Palliative rehabilitation is patient-centered, with an emphasis on collaborative goal-setting. Patients and therapists maintain shared decision-making throughout the treatment process by co-creating goals based on what is meaningful and attainable to the patient and taking into account prognosis. Therapists ensure that goals are collaborative by considering patient needs, motivations, and desires. Following these principles enables therapists to address patients' valued tasks, functions, and goals. This allows therapists to build trust and rapport, which then results in patients achieving maximum benefit from the palliative process.

Case Study: Communication and Collaboration

During his clinic visits, JP's nurses recognized the impact his progressive weakness and symptom burden had on his function, and, after educating him about the rehabilitation services available, they agreed to obtain a referral from his oncologist for rehabilitation. In his initial outpatient evaluations, he shared his frustrations regarding the debilitating effects of his condition. He experienced decreased mobility, multiple falls, difficulty managing his home and coaching boxing due to significant fatigue, and challenges in talking and sustaining safe feeding methods. He and his therapists were able to assess his needs and determine the appropriate treatment plans to address his deficits. PT assessed impairments in gait, strength, and balance that were contributing to his falls. OT assessed his routines of home maintenance and coaching and created goals to manage fatigue and adapt the way he performed relevant tasks. SLP addressed his difficulty swallowing and focused on identifying specific postural strategies to improve his airway protection rather than modifying his diet to include thick liquid. His therapists and he developed strong therapeutic relationships built on collaborative goals to support the most independent and meaningful functions.

As he experienced more frequent hospitalizations with the progression of his disease, his therapists provided ongoing inpatient support, creating new goals to prevent further decline while managing symptoms. RT was introduced into his care to support his goals of maintaining leisure engagement and coping through his prolonged hospitalizations. While he had hoped to recover to his baseline during his final admission (e.g., walking and eating normally), he understood this was infeasible; however, his therapists helped him preserve his sense of identity and QOL as much as he could toward the end of life.

Addressing Disability

Palliative rehabilitation helps patients address the disability that occurs as an illness advances so that they can maintain optimal function and physical health. Therapists design treatment plans to minimize decline in function by remediating deficits when appropriate or compensating abilities when losses become permanent. Their efforts focus on preventing the impact of disability throughout all stages of care, so that patients can continue to function in their desired manner while reducing caregiver burden.

Physical Activity

Engagement in physical activity can help patients address loss of physical abilities at any stage of disease. Physical therapists address these issues through exercise programs, gait and balance training, activity modifications, and provision of appropriate durable medical equipment (DME) (e.g., walkers, wheelchairs, lifts, etc.). Physical interventions that focus on maximizing/maintaining physical abilities and mobility can prevent the progression of weakness, allowing patients to remain physically active in their environments. Patients receiving palliative care who engage in structured physical activity can improve their functional levels, satisfaction with their abilities, and QOL, as well as improve their likelihood to discharge home as opposed to a facility.[7] These programs also offer multi-aspect interventions that are tailored to each patient and his or her specific needs, such as a patient's particular levels in strength, endurance, balance, posture, and joint health.[10,11] Patients who engage in these types of programs, such as routines consisting of warm-up, circuit/strength training, balance exercises, and cool-down, can demonstrate improvements in their physical abilities compared to remaining sedentary.[10,11]

Function and Engagement

Activities of Daily Living

Occupational therapists help patients retain their self-care abilities and performance for basic activities of daily living (ADLs) such as dressing, grooming, bathing, personal device care, and sexual activity. Patients learn strategies such as modified physical techniques to transfer to a toilet or incorporate proper body mechanics during a shower, which are important in enhancing independence and ensuring safety. Occupational therapists provide recommendations and training in adaptive equipment, such as how to use a universal cuff to compensate for loss of hand grasp when trying to handle utensils during feeding or how to utilize magnifying tools to assist with applying makeup when vision declines. They also help patients perform self-care routines in an efficient manner by integrating energy conservation principles to minimize pain or fatigue during the process. These strategies help patients preserve a greater degree of functional independence for ADLs in their personal routines, thus improving satisfaction in their abilities.[12]

Instrumental Activities of Daily Living

Occupational therapists assist patients in performing instrumental ADLs (IADLs), such as meal preparation, financial and home management, caregiving, or spiritual activities. They help patients problem-solve these activities, finding creative ways to modify tasks into more manageable processes and to reinforce the use of energy conservation and assistive devices.[8] Recommendations for environmental modifications also help patients interact in their environments in a safer and more convenient way, such as recommending where to appropriately install handrails or grab bars to enhance safety or reorganizing kitchen spaces by consistently placing objects within a reachable area to improve ease of accessibility.

Communication Management

Speech language pathologists provide communication intervention to improve active participation in communication areas such as socialization, decision-making, and expression of needs. They perform speech, language, and cognitive evaluations to identify a patient's communication strengths and weaknesses. Specific interventions vary greatly but may include low-tech augmentative and alternative communication tools such as simple letter boards, use of speaking valves with tracheostomized patients, or communication strategies such as simple "yes" or "no" questions for patients with fair auditory comprehension but poor expressive ability. Optimizing communication and providing education to family and other care providers is crucial for improving active participation in patient- and family-centered and interdisciplinary goal discussions.

Leisure Education

Recreation therapists help patients develop the awareness, knowledge, and skills needed to facilitate active leisure engagement when disability deprives them of their usual habits. They provide leisure education, which focuses on patients' individual capabilities and emphasizes their strengths and interests, so that they may competently participate in activities of their own choosing. Recreation therapists collaborate with patients to modify recreational activities they enjoy (e.g., manipulating the weight of a basketball or lowering the height of the hoop) and match challenges to their current abilities to promote self-esteem. Obtaining this balance creates an inclusive leisure experience that results in patients' feeling a greater level of self-fulfillment and achievement of potential.[13]

Supporting Caregivers

While maintaining patient function can reduce caregiver burden, therapists also help caregivers improve their abilities to support patients. Occupational and physical therapists instruct caregivers on how to perform safe transfers, as well as how to manage DME and assistive devices to better assist patients. Speech language pathologists instruct caregivers on proper feeding strategies and also provide education and support to assist in difficult decisions regarding eating and drinking, including the use of feeding tubes. Recreation therapists educate caregivers on the value of leisure engagement and recommend activity adaptations that can assist in planning recreational experiences. By improving caregiver competency in assisting patients, they can decrease feelings of helplessness and focus their efforts in productive ways. These efforts benefit patients who desire to remain in their homes and their families who wish to keep them there.

Physical Complications

Joint Integrity

To address the risk of contractures that may occur as a result of prolonged immobility, therapists can help patients maintain, maximize, or increase range of motion. Physical therapists address joint integrity through stretching programs and soft tissue and joint mobilization, each of which promotes mobility and alleviation of pain. For patients who experience innervation or pain-related issues (e.g., drop foot, plantar fasciitis, or overpronation), physical therapists can recommend and fit patients with lower extremity orthotics to support the affected joint and increase functional mobility. Similarly, occupational therapists can recommend splints for upper extremity contractures to improve function and comfort and prevent further deformity.

Skin Integrity

Therapists also contribute to efforts to reduce the risk of developing pressure ulcers. Therapists help patients become more independent in repositioning strategies and compliant with proper body mechanics to avoid conditions that increase pressure on skin areas. They also recommend appropriate assistive devices used to decrease skin breakdown during activities, such as cushions on seating surfaces. Participating in therapy provides patients the opportunity to perform out-of-bed activities and prevents prolonged periods of lying or sitting.

Dysphagia

Dysphagia can lead to pneumonia, weight loss, and poor nutrition; however, speech language pathologists provide recommendations and education to reduce these complications. Dysphagia interventions aim to improve swallow efficiency and safety, which may often include weighing the benefits and risks of choosing oral intake versus non-oral nutrition/hydration. The goal of feeding tubes may be directed toward assisting in nutritional status and weight gain; however, research suggests that non-oral nutrition does not decrease the risk of aspiration-related illness or improve QOL or longevity.[14,15] Patients receiving palliative care may choose to eat and drink regardless of aspiration risk, as this may significantly improve QOL. For these patients, speech language pathologists can offer education and training to minimize the risk of developing aspiration-related illness. As end of life nears, speech language pathologists also provide education and family support for thirst and hunger as it relates to patient comfort.

Case Study: Addressing Disability

JP's therapists provided specialized interventions to address his deficits so that he could function in a more capable manner. During his outpatient visits, PT provided JP therapeutic exercises on gait, strengthening, and balance to slow the progression of his weakness and maintain mobility and safety in his home and community. OT taught him to analyze and optimize the process of keeping his front yard within Homeowners Association standards by simplifying gardening tasks through training in adaptive tools, such as using a tractor scoot or long-handled weed cutter, to improve ergonomics. OT also suggested he modify his yard space by keeping his lawn at an even level to avoid potential falls. SLP referred him to an otolaryngologist, where he received a vocal cord injection which improved both his voice and swallowing, allowing him to safely eat and drink without restriction. In addition, SLP helped maintain and optimize his swallow function with exercise.

During JP's final admission, the progression of his disease threatened his function even further; however, his therapists bolstered their approach of maintaining his functional capacities. Through RT groups, JP was able to develop new leisure habits as he discovered recreational activities that accommodated for his deficits, such as wheelchair bocce ball, which provided ongoing opportunity to experience the competitive challenges that he enjoyed from physical sports. As a result, he gained more confidence, which motivated him to put in greater effort to interact with other patients and engage in therapy. As his lower extremity weakness escalated to paralysis, PT focused on maximizing his core strengthening and training in proper body mechanics to perform safe slide board transfers into a wheelchair. OT helped him incorporate those transfers into his ADLs, enabling him to continue to shower with minimal assistance and shave his head independently in an upright position so that he could maintain a positive image of himself. SLP assisted in communication strategies to improve his voice and respiratory speech coordination, as his ability to communicate was complicated by his respiratory status.

JP's therapists also helped prevent potential complications as he became increasingly bed-bound from worsening paralysis. He and his therapists developed daily routines of out-of-bed activity and repositioning to prevent pressure ulcers and muscle atrophy. PT fitted him with ankle-foot orthotics to keep his feet in a functional position, while OT provided the appropriate wheelchair cushion to prevent skin breakdown. As his swallowing continued to decline, JP struggled with recurrent pneumonia and weight loss and eventually required a feeding tube to meet his nutritional needs; however, SLP provided therapeutic feeding strategies so he could continue to take small amounts of his favorite foods, which allowed him a familiar comfort. These preventative efforts curbed the rate of deterioration he could have experienced.

Easing Symptom Burden

The rehabilitation team collaborates with the palliative care team to assist in symptom management, and they have unique abilities to address debilitating symptoms that impact daily function. Therapists provide interventions to improve or reduce the experience of patients' symptoms, allowing them to manage their disease more effectively and engage in daily life with more comfort.

Fatigue

Use of fatigue management strategies can complement physical activity interventions and compensate when exercise by itself is not sufficient. Occupational therapists help patients analyze their daily routines and understand how their habits, sleep, and nutrition factor into fatigue levels. They teach patients how to develop healthier habits by planning and prioritizing their activities, organizing routines based on energy levels, and breaking up tasks into manageable parts.[16] Physical therapists instruct patients on proper body mechanics, paced breathing, and activity modification to decrease physical exertion. They also grade exercise programs to match the necessary cardiovascular endurance and strength needed for optimal activity tolerance.

Pain

Therapists support interdisciplinary efforts to manage pain, providing interventions that complement their pharmacological regimens. Occupational therapists help patients understand the physiological effects of pain and teach them how to use relaxation strategies to cope with and decrease the intensity to pain.[16] Occupational therapists also teach patients to assess pain in their lifestyle, determining how behaviors trigger or exacerbate pain, which results in learning how to decrease the impact of pain on function.[17] Physical therapists help patients utilize muscle and nerve stretching, soft tissue mobilization, positioning, and posture training, all of which reduce pain in mobility and extremity range of motion during functional activities. Engaging in leisure activities facilitated by a recreation therapist may also offer patients a positive distraction that decreases their overall pain experience.[18]

Cognition

Cognitive dysfunction results from the deterioration that occurs with neurodegenerative brain disorders, as well as from the culminating effects of fatigue, anxiety, stress, and medication.[1,16] Both occupational therapists and speech language pathologists play a role in addressing cognitive skills related to attention, memory, and executive function, with each discipline focusing on its respective scopes of practice as occupational therapists address ADL and IADL function and speech language pathologists address communication. They provide attention/memory training, compensatory strategies (e.g., planners, assistive technology, etc.), and activity-related problem-solving focused on modifying component tasks to decrease cognitive burden and facilitate participation. Exercise is another tool therapists can use to address cognitive function in patients because consistent physical exercise over time can improve or maintain higher levels of executive function compared to those who are inactive.[19] Participation in RT groups that provide cognitive stimulation, such as socialization and multisensory leisure for patients with Alzheimer's disease, can improve language and memory function.[20]

Dysphagia

Traditionally, speech language pathologists provide dysphagia intervention focused on eliminating aspiration with feeding; however, this goal is often not appropriate for certain patient populations. For patients with dysphagia receiving palliation, the goal should shift to minimizing distressing symptoms related to swallowing, such as cough or dyspnea with eating. This may be accomplished with the use of compensations such as modifying diet textures, feeding rates, bolus size, or the positions in which patients eat and drink. The goal is to offer treatment that is least restrictive, which may redirect the focus on compensatory strategies over diet modification. Certain diet modifications, such as thick liquids, may not reduce the occurrence of aspiration-related illness but may increase the risk of dehydration and negatively impact QOL with eating or drinking.[21]

Dyspnea

As certain conditions lead to decline in pulmonary function, therapists can assist patients in managing dyspnea and the associated symptoms of breathlessness, poor activity tolerance, and anxiety. Patients may maladaptively respond by avoiding activity, leading to further disability and disengagement from daily life.[22] To treat these effects, occupational therapists and physical therapists provide pulmonary rehabilitation through physical conditioning to promote efficient oxygen utilization of the body and maximize activity tolerance. Occupational therapists, physical therapists, and speech language pathologists also provide respiratory retraining to improve oxygen saturation and minimize reliance on supplemental oxygen. These efforts maximize pulmonary function, helping patients breathe properly and comfortably during their activities.

Mood

To manage the psychological effects of living with progressive illness, therapists can assist patients in coping with anxiety, depression, and other emotional symptoms that affect mood. Occupational therapists help patients develop individualized coping plans by helping them practice the skills of deep breathing, meditation, progressive muscle relaxation, and guided imagery to decrease overall physiological and psychological stress.[16] Exercise can have positive effects on anxiety and depression by improving the neurobiological mechanisms of the brain, allowing the body to better regulate mood compared to the standard treatment alone (e.g., medication or psychotherapy).[23,24] When patients experience feelings of fear, helplessness, and loneliness, recreation therapists engage them in group treatments to minimize social isolation through the provision of positive peer interactions.[18] They may also provide animal-assisted therapy to alleviate stress and anxiety, allowing patients to feel a greater sense of comfort in the hospital.[18,25]

Case Study: Easing Symptom Burden

JP and his therapists worked together to alleviate the symptoms he experienced from cancer and cancer treatment. To overcome his persistent fatigue, PT graded his endurance program and encouraged maintenance of proper form throughout different physical activities to reduce overexertion. OT helped JP understand his daily fatigue patterns and spread his tasks out appropriately, with restful breaks to use his energy efficiently. To better manage his dyspnea, he was trained in incentive spirometry and pursed-lipped and diaphragmatic breathing, allowing him to minimize his oxygen requirement and decrease his anxiety associated with breathlessness. To manage his spinal pain, JP learned how to avoid pain-triggering positions and to incorporate progressive muscle relaxation to improve his tolerance for upright activities. To address dysphagia, SLP provided additional swallowing strategies to minimize cough and discomfort with eating. To cope with feelings of depression, recreation therapists engaged JP in journaling as a way of creative self-expression, providing a positive outlet while OT helped JP utilize guided meditation to redirect his focus toward calming behaviors.

Adapting through All Stages of Illness

Palliative rehabilitation takes into account the challenges of providing care when patients experience irreversible changes, prompting therapists to continually monitor and assess how fluctuations in function and increasing symptoms can create conditions for despondency. Beyond the previously noted interventions, therapists concern themselves with understanding that patients' lives will never be the same as identities are damaged by disability; however, changing the disability narrative can facilitate adaptation and help redefine identity. For example, speech language pathologists help patients cope with and accept the new normal of being dependent on tube feeds or speaking valves. Physical therapists empower patients to use their bodies in new ways to master how they interact within their environments. Occupational therapists can coach patients on how to redesign their lifestyles by establishing new behaviors and routines that maintain the essence of identity-based activities and improve motivation to manage their health.[26] To guard patients' self-esteem against the threats of progressive disability on their confidence, recreation therapists facilitate success in strengths-based leisure activities, promoting a sense of accomplishment.

Group therapy can provide adaptive experiences that support psychosocial adjustment and address the effects of prolonged hospitalizations that impact the sense of normalcy, enjoyment, and social connectivity patients would otherwise have in their normal environments. For example, recreation therapists facilitate recreational and social group treatment sessions to provide patients the opportunity to re-experience feelings of pleasure, voice their emotions, and improve comfort, all of which help them adapt in unfamiliar environments. By experiencing therapeutic leisure activity with others facing similar difficulties, patients can decrease the risk of social isolation and gain psychological support and empathetic understanding from their peers.[18]

Case Study: Adapting through All Stages of Illness

One of the most meaningful ways that JP's therapists helped him adapt was helping him redefine his role as a boxing coach. JP was accustomed to coaching his pupils in a hands-on style by physically joining them in the ring. As he could no longer confidently coach in this manner, PT helped JP develop new strategies with balance and kinesthetic awareness, allowing him to adapt his footwork and safely participate in sparring. OT adapted his daily schedule, finding an optimal way of organizing his time throughout the week to maximize energy during his lessons. He also learned a new coaching routine of substituting his pupils in his place or showing prerecorded portions of his lessons to balance teaching and conserving energy. These efforts helped him continue to coach in a satisfying manner and experience the gratification of mentoring his pupils.

During his final admission, RT helped JP adjust to his prolonged hospital experience. By routinely participating in recreation groups, he overcame his initial social isolation by developing friendships with those who also struggled with the challenges of cancer, giving him a sense of camaraderie that motivated him to remain committed to keeping a positive attitude. When he became paralyzed, RT introduced new board games he could play in bed, which provided him with an enjoyable activity that he shared with his family. The success he had in these games functioned as a way to continue to exercise his mental strengths and helped him acknowledge he was still capable of planning pleasant, enjoyable experiences with his family.

Cultivating QOL

The ultimate goal of palliative rehabilitation is to improve or preserve QOL. Outcomes of care are not only based on achievements in function, but also on how patients perceive a greater level of satisfaction and well-being within their remaining time. By addressing physical dysfunction and management of symptoms through exercise, physical therapists can help patients experience achievement, confidence, self-empowerment, and group camaraderie, resulting in perceived improvement in their QOL.[27] Occupational therapists help patients to maintain their best level of independence in their self-care and participation in meaningful life activities despite their deficits, protecting their sense of autonomy, productivity, and dignity. Speech language pathologists help patients' optimize their ability to communicate, so they can express needs and engage socially, which improves emotional and spiritual well-being. Speech language pathologists also provide families with rewarding experiences when patients can comfortably share a meal. As recreation therapists facilitate leisure engagement and group activities, patients gain an outlet in which they can express emotions, display creativity, and enhance a sense of control and self-esteem through the accomplishment of task-oriented goals.[18] The intangible benefits that result from these collective efforts contribute toward QOL and assist in allowing the true benefits of palliative care to be actualized.

Palliative rehabilitation also addresses QOL as it relates to mortality. Therapists help patients alter their experience of a terminal disease by ameliorating the effects these circumstances have on QOL. They help patients direct their efforts toward positive activities, such as legacy-building or improving the manner in which time is spent alone or with family. Therapists can also help patients and their caregivers prepare for their transition to hospice, providing guidance for how to plan their remaining time in a meaningful way and addressing any further needs for training or equipment.

Case Study: Cultivating QOL

Each interaction JP shared with his therapists functioned as a way of improving his QOL. Because of his care, he was able to continue to transfer and maintain an upright position in a chair, groom himself to keep his desired features, share meal experiences with his family, and form new social networks with which to share enjoyable moments, all of which allowed him and his family to cultivate quality moments that brought value to his palliative experience. When JP decided to transition to home hospice, his therapists helped him focus on his family even further by working together on a legacy project of compiling his barbecue recipes so that his family could remember him during their holiday gatherings after he passed. Despite the losses JP experienced toward the end of his life, the rehabilitation team was able to help him maintain a sense of comfort, autonomy, and accomplishment that helped him cope through the full spectrum of his experiences.

Conclusion

Palliative rehabilitation plays a vital role within the palliative care team by providing interventions that address various needs to support maximal function and management of symptoms. Including rehabilitation as part of the palliative care plan adds supportive elements that improve interdisciplinary collaboration, moderate the impact of disability and symptom burden on daily life, and, ultimately, support QOL through every stage of disease. Nurses work closely with therapists to screen and refer patients who can benefit from palliative rehabilitation and maintain effective communication of the needs and concerns of patients and their families. Together, nursing and rehabilitation can help to alleviate patient and caregiver suffering to ensure patients have the best possible outcomes by collaborating as a team.

CHAPTER 57

Value-Based Care

Finly Zachariah and William Dale

Key Points

- Aligning patient preferences with care delivery is fundamental to providing value-based care.
- Nurses are integral to the care team and have several opportunities to impact care delivery.
- Palliative medicine is well-positioned to substantially impact rising, unsustainable healthcare costs.

Introduction

Value-based care is defined as evidence-based care that helps patients improve their health, reduce the effects from chronic diseases, and live healthier lives.[1] This is in contrast to a fee-for-service (FFS) model, in which greater volumes of care lead to higher payments independent of outcomes. Translating this philosophical approach into effective programs is the new challenge for healthcare systems. Value-based programs offer providers incentive payments based on providing quality of care.[2] Value-based programs support a three-part goal to provide (1) better care for individuals, (2) better health for identified populations, and (3) lower costs of care.

In the United States, healthcare expenditures continue to grow at an unsustainable rate, with $ 3.3 trillion (17.9% of gross domestic product [GDP]) spent in 2016.[3] The FFS model, paying for the volume of service whether appropriate or not, has been a major driver of higher healthcare expenditures in the United States.[4] There has been a concerted effort in healthcare reform to shift payments from being centered on volume to instead paying for value.[5,6] The concept of "value" originates from the Latin word *valeir,* to "be worth," and is defined by Merriam-Webster Dictionary as the "monetary worth of something."[7] Michael Porter in the *New England Journal of Medicine* stated "achieving high value for patients must become the overarching goal of healthcare delivery, with value defined as the health outcomes achieved per dollar spent."[8] With healthcare now involving many parties, most importantly the patient and his or her family, the interdisciplinary healthcare team, the patient's community, policymakers, and insurance agencies, important questions to now ask are: (1) What are meaningful, measurable outcomes? And (2) What are the best outcomes for patients and families that can be achieved with the healthcare dollars being spent?

Depending on the interested party, outcomes of importance may shift. For the payer, the most important outcome may be what provides similar outcomes at the lowest financial cost. For the provider, it may be improving overall survival or achieving disease-based outcome targets, such as a specific level of hemoglobin A1C for patients with diabetes. Policymakers may be most concerned with providing consistent care and minimizing variance in outcomes at a population level, and for patients, their most desired outcome may be overall survival, maintaining a high quality of life, maximizing functionality, and minimizing symptoms. Keeping these different perspectives in mind and trying to reconcile them are crucial to a value-based approach.

