development of a characteristic black eschar, usually surrounded by some degree of edema and possibly secondary infection. The lesion itself is usually not painful. If untreated, infection may spread to the regional lymph nodes and bloodstream, resulting in septicemia and death. The fatality rate for untreated cutaneous anthrax is between 5% and 20%, but if appropriately treated, death seldom occurs. Before 2001 the last cutaneous case in the United States was reported in 1992. Gastrointestinal anthrax is considered rare and occurs from eating undercooked, contaminated meat. Inhalational anthrax is also considered rare, typically seen in occupations with exposure to hide tanning or bone processing. Before 2001 the last case reported in the United States was in 1976. Initially, symptoms are mild and nonspecific and may include fever, malaise, mild cough, or chest pain. These symptoms are followed 3 to 5 days later, often after an apparent improvement, by fever and shock, rapid deterioration, and death. Untreated cases of inhalational anthrax are fatal; treated cases may show as high as a 95% fatality rate if treatment is initiated after 48 hours from the onset of symptoms.

Because of factors such as the ability for aerosolization, the resistance to environmental degradation and a high fatality rate, inhalational anthrax has long been considered to have an extremely high potential for being the single greatest biological warfare threat (Cieslak and Eitzen, 1999). An accidental release from a biological research institute in Sverdlovsk, Russia, in 1979 resulted in the documented death of 66 individuals and demonstrated the capacity of this organism as a weapon. Manufacture and delivery of the spores have been considered a challenge because of a tendency for the spores to clump. During 1998 in the United States, more than two dozen anthrax threats (letters purporting to be carrying anthrax) were made. None of them were real. The events of the fall of 2001, when 11 people were sickened and 5 died from deliberate exposure, have shown that the threat of anthrax as a weapon of bioterror is all too real.

Any threat of anthrax should be reported to the Federal Bureau of Investigation and to local and state health departments. Anthrax is sensitive to a variety of antibiotics including the penicillins, chloramphenicol, doxycycline, and the fluoroquinolones. In cases of possible bioterrorism activity, individuals with a credible threat of exposure, with confirmed exposure, or at high risk of exposure are immediately started on antibiotic prophylaxis, preferably fluoroquinolones. Immunization is recommended as well. People who have been exposed are not contagious, so quarantine is not appropriate (Heymann, 2014).

In recent years, although no more deliberate acts of bioterrorism have been reported, England and the United States have seen rare cases of cutaneous, inhalational, and gastrointestinal

anthrax associated with drumming circles using drums covered with imported animal hides. Since December 2009, in the United Kingdom there has been an ongoing outbreak of anthrax among injecting drug users, in some cases resulting in death. The infection is believed to be caused by contaminated heroin. With no new cases after the summer, Scotland declared the outbreak over in December 2010 but concluded the possibility of an ongoing risk of anthrax in heroin users supported by sporadic cases occurring in England. In 2012, 13 cases were reported from Germany, Denmark, France, and the United Kingdom. Ongoing European investigation continues (Grunow et al, 2013).

Smallpox

Formerly a disease found worldwide, smallpox has been considered eradicated since 1979. The last known natural case in the United States was in 1949. The last known case of smallpox worldwide occurred in Somalia in 1977. The United States stopped routinely immunizing for smallpox in 1982. The only documented existing virus sources are located in freezers at the CDC in Atlanta and at a research institute in Novosibirsk, Russia. Controversy exists over the destruction of these viral stocks, and despite an earlier call by WHO for destruction in 2002, the date was postponed to allow for additional research needed should clandestine supplies fall into terrorist hands. The World Health Assembly expected to debate this issue in 2014.

Smallpox has been identified as one of the leading candidate agents for bioterrorism. Susceptibility is 100% in the unvaccinated (those vaccinated before 1982 are not considered protected, although they may have some immunity) and the fatality rate is estimated at 20% to 40% or higher. Immunization with a vaccinia vaccine, the immunizing agent for smallpox, can be protective even after exposure. In 2007 the U.S. Food and Drug Administration (FDA) licensed a new smallpox vaccine, derived from the only other smallpox vaccine licensed by the FDA: Dryvax, approved in 1931 and now in limited supply because it is no longer manufactured. The WHO does not recommend vaccination of the general public because currently the risk of death (1 per 1 million doses) or serious side effects is greater than that of the disease. Those who routinely are exposed to smallpox virus such as laboratory workers should be vaccinated. Because of the potential for bioterrorism and the fact that many health care providers have never seen this disease, it is important to become familiar with the clinical and epidemiologic features of smallpox and how it is differentiated from chickenpox (see the [How To](#) box). Should a nonvaricella, smallpox-like disease be detected, immediate contact with local and national health authorities is obligatory (Heymann, 2014).

HOW TO Distinguish Chickenpox from Smallpox

Despite the availability of a vaccine, chickenpox is still a common disease of childhood and may be seen in susceptible adults as well. Although many health care providers are familiar with chickenpox, most have never seen a case of smallpox. Because of the potential for smallpox to be used as a bioweapon, the CDC suggests that nurses and other practitioners familiarize themselves with the differences in presentation between the two diseases. The rash

pattern for each disease is distinctive, but in the first 2 to 3 days of development, the two may be indistinguishable. Infectious disease texts and posters provide a pictorial description. If a smallpox infection is suspected, the local health department should be notified immediately.

Chickenpox (Varicella)	Smallpox (Historical Variola Major)
Sudden onset with slight fever and mild constitutional symptoms (both may be more severe in adults)	Sudden onset of fever, prostration, severe body aches, and occasional abdominal pain and vomiting, as in influenza
Rash is present at onset	Clear-cut prodromal illness, rash follows 2-4 days after fever begins decreasing
Rash progression is maculopapular for a few hours, vesicular for 3-4 days, followed by granular scabs	Progression is macular, papular, vesicular, and pustular, followed by crusted scabs that fall off after 3-4 weeks if client survives
Rash is "centrifugal" with lesions most abundant on the trunk or areas of the body usually covered by clothing	Rash is "centripetal" with lesions most abundant on the face and extremities
Lesions appear in "crops" and can be at various stages in the same area of the body	Lesions are all at same stage in all areas
Vesicles are superficial and collapse on puncture; mild scarring may occur	Vesicles are deep-seated and do not collapse on puncture; pitting and scarring are common

From Heymann DL, editor: Control of communicable diseases manual, ed 19. Washington, DC, 2008, American Public Health Association; Henderson DA: Smallpox: clinical and epidemiologic features. Emerg Infect Dis 5:537-539, 1999.

Plague

Plague is a vector borne disease transmitted by rodent fleas carrying the bacterium *Y. pestis*. Portrayed vividly in the Bible and events throughout history, plague is believed responsible for the epidemic of Black Death that killed over a quarter of the population of Europe during the Middle Ages. The disease is endemic in much of South Asia, parts of South America, and the western United States, but the majority of outbreaks and cases today are reported from Africa, especially from the Democratic Republic of the Congo. Plague arrived in the United States as a consequence of a pandemic that began in China during the late 1800s and spread to the West Coast via shipboard rats. Although resulting plague in cities was largely controlled, the disease spread to and became enzootic in wild rodents. The current primary vertebrate reservoirs in the United States are usually ground squirrels rather than rats, rabbits, wild carnivores, and in some cases cats. Human plague in the western United States occurs infrequently and sporadically with fewer than 20 cases reported a year since 1970. Veterinarians have contracted the disease from infected cats. People with regular

outdoor exposure such as hunters, trappers, and those living in rural areas as well as cat owners are at highest risk for natural transmission (Heymann, 2014).

Initial signs and symptoms of plague are nonspecific and include myalgia, malaise, fever, chills, sore throat, and headache. As the disease progresses, lymphadenitis commonly develops in the lymph nodes, draining the area nearest the bite. This swollen node, or bubo, most frequently seen in the inguinal area, gives rise to the name bubonic plague. Whether lymphadenitis is present or not, bubonic plague may progress to septicemic plague and secondary pneumonic plague. Secondary pneumonic plague can spread through respiratory droplets, resulting in primary pneumonic plague and human-to-human outbreaks. No such transmission has been reported in the United States since 1924, but several cases of primary pneumonic plague have developed from exposure to infected cats.

Untreated cases of primary septicemic and pneumonic plague are most often fatal; the case fatality rate for untreated bubonic plague is 50% to 60%. Streptomycin is the treatment of choice; gentamicin, tetracyclines, and chloramphenicol are alternatives. Immunization may confer some protection against bubonic plague but not pneumonic. Commercial plague vaccine is no longer available in the United States. Naturally acquired plague is usually bubonic. Plague used as a means of a terrorist attack would most likely be aerosolized, resulting in pneumonic disease and human-to-human transmission (Heymann, 2014). Read more about plague at the CDC website: <http://www.cdc.gov/plague/>.

Tularemia

Sometimes referred to as “rabbit fever” or “deer fly fever,” tularemia is a zoonotic disease caused by the bacterial agent *F. tularensis* which is carried commonly by wild animals, especially rabbits, as well as muskrats, voles, beavers, some domestic animals, and some ticks, mosquitoes, and flies. Tularemia may be transmitted by the bite of an infected arthropod; contact of eyes, skin, or mucous membranes with infected tissues, blood, or water; ingestion of inadequately cooked infected meat or contaminated water; inhalation of contaminated dust; and handling of contaminated pelts and paws. Hunters handling rabbit and rodent carcasses, lawn care workers, and those working outside in rural areas may be at higher risk. Tularemia has also occurred from running over an infected rabbit with a lawn mower and by handling sick pets including dogs, cats, hamsters, and prairie dogs. Tularemia is not transmitted from person to person (Heymann, 2014).

How tularemia presents varies depending on how the infection was acquired and the virulence of the infecting agent. There are two subspecies of *F. tularensis*—one causing few deaths even without treatment and one resulting in a 5% to 15% fatality rate without treatment, primarily from respiratory disease. Commonly the onset of tularemia is sudden and may resemble influenza with high fever, myalgia, headache, nausea, and chills. Frequently an ulcerative lesion appears at the point of inoculation accompanied by swelling of associated lymph nodes. However, lymphadenitis can occur without a primary lesion. In either case, the presence of these buboes can cause

confusion with plague. Inoculation, or introduction of the organism, into the eye results in a purulent conjunctivitis accompanied by regional lymphadenitis. Ingestion of infected tissue or contaminated water produces a sore throat, abdominal pain, diarrhea, and vomiting. Infection by inhalation may cause respiratory involvement and possible sepsis. Pneumonia is a potential complication with all forms and requires prompt treatment to prevent potentially fatal complications. Aminoglycosides or ciprofloxacin are the treatment drugs of choice. There is no vaccination for tularemia currently in widespread use in the United States, although live attenuated vaccine applied intradermally by scarification is available to high-risk workers (Heymann, 2014).

Tularemia has been reported from every state except Hawaii but is not a particularly common disease, with an average of 130 cases per year reported from 2003 through 2012. The only two reported outbreaks of pneumonic tularemia in the United States have come from Martha’s Vineyard, where the disease is endemic and cases are frequently reported in lawn care workers (Feldman et al, 2003). Because of the low incidence of naturally occurring disease, tularemia was removed from the nationally notifiable disease list in 1994 but reinstated in 2000 with the growing concern over bioterrorism. Aerosolized tularemia with resulting pneumonic disease is considered the most likely scenario for use as an agent of bioterrorism (CDC, 2009b). (Read more about tularemia at the CDC website: <http://www.cdc.gov/tularemia/index.html>.)

VACCINE-PREVENTABLE DISEASES

Vaccines are one of the most effective methods of preventing and controlling communicable diseases. The smallpox vaccine, which left distinctive scars on so many shoulders, is no longer in general use because the smallpox virus has been declared eradicated from the world’s population. Despite threats of bioterrorism, there are no plans to reintroduce universal smallpox immunization because of potential side effects. Diseases such as polio, diphtheria, pertussis, and measles, which previously occurred in epidemic proportions, are now controlled by routine childhood immunization. They have not, however, been eradicated, so children need to be immunized against them. In the United States, “no shots, no school” legislation has resulted in the immunization of most children by the time they enter school. However, many infants and toddlers, the group most vulnerable to these potentially severe diseases, do not receive scheduled immunizations despite the availability of free vaccines. And infants less than six months of age who are not yet fully immunized may be susceptible to infections in unimmunized individuals around them (see the Evidence-Based Practice box). Surveys show inner-city children from minority and ethnic groups are particularly at risk for incomplete immunization, and children from religious communities whose beliefs prohibit immunization and children with parents who have philosophical objections to immunization may receive no protection at all. Studies also show low levels of vaccination against pneumonia in senior citizens and lower levels of influenza coverage in adults from minority and ethnic groups. *Healthy People*

2020 includes several objectives about obtaining and maintaining appropriate levels of immunization in all age groups. (Additional information on vaccine-preventable diseases may be found at the CDC website: <http://www.cdc.gov/vaccines/>.)

EVIDENCE-BASED PRACTICE

Because they are too young to be fully immunized, infants under six months of age are at greatest risk for complications and death from pertussis. New mothers, fathers, caretakers, and close contacts to the infant are frequently the source of infection, leading to the concept of cocooning the infant against pertussis through immunizing individuals who have close contact with the baby. In examining ways to increase Tdap (tetanus, reduced diphtheria, acellular pertussis) uptake in new mothers, researchers looked at two hospitals with zero postpartum Tdap immunization rates. One followed standard procedures and the other instituted a standing order for new mothers to receive Tdap before discharge. Implementing the standing orders raised the zero starting rate to 69%. At the hospital that followed standard procedures, the rate for postpartum Tdap immunization remained at zero. Since this study, the Advisory Committee on Immunization Practices has updated its recommendation to say women should receive Tdap, if they have not already, toward the end of their second trimester or during their third trimester of pregnancy. However, even with this new recommendation, studies find only a small percentage of unimmunized pregnant women receive a Tdap vaccination (LABioMed, 2014).

Nurse Use

The adult public has been slow to embrace Tdap. One reason may be lack of awareness of the availability of the vaccine and/or of the importance it plays in keeping infants safe. There are a variety of ways to approach this issue, starting with consumer awareness and provider education and advocacy. This study shows how a change in standard practice within an institution had a dramatic effect on Tdap immunization in postpartum mothers. Whether Tdap or other issues that require attention, nurses manage clinics and take leadership roles in hospitals, physicians' offices, health departments, and safety-net health services, which puts them in a position to both assess where there are opportunities for intervention and to change practice to address important public health concerns.

Because many children receive their immunizations at public health departments, nurses play a major role in increasing immunization coverage of infants and toddlers. Nurses track children known to be at risk for underimmunization and call or send reminders to their parents. They help avoid missed immunization opportunities by checking the immunization status of every young child encountered, whether or not the clinic or home visit is related to immunization. In addition, they organize immunization outreach activities in the community; provide answers to parents' questions and concerns about immunization; and educate parents about why immunizations are needed, inappropriate contraindications to immunization, and the importance of completing the immunization schedule on time.

Routine Childhood Immunization Schedule

The 2014 recommended immunization schedule for children and adolescents in the United States includes routine immunization against the following 16 diseases: hepatitis B, diphtheria, pertussis, tetanus, measles, mumps, rubella, polio,

Haemophilus influenzae type B meningitis, *Varicella* (chickenpox), *Streptococcus pneumoniae*-related illnesses, rotavirus, hepatitis A, influenza, HPV, and meningococcal disease (CDC, 2014d). The vaccine schedule is a rather complex and frequently changing document that makes continuing adjustments for the latest research and recommendations and is issued annually by the Advisory Committee on Immunization Practices (ACIP). More recent additions to the schedule include hepatitis A, rotavirus, seasonal influenza for all children ages 6 months through 18 years, and Tdap (the tetanus, reduced-strength diphtheria, and acellular pertussis vaccine licensed for older children, adolescents, and adults). Because many of these vaccines require three to four doses, the schedule begins at birth with succeeding staggered vaccinations designed to achieve recommended immunization levels by 2 years of age. Additional doses may be required before a child enters school and at adolescence or on entering college. The ACIP, the American Academy of Pediatrics and the American Academy of Family Physicians regularly update recommended immunization schedules. The ACIP also issues a recommended adult immunization schedule for those over 18 years old, by age group and immune status. The 2014 schedule includes, as appropriate, HPV, varicella, measles, mumps and rubella, pneumococcus, zoster to prevent shingles, and tetanus every 10 years with one dose given as Tdap. Other immunizations available in special circumstances include, but are not limited to, rabies, yellow fever, typhoid, smallpox, and anthrax. (Recommended vaccine schedules may be viewed at <http://www.cdc.gov/vaccines/schedules/index.html>.)

Measles

Measles is an acute, highly contagious disease that, although considered a childhood illness, may be seen in the United States in adolescents and young adults. Symptoms include fever, sneezing and coughing, conjunctivitis, small white spots on the inside of the cheek (Koplik's spots), and a red, blotchy rash beginning several days after the respiratory signs. Measles is caused by the rubeola virus and is transmitted by inhalation of infected aerosol droplets or by direct contact with infected nasal or throat secretions or with articles freshly contaminated with the same nasal or throat secretions. A very contagious nature, combined with the fact that people are most contagious before they are aware they are infected, makes measles a disease that can spread rapidly through the population. Infection with measles confers lifelong immunity (Heymann, 2014).

Measles and malnutrition form a deadly combination for many children in the developing world. Despite the introduction in 1963 of a live attenuated measles vaccine that is safe, effective, and widely available, measles is still endemic in many countries. The WHO estimates 20 million people are affected each year with over 100,000 deaths—mostly children under the age of five. Much of this mortality is preventable by immunizing all infants. The good news is that with the launch of the Measles and Rubella Initiative in 2001, global measles deaths have decreased by 78 percent worldwide in recent years—from 562,400 deaths in 2000 to 122,000 in 2012 (WHO, 2014b).

Immunization has dramatically decreased measles cases in the United States to the point that, in March 2000, a panel of

experts declared measles no longer endemic in the United States. Before introduction of the vaccine in 1963, 200,000 to 500,000 cases of measles were reported yearly, but by 1983 reported cases had fallen to an all-time low of less than 1500. In the late 1980s, the incidence of measles began to climb again, with more than 55,000 cases reported between 1989 and 1991. This increase resulted from low immunization rates among preschool children and was countered with efforts to increase immunization rates and the routine use of two doses of measles vaccine for all children. Except for outbreaks in 1994 that occurred predominantly among high school and college-age persons, many of whom had not received two doses of measles vaccine, reported measles cases dropped continuously from 1991 to 2004 when only 37 confirmed cases were reported to the CDC—the lowest number since measles became a nationally reportable disease in 1912.

Since measles elimination was documented in the United States in 2000, annual reported cases have ranged from the low of 37 in 2004 to a high of 644 in 2014. Years with high numbers of reports are driven by outbreaks. In 2008, 140 cases were reported with 3 outbreaks. This increase was attributed to spread in communities with groups of unvaccinated people. The 220 cases in 2011 largely resulted from cases imported from a large outbreak in France. The United States experienced 11 outbreaks in 2013, three of which had more than 20 cases and in 2014 saw 23 outbreaks and 644 cases, many of which were associated with a large, ongoing measles outbreak in the Philippines. The first three weeks of January 2015 saw 68 cases from 11 states, most of which were linked with a large outbreak in a California amusement park (CDC, 2015b).

These recent outbreaks in the United States highlight the ongoing risk of measles importation from other countries by people who travel. With first-dose vaccine coverage of preschool children at greater than 90% and schools in 49 states requiring two doses of vaccine, the pattern of infection has shifted from under immunization of infants and school-age children to disease acquired from other countries. Because imported cases had not previously resulted in large outbreaks, it appeared that vaccination efforts had been successful in increasing herd immunity against measles, but groups who remain at greatest risk for infection are those who do not routinely accept immunization, such as people with religious or philosophical objections, students in schools that do not require two doses of vaccine, and infants in areas where immunization coverage is low. The exposure of these groups to an imported case can result in a major outbreak and, indeed, beginning with the 2008 outbreaks, most increases have not been the result of a greater number of imported cases but of greater viral transmission after importation into the United States, leading to a larger number of importation-associated cases. These importation-associated cases largely occur among the unvaccinated, frequently among school-aged children who are eligible for vaccination but whose parents choose not to have them vaccinated and infants who are too young for vaccination. States vary in the ease of obtaining philosophical exemptions from immunization and requirements for vaccination of home-schooled children. The increase in importation-associated cases may result in an increase in

measles morbidity, especially in communities with many unvaccinated residents (CDC, 2015b; CDC, 2014e).

Healthy People 2020 calls for the reduction, elimination or maintained elimination of vaccine-preventable diseases including the reduction of indigenous measles cases. Efforts to meet this goal will require (1) rapid detection of cases and implementation of appropriate outbreak control measures, (2) achievement and maintenance of high levels of vaccination coverage among preschool-age children in all geographic regions, (3) continued implementation and enforcement of the two-dose schedule among young adults, (4) the determination of the source of all outbreaks and sporadic infections, and (5) cooperation among countries in measles control efforts. Nurses receive reports of cases, investigate them, and initiate control measures for outbreaks. They use every opportunity to immunize adolescents and young adults who lack documentation of two doses of measles vaccine. Nurses who work in regions where undocumented residents are common, where groups obtain exemption from immunization on religious grounds or who choose not to vaccinate for philosophical reasons, where preschool coverage is low and/or where international visitors are frequent need to be especially alert for measles cases and the necessity of prompt outbreak control among particularly susceptible populations.

Rubella

The rubella (German measles) virus causes a mild febrile disease with enlarged lymph nodes and a fine, pink rash that is often difficult to distinguish from measles or scarlet fever. In contrast to measles, rubella is only a moderately contagious illness. Transmission is through inhalation of or direct contact with infected droplets from the respiratory secretions of infected persons. Children may show few or no constitutional symptoms, whereas adults usually experience several days of low-grade fever, headache, malaise, runny nose, and conjunctivitis before the rash appears. Many infections occur without a rash (Heymann, 2014).

For many years, because it caused only a mild illness, rubella was considered to be of minor importance. Then, in 1941 the link between maternal rubella and poor pregnancy outcomes was recognized and the disease suddenly assumed major public health significance. Rubella infection, in addition to causing intrauterine death and spontaneous abortion, may result in anomalies referred to as congenital rubella syndrome (CRS), affecting single or multiple organ systems. Defects include cataracts, congenital glaucoma, deafness, microcephaly, mental retardation, cardiac abnormalities, and diabetes mellitus. CRS occurs in up to 90% of infants born to women who are infected with rubella during the first trimester of pregnancy (Heymann, 2014). During the 1962 to 1965 rubella pandemic, an estimated 12.5 million cases of rubella occurred in the United States, resulting in 2000 cases of encephalitis, 11,250 fetal deaths, 2100 neonatal deaths, and 20,000 infants born with CRS. The economic impact of this epidemic was estimated at \$1.5 billion (CDC, 2005).

The United States has established and achieved the goal of eliminating indigenous rubella transmission and CRS. Rubella

elimination is defined as the absence of continuous endemic transmission lasting ≥ 12 months. With the introduction of a vaccine in 1969, cases of rubella in the United States fell precipitously from 57,686 to less than 10 cases per year 2003 and 2004 with a large percentage of the cases imported or import linked. By the beginning of 2005, at the 39th National Immunization Conference, the director of the CDC announced that rubella was no longer endemic in the United States. From 2005 through 2011, 67 rubella cases were reported as well as two rubella outbreaks involving three cases and four cases of CRS. Of these 67 cases, 28 cases (42%) were known importations. Elimination of endemic rubella was once again documented and verified in the United States in December 2011 (CDC, 2013d).

Rubella remains endemic in parts of the world, however, and because of international travel and countries without routine rubella vaccination, imported cases of rubella and CRS cases are possible. In 2012, WHO estimated 110,000 cases of CRS worldwide, many of them in Asia and Africa where vaccination coverage is lowest. WHO also reports that intensive and widespread rubella vaccination efforts have largely eliminated rubella and CRS in many developed and in some developing countries. The WHO Region of the Americas has had no endemic (naturally transmitted) cases of rubella infection since 2009.

Unimmunized immigrants do not necessarily import disease, but their unimmunized status may leave them vulnerable to infection once they arrive. In addition to a focus on identifying and vaccinating foreign-born adults, the continued elimination of rubella and CRS in the United States will require (1) maintaining high immunization rates among children, (2) ensuring vaccination among women of child-bearing age, especially those who are foreign-born, (3) continuing aggressive surveillance, and (4) responding rapidly to any outbreak.

Pertussis

Pertussis (whooping cough) begins as a mild upper respiratory tract infection progressing to an irritating cough that within 1 to 2 weeks may become paroxysmal (a series of repeated violent coughs). The repeated coughs occur without intervening breaths and can be followed by a characteristic inspiratory “whoop.” Pertussis is caused by the bacterium *Bordetella pertussis* and is transmitted via an airborne route through contact with infected droplets. It is highly contagious and considered endemic in the United States. Vaccination against pertussis, delivered in combination with diphtheria and tetanus, is a part of the routine childhood immunization schedule. Treatment of infected individuals with antibiotics such as erythromycin may shorten the period of communicability but does not relieve symptoms unless given early in the course of the infection. Prophylactic treatment with antibiotics is recommended for family members and close contacts of infected individuals, regardless of immunization status and age, if there is a child in the house under the age of 1 year or a woman in the last 3 weeks of pregnancy or to prevent ongoing transmission within the family. Infection with pertussis does not offer permanent immunity (Heymann, 2014).

Before the development of a whole-cell vaccine—DTP (diphtheria, tetanus, pertussis)—in the 1940s, pertussis led to hundreds of thousands of cases and thousands of deaths per year, the majority in children younger than 5 years. After vaccine licensure and the introduction of universal vaccination, reported cases in the United States steadily declined, hitting a record low of just over 1000 in 1976. However, beginning in the early 1980s, pertussis cases began to show cyclical increases peaking every 3 to 5 years with the peaks getting higher and reported cases going up. In 2012, over 48,000 cases were reported, the highest number since 1955 (CDC, 2014f).

In the mid 2000s the epidemiology of pertussis appears to have changed. While infants less than 6 months were still the most likely to be infected as they are not old enough to be fully vaccinated, incidence began increasing in children 7 to 10 years old, many of whom had been fully vaccinated, suggesting that the acellular vaccine DTaP, introduced in 1997 for the entire childhood series in response to concerns over serious side effects in some children after DTP, may not offer the duration of protection seen with the whole-cell vaccine. Tdap (tetanus, reduced strength diphtheria, acellular pertussis) was licensed in 2005 as a booster for adults in place of their next tetanus vaccination and adolescents, with routine recommendation for immunization at 11 to 12 years. The reduction in rates in preteens 11 to 12 years old demonstrates immediate protection from Tdap, but increasing incidence in 13- to 14-year-olds suggests waning immunity with no durable protection. But while waning immunity may not be completely protective, evidence suggests that when infected, people who have been boosted will experience milder disease. While positive for those thus protected, this lack of symptoms may have the unintended consequence of making them excellent inapparent carriers. Nonetheless, vaccination with DTaP and Tdap continues to be recommended as the single most effective strategy in reducing illness and death from pertussis. Pregnant women and close contacts to their babies are especially encouraged to be vaccinated in an effort to prevent disease in infants, the group most likely to experience severe complications and death. In addition to maintaining high rates of immunization, prevention efforts also included publicizing Tdap, increasing awareness of pertussis in adolescents and adults among providers, and promptly implementing treatment and control in the face of outbreaks (CDC, 2012b).

Because pertussis does have a cyclical pattern (there are periodic outbreaks such as those seen in California in 2010 and in Washington state as well as numerous other states across the country in 2012), it is important for nurses to work with the community to maintain the highest possible levels of immunization coverage to minimize these occurrences. Because of the contagious nature of pertussis, nurses play a major role in limiting transmission during outbreaks by ensuring appropriate treatment of family members and close contacts. The Quality and Safety in Nursing Education box describes safety factors related to pertussis.

Influenza

Influenza is a viral respiratory tract infection often indistinguishable from the common cold or other respiratory diseases.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Targeted Competency-Safety

Minimizes risk for harm to clients and providers through both system effectiveness and individual performance. Important aspects of safety include the following:

- **Knowledge:** Discuss potential and actual impact of national client safety resources, initiatives, and regulations.
- **Skills:** Use national client safety resources for own professional development and to focus attention on safety in care settings.
- **Attitudes:** Value the relationship between national safety campaigns and implementation to local practices and practice settings.

Safety Question: Pertussis

With the focus of pertussis in the news how is it impacting your community? Look into local statistics around pertussis occurrence. Has there been an increased occurrence of pertussis over the past 5 years?

How do your local statistics compare to national statistics for pertussis from the Centers for Disease Control and Prevention?

What might be some system approaches to educating your community about the risk of pertussis?

What might be some system approaches to providing pertussis vaccinations to the appropriate populations?

What data points will you want to track to assess whether your interventions have been effective?

Prepared by Gail Armstrong, PhD(c), DNP, ACNS-BC, CNE, Associate Professor, University of Colorado Denver College of Nursing.

Transmission is airborne and through direct contact with infected droplets. Unlike many viruses that do not survive long in the environment, the flu virus is thought to exist for many hours in dried mucus. Outbreaks are common in the winter and early spring in areas where people gather indoors such as in schools and nursing homes. Gastrointestinal and respiratory symptoms are common. Because symptoms do not always follow a characteristic pattern, many viral diseases that are not influenza are often called flu. The most important factors to note about influenza are its epidemic nature and the mortality that may result from pulmonary complications, especially in older adults and children less than 2 years of age (Heymann, 2014).

There are three types of influenza viruses: A, B, and C. Type A is usually responsible for large epidemics, whereas outbreaks from type B are more regionalized; type C epidemics are sporadic, less common, and usually result in only mild illness. Influenza viruses often change in the nature of their surface appearance or their antigenic makeup. Types B and C are fairly stable viruses, but type A changes constantly. Minor antigenic changes are referred to as antigenic drift, and they result in yearly epidemics and regional outbreaks. Major changes such as the emergence of new subtypes are called antigenic shift; these occur only with type A viruses. Antigenic shift and drift lead to epidemic outbreaks every few years and pandemic outbreaks every 10 to 40 years as seen with novel influenza A H1N1 in 2009. Mortality rates associated with epidemics may or may not be higher than those in nonepidemic situations.

The preparation of influenza vaccine each year is based on the best possible prediction of what type and variant of virus

will be most prevalent that year. Because of the changing nature of the virus, yearly immunization is necessary and in the United States is given in early fall before the flu season begins. In recent history, if vaccine were available, immunization for seasonal flu was particularly recommended for children ages 6 months up to 19 years, pregnant women, people 50 years of age and older, people of any age with certain chronic medical conditions, people who live in nursing homes and other long-term care facilities, and people who live with or care for those at risk for complications from flu. During the 2009-2010 influenza season, pandemic novel influenza A H1N1 replaced other seasonal flu viruses as the predominantly circulating virus, and the recommended priority groups shifted from seniors to the young; high school students and pregnant women seemed particularly hard hit, whereas those over 65 appeared to perhaps have some degree of protection. For the 2010-2011 flu season, novel influenza A H1N1 was included in the vaccine and the ACIP recommended universal coverage for everyone ages 6 months and older (CDC, 2010b).

Flu immunizations, when matched appropriately with circulating virus strains, are estimated to provide 70% to 90% protection against infection in healthy young adults; although they do not always prevent infection, they do result in milder disease symptoms. There are now a variety of vaccines available including one that is not grown in eggs for those with egg sensitivity and one that is administered nasally as a mist. Although influenza is often self-limiting in the healthy population, serious complications, particularly viral and bacterial pneumonias, can be deadly to older adults, children under 2 years of age, and those debilitated by chronic disease. When appropriate, it is important to couple influenza immunization of this population with immunization against pneumococcal pneumonia.

The use of influenza antiviral drugs should be considered in the nonimmunized or groups at high risk for complications. New evidence also suggests that antivirals can decrease the number of deaths in hospitalized influenza patients. The neuraminidase inhibitors (oseltamivir, zanamivir) have activity against influenza A and B viruses, whereas the adamantanes (amantadine, rimantadine) have activity only against influenza A viruses. Since January 2006, the neuraminidase inhibitors have been the only recommended influenza antiviral drugs because of widespread resistance to the adamantanes among influenza A (H3N2) virus strains. There have been incidences, worldwide and in the United States, of H1N1 virus resistance to oseltamivir. Current guidelines indicate antiviral treatment should be guided by surveillance data on circulating viruses and confirmatory testing of viral subgroups. CDC annually publishes Recommendations for Influenza Antiviral Medications (CDC, 2014g). (Read more about influenza at <http://www.cdc.gov/flu/index.html>.)

Healthy People 2020 targets increasing the proportion of the population vaccinated annually against influenza and pneumococcal disease. Nurses often spearhead influenza immunization campaigns that target older adults. Examples include conducting flu clinics at polling places during elections or at community centers and churches during “senior vaccination Sundays.” Inhabitants of residences and nursing homes for older adults

are at risk, since influenza can spread rapidly with severe consequences through such living arrangements. As with children, nurses should check immunization history and encourage immunization for every older adult encountered in a clinic or home visit.

But while children, the elderly, and those with health conditions that put them at high risk for complications have traditionally been targets for immunizations, new strains of influenza such as H1N1 have more seriously affected young adults, leading to the recommendation that everyone over 6 months of age receive flu immunization. Nurses not only can promote this message, they can provide an example by choosing immunization as well. The CDC estimates that in the early flu season of 2013, 64% of health care providers were immunized against flu, and while this is higher than the general population (who were at closer to 40%), it is far from the *Healthy People 2020* goal of 90%. When nurses get immunized against influenza, they are protecting not only themselves but their patients (CDC, 2014h).

Pandemic Novel Influenza A (H1N1)

Novel influenza A H1N1, a new flu virus that quickly reached pandemic proportions, was first recognized in Mexico and the United States in the spring of 2009. Originally called swine flu, the virus is of swine origins but does not spread from swine to people. Instead, it is transmitted rapidly and easily from person to person and in some cases is suspected to have spread from humans to swine as well as other animals such as dogs, cats, and ferrets. Because the virus was new, the population lacked immunity and visitors to Mexico quickly became infected and carried it to people around the globe. By June of 2009 more than 70 countries had reported cases of novel H1N1 infection, and ongoing community-level outbreaks of novel H1N1 occurred in multiple parts of the world, prompting the WHO to declare a global pandemic. This action was a reflection of the spread of the new H1N1 virus, not the severity of illness caused by the virus.

Although novel H1N1 appeared to spread in the same manner as seasonal influenza viruses, the groups most affected were children, young adults (especially those with underlying chronic disease), and pregnant women, as opposed to seniors who are the usual targets of seasonal flu but were thought in this case to perhaps have some degree of immunity. Initial reports made it appear that the virus inflicted a high case fatality rate, but as surveillance strengthened and expanded, this did not prove to be the case; however, by the end of the year, pediatric deaths were higher than in previous years and pediatric hospitalizations higher than other age groups. The majority of 2009 novel H1N1 deaths occurred in people between the ages of 50 and 64 years of age, 80% of whom have had an underlying health condition (CDC, 2010c).

With the identification of the virus, the scramble was on for a vaccine, which became available in the fall of 2009 in limited doses and was initially targeted to priority groups, including those 6 months to 24 years of age, caretakers, infants less than 6 months of age, pregnant women, adults 25 to 64 years of age with chronic conditions, health care providers, and first responders. Initial demand for vaccine was high, but since the

virus did not appear to prove overall any more frightening than seasonal flu and more vaccine came on the market, the available supply was more than enough for anyone who wished to be immunized. The delivery of the vaccine, in addition to seasonal flu vaccine, proved a planning and logistical challenge to the public health system, demanded considerable resources, and provided a valuable exercise in implementation of preparedness strategies. Nurses were at the forefront of this expansive operation by planning for, scheduling, and immunizing—in a variety of community settings, schools, and clinics—a large portion of the population, including two doses to children. During the summer of 2009, novel H1N1 outbreaks extended the normal flu season far beyond the usual period and dominated reported circulating flu viruses from the Southern Hemisphere as well. Activity peaked at the end of October in the United States, but novel H1N1 continued into 2010 as the dominant circulating strain. Resistance to antiviral neuraminidase inhibitors was reported but remained low, and the vast majority of 2009 H1N1 viruses tested did not appear to change significantly, remaining related to the A/California/7/2009 H1N1 reference virus selected by WHO as the 2009 H1N1 vaccine virus. An H1N1 component was included in the 2010 seasonal vaccine (CDC, 2010c). H1N1 returned as the predominant strain seen during the 2013–2014 flu season.

Avian Influenza A (H5N1)

In 1997 in Hong Kong, the first known cases of human illness associated with an avian influenza type A virus H5N1 were reported. Referred to in the press as Hong Kong bird flu, this virus appeared to have been transmitted to people through contact with infected poultry. As a result of this association, Hong Kong officials ordered the slaughter of all chickens in and around Hong Kong with a resulting halt in the spread of disease. No cases were reported outside Hong Kong and, despite recurring outbreaks of avian flu in poultry, no further H5N1 virus activity in humans was reported (CDC, 1998). This situation changed dramatically in late 2003 and early 2004 when H5N1 outbreaks occurred among poultry, people, and, in some cases, other animals in nine Asian countries. And unlike the earlier situation in Hong Kong, these outbreaks have not disappeared but only subsided to again reappear. As of the beginning of 2014, human infections with H5N1 have been reported from 16 different countries with some fatality rates as high as 70%. The largest numbers have been reported from Indonesia (195), Egypt (173), and Vietnam (125). Canada has reported one case. To date, there have not been any reports of highly pathogenic avian influenza H5N1 virus infections among wild birds, poultry, or other animals or humans in the United States.

An unanswered question is whether there are actually many more human cases than are identified because symptoms are not severe enough to recognize. Most of the reported cases have resulted from contact with infected poultry, but it is believed that a few cases of human-to-human transmission have occurred. So far, the documented spread from human to human has been rare and not sustained, but because influenza viruses have the ability to change, concern exists among scientists that

H5N1 may modify to the point where people could easily infect each other; also, because H5N1 does not usually infect humans, they would have little immune protection. Such a change could give rise to pandemic influenza with a virus that appears to exact a high toll in human lives. Given this possibility, surveillance becomes of utmost importance and close attention is paid to H5N1 virus activity among poultry and humans in Asia, Europe, and North Africa. Vaccine development efforts are underway and, although licensed in some countries, are not yet generally available (CDC, 2014i).

FOODBORNE AND WATERBORNE DISEASES

In recent years attention has focused on stories related to foodborne illness associated with peanut butter, cookie dough, spinach, lettuce, tomatoes, chili peppers, strawberries, raspberries, oysters, uncooked eggs, poultry and hamburger, raw milk, unpasteurized apple cider, and so forth. Cans of beef stew suspected to be contaminated with botulism have been pulled off grocery store shelves and the term *mad cow disease* has entered the popular vocabulary. Recalls of food products have become a common occurrence. Highly centralized food production and processing systems that use food produced in far-reaching areas and distribute it through widespread distribution networks increase the potential for any contamination to result in large-scale, multistate outbreaks. One incident of contamination may affect hundreds of people across the country and result in numerous deaths. Anyone can acquire foodborne illness, regardless of socioeconomic status, race, sex, age, occupation, education or area of residence, but the very young, old, and debilitated are most susceptible and bear the highest burden of morbidity and mortality.

In 2010, the CDC developed new lower than previously estimated but more precise estimates for foodborne illness suggesting that in the United States, as many as 1 in 6 Americans (or 48 million people) gets sick, 128,000 are hospitalized, and 3,000 die from foodborne illnesses each year, most the result of unidentified agents (CDC, 2010d). Known pathogens cause an estimated 9.4 million foodborne illnesses annually in the United States (Scallan et al, 2011). Because their presentations are often not clinically distinctive and frequently self-limiting, single cases of foodborne illness may be difficult to identify. Affected individuals in single cases or in outbreak situations may not see a physician or are treated presumptively and not tested. In either case, the illness goes unreported, resulting in statistics that underestimate the true magnitude of the problem.

FoodNet is a CDC sentinel surveillance system targeting 10 sites across the country and collecting information from laboratories on disease caused by enteric pathogens transmitted commonly through food. It is a collaborative effort among CDC, the U.S. Department of Agriculture (USDA), and the FDA. In 2011 FoodNet reported 18,964 laboratory-diagnosed cases of infection, the majority caused by *Salmonella*, *Campylobacter*, and *Shigella* (CDC, 2012c).

Confirmed foodborne outbreaks are reported by states to the CDC through the Foodborne Disease Outbreak Surveillance System. During 2009–2010, a total of 1,527 foodborne disease

outbreaks were reported from all 50 states, Puerto Rico, and the District of Columbia. These outbreaks resulted in 29,444 cases of illness, 1,184 hospitalizations, and 23 deaths. Among the 790 outbreaks with a single laboratory-confirmed etiologic agent, norovirus was the most commonly reported, accounting for 42% of outbreaks, and *Salmonella* was second, accounting for 30% of outbreaks. Of the 653 outbreaks where a food source was identified, 299 were determined to originate from only one ingredient with the most outbreaks attributed to beef, fish, dairy, and poultry. The most illnesses were associated with eggs, followed by beef and poultry. Of organisms paired with food sources, the most outbreaks were from *Campylobacter* in unpasteurized dairy, *Salmonella* in eggs, STEC O157 in beef, ciguatera toxin in fish, and scombroid toxin (histamine fish poisoning) in fish, and the most outbreak-related illnesses by far resulted from *Salmonella* in eggs (2,231 illnesses) followed by *Salmonella* in sprouts (493) and *Salmonella* in vine-stalk vegetables such as tomatoes (422). The combinations responsible for the most hospitalizations were *Salmonella* in vine-stalk vegetables, STEC O157 in beef, and *Salmonella* in sprouts; those that caused the most deaths were STEC O157 in beef (three deaths), *Salmonella* in pork, and *Listeria* in dairy (two each). Thirty-eight multistate outbreaks were reported; twenty-one were caused by *Salmonella* (CDC, 2013e). (Learn more about the Foodborne Disease Outbreak Surveillance System at <http://www.cdc.gov/foodborneburden/surveillance-systems.html>.)

The ability to identify multistate outbreaks has been greatly enhanced through technology now routinely used in public health laboratories (serotyping and pulsed-field gel electrophoresis) and the rapid sharing of this information among public health officials through PulseNet, the national molecular subtyping network for foodborne disease surveillance. Since 1996, this DNA fingerprinting has allowed the detection of thousands of individual and multistate outbreaks including people sickened from eating *Salmonella* contaminated peanut butter, tomatoes and cantaloupes, *E. coli* in leafy vegetables, and *Vibrio parahaemolyticus* in oysters. (Learn more about PulseNet at <http://www.cdc.gov/pulsenet/index.html>.)

The CDC recommends three goals in achieving food safety: (1) control or eliminate pathogens in domestic and imported food, (2) reduce or prevent contamination during growing, harvesting, and processing, and (3) continue the education of restaurant workers and consumers about risks and prevention measures. Also noted is the need for continued efforts to understand how contamination of fresh produce and processed foods occurs and to develop and implement measures that reduce it.

Foodborne illness, or “food poisoning,” as it is erroneously but commonly called, is often categorized as either food infection or food intoxication. Food infection results from bacterial, viral, or parasitic infection of food by pathogens such as *Salmonella*, *Campylobacter*, hepatitis A, *Toxoplasma*, and *Trichinella*. Food intoxication is caused by toxins produced by bacterial growth, chemical contaminants (heavy metals), and a variety of disease-producing substances found naturally in certain foods such as mushrooms and some seafood. Examples of food intoxications are botulism, mercury poisoning, and paralytic

TABLE 13-4 Commonly Encountered Food Intoxications

Causal Agent	Incubation Period	Duration	Clinical Presentation	Associated Food
<i>Staphylococcus aureus</i>	30 min to 7 hr	1-2 days	Sudden onset of nausea, cramps, vomiting, and prostration, often accompanied by diarrhea; rarely fatal	All foods, especially those likely to come into contact with food-handlers' hands that may be contaminated from infections of the eyes and skin
<i>Clostridium perfringens</i> (strain A)	6-24 hr	1 day or less	Sudden onset of colic and diarrhea, maybe nausea; vomiting and fever unusual; rarely fatal	Inadequately heated meats or stews; food contaminated by soil or feces becomes infective when improper storage or reheating allows multiplication of organism
<i>Vibrio parahaemolyticus</i>	4-96 hr	1-7 days	Watery diarrhea and abdominal cramps; sometimes nausea, vomiting, fever, headache; rarely fatal	Raw or inadequately cooked seafood; period of time at room temperature usually required for multiplication of organism
<i>Clostridium botulinum</i>	12-36 hr, sometimes days	Slow recovery, maybe months	Central nervous system signs; blurred vision, difficulty in swallowing and dry mouth, followed by descending symmetrical flaccid paralysis in an alert person; "floppy baby" in infant; fatality <15% with antitoxin and respiratory support	Home-canned fruits and vegetables that have not been preserved with adequate heating; infants have become infected from ingesting honey

Based on information from Heymann DL, editor: *Control of communicable diseases manual*, ed 20, Washington, DC, 2014, American Public Health Association.

shellfish poisoning. Table 13-4 presents some of the most common agents of food intoxication and their incubation period, source, symptoms, and pathology. Although it is not a hard-and-fast rule, food infections are associated with incubation periods of 12 hours to several days after ingestion of the infected food, whereas intoxications become obvious within minutes to hours after ingestion. Botulism is a clear exception to this rule, with an incubation period up to several days or more in adults. Possessing a potent preformed toxin, capable of producing severe intoxication resulting in flaccid paralysis and death if not identified and treated early, *C. botulinum* is one of the organisms considered a strong candidate for a weapon of bioterrorism (Heymann, 2014).

The Role of Safe Food Preparation

Protecting the nation's food supply from contamination by virulent microbes is a multifaceted issue that is and will continue to be incredibly costly, controversial, and time-consuming to address. The specter of terrorist threats to the food supply adds an additional layer of complexity. However, much food-borne illness, regardless of causal organism, can easily be prevented through simple changes in food preparation, handling, and storage. Common errors include (1) cross-contamination of food during preparation, (2) insufficient cooking or reheating temperatures, (3) holding cooked food or storing food at temperatures that promote growth of pathogens and/or formation of toxins, and (4) poor personal hygiene. Because these measures are so important in preventing foodborne disease, *Healthy People 2020* has continued to include an objective directed toward them. WHO estimates that 2.2 million people, 1.9 million of them children, die annually from foodborne and waterborne diarrheal diseases in less-developed countries. In 2001 WHO released a new campaign entitled *Five Keys to Safer Food*, which reduces the former *Ten Golden Rules for Food*

BOX 13-4 WHO Five Keys to Safer Food

1. Keep food clean.
2. Separate raw and cooked food.
3. Cook thoroughly.
4. Keep food at safe temperatures.
5. Use safe water and raw materials.

From the World Health Organization: *Five Keys to Safer Food campaign*. 2009b, WHO. Available at <http://www.who.int/foodsafety/consumer/5keys/en>. Accessed March 25, 2010; Heymann DL, editor: *Control of communicable diseases manual*, ed 19. Washington, DC, 2008, American Public Health Association.

Preparation developed in the early 1990s to five even simpler and easier to remember principles (presented in Box 13-4). A poster explaining the *Five Keys* is available in 25 languages and is accompanied by a training manual titled *Bring Food Safety Home* (Heymann, 2014). (Read more about the Five Keys at the WHO website: <http://www.who.int/foodsafety/consumer/5keys/en/index.html>.)

Salmonellosis

Salmonellosis is a bacterial disease characterized by sudden onset of headache, abdominal pain, diarrhea, nausea, sometimes vomiting, and almost always fever. Onset is typically within 48 hours of ingestion, but the clinical signs are impossible to distinguish from other causes of gastrointestinal distress. Diarrhea and lack of appetite may persist for several days, and dehydration may be severe. Although morbidity can be significant, death is uncommon except among infants, older adults, and the debilitated. The rate of infection is highest among infants and small children. It is estimated that only a small proportion of cases are recognized clinically and that only 1% of clinical cases are reported. The number of

Salmonella infections yearly may actually be in the millions (Heymann, 2014).

Outbreaks occur commonly in restaurants, hospitals, nursing homes, and institutions for children. The transmission route is eating food derived from an infected animal or contaminated by feces of an infected animal or person. Unchlorinated municipal water supplies have also been implicated in *Salmonella* outbreaks. Raw or undercooked meat and meat products, raw or undercooked poultry, uncooked eggs, unpasteurized milk and dairy products, and contaminated produce are the foods most often associated with salmonellosis. Recent large outbreaks have been linked with eating tomatoes, jalapeño peppers, and peanut butter. Meat and poultry may be contaminated during preparation or cross-contaminate food being prepared with them. Improper food preparation temperatures (cooking and holding) and cross-contamination appear to be the biggest risk factors for food-associated outbreaks. Animals are the common reservoir for the various *Salmonella* serotypes, although infected humans may also fill this role. Animals are more likely to be chronic carriers. Reptiles such as iguanas have been implicated as *Salmonella* carriers along with pet turtles, poultry, cattle, swine, rodents, dogs, and cats. People have also been infected by handling *Salmonella*-contaminated dry dog food and treats. Person-to-person transmission is an important consideration in daycare and institutional settings (Heymann, 2014).