In 2012, the California Healthcare Foundation conducted a study on Californian's Attitudes and Experiences with Death and Dying, which provides information on understanding important outcomes to patients nearing the end of life. Key findings included:

- Two-thirds of Californians state that the most important factors at the end of life were (1) being comfortable and without pain and (2) assuring their families were not burdened by the financial costs of their healthcare.
- Sixty percent felt it was "extremely important" that families not be burdened by tough decisions about care, although 56% of Californians did not communicate healthcare wishes to their healthcare agents.
- Eighty-two percent said it was important to have written end-of-life (EOL) wishes, but only 23% say they have written those wishes down.
- Seventy percent stated they would prefer to die at home, but, in fact, only 32% of deaths occurred at home, while 42% were in a hospital and 18% were in a nursing home.
- Eighty percent said they would like to talk with their doctors about EOL care, but only 7% of those surveyed had a doctor speak to them about EOL care.[9]

Physicians approach their own care at the end of life with better preparation, but still do not communicate their preferences well with their own physicians. The Precursors Study enrolled 999 physicians when they were medical students attending Johns Hopkins School of Medicine from 1948 to 1964. The ongoing annual surveys revealed that although 64% had an advance directive that was discussed with spouse or family, 70% had not had a conversation with their personal physicians about EOL care. Additionally, 80% of the physicians indicated they would want pain medications and 85% would refuse life-sustaining treatment at the end of life.[10] Two other studies, one in Singapore, indicated a strong physician preference against life-sustaining treatments at the end of life.[11,12] Another study in the United States compared EOL care utilization between physician (9,947) and nonphysician (192,006) fee-for-service Medicare beneficiaries. Inpatient hospitalization was similar between the groups, but intensive care unit

(ICU) utilization and number of days in hospice was higher for the physician group.[13]

The 2014 report by the Institutes of Medicine, *Dying in America: Improving Quality and Honoring Individual Preferences Near the End of Life*, further expounded on the inadequacy of the EOL care provided by our current healthcare system. Some of the key findings included:

- Palliative care is associated with improved quality and quantity of life, improved understanding and communication, and bio-psycho-socio-spiritual (physical, emotional, social, and spiritual needs) care.
- Healthcare delivery is fragmented due to transitions and preventable admissions fueled by misaligned incentives.
- Communication with patients regarding values, goals, and preferences is lacking and timely palliative care involvement is not well-adopted.
- Advance care planning conversations are necessary, but most patients do not have them with their healthcare team.
- Training and reimbursement are inadequate for providers wanting to utilize palliative skills.
- There is a need for increased public awareness and a societal conversation around care at the end of life.[14]

The *Dying in America* report also had five key recommendations, and these provide the framework for this chapter, which explores the significant palliative care opportunities for nurses to improve the care of seriously ill and dying patients. There are opportunities for all nurses through the dissemination and adoption of primary palliative care skills, while those with more experience and certification are able to provide specialty-level palliative care.[15] The field of palliative care is dedicated to bio-psycho-socio-spiritual care and treatment of seriously ill patients and their families. This care, delivered by an interdisciplinary team, has been recognized by the World Health Organization as a human right and is included in major guideline recommendations.[16–19]

Recommendation 1: Delivery of Person-Centered, Family-Oriented End-of-Life Care

> Ideally, healthcare should harmonize with social, psychological, and spiritual support to achieve the highest possible quality of life for people of all ages with serious illnesses or injuries. Toward this end, the IOM committee recommends that integrated, person-centered, family-oriented, and consistently accessible care near the end of life be provided by healthcare delivery organizations and covered by government and private health insurers. The committee finds that a palliative approach typically affords patients and families the highest quality of life for the most time possible. . . . Although palliative care is well established in most large hospitals and professional education programs, the committee identifies the need for greater understanding of the role of palliative care—by both the public and care professionals—as one of the greatest remaining challenges in the delivery of high-quality end-of-life care.[14]

Nurses are integral to the process of care delivery across settings and have had an increasingly important leadership role in the delivery of palliative care. In improving care for the seriously ill and those at the end of life, there are several actions nurses can engage in, including improved communication and advocacy with interdisciplinary staff, optimal physical care, demonstrating care and compassion, supporting dignity and providing emotional support in death for patients and their families, and fostering a peaceful environment.[20]

The lack of qualified professionals in palliative care and concerns over staffing costs have in part led to the exploration of innovative, nurse-led models of care. The nurse is a key member of the interdisciplinary team, and, today, nurses have access to new models of care and new palliative care initiatives.[21] Nurse-led palliative interventions have been applied to a variety of clinical, supportive, and care coordination efforts including establishing survivorship clinics[22] and facilitating navigation in rural clinics,[23] and, in England, a collaborative social work and nurse clinic model has been developed to focus on meeting caregiver needs, answering questions around financial concerns, and addressing concerns related to caregivers' health and supporting ill loved ones.[24] In the CONNECT trial, nurses have also been able to provide palliative care in oncology clinics, focusing on symptom management, engaging patients and families in advance care planning, providing emotional support, and coordinating care.[25] There has been evidence of the effect of nurse-led interventions on decreasing admissions and readmission, length of stay, and healthcare costs, although further studies are necessary to understand whether the cost savings generated are sufficient to justify replication of these care models.[26]

Recommendation 2: Clinician–Patient Communication and Advance Care Planning

> Many people nearing the end of life may not be physically or mentally capable of making their own care decisions. In addition, family members and clinicians may not be able to accurately guess what a person's care preferences may be. Therefore, advance care planning is critically important to ensure that patients' goals and needs are met. Although advance directive documents can be useful, they should allow healthcare agents and care providers to make informed decisions in certain circumstances and should not take the place of open, continuous communication. According to the IOM committee, the advance care planning process can begin at any age or state of health and should center on frequent conversations with family members and care providers. Electronic storage of advance directives, statements of wishes, or other relevant materials holds promise for improving access to and effectiveness of these materials. Professional societies and other organizations that establish quality standards should develop standards for clinician–patient communication and advance care planning. Payers and healthcare delivery organizations should adopt these standards as a necessary component of high-quality care for individuals with advanced serious illness and their families and enable them to seek these services from their physicians and providers.[14]

Advance care planning was recently defined by an international panel of experts as "a process that supports adults at any age or stage of health in understanding and sharing their personal values, life goals, and preferences regarding future medical care. The goal of advance care planning is to help ensure that people receive care that is consistent with their values, goals and preferences during serious and chronic illness."[27] Where advance care planning is a process and a conversation among patient, medical team, and healthcare agents, there are also some defined products of advance care planning conversations, such as advance directives and life-sustaining treatment forms, including the physician orders for life-sustaining treatment (POLST).

An *advance directive* comprises typically two components: the *durable power of attorney* and the *living will*. The durable power of attorney indicates who one trusts to speak to the medical team on one's behalf if one is unable to or if one chooses to empower the healthcare agent immediately upon executing the document. The living will component of an advance directive indicates the preferences one has for health and includes treatments one would and would not want. One important note is that advance directives are directives for the future and are instructions to a healthcare agent to execute. These are not immediately actionable, and they require additional forms such as the POLST, medical orders for life-sustaining treatment (MOLST), medical orders for scope of treatment (MOST), physician orders for scope of treatment (POST), or more traditional out-of-hospital do-not-resuscitate (DNR) forms. These forms allow patients to indicate their preferences for resuscitation or allowing natural death, and the majority of these forms allow patients to indicate the level of treatment they may want along with preferences toward medically administered nutrition. Unlike advance directives, forms like POLST can be honored by emergency medical services.

Despite the numerous interventions to increase the rates of advance directive completion, in a review of 150 studies evaluating 795,909 patients from 2011 to 2016, only 36.7% of patients had any type of advance directive.[28] POLST forms are also underutilized.[29] A challenge is that many terminally ill patients, if not connected with palliative care or hospice, too often engage with the medical establishment and often come to the emergency room or hospital for EOL care. In the care of most of the 700,000 elderly patients who die in the hospital annually, most providers will have only known these patients for less than a week, and there is evidence that providers who engage in more serious conversations with patients, after having known the patient for only a short period of time, are perceived as having less empathy.[30–32]

These issues speak to the need to move advance care planning conversations to earlier in the course of care, ideally initiated by primary care providers and nurses who often have long-standing relationships with the patient and family. It is the long-term providers who should initiate these conversations since patients and families expect these conversations with those whom they have a relationship.[33] There has also been some demonstrable successes in advance care planning initiatives, including normalizing advance care planning and advance directive completion for a county,[34] targeting efforts to increase advance directives on file for patients undergoing transplant,[35] and utilizing a web-based advance care planning program that statistically increased advance directive completion and is potentially a scalable advance care planning solution.[36] There is some evidence to suggest that healthcare providers who have their own advance directives are more comfortable communicating with patients about them.[37,38] The use of structured communication tools also assists with the discussion and completion of advance directives.[39] Nurses should engage in advance care planning for themselves and their families to demystify the subject and so that they are further empowered to engage in such conversations to support patient values and clarify medical recommendations.

Recommendation 3: Professional Education and Development

> The education of health professionals who provide care to patients at the end of life has substantially improved in recent decades. Hospice and palliative care is now an established medical specialty, and palliative care has a strong presence in clinical education, professional organizations, and research communities. However, the IOM committee finds that important deficiencies persist. First, recent knowledge gains have not necessarily translated to improved patient care. Second, the supply of palliative care and hospice specialists is small, meaning that many patients must rely on other clinicians who provide care for individuals with serious advanced illness but who may lack training and experience necessary to meet their patients' palliative care needs. The committee recommends that educational institutions, professional societies, accrediting organizations, certifying bodies, healthcare delivery organizations, and medical centers take measures to both increase the number of palliative care specialists and expand the knowledge base for all clinicians.[14]

There is a substantial need for primary palliative skills to be integrated into the general nursing profession, which numbers nearly 3 million in the United States. The palliative care education provided in nurse practitioner and undergraduate nursing programs is inadequate. The deans of 101 nurse practitioner programs were surveyed, and, of their schools, the majority had no more than a few hours of class time and a third provided no exposure to palliative care at all.[40] The American Association of Colleges of Nursing in 2016 put forward new guidelines, Competencies and Recommendations for Educating Undergraduate Nursing Students (CARES), to prepare nurses to care for the seriously ill and their families. These guidelines have 17 components. An online curriculum based on the End-of-Life Nursing Education Consortium (ELNEC) was developed in response to prepare future generations of nurses. In addition, there has also been recent funding for advance practice oncology nurses to be trained with general palliative care skills.[41,42] ELNEC started in February of 2000 and was designed to improve palliative care in the United States and internationally. As of 2018, more than 23,880 attendees have been educated from 99 countries, with these learners taking content back to their healthcare centers and teaching others—more than 670,000 additional healthcare professionals—vital palliative care nursing skills.[43]

Education in palliative care for nurses has been shown to improve knowledge, confidence, attitudes, and communication abilities, as well as to decrease nurses' stress.[44] Targeted palliative education has also been successful in areas like the ICU, after which nurses were able to identify and advocate for alleviation of palliative needs in their patients.[45,46] In the actively dying, a mnemonic that facilitates the role of nurses in EOL care is CARES: *C*omfort, *A*irway, *R*estlessness and delirium, *E*motional and spiritual support, and *S*elf-care. Use of such a mnemonic provides a structured way to assure that patients and their families receive appropriate care in an otherwise stressful situation for patients, families, and staff.[47] Utilizing the TEAM approach, primary palliative principles can be disseminated to the oncology care team to honor the newly revised American Society of Clinical Oncology (ASCO) guidelines, which now incorporate palliative care. TEAM is a mnemonic for *T*ime (an hour per month with the palliative care team), *E*ducation (especially regarding prognosis, goals of care, and advance care planning), *A*ssessments (for symptoms, spiritual, and psychosocial health), and *M*anagement by an interdisciplinary team.[48]

Recommendation 4: Policies and Payment Systems

> Sustainable improvements in the organization and financing of end-of-life care must take into account the need to stabilize

> healthcare costs over time. The IOM committee finds that reform is needed in how resources for care provided near the end of life are organized.
>
> Current financial incentives encourage a reliance on acute care settings that often are costly and poorly suited to the needs, goals, and preferences of patients and their families. The committee recommends a major reorientation of payment systems to incentivize the integration of medical and social services, the coordination of care across multiple care settings, and the use of advance care planning and shared decision-making to better align the services patients receive with their care goals and preferences. This reorientation will improve access to services that better respond to the needs of patients and their loved ones and may also help stabilize healthcare costs.[14]

In a poignant article, Drs. Schenker and Arnold discuss the traditional model of palliative care as much more "proof of concept," and state that the rapidly expanding needs and limited workforce call for a different approach for the future of palliative care. They express: "The next era of palliative care must embrace a broader focus on systems of care, measurement and accountability for palliative services, and national policy changes that promote universal provision of high-quality advanced illness care. Without these changes, it will not be possible to achieve the goal of improving the experience of patients with serious illness."[49]

Estimates for high-income countries indicate that 69–82% of those who die will need palliative care, with increased needs expected due to the aging population, occasionally termed the "Silver Tsunami."[50,51] Studies have previously indicated that the sickest 5% of the population accounts for nearly half of the Center for Medicare and Medicaid services spending. Eleven percent of this population are in their last year of life, but nearly half have expensive procedures. In addition to this 11%, the remaining 40% are also a demonstrated opportunity for palliative care to improve the care of these patients who are often older, have multiple comorbidities (including possibly cognitive impairment), have generally significant functional dependency, suffer from pain and depression, and have the social and financial familial burden of caregiving, along with recurrent emergency room and hospital visits.[52,53] In various settings across a number of life-limiting illnesses, palliative care is fundamentally value-based care and has been shown to improve alignment of a patient's values, goals, and preferences with the care received by patient and family, which often has the secondary consequence of improved quality and quantity of life, decreased utilization, and overall decreased costs to the healthcare system.[54–61]

While hospice is well-defined and structured with appropriate regulatory requirements, the delivery of palliative care faces significant challenges. Palliative care is able to be delivered in the hospital, but otherwise has inconsistent reimbursement by insurance and is generally unavailable at home, in nursing homes, or in rural locations.[53] Ultimately, additional bipartisan support is needed to advance quality initiatives such as the Palliative Care and Hospice Education and Training Act.[53] Reimbursement by Medicare for advance care planning with CPT codes 99497 and 99498 can be utilized by physicians and healthcare providers, including advance practice nurses and clinical nurse specialists (if legally authorized to provide services in their state). In addition, other providers such as nurses may bill under "incident to" in office or home settings, as long as there is another authorized visit performed on the same day.[62]

Recommendation 5: Public Education and Engagement

> The IOM committee identifies a need for public education and engagement about end-of-life care planning at several levels:
>
> - the societal level, to build support for public and institutional policies that ensure high-quality, sustainable care;
> - the community and family levels, to raise awareness and elevate expectations about care options, the needs of caregivers, and the hallmarks of high-quality care; and
> - the individual level, to motivate and facilitate advance care planning and meaningful conversations with family members and caregivers.
>
> Although Americans' values and opinions about end-of-life care will necessarily differ, the committee emphasizes the importance of disseminating accurate information so that individual care decisions and public dialogue, as much as possible, are based on an informed understanding of facts.[14]

Both the American Medical Association and the National Institutes of Health recommend that medical literature designed for patient consumption should be written at the third- to seventh-grade reading level. A study evaluating articles using common search terms through Google found, in a sample of 100 articles, that none was written at less than a seventh-grade level and that the average was written at a twelfth-grade level, making the majority of this educational material incomprehensible to the public.[63] A public consumer website has been made available through the Center to Advance Palliative Care, and it provides content in web, print, and broadcast media to more effectively educate the public on the differences between hospice and palliative care and to demonstrate the benefits of being connected to palliative care teams.[64]

Another recent educational platform has been Death Cafes, typically 2-hour conversational events, hosted in someone's home to discuss death and dying. More than 1,000 sessions have been held internationally since 2011, when the program first started in Great Britain. Death Cafes were held in joint collaboration between the University of California–San Francisco and Zen Hospice in San Francisco and were found to be effective teaching modalities.[65]

Conclusion

Palliative medicine is the fastest growing specialty in the United States and has been shown to improve quality and quantity of life while minimizing over- and undertreatment when care is aligned with patient values through improved communication. Unfortunately, limited progress in care at the end of life has been made, and the needs will continue to outpace the field's ability to train specialists, including nurse specialists. Through disciplined effort in building out primary palliative care for nonspecialists, continuing to educate the next generation, advocating for favorable policies, building and measuring programs, and ultimately focusing on patient-centric care delivery, we will be able to demonstrate value in our care of the seriously ill and dying patient.

SECTION VI

Pediatric Palliative Care

CHAPTER 58

Symptom Management in Pediatric Palliative Care

Joan “Jody” Chrastek and Camara van Breemen

Key Points

- Assess the dying child thoroughly, with input from the interdisciplinary team, the family, and the child/young adult, if possible.
- Incorporate both nonpharmacological and pharmacological interventions for symptom management.
- Strive for good communication with the child, family, and other team members.
- Be proactive—anticipate and plan for adverse effects from treatment and/or disease progression and develop algorithms for family members’ use.
- Spiritual and psychosocial issues can affect symptoms and management and must be taken into consideration for the family as a whole.

Introduction

Managing symptoms in dying children is challenging and, if done poorly, can be a source of distress for families and children that healthcare providers may fail to recognize.[1] The child and family may fear the unknown future and worry that increasing symptoms signal disease progression and decline.[2] Therefore, aggressive symptom management must start early in the disease trajectory[3]—on diagnosis of a life-threatening/-limiting condition—and continue in conjunction with curative and/or life-prolonging treatments[4] for as long as needed. Listening to the family’s concerns and providing education and reassurance of attention to symptom management can relieve fears.

Assessment and management of symptoms can be straightforward or complex in pediatrics, as in adults. However, many pediatric palliative patients are nonverbal due to their age or condition, making it difficult to identify the cause of distress. The number of subspecialties required increases the complexity of assessment as well as the consideration that a damaged central nervous system may be the source.[2]

These potentially challenging circumstances highlight the necessity of incorporating the whole family, including siblings, as part of the team.[5] They are most familiar with the child’s reactions and methods of communicating. Ideally, the nurse will develop a trusting relationship with the family while remaining objective in assessing and treating the symptoms. Excellent symptom management in children, as in adults, requires the nurse to engage both the art and science of palliative care.

The art of pediatric palliative care is displayed in excellent communication, listening deeply, and understanding what is being asked for or said. Communication is an integral aspect of care,[6] extended to the family and team. Humility, openness, and flexibility are part of a good foundation for this essential aspect of pediatric palliative care.

The science of pediatric palliative care is a rapidly expanding field, with newly developed resources. Using current evidence-based practice provides a strong foundation for optimal symptom management.

When a dying child is distressed, the whole family suffers. Therefore, a holistic approach to all members of “the family” is essential.[7] Siblings’ quality of life (QOL) often suffers in family, academic, and social areas due to a loss of attention and place within the family.[8] Therefore, it is essential that the team consider their well-being in care planning.

Although there is a wide range of underlying conditions in pediatric palliative care, there are common symptoms that will be discussed in this chapter. Each child’s care plan is highly individualized and adjustable. This can be influenced by disease trajectory, culture, beliefs, and their community.

Symptoms arise from physical, emotional, social, and spiritual domains. This chapter focuses on physical symptoms, apart from the pain (described in other chapters), commonly found in children with palliative care needs,[4,9,10] including some respiratory, gastrointestinal, and neurological symptoms.[4,10,11] Emotional and spiritual suffering will be discussed briefly. A resource list is provided (Box 58.1), so that each symptom can be explored in depth.

Assessment

Nurses have a responsibility to assess patients in the context of a developmental, child-specific, and family-centered framework, and this requires competence in communicating, using symptom-specific tools, performing a physical exam, and recognizing specific disease/conditions. There are several tools (e.g., pediatric Memorial Symptom Assessment Scale[12]) that can be used to assess symptom burden in children and each has advantages and disadvantages.[13,14] Assessment for any presenting symptom begins with understanding the history, recent investigations, psychosocial environment, and current medications and treatments. The patient’s developmental stage, verbal ability, and cultural factors

1. *The National Paediatric Palliative Care Clinical Network*. The following guidelines have been developed by the National Paediatric Palliative Care Clinical Network with the support of the Ministry of Health of New Zealand and are intended to be used by secondary medical, nursing, and allied health providers who care for babies, children, and young people at the end of life. It is not intended that the guidelines be used by primary care providers or by providers in neonatal intensive units. These guidelines are not suitable for use outside the Palliative Care setting. Visit https://www.starship.org.nz/for-health-professionals/national-paediatric-palliative-care-clinical-guidelines/#All
2. *Together for short lives* (www.togetherforshortlive.org.uk) is a UK-based organization working to improve care and services for children with life-threatening or terminal conditions and their families. They have a list-serve and other resources. A searchable database for literature for the health professional is accessible through www.act.org.uklpageslppI1.asp
3. To look up natural medicines that families may be using, visit the *Therapeutic Research Center*'s Natural Medicines page at https://naturalmedicines.therapeuticresearch.com/
4. *The National Pediatric Hypnosis Training Institute* (http://www.nphti.org/) provides training in ongoing clinical hypnosis skill development for advanced practice pediatric clinicians to assist children and teens in developing self-regulation, optimizing resilience related to medical and mental health issues and stressful experiences, and maximizing well-being and peak performance.
5. The *Hospice and Palliative Nurses Association* (HPNA) is a US-based nursing organization with web-based resources for professionals and families (www.HPNA.org).
6. The *Initiative for Pediatric Palliative Care* (www.ippcweb.org) is a comprehensive website with curricula and resources, including videotapes and other helpful educational resources.
7. The *National Hospice Palliative Care Organization* (www.nhpco.org) hosts the ChiPPS Curriculum, a collaboration between the Children's International Project on Palliative/Hospice Services and the National Hospice and Palliative Care Organization; visit www.nhpco.org/i4a/pages/index.cfm?pageid=3409
8. The *End of Life/Palliative Education Resource Center — Fast-Facts* offers downloadable resources relating to education about end-of-life care (not specific to but includes pediatrics), oriented for physicians and applicable to other health professionals. This resource will now be housed in the American Academy of Hospice and Palliative Medicine (AAHPM) at http://www.aahpm.oral.
9. The *Growth House* (http://www.growthhouse.org/death.html) is an all-round palliative care/grief and bereavement clearinghouse with links for health professionals, families, and volunteers.
10. The *Canadian Virtual Hospice* (www.virtualhospice.ca) is for patients of all ages, their families and friends, healthcare professionals, and healthcare volunteers. It provides information about physical symptoms of illness and deals with some of the emotional reactions and spiritual questions often experienced by patients and their families. The site includes chat rooms, bulletin board discussion areas, and e-mail access to a healthcare professional with expertise in palliative care, as well as resource lists of local hospices and palliative care programs, related products and services, books, a searchable researcher database, website links, and downloadable resources.
11. The *Pediatric-Pain Mailing List* (http://pediatric-pain.ca) is an international Internet forum for informal discussion of any topic related to pain in children.
12. The *Ian Anderson Continuing Education Program in End-of-Life* (www.cme.utoronto.ca/endoflife) is an accredited national continuing education program tailored to the needs of both family physicians and specialists.
13. The *Pediatric Palliative Care Mailing List* (paedpalcare@act.org.uk) is a searchable database for healthcare professional literature.
14. The *City of Hope's Pain/Palliative Care Resource Center Website* (www.citvofhope.org/Pfc/), which Betty Ferrell has been involved in for a number of years, has a large number of online resources for professionals and practitioners.
15. The University of Michigan hosts a series of workshops (http://open.umich.edu/education/med/resources/palliative-care/2010) that provide skills to pediatric physicians, nurses, respiratory therapists, and other health professionals that will improve their ability to care for pediatric patients who are dying in the hospital. They have developed three workshops; each takes about 90 minutes. These workshops feature videos of simulated doctor–patient interactions, worksheets, self-evaluations, and more.
16. The *Music Therapy Organization* (https://www.musictherapy.org/assets/1/7/MT_Young_Children_2006.pdf) website offers a resource to learn more about music therapy for young children.
17. The goal of the *Courageous Parents Network* (https://courageousparentsnetwork.org) is to empower parents caring for children with serious illness through video, shared community, professional guidance, and palliative care.
18. The *Dana Farber Pediatric Pain and Symptom Management Guidelines 2014* (http://pinkbook.dfci.org/assets/docs/blueBook.pdf) booklet is a guide to symptom management in children and a tool for identifying areas for self-study. Pharmacologic options for pain and other distressing symptoms are provided. (Use of medications requires adequate knowledge of side effects and drug–drug interactions. These suggestions cannot replace medical consultation.)

19. The *Canuck Place Children's Hospice, Vancouver, Canada* (www.canuckplace.org) is a caring, innovative children's hospice and community-based service that fully embraces the life of each child and family. They provide leadership in improving pediatric palliative care regionally, nationally, and internationally through collaboration, education, and research.
20. The *National Institute of Nursing Research* (NINR) (https://www.ninr.nih.gov/newsandinformation/conversationsmatter/media) supports and conducts clinical and basic research and research training on health and illness across the lifespan to build the scientific foundation for clinical practice, prevent disease and disability, manage and eliminate symptoms caused by illness, and improve palliative and end-of-life care.
21. The *International Children's Palliative Care Network* (http://www.icpcn.org/) works to raise awareness of children's palliative care, lobbying for the global development of children's palliative care services and sharing expertise, skills, and knowledge.
22. The Palliative Care Network of Wisconsin (https://www.mypcnow.org/pedfastfacts) provides fast facts on pediatric issues.

must be taken into account. Parental participation is essential in assessments and treatment. Nurses must have a dynamic process of assessment, treatment, evaluation, documentation, and communication with the child, parents, and interdisciplinary team members. Children with palliative care needs often have multiple providers in healthcare settings, schools, and social services. A care coordinator, either a nurse or a social worker, can improve communications between settings.

Underlying Causes of Symptoms and Goals of Care

With any new or ongoing symptoms, nurses need to be keenly aware of the pathophysiologic causes that may be causing or contributing to the symptom. In addition, the burdens and benefits of any investigation and/or potential treatment resulting from the investigation must be weighed. It is vital that healthcare providers do their best to ensure the family understands the stage of the child's illness. Although prognostication is fraught with many inaccuracies, especially in pediatric illness, children and families deserve some context.

Tensions may arise between different members of the healthcare team and even between family members in terms of how aggressively to pursue treatments or interventions. Some may see the benefits outweighing the burdens, while others may feel the benefits are too burdensome. Palliative care teams are experts in helping to navigate these types of situations.

Informed recommendations provided by pediatric palliative care clinicians can help families make the best decisions for the child in terms of location of care, intensity of treatment, goals of care, and support regarding advance care planning. For example, twice weekly blood transfusions for a child with a good QOL would likely be worth the burden, whereas for an unresponsive child at the end of life, it likely would not. However, each situation is unique, and the team and family together should make the best choice for the child.

Treatment of Symptoms

Symptom management must include both nonpharmacological interventions and pharmacological interventions.[15] A step-wise approach to increase interventions in response to the nature and severity of the symptoms is often used. This reduces the potential of overwhelming the family with too many choices all at once. Once symptoms are brought under control, the interventions can be tapered to determine which ones are most effective. An example of a symptom management algorithm can be seen in Figure 58.1.

Nonpharmacological or Integrative Therapies

> "Look, I am already taking nine medications and I am just a kid! Even adults won't want to take that many medicines."
>
> —10-year-old cancer patient

Nonpharmacological and integrative modalities are commonly used by parents and children with reported good effect for relief of adverse symptoms.[16] This can include cultural or religious interventions and can enhance or even provide better relief than the medication. It is important for the healthcare team to be aware of nonpharmacological interventions which may adversely interact with medications and treatment protocols. Exchanging information in an unbiased manner allows for clinicians and parents to hear about the potential benefits and burdens of any given treatment.