Enterohemorrhagic *Escherichia coli* (EHEC or *E. coli* 0157:H7)

Escherichia coli 0157:H7 belongs to the enterohemorrhagic category of *E. coli* serotypes producing a strong cytotoxin called a Shiga toxin and are collectively known as Shiga toxin-producing *E. coli* (STEC). *E. coli* serotypes in this group can cause a potentially fatal hemorrhagic colitis. This pathogen was first widely described in humans in 1992 following the investigation of two outbreaks of illness associated with consumption of hamburger from a fast-food restaurant chain. Transmission is through ingestion of food contaminated by infected feces. Ruminants, particularly cattle, are the most important reservoir, although humans may also serve as a source for person-to-person transmission. Undercooked hamburger has been implicated in several outbreaks, as have roast beef, alfalfa sprouts, melons, lettuce, uncooked spinach, unpasteurized milk and apple cider, municipal water, and person-to-person transmission in daycare centers, homes, and institutions. Recent large outbreaks have been associated with uncooked spinach and petting zoos. Infection with *E. coli* 0157:H7 causes bloody diarrhea, abdominal cramps, and, infrequently, fever. Children and older adults are at highest risk for clinical disease and complications. Hemolytic uremic syndrome (HUS) is seen in approximately 15% of cases among children and a smaller number of adults and may result in acute renal failure. The case fatality rate for infection that results in HUS can be as great as 5% (Heymann, 2014).

Hamburger often appears to be involved in outbreaks because the grinding process exposes pathogens on the surface of the whole meat to the interior of the ground meat, effectively mixing the once-exterior bacteria thoroughly throughout the hamburger so that searing the surface no longer suffices to kill

all bacteria. Tracking the contamination is complicated by the fact that hamburger is often made of meat ground from several sources. The best protection against this pathogen, as with most foodborne agents, is to thoroughly cook food before eating it.

WATERBORNE DISEASE OUTBREAKS AND PATHOGENS

Waterborne pathogens usually enter water supplies through animal or human fecal contamination and frequently cause enteric disease. They include viruses, bacteria, and protozoans. Hepatitis A virus is probably the most publicized waterborne viral agent, although other viruses may also be transmitted by this route (enteroviruses, rotaviruses, and paramyxoviruses). The most important waterborne bacterial diseases are cholera, typhoid fever, and bacillary dysentery. However, other *Salmonella* spp. as well as *Shigella*, *Vibrio*, and *Campylobacter* species and various coliform bacteria including *E. coli* 0157:H7 may be transmitted in the same manner. Recently, since added to surveillance in 2001, *Legionella* spp. have frequently been implicated in waterborne disease outbreaks (WBDOs) in the United States. In the past, the most important waterborne protozoans have been *Entamoeba histolytica* (amebic dysentery) and *Giardia lamblia*, but major outbreaks of cryptosporidiosis in municipal water, as seen in the diarrheal outbreak that crippled the city of Milwaukee in 1993, have pushed *Cryptosporidium* into the debate over how to best safeguard municipal water supplies. Protozoans do not respond to traditional chlorine treatment as do enteric and coliform bacteria, and their small size requires special filtration.

The CDC defines a WBDO as an incident in which two or more persons experience similar illness after consuming water that epidemiologic evidence implicates as the source of that illness. Recreational water and other water not intended for drinking as well as drinking water may be involved in waterborne outbreaks. Facilities with inadequate chlorination and pools allowing diapered children pose particular risk for infection, as does drinking water without adequate disinfection while hiking and camping in the backcountry.

Since 1971, the CDC, the U.S. Environmental Protection Agency (EPA), and the Council of State and Territorial Epidemiologists have maintained a collaborative Waterborne Disease and Outbreaks Surveillance System for collecting and reporting data related to occurrences and causes of waterborne disease and outbreaks. This surveillance system is the primary source of data concerning the scope and effects of WBDOs in the United States. The CDC and the EPA, to improve timeliness and completeness of reporting, are collaborating with public health jurisdictions to implement electronic reporting through the National Outbreak Reporting System (NORS) (CDC, 2013f).

VECTORBORNE DISEASES

Vectorborne diseases refer to illnesses for which the infectious agent is transmitted by a carrier, or vector, which is usually an arthropod (mosquito, tick, fly), either biologically or mechanically. With biological transmission, the vector is necessary for

the developmental stage of the infectious agent. Examples include the mosquitoes that carry WNV and the fleas that transmit plague. Mechanical transmission occurs when an insect simply contacts the infectious agent with its legs or mouth parts and carries it to the host. For example, flies and cockroaches may contaminate food or cooking utensils. Most vector borne diseases involve zoonotic cycles requiring some sort of animal host or reservoir.

Vectorborne diseases commonly encountered in the United States are those associated with ticks, such as Lyme disease (*Borrelia burgdorferi*), Rocky Mountain spotted fever (*Rickettsia rickettsii*), ehrlichiosis (*Ehrlichiae*), and anaplasmosis (*Anaplasma phagocytophilum*), formerly known as human granulocytic ehrlichiosis. Nurses who work with large immigrant populations or with international travelers may encounter malaria and dengue fever, both carried by mosquitoes. More recently in the news, WNV is an example of endemic mosquito-borne viruses that include St. Louis, LaCrosse, and western and eastern equine encephalitis. Plague (*Y. pestis*) is carried by fleas of wild rodents. Other more rarely seen tick-associated diseases include babesiosis (*Babesia microti*), tularemia (*F. tularensis*), and Q fever (*Coxiella burnetii*). Southern tick-associated rash illness (STARI) is a newly described illness for which the causative organism has not been determined. STARI resembles Lyme disease in appearance but does not result in the neurologic, arthritic, and other chronic conditions seen with Lyme disease. It is mainly found in the southeast and is associated with the bite of the Lonestar tick (*Amblyomma americanum*) (CDC, 2011b) and ticks (CDC, 2014j).

Lyme Disease

Parents in Lyme, CT, concerned about the unusual incidence of juvenile rheumatoid arthritis in their children, were the first to bring attention to this tick borne infection that now bears their town's name. First described in 1975, Lyme disease became a nationally notifiable disease in 1991 and is now the most common vector borne disease in the United States, with over 30,000 confirmed cases and probable cases reported to CDC in 2012. However, new studies suggest that the actual number of diagnosed cases may be as many as 10 times that number, making Lyme disease a major public health problem and with an urgent need for improved prevention (Kuehn, 2013). The causative agent, the spirochete *B. burgdorferi*, was identified in 1982. Lyme disease is transmitted by ixodid ticks that are associated with white-tailed deer (*Odocoileus virginianus*) and the white-footed mouse (*Peromyscus leucopus*). Lyme disease usually occurs in summer during tick season and it has been reported throughout the United States, with 95% of cases concentrated in rural and suburban areas of the northeast, mid-Atlantic and north-central states, particularly Wisconsin and Minnesota.

The clinical spectrum of Lyme disease can be divided into three stages. Stage I is characterized by erythema chronicum-migrans, a distinctive skin lesion often called a bull's-eye lesion because it begins as a red area at the site of the tick attachment that spreads outward in a ring-like fashion as the center clears. About 50% to 70% of infected persons develop this lesion 3 to 30 days after a tick bite. The skin lesion may be accompanied

or preceded by fever, fatigue, malaise, headache, muscle pains, and a stiff neck, as well as tender and enlarged lymph nodes and migratory joint pain. Most clients diagnosed in this early stage respond well to 10 to 14 days of oral tetracycline or penicillin.

If not treated during this first stage, Lyme disease can progress to stage II, which may include additional skin lesions, headache, and neurologic and cardiac abnormalities. Clients who progress to stage III have recurrent attacks of arthritis and arthralgia, especially in the knees, which may begin months to years after the initial lesion. The clinical diagnosis of classic Lyme disease with the distinctive skin lesion is straightforward. Illness without the lesion is more difficult to diagnose, because serologic tests are more accurate in stages II and III than in stage I (Heymann, 2014).

Rocky Mountain Spotted Fever

Contrary to its name, Rocky Mountain spotted fever (RMSF) is seldom seen in the Rocky Mountains and most commonly occurs in the southeast, Oklahoma, Kansas, and Missouri. The infectious agent is *R. rickettsii*. The tick vector varies according to geographic region. The dog tick, *Dermacentor variabilis*, is the vector in the eastern and southern United States. RMSF is not transmitted from person to person. It is thought that one attack confers lifelong immunity.

Clinical signs include sudden onset of moderate to high fever, severe headache, chills, deep muscle pain, and malaise. About 50% of cases experience a rash on the extremities that spreads to most of the body. Many cases of what has been referred to as "spotless" RMSF may actually be caused by recently identified forms of human ehrlichiosis, another tick-borne infection. RMSF responds readily to treatment with tetracycline. Definitive diagnosis can be made with paired serum titers. Because early treatment is important in decreasing morbidity and mortality, treatment should be started in response to clinical and epidemiologic considerations rather than waiting for laboratory confirmation (Heymann, 2014).

Prevention and Control of Tickborne Diseases

In *Healthy People 2020*, the HP2010 objective for reducing Lyme disease has been archived because of lack of proven interventions to prevent transmission. A vaccine for Lyme disease, recommended for use by persons living in high-risk areas, was licensed in 1998; however, in 2002 the manufacturer withdrew it from the commercial market because of low demand and sales. Measures for preventing exposure to ticks include reducing tick populations, avoiding tick-infested areas, wearing protective clothing when outdoors (long sleeves and long pants tucked into socks), using repellants, and immediately inspecting for and removing ticks when returning indoors. The CDC reports that landscaping modifications such as removing brush and leaf litter or creating a buffer zone of wood chips or gravel between yard and forest may reduce exposure to ticks as well as appropriate pesticide application to lawns. Ticks require a prolonged period of attachment (6 to 48 hours) before they start blood-feeding on the host; prompt tick discovery and removal can help prevent transmission of disease. Ticks should be removed with steady, gentle traction on tweezers applied to the

head parts of the tick. The tick's body should not be squeezed during the removal process to avoid infection that could be transmitted from resultant tick feces and tissue juices (Heymann, 2014). When outdoors, permethrin sprayed on clothing and tick repellents on bare skin containing 20% to 30% diethyltoluamide (DEET) can offer effective protection; use of DEET should be avoided on children less than 2 years of age because of reports of significant toxicity, including skin irritation, anaphylaxis, and seizures. Read more about tick-associated diseases at the CDC website (<http://www.cdc.gov/ticks/index.html>) and the prevention of tick-associated diseases on the Lyme Disease Resources CDC website, which includes handouts that can be ordered and the Handbook on Tick Management produced by the state of Connecticut (http://www.cdc.gov/ncidod/dvbid/Lyme/ld_resources.htm) (CDC, 2014j).

DISEASES OF TRAVELERS

Individuals traveling outside the United States need to be aware of and take precautions against potential diseases to which they may be exposed. Which diseases and what precautions to take depend on the individual's health status, the destination, the reason for travel, and the length of travel. Persons who plan to travel in remote regions for an extended period may need to consider rare diseases and take special precautions that would not apply to the average traveler. Consultation with public health officials can provide specific health information and recommendations for a given situation. Nurses often staff public health travel clinics and provide this information based on CDC recommendations. The CDC offers information for both medical professionals and travelers at their Travelers' Health webpage including the Yellow Book, *CDC Health Information for International Travel*, which in addition to being available online, can be ordered in hardcopy or accessed from mobile devices. (To read more about Travelers' Health and the Yellow Book, see <http://wwwnc.cdc.gov/travel/page/yellowbook-home-2014>.)

On return from visiting exotic places, travelers may bring back with them an unplanned souvenir in the form of disease. Therefore, in a presenting client, it is important to ask about a history of travel. Even the apparently healthy returned traveler, especially one who was in a tropical country for some time, should undergo routine screening to rule out acquired infections. Likewise, refugees and immigrants may arrive with infectious disease problems ranging from helminthic infections to diseases of major public health significance, such as TB, malaria, cholera, HIV disease, and hepatitis. Nurses may find themselves dealing with these diseases, since refugees and immigrants, especially the undocumented, are often treated through the public health system.

Malaria

Caused by the bloodborne parasite *Plasmodium*, malaria is a potentially fatal disease characterized by regular cycles of fever and chills. Transmission is through the bite of an infected *Anopheles* mosquito. The word *malaria* is based on an association between the illness and the "bad air" of the marshes where

the mosquitoes breed. Malaria is an old disease that appears in recorded history in 2700 BC China. Although no longer endemic in most temperate countries, malaria is the most prevalent vector borne disease worldwide, occurring in over 100 countries and territories. Half of the world's population is considered at risk; 90% of cases occur in Africa. Malaria is the fifth-leading cause of infectious disease death worldwide and the second-leading cause of infectious disease death (after HIV disease) in Africa. There is no vaccine available to protect against this disease, which in 2012 resulted in an estimated 207 million cases and 627,000 deaths, most in the Africa Region. The WHO reports malaria mortality rates have fallen by 42% globally since 2000, and by 49% in the WHO African Region. This move in a positive direction is attributed to international funding for bed net campaigns and increased access to treatment (WHO, 2014c).

Malaria prevention depends on protection against mosquitoes and appropriate chemoprophylaxis. Drug resistance is an increasing problem in combating malaria. Of the four *Plasmodium* species causing human malaria, *P. ovale* and *P. vivax* result in disease that can progress to relapsing malaria and *P. vivax* is increasingly drug resistant. *P. falciparum* causes the most serious malarial infection and is highly drug resistant. Thus decisions about antimalarial drugs must be tailored individually on the basis of the type of malaria in the specific area of the country to be visited, the purpose of the trip, and the length of the visit. The CDC and the WHO publish guides on the status of malaria and recommendations for prophylaxis on a country-by-country basis. At this time, there is no one drug or drug combination known to be safe and efficacious in preventing all types of malaria. Antimalarials are generally started a week to several weeks before leaving the country and are continued for 4 to 6 weeks after returning.

Despite appropriate prophylaxis, malaria may still be contracted. Travelers should be advised of this fact and urged to seek immediate medical care if they exhibit symptoms of cyclical fever and chills up to 1 year after returning home. Immigrants and visitors from areas where malaria is endemic may become clinically ill after entering the United States. Approximately 1500 cases of malaria in travelers and immigrants are reported in the United States every year. Also, although malaria is eliminated from the United States, the mosquito vectors are not, so local cases still can occur if these vector mosquitoes bite people infected outside the country. From 1957 to 2011, 63 outbreaks of locally transmitted mosquito-borne malaria have been reported in the United States. In these outbreaks, local mosquitoes become infected by biting persons carrying malaria parasites (acquired in endemic areas) and then transmit malaria to local residents. From 1963 to 2011, 97 individuals have acquired malaria through blood transfusions (CDC, 2014k). (For more information about malaria in the United States as well as worldwide, visit the malaria homepage at the CDC website: <http://www.cdc.gov/malaria/>.)

Foodborne and Waterborne Diseases

As in the United States, much foodborne disease abroad can be avoided if the traveler eats thoroughly cooked foods prepared

with reasonable hygiene; eating foods from street vendors may not be a good idea. Trichinosis, tapeworms, and fluke infections, as well as bacterial infections, result from eating raw or undercooked meats. Raw vegetables may act as a source of bacterial, viral, helminthic, or protozoal infection if they have been grown with or washed in contaminated water. Fruits that can be peeled immediately before eating, such as bananas, are less likely to be a source of infection. Dairy products should be pasteurized and appropriately refrigerated.

Water in many areas of the world is not potable (safe to drink), and drinking this water can lead to infection with a variety of protozoal, viral, and bacterial agents including amoebae, *Giardia*, *Cryptosporidium*, hepatitis, cholera, and various coliform bacteria. Unless traveling in an area where the piped water is known to be safe, only boiled water (boiled for 1 minute), bottled water, or water purified with iodine or chlorine compounds should be consumed (CDC, 2013g). Ice should be avoided because freezing does not inactivate these agents. If the water is questionable, choose coffee or tea made with boiled water, carbonated beverages without ice, beer, wine, or canned fruit juices.

Diarrheal Diseases

Travelers often suffer from diarrhea, so much so that colorful names, such as Montezuma's revenge, turista, and Colorado quickstep, exist in our vocabulary to describe these bouts of intestinal upset. Some of these diarrheas do not have infectious causes; they result from stress, fatigue, schedule changes, and eating unfamiliar foods. Acute infectious diarrheas are usually of viral or bacterial origin. *E. coli* probably causes more cases of traveler's diarrhea than all other infective agents combined. Protozoan-induced diarrheas such as those resulting from *Entamoeba* and *Giardia* are less likely to be acute, and they more commonly present once the traveler returns home. Travelers need to pay special attention to what they eat and drink. (Read more about travelers' health at the CDC website: <http://www.cdc.gov/travel/>.)

ZOO NOSES

A zoonosis is an infection transmitted from a vertebrate animal to a human under natural conditions. The agents that cause zoonoses do not need humans to maintain their life cycles; infected humans have simply managed somehow to get in their way. Means of transmission include animal bites (bats and rabies), inhalation (rodent excrement and hantavirus), ingestion (milk and listeriosis), direct contact (rabbit carcasses and tularemia), and arthropod intermediates. This last transmission route means that many vector borne diseases are also zoonoses. For example, white-tailed deer harbor ticks that can carry Lyme disease, and rats and ground squirrels may be infested with fleas capable of transmitting plague. Other than vector borne diseases, some of the more common zoonoses in the United States include toxoplasmosis (*Toxoplasma gondii*), cat-scratch disease (*Bartonella henselae*), brucellosis (*Brucella* species), leptospirosis (*Leptospira interrogans*), listeriosis (*Listeria monocytogenes*), salmonellosis (*Salmonella* serotypes), and

rabies (family Rhabdoviridae, genus *Lyssavirus*). Many of the emerging infectious diseases such as avian influenza A H5N1, WNV, monkey pox, hantavirus pulmonary syndrome, and variant Creutzfeldt-Jakob disease are examples of zoonoses. Also, among the diseases considered best candidates for weapons of bioterrorism, anthrax, plague, tularemia, and some of the hemorrhagic fever viruses (e.g., Lassa) are all zoonoses. The CDC estimates that 75% of recently emerging infectious diseases affecting humans are diseases of animal origin and that approximately 60% of all human pathogens are zoonotic.

Rabies (Hydrophobia)

One of the most feared of human diseases, rabies has the highest case fatality rate of any known human infection, essentially 100%. Despite the availability of intensive medical care, only six individuals have been known to recover after the onset of rabies, three in the United States, and only one survivor who did not receive pre-exposure or postexposure prophylaxis (PEP) has been reported (CDC, 2012d). A significant public health problem worldwide with as many as 50,000 deaths a year, mostly in developing countries, rabies in humans in the United States is a rare event because of the widespread vaccination of dogs begun in the 1950s. Today, the major carriers of rabies in the United States are not dogs but wild animals—raccoons, skunks, foxes, coyotes, and bats. Small rodents, rabbits and hares, and opossums rarely carry rabies. Epidemiologic information should be consulted for information on the potential carriers for a given geographic region. When the virus spreads from wild to domestic animals, cats are often involved. Of the 31 human cases of rabies reported in the United States from 2003 through June 2013, 36% were acquired outside the continental United States. Domestically acquired cases were largely associated with insectivorous bats (85%) and raccoons (15%). However, five of these domestic cases occurred not through direct contact but as the result of organ transplant. Cases contracted outside the United States most commonly resulted from the bites of infected dogs (82%), with one fox and one bat exposure (Dyer et al, 2013). Rabies is transmitted to humans by introducing virus-carrying saliva into the body, usually via an animal bite or scratch. Transmission may also occur if infected saliva comes into contact with a fresh cut or intact mucous membranes. Rabies is found in neural tissue and is not transmitted via blood, urine, or feces. Airborne transmission has been documented in caves with infected bat colonies. Transmission from human to human is theoretically possible but has not been documented except through transplant organs harvested from individuals who died of undiagnosed rabies. Guidelines for organ donation exist to minimize this possibility (Heymann, 2014).

The best protection against rabies remains vaccinating domestic animals—dogs, cats, cattle, and horses. If a person is bitten, the bite wound should be thoroughly cleaned with soap and water and a physician consulted immediately. Be suspicious of bites from a wild animal or an unprovoked attack from a domestic animal. Even when there is no suspicion of rabies, contact a physician because tetanus or antibiotic prophylaxis may be needed. An estimated 23,000 people per year require

PEP after being in contact with potentially rabid animals (Christian et al, 2009).

No successful treatment exists for rabies once symptoms appear, but if given promptly and as directed, PEP with human rabies immunoglobulin (RIG) and rabies vaccine can prevent the development of the disease. Three products are licensed for use as rabies vaccine in the United States: human diploid cell vaccine (HDCV), purified chick embryo cell culture vaccine (PCECV), and rabies vaccine adsorbed (RVA); only HDCV and PCECV are available for use in the United States (CDC, 2008a). In 2010, the previously recommended series of five 1-mL doses of vaccine injected into the deltoid muscle was changed to four (CDC, 2010e). Reactions to the vaccine are fewer and less serious than with previously used vaccines. Individuals who deal frequently with animals, such as zookeepers, laboratory workers, and veterinarians, may choose to receive the vaccine as pre-exposure prophylaxis. The decision to administer the vaccine to a bite victim depends on the circumstances of the bite and is made on an individual basis.

The Compendium of Animal Rabies Prevention and Control compiled by the National Association of State Public Health Veterinarians, Inc. gives recommendations for prevention of and vaccination for rabies in animals. Recommendations for administering PEP are provided by the Advisory Committee for Recommendations on Immunization Practices and are available through local public health officials or the CDC. In general, cats and dogs that have bitten someone and have verified rabies vaccinations are confined for 10 days for observation. Treatment is initiated only if signs of rabies are observed during this period. If the animal is known or suspected to be rabid, treatment begins immediately. If the animal is unknown to the victim and escapes, public health officials should be consulted for help in deciding whether treatment is indicated. With wild animal bites, treatment is begun immediately. With bites from livestock, rodents, and rabbits, treatment is considered on an individual basis. Decisions to treat become more complicated for possible nonbite exposure to saliva from known infected animals, and again public health officials are helpful in making these treatment decisions (CDC, 2011c).

PARASITIC DISEASES

Parasites are organisms that depend on a host to survive. Endoparasites, those that live within the body, are classified into four major groups: nematodes (roundworms), cestodes (tapeworms), trematodes (flukes), and protozoa (single-celled animals). Nematodes, cestodes, and trematodes are all referred to as helminths along with acanthocephalins or thorny-headed worms, which are not as commonly involved in human infections. Table 13-5 presents examples of relatively common diseases caused by parasites from these groups. Parasites that remain on the surface of a host's body to feed rather than within it such as ticks, fleas, lice, and mites that attach or burrow into the skin are called *ectoparasites*. Many parasitic infections are vector borne and/or zoonotic.

Parasitic diseases are more prevalent in rural areas of low-income countries than in the United States. Contributing

TABLE 13-5 Examples of Diseases Resulting from Endoparasitic Infection by Category

Category	Parasite	Disease
Cestodes	<i>Taeniasaginata</i> , <i>Taeniasolium</i>	Beef tapeworm, pork tapeworm
Nematodes	<i>Ancylostoma</i> , <i>Necator</i>	Ancylostomiasis, necatoriasis (hookworm)
Intestinal	<i>Ascaris</i> , <i>Toxocara</i>	Ascariasis, toxocariasis (roundworm)
	<i>Enterobius vermicularis</i>	Enterobiasis (pinworm)
	<i>Trichuris trichiura</i>	Trichuriasis (whipworm)
Blood/Tissue	<i>Dracunculiasis medinensis</i>	Guinea worm
	<i>Onchocerca volvulus</i>	Onchocerciasis (river blindness)
	<i>Wuchereria bancrofti</i>	Lymphatic filariasis (elephantiasis)
Trematodes	<i>Schistosoma</i> sp.	Schistosomiasis (snail fever)
Protozoans	<i>Entamoeba histolytica</i>	Amebiasis
	<i>Giardia lamblia</i>	Giardiasis
	<i>Leishmania</i> spp.	Leishmaniasis
	<i>Plasmodium</i> spp.	Malaria
	<i>Toxoplasma gondii</i>	Toxoplasmosis
	<i>Trichomonas vaginalis</i>	Trichomoniasis
	<i>Trypanosoma</i> spp.	African sleeping sickness, Chagas' disease

Based on information from Heymann DL, editor: *Control of communicable diseases manual*, ed 20, Washington, DC, 2014, American Public Health Association.

factors are tropical climate and inadequate prevention and control measures. Poor sanitation, a lack of cheap and effective drugs, and a scarcity of funding lead to high reinfection rates even when control programs are attempted. Parasitic organisms result in a wide spectrum of diseases including leading causes of death and disability in Africa, Asia, Central America, and South America. Examples include malaria, guinea worm disease, river blindness (onchocerciasis), leishmaniasis, amoebiasis, African sleeping sickness, Chagas' disease, schistosomiasis, and lymphatic filariasis. These parasitic diseases not only cause major mortality in endemic regions but also tremendous morbidity. Debilitation from infection may result in an inability to attend school or work as well as growth retardation, developmental disabilities, and cognitive impairment in young children, all of which contribute to significant economic burden for the countries affected.

Parasitic infections also affect persons living in developed countries. In the United States parasitic organisms frequently cause foodborne and waterborne diarrheal illness (*Giardia*, *Entamoeba*, *Cryptosporidia*) and sexually transmitted infections (*Trichomonas*), and they pose a particular problem for immunodeficient individuals (*Cryptosporidia*, *Toxoplasma*, *Cyclospora*). Trichomoniasis is a common, easily treated with antibiotics, sexually transmitted disease caused by the protozoan parasite *Trichomonas vaginalis*. An estimated 3.7 million people are estimated to be infected but only 30% may show symptoms (CDC, 2012e). *Giardiasis* is a diarrheal illness caused by the

parasite *Giardia intestinalis*. It is the most common intestinal parasitic infection in the United States and results in 19,000 to 20,000 reported cases annually (CDC, 2012f). Cryptosporidiosis is also a diarrheal disease caused by the microscopic parasite *Cryptosporidium*. Because *Cryptosporidium* possesses an outer shell that allows it to survive outside the body for extended periods of time and tolerate low levels of chlorine disinfection, it is a frequent cause of water-related disease outbreaks in swimming pools and splash parks. In the United States “crypto” is a common cause of both foodborne and waterborne disease resulting in an estimated 740,000 cases each year (Scallan et al, 2011).

New technology for recognizing protozoan parasites, the ease of international travel, immigration from developing countries, and diseases that affect the immune system such as HIV disease (thus leaving individuals susceptible to secondary parasitic infections) all contribute to rising reports of and a greater attention to parasitic diseases in the United States. The CDC speaks about the major neglected diseases of poverty in the United States, which it defines as diseases that disproportionately affect people in poverty, infect a significant number of people, and receive limited attention in tracking, prevention, and treatment. Five of the six are parasitic: Chagas’ disease, cysticercosis, toxocariasis, toxoplasmosis, and trichomoniasis. To ensure an accurate diagnosis, nurses and other health professionals need to familiarize themselves with the clinical presentations and risk factors associated with these parasitic diseases.

Intestinal Parasitic Infections

Although intestinal parasites are major contributors to morbidity and mortality in developing countries, climate, improved sanitary conditions, and effective drug therapy have served to greatly reduce widespread indigenous transmission in the United States, so much so that surveillance for many of these organisms is not widely practiced. A study using 1988-1994 NHANES III data reported that 14% of Americans have antibodies to *Toxocara*, a roundworm carried by dogs and cats that can be passed to humans. While this suggests that tens of millions of Americans have been exposed, it does show how many are actually infected (Won et al, 2008). Although most people show no signs of infection, this parasite can cause systemic illness and blindness. Technological advances have allowed for improved recognition of protozoans, leading to increased reporting of some organisms like *Cryptosporidium*. Cryptosporidiosis became a nationally notifiable disease in 1995 and giardiasis in 2002. However, many other parasitic infections such as toxocariasis and toxoplasmosis are not reportable.

Enterobiasis (pinworm) is the most common helminthic infection in the United States. Pinworm infection is seen most often among school-aged children and is most prevalent in crowded and institutional settings. Transmission is via consumption of infected eggs found in soil contaminated by human feces. Pinworms resemble small pieces of white thread and can be seen with the naked eye. Diagnosis is usually accomplished by pressing cellophane tape to the perianal region early in the morning. Treatment with oral vermicides and concurrent disinfection is highly effective (CDC, 2013h).

Parasitic Opportunistic Infections

Opportunistic infections (OIs) are infections that occur more frequently or more severely in individuals immunocompromised by HIV infection. Before the introduction of routine prophylactic treatment and potent-combination, highly active antiretroviral therapies (ARTs) in the 1990s, OIs were the leading cause of illness and death in this group. Some of the protozoan parasitic OIs seen in clients with HIV disease and others who are immunocompromised include PCP; cryptosporidiosis, microsporidiosis and isosporiasis, all producing diarrheal disease and transmitted by fecal–oral contact; and toxoplasmosis. With the advent of ARTs, the incidence of OIs in American HIV disease clients has dropped dramatically. Isosporiasis was always rare, but the rates for cryptosporidiosis and microsporidiosis have also declined markedly. Although no longer seen with the frequency of the past, toxoplasmosis and PCP have not disappeared. OIs are more likely to appear in individuals unaware of their HIV disease or without good access to health care. Guidelines for prevention and treatment of OIs are now regularly updated by the Panel on Opportunistic Infections in HIV-Infected Adults and Adolescents representing opinion from the Centers for Disease Control and Prevention, the National Institutes of Health, and the HIV Medicine Association of the Infectious Diseases Society of America. Because of rapid evolution in HIV management, the Panel makes the most recent information readily available on the AIDS information website (<http://aidsinfo.nih.gov>).

Toxoplasma gondii is a coccidial organism harbored by cats infected by eating other infected animals. While rodents, ruminants, swine, poultry, and other birds may have infective organisms in their muscle tissue, only cats carry this parasite in their intestinal tract, allowing the excretion of infected eggs. People contract the disease through contact with infected cat feces or eating improperly cooked meat. In most healthy people, toxoplasmosis produces a mild to inapparent infection, but in immunodeficient individuals, the disease may, in addition to rash and skeletal muscle involvement, result in cerebritis, pneumonia, chorioretinitis, myocarditis, and/or death. Infection early in pregnancy may cause fetal death or deformity. CNS infection is common with HIV disease. Because toxoplasmosis is not a nationally reportable disease, reliable case numbers are not readily available. On their website, CDC estimates there are over a million new *Toxoplasma* infections and 400 to 4000 cases of congenital toxoplasmosis in the United States each year; an estimated 4,800 people experience ocular involvement as part of infection; and toxoplasmosis is a leading cause of foodborne illnesses deaths, resulting in an estimated 327 deaths and 4,428 hospitalizations per year (CDC, 2014l).

Control and Prevention of Parasitic Infections

Correct diagnosis by nurses and other health care workers allows the provision of early and appropriate treatment and client education for preventing and controlling parasitic infections. Diagnosis of parasitic diseases is based on history, including travel, characteristic clinical signs and symptoms, and the use of appropriate laboratory tests to confirm the clinical

diagnosis. Knowing what specimens to collect, how and when to collect, and what laboratory techniques to use are all important in establishing a correct diagnosis. Effective drug treatment is available for most parasitic diseases. The high cost of the drugs, drug resistance, and toxicity are some of the common therapeutic problems. Measures for prevention and control of parasitic diseases include early diagnosis and treatment, improved personal hygiene, safer sex practices, community health education, vector control, and improvements in sanitary control of food, water, and waste disposal.

HEALTH CARE–ASSOCIATED INFECTIONS

Previously referred to as nosocomial infections and hospital-acquired infections, **health care–associated infections** (HAIs) are, as the name implies, those transmitted during hospitalization or developed within a hospital or other health care setting. They may involve clients, health care workers, visitors, or anyone who has contact with a hospital or doctor's office. Invasive diagnostic and surgical procedures, broad-spectrum antibiotics, and immunosuppressive drugs, along with the original underlying illness, leave hospitalized clients particularly vulnerable to exposure to virulent infectious agents from other clients and indigenous hospital flora from health care staff. In this setting, the simple act of performing hand hygiene before approaching every client becomes critical. A CDC prevalence survey of U.S. acute care hospitals in 2011 estimated 722,000 HAIs annually, suggesting that on any given day, 1 in 25 hospital patients has at least one health care–associated infection. An estimated 75,000 hospital patients with HAIs died during their hospitalizations. More than half of all HAIs occurred outside of the intensive care unit (Magill et al, 2014). Another recent report estimates total annual costs for five major health care–associated infections (HAIs) at \$9.8 billion, with surgical site infections contributing the most to overall costs (Zimlichman et al, 2013). In addition, HAIs have a high likelihood of involving and contributing to antibiotic resistance.

The CDC maintains the National Healthcare Safety Network (NHSN), a voluntary, Internet-based surveillance system that

provides national data on the epidemiology of HAIs in the United States. (Read more about preventing health care–associated infections and antibiotic resistance at the CDC HAI website: <http://www.cdc.gov/ncidod/dhqp/hai.html>.)

Infection control practitioners play a key role in hospital infection surveillance and control programs. Without a qualified and well-trained person in this position, the infection control program is ineffective. A great majority of infection control practitioners are nurses. Their common job titles are infection control nurse, infection control coordinator, and nurse epidemiologist.

Universal Precautions

In 1985, in response to concerns regarding the transmission of HIV infection during health care procedures, the CDC recommended a **universal precautions** policy for all health care settings. This strategy requires that blood and body fluids from *all clients* be handled as if infected with HIV or other bloodborne pathogens. When in a situation where potential contact with blood or other body fluids exists, health care workers must always perform hand hygiene and wear gloves, masks, protective clothing, and other indicated personal protective barriers. Needles and sharp instruments must be used and disposed of properly (CDC, 1989). The CDC also made recommendations for preventing transmission of HIV and hepatitis B during medical, surgical, and dental procedures (CDC, 1991). Updated guidelines and recommendations for preventing HAIs including universal precautions were published in 2007 (Siegel et al, 2009). Today the Healthcare Infection Control Practices and Advisory Committee is charged with providing guidance on hospital infection control and developing strategies for surveillance, prevention and control of HAIs. The most recent guidance may be found on the Guidelines and Recommendations page of the CDC's Healthcare Associated Infection web pages at http://www.cdc.gov/hai/prevent/prevent_pubs.html. The following Linking Content to Practice box applies the three public health core functions to infectious diseases.

LINKING CONTENT TO PRACTICE

Public health involves the prevention of disease, promotion of health, and protection against hazards that threaten the health of the community as reflected in the public health logo and summed up in the mission “assuring conditions in which people can be healthy.” The three core functions of public health in achieving this mission as defined in 1988 by the Institute of Medicine in *Recommendations for the Future of Public Health* are *Assessment*, *Policy Development*, and *Assurance*. These three have been further divided into the “Ten Essential Services of Public Health” as a means of evaluating the effectiveness of public health efforts.

This chapter presents communicable diseases that commonly challenge the health of a community as well as prevention and control roles for public health nurses. Examples of some of the “Essential Services” under which these roles fall are presented by core function.

Assessment: (1) Monitor health/identify problems and (2) Diagnose and investigate health problems. Examples include surveillance, investigation, and identification of reportable communicable disease cases. **Policy Development:** (3) Inform, educate, and empower and (4) Mobilize community partnerships. Examples include evaluating immunization status, explaining the reason for immunizations and how to comply with the immunization schedule, organizing community partners to provide immunizations and documentation through a registry, and mounting a community campaign to inform the community of the importance of age-appropriate immunization. **Assurance:** (5) Enforce laws and regulations and (6) Link to services and provide care. Examples include assuring compliance with communicable disease control laws through treatment or prophylaxis for exposure to reportable diseases; excluding diseased students from daycare or school; linking individuals without insurance to follow-up care for communicable disease treatment or exposure.

PRACTICE APPLICATION

The rising numbers of foreign-born residents in communities that did not previously have large immigrant populations provides a challenge to those involved with communicable disease control, especially in outbreak situations. Language barriers, specific cultural practices, and undocumented status all contribute to opportunities for infection as well as presenting obstacles to prevention and control. Diseases such as TB, brucellosis, measles, hepatitis B, and parasitic infections often originate in other countries and are diagnosed only after the individual arrives in the United States. People coming from countries without, with newly established, or with poorly enforced vaccination programs may be unimmunized. These people are particularly susceptible to infection in outbreak situations. For example, many people coming from Latin America have not been immunized against rubella. Differences in cultural practices can lead to outbreaks of foodborne illness. Listeriosis outbreaks have been traced to the use of unpasteurized milk in cottage industry cheese production.

In the face of a single infectious disease report or an outbreak situation, when working with communities whose members speak limited English, it is vital (1) to have a means of communication, (2) to be able to provide a culturally appropriate message, and (3) to have an established level of trust. Ideally, these requirements are addressed before an outbreak occurs, allowing a prompt and efficient response when immediate action is needed.

- A.** What would be a useful first step in building trust with a largely non-English-speaking immigrant community?
1. Hold a health fair in the community.
 2. Provide incentives to use health department services.
 3. Identify trusted community leaders such as religious leaders and ask their help in developing a plan.
 4. Distribute a brochure in the target community language.

- B.** What might best encourage undocumented residents to respond to a request to be immunized during an outbreak situation?
1. Using an already established public health program to provide interpreter services, making it clear that proof of immigration status is not required for services
 2. Printing a request in the newspaper in the language of the targeted individuals
 3. Involving trusted community leaders in making the request
 4. Emphasizing to the individuals the severity of the consequences if immunization does not occur
- C.** What means of communication would work best when targeting largely non-English-speaking communities of recent immigrants?
1. Newspaper articles in target language
 2. Radio announcements in target language
 3. Fliers in target language posted in the community
 4. Announcements from trusted community leaders
- D.** How would public health officials best undertake the development of information to effectively reach a largely non-English-speaking community of recent immigrants?
1. Use the services of the local university communications department.
 2. Ask community leaders to work with translators and prevention specialists to develop messages using their own words.
 3. Hire a professional to translate an existing well-developed English-language brochure.
 4. Use brochures provided by the state health department.

Answers can be found on the Evolve site.

KEY POINTS

- The burden of infectious diseases is high in both human and economic terms. Preventing these diseases must be given high priority in our present health care system.
- The successful interaction of the infectious agent, host, and environment is necessary for disease transmission. Knowledge of the characteristics of each of these three factors is important in understanding the transmission, prevention, and control of these diseases.
- Effective intervention measures at the individual and community levels must be aimed at breaking the chain linking the agent, host, and environment. An integrated approach focused on all three factors simultaneously is an ideal goal to strive for but may not be feasible for all diseases.
- Health care professionals must constantly be aware of vulnerability to threats posed by emerging infectious diseases. Most of the factors causing the emergence of these diseases are influenced by human activities and behavior.
- Communicable diseases are preventable. Avoiding infection through primary prevention activities is the most cost-effective public health strategy.
- Health care professionals must always apply infection control principles and procedures in the work environment. They should strictly adhere to universal blood and body fluid precautions to prevent transmission of HIV and other blood-borne pathogens.
- Effective control of communicable diseases requires the use of a multisystem approach focusing on enhancing host resistance, improving safety of the environment, improving public health systems, and facilitating social and political changes to ensure health for all people.
- Communicable disease prevention and control programs must move beyond providing drug treatment and vaccines. Health promotion and education aimed at changing individual and community behavior must be emphasized.

KEY POINTS—cont'd

- Nurses play a key role in all aspects of prevention and control of communicable diseases. Close cooperation with other members of the interprofessional health care team must be maintained. Mobilizing community participation is essential to successful implementation of programs.
- The successful global eradication of smallpox proved the feasibility of eradication of selected communicable diseases. As professionals and concerned citizens of the global village, health care workers must support the current global eradication campaigns against poliomyelitis and dracunculiasis.

CLINICAL DECISION-MAKING ACTIVITIES

1. Accompany a nurse who makes home visits. Discuss living situations and other risk factors that may contribute to the development of infectious diseases, as well as possible points at which the nurse may intervene to help prevent these diseases, such as checking the immunization status of all individuals in the household. What are realistic interventions and how much responsibility should a nurse take in attempting to affect the living situation?
2. To become familiar with the reportable diseases that are a problem in your community, look at how many cases have been reported during the past month, 6 months, and year. Contrast these numbers with national and state statistics. How is your county or city different from or similar to these larger jurisdictions? If different, what environmental, political, or demographic features may contribute to this difference?
3. Spend time with the persons who are responsible for reporting and investigating communicable disease in your community. Discuss types of surveillance conducted and outbreak procedures that may accompany the reporting of some of these diseases. If possible, attend an outbreak investigation. Would the existing surveillance systems and outbreak control policies be sufficient in the case of a bioterrorism event?
4. Review the demographic profile of your community including trends from the past 10 years and projections for the next decade. Pay special attention to growth patterns of particular populations such as racial and ethnic groups or specific age groups (e.g., children under 18, adults 65 and older). How do changes in these populations affect the delivery of interventions for infectious disease control such as immunization?
5. Visit a clinic that serves a refugee, immigrant, or migrant labor population to observe the infectious diseases commonly seen in these groups. Compare and contrast this visit with a visit to a clinic that serves an inner-city population and a visit to a clinic that serves a rural population. How are the infectious disease control issues different and/or similar for these varied populations?
6. Sit in a clinic waiting room for immunization services and talk with parents about their concerns and the barriers they may perceive in obtaining immunizations for their children. How can this information be used to better facilitate immunization services?
7. Spend time with a school nurse to see what infectious diseases are routinely encountered in the educational setting. Discuss risk factors for disease in school-age youths and the strategies used to prevent infectious diseases in this age group. Do school policies support the strategies needed for the prevention of infectious diseases in students?
8. Visit a daycare center. Observe potential situations for the communication of infectious diseases and discuss with the director the steps taken to prevent and control infection, including immunization requirements and procedures for hand hygiene and food preparation. Does the center have specific infection control policies and procedures, and does the staff appear to be following them?

Communicable and Infectious Disease Risks

Patty J. Hale, RN, FNP, PhD, FAAN

Dr. Patty Hale is Professor and Graduate Program Director at James Madison University in Harrisonburg, Virginia. She has practiced public health nursing in Wisconsin and Virginia and has consulted widely with many organizations on community health and infectious diseases, most notably the World Health Organization. Dr. Hale has taught undergraduate and graduate courses in epidemiology, curriculum development and evaluation, community health, and population-focused nursing. Dr. Hale was named a Carnegie U.S. Professor of the Year in 2003, and was the first nurse ever to receive this honor. Dr. Hale holds a bachelor of science from the University of Wisconsin-Milwaukee. She has a master's in community health nursing and family nurse practitioner from the University of Virginia, and a doctorate in nursing from the University of Maryland at Baltimore.

Erika Metzler Sawin, PhD, RN

Erika Metzler Sawin is a second-degree nurse who received her master's in community health nursing from The University of Texas, Austin, and her doctorate in nursing from the University of Virginia. She is an Assistant Professor in the Department of Nursing at James Madison University in Harrisonburg, Virginia, where she teaches community health nursing to BSN students. Her research interests are in the areas of domestic violence and culturally aware care. She was selected for a 2014-15 U.S. Fulbright-Nehru Scholar Teaching Award.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Describe the natural history of human immunodeficiency virus (HIV) infection and appropriate client education at each stage.
2. Explain the clinical signs of selected communicable diseases.
3. Evaluate the trends in incidence of HIV, STDs, hepatitis, and tuberculosis, and identify groups that are at greatest risk.
4. Analyze behaviors that place people at risk of contracting selected communicable diseases.
5. Evaluate nursing activities to prevent and control selected communicable diseases.
6. Explain the various roles of nurses in providing care for those with selected communicable diseases.

KEY TERMS

Diagnosis and Treatment

Nurse's Role in Providing Preventive Care for Communicable Diseases

Primary Prevention

Secondary Prevention

Tertiary Prevention

Knowledge about the risk of communicable diseases has changed dramatically in recent years. For example, in the decades following the development of antibiotics in the 1940s, **sexually transmitted diseases** (STDs) were considered to be a problem of the past. The recent emergence of new viral STDs and antibiotic-resistant strains of bacterial STDs has posed new challenges. Left unchecked, STDs can cause poor pregnancy outcomes, infertility, and cervical cancers. There is also the problem of co-infection, with one STD increasing the susceptibility to other STDs, such as human immunodeficiency virus (HIV). STDs are also called sexually transmitted infections (STIs) because many times, the infections are asymptomatic. In this chapter, the term STDs will be used.

This concern about infectious diseases has prompted the development of standards for STDs, HIV and acquired immunodeficiency syndrome (AIDS), hepatitis, and tuberculosis (TB) in the *Healthy People 2020* report. The *Healthy People 2020* box shows some objectives used to evaluate progress toward decreasing communicable diseases by the year 2020.

HEALTHY PEOPLE 2020

The following selected objectives pertain to the communicable diseases discussed in this chapter:

- HIV-3: Reduce the rate of HIV transmission among adults and adolescents.
- STD-8: Reduce congenital syphilis.
- IID-26: Reduce new hepatitis C infections.
- STD-1: Reduce the proportion of adolescents and young adults with *Chlamydia trachomatis* infections.

From U.S. Department of Health and Human Services: *Healthy People 2020 Objectives*, Washington, DC, 2010, Office of Disease Prevention and Health Promotion, USDHHS.

Several communicable diseases and all STDs are acquired through behaviors that can be avoided or changed, and thus intervention efforts by nurses have focused on disease prevention. Prevention can take the form of vaccine administration (as with hepatitis A and hepatitis B), early detection (of infections like TB, for example), or instruction of clients about abstinence or safer sex. Individuals who live with chronic infections can transmit them to others.

This chapter describes selected communicable diseases and their nursing management. It concludes with implications for nursing care in primary, secondary, and tertiary prevention.

HUMAN IMMUNODEFICIENCY VIRUS INFECTION

Human immunodeficiency virus (HIV) infection has had an enormous political and social impact on society. Controversies have arisen over many aspects of HIV. Fears about HIV may lead to attitudes of blaming clients for their infections and to discrimination. These beliefs are magnified by the fact that this disease has commonly afflicted two groups who have been largely scorned by society: homosexuals and injection drug users (Fair and Ginsberg, 2010). Debates have arisen over how to control disease transmission and how to pay for related health services. An ongoing debate involves whether clean needles should be distributed to injection drug users to prevent the spread of HIV.

Economic costs of HIV/AIDS result from premature treatment and disability. The fact that nearly 55% of HIV infections occur in persons between the ages of 20 and 39 years may result in disrupted families and lost creative and

economic productivity at a period of life when vitality is the norm (CDC, 2013l). In 2009, 39% of new HIV infections occurred in the 13- to 29-year-old age group (CDC, 2013i). Medicaid and Medicare primarily support the health care delivery costs of those infected. Many people with HIV qualify for Medicaid or Medicare because they are indigent or fall into poverty when paying for health care over the course of the illness. The lifetime cost of HIV care for one client is \$379,668 (CDC, 2013j). The Ryan White HIV/AIDS Program, through the Ryan White HIV/AIDS Treatment Extension Act of 2009, provides care for persons with HIV infection (USDHHS, 2014a). This program provides funds for health care in the geographic areas with the largest number of AIDS cases. Health services that are covered include emergency services, services for early intervention and care (sometimes including coverage of health insurance), and drug reimbursement programs for HIV-infected individuals. The AIDS Drug Assistance Programs (ADAPs) are awards that pay for medications on the basis of the estimated number of persons living with AIDS in the individual state (USDHHS, 2014b).

Natural History of HIV

The natural history of HIV includes three stages: the primary infection (within about 1 month of contracting the virus), followed by a period when the body shows no symptoms (clinical latency), and then a final stage of symptomatic disease (Buttaro et al, 2013).

When HIV enters the body, a person may experience a mononucleosis-like syndrome, referred to as a primary infection, which lasts for a few weeks. This may go unrecognized. The body's CD4 white blood cell count drops for a brief time when the virus is most plentiful in the body. The immune system increases antibody production in response to this initial infection, which is a self-limiting illness. Symptoms include lymphadenopathy, myalgias, sore throat, lethargy, rash, and fever (CDC, 2013g). Even if the client seeks medical care at this time, the antibody test at this stage is usually negative, so it is often not recognized as HIV.

After a variable period of time, commonly from 6 weeks to 3 months, HIV antibodies appear in the blood. Although most antibodies serve a protective role, HIV antibodies do not. However, their presence helps in the detection of **HIV infection** because screening tests show their presence in the bloodstream.

HIV-infected persons live several years before developing symptomatic disease. During this prolonged **incubation** period, clients have a gradual deterioration of the immune system and can transmit the virus to others. The use of **highly active anti-retroviral therapy** (HAART) has greatly increased the survival time of persons with HIV/AIDS.

Acquired immunodeficiency syndrome (AIDS, a.k.a. HIV Stage 3) is the last stage in the long continuum of HIV infection and may result from damage caused by HIV, secondary cancers, or opportunistic organisms. AIDS is defined as a disabling or life-threatening illness caused by HIV; it is diagnosed in a person with a CD4 T-lymphocyte count of less than 200/mL with documented HIV infection (CDC, 2008).

Many of the AIDS-related opportunistic infections are caused by microorganisms that are commonly present in healthy individuals but do not cause disease in persons with an intact immune system. These microorganisms proliferate in persons with HIV/AIDS because of a weakened immune system. Opportunistic infections may be caused by bacteria, fungi, viruses, or protozoa. The most common opportunistic diseases are *Pneumocystis jiroveci* (carinii) pneumonia and oral candidiasis, but also include pulmonary TB, invasive cervical cancer, or recurrent pneumonia.

In 2008 the case definition for HIV infection was revised to include the HIV classification/staging system based on the number of CD4+ T-lymphocytes. Criteria for defining HIV infection include a positive result from the antibody screening test or a positive result from a nucleic acid test (DNA or RNA). In situations where the mother of a newborn is HIV infected, the HIV nucleic acid test (DNA or RNA) is used to identify HIV/AIDS in infants (CDC, 2008).

TB, an infection that is becoming more prevalent because of HIV infection, can spread rapidly among immunosuppressed individuals. Thus, HIV-infected individuals who live in close proximity to one another, such as in long-term care facilities, prisons, drug treatment facilities, or other settings, must be carefully screened and in some instances deemed noninfectious before admission to such settings. TB is covered in more depth later in this chapter. See the following **QSEN** box for suggestions about implementing quality and safety in the care of patients with HIV and other communicable and infectious diseases.