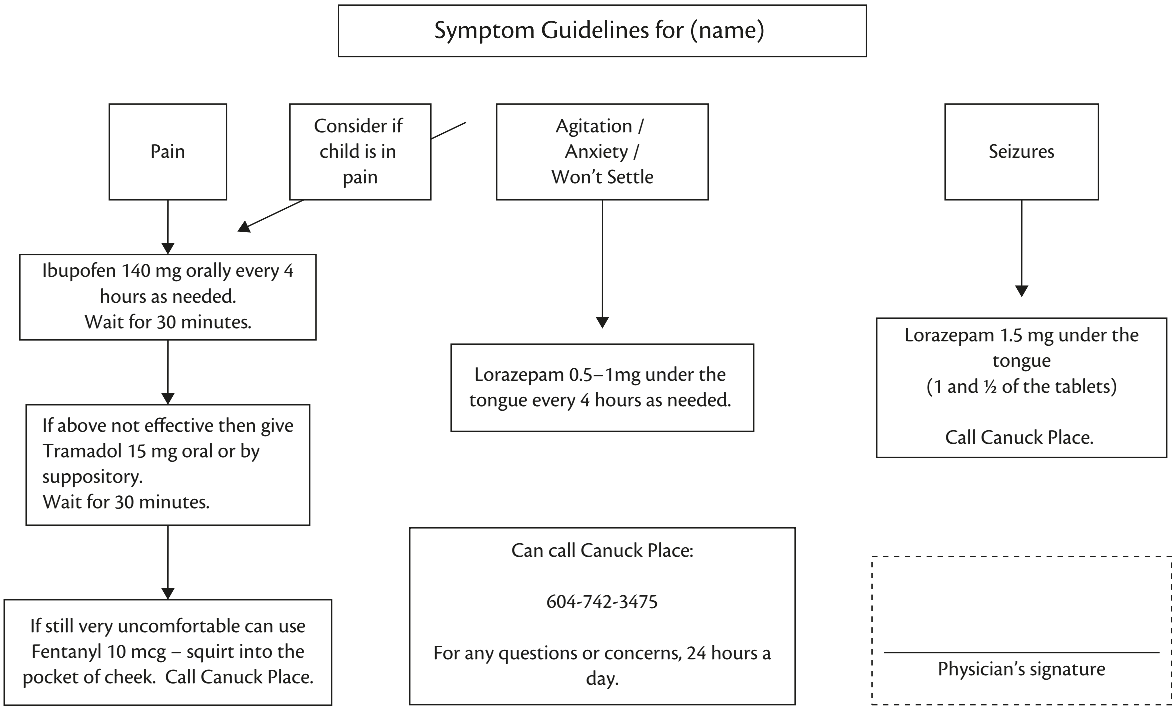
Mind–body modalities rely on the body's ability to self-regulate. Common practices include prayer, hypnosis, biofeedback, mental imagery, and music therapy. Hypnosis is best understood as an alternative state of awareness,[17] one of concentration and intense focus. Children have active imaginations that help them enter into a world of "make believe."[18]

Clinical hypnosis has proved useful for pain and symptom management, including nausea, in pediatric palliative care as well as for painful procedures such as lumbar punctures and blood draws.[18]

Music can bring comfort and distraction. Many parents sing songs or recite rhymes for young children, while older children may listen to music on headphones. Music therapists offer insight into deepening the effectiveness of this intervention.[19] Nurses can encourage parents to use this modality.

Biologically based integrative modalities include herbs, supplements, and related nutritional therapies. "Natural" does not guarantee safety; supplements can interact with other medications, have adverse effects, or even cause toxicity. A trusting relationship between the nurse and parents allows honest sharing to discuss the burdens, cost, and potentially unrealistic hope for cure.

Aromatherapy generally involves diluted topical application or inhalation of an essential oil. It is thought that topical essential oils can reduce pain and inflammation and that inhaled oils act on the central nervous system to produce a calming or arousing effect via the limbic system. Essential oils can also be a way to invoke



Symptom Guidelines for (name)
Pain
Consider if child is in pain
Agitation / Anxiety / Won't Settle
Seizures
Ibupofen 140 mg orally every 4 hours as needed. Wait for 30 minutes.
If above not effective then give Tramadol 15 mg oral or by suppository. Wait for 30 minutes.
If still very uncomfortable can use Fentanyl 10 mcg – squirt into the pocket of cheek. Call Canuck Place.
Lorazepam 0.5–1mg under the tongue every 4 hours as needed.
Can call Canuck Place:
604-742-3475
For any questions or concerns, 24 hours a day.
Lorazepam 1.5 mg under the tongue (1 and ½ of the tablets)
Call Canuck Place.

memories or to distract from noxious smells. Inhaled aromatherapy can be delivered via an infuser or simply by taping a cotton ball saturated with the oil to a pillow case. Lavender is typically used for relaxation.[20] Oral peppermint may relieve gas, and oral ginger may alleviate nausea.[21] Although aromatherapy is not well researched,[20] it is easy to use and has few adverse effects.

Manipulation and body-based therapies include techniques like massage, chiropractic, acupuncture, acupressure, and other forms of physical manipulation that may be used in consultation with the treating team. Practitioners experienced with children are preferred. Some express concerns that acupuncture needles many add to the child's distress, but there is some research that has shown that it is well-tolerated and effective.[22]

Energy therapies include esoteric arts, such as Reiki, healing touch, craniosacral therapy, Chi Gong, and related arts. These interventions involve a trained practitioner employing techniques to manipulate the naturally occurring energy fields or life energy within and around the body. These techniques are noninvasive, rarely cause complications, and can produce a sense of calm or relaxation. However, some families are not comfortable with these therapies.

Pharmacotherapy

Generally, the medications utilized for symptom management in pediatric palliative care are the same as those for adult palliative care, albeit with specific dosing recommendations. For example, neonates have limited ability to metabolize or excrete certain medications, often requiring low doses of medications which change as they mature. Medication doses are not included in this chapter but may be found online or in databases (e.g., Lexicomp or Epocrates). It is helpful for nurses to have ready access to the local children's hospital formulary and cross-reference with other resources (e.g., hospital or community pharmacist), as new information and safety considerations are informing practice all the time.

Nurses also need to consider which route of administration is most appropriate for the child, taking into account the compatibilities of medications, adverse effects, and the benefit/burden at any given interval in the child's trajectory. Medications should be selected in the context of the child and family. Rectal administration may be unacceptable for some families. Sensitive education may help a family agree to try a method or medication that is initially unacceptable; however, family members should never be pressured or made to feel guilty for their decisions.

Dyspnea/Respiratory Distress

Dyspnea is the subjective feeling of being short of breath. Respiratory distress can be observed by others as a symptom that includes increased work of breathing, decreased ability to exert oneself, panic, or agitation. In babies, retraction of the ribs and head bobbing is often observed. Parents often describe dyspnea as one of the most difficult symptoms to witness in their child, and many voice concerns about their child feeling like he or she is suffocating. Dyspnea must be anticipated and responded to quickly. Dyspneic symptoms can present at any age and with a variety of conditions; anticipation of dyspnea is essential in care planning. It is the nurse's role to ensure that the parents can assess respiratory distress, treat with nonpharmacologic interventions (fan, cool room, positioning), and escalate the medications safely and confidently. Opioids and benzodiazepines are first-line options for managing dyspnea.[23] Different agents have different pharmacokinetic profiles and are therefore suitable for certain situations. For temporary breathlessness that occurs with increases in activity (such as during a shower), a quick-acting, ultra-short-acting opioid such as sublingual fentanyl is an appropriate choice. Writing an algorithm for staff and family provides a guide to which interventions can be escalated; a breakthrough dose may be needed if background medications are insufficient.

Case Study: A Pediatric Patient with Dyspnea and Panic

Rachel is a 17-year-old with metastatic osteosarcoma and extensive lung disease. Recently, she has experienced increasing work of breathing with activity. She was having difficulty getting to class using her crutches, and showers were exhausting. She was more comfortable when sitting and found a handheld fan helpful for dyspnea. She had a mild cough but no secretions, fever, or nasal congestion. Her hope was to continue to attend school. Rachel started on 5 mg of immediate-release morphine to be taken hourly as needed. A salbutamol inhaler every 4 hours as needed decreased her cough. After a few days, her morphine was converted to a long-acting formulation of 30 mg every 12 hours (she had used an average of 12 breakthrough doses/day) with a breakthrough dose of 3 mg every hour as needed. This provided much better control of her dyspnea.

Rachel's dyspnea continued to worsen over several weeks, especially at night when prone. She was struggling to arise, shower, and get to class. The breakthrough doses helped but left her drowsy and unable to pay attention in class. Rachel was getting weaker. She found that the short-acting opioid fentanyl 25 mcg sublingually prior to exertion reduced her dyspnea without making her "zoned-out." A fan at her bedside was helpful, while oxygen was not. She agreed to try lorazepam 1 mg as needed and relaxation tapes.

As the dyspnea got more severe, her panic increased. She identified that it was not only the sensation of feeling breathless but was also due to her sadness and fear of knowing she was dying. She said talking helped sometimes. Other times, she just wanted her mom to hold her hand and look at old photos. The lorazepam helped control the overwhelming fear. Meditating to a safer place, which she identified as a beach setting with a cool breeze, was also helpful for her. By having a number of interventions to use, Rachel was able to control her dyspnea and improve her comfort.

Excessive Secretions Can Cause Respiratory Distress

Secretions can be problematic at different times across the child's palliative journey and do not need to be treated unless causing distress. Increased salivation is very common in children with neuromuscular disorders such as cerebral palsy. At times, a dry bib will suffice, but drooling/excessive secretions can cause perioral dermatitis, dental problems, dehydration, respiratory distress, and aspiration pneumonia.[24] Thick secretions may be hard to mobilize and cause respiratory issues, but increased humidity or nebulized saline can be helpful.

As with other symptoms, it is vital to assess whether any of the treatments or medications are exacerbating the problem. Excessive medical hydration can cause increased oral secretions,[25] and this issue needs to be examined carefully. Nonpharmacological measures to treat excessive secretions include adjusting fluid intake, positioning, and good pulmonary toilet.

If chronic and problematic, secretions can be managed with oral anticholinergic agents such as glycopyrrolate[26] or hyoscine, and atropine 1% ophthalmic drops can be used orally. However, adverse effects, such as thick secretions and urinary retention, can occur. In some children, injection of Botulinum toxin (Botox) into the salivary gland can be helpful to reduce secretions.[24]

At the end of life, some children have secretions that collect in the back of the throat as the swallowing muscles become too weak to function. The associated gurgling noise can be very distressing for family members. The nurse can help family members recognize signs of distress in the child's face and know which comfort medications should be given to help relieve the symptoms as much as possible.

Case Study: A Patient with Excessive Secretions

At age 3 years, Ali was diagnosed with a neurodegenerative condition. He slowly lost his ability to swallow. A gastrostomy tube was inserted for nutrition. His increased secretions irritated his face, and neck requiring frequent clothing changes. Barrier creams and bibs helped for a short time but frequent aspiration pneumonia and chronic sores in the folds of his neck became serious complications. Oral glycopyrrolate was prescribed and, later in his disease course, sublingual atropine and Botox injections to his salivary glands were employed but did not resolve the issue. The family chose no other aggressive interventions. As Ali's disease progressed, the secretions increased, requiring suctioning every 10–15 minutes, while his gastrostomy feeds continued at the same rate. Palliative care staff talked with the family about the burdens of overhydration causing increased secretions at end of life. Ali's mother said she would allow Ali to "tell her" when he had too much by the amount of secretion he was experiencing. With the technique of "feed to comfort," his comfort level improved.

Gastrointestinal Symptoms

Nausea/Vomiting

Nausea is a complex symptom with a wide variety of causes.[27] It can be caused by chemicals such as drugs or toxins, central nervous system abnormalities, vestibular changes, and multiple issues in the gastrointestinal tract including constipation. When the underlying cause can be identified, it will determine the most effective intervention. A careful assessment is essential.

Psychosocial and emotional aspects play a significant role in gastrointestinal symptoms and managing anxiety, anger, and other stressful emotions can provide relief of these symptoms. Therefore, a very careful history and assessment, involving the parent and, if possible, the child, is essential. Understanding the frequency, duration, and timing of nausea/retching or vomiting can help delineate contributing factors, but further investigation may be needed.

Reducing intestinal distention can relieve nausea, retching, or vomiting. Regular bowel movements are key. For some children, this may mean multiple bowel movements in a day. Children who receive their nutrition orally have control over their intake, while those who are "tube-fed" do not. It is important to adjust the amount and rate of the feeding to the child. Children with severe neurological impairment often have lower energy requirements than healthy children, and overfeeding may cause abdominal distention and discomfort.[28] In collaboration with their managing team, families may try Pedialyte, adjusting the rate and concentration of formula, or try temporarily stopping the medically provided nutrition.

Hypnosis, music therapy, and aromatherapy can be tried. Acupressure is commonly used for nausea. The pressure point for nausea control is the P6 or Neiguan pressure point. This is on the inside of the forearm three of the child's finger widths distance from the wrist crease.[29] Elastic straps (Sea-Bands) that provide continuous gentle pressure are available, and intermittent pressure on the P6, or for older children, a dried bean—a "magic bean"—taped on to the P6 point works well. Research has shown that acupuncture is well tolerated and effective for nausea as well.[30]

Peppermint, chamomile, fennel, ginger, or other mild teas may settle an upset stomach. Chicken soup, tea and toast, or family remedies, although not scientifically proven, may be helpful. The power of the placebo is not to be ignored.

Establishing the cause of the nausea, if possible, will determine the medications used. Some common medications used for nausea and vomiting include dimenhydrinate, 5HT-3-receptor antagonists (e.g., ondansetron), corticosteroids (e.g., dexamethasone), benzodiazepines (e.g., lorazepam), and prokinetics (e.g., domperidone). Note that these medications can cause extrapyramidal effects. The best route for medications is the one that is simplest and most acceptable for the child and family. This may be intravenous, rectal, sublingual, or transdermal.

Case Study: A Patient with Nausea

Olivia was a 6-year-old with a rare fatal condition. Olivia's mother reported that her daughter was complaining of feeling sick. After a thorough assessment, no clear physical reasons were evident. Oliva said when her mother left the room, "My fish died and we flushed him down the toilet. That is what happens when you die! I heard the Doctor tell mama that I might die. If I die, will they flush me down the toilet?"

The team, including a child life professional and a massage and music therapist worked with Olivia's mother to give her age-appropriate information to address the anxiety. Further medical tests were discussed with the family to ensure all aspects of this symptom were addressed.

Constipation: Prevention Is Better Than Cure

"My nurse is always asking about poop!!" said an 8-year-old boy in hospice. Each child's normal bowel routine is different and constipation must be assessed in that context. Assessment of the cause, history, and usual bowel habits will guide the interventions suggested to the family. Constipation commonly occurs secondary to medications, neurological disorder, and disease process. In mild cases, pear juice, prune juice, increased fiber and fluids, or a bulk-forming laxative can be effective. When constipation is more severe or long-standing, polyethylene glycol powder, stimulant laxatives such as senna or bisacodyl, and lactulose can be used. The dosage and formulation will depend on the child's weight and ability to swallow. In younger children, rectal medications may be the simplest solution to treat constipation, whereas older children typically dislike rectal administration. Sodium phosphate enemas and glycerin or stimulant suppositories can be used if there is impaction but not obstruction. When tumor obstruction or structural abnormalities are present, surgery or subcutaneous injections of octreotide may be used. In cases of severe opioid-induced constipation, intravenous methylnaltrexone can be effective.[31] A sample of a constipation algorithm can be found in the CPCH Symptom Assessment Guidelines.

Case Study: A Patient with Constipation

Jennifer was a single mother of Tyler, who had encephalopathy secondary to birth asphyxia. He was fed by gastrostomy tube. During one home visit with the nurse, Jennifer mentioned that Tyler has started vomiting after his feeds. On further discussion, she reported he had not had a bowel movement for 1 week. The nurse discussed the possible connection between the vomiting and constipation. Polyethylene glycol was prescribed, but Jennifer preferred to give him prune juice, which worked well.

Feeding Difficulties/Appetite Issues

Across all ages and many cultures, food is symbolic of love and interconnectedness. Intake of food is seen as the most basic human need. When disease or treatments decrease the child's appetite, families are distressed, even if the child is not. A careful assessment of medications, nutritional history, physical condition, and disease process must be done. This may reveal rectifiable issues such as poor oral hygiene, mouth sores, or dental issues that can contribute to nutritional problems. Finances may prevent families from access to nutritious food, but they may hesitate to mention this. Social workers can be particularly helpful in these situations. Appetite stimulants have a role in some cases but may have adverse effects.

A child's inability to eat can be mistakenly interpreted as a personal rejection or giving up. For some families, food becomes a point of great discord, and parents may pressure the child to eat, resulting in frustration for both. The nurse must gently listen, educate, and support the family at this difficult time, helping them to find ways to reduce stress around eating. Small frequent snacks may be more palatable for the child. Families can be encouraged to find other ways to share their love for each other when food is not involved, such as watching a special movie together, doing an activity, or sharing story time.

In children whose condition is close to the end of life, weight loss is part of the natural process of the body shutting down; therefore, monitoring weight is less important and can cause family distress. However, an accurate weight may be needed to prescribe new medications.

Children who receive long-term medical nutrition and hydration (MHN) via medical interventions (e.g., gastrostomy, jejunostomy, or parenteral infusions) do not have the natural control over their body's intake. At the end of life, MHN can be more burdensome than beneficial. This may be shown in increased edema, vomiting, and increased secretions.[32] At this point, the team needs to help the family reidentify their goals of care and determine what actions would be most effective. The family can learn to adapt the interventions to meet those goals. Often, this is a long process, as families and the team adjust the rate, frequency, amount, and type of formula in an attempt to find what other forms of nutrition the child can benefit from before accepting the child's change in condition. At times a "feed to comfort" medical order may be needed to relieve the child of the suffering from an inability to process MNH.

Figure 58.2 Morning glory.

Box 58.2 Neuro-irritability Assessment

A child may have neuro-irritability if:

- Actions known not to be painful (wearing socks, touching) seem to cause pain or distress
- Child fusses or cries for no apparent reason
- Child's crying is difficult to control or is prolonged
- Parent cannot tell the difference between the child's cries for attention and cries due to pain/discomfort
- Child's pain/discomfort cannot be localized

Nonpharmacological Measures for Inconsolability

- Environment: Quiet, dim lighting; rested parents
- Swaddling
- Music therapy
- Aromatherapy: Lavender oil diffuser or drop on a cotton ball on the pillow
- Massage
- Prayer
- Rocking: Infant swing, rocking chair
- Therapeutic touch or Reiki

Source: Adapted with permission from Reference 34.

This type of order allows for feeding flexibility to adjust to the child's comfort, even if that means decreasing or stopping feeds. This period is a sensitive and particularly difficult time as feeding is seen as an inherent part of providing care. The team's understanding, patience, and ongoing support for the family are essential at this time; it may be an issue that takes time to resolve. A spiritual care provider working in collaboration with the team can be of great support, particularly at the end of life when a child refuses to eat or cannot tolerate MNH.

At end of life, when a child's body is no longer able to tolerate nutrition or hydration, natural changes occur in the body. Children may start to look very gaunt or skinny, and the skin may be dry and loose, which can be upsetting. For some families, the analogy of the morning glory flower is helpful (Figure 58.2). This flower in full bloom is open but at the end of the day it closes and looks wrinkled and shrunken, yet it is the same flower inside.

The dying process can be very protracted. Dying infants have lived comfortably and very alertly for as long as 3 weeks without any medically administered nutrition or hydration. This can be an intense time of waiting and watching for the family and healthcare providers. The ongoing support of the team for both parties is essential.

Neurological Symptoms

Children with serious neurological impairment, with or without an underlying progressive condition, typically experience a complicated disease course, with times of stability interrupted by acute health decline and recovery, followed by a new plateau with an uncertain trajectory.[2] Seizures, increased tone or spasticity, and irritability wreak havoc on the QOL of the child and the family. The wide range of specialist teams involved can make sharing information a challenge. But, ideally, the various team members will coordinate and collaborate to create a care plan with parents.

A comfort log is an individualized tool for determining the extent or severity of the symptoms and the helpfulness of an intervention. They are easy to design and can be used during a hospital stay or at home. They can include descriptions of the symptom, duration, helpful interventions (pharmacological or nonpharmacological), and effect of interventions. This enables clinicians and family members to get an overview and assess the effectiveness of interventions. For example, the questions listed in the neuro-irritability assessment at the end of the chapter in Box 58.2 can be helpful for healthcare providers and family members to examine neuro-irritability symptoms. In assessing a child for neuro-irritability, it is also important to identify any signs of allodynia and hyperalgesia.[33] Benzodiazepines, gabapentin, or pregabalin, neuroleptics, and adrenergic agonists and antagonists are the medications most often used for neuro-irritability symptoms.[34]

Children who have increasing frequency of seizures or a potential to have a seizure (e.g., brain tumor) require a step-wise approach to management involving regular antiseizure medications (e.g., levetiracetam) and rescue medications (e.g., diazepam). An individualized algorithm that incorporates interventions and next steps is helpful. When there is potential for life-threatening seizures, clinicians have an obligation to discuss this with the family, so direction of care can be considered. For example, a child with a progressive brain tumor may need treatment for a seizure within the context of her dying. Part of the algorithm may explicitly state that the parent's role is to not only medicate the seizure, but also to hold and comfort the dying child. For children who are otherwise stable, the plan may include responding to the symptom with medication and then engaging emergency services for further treatment.

Emotional and Existential Distress

It is beyond the scope of this chapter to critically explore anxiety and depression from emotional and existential distress in children with palliative conditions. Children of any age may experience suffering during the dying process that goes beyond the physical.

Moreover, parents and children are connected in ways that are not like other relationships, with each influenced by the other in the face of ultimate physical separation.

Children of any age should be assessed from a developmental framework in regard to their emotional and spiritual health. Are they experiencing joy and times of pleasure and having opportunities to play and express themselves? What is it like to spend months in neonatal intensive care or receive chemotherapy? How are they adjusting to the changes in friendships and activities? What gives them hope and purpose?

Families and children have different capacities in which to communicate, find meaning, and adjust to the multitude of changes that serious illness brings. An interdisciplinary palliative care team can be instrumental in supporting the family unit and the child in these tasks. If physical symptoms can be controlled, it may allow the child and the family to better process the symptoms of emotional and spiritual distress. Often, families need coaching in how to listen to their children's questions about the changes in their body and how to respond with both honesty and hope. Children and parents may need different and separate confidants to share their questions, worries, and fears as a way to protect the other loved one.

When suffering in this realm is not responding to multiple attempts from family, community, healthcare providers, counseling professionals, spiritual support, and other therapy, medications such as long-acting antidepressants, benzodiazepines, antipsychotics, or stimulant medication may be helpful in the short or medium term.

Case Study: A Patient with Multiple Symptoms

Mya was born with a fatal genetic disorder and irreparable cardiac condition; she was expected to live only weeks to months after birth. The parents wanted comfort care only and were eager to go home.

They were happy to have her home, but struggled to cope with her long periods of crying. No curable causes for the crying could be found. The team was concerned that this was neuro-irritability, also known as *central neuropathy*. Nonpharmacological interventions along with an over-the-counter medication were tried. These helped but did not resolve the problem.

There was parental resistance to medications, but, with further discussion they decided to "listen" to what Mya was "saying" she needed. Gabapentin was helpful during the day, and lorazepam at night allowed everyone to sleep.

While initially the parents did not want any tubes, they now feared she was hungry and requested a nasogastric tube be placed for extra feeds. The palliative care team taught the parents how to place the tube and had the family use a reliable YouTube video as an additional guide.

The extra feeds increased Mya's oral secretions, requiring frequent suctioning, and she began to vomit with feeds. None of the medications or adjustments prevented this. This was a difficult time for the family, but they decided to remove the tube and feed her orally. Mya was more comfortable and died peacefully.

Conclusion

> Blessed are the flexible for they shall not be bent out of shape.
> —An old Southern saying.

Although many of the symptoms commonly seen in dying children are similar to those in adult palliative patients, children are often less able to describe and localize their symptoms. Nurses must therefore be careful listeners, imaginative problem-solvers, and evidenced-based professionals. They need to be able to draw on a broad skill set, including excellent assessment, critical thinking, and communication skills, and flexibility.

The family must be closely integrated with the palliative care team as care planning and decision-making are done. If this collaboration is not present, success may be difficult. Building trusting relationships is vital to ensure excellent care with the designated "family" of the child, the medical team, and community resources.

Nonpharmacologic interventions, medication dosages, and routes of administration must be tailored to the child and family. Acceptance of the care can be influenced by culture, religion, past experiences, and the child's stage of development. Evidence-based clinical guidelines and algorithms can be helpful as a starting point for the individualized care plans.

Pediatric symptom management can be complex and challenging but often rewarding, as you see a child and family move from a focus on the distressing symptom to an improved QOL.

CHAPTER 59

Pediatric Hospice and Palliative Care

Vanessa Battista and Gwenn LaRagione

Key Points

- Pediatric palliative and hospice care (PPHC) is multifaceted care that focuses on a child's and family's well-being along a physical, psychological, emotional, spiritual, and social continuum.
- Pediatric hospice should be considered a necessary part of comprehensive palliative care.
- Pediatric palliative care (PPC) involves a family-centered approach to caring for infants, children, and adolescents and considers all family members as part of a dynamic web of interconnected lives and relationships.
- Initial and ongoing education and care delivered by an interdisciplinary team (IDT) of healthcare professionals is essential in addressing the complex physical, emotional, spiritual, and practical needs and concerns of children and their families.
- Relieving suffering and improving quality of life, for even a brief life, can benefit not only the child, but all those affected by the illness or death of the child, including siblings, parents, grandparents, other relatives, teachers, school friends, faith community, and neighbors, as well as the healthcare professionals involved in their care.
- Nurses who care for dying children and their families need a significant personal and professional support system and opportunities for renewal, personal growth, and ongoing education.
- PPHC is a rapidly developing field with many opportunities for growth and expansion.

Overview of Pediatric Hospice and Palliative Care

Universally, children symbolize the "future," representing dreams and the promise of accomplishments yet to be fulfilled. The experience of serious illness or the death of an infant, child, or adolescent (referred to collectively as "children" for the purposes of this chapter) therefore generates a legitimate threat to such hopes. Bearing witness to these experiences motivates clinicians to do their best to prevent and relieve the suffering of children likely to die, both through interventions aimed at cure and, when cure is no longer possible, through the provision of interdisciplinary pediatric hospice and palliative care (PPHC). PPHC is an area of nursing that requires specialized knowledge and training and great sensitivity to the unique needs of families enduring some of the most arduous moments of their lives. Providing this type of care throughout the illness process, from the time of diagnosis until the time of death, can be simultaneously physically and emotionally challenging, as well as enriching and rewarding. This chapter provides an overview of PPHC and the special considerations necessary for nurses who are called on to provide this unique type of care for children and their families.

Definition of Pediatric Palliative Care

The World Health Organization (WHO) developed one of the earliest and most widely accepted definitions of pediatric palliative care (PPC), describing it as the active total care of the child's body, mind, and spirit and involving an evaluation of a child's psychological, physical, and social distress.[1] That definition has since evolved to include care aimed at improving quality of life (QOL) of patients facing life-threatening illnesses and of their families through the prevention and relief of suffering by early identification and treatment of pain and other problems, whether physical, psychological, social, or spiritual.[1] The American Academy of Pediatrics defines PPC as care that should aim to achieve the best QOL for patients and families consistent with their values.[2] The Institute of Medicine states that PPC should consider the needs of patients and families in order to provide timely, accurate, and compassionate information regarding diagnosis, prognosis, and treatment options.[3] As the field of PPC has advanced over the past decade, understanding the emotional well-being of the child and family and the importance of an interdisciplinary approach to care have been incorporated in defining optimal PPC.[4,5]

Combining all of these definitions, PPC can be described generally as a family-centered approach to care that encompasses the physical, psychological, emotional, social, and spiritual components of a child's needs and focuses on overall QOL. Ideally, PPC should be provided by an interdisciplinary team (IDT) of professionals from medicine, nursing, psychiatry, psychology, social work, chaplaincy, child life, physical/occupational/speech therapy, art and music therapy, nutrition, pharmacy, and other areas of healthcare (e.g., integrative health and other therapies). PPC offers expert pain and symptom prevention and management and honest discussion around the child's medical condition, which serves as the foundation for collaborative decision-making regarding goals of care. This child-focused, family-centered, holistic care should be initiated as early as possible in the illness trajectory in order to provide the child and family with the opportunity to receive support that will enhance their capacity to cope with a life-threatening or life-limiting condition. PPC aims to preserve the integrity of the family throughout disease progression, addresses anticipatory grief, and also includes bereavement support following death.

Definition and Evolution of Hospice Care

The word "hospice" is thought to have originated in the early eleventh century, stemming from the Latin word *hospes* or *hosptium*, meaning "guest house" and referring to both guests and hosts.[6] The National Hospice and Palliative Care Organization (NHPCO) describes hospice as a model of care designed to provide quality compassionate care to people with a life-threatening/-limiting illness that centers around their individual needs and wishes and is delivered through a team approach (e.g., pain and symptom management and medical, spiritual, and psychosocial care/support). Hospice care focuses on caring for, not curing, the patient while also providing support to family, friends, loved ones, and communities.[7]

The modern hospice movement began with Dame Cicely Saunders, trained as a registered nurse, social worker, and physician, who founded St. Christopher's Hospice in the United Kingdom in 1967. As her career evolved, so did her realization that a dying person needs more than symptom management; she felt they needed a holistic approach to care; that is, they needed to be treated medically, physically, emotionally, spiritually, and socially. She also pioneered the development of bereavement services, as she recognized that the patient and family were a single entity that needed support both during the dying process and after the death of the patient.[8]

As the hospice philosophy and movement grew throughout the United Kingdom and into the United States, Medicare recognized the need to cover hospice services and introduced the hospice benefit in 1983. The benefit was designed to provide nursing care, medications, medical supplies, psychosocial support, and volunteer services for end-of-life (EOL) care through a daily per diem reimbursement rate. To be eligible for the benefit, a patient had to have a life expectancy of 6 months or less, as defined by a physician, and had to relinquish aggressive, disease-related curative treatment in exchange for supportive care during the dying phase of life.[9] As a result, society's view of death and dying changed, an economic value was placed on dying, and EOL care became a public policy issue.

Comparing Pediatric Palliative and Hospice Care

The terms "palliative care" and "hospice care" are often used interchangeably (as in this chapter) because of their similar core values and philosophical approaches to care. However, it is important to appreciate and understand their distinctive features. Primarily, palliative care can be provided at any time during the course of the disease (including the time of diagnosis), whereas hospice care focuses more around true EOL care.[10]

When compared with adult care, there are many differences in the provision of PPHC, and the NHPCO's *Standards of Practice for Hospice Programs*, Appendix IV: Pediatric Palliative Care (see Box 59.1), provides in-depth insight into these differences. Most

Box 59.1 Patient- and Family-Centered Care (PPC PFC) Principle

The palliative care and/or hospice interdisciplinary team provides family-centered care that includes the child and family as one unit of care, respecting individual preferences, values, and cultural beliefs, with the child and family active in decision-making regarding goals and plan of care.

Patient and Family-Centered Care (PPC PFC) Standards

PPC PFC 1 The goals of the child and family are foremost at the center of all services provided.

PPC PFC 1.1 Services should be available to all children and families who are referred, regardless of their financial or health insurance status.

PPC PFC 1.2 Family is defined as the persons who provide physical, psychological, and spiritual comfort to the child, and who are close in knowledge, care, and affection—regardless of genetic relationships. Family members may be biological, marital, adoptive, custodial relations, friends, as well as pets. Parents, siblings, grandparents, schoolmates and others are part of the child's community who may need particular support.

PPC PFC 1.3 All aspects of care are provided in a manner that is sensitive to: the child's developmental stage; the personal, cultural, and spiritual beliefs and practices of the child and family; and their preparedness to deal with dying or its possibility.

PPC PFC 1.4 The child has the right to age-appropriate information about his or her illness, as well as potential treatments and outcomes, within the context of family decisions. The program has trained staff and a full range of clinical and educational resources that meet the needs of each child served regardless of age, cognitive and educational ability.

PPC PFC 1.5 The family and caregivers have the right to be informed about the illness, potential treatments and outcomes.

PPC PFC 1.6 Decisions are made by the family, including the child to the level of his/her capacity, in collaboration with the interdisciplinary team and additional service providers.

PPC PFC 2 Comprehensive anticipatory loss, grief and bereavement support methodologies are offered as an integral component of care to the child and all family members from diagnosis or at admission into the program.

PPC PFC 2.1 Methods to address loss, anticipatory grief and bereavement are age-appropriate and include information about the needs of dying and grieving children at all developmental stages.

PPC PFC 2.2 Educational materials describing children's grief and supportive strategies for bereaved children are made available to family members.

PPC PFC 2.3 Partnerships among palliative care providers and community agencies (e.g., schools, faith communities) are established to facilitate outreach and support for children affected by loss.

PPC PFC 2.4 The needs of siblings are an integral part of each child/family plan of care.

(*continued*)

Box 59.1 Continued

Ethical Behavior and Consumer Rights (PPC EBR) Principle

The best interests of the child shall be the primary consideration in decision-making.

Ethical Behavior and Consumer Rights (PPC EBR) Standards

PPC EBR 1 Staff communication with the child and family is open and honest, in accordance with each child's level of understanding. Without full disclosure, the child and family cannot participate in decision-making about treatment choices. When, what, and how to disclose information to children must take into account the child's and the family's cultural or religious values, the parents'/guardians' choices of what the child can be told, and the child's capacity and desire to understand.

PPC EBR 1.1 Every child has equal access to palliative care and/or hospice, irrespective of the family's financial circumstances.

PPC EBR 1.2 Children are not subjected to treatments that impose undue burden without potential benefit.

PPC EBR 1.3 Every child receives effective pain relief and symptom management, incorporating the use of pharmacological and non-pharmacological methods.

PPC EBR 1.4 Every child is treated with dignity and respect, and is afforded privacy.

PPC EBR 1.5 The needs of adolescents and young people and their role in decision-making are addressed and planned for, well in advance.

PPC EBR 1.6 The practice of physician-assisted suicide or euthanasia is not supported or endorsed.

PPC EBR 1.7 The principles of negotiation and conflict resolution are used to address disagreements among or between healthcare providers, the child and the child's family about disclosing information to the child.

PPC EBR 1.8 When resolution is not achieved, the interdisciplinary team enlists the assistance of a cultural interpreter/advisor, chaplain and/or an ethics consultant.

PPC EBR 1.9 In the event of an ethics consult, the team meets afterwards, with the family and/or child present *(as preferred by the child and his/her family)* to discuss options, and to assist in implementing changes to the plan of care.

PPC EBR 2 The interdisciplinary team provides guidance to the child/family in choosing medically and ethically appropriate treatment options that are consistent with their values and beliefs. Team members should not attempt to influence families to make decisions that are not compatible with their values. Children with chronic illness often have a level of understanding greater than would be assumed based on their age.

PPC EBR 2.1 Every child is given the opportunity to participate in decisions affecting his or her care, according to age, understanding, capacity and parental support.

Emphasizing competence or capacity to assent or dissent, rather than the age of the child, allows children to participate in decisions regarding their care whenever possible and appropriate.

PPC EBR 2.2 While most children under the age of 18 have no legal decision-making rights, they should be included in decision-making according to their capacity. For children without complete decision-making capacity, parents or guardians make decisions based on the best interests of the child, assisted by the interdisciplinary team.

PPC EBR 2.3 For older children who demonstrate some healthcare decision-making capacity, parents/guardians and the interdisciplinary team should share age-appropriate information, seek assent, and take into consideration dissent, while ensuring the child's best interests remain at the core of decisions.

PPC EBR 2.4 For adolescents under the age of 18 who demonstrate healthcare decision-making capacity, every effort must be made to obtain parental approval to include these children in the decision-making process, thus allowing them to exercise independence.

PPC EBR 2.5 Emancipated minors with demonstrated capacity have the legal right to participate in all decisions regarding their medical care.

PPC EBR 2.6 There is an established process for anticipating, identifying, and resolving conflict, including consultation with specialists and/or a bioethics committee.

Clinical Excellence and Safety (PPC CES) Principle

Health professionals providing pediatric palliative care and/or hospice have a responsibility to pursue comfort aggressively and minimize the child's physical, psychosocial, and spiritual pain and suffering.

Clinical Excellence and Safety (PPC CES) Standards

PPC CES 1 Clinical care will be guided by the ethical principles of beneficence, nonmaleficence and promotion of the best interests of the child.

PPC CES 1.1 In the absence of pediatric medical expertise, the palliative care and/or hospice organization will develop a collaborative consultative relationship with pediatric providers and/or a tertiary healthcare facility to support provision of care suited to the unique needs of pediatric patients.

PPC CES 1.2 A primary care coordinator for all pediatric patients is identified.

PPC CES 1.3 A plan for anticipated pain and symptom management is part of every plan of care.

PPC CES 1.4 Pain prevention and treatment should be anticipated for all procedures or interventions related to the plan of care. Procedures or interventions not related to the goals of care should be avoided.

(*continued*)

Box 59.1 Continued

PPC CES 1.5 Members of all disciplines providing direct services to children will complete annual competencies in pediatric pain and symptom management.

PPC CES 1.6 Utilization of age-appropriate assessment tools is confirmed in all documentation.

PPC CES 1.7 Pain and all distressing symptoms will be assessed on every visit, by each discipline.

PPC CES 1.8 Families, and the child as age-appropriate, will be educated about pain and symptom assessment and management as it relates to their child's plan of care. Education materials are made available at time of admission and/or when pain and symptoms occur.

PPC CES 1.9 A pediatric physician and/or pharmacist are available for consultation to the interdisciplinary team as needed.

PPC CES 1.10 Adequate doses of analgesics are administered "around the clock" and not only on an "as-needed" basis. Additional doses are given to treat breakthrough pain, or predicted intermittent exacerbation.

PPC CES 1.11 When indicated, a sufficient dose and an appropriate pharmacological formulation (for example, sustained-release preparation or continuous infusion) is chosen to enable children and their families to sleep through the night, without waking in pain or waking to take their medications.

PPC CES 1.12 The appropriate opioid dose is the dose that effectively relieves pain and is not based solely on doses per body weight.

PPC CES 1.13 Age-appropriate, non-pharmacological therapies are an integral part of the pain and symptom management plan of care.

Inclusion and Access (PPC IA) Standards

No pediatric-specific additions to this standard are suggested.

Organizational Excellence (PPC OE) Principle

Flexibility in pediatric program design and service delivery facilitates access to services for children. A pediatric palliative care and/or hospice model that offers multiple support services over time and across settings ensures enhanced access for this underserved population.

Organizational Excellence (PPC OE) Standards

PPC OE 1 Pediatric programs may serve patients in the perinatal period, infancy, childhood, adolescence and young adulthood. The program must have policies and procedures in place to address all developmental, physical, social, psychological and spiritual needs of children served.

PPC OE 1.1 Care by providers trained in pediatric palliative care and/or hospice is available 24 hours a day, 7 days a week.

PPC OE 1.2 Families have a key contact person to assist with coordination of care, and they are instructed on how to contact the team in the event of a crisis or if they have needs after designated business hours.

PPC OE 1.3 Coordination of care among the interdisciplinary team, the family, and all sites of care occurs regularly and is discussed routinely at interdisciplinary team meetings.

PPC OE 1.4 Pediatric palliative care and/or hospice services are accessible to children and families in a setting that is appropriate to their needs and resources.

PPC OE 1.5 Respite care is recognized as a valuable need and the team makes every effort to ensure that families have access to respite care in their own home and/or in a home-away-from-home setting or facility with pediatric interdisciplinary care.

PPC OE 2 The program partners with community agencies and others that provide resources for children.

PPC OE 2.1 The program partners with local schools.

PPC OE 2.2 The program partners with social service agencies.

PPC OE 2.3 The program partners with specialty healthcare agencies.

PPC OE 2.4 The program partners with faith groups in the community.

Workforce Excellence (PPC WE) Principle

The organization's leadership develops and monitors systems to ensure that pediatric palliative care and/or hospice interdisciplinary team members, including volunteers, are adequately trained, staffed and supported to provide the services offered by the program, and that sufficient support is in place for staff to engage in routine self-care.

Workforce Excellence (PPC WE) Standards

PPC WE 1 All staff caring for children receive pediatric-specific orientation, training, mentoring, development opportunities and continuing education appropriate to their roles and responsibilities.

PPC WE 1.1 Pediatric-specific training is completed by all staff caring for children with life-threatening conditions.

PPC WE 1.2 Volunteers directly working with children or their families are also trained in developmental needs, family dynamics, communication challenges, and pain and symptom management.

PPC WE 1.3 When pediatric providers are not available within an organization, partnerships or consultative agreements are established with those in the community and/or at tertiary healthcare centers who are experts in working with children and adolescents.

PPC WE 1.4 Clinical policies and procedures are developed and implemented for the care of children of any age. Policies and procedures reflect evidence-based pediatric practice and guide the provision of care by all disciplines.

(*continued*)

Box 59.1 Continued

PPC WE 1.5 On-call or after-hours staff are competent to take pediatric calls and provide pediatric care.
PPC WE 1.6 Pediatric consultative support is made available to staff as needed 24 hours/day.
PPC WE 2 Pediatric visit frequency and length of visit is assessed and adjusted to reflect the needs of both the child and family in the plan of care.

Standards (PPC S) Principle

Palliative care and/or hospice programs adopt the NHPCO Standards of Practice for Hospice Programs, and utilize the appendix "Standards of Practice for Pediatric Palliative Care and Hospice" as the foundation for their pediatric care.

Compliance with Laws and Regulations (PPC CLR) Standards

No pediatric-specific additions to this standard are suggested.

Stewardship and Accountability (PPC SA) Standards

No pediatric-specific additions to this standard are suggested.

Performance Measurement (PPC PM) Principle

The program develops, defines and utilizes a systematic approach to improving performance. This approach is authorized and supported by the program's governing body and leaders. The approach assures that information is collected and analyzed, actively uses performance measurement data to foster quality assessment performance improvement, and is specific to pediatric patients being served.

Performance Measurement (PPC PM) Standards

PPC PM 1 The palliative care and/or hospice organization has a quality improvement plan in place to measure and evaluate services rendered to children and their families.
PPC PM 1.1 Measures of children's clinical outcomes are developed.
PPC PM 1.2 All adverse events are documented and investigated.
PPC PM 1.3 All medication errors are documented and investigated.
PPC PM 1.4 Resource utilization is analyzed.
PPC PM 1.5 Child and family satisfaction surveys are developed and sent to families.

Source: https://www.nhpco.org/sites/default/files/public/quality/Ped_Pall_Care%20_Standard.pdf.pdf

notably, PPC is unique because children go through developmental stages while having more complex, lifelong chronic conditions, thereby complicating the identification of treatment plans, trajectories, and ethical issues around legal decision-making, all while dealing with larger community involvement, less palliative and hospice care resources, and more complicated grief.[11]

Concurrent Care

When first developed, state and federal regulations and standards governing hospice care and the clinical guidelines for ongoing appropriateness (Medicare and Medicaid) did not address pediatrics. Determining the required 6-months-or-less prognosis is extremely difficult for pediatric physicians because of the wide variability of prognoses in children, often varying from days to weeks or from months to years. Referral to hospice care by physicians made them feel as though they were "giving up."

In addition, there was a question as to what, if any, treatments might be acceptable under hospice admission guidelines. Programs varied on whether blood products, antibiotics, infusions, lab tests, and more were considered "too aggressive" an approach to care, expecting parents to surrender all means of therapies before enrollment in hospice. These interventions were also a great financial burden or unfeasible for many programs without substantial foundational support, as most hospice programs did not have the financial allowance to provide these more liberal interpretations. The option of forgoing treatment in order for their child to receive palliative or hospice care was simply too difficult a decision for parents to make.

The US government has since responded with the enactment of the provision "Concurrent Care for Children" in Section 2302 of the Patient Protection and Affordable Healthcare Act (PPACA) on March 23, 2010.[12] This provision allows patients with state Medicaid or Children's Health Insurance Programs (CHIP) to receive hospice care while still receiving curative treatment. Its ratification demonstrated that healthcare systems and government better understand that the needs of children with life-threatening illnesses/conditions are distinctly different from those of adults.

To better understand and interpret this new act, in 2012, a pediatric-focused Continuum Briefing titled "Pediatric Concurrent Care" was composed at the Mary J. Labyak Institute for Innovation at the National Center for Care at the End-of-Life. This briefing included some barriers to the provision: (1) a physician still needs to certify that the child is expected to die in less than 6 months, (2) every state has different Medicaid covered services/resources, and (3) the provision itself does not specify what treatments/services are deemed curative.[13] The District of Columbia Pediatric Palliative

Care Collaborative and the National Hospice and Palliative Care Organization also recognized these barriers, as well as the effort involved for individual states to acclimate to and utilize concurrent care. In response, they developed a Concurrent Care for Children Implementation Toolkit, designed to guide providers and interested parties in understanding the effect that concurrent care could have on their individual state Medicaid programs. It describes how each state has its own amendment and waiver options and encourages learning from other states' experiences to help facilitate a statewide collaborative approach in adapting and implementing effective and efficient concurrent PPC services.[14]

In "Concurrent Care for the Medically Complex Child: Lessons of Implementation," Miller, LaRagione, Kang, and Feudtner[15] discussed some general issues they identified in coordinating concurrent care for medically complex children. They found that, when adding hospice services to care, existing providers (some who cared for the patient for many years) needed much education and support regarding the concept and the clinical interventions/treatment. They also discovered a high level of complexity in coordinating and integrating hospice care with the current services and providers already in place. Frequent and ongoing communication was necessary to ensure a safe and effective interdisciplinary approach to care. Last, determining who was responsible to provide equipment, either the current durable medical equipment company or hospice agency, and what services were still covered under the primary commercial insurance (if applicable) was challenging and complex. Despite these issues and challenges, Miller et al. found the effort worthwhile in helping to improve palliative and EOL care.[15]

Progress and Challenges

The advancement of palliative care as a model for care in the United States has reached unprecedented levels in many types of settings. Following that surge is now a robust effort to develop and integrate programs and services for those facing a life-threatening condition from a prenatal diagnosis of a lethal condition to young adults on the brink of adulthood. Growth has been evidenced on many fronts: legislative action, research, hospital-based palliative care, community-based hospice teams/programs, and specialty areas of palliative care, such as prenatal palliative care and palliative care in the emergency setting. Palliative and end-of-life care–specific curricula have now been integrated into many nursing and medical school programs, and several educational models and programs exist for clinicians to better understand the role of PPC and how to best provide this type of care. Despite this, many challenges to delivering optimal PPC and improving the QOL of children and families still exist. Much work remains regarding understanding the differences between palliative care and hospice, clearly defining the population being served, better understanding the needs of children with life-threatening conditions and of their families, developing an approach that will be appropriate across different communities, and providing timely care that responds adequately to suffering.[16] Changing the pervasive stigma of how PPC and hospice are often perceived by the general public and healthcare professionals as synonymous with "no more hope," "giving up," "there's nothing more that can be done," or "death must be near," is a long-term goal.

The ongoing painful dilemmas and struggles for families with children who are facing life-threatening illness and end of life remain hidden from society's view, yet the demands and challenges of caring for a dying child are being addressed continually within hospitals and homes. Individuals, institutions, universities, and community organizations, including hospices, are making a difference in addressing the needs of children with life-threatening illnesses in their communities. One of the most difficult parts of providing PPC, however, is that this type of care is often necessary at the beginning of young lives, a stage of life when almost anyone is naturally uncomfortable with the idea of serious illness or the concept of end of life. Nurses are instrumental in incorporating this contradiction of beginnings and endings into a realistic and compassionate framework for the care of children and families dealing with life-threatening or life-limiting illnesses. The landmark report from the Institute of Medicine, *When Children Die: Improving Palliative and End-of-Life Care of Children and Their Families*, set forward the challenge and a "call to action" to improve all aspects of EOL care for children and families, including improved quality and access to pediatric hospice.[3] It became the catalyst for a cascade of national initiatives, research, funding, and heightened awareness that continues to evolve today. In addition, the National Consensus Project Guidelines for Quality Palliative Care, originally published in 2004, provide clinical practice guidelines to foster consistent and high standards in palliative care and to encourage continuity of care across settings for both children and adults living with life-threatening illness.[17]

The ultimate goal, however, is not only to promote excellent PPC for children and families from the time of diagnosis through the time of death, but also to achieve success in heightening awareness of PPC in healthcare professionals and the general public. Improving QOL for even a brief life can benefit not only the child, but everyone affected by his or her death, which often extends beyond parents and siblings to grandparents, other relatives, teachers, friends, and community members, as well as to the many healthcare professionals who have been involved in the child's care and treatment. Each individual involved has played a unique role in the child's life, and the extensive constellation of those impacted by a child's illness and death may be exponentially greater than one might imagine. Often the individuals involved have not had any previous experience with the death of a child and thus an essential role for the PPC provider, and often the nurse directly caring for the child, is to provide guidance and support to other family members or professionals, especially when the goals of care change throughout the evolving journey of a child's illness, up to and including at the time of death.

The Settings where Pediatric Palliative Care Occurs

"Hospice and palliative care can be provided in almost any setting as long as those providing the care are willing to enter the patient's world and honor their setting of choice."[18(p. 310)] PPC can be implemented in a variety of inpatient and outpatient settings, including acute, chronic, intensive care units, emergency departments, long-term care facilities, at home, in school, and in communities. Irrespective of the setting, PPC should be patient-/family-centered, interdisciplinary, and collaborative with optimal and ongoing communication among all care givers.[19]

The American Academy of Pediatrics recommends that large healthcare organizations should have interdisciplinary PPC teams with expertise and experience to effectively manage and coordinate the complex and intricate arrangements in transitioning pediatric patients between healthcare and/or home settings while maintaining the highest quality of care possible.[20] Recommendations also include that these PPC teams stay involved and fully engaged across all settings to ensure continuity of care and appropriate treatment and interventions which align with the patient's and family's goals of care at all times.[20]

PPC nurses, advanced practice registered nurses (APRNs), and nurse coordinators have key roles within the interdisciplinary PPC team in transitioning patients across settings. They often have the most consistent, frequent, and intimate contact with the patient, family, healthcare providers, and community. They are key in the development of care plans and discharge plans that assure the patient is receiving the highest quality of palliative and EOL care in all settings.[19]

PPC for children living with chronic and/or serious illnesses should include aggressive and safe management of symptoms that help children and families feel well-supported at all times and across all settings.[18]

PPC and Hospice Service Availability

In evaluating the available outpatient PPC and hospice agencies that care for children, the NHPCO released facts and figures in their 2015 edition which found that, of the 4,000 hospice agency members surveyed, 78% reported that they served pediatric patients, with 36% having a pediatric program and 21.7% having staff members with pediatric experience.[21] The survey also revealed that the average number of pediatric patients who received palliative care were 0 to 10 and that those receiving hospice services were between 1 and 20.[21] Although there are fewer resources for pediatric patients than for adults, there is a growing interest in and number of resources to help care for children requiring PPC. The hope is to continue to build on this foundation both in quantity and quality of services.