QSEN FOCUS ON QUALITY AND SAFETY EDUCATION FOR NURSES

Sexually Transmitted Diseases

Targeted Competency

Evidence-based practice (EBP): Integrate best current evidence with clinical expertise and client/family preferences and values for delivery of optimal care.

Knowledge: Explain the role of evidence in determining best clinical practice.

Skills: Locate evidence reports related to clinical practice topics and guidelines

Attitudes: Value the concept of EBP as integral to determining best clinical practice.

Client-centered Care Question

Evidence supports the fact that some medications previously effective in treating STDs no longer are effective. If you learned that a colleague was planning to use a treatment that is no longer considered effective to treat a specific STD, what would you do to assure that the care the client receives is based on current evidence?

Answer: With your colleague collect current treatment guidelines information about that specific STD. The first place that you might look would be the Centers for Disease Control and Prevention guidelines for that disease. For example, you might look at "HIV treatment guidelines for adults and adolescents updated" at the following website to find out what is the most effective antiretroviral therapy (ART) for the treatment of HIV infection. See <http://aids.info.nih.gov/guidelines>.

Transmission

HIV is transmitted through exposure to blood, semen, transplanted organs, vaginal secretions, and breast milk (Heymann, 2014). Persons who had blood exposure or sexual or needle-sharing contact with an HIV-infected person are at risk for contracting the virus. The virus is not transmitted through casual contact such as touching or hugging someone who has HIV infection or through mosquitoes or other insects. Although HIV has been found in saliva and tears in some instances, there are no reports of transmission through contact with these body fluids (Heymann, 2014). The modes of transmission are listed in Box 14-1, and the exposure categories of HIV are shown in Figure 14-1.

Potential donors of blood and tissues are screened through interviews to assess for a history of high-risk activities and screened with the **HIV antibody test**. Blood or tissue is not used from individuals with a history of high-risk behavior or who are HIV infected. In addition to being screened, coagulation

BOX 14-1 Modes of Transmission of Human Immunodeficiency Virus (HIV)

HIV can be transmitted in the following ways:

- Sexual contact, involving the exchange of body fluids, with an infected person
- Sharing or reusing needles, syringes, or other equipment used to prepare injectable drugs
- Perinatal transmission from an infected mother to her fetus during pregnancy or delivery, or to an infant when breastfeeding
- Transfusions or other exposure to HIV-contaminated blood or blood products, organs, or semen

From Heymann D: *Control of Communicable Diseases Manual*, Washington, DC, 2008, APHA.

FIG 14-1 Estimated numbers of cases of HIV by exposure category in 2011, United States. Note that the “other” category includes hemophilia, blood transfusion, perinatal exposure, and risk factors not reported or not identified. (Data from Centers for Disease Control and Prevention: *HIV Surveillance Report*, vol. 23, Diagnoses of HIV infection in the United States and Dependent Areas, 2011. Published February 2013. Available at http://www.cdc.gov/hiv/library/reports/surveillance/2011/surveillance_Report_vol_23.html. Accessed March 9, 2014.)

factors used to treat hemophilia and other blood disorders are made safe through heat treatments to inactivate the virus. Screening has significantly reduced the risk of transmission of HIV by blood products and organ donations.

When a person has an STD infection such as chlamydia or gonorrhea, the risk of HIV infection increases and HIV may also increase the risk for other STDs. This may result from any of the following: open lesions providing a portal of entry for pathogens; STDs decreasing the host’s immune status, resulting in a rapid progression of HIV infection; and HIV changing the natural history of STDs or the effectiveness of medications used in treating STDs (Heymann, 2014).

The nurse serves both as an educator about the modes of transmission and as a role model for how to behave toward and provide supportive care for those with HIV infection. An understanding of how transmission does and does not occur will help family and community members feel more comfortable in relating to and caring for persons with HIV (see Box 14-1).

Epidemiology of HIV/AIDS

Worldwide 35.3 million persons live with HIV infection. Sub-Saharan Africa accounts for more than 70% of all HIV infections (UNAIDS, 2013). The epidemic is also growing in Eastern Europe, the Middle East, and central Asia (UNAIDS, 2012). Women are at highest risk for infection because of unprotected sex with infected partners. However, there is some evidence that HIV prevention programs may be changing risk behavior in southern Africa. Worldwide, the treatment of HIV infection has been given higher priority, and the use of highly active antiretroviral therapy has increased to 61% for those who need it under the 2010 WHO Guidelines, and 34% of those eligible under the 2013 guidelines (UNAIDS, 2013).

Nurses must identify the trends of HIV infection in the populations they serve, so that they can screen clients who may be at risk and can adequately plan prevention programs and illness care resources. For example, knowing that AIDS disproportionately affects minorities helps nurses set priorities and plan services for these groups. Factors such as geographic location, age, and ethnic distribution are tracked to more effectively target programs. It is important to identify persons infected with HIV before symptomatic AIDS develops, so that treatment can begin as early as needed. It is estimated that about 1.1 million people in the United States are infected with HIV, but 15.8% (180,900 people) are not aware of their infection (CDC, 2013k).

Since the first cases of AIDS were identified in 1981, the total reported number of persons living with AIDS in the United States grew to 487,692 by the end of 2010 (CDC, 2013l). Note that this number reflects only those who are living; it does not include those who have died. The **prevalence** of AIDS has increased from 2004 to 2007, reflecting increased life expectancy from the use of antiretroviral therapy (CDC, 2013l).

Figure 14-1 shows the exposure categories for persons with HIV in 2011. Men who have sex with men (MSM) make up the largest group with HIV in the United States, and the number of persons contracting HIV through heterosexual transmission is

the second largest. Heterosexual transmission has surpassed **injection drug use** (IDU) as the primary mode of HIV transmission in women (CDC, 2013l).

The distribution of pediatric HIV infection has fallen dramatically as a result of prenatal care that includes HIV testing, antiretroviral therapy for the mother, and cesarean delivery. **Perinatal HIV transmission** has declined, and two thirds of pediatric HIV infection results from perinatal exposure (CDC, 2013l).

As seen in Table 14-1, HIV has disproportionately affected minority groups. African Americans have the largest HIV disease burden of any racial/ethnic group in the United States; African American rates of new HIV infection are 8 times higher than in whites, the highest prevalence of those living with HIV is in the African American community, and the highest proportions of people diagnosed with HIV Stage 3 (AIDS) are African American (CDC, 2014h). This overrepresentation is associated with poverty, since African Americans have a higher poverty rate than other groups do. This reflects decreased access to prevention and treatment, and lack of awareness of HIV infection. Stigma, fear, and homophobia play a role as well (CDC, 2014h). Transgender people are also at high risk, particularly transgender women. Because of data collection limitations, it is difficult to estimate HIV prevalence in transgender communities. However, data from countries that collect data for transgender women separately from men who have sex with men indicate that HIV prevalence is nearly 50 times higher than for other adults of reproductive age (CDC, 2013h).

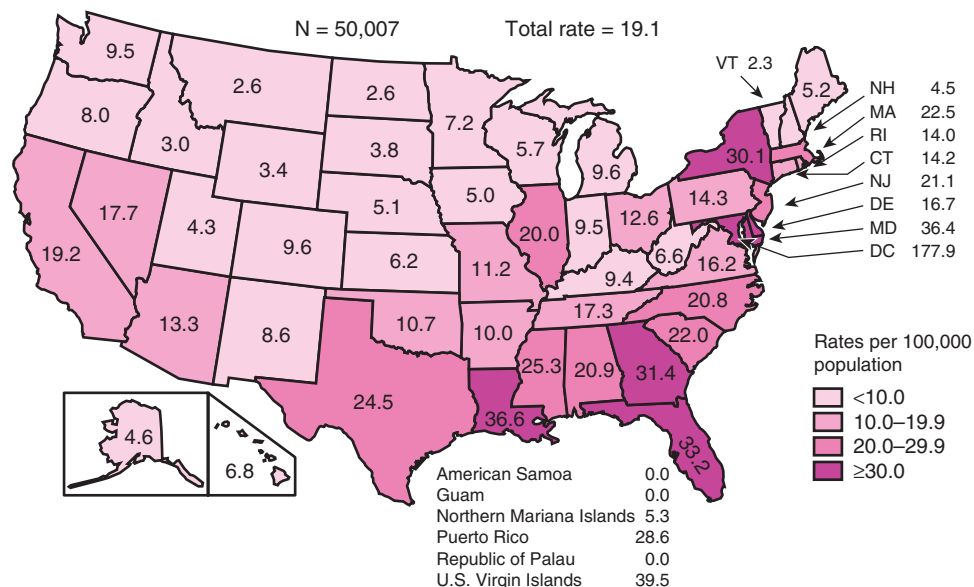

As seen in Figure 14-2, the geographic distribution of HIV infection is clustered in urban areas. Regionally, the southern

United States and the U.S. territories of the Virgin Islands and Puerto Rico report the highest rates (CDC, 2013l). States with AIDS prevalence greater than 12.5 per 100,000 population in 2011 were Delaware (13.8), Florida (21.2), Georgia (27.9), Louisiana (22.4), Maryland (24.0), Mississippi (16.4), New

Jersey (13.0), New York (21.7), South Carolina (16.4), Texas (16.5), and the District of Columbia (94.2) (CDC, 2013l). As shown in Table 14-2, both HIV and HIV Stage 3 (AIDS) affect people across the life span, with peak HIV rates occurring for those in the 25- to 29-year-old age group. Peak HIV Stage 3 (AIDS) rates occur in individuals age 40 to 44.

HIV Surveillance

A study of diagnosed cases of AIDS does not reveal current HIV infection patterns because of the interval between infection with HIV and the onset of clinical disease. Moreover, the effectiveness of antiretroviral drugs given early in the HIV infection before symptoms start provides impetus for early identification of infection. Thus in 2008 confidential laboratory reporting of HIV-positive status by name was required in all 50 states and the District of Columbia (CDC, 2013l), although not all states require viral load and CD4 counts (CDC, 2013o).

HIV Testing

The HIV antibody test is the most commonly used screening test for determining infection. This test does just as its name implies: it does not reveal whether an individual has symptomatic AIDS, nor does it isolate the virus. It does indicate the presence of the antibody to HIV. The most commonly used form of this test is the enzyme-linked immunosorbent assay (EIA). The EIA effectively screens blood and other donor products. To minimize false-positive results, a confirmatory test, the Western blot, is used to verify the results. False-negative results may also occur after infection and before antibodies are produced. Sometimes referred to as the window period, this can last from 6 weeks to 3 months.

Rapid HIV antibody testing using oral fluid samples (e.g., OraQuick, Home Access HIV-1 Test System) is 99.5% accurate and provides results within 20 minutes, allowing immediate results to be given (CDC, 2013q; USPSTF 2013). In addition to the rapid results, this test may appeal to persons who fear having their blood drawn. If the test is positive, it requires a second specific confirmatory test.

Routine voluntary HIV testing is recommended for all adults ages 15 to 65 (USPSTF, 2013). Voluntary screening programs for HIV may be either confidential or anonymous; the process for each is unique. Confidential testing involves reporting by identifying the person's name and other identifying information; this information is considered protected by confidentiality. With anonymous testing, the client is given an identification code number that is attached to all records of the test results and is not linked to the person's name and address (CDC, 2013q). Demographic data such as the person's sex, age, and race may be collected, but there is no record of the client's name and associated identifying information. An advantage of anonymous testing may be that it increases the number of people who are willing to be tested, because many of those at risk are engaged in illegal activities. The anonymity eliminates their concern about the possibility of arrest or discrimination. However, anonymous testing does not allow for follow-up if the test is positive because the client's name and address are not available.

Perinatal and Pediatric HIV Infection

Perinatal transmission accounts for nearly all HIV infection in children and can occur during pregnancy, labor and delivery, or breastfeeding. The effectiveness of antiretroviral therapy in pregnant women and newborns in preventing transmission from mother to fetus or infant has made pediatric HIV rates decline sharply. On the basis of the effectiveness of antiviral therapy, it is recommended that HIV testing be a routine part of prenatal care and that all pregnant women be tested for HIV—even a mother who presents in labor who is untested and whose HIV status is not known (USPSTF, 2013). Rapid testing allows rapid results in women who are giving birth, but have not been previously tested for HIV. HIV prevention in women must remain the primary focus of efforts to reduce pediatric HIV infection.

If left untreated, the clinical picture of pediatric HIV infection involves a shorter incubation period than in adults, and symptoms may occur within the first year of life. The physical signs and symptoms in children include failure to thrive, unexplained persistent diarrhea, developmental delays, and bacterial infections such as TB and severe pneumonia (WHO, 2010b).

Detection of HIV infection in infants of infected mothers is made through different tests from those used in children over 18 months. Virologic assays that directly detect HIV (e.g., nucleic acid amplification tests [NAT] such as HIV DNA, RNA polymerase chain reaction [PCR] assays, and related RNA qualitative or quantitative assays) must be used (Panel on Antiretroviral Therapy and Medical Management of HIV-Infected Children, 2014). The EIA test is not valid because it tests for antibodies, which in the infant reflect passively acquired maternal antibodies.

Despite having an HIV-infected mother, many children do not acquire HIV. However, one or both parents may die from HIV infection. The families of many children with AIDS are impoverished, with limited financial, emotional, social, and health care resources. The added strain of this illness makes many individuals and families unable to provide for the emotional, physical, and developmental needs of affected children.

HIV Stage 3 (AIDS) in the Community

AIDS is a chronic disease, so individuals continue to live and work in the community. Persons with AIDS have bouts of illness interspersed with periods of wellness when they are able to return to school or work. When ill, much of their care is provided in the home. The nurse teaches families and significant others about personal care and hygiene, medication administration, standard precautions to ensure infection control, and healthy lifestyle behaviors such as adequate rest, balanced nutrition, and exercise.

Adherence to HAART is critical for clients because administration must be consistent to be effective (CDC, HRSA, NIH, et al., 2014). It is important for nurses to educate clients about accurate medication administration. Peer advocates and persons living with HIV infection who are trained to work with infected persons play a vital role in advocacy and teaching self-care management.

The Americans with Disabilities Act of 1990 and other laws protect persons with asymptomatic HIV infection and AIDS against discrimination in housing, at work, and in other public situations (USDJ, 2012). Policies regarding school and worksite attendance have been developed by most states and localities on the basis of these laws. These policies provide direction for the community's response when a person develops HIV infection. The nurse can identify resources such as social and financial support services and interpret school and work policies.

Mental health issues such as depression, substance abuse, and bipolar disorder are often present in someone newly diagnosed with HIV. These conditions must be addressed prior to or simultaneously with HIV treatment to be effective. It is vitally important that a variety of health and social services be available to support persons with HIV (CDC, HRSA, NIH, et al, 2014).

Nurses can assist employers by educating managers about how to deal with ill or infected workers to reduce the risk of breaching confidentiality or wrongful actions such as termination. Disclosing a worker's infection to other workers, terminating employment, and isolating an infected worker are examples of situations that have led to litigation between employees and employers. The CDC supports workplace issues through programs offered by its Business and Labor Resource Service. (See resources on the Evolve website at <http://evolve.elsevier.com/Stanhope>.)

HIV-infected children should attend school because the benefit of attendance far outweighs the risk of transmitting or acquiring infections. None of the cases of HIV infection in the United States have been transmitted in a school setting. An interprofessional team that includes the child's physician, the

nurse, and the child's parent or guardian should make decisions about educational and care needs.

Because of impaired immunity, children with HIV infection are more likely to get childhood diseases and suffer serious sequelae. Therefore, DPT (diphtheria, pertussis, tetanus), IPV (inactivated polio virus), and MMR (measles, mumps, rubella) vaccines should be given at regularly scheduled times for children infected with HIV. HiB (*Haemophilus influenzae* type B), hepatitis B, pneumococcus, and influenza vaccines may be recommended after medical evaluation (CDC, 2009a). Additionally the [Panel on Opportunistic Infections in HIV-Exposed and HIV-Infected Children guidelines \(2013\)](#) recommends meningococcal disease vaccination, as well as hepatitis A and varicella vaccination, provided that the infant or child is not severely immunocompromised.

Individual decisions about risk to the infected child or others should be based on the behavior, neurological development, and physical condition of the child. Attendance may be inadvisable in the presence of cases of childhood infections, such as chickenpox or measles, within the school, because the immunosuppressed child is at greater risk of suffering complications. Alternative arrangements, such as homebound instruction, might be instituted if a child is unable to control body secretions or displays biting behavior.

Resources

As the number of individuals with HIV/AIDS has increased, services to meet these needs have grown. Voluntary and faith-based service organizations, such as community-based organizations or AIDS support organizations, have developed in many localities to address these needs. These services may include counseling, support groups, legal aid, personal care services, housing programs, and community education programs. Nurses collaborate with workers from community-based organizations in the client's home and may advise these groups in their supportive work. The federal government and many organizations have established toll-free numbers and websites to provide information, as noted on the Evolve website at <http://evolve.elsevier.com/Stanhope>.

SEXUALLY TRANSMITTED DISEASES

The number of new cases (the **incidence**) of STDs such as gonorrhea, herpes simplex virus, human papillomavirus (HPV), and chlamydia continues to increase. Chlamydia is the most commonly reported infectious disease; gonorrhea is the second most common. Because of the impact of STDs on long-term health and the emergence of eight new STDs since 1980, continued attention to their prevention and treatment is vital.

The common STDs listed in [Table 14-3](#) are categorized by cause, either viral or bacterial. The bacterial infections include gonorrhea, syphilis, and chlamydia. Most of these are curable with antibiotics, with the exception of the newly emerging antibiotic-resistant strains of gonorrhea.

STDs caused by viruses cannot be cured. These are chronic diseases resulting in a lifetime of symptom management and infection control. The viral infections include herpes simplex

TABLE 14-3 Summary of Sexually Transmitted Diseases

Disease/ Pathogen	Incubation	Signs and Symptoms	Diagnosis	Treatment	Nursing Implications
Bacterial					
Chlamydia: <i>Chlamydia trachomatis</i>	3-21 days	<i>Man:</i> None or non-gonococcal urethritis (NGU); painful urination and urethral discharge; epididymitis <i>Woman:</i> None or mucopurulent cervicitis (MPC), vaginal discharge; if untreated, progresses to symptoms of PID: diffuse abdominal pain, fever, chills	Nucleic acid amplification test (NAAT) of male urine and female endocervix	One of following treatments: Doxycycline 100 mg PO bid × 7 days Azithromycin 1 g PO × 1 Alternative regimens: Erythromycin base 500 mg PO qid × 7 days Erythromycin ethylsuccinate 800 mg PO qid × 7 days Levofloxacin 500 mg PO, daily × 7 days Ofloxacin 300 mg PO bid × 7 days Doxycycline, effective and cheap Azithromycin, good because single dose is sufficient	Refer partners of past 60 days; counsel client to use condoms and to avoid sex for 7 days after start of therapy and until symptoms are gone in both client and partners; medication teaching Annual screening recommended for all sexually active women under 25, and women over 25 with new or multiple sexual partners
Gonorrhea: <i>Neisseria gonorrhoeae</i>	3-21 days	<i>Man:</i> Urethritis, purulent discharge, painful urination, urinary frequency; epididymitis <i>Woman:</i> None, or symptoms of PID	Nucleic acid amplification test (NAAT)	For uncomplicated gonorrhea: Ceftriaxone 250 mg. IM PLUS EITHER Azithromycin 1 gm PO × 1 OR Doxycycline 100 mg PO qd × 7 days If ceftriaxone not readily available, PO cefixime may be used in combination with doxycycline or azithromycin, but patient should return at one week for a test-of-cure at the site of infection	Refer partners of past 60 days; return for evaluation if symptoms persist; counsel client to use therapy until complete and symptoms are gone in both client and partners; medication teaching
Syphilis: <i>Treponema pallidum</i>	10-90 days 6 weeks to 6 months Within 1 year of infection After 1 year from date of infection <i>Late active:</i> 2-40 years 20-30 years 10-30 years	<i>Primary:</i> usually single, painless chancre; if untreated, heals in few weeks <i>Secondary:</i> low-grade fever, malaise, sore throat, headache, adenopathy, and rash <i>Early latency:</i> Asymptomatic, infectious lesions may recur <i>Late latency:</i> Asymptomatic, noninfectious except to fetus of pregnant women Gummas of skin, bone, mucous membranes, heart, liver <i>CNS involvement:</i> Paresis, optic atrophy <i>Cardiovascular involvement:</i> Aortic aneurysm, aortic valve insufficiency	Visualization of pathogen on dark field microscopic examination; single painless ulcer (chancre); FTA-ABS or MHA-TP, VDRL (reactive 14 days after appearance of chancre) Clinical signs of secondary syphilis VDRL: FTA-ABS or MHA-TP Lumbar puncture, CSF cell count, protein level determination and VDRL	Penicillin G 2.4 million units, IM once If penicillin allergy: Doxycycline 100 mg PO bid × 14 days (p.30) Tetracycline 500 mg four times daily × 14 days Tetracycline should not be administered to pregnant women or those with neurosyphilis or congenital syphilis <i>Early syphilis:</i> Ceftriaxone (1 g daily either IM or IV for 10-14 days) Azythromycin 2-g PO once <i>Early latent:</i> Benzathine penicillin G 2.4 million units IM in a single dose <i>Late latent or latent:</i> Benzathine penicillin G 7.2 million units total in three doses of 2.4 million units IM at 1-week intervals <i>Tertiary:</i> Benzthine penicillin G 7.2 million units total, in three doses of 2.4 million units IM each at 1-week intervals In general, penicillins are prescribed in varying doses depending on diagnosis	Counsel to be tested for HIV; screen all partners of past 3 months; re-examine client at 3 and 6 months

TABLE 14-3 Summary of Sexually Transmitted Diseases—cont'd

Disease/ Pathogen	Incubation	Signs and Symptoms	Diagnosis	Treatment	Nursing Implications
Viral					
Human immunodeficiency virus (HIV)	4-6 weeks <i>Seroconversion:</i> 6 weeks to 3 months <i>AIDS:</i> month to years (average, 11 years)	<i>Possible:</i> Acute mononucleosis-like illness (lymphadenopathy, fever, rash, joint and muscle pain, sore throat) Appearance of HIV antibody <i>Opportunistic diseases:</i> Most commonly <i>Pneumocystis jiroveci</i> pneumonia, oral candidiasis, Kaposi's sarcoma	<i>HIV antibody test:</i> EIA or Western blot test; OraSure (SmithKline Beecham) is an oral HIV-1 antibody testing system, test results in about 3 days CD4+ T-lymphocyte count of less than 200/ μ l with documented HIV infection, or diagnosis with clinical manifestation of AIDS as defined by CDC	Prophylactic administration of zidovudine (ZDV) immediately after exposure may prevent seroconversion Post-exposure prophylaxis (PEP) should begin as soon as possible. Choice of antiviral drug therapy is made based on toxicity and drug resistance. Combinations of drugs are considered such as zidovudine (ZDV) and 3TC. Drug selection is complicated and evolving. Pre-exposure prophylaxis (PrEP) was approved in 2012, consisting of daily tenofovir disoproxil fumarate plus emtricitabine (TDF/FTC), for use among sexually active, at-risk adults.	HIV education and counseling; partner referral for evaluation; medication education; assessment and referral Men who have sex with men should be tested annually for HIV, chlamydia, syphilis, and gonorrhea
Genital warts: human papillomavirus (HPV)	4-6 weeks most common; up to 9 months	Often subclinical infection; painless lesions near vaginal openings, anus, shaft of penis, vagina, cervix; lesions are textured, cauliflower appearance; may remain unchanged over time	Visual inspection for lesions; Pap smear; hybrid capture 2 HPV DNA test; colposcopy	Prevention: Gardasil vaccine No cure; one third of lesions will disappear without topical treatment Client-applied: topical podofilox 0.5% bid \times 3 days, 4 days of no therapy; or imiquimod 5% cream daily at bedtime for up to 16 weeks Provider-administered: podophyllum resin 10%-25% or trichloroacetic acid 80%-90%; repeat weekly if needed; cryotherapy with liquid nitrogen, laser, or surgical removal	Education about HPV vaccine Warts and surrounding tissues contain HPV, so removal of warts does not completely eradicate virus; examination of partners not necessary, since treatment is only symptomatic; condom use may reduce transmission; medication application
Genital herpes simplex virus (HSV)	2-20 days; average, 6 days	Vesicles, painful ulceration of penis, vagina, labia, perineum, or anus; lesions last 5-6 weeks and recurrence is common; may be asymptomatic	Presence of vesicles; viral culture (obtained only when lesions present and before they have scabbed over)	No cure; treatment may be episodic or suppressive for frequent recurrence <i>Episodic treatment:</i> acyclovir 400 mg PO tid \times 7-10 days; OR Acyclovir 200 mg PO five times a day \times 7-10 days; OR famciclovir 250 mg PO tid 7-10 days; or valacyclovir 1 g PO bid \times 7-10 days	Refer partners for evaluation; teach client about likelihood of recurrent episodes and ability to transmit to others even if asymptomatic; condom use; annual Pap smear

virus and human papillomavirus (HPV), also referred to as genital warts. The hepatitis A, B, and C viruses, which may also be transmitted via sexual activity, are discussed later in this chapter.