Identifying the Children Who Could Benefit from Hospice and Palliative Care

The most recent data available report that a range of children can benefit from PPC, and it is estimated that more than 8,600 children have a need for PPC on any given day given their limited life expectancy and serious healthcare needs.[21] In the United States alone, there are about 50,000 pediatric deaths annually, and only about 5,000 children receive hospice services each year.[21]

There are four generally recognized pathways of conditions that lead to death in children. In brief, they are (1) life-threatening conditions for which curative treatment may be feasible but can fail (e.g., cancer, heart disease, trauma or sudden illness, or extreme prematurity); (2) conditions with inevitable premature death, often with long periods of intensive treatment aimed to prolong life and allow participation in normal childhood activities (e.g., cystic fibrosis, human immunodeficiency virus infection, chronic or severe respiratory failure, muscular dystrophy); (3) progressive conditions without curative treatment options, although children may live several years (e.g., severe metabolic disorders, certain chromosomal disorders, other rare diseases); and (4) irreversible but nonprogressive conditions with complex healthcare needs leading to complications and likely premature death (e.g., severe cerebral palsy, multiorgan dysfunction, severe pulmonary disability, multiple disabilities following brain or spinal cord infections, severe brain malformations). The illness trajectory of children can vary greatly depending on age and other factors, and, overall, the highest rate of death is reported as occurring in the first year, with a high proportion occurring in the first month of life.[3]

It is important to recognize that the type and length of a child's illness may impact the timing and ways in which PPC may be implemented and may also have an effect on how the family copes with the illness and/or death and the ways in which they grieve. For example, in the first group described, children may experience initial response to treatment, return of disease, and then poor to no response to treatments. Preoccupation with therapies, labs, or tests may overshadow any discussion about the possibility of dying, and focus remains on the tasks of managing the medical aspects of disease. Maximizing opportunities for comfort may be passed over or delayed in the intensive search for cure and life-extending alternatives. PPC may be necessary during periods of prognostic uncertainty, throughout the treatment course, and/or when treatment fails. In cases of death by trauma or accident, there may be little time to establish relationships, and immediate grief support might be the most helpful for the family. Conversely, children with very extended and variable pathways through illness, often referred to as *complex chronically ill children*, have multiple "peaks and valleys" and extensive needs over time. Life can become consumed by the constant focus on appointments, therapy, transportation, shift care, special needs, and ongoing obstacles to accessing adequate comprehensive care. Regardless of the particular condition or disease pathway, accessing PPC can be challenging for all the emotional reasons one might imagine when it is a child's life at stake. In some instances, the best introduction of PPC may be to emphasize the philosophy of comprehensive symptom management and simultaneous care for the body, mind, and spirit of both the child and family while shifting slowly from the sole focus of preserving life to measures to relieve suffering and maintain comfort. Nurses are often present for the highest ratio of time with the child and family and, along with others members of the IDT, have an extraordinary role in adeptly guiding families through this emotionally laden course.

Barriers to Accessing Pediatric Palliative and Hospice Care

Barriers to providing hospice or palliative care services for pediatric patients differ from those for adult patients. In general, society's belief that "children shouldn't die," along with denial of the process, make EOL care for this population a difficult and often misunderstood concept. Within the healthcare profession, a profound silence of discomfort and denial exists regarding babies and children dying. In many cases, healthcare professionals' attitudes and denial become the greatest barriers to their patients'/families' abilities to access additional options for expert palliative care and support services. In effect, this denies families the possibility of making an informed decision regarding the range of choices available during a child's illness. Clinical expertise in advanced illness or EOL care should be available for families who may transition their focus of care from a strictly curative mode to one of comfort and QOL.

In PPC, ethical issues, law, and policy are sensitive and complex and therefore create additional barriers that may intimidate providers regarding palliative and EOL care. Healthcare providers, as well as the public, need to be aware of local and state laws, especially about adolescents having a say in their medical decision-making and goals/limitations of care. Also, the 18- to 21-year-olds who are either neurologically devastated or have the developmental age of a young child need to have advocates who understand the law (individual states may differ) and have their best interests in mind at all times when making decisions about their EOL care.[22]

Children with complex chronic conditions often have frequent life-threatening events and acute illnesses. Advanced technology and treatments have helped children survive these events, making care, decision-making, and instituting limitations more difficult for both providers and patients/families. Common thought becomes, "if the child survived the last life-threatening event, therefore he will survive the next." As a result, another barrier has emerged over the years: death is seen as a failure of the healthcare system and not a natural process of the illness/disease.[22] Advocates for PPC recognize that advanced technology/treatment saves lives, but fear it may cloud decision-making and prolong suffering.

Pain and symptom management also have become more complex and challenging. Children with complex conditions often end up on multiple medications and/or treatment modalities, making it harder to cross-check interactions and determine doses and effectiveness. Primary care providers lack expertise due to limited experience with these complex patients and therefore shy away from caring for them. Hospice agencies tend to feel their expertise in EOL care is insufficient in caring for the complex pediatric patient. Provider education and ongoing support from palliative care colleagues help diffuse some of the anxiety in caring for these children and therefore should optimally remain an integral part of caring for children and families within the context of PPC.

Last, the cost of caring for children with chronic life-limiting illnesses/conditions has been a barrier to pursuing pediatric hospice. Pediatric hospice or palliative care typically requires longer, more frequent home visits; longer time for family meetings and decision-making; more coordination of care with multiple physicians, other providers, and insurance companies; visits to schools by members of the team on behalf of the sick child or siblings; and hiring or access to pediatric experienced nurses, social workers, and child life specialists and aides. Ongoing therapies for palliation of distressing symptoms, including blood transfusions, antibiotics, chemotherapy, and enteral and gavage feedings, typically continue longer for children than for adults. The cost and responsibility for covering these therapies may be an additional factor for home-based providers in deciding whether to serve children. Now with concurrent care and Medicaid waiver programs, this barrier is being addressed and will hopefully become less of an issue as implementation becomes more uniform and consistent across healthcare settings.

Nursing Considerations

Nurses providing PPC and EOL care often experience emotional pain and suffering themselves related to their young patients' declining conditions and poor prognoses. In programs where nurses are not clinically trained or emotionally prepared to manage pediatric patients, many issues can emerge as a result of their anguish. Previous losses of a similar nature, unresolved grief issues, conflicting beliefs regarding "supportive care-only" interventions, and insecurities and self-doubt are all common, even within the hospice setting. Personal and ethical dilemmas can emerge regarding withdrawal of aggressive care or nutritional support. Interdisciplinary ethics consultations can bring an invaluable contribution to the decision-making process and often raise the option of a PPC consult or referral to hospice care. Nurses working in predominantly adult-oriented care settings may lack pediatric physical assessment and symptom management skills, as well as knowledge of the diverse disease processes and developmental stages and related needs essential to care for neonatal, pediatric, or adolescent patients. Those with a background in aggressive and curative care may find it difficult to support a family in transition to a palliative focus of care. It is not enough to just provide education; they need ongoing mentoring, opportunities to process and get feedback on outcomes, interventions, communication, and real-time direction from experienced palliative care nurses and others.

Hospices, palliative care teams, and hospital inpatient teams should always consider and remember that nurses have the most frequent and direct contact with patients and families. They are the clinicians who provide ongoing care and education and are often the ones present during the child's death. Their support and clinical care has a high potential to greatly affect the entire experience that the family will reflect on for the rest of their lives. Nurses who are trained properly can and do report feeling honored and privileged to help patients and families during one of their most painful, private, and intimate experiences. They find it rewarding to know they were able to provide support through such a difficult experience by simply acknowledging and respecting their patient and the family's pain and grief. Therefore, the better prepared, supported, and educated nurses are, the better chance they have to help influence a more positive and less traumatizing experience for all involved.[23]

Respecting What Parents Want and Need from Their Healthcare Providers

Nurses can support parents and families in the hospital and at home by identifying their concerns and fears regarding things such as routine care in the hospital, life outside the security of the hospital, what to expect at home, how to handle emergencies, and knowing when to call for help. Nurses have an important role in creating plans for how they will communicate with the family and in helping families anticipate what may happen in different situations, as well as having appropriate medications, resources, and contacts in place when needed. In the home setting, it may be helpful to think of parents as "first responders," and, as such, they require adequate access to what is needed to respond best to their child's issue when it arises. For example, having an "emergency kit" with a few basic medications in one or two doses for common crisis situations can prevent needless fear and suffering until a home care nurse arrives. Educating parents as thoroughly as possible for transitions in care and settings will reduce anxiety and unnecessary problems faced at home.

Imagine how overwhelmed parents must feel when their child is diagnosed with a serious illness. Nurses' goals are to help parents and children feel confident and competent in the hospital setting and at home, to feel cared for and connected to their care team, to be respected in how their cultural and religious or spiritual beliefs influence decision-making and provision of care, and to preserve hope. Parents also desire to remain in the role of parent to their child and may want to have control over time, routines, and ritualizing care to make their child feel safe and comfortable. They want to have their child recognized as unique and special and have some semblance of "normalcy" and intimacy allowed in the framework of their existence, whether at home or in a facility. Discussing the role and impact on siblings and/or others at home is necessary on an ongoing basis, and support for other family members may be an essential part of care. The communication between professionals and parents and children throughout the time of illness and at the end of life must be grounded in caring and compassionate relationships and mutual trust. PPC places special demands on healthcare providers, not the least of which is an obligation to nurture relationships that can hold both vulnerability and suffering within their embrace.[24]

Intrinsic to the adaptation of pediatric-specific palliative care is that care is firmly anchored in developmental standards and that pertinent modifications are made to care based on the individual child's cognitive, emotional, physical, and spiritual development. The NHPCO launched an effort to create pediatric-specific hospice standards to guide programs and direct how care is rendered, regardless of whether care is delivered in the home, hospital, or long-term care or respite facility.[11] Box 59.1 was created to serve as a pediatric-specific appendix to the existing NHPCO Standards of Practice for Hospice.[11]

General Considerations for Pediatric Palliative and Hospice Care

As described in detail earlier, PPC is an approach to care for children living with life-threatening illness and for their families, one that aims to improve QOL along a physical, psychological, social, emotional, and spiritual continuum and is best delivered through the collective efforts of an IDT that includes the child and the family as the center of care.

Essential components of interdisciplinary PPC include, but are not limited to:

- Enhancement and promotion of QOL
- Respect for the uniqueness of each child and family
- Care that is introduced early and remains in place in conjunction with other therapies/treatments
- Care plans based on goals that reflect the child's and family's values and preferences
- Integration of physical, psychological, spiritual, emotional, and social aspects of care
- Coordinated care provided by an IDT that includes the child's primary team
- Relationships based on trust and mutual respect between child, family, and IDT members
- Effective management of pain and other symptoms
- Use of effective communication strategies
- Care that involves community support (i.e., schools, places of worship, community groups/teams)
- Inpatient and outpatient hospice support and services
- Anticipatory guidance and bereavement support[25]

The essential elements of PPC (see Figure 59.1),[26] which will be reviewed in more detail later, need to be woven into every aspect of nursing care, with consideration given to how each component of care will affect each child's and family member's daily life, as well as their lives over time.

Addressing the Particular Needs of Children and Families

The philosophy of palliative care for children is similar to that for adults; however, the practical elements of palliative care differ in many ways when providing this type of care for children. Clinicians providing PPC must not only learn the nuances inherent to this type of care, but must also pay particular attention to the specific needs of children and families as they assist them through their illness experience and death. One must consider the reality of the burdens placed on families when caring for children with life-threatening illnesses and how their entire existence can center on details of medication schedules, treatment plans, medical appointments and trips to the hospital, and the minutiae of providing constant care, leaving little time or energy for anyone or anything else. Taking these elements into consideration, it is the responsibility of interdisciplinary PPC providers to create individualized plans of care that are consistent with the goal of maintaining "normalcy" as much as possible while simultaneously adjusting to the "new normal" that families are often challenged to embrace. In these situations, one must consider the support and guidance that families will need when the focus of care changes as the end of life draws near. Nurses have a crucial role in supporting families through their fears and frustrations along with normalizing the full range of feelings that may ebb and flow throughout the course of a child's illness and death.

The Team

As mentioned earlier, it is widely recognized that PPC is best delivered using an interdisciplinary approach, although the make-up of inpatient PPC teams will vary depending on available resources. Common members of interdisciplinary PPC teams include physicians, nurse practitioners, nurse coordinators, social workers, chaplains, child life specialists, therapists from different disciplines (such as art and music), bereavement coordinators, and/or psychologists. Members of an interdisciplinary PPC team are professionals who have received specialized education and preparation for the care of children and families living with life-threatening illness and can serve as good resources for other allied professionals (i.e., psychiatrists, psychologists, representatives from other consulting services, primary care providers, other therapists—physical, occupational, respiratory, community representatives—teachers, coaches, religious leaders, hospice team members) who are also part of a child's care team. Together, they can provide comprehensive care for children and families, while nurses and APRNs may serve as coordinators of such interdisciplinary care as well as liaisons between the child, family, and team. Collectively, it is the role of the IDT to accompany the child and family throughout illness, death, and bereavement and to support families in coping with the challenges of living with a life-limiting illness and the suffering that may come along with it (Figure 59.1).[27]

An interdisciplinary approach to care should include optimal communication focused on patients' and families' goals of care, symptom management, and psychosocial support while relieving suffering, ensuring comprehension, and maintaining a sense of collaboration between the providers and patients/families.[28] Clinicians must be willing to listen and empathize as they build trust with families because trust and mutual respect serve as the foundation for positive and successful interactions between members of the IDT and the child and family. This interdisciplinary system of care can be defined as complex and adaptive because of the diversity among the various professionals on the team. Positive patient, family, and provider experiences can evolve from having a common goal and how well members relate to and interact with each other while maintaining a holistic approach to care, including trust and respect for one another and the patient's and family's autonomy.[29]

Family-Centered Care

In essence, palliative care considers the patient and family as a unique entity whose members all require care.[22] When a child is diagnosed with a life-threatening condition, the entire family, whomever that may include, is affected both on an individual and a collective level.[28] Special attention should be paid to the role of each person in the family and to how those roles may change throughout the course of a child's illness; thus, understanding existing and evolving relationships among family members is extremely important. Understanding the meaning of the illness and/or death experience must also be considered within the historical, cultural, spiritual, and environmental context of each family.[28] See Table 59.1[30] for guidelines for children's developmental understanding of death. Please refer to Chapter 32 for more information on supporting families in palliative care.

Support for Parents/Guardians

Families often describe their experiences of living with a child with a life-threatening illness as "being on a roller coaster." From the first time a parent senses something is wrong until the time of death, parents are faced with the myriad stressors associated with daily life/providing care, making difficult decisions, and often feelings of anger, sadness, disbelief, and withdrawal.[28] Parents and other family members will have needs that range from needing to understand their child's diagnosis and illness course to working through the different emotional experiences, integrating a sense of meaning (spiritually) from the experience, and requiring support for issues regarding housing, finances, childcare, and work.[28] Parents may feel as if they are losing control over several aspects of their lives, and it is therefore helpful for nurses and other members of the IDT to find ways to continually allow parents to remain in control, for example, by involving them in planning the child's daily routine, allowing them to participate in care, and asking if there is a certain way they would like things done. The need to feel a sense of control is also relevant to the sick child who may be

Table 59.1 Developmental stages and perceptions of death

Age	Basic conflict	View of death	Suggestions
Birth–18 months	Trust vs. mistrust	No sense of finality; death is viewed as continuous with life, child is reactive to the stress.	Use simple physical communication and provide comforting and nurturing care.
Early childhood: 2–3 years	Autonomy vs. shame and doubt	Death is seen as reversible and not final; the child may feel that death is a punishment. Children may feel that they are responsible for death.	Expect regression, clinging, or aggressive behavior. Encourage expression, as the child may be concerned about family function after a member dies. Use honest and clear language to explain death and dying.
Preschool: 3–5 years	Initiative vs. guilt	Death continues to be understood as temporary. The child may have a literal understanding of death and will respond with curiosity and questioning.	Open communication with clear language should continue to be utilized. The child should be encouraged to ask questions about death and dying.
School age: 6–11 years	Industry vs. inferiority	Death is understood as permanent, and the child understands that the body does not function (no breathing, heart stops beating). The child may also feel responsible and guilty for the illness. The child may have spiritual ideas about afterlife. The child may not want to discuss feelings.	Reassure the child that death is not their fault. Aim to maintain as normal a structure as possible. Include the child in after-life plans (funeral planning, last wishes).
Adolescence: 12–18 years	Identity vs. role confusion	Adolescents understand the finality of death and may develop a mature understanding of death. They may try to take responsibility for adult concerns within the family (such as finances and caretaking). Feelings of anger may be present.	Allow time for the child to reflect. Listen to concerns and questions. Support efforts for autonomy and control.

Source: From Reference 10.

fearful from experiencing many physical and emotional changes. Nurses can assist parents with methods to help themselves and their child feel in control regarding aspects of their experience. Things such as establishing a daily routine; having children participate in conversations about care, when appropriate; and knowing what side effects to anticipate from medications, treatments, and therapies is empowering and fosters an environment of mutual trust and respect.

Support for Siblings

Caring for the entire family is an essential component of palliative care. Along with parents' needs, siblings' unique needs must also be considered when caring for a child and family living with life-threatening illness. Parents may find it difficult to provide support for both their sick child and their other children due to the controlling nature of the needs of a child with a serious or life-threatening illness. For this reason, caregivers and healthcare providers must pay close attention to the siblings for signs and symptoms of emotional distress and then identify strategies and resources to support their needs accordingly.[31]

Strategies for engaging with siblings may be as simple as including siblings during visits (e.g., greeting them by name first when entering a room), asking about their favorite toys or interests, or participating in a small activity together during a home visit. It is important to repeatedly evaluate the well child's level of understanding about the sibling's condition. Family meetings are also a good setting in which to discuss how everyone is doing (including sick and well siblings), how they each perceive the situation, how their needs are/are not being met, and how their fears and concerns can be addressed. Hospice and hospital volunteers, art therapists, and child life specialists are also extremely helpful for activities specifically with siblings such as picnics, outside play, reading stories, or memory-making activities such as handprints/molds, "memory boxes" to store keepsakes, memory beads, and/or picture collages. The goal for siblings of terminally ill children is to enhance their feelings of involvement from the time of diagnosis to the greatest degree possible to facilitate a healthy adjustment and eventual grieving process.

Interaction with Schools

In addition to family members, multiple professionals are involved in the care of children living with life-threatening illnesses and are committed to maintaining their QOL. Children living with complex chronic and/or life-threatening illnesses may also have an IDT of caretakers at school, including teachers, healthcare providers, and a range of therapists (e.g., occupational, speech and language, physical). Because children spend significant time at school, school personnel are intimately involved in helping meet their various educational, therapeutic, medical, and basic care needs (i.e., feeding, toileting, hygiene) and play a fundamental role in advocating for them. Families often develop supportive relationships with members of their children's school-based care teams and rely on them for support and guidance as they face different care choices throughout their children's lives, as well as for responsible execution of care plans to meet children's individual needs. Thus, it is essential to keep school team members informed of any choices that families make, especially if those decisions impact the care provided to the child at school, and to include the school team in decision-making conversations. It is also important and helpful to provide education, support, and resources to members of the school team, as well as to children's classmates and/or their family members, whenever possible.

Components of Care

This section will address some of the essential components of effective PPC. Each section is meant to give a brief overview and explain why the topic is important or relative to comprehensive palliative care. Because these topics will be reviewed in greater detail in other chapters of this text, the following sections are not meant to provide an exhaustive explanation or to be all-inclusive regarding all aspects of how to provide such care.

Communication

> Let us communicate with each other clearly, compassionately, and collaboratively, as we strive to improve the quality of life for children including, when necessary, that part of life that is dying.[26(p. 583)]

Good communication is the cornerstone of palliative care and serves as the foundation for building and maintaining relationships with families and other team members. Communication serves several purposes, among which are providing and gathering information, expressing sensitivity and/or empathy, and building partnerships. Having conversations with families about goals of care as early as possible has been shown to reduce suffering.[10] Effective communication considers everyone's needs, including all family members and children, and allows for an open exchange of information and flow of emotions.[32] It involves the use of verbal and nonverbal cues, and thus it is important to pay attention to subtle cues that may be offered by both children and adult family members. In pediatrics, it is important to ask families whether and how they would like to include their child in discussions, and it is also essential to consider the child's chronological and developmental age. Effective communication is a skill that must be learned and can be developed over time by all healthcare team members so that all palliative interactions with children, families, and other healthcare team members facilitate the development of trust and allow children and families the opportunity to ask questions and engage in a healthy, honest dialogue with their healthcare team.[33]

Please see Chapter 5 for more information on the essential components of communication.

Pain and Symptom Management

Pain and symptom management is another essential component of comprehensive and effective PPC as no parent or healthcare provider wishes for children to suffer unnecessarily. Some hospitals have separate pain teams, and many primary teams will manage children's pain and symptoms independently; however, the PPC team may be consulted to recommend a plan, and it is important for nurses to be familiar with general principles of pain and symptom management in regard to PPC. It is also important to recognize that there is often reluctance to manage pain aggressively in children based on myths and societal, cultural, religious, and familial beliefs that may make parents/guardians leery of opioid use to treat pain, such as the fear of "giving up" on their children, along with the notion that opioids may be "too strong" or that their children will become addicted. Healthcare providers' reluctance may stem from significant gaps in the existing evidence base; lack of sufficient education regarding pain management[34];

and misconceptions about opioids, such as frequency and severity of side effects, shortened life expectancy, and increased tolerance leading to difficulty managing pain at the end of life. Being aware of these hesitancies is helpful so that fears can be addressed and healthcare team members and family members can be educated about the realities of pain management in children with life-threatening illness and at the end of life.

Aside from pain, there are three other categories of symptoms that are known to be the most distressing to children and families receiving PPC: dyspnea, gastrointestinal disturbances, and neurological changes.[10] Adequate symptom control is a necessary part of effective PPC, and assessment and treatment of symptoms should be done in the least invasive way possible and should not contribute to more distress and/or suffering.[10] Gastrointestinal disturbances, including nausea, vomiting, decreased appetite, and constipation, are common in children with chronic and advanced illness, and identifying and treating the underlying cause,[10] using both pharmacological and nonpharmacological techniques, is a necessary part of care.

Many of the symptoms experienced, as well as the principles and medications used for pain and symptom management, are similar in adult and pediatric palliative care. The differences stem from the age- and developmentally appropriate assessment of pain and symptoms and from dosing medications, as pediatric doses are based on children's weight. Detailed and repeated assessment of children's pain or other symptoms is a crucial first step toward effective management. This includes a thorough evaluation and history, a detailed assessment, and a physical exam, as well as pharmacological and integrative management of pain.[34] It is also important to recognize that a child may be playing or sleeping and not appear to be in pain, but that does not mean that he or she isn't experiencing pain. Many excellent resources are available to nurses for gaining competence in pain and symptom management for children, and nurses who care for children over time will become adept at recognizing when children are in pain or are uncomfortable. In addition, families require practical help, information, explanations, and support. Attention must be paid to the practical issues of preparing for pediatric-appropriate supplies, medications, formulas, feeding tubes, medical equipment, documentation, and teaching tools for parents and children. Ongoing support and education for children and families is an essential part of delivering effective PPC.

Please see Chapters 8 and 9 for more information on the essential components of symptom and pain management in PPC.