Gonorrhea

Neisseria gonorrhoeae is a gram-negative intracellular diplococcal bacterium that infects the mucous membranes of the genitourinary tract, rectum, and pharynx. It is transmitted through genital-genital contact, oral-genital contact, and anal-genital contact.

Gonorrhea is identified as either uncomplicated or complicated. Uncomplicated gonorrhea refers to limited cervical or urethral infection. Complicated gonorrhea includes salpingitis, epididymitis, systemic gonococcal infection, and gonococcal meningitis. The signs and symptoms of infection in males are purulent and copious urethral discharge and dysuria. Symptoms in males are usually sufficient to seek treatment. Gonococcal infection in women however, is commonly asymptomatic, and treatment may not be sought. The disease will continue to be spread to others through sexual activity and may not be recognized until **pelvic inflammatory disease** (PID) occurs (CDC, 2010b).

Some individuals may continue to be sexually active and infect others while symptomatic. Co-infection with gonorrhea and chlamydia is common; therefore treatment containing ceftriaxone combined with either doxycycline or azithromycin is recommended (CDC, 2012g).

Reported gonorrhea rates are on the rise again after a long period of decline, particularly in the Northeast, Midwest, and West, although overall rates are still highest in the South (CDC, 2014b). The reported number of cases in the United States in 2012 was 334,826. The difference between the actual cases and reported cases occurs because gonorrhea may be unreported by health care providers, and because clients who are asymptomatic do not seek treatment and are therefore not identified. Groups with the highest incidence of gonorrhea are African Americans, persons living in the southern United States, and women 15 to 24 years of age (CDC, 2014b).

The number of antibiotic-resistant cases of gonorrhea in the United States has risen at an alarming rate. Penicillin-resistant gonorrhea was first identified in 1976 when 15 cases were reported (Phillips, 1976). By 1990, 64,972 resistant cases were reported (J. Blount, personal communication, January 18, 1991). Antibiotic-resistant *N. gonorrhoeae* has continued to develop exponentially, with gonorrhea becoming resistant to every antibiotic used for treatment, starting with penicillin and moving through sulfonamides, tetracycline, and fluoroquinolones, (CDC, 2013a). In 2012, the CDC revised its treatment guidelines and no longer recommended oral cephalosporins, specifically cefixime, as a first-line treatment for gonorrhea (CDC, 2012g), in an effort to preserve the last remaining treatment option (CDC, 2013a). At this time, combination therapy of ceftriaxone IM along with either oral doxycycline or azithromycin is the most reliably effective treatment for uncomplicated gonorrhea (CDC, 2012g). The injection

route versus the previously recommended oral cefixime may make treatment more challenging due to patient fear of injection and health care facilities having to stock injectable medication (CDC, 2013a).

The increase in antibiotic-resistant infections is partially attributed to the indiscriminate or illicit use of antibiotics as a prophylactic measure by persons with multiple sexual partners. To ensure proper treatment and cure, those diagnosed with gonorrheal infection should return for health care if symptoms persist, have their partners of the previous 60 days evaluated for infection, and remain sexually abstinent until antibiotic therapy is completed (CDC, 2010b).

The development of PID is a risk for women who remain asymptomatic and do not seek treatment. PID is a serious infection involving the fallopian tubes (salpingitis) and is the most common complication of gonorrhea, but may also result from chlamydia infection. Its symptoms include fever, abnormal menses, and lower abdominal pain, but PID may not be recognized because the symptoms vary among women. PID can result in ectopic pregnancy and infertility related to fallopian tube scarring and occlusion. It may also cause stillbirths and premature labor (CDC, 2010b).

Syphilis

Syphilis is caused by a member of the treponemal group of spirochetes called *Treponema pallidum*. It infects moist mucous or cutaneous membranes and is spread through direct contact, usually by sexual contact or from mother to fetus. Transmission via blood transfusion may occur if the donor is in the early stages of disease (Heymann, 2014).

Syphilis rates in the United States declined between 1990 and 2000, but then increased between 2001 and 2009. Rates increased again in 2012 (CDC, 2014d). The highest rates are among men having sex with men, but in recent years the number of infected women has increased.

The clinical signs of syphilis are divided into primary, secondary, and tertiary infections. Latency, a period when an individual is free of symptoms but has serologic evidence, may occur early or late in the infection. Latency that occurs during the first year of infection is called early latency. Late latency may occur after this first year. During latency, the possibility of relapse remains (CDC, 2010b).

Primary Syphilis

When syphilis is acquired sexually, the bacteria produce infection in the form of a chancre at the site of entry. The lesion begins as a macula, progresses to a papule, and later ulcerates. If left untreated, this chancre persists for 3 to 6 weeks and then in most cases disappears (Heymann, 2014).

Secondary Syphilis

Secondary syphilis occurs when the organism enters the lymph system and spreads throughout the body. Signs include rash, lymphadenopathy, and mucosal ulceration. Symptoms of secondary syphilis may include skin rash, lymphadenopathy, and lesions of the mucous membranes (CDC, 2010b).

Tertiary Syphilis

Tertiary syphilis can lead to blindness, congenital damage, cardiovascular damage, or syphilitic psychoses. A further complication can be the development of lesions of the bones, skin, and mucous membranes, known as gummatous lesions. Tertiary syphilis usually occurs several years after initial infection and is rare in the United States because the disease is usually cured in its early stages with antibiotics. Tertiary syphilis is a major problem in developing countries.

Congenital Syphilis

When primary and secondary syphilis rates increase, so do the rates of congenital syphilis (CS), which increased 23% in 2008 (CDC, 2010a). Syphilis is transmitted transplacentally and, if untreated, can cause premature stillbirth, blindness, deafness, facial abnormalities, crippling, or death. Signs include jaundice, skin rash, hepatosplenomegaly, or pseudoparalysis of an extremity. Treatment consists of penicillin given intravenously or intramuscularly (CDC, 2010a).

Chlamydia

Chlamydia infection results from the bacterium *Chlamydia trachomatis*. It infects the genitourinary tract and rectum of adults and causes conjunctivitis and pneumonia in neonates. Transmission occurs when mucopurulent discharge from infected sites, such as the cervix or urethra, comes into contact with the mucous membranes of a noninfected person. Like gonorrhea, the infection is often asymptomatic in women, where up to 70% may experience no symptoms (Heymann, 2014). If left untreated, chlamydia can result in PID. When symptoms of chlamydial infection are present in women, they include dysuria, urinary frequency, and purulent vaginal discharge. In men, the urethra is the most common site of infection, resulting in **non-gonococcal urethritis** (NGU). The symptoms of NGU are dysuria and urethral discharge. Epididymitis is a possible complication (CDC, 2013p). The CDC recommends annual chlamydial screening of all sexually active women younger than 26 (CDC, 2014a). Older women with new or more than one sex partner and all pregnant women should also be tested (CDC, 2014g).

Chlamydia is the most common reportable infectious disease in the United States, and in 2012 a total of 1,422,976 cases of genital chlamydial infection were reported. Between 1992 and 2012, the rate of reported chlamydia infection increased from 182.3 to 456.7 cases per 100,000 population, reflecting increased screening rates, an emphasis on case reporting, and more sensitive testing (CDC, 2014a). Prevention is important because chlamydia can cause PID, ectopic pregnancy, infertility, and neonatal complications. Women under 25 years of age are the most commonly infected with chlamydial infection because of inconsistent use of barrier contraceptives, multiple sexual partners, and a history of infection with other STDs (CDC, 2014g). The high frequency of chlamydial infections in individuals infected with gonorrhea requires that effective treatment for both organisms be given when a gonorrheal infection is identified (CDC, 2010b).

Herpes Simplex Virus (Genital Herpes)

Herpes simplex viruses (HSV-1 and HSV-2) cause **genital herpes**, and an increasing number of genital herpes infections are caused by HSV-1 (CDC, 2013c). The majority of genital herpes infections are caused by HSV-2, and these herpes infections are more likely to be recurrent (Buttaro, 2013).

As is true for other viral STDs, there is no cure for herpes infection, and it is considered a chronic disease. The virus is transmitted through direct exposure and infects the genitalia and surrounding skin. After the initial infection, the virus remains latent in the sacral nerve of the central nervous system and may reactivate periodically with or without visible vesicles.

Signs and symptoms of HSV infection include the presence of painful lesions that begin as vesicles and ulcerate and crust within 1 to 4 days. The first episode is typically longer and is usually characterized by more lesions than seen in subsequent infections. Lesions may occur on the vulva, vagina, upper thighs, buttocks, and penis and have an average duration of 11 days (Figure 14-3). The vesicles can cause itching and pain and may be accompanied by dysuria or rectal pain. Although the ability to pass the infection to others is higher with active lesions, some individuals can spread the virus even when they are asymptomatic. There can be a prodromal phase before lesions develop that includes tingling and paresthesia at the site (Heymann, 2014).

HSV-2 occurs in 16.2% of American adolescents and adults (CDC, 2013c). This prevalence is likely underrated because HSV-1 infections are rising, and a large number of people have no symptoms, thus HSV is difficult to identify. The consequences of genital herpes are of particular concern for women and their children. HSV-2 infection is linked with the development of cervical cancer. There is also an increased risk of fatal newborn infection during vaginal delivery with active lesions (Heymann, 2014). A pregnant woman who has active lesions at the time of giving birth should have a cesarean delivery before the rupture of amniotic membranes to avoid fetal contact with the herpetic lesions, whereas those who have no clinical evidence of herpes lesions should be delivered vaginally. A small number of infants are infected in utero. The clinical infection

FIG 14-3 Herpes genitalis. (From Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy*, ed 5. St Louis, 2010, Mosby.)

in infants may present as liver disease, encephalitis, or infection limited to the skin, eyes, or mouth (Heymann, 2014).

Human Papillomavirus Infection

Human papillomavirus (HPV) results in **genital warts**. Specific types of HPV cause cervical cancer, which is the second most common cancer worldwide (Heymann, 2014). HPV is the most common STD in the United States (CDC, 2014f). Transmission of HPV occurs through direct contact with warts that result from HPV and can infect the mouth, genitals, and anus. Genital warts are most commonly found on the penis and scrotum in men, and on the vulva, labia, vagina, and cervix in women. They appear as textured surface lesions, with what is sometimes described as a cauliflower appearance. The warts are usually multiple and vary between 1 mm to 1 cm in diameter. They may be difficult to visualize, so careful examination is required (Buttaro et al, 2013).

Since 2006, two FDA-licensed vaccines have been developed, bivalent and quadrivalent, both of which stimulate the immune system to block cancer-causing HPV infection before it occurs. The quadrivalent vaccine has the added benefit of preventing anogenital warts (CDC, 2014f). The recommended age for vaccination in both girls and boys is 11 to 12 years old, but it can be given in those aged 9 to 26 years old (CDC, 2014c). Complete vaccination coverage is an issue, however. In 2012, first dose vaccination rates for adolescent girls was low at 53.8%, and this dropped to 33.4% for all three doses. Experts recommend several strategies to increase vaccination rates in adolescent girls and boys, such as a reminder/recall system to increase vaccination rates and consideration of use of schools as a vaccination site. In some areas, requiring HPV vaccination for school entry has been successful, but this practice is not widely utilized to date (CDC, 2014f).

Once HPV infection occurs, the goal of therapy is to eliminate the warts. Genital warts spontaneously disappear over time, as do skin warts. However, because the condition is worrisome for the client and HPV may lead to the development of cervical neoplasia, treatment of the warts through surgical removal, laser therapy, or cytotoxic agents is often done (Buttaro, 2013).

Complications of HPV infection may be especially serious for women. The link between HPV infection and cervical cancer has been established and is associated with specific types of the virus. Other cancers attributed to HPV include vaginal, anal, and oropharyngeal (CDC, 2014f). Pap smears are vitally important because they allow for microscopic examination of cells to detect HPV, which can be surgically removed if detected early (Heymann, 2014). HPV infection is exacerbated in both pregnancy and immune-related disorders, which are believed to result from a decrease in cell-mediated immune functioning. HPV may infect the fetus during pregnancy and can result in a laryngeal papilloma that can obstruct the infant's airway. Genital warts may enlarge and become friable during pregnancy, and therefore surgical removal may be recommended. One challenge of HPV prevention is that condoms do not necessarily prevent infection. Warts may grow where barriers, such as condoms, do not cover and skin-to-skin contact may occur.

HEPATITIS

Viral hepatitis refers to a group of infections that primarily affect the liver. These infections have similar clinical presentations but different causes and characteristics. Brief profiles of the types of hepatitis are presented in Table 14-4.

Hepatitis A Virus

Hepatitis A virus (HAV) is most commonly transmitted through the fecal–oral route. Sources may be water, food, feces, or sexual contact. The virus level in the feces appears to peak 1 to 2 weeks before symptoms appear, making individuals highly contagious before they realize they are ill (Heymann, 2014).

The vaccine for hepatitis A infection has been available since 1995, and since that time the incidence has steadily declined (CDC, 2011). The vaccine makes HAV a completely preventable disease. Persons most at risk for HAV infection are travelers to countries with high rates of the disease, children living in areas with high rates of HAV infection, injection drug users, MSM, and persons with clotting disorders or chronic liver disease. Since routine childhood vaccination was recommended in 1996, the overall hepatitis A rate has declined 53%, from 2,979 cases reported in 2007 to 1,398 in 2011 (CDC, 2011).

Hepatitis A is found worldwide. In developing countries where sanitation is inadequate, epidemics are not common because most adults are immune from childhood infection. In countries with improved sanitation, outbreaks are common in daycare centers whose staff must change diapers, among household and sexual contacts of infected individuals, and among travelers to countries where hepatitis A is endemic. In many outbreaks, one individual is the source of an infection that may spread in the community. In other cases, hepatitis A is spread through food contaminated by an infected food-handler, contaminated produce, or contaminated water. The source of infection may never be identified in many outbreaks (Heymann, 2014).

The clinical course of hepatitis A ranges from mild to severe and often requires prolonged convalescence. Onset is usually acute, with fever, nausea, lack of appetite, malaise, and abdominal discomfort followed by jaundice after several days.

Vaccination and appropriate sanitation and personal hygiene remain the best means of preventing infection. The HAV vaccine is recommended for those who travel frequently or who spend long periods in countries where the disease is endemic. In cases of exposure through close contact with an infected individual or contaminated food or water, an injection of prophylactic immunoglobulin (IG) is indicated. IG should be given as soon as possible, but can be given within 2 weeks of exposure. Candidates for hepatitis A vaccine are listed in Box 14-2 (CDC, 2013d).

Hepatitis B Virus

The number of new cases of **hepatitis B virus** (HBV) has steadily declined since HBV vaccination became available. In 2011 a total of 2,890 acute hepatitis B cases were reported, down 36% overall since 2007 (CDC, 2011). The groups with the highest prevalence are users of injection drugs, persons with

TABLE 14-4 Viral Hepatitis Profiles

	Hepatitis A	Hepatitis B	Hepatitis C
Incubation period	Average, 28 days; range, 15-50 days	Average, 90 days; range, 60-150 days	Average, 45 days; range, 14-180 days
Mode of transmission	Fecal–oral, contaminated food/water, sexual	Bloodborne, sexual, perinatal	Primarily bloodborne; also sexual and perinatal
Incidence	Estimated number of new infections: 17,000 in 2010 in the United States. Reported in the U.S. in 2011: 1,398	Estimated 38,000 cases/yr in United States in 2010. Reported in the U.S. in 2011: 2,890	Estimated 16,500 cases/yr in United States in 2011. Reported in the U.S. in 2011: 1,229
Chronic carrier state?	No	Yes, 5% of adult cases; 90% of infants; 25-50% of children aged 1-5 years	Yes, 75-85% or more of cases
Diagnosis	Serologic test (anti-HAV), viral isolation	Serologic tests (e.g. HBsAg), viral isolation	Serologic tests (anti-HCV)
Sequelae	No chronic infection	Chronic liver disease; liver cancer	Chronic liver disease; liver cancer
Vaccine availability	Yes, vaccination of all children at one year, children in areas of high disease rates recommended; travelers to endemic regions; men who have sex with men; injection and noninjection drug users.	Yes, vaccination of infants recommended; All children who have not been already immunized; individuals with exposure risks; men who have sex with men; people with end stage renal disease, people with HIV infection	No
Control and prevention	Good hygiene (e.g., handwashing); proper sanitation	Pre-exposure vaccination; reduce exposure risk behaviors	Screening of blood/organ donors; reduce exposure risk behaviors

BOX 14-2 Recommendations for Administration of Hepatitis A Vaccine or Ig After Exposure

- All household or sexual contacts of persons with HAV
- Persons who have shared illicit drugs with someone with HAV
- All staff and attendees of daycare centers if a case of HAV occurs among children or staff
- Household members whose children attend a daycare center where two or more families are infected
- Food-handlers who have a coworker infected with HAV; patrons in unhygienic situations or involvement where food is not heated

STDs or multiple sex partners, immigrants and refugees and their descendants who came from areas where there is a high endemic rate of HBV, health care workers, clients on hemodialysis, and inmates of long-term correctional institutions (Buttaro, 2013).

The HBV is spread through blood and body fluids and, like HIV, is a bloodborne pathogen. It has the same transmission properties as HIV, and thus individuals should take the same precautions to prevent spread of both HIV and HBV. A major difference is that HBV remains alive outside the body for a longer time than does HIV and thus has greater infectivity. The virus can survive for at least 1 week dried at room temperature on environmental surfaces, and thus infection control measures are paramount in preventing transmission from client to client (Heymann, 2014).

Infection with HBV results in either acute or chronic HBV infection. The acute infection is self-limited, and individuals develop an antibody to the virus and successfully eliminate the virus from the body. They subsequently have lifelong immunity against the virus. Symptoms range from mild, flu-like symptoms to a more severe response that includes jaundice, extreme lethargy, nausea, fever, and joint pain. Any of these more severe symptoms may result in hospitalization. A second possible outcome from infection is chronic HBV infection, which more likely occurs in persons with immunodeficiency (Heymann, 2014). Chronically infected individuals are unable to rid their bodies of the virus and remain lifelong carriers of the hepatitis B surface antigen (HBsAg). As carriers, they are able to transmit the HBV to others. They may develop hepatic carcinoma or chronic active hepatitis. The signs and symptoms of chronic hepatitis B include anorexia, fatigue, abdominal discomfort, hepatomegaly, and jaundice (Heymann, 2014).

Strategies for preventing HBV infection include immunization, prevention of nosocomial occupational exposure, and prevention of sexual and injection drug–use exposure. Vaccination is recommended for persons with occupational risk, such as health care workers, and for infants. The series of vaccines required for protection from HBV consists of three intramuscular injections, with the second and third doses administered 1 and 6 months after the first (CDC, 2014e). Pregnant women should be tested for HBsAg; if the mother is positive, newborns require hepatitis B immune globulin in addition to the hepatitis B vaccine within 12 hours of birth, and then at 1 and 6 months

thereafter (CDC, 2014e). In instances in which the individual is not protected by vaccination and exposure to HBV occurs, hepatitis B immune globulin is given as soon as possible (within 24 hours is optimal) and the hepatitis B vaccine given (CDC, 2012a).

OSHA Regulations

The Occupational Safety and Health Administration (OSHA) mandates specific activities to protect workers from HBV and other bloodborne pathogens. Potential exposures for health care workers are needlestick injuries and mucous membrane splashes. The OSHA standard requires employers to identify the risk of blood exposure to various employees. If employees perform work that involves a potential exposure to others' body fluids, employers are mandated to offer the HBV vaccine to the employee at the employer's expense, and to offer annual educational programs on preventing HBV and HIV exposure in the workplace. Employees have the right to refuse the vaccine. Employees may decline the vaccine for a variety of reasons including thinking they are not at risk since they are married or in a monogamous relationship, that the vaccine is too new to have adequate information about it, or that there may be side effects to the vaccine (CDC, 2013b).

Hepatitis C Virus

Hepatitis C virus (HCV) infection is the most common chronic bloodborne infection in the United States (USPSTF, 2014). The HCV is transmitted when blood or body fluids of an infected person enter an uninfected person. Those groups at highest risk include health care workers and emergency personnel who are accidentally exposed, infants who are born to infected mothers, those born between 1945 and 1965 (CDC, 2012d), and 1-time or chronic injection drug users, particularly those who share needles or other drug-use equipment (Hande, 2014). Others at risk include hemodialysis patients (from dialysis equipment shared with infected persons) and recipients of donor organs and blood products before 1992 (USPSTF, 2014). The greatest risk factor is past or current injection drug use, with a hepatitis C prevalence rate of 50% (USPSTF, 2014).

During the 1980s, HCV spread rapidly. It is estimated that 2.7 to 3.9 million people are infected in the United States, and they are often unaware that they have hepatitis C. Although those born between 1945 and 1965 represent only 27% of the population, they account for a disproportionate 75% of all hepatitis C cases in the United States (CDC, 2012d). Chronic liver disease from hepatitis C is the most common indication for liver transplants, representing 30% of all transplants (USPSTF, 2014).

The clinical signs of hepatitis C may be so mild that an infected individual does not seek medical attention. The incubation period ranges from 2 weeks to 6 months. Clients may experience fatigue and other nonspecific symptoms. Although some have spontaneous resolution of the infection, 50% to 80% develop chronic liver disease. HCV infection may lead to cirrhosis or hepatocellular carcinoma (Heymann, 2014). Hepatitis C infection is related to about half of hepatocellular carcinoma cases, which have increased threefold (USPSTF, 2014).

Primary prevention of HCV infection includes screening of blood products and donor organs and tissue; risk reduction counseling and services, including obtaining injection drug use (IDU) history; and infection control practices. Secondary prevention strategies include testing of high-risk individuals, including those who seek HIV testing, and appropriate medical follow-up of infected clients. HCV testing should be offered to persons who received blood or an organ transplant before 1992; persons who have been on dialysis for many years; persons with signs and symptoms of liver disease; persons born between 1945 and 1965; and persons who received clotting factor before 1987. Routine testing for HCV is not recommended for health care workers, pregnant women, household contacts of HCV-positive persons, or the general population (CDC, 2013e).

Non-ABC Hepatitis

Hepatitis viruses exist that are structurally unrelated to hepatitis A, B, or C. All are very uncommon in the United States, representing less than 5% of total cases (CDC, 2009b). Hepatitis D (HDV), called Delta hepatitis, can be acute or chronic and can only exist in people who are already infected with hepatitis B, either as a co-infection or as a superinfection. In the United States, between 1.5% and 7.2% of HBV cases had serologic evidence of HDV co-infection (CDC, 2009b). It is possible to become a chronic carrier in 70% to 80% of cases. Although there is no vaccination for HDV, infection can be prevented by being vaccinated for HBV (CDC, 2013f).

Hepatitis E virus (HEV) is an acute hepatitis infection that is transmitted through the fecal-oral route. Because it is not a chronic infection, one cannot become a chronic carrier for HEV. Although there is no hepatitis E vaccination, HEV can be prevented by protecting water systems from fecal contamination (CDC, 2012b).

Another type of hepatitis virus is hepatitis G (GB virus C). This type of virus has been isolated from patients with post-transfusion hepatitis, but has not been found to be the cause of either acute or chronic hepatitis (CDC, 2009b).

TUBERCULOSIS

Tuberculosis is a mycobacterial disease caused by *Mycobacterium tuberculosis*. Transmission usually occurs through exposure to the tubercle bacilli in airborne droplets from persons with pulmonary tuberculosis who talk, cough, or sneeze. Common symptoms are cough, fever, hemoptysis, chest pains, fatigue, and weight loss. The incubation period is 4 to 12 weeks. The most critical period for development of clinical disease is the first 6 to 12 months after infection. About 5% of those initially infected may develop pulmonary tuberculosis or extrapulmonary involvement. The infection in about 95% of those initially infected becomes latent, but in about 10% of otherwise healthy individuals, it may be reactivated later in life. The chance of reactivation of latent infections increases in immunocompromised persons, substance abusers, underweight and undernourished persons, and persons with diabetes, silicosis, or gastrectomies (Heymann, 2014).

Epidemiology

The WHO (2013) reported 8.6 million new cases of TB worldwide in 2012, and 1.3 million deaths due to TB. Prevalence is more difficult to determine, but WHO has reported 12 million prevalent cases in 2012, a number that has fallen dramatically since 1990. Worldwide, the Southeast Asia and Western Pacific Region accounts for 58% of the cases, and Africa accounts for 25% in 2012. India and China are the countries with the highest number of cases in the world (WHO, 2013). TB infection prevalence in Africa reflects the infection with HIV, where 37% of TB cases are co-infected with HIV (WHO, 2013). In the United States, the incidence of TB increased between 1985 and 1992, but since then has shown a steady rate of decline (CDC, 2013n). Of the new cases, 59% are foreign-born persons living in the United States, with Asians and Hispanics being the most common ethnic groups, representing 30% and 28% of national TB cases. Half of all new cases are concentrated in four states: New York, Florida, Texas, and California (CDC, 2013n). Table 14-5 shows TB case rates in the United States by race/ethnicity.