Psychological, Emotional, Social, Religious, Spiritual, and Cultural Care

Pediatric palliative care is best delivered by an IDT, including individuals who can provide psychological, social, emotional, and spiritual support, such as psychiatrists, psychologists, social workers, and chaplains; however, it is important to recognize that all members of the team are also an integral part of providing this type of support to families. Colleagues from psychiatry and/or psychology should be consulted to fully assess concerns for psychological and/or emotional distress. Although there are no validated assessment tools to gauge the precise social and emotional needs of children and families, careful assessment should be conducted regarding the child's and family's developmental level and ability to complete developmental tasks; the experience of emotional symptoms; practical factors such as financial status, living situation, and social support; and religious or spiritual/existential background, preferences, beliefs, rituals, and practices.[33] Thus any comprehensive palliative care assessment and plan should include conversations and activities that explore all of these aspects of children's and families' lives. See Table 59.2 for examples of open-ended questions and behaviors to observe when assessing psychosocial concerns and strengths in children receiving palliative care and in their families.[33]

Psychological Symptoms and Suffering

It is essential to recognize that the experience of caring for a child with a life-threatening illness may cause increased psychological and emotional distress for family members as the illness progresses and the level of care needed increases. For example, the extended time required to provide physical care for affected children may result in increased energy expenditure by parents and the feeling that the time and energy necessary for other family responsibilities (e.g., other siblings) and activities (e.g., work, community activities, etc.) are being depleted. This can also be accompanied by a sense of guilt. It is important for the IDT to recognize the stresses that families endure and talk with them about this routinely. It is also important to be aware that while worry and sadness are natural in the context of having or caring for a child with a serious illness, increasing frequency of these symptoms or significant impairment in functioning are signs that the individual and/or family should be evaluated by a mental health clinician.[35]

Thus, it is appropriate for families and children to be offered early psychological and psychiatric consultations to assess the intensity of potential emotional distress, especially given that the symptoms of anxiety and depression are common, treatable, and associated with distress and morbidity, yet are often unrecognized and undertreated in this population.[36] Also, it is essential to offer resources for coping (via social workers, chaplains, psychologists, etc.) in an attempt to support the best functioning possible for the child and family members.[37] Consultations may facilitate open discussions, relationship-building, and survival strategies that may help to offset the emotional distress experienced by family members. Effective strategies should help equip affected children and their family members with constructive coping mechanisms (e.g., self-care activities, relaxation exercises, yoga, meditation or prayer, memory-making, journal writing, expanding or enlisting community resources, reframing cognitive distortions, or limiting catastrophic thinking, etc.). Also, strategies offered by healthcare providers may enable family members to plan effectively for the future when the child's prognosis is unclear and if the child's life span may be limited.[38]

Anxiety and depression are forms of suffering commonly experienced by children with chronic or life-threatening illnesses and can also encumber the primary caregivers of the child as well as other family members, friends, and siblings. While there are clear differences in the treatments for anxiety and depression, both disorders/states are treatable with nonpharmacological methods such as cognitive-behavioral techniques that can be used quite easily by affected children and adults, as well as with medications in conjunction with talk therapy. Examples of nonpharmacological methods include guided imagery, use of relaxation and breathing exercises, meditation, reframing automatic negative thoughts, and hypnotherapy (which children can learn to do themselves). Complimentary medical therapies such as physical massage,

Table 59.2 Examples of open-ended questions and behaviors to observe when assessing psychosocial concerns and strengths in children receiving palliative care and their families

Area being assessed	Open-ended questions	Patient behaviors to observe	Parent behaviors to observe
Developmental appropriateness and understanding	Tell me about what is happening with your treatment. What questions do you have that you have been too shy/too scared to ask? Why do you think this is happening to you? (Same questions can be asked of parents)	Indications of fearing sleep (will not go to sleep, resists sedative medication) Indications of fear of separation Degree to which patient can enjoy some developmentally appropriate activities (artwork, talking to peers, planning fun activities)	Coddling an older child Apparent discord between treatment of child and child's developmental level Ability to let child explore some developmentally appropriate activities Ability to effectively soothe/nurture or comfort the child
Beliefs about pain	What do you think is happening now that is making you hurt? How worried do you get when you feel pain? What do you worry about? What do you like (or not like) about using your pain meds? What concerns do you have about using your patient-controlled analgesia? (Same questions can be asked of parents)	Use of a range of physical behaviors to demonstrate different levels of pain Behavioral manifestations of anxiety with increased pain Over- or underuse of pain medications	Degree of own distress or focus on child's daily pain experience Ability to comfort and reassure the child Ability to distract the child from pain and engage in other activities
Emotional issues	How are you feeling? What are the things you are sad about? What are you missing because you are sick? What are you worried about?	Sadness, apathy Lethargy Unwillingness to engage in activities or conversation (must rule out physical causes for these symptoms)	Hypervigilance over child's pain, labs, or physical condition Signs of anxiety or excess sadness Avoidance of discussing important issues or of seeing the child or physician Asking same questions over and over again of the medical team
Communication	Sometimes it's hard to talk about some medical things. Who can you talk to about the hardest things? What things would you like to talk or hear about, but haven't been able to find someone to listen or talk to? What opportunities are people offering you to talk, and how does it work if you tell them you don't feel like talking?	Patient asking questions about death, dying, prognosis, or related issues Patient becoming annoyed when people "push" him or her to talk	Reluctance to talk to child or to be alone with him or her Eager insistence that child needs to talk despite child indicating need not to talk Expressing anger or exaggerated conflicts regarding the medical care
Practical issues	To parents: How have the extra medical expenses and any lost income you may have experienced affected your family? How do you get to the hospital for visits? What meals do you eat when here? Who is caring for members of the family still at home? Who lives at home? Who cares for your child when he or she is not in the hospital? What space is available in your home for hospital equipment? What would it be like for your family to have home care nursing in the house?	Missed appointments Frequently bouncing back to the hospital after discharge Desire to want to stay in the hospital despite being medically cleared to go home Strong desire to have no medical intervention (including equipment or home care staff) at home	Same as child observations

(continued)

Table 59.2 Continued

Area being assessed	Open-ended questions	Patient behaviors to observe	Parent behaviors to observe
Spiritual needs	What religious group, if any, do you belong to? What help would you like in thinking about religious or spiritual issues? What does your family believe about what happens after death? What traditions or rituals does your family practice when someone is sick or dying? What support from the hospital would be most helpful to you?	Confusion or distress regarding afterlife issues Worries about what kind of service to have Unusual behaviors that may be explained or understood as cultural rituals around illness or death	Same as child observations

Source: From Reference 33.

acupuncture, biofeedback, Reiki, and aromatherapy can also be extremely helpful in reducing the symptoms of anxiety and depression. Pharmacological treatment would be prescribed by a psychiatrist consulting with the primary team. As mentioned previously, it is imperative for healthcare providers to regularly monitor for the presence of psychological distress among children and family members over time and to consult clinical colleagues who are trained to properly assess, diagnose, and provide treatment plans for patients or families struggling with anxiety and depression.[38]

Social Aspects

Practical factors in a child's and family's life can have a direct impact on physical as well as psychological symptoms and treatment. Things such as family constellation, financial resources and constraints, employment status, healthcare benefits, childcare, transportation, and the ability to manage the myriad practical demands of living with and caring for a child with a life-threatening illness should be considered.[33] Social workers are usually the members of the IDT most prepared to assess these factors and to identify and connect families with the appropriate resources.

Religious/Spiritual and Cultural Considerations

Another integral part of providing PPC is an understanding of children's and families' spiritual, religious, and cultural beliefs and how these beliefs influence the decisions that they make,[33] and addressing spiritual needs of children and families is an important component of palliative care nursing. Families will often have their own ways to express their beliefs—some will consider themselves "religious" and partake in traditional rites and rituals; others may say "spiritual" and tend to have more universal beliefs not rooted in specific practices,[39] and others may not find it helpful to discuss their beliefs in terms of a structured or identified system of belief. Regardless, it is necessary for members of the PPC IDT to conduct spiritual assessments with families in a variety of ways because parents of children with serious illness believe that religious or spiritual beliefs are important factors in their coping efforts and decision-making.[33] Chaplains serve to address spiritual suffering, improve family–team communication, and provide rituals that families may request, such as ceremonies or sacraments.[40] Although matters of faith are often discussed with chaplains, any member of the PPC IDT should have some level of comfort in giving families the space they need to talk about religious and spiritual beliefs, practices, and values. Having these types of discussions may be considered one of the most challenging parts of PPC, but these same discussions may also be what allows both family members and clinicians to remain grounded and to maintain a sense of normalcy.[41] It is therefore important for PPC teams to be open to such discussions and to be aware of and utilize available hospital- and community-based pastoral care services.[33]

Table 59.2 provides examples of some open-ended questions to use and behaviors to observe when assessing psychosocial concerns and strengths in children and families and serves as a guideline for having conversations about such topics.[33]

Talking to families about their cultural and ethnic beliefs, customs, and practices is also important and may or may not be tied into their religious or spiritual beliefs. Of note, using a certified interpreter (i.e., not a family member or other staff member) may be necessary and should not be overlooked when children and families do not speak English, even if they say they understand what is being said. Various cultures approach children with life-threatening illnesses differently and have different beliefs and practices or rituals surrounding illness and/or death. It may be unacceptable to speak about illness or death or to discuss medical information in front of children. Nurses and other members of the healthcare team cannot be expected to be familiar with customs from every cultural background, and assuming a posture of humble curiosity is welcomed by individuals of other cultures when one does not know the culture and customs in depth. It should also not be assumed that just because someone comes from a particular cultural or ethnic background that he or she subscribes to the particular beliefs and practices from that group; thus, it is always important to ask children and families about their personal preferences.

Preserving Hope

A common characteristic of children living with life-threatening illness and their families is a prevailing and powerful experience of hope, evidenced in their language and decision-making. It is important to preserve and nurture hope during all stages of the child's illness. No matter how grim the situation, one should always strive to deal with matters in a positive, yet realistic, manner, taking the lead from the child and family. The focus of hope may change over time; for example, from hope for cure to hope for a longer remission than previously, to hope that the child can continue to be cared for at home, or to hope that the child will die without pain. Hope may also be centered on a child-specific wish, such as to return to school once more, to celebrate an important birthday, or to reach a significant milestone or rite of passage. Other expressions of hope include planning for a visit from grandparents, having friends gathered together, or even gaining the understanding for children, particularly adolescents, that their loved ones will survive and be "OK" after they die. Hope offers opportunities for growth for the child and family, yet it can also become challenging for both families and IDT members to try to balance remaining hopeful while also having realistic expectations. Thus it is important to openly discuss hopes and fears with children and family members, as well as with other members of the IDT.

Please see Chapters, 30, 34, and 35 for more information on the essential components of spirituality and hope in palliative care.

Ethical Considerations

A large part of PPC involves helping families with decision-making. Clinical ethical dilemmas are inherent to issues surrounding palliative and EOL care, and it will often be the role of the nurse and/or APRN to anticipate, recognize, define, examine, and manage ethically problematic situations[42] that arise in the care of patients and families, particularly during times of serious illness and/or at the end of life. Ethical dilemmas abound when providing such a wide array of care surrounding topics that are deeply rooted in personal, cultural, religious, and social values. Although nurses and other members of the PPC IDT are not expected to be ethicists, it is helpful to be mindful of the potential ethical dilemmas that will arise when working with families in these circumstances and to be aware of when to consult with the hospital's ethics committee when additional support is needed. It is, therefore, also the role of the nurse/APRN to recognize, contemplate, and use appropriate resources to guide such discussions and decision-making processes with patients and families.[42]

Ethical issues that are associated with EOL situations include decision-making under conditions of ambiguity, adequately informing patients and their families about treatment options, balancing QOL against extending suffering, managing intractable suffering, and futile treatments. Resources are available to help guide the decision-making process and to help children, adolescents, and adults express how they want to be treated throughout their illness and at the time of death from a medical, personal, emotional, and spiritual perspective.[43] Some helpful documents include *My Wishes* (for young children), *Voicing My Choices* (for adolescents), and *Five Wishes* (for adults) published by Aging with Dignity and available at www.aging-withdignity.org.[44] This section does not serve to provide an all-inclusive discussion of ethics in PPC, but rather to highlight some of the dilemmas nurses may face. Please see other chapters in this text for a more thorough discussion of ethical considerations and EOL decision-making, such as Chapter 61.

Perinatal Palliative Care

Perinatal palliative care is a unique component of PPC that is expanding rapidly as an increasing number of expecting parents receive diagnoses of life-limiting fetal conditions (LLFC) during pregnancy.[45] Many families are faced with difficult decisions that need to be made shortly after birth and, in some instances, even before a child is born; therefore, it is necessary to recognize the unique need for palliative care in the perinatal and neonatal period. The model for perinatal palliative care has become internationally recognized and is often introduced during pregnancy. Nurses play a unique and vital role in assisting and supporting families in creating palliative care plans for pregnancy and/or birth.[45]

Perinatal palliative and hospice care is an innovative and compassionate model of support that can be offered to parents who learn during pregnancy that their baby has a fatal condition, an unfortunate situation that occurs with increasing frequency as prenatal testing advances. This unique group of parents faces the daunting challenge of anticipating and preparing for the birth *and* the possibility of death of their baby simultaneously. For parents who receive terminal prenatal diagnoses, perinatal palliative care can be instrumental in helping them make the decision that is best for their family regarding whether or not to continue the pregnancy. For families who choose to continue their pregnancies, even if the baby may die shortly after birth, perinatal hospice helps them embrace whatever life their baby might have, before and after birth. Perinatal hospice support begins at the time of diagnosis, even before the child is born. It can be thought of as "hospice in the womb," including birth planning and preliminary medical decision-making prior to birth, as well as more traditional hospice care after birth, depending on how long the child survives. With the support of perinatal palliative care, families are given the opportunity to feel some level of control by making plans for the baby's birth, life, and death based on their individual needs for supporting themselves, their other children, the grandparents, and friends.[46] It also provides families the opportunity to honor their baby in a way that is meaningful to them and helps families participate in memory-making experiences. Strengthening this experience during this time may help diminish long-term psychological implications for parents and siblings.

Perinatal hospice is not a place. Ideally, it is a comprehensive team approach that includes obstetricians, perinatologists, labor and delivery nurses, neonatologists, neonatal intensive care unit (NICU) staff, chaplains/pastors, and social workers as well as genetic counselors, therapists, and traditional hospice professionals. Perinatal hospice is a beautiful and practical response to some of the most heartbreaking challenges of prenatal testing.[47] Some programs exist within a hospital setting, such as the labor and delivery unit, NICU, and maternal and child areas. Other times, it presides within community settings. It naturally creates a seamless continuum of care across settings (office to inpatient to home) and providers and includes advanced decision-making within the framework of a "birth plan," which includes the "who, what, when, and where" for the delivery and beyond.[45] Perinatal palliative care may naturally extend into neonatal palliative care, as some infants will live anywhere from days to months to years after birth.

Please see Chapter 62 for more information on the essential components of neonatal palliative care.

Care at the Time of Death

Nothing can fully prepare families for the final moments of their loved ones' lives and the precise time of death, but there is much that can be done to help families anticipate what to expect so as to avoid unnecessary surprises when the time comes. Conversations about such sensitive topics may feel difficult to initiate, but parents are often wondering about these things and may be afraid to ask. Thus, initiating the conversation after a relationship has been established and at a time that feels appropriate is essential. Families should be reminded that PPC clinicians cannot predict exactly when and how death will occur as it can be different for everyone, but parents and family members should be prepared for the possible range of changes that can happen, along with when they might expect such changes and what things may look like, feel like, sound like, smell like, and so forth. Consider all the senses for both the adults and any other children who will be present. Parents also may appreciate written handouts in language that is not too clinical or frightening so that they have them to review at a time when they feel ready to do so. Having such knowledge may also prepare parents to talk with each other, other children, and family members. Families may have memories from previous experiences of death of other family members and may conjure images or memories from that time that may or may not be helpful, depending on what the particular experience was like for them.

Children and family members will likely have fears associated with death and the dying process. This may include fears about what dramatic events can unfold, fear of being alone at time of death, fear of a loved one missing the death, and fear of being unprepared for an unexpected emergency. Understanding the physical progression of events and the nearing-death awareness that is common among children and adolescents may be reassuring for both members of the team and the family. It is essential to review goals for the time of death well before the time comes so that families feel as in control of the situation as possible. For example, children and families likely will have an idea of where they would like for the final hours or days of life to occur, and, when possible, nurses and other members of the IDT can try to align the proper resources to allow this to happen. If families desire to remain in the hospital, they should be given a private space or room to be together as a family. Several children's hospitals allocate a specific room or space, often called a "comfort corner" where children may be moved to spend their final hours together with their family. Typically, changing locations close to EOL is not desired; however, for some families, it may be very important to make it home from the hospital or to get to the hospital in the event of an emergency before death. Thus it is again important to talk with families about their wishes for this time. It is also crucial to consider whom a family may want to be present. In most instances, family members will be called to visit as the time of death nears, and the child's bedside, whether in the hospital or at home, can become the gravitational force for loved ones to gather. Families may also have particular wishes about who should be present at the actual moment of death, as sometimes parents want to be alone with their child, with or without other children being present. Other times, families may choose to get in bed with their child. The tenderness and intimacy of these final moments is beyond description, and being present at this time with a family is a very precious privilege for everyone involved in the child's care, especially nurses who often spend the most time at the bedside.

Creating a Sacred Space

When a child is dying, regardless of his or her age, the very space becomes sacred ground, and it is important to maintain the holiness of that space immediately following the death, if only for a brief period of time. This also allows for a brief pause to honor the nurse's role in maintaining the dignity of a child and his or her family surrounding death before moving on to the next task. Some programs place a special sign on the door, or an image of a dove, butterfly, flower, or leaf to subtly designate this sacred space and to minimize interruptions in and out of the room during this time. Honoring and respecting the space also models to staff that it is not just "business as usual," at least for a brief time. If a child dies at home, some families may choose to have the child remain in their bed or keep the space intact for a short time before having the body removed. Other families may desire the prompt removal of their child's body, which is a personal decision that should also be respected. Cultural and religious practices may guide what happens at time of death and immediately following, but generally time is allowed for bathing, dressing, holding or rocking the child, offering prayers, obtaining handprints (if not obtained before), cutting a lock of hair, and gathering the clothing items that may have the child's scent on them (to be preserved in a timely manner in a zipper bag). Families may or may not choose to partake in these activities. Some families may wish to accompany their child's body to the morgue, if the child dies in the hospital and hospital policy allows for this to happen, or out of the house if the child dies at home. Siblings and parents or others may choose to send along a note or a little something with the child's body as a symbolic way to remain connected while apart, and sometimes children may have previously stated their wishes about what objects they would like to keep with them. It is also important to recognize that some families may choose to consider organ donation or autopsy, which ideally should be discussed with families before the time of death. Hospitals usually have programs that require that the option for organ donation be presented to families, and procedures are in place for representatives from the appropriate organizations to be notified near or at the time of death to have these discussions with families. If families elect to donate organs or have an autopsy performed, timing will be of the essence, and members of the team and the nurse should be aware of what needs to happen within what time frame to ensure that a family's wishes are met appropriately.

Self-Care

It is also important to recognize that the team members caring for the child and family will need support before, during, and following the time of death. The nurses present with the family will likely have other tasks to move on to, but it is very important to have support available to allow for at least a brief respite, break, or time away from the immediate setting. In some instances, nurses may be given a lighter caseload or, when possible, have time to debrief with another colleague, chaplain, or member of the PPC IDT both immediately following and/or at a period after the death has occurred. Great wisdom can be shared, burdens lessened, and insights and renewal gained from the time spent debriefing clinically as well as through other efforts to support colleagues. It takes a lot of energy to care for seriously ill children and members of their family physically as well as emotionally and psychologically. Preserving the meaning of and sustaining this type of work requires self-discipline and intentionality to tend to one's own centering practices and methods of self-care, whether physical, spiritual, and/or emotional. Some coping strategies may be personally beneficial, such as self-reflection and self-care, even for a few minutes throughout the day, along with building in time for ongoing renewal and reflection outside of work. Time spent focusing on other activities completely unrelated to work and taking breaks from work on a regularly scheduled basis (i.e., vacations and time with friends and family) are necessary in order to sustain this type of intense and rewarding work.[16] Also important is professional support, as many team members find relationships with colleagues in PPC to be especially supportive because no one else quite understands the emotional stressors of the work. The burden and grief experienced from caring for children with life-threatening illness and their families can be intense and serious and requires formal and informal support to prevent burnout and to cope effectively with the challenges of this work.[16]

Anticipatory Grief and Bereavement

Chapter 63 is devoted entirely to grief and bereavement in PPC, and thus it will not be discussed at length in this chapter. It would be remiss, however, to not mention the importance of anticipatory grief, grief surrounding death, and bereavement. Children and families will often begin the process of anticipatory grief at the time of diagnosis, and it is helpful for PPC team members to talk with children and families continually about the ongoing losses they are experiencing. Grief continues through and beyond the time of death, and families, community members, and team members who cared for the child and family will need ongoing bereavement support. Many hospitals have at least annual ceremonial remembrance services that families and team members find helpful for honoring and remembering the children who have died.

Overview of Nursing Care Issues for Pediatric Palliative Care

As evident, the responsibilities of caring for children living with life-threatening illnesses and their families are extensive and require an understanding of the interconnectedness of the myriad aspects of illness and suffering: physical, emotional/psychological, spiritual, and social. Nurses and members of the PPC IDT must assess for imbalances and indications of suffering in each of these areas to appropriately intervene and provide comprehensive and effective PPC. They must ensure that families are well-supported while also supporting each other and not allowing all of the burden to fall on one member of the team.[47] PPC nurses and other professionals may also experience pain and suffering,[24] and self-care, adequate support, and ongoing education and professional training are also essential components of delivering effective PPC.

Education and Training

Healthcare professionals face many obstacles and challenges while providing this type of intense and unique care to seriously ill children and their families, including lack of professional education and training.[24] Nurses specifically have reported perceived lack of skill in providing PPC, including inadequate knowledge and expertise, as well as fears regarding appropriate communication with families.[24] Many educational programs exist to train nurses and other healthcare professionals in various aspects of PPC, and there are a variety of ways to implement curriculum-based training on key topics inherent to caring for children with life-threatening illness and/or at the end of life. Interdisciplinary case discussions, "lunch-and-learn" sessions, journal clubs, and/or regularly scheduled community-based educational seminars can result in a commitment from nursing and other team members to work together and support each other or form committees on specific units or other areas. Funding from small educational grants may also be available to support training programs in PPC that include specific topics such as pain and symptom management, communication, addressing culture and spiritual needs, bereavement, ethics, and decision-making in PPC. Children's hospitals with emerging PPC programs are now offering more palliative care seminars, conferences, "just in time" teaching sessions, and trainings for new nurses, residents, and therapists, as well as staff debriefing sessions, as a way to educate others about PPC and to allow for professional development in this emerging field. Of note, PPC has been integrated into national nursing professional practice guidelines and standards, such as those of the Society of Pediatric Nursing.[48]

In recognizing that hospice and palliative nursing care has become a specialized area of nursing, the Hospice and Palliative Nurses Association (HPNA) was established in 1986. This membership organization relies on evidence-based research and data to assist members in delivering quality nursing care, symptom management, grief and bereavement support, guidance with difficult conversations, education, and encouragement in leadership and mentoring efforts. The HPNA supports credentialing for APRNs, RNs (adult and pediatric), licensed practical/visiting nurses (LP/VNs), nursing assistants, and administrators through the National Board for Certification of Hospice and Palliative Nurses (NBCHPN).[49]

Additionally, recognizing that nurses need specialized training in hospice and PPC, many professional associations are supporting localized efforts by co-sponsoring educational efforts with other entities. For example, End-of-Life Nursing Education Consortium (ELNEC) is a well-established and respected "train the trainer" initiative to teach nurses at all levels how to provide effective PPC, as well as how to teach this information to other nursing students and colleagues.[50] The curriculum is updated annually, and a pediatric curriculum is available that includes learning modules that highlight current practices and include cases, key references, supplemental teaching tools, and resources. A curriculum for APRNs was launched by ELNEC in 2012, which also includes pediatric-specific training modules. Although too numerous to list, there are several national professional organizations that offer specific training in both adult and pediatric palliative care for healthcare providers in all disciplines. The Center to Advance Palliative Care (CAPC) provides healthcare professionals with the tools, training, and technical assistance necessary to start and sustain palliative care programs in hospitals and other settings and includes an extensive listing of other trainings that are available on its website: http://www.capc.org. The Initiative for Pediatric Palliative Care (IPPC), sponsored by the Educational Development Center (EDC), is an interdisciplinary model of case-based experiential training offering PPC specific training events. More information and additional training materials can be found at the IPPC website: http://www.ippcweb.org/.[51] The NHPCO[7] also has a pediatric curriculum to address the ongoing demand for training for adult hospice programs to be prepared to care for children http://www.nhpco.org. In short, there are an increasing number of educational offerings and opportunities for nurses and other healthcare professionals to expand their knowledge of PPC.

The Future Unfolding for Pediatric Palliative Care

PPC is a rapidly expanding field with an increasing number of individual providers specializing in this type of care, growth of new and existing interdisciplinary care teams, and the expansion of available community resources.[10] Infants, children, adolescents, and their families are part of the continuum of PPC, and there is much to be done to support them and to advance the quality of pediatric palliative and EOL care. Each step toward increasing awareness about PPC is a step forward on behalf of the children who are dying without access to all of the resources that should be available to them and their loved ones. The future of PPC is aimed at improved recognition and increased utilization of PPC services and better reimbursement for palliative care providers.[10] Nurses who choose to care for seriously ill and dying children and their families need a significant support system to maintain the difficult and delicate task of balancing perspectives, as well as opportunities for ongoing personal and professional development. While challenging, this type of work is also humbling and rewarding, as those caring for children with life-threatening illnesses have the privilege of being a part of families' most intimate and powerful experiences, both throughout children's lives and during the time of their death.

> Her life would be told in days, rather than years, and yet, she changed the world and all who knew her forever. They had waited five years for her arrival and now they desired her departure to be a celebration. Her 6-year-old brother drew colorful pictures of his "angel sister" so he could "remember her always when she went back to heaven." In her brief life she knew what it was to be comforted, to be free of distressing physical pain, to have blessings said over her, to be cherished and not forgotten. Her parents were surrounded with the loving presence of those who had the privilege to care for them. They were deeply listened to, and had honest discussions as to their goals and preferences. What we discover is that the children are teaching us about living through their dying. An ever-enlarging circle of love and expertise so that all children whose lives are threatened or limited will live well and die gently. This is pediatric hospice and palliative care. (G. Walker, personal communication, November 5, 2017)

CHAPTER 60

Pediatric Goals of Care

Leading through Uncertainty

Christina McDaniel and Jordan M. Desai

Key Points

- End-of-life goals of care communication requires effective communication, empathy, and active listening.
- It is critical to understand the values of the patient and family in order to enable decision-making that centers on what they consider important.
- Quality, as a metric used to help guide the decision-making of pediatric palliative care patients and their families, is bound in and to the culture of the individual family.
- Understanding parent and family perspectives is essential not only for providing care during the illness trajectory, but also in assisting families through their bereavement.
- Guiding conversations around goals to address physical, emotional, spiritual, and social needs is necessary to ensure holistic care is delivered.

Introduction

> My obstetrician asked, "What is the point of going on with a pregnancy when you know that the baby is going to die?" I was unable to formulate a coherent response. Now I can. From the moment I knew of my baby's existence, I loved her unconditionally.[1]

From the moment a family is faced with the life-limiting illness of a child, they are thrust into a stressful, perhaps devastating, new world. This world often communicates with a medical culture and language that is unfamiliar to most families. From an ethnographic perspective, the language and culture of medicine requires clinicians' fluency and essentially demands that ill children and their families learn at least some level of competency. The palliative care clinician must serve as a kind of "bicultural" figure and must have "one foot in both worlds."[2] The pediatric care clinician must consistently find ways to bridge the gap between the culture of medicine and the culture of the individual families served.

When asked to reflect on his rotation with a local hospice, a general pediatrics resident noted, "I had no idea his life [the patient] had *quality*. Every time I've seen this patient in the hospital he looks miserable and never interacts with anyone. Here at home, he was smiling, he was laughing; that was an entirely different kid." Any clinician who has had the privilege of being invited into the sacred ground of a pediatric hospice patient's home can appreciate this assessment.

Quality, as a metric used to help guide the decision-making of pediatric palliative care patients and their families, is bound in and to the culture of the individual family. It is also tied into setting; quality of life (QOL) defined by the bed-bound patient residing in the intensive care unit (ICU) might look very different from quality as defined by the newly diagnosed asymptomatic patient. The suggestion then becomes that quality must be a fluid metric that is influenced by values and goals established by the patient and family. However, it is possible that clinicians interacting with families have an entirely different definition of quality and subsequent outcomes. Understanding the need for early palliative care integration is perhaps best demonstrated by the following case example.

Case Study: A Patient's Quality of Life

WS was diagnosed at birth with trisomy 13. She initially presented with a ventricular septal defect, rocker bottom feet, low-set ears, microcephaly, clenched hands, and a high risk for aspiration. She was immediately transferred to the neonatal ICU (NICU) where she spent the first 4 weeks of her life. Palliative care consultation was requested to assist her family with decision-making. WS's mother explained, "This feels like it's all been a bad dream, I just want her to get better." WS's father reported feeling overwhelmed by the medical decisions presented by the specialists involved in his daughter's care. After a series of family meetings, her parents decided to bring WS home with a nasogastric (G) tube and safety medications for potential seizures and to make decisions about ventricular septal defect closure and other surgical interventions at a later date. WS's mother spoke often about the nursery waiting at home for WS, and she reported feeling confident that WS would improve if she could just go home.

WS was discharged home with hospice. Her parents had elected to make every effort to keep WS comfortable and had agreed with adjusting her code status to allow for natural death. During a social work hospice visit, WS's mother reported that neither parent had been sleeping and that they felt as though they were staring at her waiting for her to die. She noted, "We really aren't living, we are just walking around like zombies." Home health was introduced to assist with night nursing hours, and, as WS began to gain weight, her parents reported feeling a renewed sense of hope.

After 2 months of home hospice, WS's mother began to question the direction of WS's goals of care. She felt that with WS improving, the family could now revisit the potential for surgical interventions, and she decided to amend WS's code status. She had become engaged online with a network of mothers who also had children with trisomy 13 and began to feel more empowered in advocating for WS. WS's parents requested a transfer from hospice care to palliative care and were excited by the opportunity to throw WS a "hospice graduation" party.

While being followed by the outpatient palliative care team, WS had a successful ventricular septal defect closure and had a button G-tube placed. WS had regular appointments with a variety of specialists, and, after a year of being followed by the palliative care team, her mother would report, "We are doing good!" and even asked, "We love you guys, but do we still need you?" By age 2, WS had surpassed all expectations for her life expectancy.

Shortly after her third birthday, WS began experiencing seizures and increased hospitalizations. Palliative care was reintroduced, and her mother noted that, "This feels different, this feels like the big one." She reported that WS had become much less interactive and worried that WS was experiencing significant neurological delay following the seizures. After a major ICU stay, WS's parents decided to again take WS home with hospice. She died in her own room surrounded by her family and favorite stuffed animals. The mother told her hospice social worker, "WS never had it easy, but she always did things her own way and was the strongest person I know."

Outcomes Considerations and the Power of Social Networking

The experiences described in WS's case study illustrate the challenges families face when navigating goals of care. In the case of trisomy 13 and 18, many clinicians refer to both diagnoses as "lethal conditions," and many families have reported experiencing bias by clinicians due to their child's diagnostic label.[3] While WS's parents were not aware of her diagnosis until birth, the research suggests that when trisomy 13 and 18 are discovered in utero, families are often counseled toward termination.[4] Remarkably, despite feeling the pressure to terminate, the majority of parents elected to continue their pregnancy. In a survey of parents facing prenatal diagnosis of trisomy 13 and/or 18, parents chose to ignore recommendations toward termination based on their own reported moral beliefs (68%), child-centered reasons (64%), religious beliefs (48%), parent-centered reasons (28%), and practical reasons (6%).[5] This research demonstrates the disconnect that can exist between clinicians and parents when determining treatment courses for their medically fragile children.

The working assumption that trisomy 13 and 18 were lethal congenital anomalies that were not compatible with life was generally validated by what clinicians were seeing in practice.[6] A retrospective cohort study found that among children born with trisomy 13 and 18 in Ontario, Canada, early mortality was the most common outcome; however, 10–13% of children survived for 10 years, and, among children who underwent surgical interventions, 1-year survival was actually high.[7] So how should palliative care clinicians approach assisting families with decision-making in the face of such prognostic ambiguity and potential clinician bias?

The palliative care clinician should not only attune him- or herself to what families might be hearing from their primary medical providers, but also consider what families might be learning in their own examination of the diagnosis. In the example of trisomy 13 and 18, clinicians relied on the multitude of resources that suggested this diagnosis will mean extreme suffering and shortened life span. Meanwhile, families researching the condition on the Internet were introduced to an alternative narrative, one that suggested that patients who do survive experienced meaningful lives and QOL.

Parents, like WS's mother, who engage with parental support groups online may discover an alternative positive description about children with trisomy 13 and 18.[5] A quick Internet search reveals shockingly different results when the words "trisomy 13 and 18" are used alone versus "trisomy 13 and 18 support." While the diagnosis-alone Internet search yields a clinical, medically complex, and seemingly negative perspective, the diagnosis and support search brings one to a multitude of support groups such as the Support Organization for Trisomy (SOFT), which presents smiling children and relatable language. Understanding that families might hold the clinical perspective and the support perspective in equal regard will help the palliative care clinician help families navigate decision-making through uncertain outcomes.

Guiding with Uncertainty

The sometimes dichotomous relationship between the perspective of the clinician and the patient and family is no more evident than when considered through the lens of prognostication in pediatric life-limiting illness. In the case of cancer, which remains one of the leading causes of nonaccidental death in childhood, one study reports that children who die of cancer experience significant suffering and inadequate palliation in the last month of life.[8,9] The team investigating these parent-reported outcomes suggested that unrealistic prognostic expectations, by both physicians and/or parents, may be leading to inappropriate treatment goals. A survey of parents of children who died of cancer between 1990 and 1997, along with 42 pediatric oncologists, confirmed that parents first recognized that the child had no realistic chance for cure a mean of 109 days before the child's death, while physician recognition occurred earlier at 206 days before death,[10] furthering the idea that palliative care often acts as a bridge between medical understanding and family understanding.

Considerable delay exists in parental recognition that children have no realistic chance for cure, but earlier recognition of this prognosis by both physicians and parents is associated with a stronger emphasis on treatment directed at lessening suffering and greater integration of palliative care.

Case Study: A Patient Undergoing Hematopoietic Stem Cell Transplantation

MM was a 17-year-old boy of Indian descent. He lived at home with his parents and younger sister. He was born with a severe primary immunodeficiency which had presented through his life as recurring, long-lasting infections. These infections caused MM to spend the majority of his school-aged years in the ICU for treatment. Despite these challenges, MM maintained high grades in school and even managed to frontload his classes to allow him to graduate a semester early. Under advisement of his medical team, MM and his family decided to pursue hematopoietic stem cell transplant through bone marrow transplant.

Following hospital protocol, the pediatric palliative care team was consulted to meet MM and his family at time of transplant. During the initial consultation, MM described his choice in timing for transplant and explained, "I'd rather take a year off now, finish up my last semester, and go into college without having to worry about this." When asked if there were things he worried about regarding transplant, he remarked, "I mean, I guess I'm worried it won't work, but I don't want to spend the rest of my life in and out of hospitals, so it's worth it." MM's parents were actively involved in his decision-making process and remained hopeful and confident in their decision to proceed with transplantation.

During the engraftment period, MM and his family engaged easily with care team providers. Like many of his peers, he loved discussing sports and technology with all providers who visited him. MM was discharged from the hem/onc unit after 30 days of engraftment. MM reported looking forward to getting home and playing video games and catching up with his friends as he continued the recovery process. A week after discharge, MM returned to the unit with low counts and fever. His family was understandably discouraged by this admission and worried that this was indicative of complications from transplantation. MM had lost almost all of his hair and had severe nausea. This was especially challenging for his family, as his mother identified feeding MM as a primary exhibition of her love and care.

MM would always be the first to tell staff that he loved food, and any restrictions on his eating habits felt like a major setback. MM had grown close to his primary nurses, palliative care social worker, and child life specialist, routinely requesting visits to "check in" and report on new Apple products or projects he was working on. He arranged a special Super Bowl viewing party in his room on the floor and invited all staff and his friends to attend. While MM remained upbeat in his interactions with his teams, his condition worsened.

MM developed graft-versus-host disease, which presented with skin sloughing and progressive gastrointestinal involvement. MM was acutely aware of his decline, and, during one visit with his palliative care social worker, when asked if there were things he was worried about, he tearfully replied, "I'm worried I won't get to do the things I want to do with my life." MM was a very imaginative young man and was able to explore some of these "bucket list" items through guided imagery. All of the teams involved in MM's care had grown close to MM and his family. In a preconference to a care team meeting, each of his specialists had begun speaking about the aspect of MM's disease process that he or she was responsible for when the palliative care physician interjected, "no one is acknowledging the reality here; MM is dying."

While each clinician cognitively understood this clinical reality, the team was challenged with how to communicate this to a family who had been such strong advocates for hoping against hope. When the change in MM's prognosis was presented to his parents, they explained that they needed to maintain hope and that there were forces outside those of medicine that might intervene. They both felt that the care team had become "like family" and reported that MM would want to be on the unit in the event he should die. When asked what they felt brought their son comfort, MM's parents reported that he loved listening to his favorite book read aloud. During the last 3 days of MM's life, he remained unresponsive while members of the care team and MM's parents took turns reading MM's favorite book aloud to him.

Parent Outlook and Understanding

While hematopoietic stem cell transplantation presents the potential for cure for patients like MM, it remains an intensive therapy that presents many risks for complications and lasting health effects.[11] Can families truly understand what the transplantation process could look like? Understanding patient and family perspectives on proposed interventions is essential to facilitating goals of care conversations. In the case of bone marrow transplantation, one qualitative study found that parents reported being either incapable or unwilling to think about the potential for negative outcomes. Some parents refused to acknowledge the possibility that their child might die, in order to move forward with transplantation.[12]

In MM's case, this was certainly true for his parents. He had spent his life dealing with infections that had the potential for significant harm, so a path without transplantation still presented significant risk to MM's life. If they elected not to move forward with transplantation, they could imagine a future decline. However, transplantation presented the possibility of a different future, a future that was *potentially* symptom-free and curative. At one point MM's mother even remarked, "If it doesn't work, he will be sick, and he's always been sick." What they repeatedly reported not "being ready for" was the way things like graft-versus-host would present. They had read that this was possible, but they had not imagined what it would be like to see MM experience significant pain with the slightest touch. They had not imagined seeing MM's skin break down to the point of bleeding, or that he would become too weak to walk the short distance to his bathroom.

Fortunately, palliative care consultation began early for MM, and continued conversations about his parents' outlook and concerns throughout the entire transplantation course were possible. This type of communication can greatly assist parents with coping during this uncertain process.[13] Research centered on parent outlook in hematopoietic stem cell transplantation helps make the case for early and often goals of care conversations. The team concluded that, "understanding parent outlook is a cornerstone of clear and compassionate communication throughout the course of hematopoietic stem cell transplantation, allowing mutual understanding of hopes, fears, expectations, and goals of care."[14] In MM's case, this meant continued readjustment of goals of care as his disease progressed. The trust necessary to hold both hope and prognosis was well established through continued open and honest communication.

Clinician Impact on Bereavement Course

Understanding parent and family perspectives is essential not only for providing care during the illness trajectory, but also in assisting families through their bereavement. Communication and continuity of care are two of the most important aspects of the parent-reported grief experience that the clinician can impact.[15] Many families will want to reconvene their care team to ask, "Did I make the right decision?" or "What could I have done differently?" These meetings can be an important opportunity to revisit family decision-making and reiterate that parents have made the most loving decisions possible with the information they had available.

These bereavement care team meetings can have significant impact for families. Four major meaning-making processes have been identified in qualifying the impact of these meetings. These processes include sense-making, benefit-finding, continuing bonds, and identity reconstruction.[16] See Tables 60.1, 60.2, 60.3 and 60.4 for detailed descriptions of the four processes and examples of parental response. While it remains unknown the extent to which meaning-making during bereavement meetings affects parent health outcomes, the research in the PICU setting suggests that bereaved parents are at a high risk for complicated grief and that meaning-making is associated with a reduction in the severity of these symptoms.[16]

Consideration should also be given to the bereaved sibling. The loss of a sibling can have significant impact on the life course of the surviving sibling. In MM's case, his sister, CM, spent most of her afternoons doing homework in MM's hospital room. If she wanted her parents present for something in her life, MM's illness always had to be considered. Many of the same challenges in meaning-making exist in the bereavement course of a sibling. How a sibling experiences the death of a child could impact his or her long-term psychosocial well-being. Sibling-directed communication and concurrent supportive care during the illness experience and the immediate bereavement course may mitigate poor long-term outcomes.[17]

Communication throughout the Trajectory

When caring for children with complex life-limiting illnesses, communication needs change rapidly and sometimes unexpectedly. Given the uncertainty of prognostication, effective communication surrounding goals of care is essential. Guiding conversations around goals to address physical, emotional, spiritual, and social needs is

Table 60.1 Sense-making processes observed during follow-up meetings ($N = 35$)

Sense-making process	Example (follow-up meeting number)	n (%)[a]
Biomedical explanations	Do you think there's anything we should be asking as far as from a medical perspective that maybe we're just not—any information that we should know that we might not already know? (#21)	34 (97)
Details of illness	What about the high blood sugar? . . . And did his weight have anything to do with it? (#4)	32 (91)
Course of illness	My question was how things happened chronologically. For me it was a blur. (#28)	27 (77)
Counterfactuals	I just have the "what-ifs," like what if we waited one day and they would have done surgery. (#23)	23 (66)
Cause of death	Do you know what her cause of death is? Is it blunt force trauma to her head? (#8)	20 (57)
Autopsy	So was there anything in the autopsy that was surprising or significant? (#25)	13 (37)
Parents' prior decisions	You're always going to have that question whether or not you made the right decision. (#21)	24 (69)
End-of-life care	One of B's main concerns is that we didn't pull the plug too soon or gave up on her too soon. (#23)	17 (49)
Treatment	The feeding tube, we understand we want to try to feed him . . . But was it worth it? (#15)	14 (40)
Blame	What happens is a lot of times when you try to get all the answers' you're trying to find somebody to blame. (#30)	18 (51)
For child's death	You can tell me when my pizza's going to be here. But you can't tell me when they're going to be here to pick up a child who's dying? It's just unacceptable. (#41)	9 (26)
For parents' experience	Why did it take 4 hours for the nurse to call us? If they're telling us everything started around 9 P.M., we didn't we get a call until 1:15 A.M., and we're a half an hour away. (#16)	16 (46)
Blessings	And every day he lived was a blessing. Every day was better than anybody had ever told me. (#29)	18 (51)
Inevitability of death	Even though he had his ups and downs, he was on a downward cycle. (#25)	18 (51)
Parents' role in the death	Has smoking ever been connected to any kind of heart problem in pregnancy? I smoked when I was pregnant. (#32)	15 (43)
Downward comparisons	There's been a couple sudden deaths in our area . . . In some ways that would be even harder. (#13)	14 (40)
God's will	Maybe that was her day to be with the Lord. (#11)	13 (37)
Did everything	I do believe you all did everything you could to save my daughter. (#20)	11 (31)
No longer suffering	He's in a good place, he's not suffering anymore. (#3)	7 (20)
Exceeded expected age	I had 9 months. Nine months that technically I never should have had. (#10)	7 (20)
Child's will	He (child) told Dr. S, "I'm not having no more surgery." He said, "This is my last one." (#22)	4 (11)
Why me?	It's unfair, but it's my life, you know. This is what I was dealt. (#2)	3 (9)
Parent not capable	I know I can't handle a sick baby . . . I wouldn't be able to take care of a sick child forever. (#2)	2 (6)
No sense made	When we got the results back, basically we were told they didn't find anything wrong. So we're still left without an answer. . . . It's like getting handed a blank piece of paper. It's like, why? Why did we go through what we went through for no answer? (#16)	9 (26)
No need to make sense	I believe this stuff happens and that's just how it was supposed to happen, you know. Left your house an hour early, got in a car accident, that's just what was supposed to happen. (#2)	9 (26)

necessary to ensure holistic care is delivered. Communication is the basis for all decision-making, and, throughout an illness trajectory, decision-making hinges on effective communication.[18] Providers must understand how to meet a family where they are in order to foster open communication around the issues that are most important to the patient and the family.

When families are faced with having to make hard healthcare decisions for their children, open and effective communication impacts how information is received. The necessary communication skills that the provider must possess include marrying effective general communication with complex medical topics and patient-centered decisions.[19] Training medical professionals how to effectively communicate with their patients builds confidence in the provider. This confidence then facilitates a trusting relationship in which difficult conversations are more productive.[20]

Preparation for the conversation is key for the provider and the family. Understanding the goals of the communication and the topics that will be covered allows the participants to feel more at ease with the expectations. Giving space for the concerns of the family and how they will best be supported in having difficult

conversations is essential to ensuring productivity. This facilitation fosters trust and opens the door to effective communication regardless of how difficult the topic. Conversations that help align family perspectives and values with anticipated medical outcomes will be more accepted if the communication is trusted and facilitated appropriately. This rapport allows for trust during the times when communication is occurring with medical uncertainty and the communication is rapidly changing. "Parents consider communication to be the principal determinant of QOL, regardless of symptom management."[21]

Communication surrounding goals of care across the illness trajectory empowers the patient and family to make informed decisions in the face of uncertainty. An interdisciplinary approach to goals of care communication ensures that all aspects of the patient's care are being addressed. Cohesive goal conversations hinge largely on care providers being consistent in their messaging and collaboration as a healthcare interdisciplinary team. When planning communication, whether there is a need to revisit goals or have an initial meeting, making sure that all disciplines are involved will ensure that the patient's needs are effectively and globally addressed.

Case Study: A Patient with a Congenital Heart Defect and Hydrocephalus

JR was diagnosed at birth with a congenital heart defect and hydrocephalus with shunt placement. He spent 9 months in the NICU/PICU. He was discharged home with private duty nursing services and the durable medical equipment needed to provide his in-home care. His mother was given education and training over a 3-day period, and she had attended roughly six care team meetings throughout his hospitalization.

He was home for a week and returned to the hospital following a code event at home. During his rehospitalization, it was discovered that his shunt had malfunctioned and would have to be replaced. During surgery, he suffered a cardiac arrest and was resuscitated. His shunt was externalized due to infection, and he was admitted from the operating room to the PICU on ventilator support. JR spent another 4 weeks in the PICU prior to a palliative care consult occurring. The palliative care consult occurred following another code event and unsuccessful conversations with the mother regarding his code status and prognosis.

Following the palliative care consult, a care team meeting was scheduled with the mother. The meeting was to include the PICU physician, PICU nurse, neurosurgeon, cardiologist, social worker, palliative care MD and nurse, and the child life specialist for the PICU. The palliative care team nurse met with the mother prior to the care team meeting and discussed JR's trajectory and care goals. The mother stated that, prior to the palliative care consult, she had not understood the severity of the patient's condition even though he had multiple code events and there had been previous conversations about the futility of treatment. She understood from previous meetings that JR would have unique healthcare needs, but she did not understand that the illness trajectory would include making decisions regarding limiting interventions. JR's mother stated that she understood that, due to his fragile state and the recent decline in his health status, changing the focus of his medical treatment would need to be discussed in the upcoming meeting. She expressed that she felt that his QOL during this hospitalization had declined. She reiterated understanding the need for the upcoming care team meeting.

The morning of the care team meeting, the palliative care nurse met with JR's mother once again and reiterated the goal of the meeting and who would be in attendance. JR's mother was given the opportunity to ask preliminary questions of the palliative care nurse so that the care team would be prepared for the meeting as well. During this meeting, JR's mother was engaged and asked appropriate questions. Care goals were discussed, and JR's mother asked for more information on a tailored resuscitation plan for JR instead of signing a do-not-resuscitate (DNR) form. The care team met after the mother left the meeting and agreed that this was the most productive care goal meeting since JR was admitted in the PICU. The palliative care nurse also met with the mother following the meeting to ensure that the message she received during the meeting was consistent with the team's intentions. The overall satisfaction of the team and JR's mom improved following this level of communication.

Communication and Impact on Outcomes

JR's case illustrates how patient outcomes are directly impacted by the way communication is handled. Parental reports of dissatisfaction can stem from the way in which communication was handled during the critical times of their child's illness trajectory. Similar to JR's case, families report that they are not confident in the medical knowledge provided; they feel there is a lack of emotional consideration, a continued emphasis on a cure without realistic conversations surrounding refocusing care goals, a delay in this realistic communication, and a lack of privacy during these delicate conversations.[19]

Even though the intention of the care team was to provide JR's mother with education and guidance regarding his diagnosis and prognosis, the tenuous environment of the PICU challenged JR's mother's communication needs. The rapport necessary to foster the trusting relationship needed for these difficult conversations effectively has to be established early on in the trajectory.[22]

Families express that the information they find most critical during early diagnostic discussions are "symptom management, what to expect from the diagnosis, and what testing is necessary."[19] Parents who report good communication experiences with their healthcare providers include such contributing factors as communication skills that included open and sympathetic dialogue and direct communication regarding the diagnosis in private with adequate time to absorb and clarify the information provided.[19] Parents like JR's mom express the inherent desire to have their needs valued and heard.

Value-Based Decision-Making

Just as parents want their child's needs communicated and valued, they also want to know that the decisions they are making regarding the care of their child are based on the values that are important to them. The child's value and significance is important to the family, and how care goals are handled by providers has a reflection on this value. Engaging conversations around goals of care not only to include what medical needs may be present, but also understanding the importance of the family's values will guide these goals regardless of the medical trajectory. "Quality of life" is defined by the World Health Organization as "an individual's perception of their position in life, in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns."[23,24] Promoting an environment where QOL and personal values are at the forefront when discussing goals of care will foster collaboration and cohesiveness.

The hematology-oncology team at San Diego's Rady's Children's Hospital established a Supportive Care Program to ensure that QOL was at the center of the care provided to patients dealing with life-limiting hematological and oncology disorders. This embedded service did not require a consult and rather was considered an extension of the primary team.[25] The service facilitates supportive care rounding with patients and their families to ensure that their QOL is being addressed and decisions are value-based. The team utilizes a decision-making tool to "improve communication, identify goals of care, optimize the patient's quality of life, and formulate a plan of care."[26] An evaluation study was conducted to evaluate family satisfaction with the supportive care team and the effectiveness of the decision-making tool. The study also captured what impacted a family's decision-making.[19] "The child's quality of life, chances of improvement, and level of pain and discomfort were all rated significantly higher in importance than other factors."[26] Participants in the study were also asked which members of the team had a significant impact on the decisions that they made for their child, and every participant listed the nurse as a key component. The use of clear and concise communication throughout the illness trajectory, as illustrated through this study, improves perceived QOL and support throughout the decision-making process.[9]

Preparing Families for Uncertainty

> "If we focus on what we can't do, we will never get anywhere."[23]

Patients and families report realistic expectations about the possibility for decline when faced with life-limiting illnesses, but uncertainty around when or how this decline will occur.[27] The complexity of the illness and making value-based decisions for their child's health management can be complicated by this unknown. "Parents confronted with the fact that their child's health had declined over time talked about *when* the child would die in contrast to parents faced with the immediate threat of acute changes who talked about *whether* the child would die."[21]

Pediatric palliative care is designed to support families through this uncertainty with a collaborative team approach that changes as the patient's and/or family's needs change.[28] Understanding the changing landscape of the illness trajectory is both crucial and difficult for healthcare providers and parents alike. Parents do not expect that healthcare providers have all of the answers, but instead seek honest and caring providers who are available to answer their questions.[22] Uncertainty throughout the illness trajectory is not an unexpected difficulty; however, the challenge comes with preparing families and patients to anticipate changing care goals. Palliative care should be delivered in a way that anticipates these unique and changing needs. This care should be delivered in a flexible and collaborative manner while anticipating the needs of the patient and family.[28]

The timing of palliative care involvement plays an important part in establishing care goals that transcend the initial diagnosis. Integrating the palliative care team as part of the primary care team will foster the trust necessary when uncertainty and difficult conversations present themselves. "Key components of palliative care, for both children and adults, include not only pain and symptom management, but effective patient–provider communication, support for decision-making, coordination of care, spiritual, emotional and psychological care, and bereavement support."[29]

Whether the child has been chronically or acutely ill, changing trajectories and uncertain outcomes are stress-inducing for the parent. Parental fear and anticipation of the next hospitalization or setback is a constant when caring for a child with a life-limiting illness. The decline may have been seen over a longer period of time, or it may be a more rapid illness that prompts the hospitalization that could mean the change in their current trajectory. Provider support for both the physical and emotional needs during this critical time is invaluable. Palliative care has often been considered when having end-of-life conversations, when, in reality, palliative care is most supportive when utilized across the illness trajectory to ensure the anticipation of changes in the patient's goals of care.[30]

Case Study: A Patient with a Changing Trajectory of Care

Payton was diagnosed right after birth with a rare genetic disorder that affected her overall health. She started her life complicated by cataracts, hip dysplasia, a heart murmur, and hearing loss. By her first birthday, she would endure eight surgeries. This would be the beginning of a long, complicated medical course that would be defined by uncertainty. Her mental capacity never developed past a 9-month-old level, and she would never have the ability to sit, crawl, or talk. Her trajectory was complicated by new medical challenges constantly, and, over the span of 6 years, she would endure 20 surgeries and countless hospitalizations. Each hospitalization brought a new set of concerns and goal changes, but what was considered a return to baseline at the conclusion of each hospitalization. Her mother reported, in retrospect, that there had been a very slow and steady decline in her overall baseline that was not overtly apparent to her, given the fact that she was her caregiver every day.