Worldwide, TB drug resistance is a significant issue. This can be caused by people not completing the full course of treatment, provider prescription error, poor quality drugs, or lack of TB drug availability. Types of drug-resistant TB include multidrug resistant TB (MDRTB), defined by resistance to rifampin and isoniazid, and extremely drug-resistant TB (XDRTB), which is MDRTB plus added resistance to fluoroquinolones and at least three injectable second-line drugs (e.g., amikacin, kanamycin, and capreomycin) (WHO, 2013). Drug-resistant TB is a significant concern to people with weak immune systems, such as HIV-infected individuals.

To prevent TB, the CDC works with public health agencies in other countries to improve screening and reporting of cases and to improve treatment strategies. This includes coordination of treatment for infected individuals who migrate to the United States. This coordination is particularly significant between Mexico and the United States (WHO, 2013).

TABLE 14-5 U.S. Tuberculosis (TB) Case Rates by Ethnicity and Sex, 2012

Ethnicity/Sex	Number of Cases	TB Case Rate Per 100,000
Asian	2,957	18.9
Native Hawaiian/other Pacific Islander	64	12.3
Black/African American	2,234	5.8
Hispanic/Latino	2,790	5.3
American Indian/Alaska Native	146	6.3
White	1,572	0.8
Multiple Race	148	2.5
Female	3,914	2.5
Male	6,028	3.9
Total population	9,945	3.2

Fr: Centers for Disease Control and Prevention: *Reported tuberculosis in the United States, 2012*. Atlanta: U.S. Department of Health and Human Services, CDC, October, 2013. Available at <http://www.cdc.gov/tb/statistics/reports/2012/pdf/report2012.pdf>.

Diagnosis and Treatment

The standard and preferred TB screening test is the Mantoux tuberculin skin test (TST) (CDC, 2012f). The TST, previously referred to as the purified protein derivative (PPD) test, is used for initial screening. It can be followed by chest radiography for persons with a positive skin reaction and pulmonary symptoms. Persons who are immunosuppressed by drugs or who have diseases such as advanced tuberculosis, measles, or chicken pox may not have the ability to mount an immune response to the TST, so the result may be a false-negative skin test reaction resulting from cutaneous anergy (nonreaction due to weakened immune system). A second issue with the TST is that a positive result may come from an earlier TST or BCG vaccination boosting one's ability to respond to the infection, and not reflecting a recent infection. Therefore, it is difficult to determine if the infection is old or recent. A blood test (in vitro gamma release interferon assays or IVGRA) is available and is increasingly used for providing clinical care in lieu of the TST (CDC, 2012e; Buttaro, 2013). One example is the QuantiFERON-TB blood test to detect *M. tuberculosis* infection. Diagnosis can also be made through stained sputum smears and other body fluids to determine the presence of acid-fast bacilli (for presumptive diagnosis), and culture of the tubercle bacilli for definitive diagnosis. The following **How To** box describes how to read a TST.

HOW TO How to Perform a Tuberculin Skin Test (TST)

Apply and Read the TST

- For the Mantoux test, inject 0.1 mL containing 5 tuberculin units of purified protein derivative PPD tuberculin.
- Read the reaction 48 to 72 hours after injection.
- Measure only induration, not redness.
- Record results in millimeters.

Interpret the TST (Buttaro, 2013)

Test is positive if the induration is greater than or equal to 5 mm in the following:

- Immunosuppressed clients
- Persons known to have HIV infection
- Persons whose chest radiograph is suggestive of previous TB that was untreated
- Close contacts of a person with infectious TB
- Organ transplant recipients

Test is positive if the induration is greater than or equal to 10 mm in the following:

- Persons with certain medical conditions, such as diabetes, alcoholism, or drug abuse
- Persons who inject drugs (if HIV negative)
- Foreign-born persons from areas where TB is common
- Children under 4 years old
- Residents and staff of long-term care facilities, jails, and prisons

Test is positive if the induration is greater than or equal to 15 mm in the following:

- All persons more than 4 years of age with no risk factors for TB

(CDC, 2003; CDC, 2012e; Buttaro, 2013)

Fr: Heymann D: *Control of Communicable Diseases Manual*, Washington, DC, 2008, American Public Health Association.

Clients with TB should be treated promptly with the appropriate combination of multiple antimicrobial drugs. Effective

drug regimens used in the United States include isoniazid, and in some instances, rifampin. Treatment regimens for persons with active symptomatic infection may be different from the regimens used for persons with latent TB infection or with HIV (Buttaro, 2013). Treatment failure may be due to clients' poor adherence in taking the medication, which can result in drug resistance. Nurses usually administer TSTs and provide education on the importance of compliance to long-term therapy. They may also be involved in directly observed therapy (DOT) and contact investigations of cases in the community.

NURSE'S ROLE IN PROVIDING PREVENTIVE CARE FOR COMMUNICABLE DISEASES

From prevention to treatment, the nurse functions as a counselor, educator, advocate, case manager, and primary care provider. Appropriate interventions for primary, secondary, and tertiary prevention are reviewed in the following sections (see [Levels of Prevention](#) box). In the following discussion of primary prevention, the nursing process is applied to the care of clients with communicable diseases. Nurses are in an ideal position to affect the outcomes of communicable diseases, and their influence begins with primary prevention.

LEVELS OF PREVENTION

Primary Prevention

- Provide community education about prevention of communicable diseases to well populations.
- Vaccinate for hepatitis A virus (HAV) or hepatitis B virus (HBV).
- Provide community outreach for education and needle exchange.

Secondary Prevention

- Administer tuberculin skin test (TST).
- Test and counsel for human immunodeficiency virus (HIV).
- Notify partners and trace contacts.

Tertiary Prevention

- Educate caregivers of persons with HIV about standard precautions.
- Maintain long-term directly observed therapy (DOT) for tuberculosis treatment.
- Identify community resources for providing supportive care (e.g., funds for purchasing medications).
- Set up support groups for persons with genital herpes.

Primary Prevention

Primary prevention consists mainly of activities to keep people healthy before the onset of disease. This begins with assessing for risk behavior and providing relevant intervention through education on how to avoid infection, mostly through healthy behaviors.

Assessment

To assess the risk of acquiring an infection, the nurse takes a history that focuses on risk behaviors and potential exposure, which varies with the specific organism by its mode of transmission. The specific questions that must be asked can be

especially challenging when STDs are the object of the study. In these situations, the nurse should obtain a sexual and IDU history for clients and their partners. The sexual history provides information that leads to the need for specific diagnostic tests, treatment modalities, and [partner notification](#). It also facilitates evaluation of risk factors and is necessary for the nurse to be able to provide relevant education for the client's lifestyle.

Assessing a client's risk of acquiring an STD should be done with all sexually active individuals. Such risk assessments should be included as baseline assessment data for those attending all clinics and those who receive school health, occupational health, public health, and home nursing services.

A thorough sexual history requires obtaining personal and sensitive information. It includes information about the types of relationships, the number of sexual partners and encounters, and the types of sexual behaviors practiced. The confidential nature of the information and how it will be used should be shared with the client to establish open communication and goal-directed interaction. Most clients feel uneasy disclosing such personal information. The nurse can ease this discomfort by remaining supportive and open during the interview to facilitate honesty about intimate activities. The nurse serves as a model for discussing sensitive information in a candid manner. When discussing precautions, direct and simple language should be used to describe specific behaviors. This encourages the client to openly discuss sexuality during this interaction and with future partners.

Nurses who are uncomfortable discussing topics such as sexual behavior or sexual orientation are likely to avoid assessing risk behaviors with the client. They will, consequently, be ineffective in identifying risks and helping clients modify risky behaviors. Nurses need to be adept at helping clients prevent and control STDs. Nurses can gain confidence in conducting sexual risk assessments by understanding their own values and feelings about sexuality and realizing that the purpose of the interaction is to improve the client's health. The nurse's comfort in discussing sexual behavior can be improved by using role playing to practice assessments of sexual and IDU behavior, and by contracting with clients to make behavior changes.

Identifying the number of sexual and injection drug-using partners and the number of contacts with these partners provides information about the client's risk. The chance of exposure decreases as the number of partners decreases, so people in mutually monogamous relationships are at low risk for acquiring STDs. You can gather this information by asking, "How many sex (or drug) partners have you had over the past 6 months?" Try to avoid basing assumptions about the sexual partner or partners on the client's sex, age, ethnicity, or any other factor. Stereotypes and assumptions about who people are and what they do are common problems that keep interviewers from asking the questions that lead to obtaining useful information. For example, it should not be taken for granted that a homosexual man always has more than one partner. Be aware also that the long incubation of HIV and the subclinical phase of many STDs lead some monogamous individuals to assume erroneously that they are not at risk.

EVIDENCE-BASED PRACTICE

Vaccination to prevent transmission of HPV has been recommended for several years for young men as well as women, with primary vaccination recommended for boys at 11-12 years and secondary vaccination to catch those never vaccinated through age 26. There is an emphasis on vaccination because half of new HPV infections occur in young people between the ages of 15 and 24.

In this study, nurse researchers surveyed 735 male college students (ages 18-25) who were sexually active (previously or currently) with men, women, or both, and examined their vaccination rates, personal perceptions of risk for sexually transmitted infections, and barriers to vaccination. Researchers collected both quantitative and qualitative data from the student participants, consisting of demographic data, vaccination rates, data about sexual practices, and qualitative data about perspectives on the HPV vaccination, such as why they had not received it, or why they may not have completed the three-dose vaccination.

The researchers found that, although the student participants engaged in risky sexual practices such as high number of lifetime sexual partners (mean 6.3) and over half either never using condoms (10%) or sometimes using condoms (41%), 93% of participants did not view themselves as being at risk for sexually transmitted infections. Multivariate analysis revealed that participants who always wore condoms were more likely to have received the vaccine, and the older the participant was, the less likely he was to have received the vaccine.

Quantitative data about the HPV vaccination focused on barriers to obtaining the vaccine, such as cost and inconvenience. Many participants had not heard of either HPV itself or the vaccine, or did not know that men could get the vaccine. The male participants also did not know about the link between oropharyngeal cancer and HPV for men, and only some participants knew about the link between cervical cancer and HPV for women.

Nurse Use

This study highlights the importance of education and awareness about HPV and the HPV vaccination for both men and women. Nurses can play a large role in information dissemination and vaccination promotion effort.

Fontenot HB, Fantasia HC, Charyk A, et al: Human papillomavirus (HPV) risk factors, vaccination patterns, and vaccine perceptions among a sample of male college students. *Journal of American College Health* 62(3):186-192, 2014. DOI: 10.1080/07448481.2013.872649.

It is important to identify whether the person has sexual contact with men, women, or both. This information can be obtained by simply asking, “Do you have sex with men, women, or both?” This lets the client know that the nurse is open to hearing about these behaviors, and thus the nurse is more likely to obtain information that is relevant to sexual practices and risk. Women who are exclusively lesbian are at low risk for acquiring STDs, but bisexual women may transmit STDs between male and female partners. In addition, it is possible for men to have sexual contact with other men and not label themselves as homosexual. Therefore, education to reduce risk that is aimed at homosexual men will not be heeded by men who do not see themselves as homosexual. In such situations the nurse can ask, “When was the last time you had sex with another man?”

Certain sexual practices are more likely to result in exposure to and transmission of STDs. Dangerous sexual activities include all unprotected intercourse (anal, oral, or vaginal), oral-anal contact, and insertion of finger or fist into the rectum.

These practices introduce a high risk of transmission of enteric organisms or result in physical trauma during sexual encounters. The nurse can obtain information about sexual encounters by asking, “Can you tell me the kinds of sexual practices in which you engage? This will help determine what risks you may have and the type of tests we should do.” Clients who engage in genital-anal, oral-anal, or oral-genital contact will need throat and rectal cultures for some STDs as well as cervical and urethral cultures.

HOW TO How to Effectively Obtain a Client's Sexual History

To be most effective, the nurse obtaining a client's sexual history should do the following:

- Remain supportive and open to facilitate honesty.
- Use terms the client will understand (be prepared to suggest multiple terms).
- Speak candidly so the client will feel comfortable talking.
- Ask open-ended questions in a nonthreatening and nonjudgmental manner.
- Acknowledge that many people are uneasy disclosing personal information.
- Use the Five P's Approach (CDC, 2010b). Sample questions in each category are:
 - Partners: “In the past 2 months, how many partners have you had sex with?”
 - Prevention of pregnancy: “What are you doing to prevent pregnancy?”
 - Protection from STDs: “What do you do to protect yourself from STDs and HIV?”
 - Practices: “To understand your risk for STDs, I need to understand the kind of sex you've had recently.”
 - Past history of STDs: “Have you ever had an STD?”

Drug use is linked to STD transmission in several ways. Drugs such as alcohol put people at risk because they can lower inhibitions and impair judgment about engaging in risky behaviors. Addictions to drugs may cause individuals to acquire the drug or money to purchase the drug through sexual favors. This increases both the frequency of sexual contacts and the chances of contracting STDs. Thus, the nurse should obtain information on the type and frequency of drug use and the presence of risk behaviors.

The administration of immunizations is another example of primary prevention, because they prevent infection. Of the diseases presented here, vaccines are available for human papillomavirus and hepatitis A and B.

Interventions

Interventions to prevent infection are aimed at preventing specific infections. These interventions can take several forms and include things such as education on how to prevent infection or the availability of vaccines. For example, on the basis of the information obtained in the sexual history and risk assessment just described, the nurse can identify specific education and counseling needs of the client. The nursing interventions focus on contracting with clients to change behavior and reduce their risk in regard to sexual practice.

Sexual Behavior

Sexual abstinence is the best way to prevent STDs. However, for many people, sexual abstinence is not realistic and providing instruction about how to make sexual behavior safer is critical. Safer sexual behavior includes masturbation, dry kissing, touching, fantasy, and vaginal and oral sex with a condom.

If used correctly and consistently, properly fitted condoms can prevent both pregnancy and most STDs because they prevent the exchange of body fluids during sexual activity. Condom failure may occur from incorrect use rather than condom failure. Thus, information about proper use and how to communicate about them with a partner is also necessary. The nurse has many opportunities to convey this information during counseling. Most agency protocols recommend the use of latex condoms. Some may be lubricated with nonoxynol-9, a spermicide. If used frequently, nonoxynol-9 may result in genital lesions, which may provide openings for viruses to enter the body.

Condom use may be viewed as inconvenient, messy, or decreasing sensation. Moreover, alcohol consumption may accompany sexual activity, which may also decrease condom use. The nurse can help clients become more skilled in discussing safer sex through role modeling and practicing communication skills through role play. Role-playing scenarios with partners who are reluctant to use condoms can help individuals prepare for situations before they occur.

Female condoms are a barrier to body fluid contact and therefore protect against pregnancy and STDs. The main advantage of the female condom is that its use is controlled by the woman. The FC2 Female Condom is the only female condom that is FDA approved for use in the United States. Since it is made of nitrile it is also useful if a latex sensitivity develops to male condoms. Symptoms of latex allergy include penile, vaginal, or rectal itching or swelling after use of a male condom or diaphragm. The female condom consists of a sheath over two rings, with one closed end that fits over the cervix. The condoms are often free at public health clinics, or can be purchased in boxes of multiple condoms, making the overall cost per condom less than \$1.50 each. [Figure 14-4](#) provides instructions on its insertion.

Clients should understand the importance of knowing the risk behavior of their sexual partners, including a history of IDU and STDs, sexual preference, and any current symptoms. Each sexual partner is potentially exposed to all the STDs of all the persons with whom the other partner has been sexually active.

Drug Use

IDU is risky because the potential for injecting bloodborne pathogens, such as HIV, HBV, and HCV exists when needles and syringes are shared. During IDU, small quantities of drugs are repeatedly injected. Blood is withdrawn into the syringe and is then injected back into the user's vein. Individuals should be advised against using injectable drugs and sharing needles, syringes, or other drug paraphernalia (a.k.a. works) ([CDC, 2014i](#)). If equipment is shared, it should be in contact with full-strength bleach for 30 seconds, and then rinsed with water

- 1 Use your thumb and middle finger, and squeeze the ring toward the bottom so that it becomes thin and narrow. If you squeeze the inner ring near the top, when you insert it, your hand will be in the way.

- 2 Push the inner ring into your vaginal canal, behind your pubic bone. You will feel the female condom slide into place. IF you can feel the inner ring, or IF it causes any pain or discomfort, the ring is not up high enough near the cervix. Don't worry, you can't push it too far inside.

- 3 Next, take your index finger, put it inside the condom, and push the condom up higher into the vagina. This way, the outer ring will be closer to the outside of your vagina. YES, it has to be on the outside of you, because HE has to go inside the condom.

- 4 The condom is in place. Be sure that:
 - Your partner puts his penis inside of the female condom
 - Enough lubricant so the penis slips easily inside and out
 - A new female condom for each sex act

FIG 14-4 Insertion and positioning of the female condom. (Reproduced from The Female Health Company, Chicago, IL.)

several times to prevent injecting bleach ([CDC, 2004](#)). This is a last-resort option.

People who inject drugs are difficult to reach for health care services. Effective outreach programs include using community peers, increasing accessibility of drug treatment programs

combined with HIV testing and counseling, and encouraging long-term repeat contacts after completion of the program.

Community Outreach

Because of the illegal nature of injectable drugs and the poverty associated with HIV, many people at risk have neither the inclination nor the resources to seek health care. Nurses may work to establish programs within communities because the opportunities for counseling on the prevention of HIV and other STDs are increased by bringing services into the neighborhoods of those at risk. Workers go into communities to disseminate information on safer sex, drug treatment programs, and discontinuation of drug use or safer drug use practices (e.g., using new needles and syringes with each injection). Some programs provide sterile needles and syringes, condoms, and literature about testing services.

Community Education

Education of well populations about prevention of communicable diseases by a nurse educator is an example of primary prevention. Relevant information about the modes of transmission, testing, availability of vaccines, and early symptoms can be provided to groups in the community. Providing accurate health information to large numbers of people is vital for preventing the spread of STDs. Nurses can provide educational sessions to community groups about HIV and other STDs. Such educational sessions are most effective in settings where groups normally meet and may include schools, businesses, and churches.

When addressing groups about HIV infection, it is important to discuss the number of people infected with HIV, the number of people living with AIDS, modes of transmission of the virus, how to prevent infection, testing services, common symptoms of illness, the need for a compassionate response to those afflicted, and available community resources. Teaching about other STDs can be incorporated into these presentations because the mode of transmission (sexual contact) is the same. Other information on these diseases can include the distribution and incidence in society, and the consequences of the infection for individuals and families.

Evaluation

Evaluation is based on the extent of vaccination within a population, whether risky behavior has changed to safe behavior, and, ultimately, whether illness is prevented. Condom use can be evaluated for consistency of use if the client is sexually active. Other behaviors, such as abstinence or monogamy, can be evaluated for their implementation. At the community level, behavioral surveys can be done to measure reported condom use and condom sales, and measures of disease incidence and prevalence can be calculated to evaluate the effectiveness of intervention.

Secondary Prevention

Secondary prevention includes screening for diseases to ensure their early identification, treatment, and follow-up with contacts to prevent further spread. In general, client teaching and counseling should include education about avoiding self-reinfection, managing symptoms, and preventing the infection of others.

Testing and Counseling for HIV

Universal testing for HIV infection should be routine for all clients aged 15 to 65 years (USPSTF, 2013). Younger adolescents and older adults who are at increased risk should be screened as well (CDC, 2013q; USPSTF, 2013). Therefore, routine HIV testing should be a part of all annual physicals, labs for every pregnancy, and all hospital visits, without securing special permission. Clients can decline or “opt out” of HIV testing, but the benefits of testing are considerable. For persons who have engaged in high-risk behavior, the nurse should recommend annual HIV testing (Box 14-3). Individuals with the following characteristics are considered at risk and should be offered HIV testing: those with a history of STDs (which are transmitted through the same behavior and may decrease immune functioning), multiple sex partners, or IDU; those who have unprotected intercourse (i.e., without using a condom or pre-exposure prophylaxis [PrEP]) (CDC, 2013m); those who have intercourse with someone who has another partner and those who have had sex with a prostitute; men with a history of homosexual or bisexual activity; and those who have been a sexual partner to anyone in one of these groups.

Testing enables clients to benefit from early detection and treatment, as well as risk reduction education. If HIV infection is discovered before the onset of symptoms, early monitoring of the disease process and CD4 lymphocyte counts or viral loads is indicated. In addition, prophylactic therapy with antiretroviral therapy and/or antibiotics may begin in order to delay the onset of symptomatic illness.

BOX 14-3 Who Should Be Advised to Receive HIV Testing and Counseling?

For clients in all health care settings:

- HIV screening is recommended for clients in all health care settings after the client is notified that testing will be performed unless the patient declines (opt-out screening).
- Persons at high risk for HIV infection should be screened for HIV at least annually.
- Separate written consent for HIV testing should not be required; general consent for medical care should be considered sufficient to encompass consent for HIV testing.
- Prevention counseling should not be required with HIV diagnostic testing or as part of HIV screening programs in health care settings.

For pregnant women:

- HIV screening should be included in the routine panel of prenatal screening tests for all pregnant women.
- HIV screening is recommended after the client is notified that testing will be performed unless the client declines (opt-out screening).
- Separate written consent for HIV testing should not be required; general consent for medical care should be considered sufficient to encompass consent for HIV testing.
- Repeat screening in the third trimester is recommended in certain jurisdictions with elevated rates of HIV infection among pregnant women.

From Centers for Disease Control and Prevention: Revised recommendations for HIV testing of adults, adolescents, and pregnant women in health-care settings, *MMWR Morbidity and Mortality Weekly Report* 55(RR-14), 2006.

BOX 14-4 Responsibilities of Persons Who Are HIV Infected

- Have regular medical evaluations and follow-ups.
- Do not donate blood, plasma, body organs, other tissues, or sperm.
- Take precautions against exchanging body fluids during sexual activity.
- Inform sexual or injection drug-using partners of the potential exposure to HIV, or arrange for notification through the health department.
- Inform health care providers of the HIV infection.
- Consider the risk of perinatal transmission and follow up with contraceptive use.

Post-test Counseling. Persons who have a negative test should be counseled about risk reduction activities to prevent any future transmission. Clients should understand that the test may not be truly negative because it does not reveal infections that may have been acquired within the several weeks before the test. Evidence of HIV antibody takes from 6 to 12 weeks to develop. Newer immunoassay tests can produce results in as little as three weeks (CDC, 2013q)

Clients must be aware of the ways viral transmission occurs, and how to avoid infection. All clients who are antibody positive should be counseled about the need to reduce their risks and notify partners. If the client is unwilling or hesitant to notify past partners, the nurse will do partner notification (or contact tracing), as described later in this chapter. Clients should seek treatment from their primary health care provider so physical evaluation can be performed and, if indicated, antiviral or other therapies begun. Box 14-4 describes the responsibilities of individuals who are HIV positive.

Psychosocial counseling is indicated when positive HIV test results precipitate acute anxiety, depression, or suicidal ideation. The client should be informed about available counseling services. The person should be cautioned to consider carefully who should be informed of the test results. Many individuals have told others about their HIV-positive test, only to experience isolation and discrimination. Plans for the future should be explored, and clients should be advised to avoid stress, drugs, and infections in order to maintain optimal health.

Partner Notification and Contact Tracing

Partner notification, also known as contact tracing or disclosure, is an example of a population-level intervention aimed at controlling communicable diseases. Partner notification programs usually occur in conjunction with reportable disease requirements and are carried out by most health departments. It involves confidentially identifying and notifying exposed individuals of clients who are found to have reportable diseases, especially sexually transmitted diseases.

Individuals diagnosed with a reportable STD are asked to provide the names and locations of all partners so that these individuals can be informed of their exposure, receive counseling, and obtain the necessary referral and/or treatment. The originally diagnosed (index case) clients may be encouraged to notify their partners (can be sexual and/or injection drug partners) and to encourage them to seek treatment. If the client agrees to do so, suggestions on how to inform their partners

LINKING CONTENT TO PRACTICE

This chapter emphasizes the epidemiology and prevention of selected communicable diseases, as well as the public health nursing services provided to clients. *The Council on Linkages Between Academia and Public Health Practice (2010)* Domains and Core Competencies are addressed through activities in caring for clients with communicable diseases. Examples of how these eight domains are used in providing nursing care to clients with communicable disease are as follows:

Domain #1, Analytic/Assessment Skills, is achieved through the review of the incidence and prevalence rates of communicable diseases to determine population health status.

Domain #3, Communication Skills, is applied when PHNs teach how to prevent and treat infections.

Domain #4, Cultural Competency Skills, is met through understanding the various social and behavioral factors that make health care acceptable to diverse populations (groups of people who are diverse in terms of culture, socioeconomic status, education level, race, gender, age, ethnicity, sexual orientation, profession, religious affiliation, and mental/physical capability).

From Public Health Foundation, Council on Linkages:

Core Competencies for Public Health Professionals, 2008. Available at <http://www.phf.org/link/corecompetencies.htm>. Accessed March 2010.

and how to deal with possible reactions may be explored. In some instances, clients may feel more comfortable if the nurse notifies those who are exposed. If clients contact their partners about possible infection, the nurse contacts health care providers or clinics to verify positive test results or microscopic findings and treatment of the index case.

If the originally diagnosed client prefers not to participate in notifying partners, the public health nurse contacts the partners by phone, certified delivery letter, or home visit, depending on the nature of the individual circumstances, and counsels them to seek evaluation and treatment. Many times the client is treated for the sexually transmitted infection at the health department. At this appointment, the client is offered literature regarding the STD for which they need treatment, receives risk-reduction counseling, and is offered testing for the other STDs. The identity of the infected client who names sexual and injection drug-using partners cannot be revealed. Maintaining confidentiality is critical with all STDs.

Tertiary Prevention

Tertiary prevention can apply to many of the chronic viral STDs and TB. For viral STDs, much of this effort focuses on managing symptoms and maintaining psychosocial support. Many clients report feeling contaminated and thus feel lower self-worth. Support groups may be available to help clients cope with chronic STDs, such as genital herpes or genital warts.

Directly Observed Therapy

In **directly observed therapy** (DOT) programs for TB medication nurses observe and document individual clients taking their TB drugs. When clients prematurely stop taking TB medications, there is a risk of the TB becoming resistant to the medications. This can affect an entire community of people who are susceptible to this airborne disease. Health professionals share in the responsibility of adhering to treatment, and

DOT ensures that TB-infected clients have adequate medication. Thus, DOT programs are aimed at the population level to prevent antibiotic resistance in the community and to ensure effective treatment at the individual level. Many health departments have DOT home health programs to ensure adequate treatment (CDC, 2012c). Directly observed treatment, short course (DOTS) is a variation applied worldwide to combat multidrug-resistant TB (WHO, 2010a).

The management of AIDS in the home may include monitoring physical status and referring the family to additional care services for maintaining the client in the home. Case management is important in all phases of HIV infection. It is especially important to ensure that clients have adequate services to meet their needs. This may include ensuring that medication can be obtained through identifying funding resources, maintaining infection control standards, reducing risk behaviors, identifying sources of respite care for caretakers, or referring clients for home or hospice care. Nursing interventions include teaching families about managing symptomatic illness by preventing deteriorating conditions such as diarrhea, skin breakdown, and inadequate nutrition.

Standard Precautions

It is important to teach caregivers about infection control in the home. Clients, families, friends, and others may express

concerns about the transmission of HIV. Whereas fear may be expressed by some, others who are caring for loved ones with HIV may not take adequate precautions, such as glove wearing, because of concern about appearing as though they do not want to touch a loved one. Others may believe myths that suggest they cannot be infected by someone they love.

Standard precautions must be taught to caregivers in the home setting. All blood and articles soiled with body fluids must be handled as if they were infectious or contaminated by bloodborne pathogens. Gloves should be worn whenever hands might touch nonintact skin, mucous membranes, blood, or other fluids. A mask, goggles, and gown should also be worn if there is potential for splashing or spraying of infectious material during any care. All protective equipment should be worn only once and then disposed of. If the skin or mucous membranes of the caregiver come in contact with body fluids, the skin should be washed with soap and water, and the mucous membranes should be flushed with water as soon as possible after the exposure. Thorough handwashing with soap and water—a major infection control measure—should be conducted whenever hands become contaminated and whenever gloves or other protective equipment (e.g., mask, gown) is removed. Soiled clothing or linen should be washed in a washing machine filled with hot water using bleach as an additive and dried on a hot-air cycle of a dryer.

PRACTICE APPLICATION

Yvonne Jackson is a 20-year-old woman who visits the Hope-town City Health Department's maternity clinic. Examination reveals she is at 14-weeks' gestation. She is single but has been in a steady relationship for the past 6 months with Ramón. She states that she has no other children. A routine test taken during the initial prenatal visit is an HIV test; the results are positive.

Ms. Jackson is shocked and emotionally distraught about the positive test results. Understanding that the client will not be able to concentrate on all of the questions and information that

need to be covered, the nurse prioritizes essential information to obtain and provide during this visit.

- A. List the relevant factors to consider on the basis of this information.
- B. What questions do you need to ask with regard to controlling the spread of HIV to others?
- C. What information is most important to give to Ms. Jackson at this time?
- D. What follow-up does the nurse need to arrange for this client?

Answers can be found on the Evolve site.

KEY POINTS

- Nearly all communicable diseases discussed in this chapter are preventable because they are transmitted through specific, known behaviors.
- STDs are among the most serious public health problems in the United States. Not only is there an increased incidence of drug-resistant gonococcal infection, but other STDs, such as HPV (genital warts), HIV, and HSV (genital herpes), are associated with cancer.
- STDs affect certain groups in greater numbers. Factors associated with risk include being less than 25 years of age, being a member of a minority group, living in an urban setting, being poor, and using crack cocaine.
- The increasing incidence, morbidity, and mortality of specific communicable diseases highlight the need for nurses to educate clients about ways to prevent communicable diseases.
- Many STDs do not produce symptoms in clients.
- Aside from death, the most serious complications caused by STDs are pelvic inflammatory disease, infertility, ectopic pregnancy, neonatal morbidity and mortality, and neoplasia.
- Hepatitis A is often silent in children, and children are a significant source of infection to others; thus, the use of the vaccination in children has caused a reduction in the number of cases.

KEY POINTS—cont'd

- Hepatitis C is the most common bloodborne pathogen in the United States.
- The emergence of multidrug-resistant TB has prompted the use of directly observed therapy (DOT) to ensure adherence with drug treatment regimens.
- Early detection of communicable diseases is important because it results in early treatment and prevention of additional transmission to others. Treatment includes effective medications, stress reduction, and proper nutrition.
- Partner notification, or contact tracing, is done by identifying, contacting, and ensuring evaluation and treatment of

persons exposed to sexual and injectable drug—using partners. Contact tracing is also conducted with TB and HAV.

- HIV infection has created an entirely new group of people needing health care. This rapidly growing population is straining a health care system that is already unable to meet the needs of many.
- Most of the care (both home and outpatient) that is provided for HIV is done within the community setting, which reduces direct health care costs but increases the need for financial support of home and community health services.

CLINICAL DECISION-MAKING ACTIVITIES

1. Identify sources of TB treatment in your community. Is there a DOT program available through the health department or home health agency? What factors make TB infection a difficult problem?
2. To whom does one report communicable diseases, such as HAV, in your community? How is this information given?
3. Identify the number of reported cases of AIDS and the number of reported cases of HIV infection within your state

and locale (if reportable in your state). How are the cases distributed by age, sex, geographic location, and ethnicity?

4. Identify the location(s) of HIV testing services in your community. Are the test results anonymous or confidential? Describe how and to whom the results are reported.
5. Form small groups and role play a nurse–client interaction involving risk assessment and counseling regarding safer sex and injection drug–using practices.

Evidence-Based Practice

Marcia Stanhope, PhD, RN, FAAN

Dr. Marcia Stanhope is currently an Associate of the Tufts and Associates Search Firm, Chicago, Ill. She is also a consultant for the nursing program at Berea College, Kentucky. She has practiced community and home health nursing, has served as an administrator and consultant in home health, and has been involved in the development of two nurse-managed centers. At one time in her career, she held a public policy fellowship and worked in the office of a U.S. Senator. She has taught community health, public health, epidemiology, policy, primary care nursing, and administration courses. Dr. Stanhope formerly directed the Division of Community Health Nursing and Administration and served as Associate Dean of the College of Nursing at the University of Kentucky. She has been responsible for both undergraduate and graduate courses in population-centered nursing. She has also taught at the University of Virginia and the University of Alabama, Birmingham. During her career at the University of Kentucky she appointed to the Good Samaritan Foundation Chair and Professorship in Community Health Nursing, and was honored with the University Provost's Public Scholar award. Her presentations and publications have been in the areas of home health, community health and community-focused nursing practice, as well as primary care nursing.

OBJECTIVES

After reading this chapter, the student should be able to do the following:

1. Define *evidence-based practice*.
2. Understand the history of evidence-based practice in health care.
3. Analyze the relationship between evidence-based practice and the practice of nursing in the community.
4. Provide examples of evidence-based practice in the community.
5. Identify barriers to evidence-based practice.
6. Apply evidence-based resources in practice.

Appropriate Evidence-Based Practice Methods for
Population-Centered Nursing Practice

Healthy People 2020 Objectives

Example of Application of Evidence-Based Practice to
Public Health Nursing

Emphasis on evidence-based practice (EBP) is a standard to be met in health care delivery in the United States. It is a relevant approach to providing the highest quality of health care in all settings, which will result in improved health outcomes. EBP is important for all professionals who work in social and health care environments, regardless of the client or the setting with which professionals are dealing, including public health nurses who work with populations. Emphasis on EBP has resulted from increased expectations of consumers, changes in health care economics, increased expectations of accountability, advancements in technology, the knowledge explosion fueled by the Internet, and the growing number of lawsuits occurring when there is injury or harm as a result of practice decisions that are not based on the best available evidence (Makic et al, 2014). Nurses at all levels have an opportunity to improve the practice of nursing and client outcomes.

The Institute of Medicine has set a goal that by 2020, the best available evidence will be used to make 90% of all health care decisions, yet most nurses continue to be inconsistent in implementing EBP. An even greater concern in public health is that the field is lagging behind in developing evidence-based guidelines for the community setting. It is important to recognize that regardless of the level of education, undergraduate or graduate, nurses can be involved in the development, implementation, and evaluation of the effects of EBP (Florin et al, 2012; Gerrish and Cooke, 2013; Mattila et al, 2013; Merrill et al, 2013; Sprayberry, 2014).

Comprehensive databases are available through various Internet sites to assist nurses in applying the most recent best evidence to their clinical practice, like the Cochrane Library Database, the Centers for Disease Control and Prevention: Guide to Community Preventive Services, and others. (See the WebLinks for this chapter on the book's Evolve website.)

DEFINITION OF EVIDENCE-BASED PRACTICE

The term *evidence-based* was first attributed to Gordon Gyatt, a Canadian physician at McMaster University in 1992 (Evidence Based Medicine Working Group, 1992). The term was first applied in medicine to begin the development of new ways of guiding professional decision making by using the best available evidence. Because the concept was developed in medicine, some of the first definitions focused on evidence-based medicine.

The definition of **evidence-based medicine** by Sackett and associates (Sackett et al, 1996) became the industry standard. Sackett et al (1996) defined evidence-based medicine as “the conscientious, explicit, and judicious use of current best

evidence in making decisions about the care of individual clients” (p. 71). Without current best external evidence, they said, “practice risks become rapidly out of date, to the detriment of clients” (Sackett et al, 1996, p. 72). A more succinct definition was proposed as the conscientious use of the current best evidence in making decisions about patient care (Sackett et al, 2000).

Adapting the definition by Sackett et al (1996), Rychetnik et al (2003) defined **evidence-based public health** as “a public health endeavor in which there is an informed, explicit, and judicious use of evidence that has been derived from any of a variety of science and social science research and evaluation methods” (p. 538). Brownson et al (2009) expanded the definition of evidence-based public health to include “making decisions on the basis of the best available evidence, using data and information systems, applying program planning frameworks, engaging the community in decision making, conducting evaluations, and disseminating what has been learned” (p. 175).

In a position statement on EBP, the Honor Society of Nursing, Sigma Theta Tau International, defined **evidence-based nursing** as “an integration of the best evidence available, nursing expertise, and the values and preferences of the individuals, families, and communities who are served” (Honor Society of Nursing, Sigma Theta Tau International, 2005). The definition of EBP continues to be broadened in scope and now includes a life-long problem-solving approach to clinical practice, integrating both external and internal evidence to answer clinical questions and to achieve desired client outcomes (Melnyk and Fineout-Overholt, 2011). *External evidence* includes research and other evidence such as reports and professional guidelines for example, whereas *internal evidence* includes the nurse's clinical experiences and the client's preferences.

Applied to nursing, **evidence-based practice** includes the best available evidence from a variety of sources including research studies, nursing experience and expertise, and community leaders. Culturally and financially appropriate interventions need to be identified when working with communities. The use of evidence to determine the appropriate use of interventions that are culturally sensitive and cost-effective is essential.

HISTORY OF EVIDENCE-BASED PRACTICE

During the mid to late 1970s, there was growing consensus among nursing leaders that scientific knowledge should be used as a basis for nursing practice. During that time, the Division of Nursing in the U.S. Public Health Service began funding research utilization projects. **Research utilization** has been defined as

EVIDENCE-BASED PRACTICE

Chronic diseases are considered a major disease burden in the United States, accounting for 75% of all medical care costs, and 7 of 10 deaths per year. Diabetes is one of the chronic diseases considered to have a major public health impact. To meet the *Healthy People 2010* goal of eliminating racial and ethnic disparities, the CDC created a demonstration project called REACH. Community projects were funded to develop, implement, and evaluate community action plans to improve health care and outcomes for racial and ethnic groups. One funded project was the Charleston and Georgetown, South Carolina Diabetes Coalition. The coalition is described as a community campus partnership with the Medical College of South Carolina and community agencies, organizations, and neighborhoods. The project serves about 12,000 African Americans with diabetes.

To implement the project, the coalition looked at the Chronic Care Model and after a systematic review of the literature, decided to expand the model and developed the Community Chronic Care Model. The goals of the project were to use community-based participatory actions to decrease disparities, improve health systems using the continuous quality improvement process, educate and empower communities, and build and sustain interpersonal and interorganizational links among communities and health professionals to improve diabetes outcomes and eliminate disparities. Local coalitions were developed, funds were provided to sustain diabetes activities, two new health facilities were opened in areas of need, and free medications were offered as samples.

One of the specific health outcomes was to reduce amputations among African American males. The University's college of nursing participated by developing and marketing a self-paced foot care educational program to train professionals in foot care. Lay educators were trained and health professionals provided patient care to the uninsured. A center for community health partnerships was established in the college of nursing and is a part of the ongoing plans for the college.

Nurse Use

Nurses can be active in establishing small groups of partners in the community to develop a plan to meet a health care need, or participate in larger coalitions like this one. The focus on developing projects to meet needs and improve health care outcomes must be based on the evidence that shows these partnerships are needed to solve the health care need and improve health care outcomes (Jenkins et al, 2010).

Jenkins C, Pope C, Magwood G: Expanding the chronic care framework to improve diabetes management: The REACH Case Study. *Prog Community Health Partnersh* 4(1):65–79, Spring 2010.

“the process of transforming research knowledge into practice” (Stetler, 2001, p. 272) and “the use of research to guide clinical practice” (Estabrooks, Winther, and Derksen, 2004, p. 293).

Three projects funded by the Division of Nursing received the most attention and were the most influential in shaping nursing's view of using research to guide practice: the Nursing Child Assessment Satellite Training Project (NCAT) (Barnard and Hoehn, 1978; King, Barnard, and Hoehn, 1981), the Western Interstate Commission for Higher Education (WICHE) Regional Program for Nursing Research Development (WICHEN) (Krueger, 1977; Krueger, Nelson, and Wolanin, 1978; Lindeman and Krueger, 1977), and the Conduct and Utilization of Research in Nursing Project (CURN) (Horsley, Crane, and Bingle, 1978; Horsley et al, 1983). Using very different approaches and methods, each project tested interventions to facilitate research use in practice.

Although nursing continued to focus on research utilization projects, medicine also began to call for physicians to increase their use of scientific evidence to make clinical decisions. In the late 1970s, David Sackett, a medical doctor and clinical epidemiologist at McMaster University, published a series of articles in the *Canadian Medical Association Journal* describing how to read research articles in clinical journals. The term *critical appraisal* was used to describe the process of evaluating the validity and applicability of research studies (Guyatt and Rennie, 2002). Later, Sackett proposed the phrase “bringing critical appraisal to the bedside” to describe the application of evidence from medical literature to client care. This concept was used to train resident physicians at McMaster University and evolved into a “philosophy of medical practice based on knowledge and understanding of the medical literature supporting each clinical decision” (Guyatt and Rennie, 2002, p. xiv).

With Gordon Guyatt as Residency Director of Internal Medicine at McMaster, the decision was made to change the program to focus on “this new brand of medicine” that Guyatt eventually called *evidence-based medicine* (Guyatt and Rennie, 2002, p. xiv). Guyatt and Rennie described the goal of evidence-based medicine as being “aware of the evidence on which one's practice is based, the soundness of the evidence, and the strength of inference the evidence permits” (2002, p. xiv).

PARADIGM SHIFT IN USE OF EVIDENCE-BASED PRACTICE

In 1992 the Evidence-Based Medicine Working Group published an article in the *Journal of the American Medical Association* expanding the concept of evidence-based medicine and calling it a *paradigm shift*. A paradigm shift simply means a change from old ways of knowing to new ways of knowing and practicing. Ways of knowing in nursing have included the empirical knowledge, or the science of nursing; the aesthetic knowledge, or the art of nursing; personal knowledge, or interpersonal relationships and caring; and ethical knowledge, or moral and ethical codes of conduct usually established by professional organizations (Bradshaw, 2010; Sandström et al, 2011). Nursing practice in the past often focused less on science and more on the other four ways of knowing described here.

According to the Working Group (Evidence-Based Medicine Working Group, 1992), the old paradigm viewed unsystematic clinical observations as a valid way for “building and maintaining” knowledge for clinical decision making (p. 2421). In addition, principles of pathophysiology were seen as a “sufficient guide for clinical practice” (p. 2421). Training, common sense, and clinical experience were considered sufficient for evaluating clinical data and developing guidelines for clinical practice. The Working Group cited developments in research over the past 30 years as providing the foundation for the paradigm shift and a “new philosophy of medical practice” (p. 2421).

The new paradigm, evidence-based medicine, acknowledged clinical experience as a crucial, but insufficient, part of clinical decision making. Systematic and unbiased recording of clinical observations in the form of research will increase confidence in the knowledge gained from clinical experience. Principles of

pathophysiology were seen as necessary but not sufficient knowledge for making clinical decisions. The Working Group emphasized that physicians needed to be able to critically appraise the research literature in order to appropriately apply research findings in practice. Knowledge gained from authoritative figures was also deemphasized in the new paradigm (Working Group, 1992).

In the years since the Working Group began, the term *evidence-based practice* has been proposed as a term to integrate all health professions. The underlying principle was that high-quality care is based on evidence rather than on tradition or intuition (Beyers, 1999).

Nurses have always used various resources for problem solving. Intuition, trial and error, tradition, authority, institutional standards, prior knowledge, and clinical experience have often been used as the basis for decision making in clinical settings. However, not all of these resources are reliable and all have not consistently produced desired outcomes (Bradshaw, 2010; Sandström et al, 2011). A procedure performed based on intuition or trial and error might be performed successfully sometimes and not at other times. For example, tradition and authority, which comes from texts and policy and procedure manuals, can lead to faulty clinical decision making.

Institutional standards are developed by accrediting agencies (e.g., The Joint Commission), by licensing agencies, and by professional organizations. These standards have been developed in the past primarily by expert opinion and past experiences. The standards may not reflect the best practices in the current environment or from the literature.

Although prior knowledge gained in educational programs, through continuing education, or through experience can be a good teacher, it can also contain bias and quickly become outdated unless a nurse participates in constantly refreshing knowledge. For example, just because a nurse has experience in successfully performing an intervention a certain way today does not mean it is the best way or that it will be successful every time and in the future unless practices are changed based on the most current data.

When EBP was first emphasized in medicine, the focus was on the answer to clinical questions concerning an individual client problem in order to provide the best diagnosis to implement the best treatment. When nursing became involved in EBP, the focus seemed to shift to answering a clinical question about a health problem experienced by a group of clients (Levin et al, 2010).

The current nursing literature on EBP is primarily associated with applications in the acute and primary care settings and little is reported about its use in community settings. However, the basic principles of EBP can be applied at the individual level or at the community level. Although definitions of EBP vary widely in the literature, the common thread across disciplines is the application of the best available evidence to improve practice (Makic et al, 2014).

EBP has been described as both a process and a product (Bradshaw, 2010; Sandström et al, 2011; Scott and McSherry, 2009). The product is the use of evidence to make practice changes, whereas the process is a systematic approach to

locating, critiquing, synthesizing, translating, and evaluating evidence upon which to base practice changes. Systematic reviews of research evidence can potentially assist nurses in putting evidence into practice. Systematic reviews, also known as evidence summaries, provide reliable evidence-based summaries of past research, making it easier for health care professionals to stay current on best practices without having to read a lot of research papers (Holly, Salmund, and Saimbert, 2011).

Scott and McSherry (2009) engaged in a process using an extensive literature review to arrive at a definition of evidence-based nursing and to differentiate the definition from evidence-based practice. Based on their review they arrived at the following definition: evidence-based nursing is a process whereby evidence, nursing theory, and the nurse's clinical expertise are evaluated and used, in conjunction with the client's involvement, to make critical decisions about the best care for the client. Continuous evaluation of the implementation of care is essential to make clinical decisions about client care for the best possible outcomes. In Chapter 9 there is extensive discussion of an example of how public health nurses have developed and used evidence on which to base population-centered nursing.

TYPES OF EVIDENCE

No matter which definition of EBP is supported, what counts as evidence has been the issue most hotly debated. A hierarchy of evidence, ranked in order of decreasing importance and use, has been accepted by many health professionals. The double-blind **randomized controlled trial (RCT)** generally ranks as the highest level of evidence followed by other RCTs, nonrandomized clinical trials, quasi-experimental studies, case-controlled reports, qualitative studies, and expert opinion (Russell-Babin, 2009). Some nurses would argue that this hierarchy ignores evidence gained from clinical experience. However, the definition of evidence-based nursing presented previously indicates that clinical expertise as evidence, when used with other types of evidence, is used to make clinical decisions. Also in the hierarchy of evidence, expert opinion can be gained from non-research-based published articles, professional guidelines, national guidelines, organizational opinions, and panels of experts, as well as the nurse's clinical expertise.

Because it is difficult to find or perform RCTs in the community, other types of evidence have been highlighted as the best evidence in public health literature on which to base evidence-based public health practice: scientific literature found in systematic reviews, scientific literature used or quoted in one or more journal articles, public health surveillance data, program evaluations, qualitative data obtained from community members and other stakeholders, media/marketing data such as the results of a media campaign to reduce smoking, word of mouth, and personal/professional experience (Brownson et al, 2009; Jacobs et al, 2012).

Within public health practice, guidelines for finding and using evidence include the following:

- Engaging the community in assessment and decision making;
- Using data and information systems systematically;

- Making decisions on the basis of the best available peer-reviewed evidence (both quantitative and qualitative);
- Applying program planning frameworks (often based in health behavior theory);
- Conducting sound evaluation; and
- Disseminating what is learned (Jacobs et al, 2012).

FACTORS LEADING TO CHANGE

EBP represents a cultural change in practice. It provides an environment to improve both nursing practice and client outcomes. Nursing is known for providing care based on environmental and client assessments; critical observations; development of questions or hypotheses to be explored; collecting data from the environment through community or organizational assessments, or from the client through history, physical assessment, and review of past health records; analyzing the data to develop plans of care, whether for the individual client, family, group or community; and drawing conclusions upon which to base care for the purpose of improving client outcomes (Gerrish and Cooke, 2013). However, several factors have been identified in the literature that support implementation of EBP or that will need to be overcome for nursing and other disciplines to successfully implement EBP. These factors include the following:

- Knowledge of research and current evidence
- Ability to interpret the meaning of the evidence
- Individual professional's characteristics, such as a willingness to change, or personal viewpoints about the quality and credibility of evidence
- Commitment of the time needed to implement EBP and to engage in education and directed practice
- The hierarchy of the practice environment and the level of support of managers and the ability to engage in autonomous practice,
- The philosophy of the practice environment and the willingness to embrace EBP
- The resources available to engage in EBP, such as amount of work, proper equipment, computer-based EBP programs, and information systems
- The practice characteristics, such as leadership and colleague attitudes
- Links to outside supports such as teaching facilities like a teaching health department or a university
- Political constraints and the lack of relevant and timely public health practice research (Asadoorian Hearson, Satyanarayana, and Ursel, 2010; Brownson et al, 2009; Gerrish and Cooke, 2013)

BARRIERS TO EVIDENCE-BASED PRACTICE

Although a community agency may subscribe in theory to the use of EBP, actual implementation may be affected by the realities of the practice setting. Community-focused nursing agencies may lack the resources needed for its implementation in the clinical setting, such as time, funding, computer resources, and knowledge. Nurses may be reluctant to accept findings and feel threatened when long-established practices are questioned. Cost

can also be a barrier if the clinical decision or change will require more funds than the agency has available. Compliance can be a barrier if the client will not follow the recommended intervention. Public health departments are moving toward EBP and are seeking accreditation through the national public health accreditation board. The accreditation process began in 2011. As of March 2014, 31 public health departments had achieved national accreditation (Public Health Accreditation Board, 2014).

STEPS IN THE EVIDENCE-BASED PRACTICE PROCESS

EBP is a philosophy of practice that respects client values. Melnyk and associates (2010) have described a seven-step EBP process:

0. Cultivating a spirit of inquiry
1. Asking clinical questions
2. Searching for the best evidence
3. Critically appraising the evidence
4. Integrating the evidence with clinical expertise and client preferences and values
5. Evaluating the outcomes of the practice decisions or changes based on evidence
6. Disseminating EBP results