At age 6, Payton was hospitalized with what was thought to be feeding intolerance. During this hospitalization, Payton's parents participated in daily rounding with the medical team. They were briefed on her changing health status and the uncertainty of what might be occurring. They reported that this was not new for Payton. Given the rarity of her case, it was common for there to be uncertainty. The difference with this hospitalization would be the uncertainty in not what was acutely happening with Payton, but whether she would recover from this setback. With no pediatric palliative care team available, the general pediatric team managed her care day to day and consulted specialists who could speak to the many complex health needs Payton and her family were experiencing.

Payton had been hospitalized for 2 weeks when it was apparent that this was not going to be a typical hospitalization. Her lab values could not be normalized, and her body seemed to be "shutting down" according to her mother. On hospital day 17, an outside pediatric hospice team was called in to consult on Payton's case and determine the possibility of providing care at home. Upon meeting with Payton's mother, it was determined that she understood that the likelihood of Payton returning to her baseline health status was not expected. During this meeting, it was discussed that Payton's parents wished to begin focusing on her symptom management and not continuing to put her through the exhaustive testing she had endured while trying to come to a conclusion about her decline. The primary pediatrician caring for her during this hospitalization was also present for the meeting and obtained the documentation of the family's wishes for Payton's care directives. Payton now had an order to allow natural death in place, and, due to the symptom burden of her enteral feeds, they were discontinued.

Her family was given time to absorb the information delivered in the care team meeting, and a follow-up meeting was scheduled for the following day to discuss further care planning. During this follow-up meeting, the pediatrician, hospice nurse, social worker, and child life specialist conferenced with the family to answer questions and discuss where the family would like to be when Payton died. Given the complexity of Payton's care and a sibling living in the home, it was decided that she would remain in the hospital under the care of the hospice team, in collaboration with the hospital care team. The family was provided with memory-making and legacy-building opportunities. A hospice care plan was developed to provide physical, emotional, and spiritual support during this time. On the 40th day of her hospitalization, Payton died with her family present. Her family was provided bereavement support for 2 years following her death.

Payton's mother reflected that "there were so many increasingly complex medical issues at play, and no form of treatment was going to 'fix' her condition. Being connected to the appropriate hospice team members allowed our family to have concurrent support as we dealt with our daughter's life-limiting illness on the medical side. The decision to allow hospice to enter the picture was to endeavor to have a compassionate support team come alongside us as we journeyed through the end of our daughter's life on day 40 of our stay. The compassion and empathy demonstrated to our family during this time truly helped in our transition from illness to loss and grief. Hospice care became an invaluable resource for each of us during this time."

Clinician Challenges when Leading through Uncertainty

As illustrated in Payton's case, uncertainty is a constant when caring for patients with life-limiting illnesses. Supporting families through rapidly changing health status and goals of care is challenging at best. Understanding the delicate balance between hope and realistic expectations is essential to the well-being of the patient, family, and clinician. Clinician support is often overlooked in the pursuit to care for the patient and family. "The severe illness and death of a child is out of the 'natural order' of things. Bearing witness to the isolation or suffering of children is distressing for families and providers alike."[31]

Clinicians need support while guiding families through uncertainty. Without proper support, clinicians can become ineffective in the care they are able to provide, which will further complicate the course. Promoting a professional environment that validates the providers' needs throughout the time they are caring for a complex patient will foster healthy discussion and support.[30] Understanding their own grief is paramount, given how this grief can impact the care the clinician is able to provide. Clinicians may have been providing care for this patient throughout the illness trajectory, and acute changes in the patient's health status or the patient entering into a terminal phase is emotionally distressing.[32]

Families express effective communication as a consistent theme when discussing their satisfaction with the delivery of care to patients living with complex health needs. In order for clinicians to be effective communicators, they must first understand their personal comfort level with having these conversations and supporting families through uncertainty. To avoid their discomfort being misconstrued as insensitivity, the clinician must fully grasp this concept. Self-awareness is crucial.[33] Understanding this emotional intelligence will aid the clinician in identifying the skills necessary to cope with the emotional challenges that caring for this patient population brings. Clinicians are faced with identifying their own emotions surrounding their mortality and grief processes. Continuously providing care to critically ill children, where the focus needs to shift from curative to more palliative care, is emotionally taxing. Having a grasp of how each clinician handles this emotion is essential to ensure quality care for the patient and sustainability for the clinician.[34]

CHAPTER 61

End-of-Life Decision-Making in Pediatric Oncology

Deborah A. Lafond and
Katherine Patterson Kelly

Key Points

- Decision-making for parents facing the serious illness of a child is, in most cases, extraordinarily difficult, particularly facing end of life.
- Healthcare providers can influence the extent to which patients and parents participate in end-of-life decision-making by communication style and timing of the discussion.
- Children and adolescents may need assistance making decisions based on their cognitive development, and each patient should be assessed as an individual to determine his or her competence and preference for decision involvement.
- Preferences for treatment should be balanced between the child or adolescent patient and the caregiver or surrogate.
- Nurses have a professional responsibility to facilitate informed patient decisions at the end of life.

Introduction

"Your child has cancer." These are words no parent ever expects or wants to hear. After hearing these words, parents are faced with a myriad of decisions, such as where to seek cancer treatment for their child, what therapies to choose, and how to tell their child about the diagnosis. *Treatment decision-making* refers to the choice between two or more treatment options. Families are also faced with decisions about everyday life, such as whether or not to return to work while their child is undergoing cancer treatment, which family members to involve in care, and who to trust for accurate information. While adults with cancer or other serious illnesses typically make their own healthcare decisions, parents must make decisions in the best interest of their child. In this chapter, we refer to "parents" as the biological parents or legal guardians who have decision-making authority for a child. We use the term "child" to refer to all infants, children, adolescents, and young adults unless we are referring to a particular developmental stage of a child.

Parents' treatment decision-making for their child may be impacted by family dynamics, prior decision-making experiences, prior healthcare experiences, and the impact of culture and/or spirituality. Members of the healthcare team must provide accurate and timely information about the child's underlying illness and treatment options. This information, along with the child's and parents' prior experience, guides decision-making. Parents struggle to make the best decisions for their child to minimize decisional regret.[1] Nurses are in a unique position to support the child, parents, and other family members through their relationships forged by providing direct care at the bedside. In this chapter, we provide an overview of decision-making in pediatric oncology, including legal and ethical issues impacting decision-making, styles of decision-making, advance care planning, and advance directives. We will describe guidelines to assist decision-making for the child, parents, and the healthcare team, including the role of the nurse (Box 61.1).

Background

The Centers for Disease Control (CDC) reported 23,215 deaths of children from birth to age 1 year, 9,080 deaths from age 1 to 14 years, 28,291 deaths from ages 15 to 24 years, and 21,925 deaths in young adults 24 to 29 years in the United States (most recent data reported for 2014).[2] Infant mortality represents the largest group (28%), with the leading cause of death being related to congenital anomalies. Accidents remain the leading cause of death in all age groups, with suicide being the leading cause of nonaccidental, non–disease-related deaths for adolescents and young adults aged 15–24 years.[2] Cancer is the leading disease-related cause of death for children, adolescents, and young adults aged 1–24 years of age.[2]

While death in pediatrics is relatively rare compared to in adults, these lives represent the loss of the future in our society.[3] These lives also represent significant impact on families and friends. There is also impact on the workforce through loss of parents and/or other family members to care for the ill child or delay in return to work following the death of a child. The kinds of decisions and how they are made may impact parent grief and bereavement as well. Many parents indicate that feeling that they have been good parents, doing everything possible and having their wishes for their child's care respected, is a priority in making decisions at end of life.[4]

Decision-Making in Pediatric Oncology

After a child's diagnosis, parents are faced with decisions regarding cancer-directed and supportive care treatment options. Because pediatric cancer treatment is commonly guided by clinical trials,

Box 61.1 Definitions of Key Terms

Decision: The final choice between two or more treatment-related options.

Capacity: The ability of a person to make a decision, based on developmental and cognitive factors, including age and cognition which impact the person's ability to (1) receive information about the underlying illness and proposed treatments, (2) understand the relevant information and apply it to his or her own condition or the condition of their ill child, (3) have insight into the condition and consequences of treatment options, (4) be able to communicate the decision and reasoning for choices.[13]

Phase I study: The initial stage of human testing of a drug, in which the maximum tolerated dose is established; in oncology, the subjects are usually patients who have refractory disease.

Allow natural death (AND): A term becoming more widely used to describe death from the natural consequences of a disease or injury that emphasizes ongoing supportive care to promote comfort and optimize quality of life.[49]

Do not resuscitate: A physician's order written in the medical record directing that no cardiopulmonary resuscitation is to be performed in the case of an acute event such as cardiac, respiratory, or neurological decompensation.[49]

Withdrawal of life support: The act of discontinuing life-sustaining medical treatments, such as mechanical ventilation, pharmacological support of blood pressure, dialysis, and vasoactive infusions, that will likely lead to death.

Life-sustaining medical treatment: Interventions that may not control the patient's disease but may prolong the patient's life; these may include not only ventilator support, dialysis, and vasoactive infusions, but also antibiotics, insulin, chemotherapy, and nutrition and hydration provided by tubes and intravenous lines.

Supportive care: Comfort measures that exclude curative efforts but could include aggressive symptom management (such as pain relief and hydration) or symptom prevention (such as limited blood product support) as well as interventions to optimize quality of life (such as integrative therapies and play therapy).[50]

many parents do not perceive a choice during initial treatment decision-making. Often parents' first perceived choices occur when initial therapies fail. At this time, parents report factors such as the impact of the proposed treatments on quality of life (QOL), likelihood of relief of symptom distress and ease of suffering, what the child wants, and trust in their child's medical team as being influential to their treatment decision-making.[4,5] Discussion about what parents and the child with cancer value as most important to them is important for decision-making throughout the trajectory of illness but most critical at end of life. Transparent and honest communication with the parents, the child, and with the healthcare team is essential in assisting families with decision-making at end of life.[6,7] Factors that affect decision-making in pediatrics at end of life are summarized in Table 61.1.

Ethical/Legal Considerations in Decision-Making

Healthcare traditionally respects the rights of persons to make their own decisions regarding their health. This is challenging in pediatrics when the child, by virtue of age or developmental capacity, may not be able to make decisions independently. Parents are tasked with making decisions in the best interest of their child. The American Academy of Pediatrics (AAP),[8,9] the American Medical Association (AMA),[10,11] the Association of Pediatric Hematology/Oncology Nurses (APHON),[12] the Hospice and Palliative Nurses Association (HPNA),[13] the National Academies of Science, Engineering and Medicine (formerly the Institute of Medicine [IOM]),[14] and the Hastings Center[15] endorse shared decision-making in pediatrics. In most cases, parents act as surrogates to represent the best interests of their child. When parents cannot act as surrogate decision-makers due to legal or lack of capacity issues, the courts may appoint another legal decision-maker. For some, religious or cultural factors may impact decision-making. For example, in some Islamic cultures, there is a hierarchy of decision-making where Islamic laws influence who can make final decisions and the context in which decisions are evaluated (i.e., if the proposed decision would jeopardize the sanctity of human life).[16] Informed consent is generally required for most treatments and invasive testing, but legal, religious, cultural, and developmental issues may influence what, how, and to whom information is provided to inform decision-making. Providing information to inform decision-making and issues of consent/assent are related but separate issues.

Decision-Making as a Quality Outcome in Healthcare and in Palliative Care

Stakeholders, including payers and consumers of healthcare, want to know what healthcare programs do for patients and families. This may be challenging in palliative care, where the scope of practice crosses many domains. Stakeholders may place different values on any given domain, yet assistance with decision-making is an essential skill for palliative care practitioners and in pediatric oncology care. The National Consensus Project Clinical Practice Guidelines for Quality Care[17] and the American Society of Pediatric Hematology Oncology[18] state that the comprehensive psychosocial care plan includes assistance with decision-making through assessment of capacity, values, and preferences for treatment. Furthermore, they advocate that the child's views and preferences be documented and seriously considered in decision-making.[17]

Section 3506 of the Affordable Care Act advocates for shared decision-making through consensus-based standards and patient decision-making aids.[19] These evidence-based decision aids are designed to improve patient and family understanding of treatment options to assist them to make informed decisions. In adults, decision-making aids helped to elicit and clarify explicit values, resulting in patients making informed decisions that were congruent with those values, produced less decisional regret due to feeling uninformed, and produced less decisional regret due to unclear personal values, and patients felt more active participation in decision-making. Provider–patient communication was also enhanced.[20]

Decisions for children with cancer occur throughout the illness trajectory. The use of decision-making aids could be useful

Table 61.1 Factors that affect end-of-life discussions in pediatrics

Healthcare provider factors
1. Lack of confidence in discussing prognosis and end-of-life issues with patient and family
2. Lack of confidence to face the patient and family after difficult conversations.
3. Lack of comfort in having the conversation at all
4. Lack of experience
5. Lack of knowledge of how to address the patient and/or family's reaction to the information discussed
6. Their own discomfort with death and dying
7. Uncertain prognosis
8. Not knowing or understanding patient and family preferences for receiving prognostic information
9. Lack of understanding of the child's voice in decision-making
10. Lack of knowledge on how much specific information to provide
11. Not knowing when is the right time in the trajectory of the disease to discuss prognostic and end-of-life care information
12. Children may not show serious physical manifestations of disease until near end of life, unlike many adult cancer patients.
Patient factors
13. The child's developmental understanding of their illness and proposed treatments
14. The child's willingness to have the discussion
15. Lack of understanding of the possibility of death due to disease
16. The child may wish to protect their parents by ignoring the need to have the conversation
Parent factors
17. Lack of willingness to include the child in decision-making conversations
18. Lack of parent capacity or confidence to have the discussion with the child
19. Lack of acknowledgement or understanding that the child's illness is a terminal condition
20. Unrealistic expectations for cure
Institutional and/or cultural factors
21. Unspoken standards of care that may limit the child's voice in decision-making
22. Lack of support systems for staff to deal with potential moral distress derived from these difficult conversations
23. Cultural and spiritual/religious norms within the institution and/or community

in guiding parents throughout their child's life to acknowledge that a decision must be made, identify the key stakeholders, and create equity in the decision-making process. Decisions can be presented without bias, investigating the values and preferences of all persons involved in the decision-making process.[9] An important example of decision-making aids being used in clinical care include a variety of tools for advance care planning, which is discussed later in this chapter. Regardless of the approach to decision-making, the individual and family styles of decision-making should be considered in how to present information.

Styles of Decision-Making

Decision-making styles range from being autonomous to following recommendations of the medical team and are influenced by individual child and family preferences, religious and/or spiritual beliefs, and culture (including those of the healthcare team themselves). Regardless of how a child and/or family makes decisions, they must be provided with accurate and timely information regarding the diagnosis, diagnostic testing results, treatment options, risks, and benefits of all potential options, including adverse events and alternatives to treatment, including the option for no treatment.

Autonomous Decision-Making

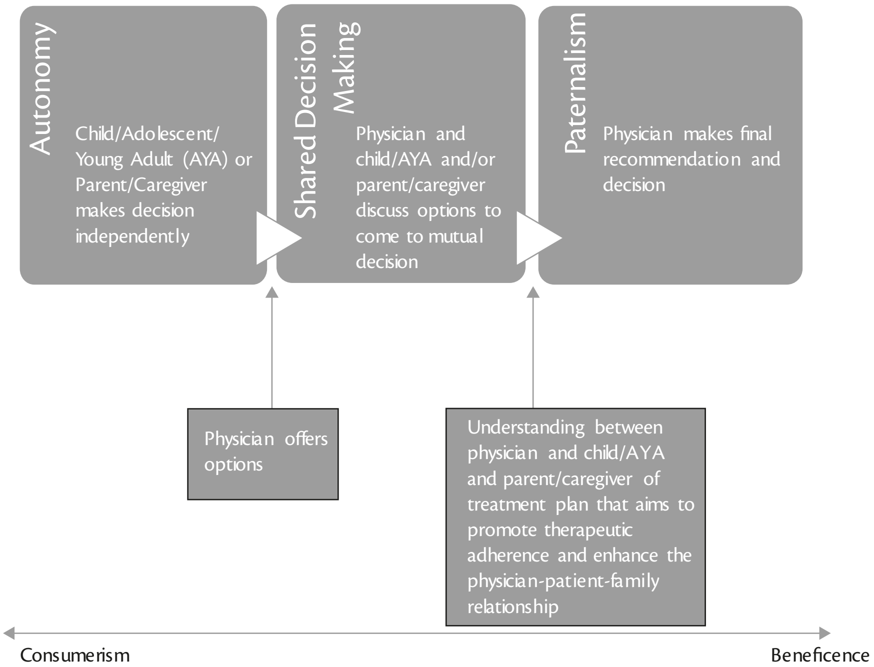
Some parents prefer to make independent decisions regarding their child's treatment. An older adolescent or young adult may also prefer autonomous decision-making, but in the United States this is only legal for those 18 years of age and older who also have the developmental capacity to make these decisions. While autonomous decision-making respects the ethical principle of autonomy, it does not negate the healthcare team's responsibility to provide timely and accurate information. In autonomous decision-making, the child and family are provided with all information to inform their decision, after which they thoughtfully consider this information and inform their healthcare team of the decision they have made. The healthcare team then acts upon this decision to embark upon the course of treatment.

Can any complex healthcare decision be truly autonomous? Members of the healthcare team have potential biases that can influence what and how information is presented. Unconscious biases can influence which clinical trial is presented or how the clinician's preference for a specific choice is conveyed through verbal or nonverbal communication. For example, phase I clinical trials, which are designed to establish safe dosing and toxicity profiles and not treatment efficacy can be presented to families with either a primary emphasis on the potential for the trial to help the child and secondary emphasis on the purpose of these types of treatment trials, or with a primary emphasis on the specific aims of a phase I trial and secondary emphasis on a small chance that the trial might help the child. Researchers have demonstrated that parents of children and adolescents and young adults (AYAs) who are enrolled in clinical trials cannot always state the correct purpose of the trial.[21] Research is needed to help clinicians communicate effectively in these difficult situations to meet family needs for clear and accurate information and needed emotional support during such decision-making discussions.

Shared Decision-Making

Collaborative or shared decision-making (SDM) honors the expertise of both the healthcare team in understanding the underlying illness and potential usefulness of treatment options; the expertise of the child, as developmentally appropriate; and parents in making decisions in the best interest of their child. This occurs along a continuum (Figure 61.1) where the family considers the expertise and information provided by the healthcare team in light of their own values and preferences. The AAP has long endorsed the involvement of the child and family in the informed consent process; however, discussions continue on how best to engage them in the process.[8]

A recent systematic review of pediatric decision-making intervention trials showed that SDM interventions improved knowledge



Autonomy
Child/Adolescent/ Young Adult (AYA) or Parent/Caregiver makes decision independently
Shared Decision Making
Physician and child/AYA and/or parent/caregiver discuss options to come to mutual decision
Paternalism
Physician makes final recommendation and decision
Physician offers options
Understanding between physician and child/AYA and parent/caregiver of treatment plan that aims to promote therapeutic adherence and enhance the physician-patient-family relationship
Consumerism
Beneficence

Figure 61.1 Continuum of decision-making.

and decreased decisional regret but did not improve satisfaction with the decision-making process.[22] The use of randomized clinical trials in SDM research in pediatrics is rare. Most studies are small quality improvement or pilot projects. Researchers primarily targeted parents in SDM research; children were rarely studied. When asked in a developmentally sensitive manner, children can articulate their feelings and what is most important to them. This information can be incredibly valuable to guide parents and the healthcare team in decision-making and about what interventions to offer.[22,23]

Defining the role of the parent relative to the role of the child is not well understood because most studies of pediatric SDM targeted parents and not the child.[22] Results from a synthesis of pediatric oncology end-of-life (EOL) decision-making qualitative research showed that parents desire clear and honest communication, delivered with compassion that honors their values and preferences.[4] Continuing to provide hope, focusing on optimizing QOL, and reinforcement by the healthcare team that parents are making good and thoughtful decisions promotes a trusted relationship.

Many parents wanted more time to spend with their ill child, which prompted their decisions to use palliative disease-directed treatments to extend the life of their child; however, in one retrospective study 70% of parents would have decided to forgo life-sustaining therapies, including resuscitation, as the child neared end of life and 20% of parents would have terminated aggressive medical interventions.[4] It is therefore incumbent upon providers to give accurate information about the likelihood for disease control of all therapies and information about anticipated side effects. The healthcare team can assist parents by discussing options for symptom-directed treatments to optimize comfort and QOL at the same time that disease-directed therapies are being introduced. They can emphasize that the option to redirect care from a focus on the disease to a focus on comfort and QOL is available to the family at any time if it is in the child's best interest.

In their systematic review of studies from 2000 to 2016, Sisk et al.[6] noted that parents also need to understand the diagnosis and prognosis. At diagnosis, approximately 66% of parents believed that their child would survive, and, in another study, 50% of mothers and 58% of fathers believed their child would be cured.[4] Parents were more optimistic than their child's physician that the child would be cured.[4,6] Communication of prognosis is essential to parents' understanding and will allow them to make decisions regarding their child's treatment that best align with their values and preferences. What is essential to facilitate effective SDM with parents is accurate and honest communication between the healthcare team and the family (Table 61.2).

Recommendation from the Medical Team

Sometimes parents either ask specifically for or intimate that they need a recommendation about treatment. Whitney and colleagues describe a model of SDM that outlines the conditions under which the physician should make a treatment recommendation (e.g., good prognosis, effective treatment known, as in low-stage Wilms tumor) as compared to times when SDM including the child or adolescent is more necessary (e.g., poor prognosis, no clear best option with lower likelihood of cure, as in relapsed acute lymphoblastic leukemia [ALL] in an adolescent).[24] When a parent asks "what would you do if this was your child?" they earnestly desire an answer.[25] Desiring a recommendation from the healthcare team may be influenced by several factors, such as language barriers, where a family does not clearly understand the information provided, or when the healthcare team has evidence to support that a specific treatment is most likely to obtain cure where others may be sufficiently suboptimal as to cause harm. In addition, this style of decision-making may be utilized when

Table 61.2 Six essential core functions of clinician–patient/parent communication defined for pediatrics[6]

Core function	Definition	Examples
Foster healing relationships	Providing emotional supports and anticipatory guidance to inform understanding of the child's underlying illness and treatment options.	The primary oncologist relays information from the time of diagnosis in an honest, clear, and compassionate way which facilitates trust throughout the trajectory of the child's illness.
Exchanging information	The child, parents, and healthcare team share information about their understanding of the diagnosis, treatment options, prognosis, and anticipated adverse events.	At relapse, the parents provide the primary oncologist with information they have found on the Internet about a promising phase I clinical trial and seek the healthcare team's guidance on enrolling their child in this clinical trial. The healthcare team provides information about any results in previous studies, risks and benefits of this clinical trial, and the child's prognosis.
Responding to emotions	From the time of diagnosis throughout the trajectory of the child's illness, parents and the child may experience a variety of emotions, from anger, denial, sadness, worry, anxiety, depression, etc. The healthcare team acknowledges these emotions and actively seeks to provide appropriate resources to support the child and parents, clarifying their emotional state, communicating understanding, and responding in an empathetic manner.	The mother of a child with a high-risk malignant brain tumor is noted to be crying in the MRI waiting room, while her child is undergoing the scan. The social worker acknowledges that she can see that the mother is upset and asks her to explain why she is in distress. The social worker listens actively to the mother's expressed worries and fears that her child's tumor has progressed because she has seen physical signs and symptoms that are similar to those seen at diagnosis. The social worker validates that she understands why the mother may be worried and reassures her that she will stay with her until the scan is completed, then let the primary oncologist know her worries so he or she can communicate the results of the scan as soon as possible.
Managing uncertainty	There are many periods of uncertainty during the trajectory of childhood cancer. For example, prognosis, unanticipated adverse events, survivorship, late effects of treatment, options for treatment, etc. In managing uncertainty, the healthcare team provides as much information as known to anticipate periods of uncertainty and dispel uncertainty when answers are known.	A child with a relapsed, refractory solid tumor is entering the active dying phase. The family asks when to anticipate death. The advanced practice nurse provides anticipatory guidance of the signs and symptoms of the dying process and how the family can comfort their dying child during this time.
Making decisions	Accurate and timely information on the diagnosis, prognosis, treatment options, anticipated side effects, and alternatives to treatment are essential to making decisions. Communication of this information must be clear, honest, and given in a developmentally appropriate way. The family's values, preferences, and style of decision-making must be assessed carefully.	The physician, nurse, and social worker meet with the family of a patient with a newly diagnosed brainstem glioma. The team assesses the family's understanding of the diagnosis and their values, preferences, and fears. Options for enrollment on a clinical trial, radiation therapy, and palliative care are discussed with the family. The physician discusses the risks/benefits, anticipated side effects, and required testing with the family.
Enabling patient and family health-seeking behaviors	The healthcare team carefully assesses the family's past history with medical care and decision-making, the child's current medical condition with anticipated treatments, and other variables which may affect the child and family's ability to cope effectively. By acknowledging the role of the child, the family, and the healthcare team, better health-seeking behaviors can lead to improved coping skills throughout treatment and beyond into survivorship or a peaceful death, if that is the ultimate outcome.	The social worker performs a thorough psychosocial assessment of the child and family to identify strengths and areas for needed supports. These are communicated to the healthcare team so that a comprehensive plan of care can be developed to address physical, emotional, spiritual, and environmental needs.

cultural or spiritual/religious practices dictate a certain approach to decision-making.

Influences on Decision-Making

Decision-making is impacted by various factors, with communication being one of the most important. Parents who were not offered treatment options report more decisional conflict than those who were offered options. Parents who have choices between treatment options are more likely to feel sure about the decision, understand the information, be clear about the risks and benefits, and have sufficient support and advice to make a choice.[1] Providers should exert extra caution to provide accurate, honest, timely, and compassionate information regarding diagnosis, prognosis, and treatment options, including likelihood of disease control and anticipated side effects. Ample opportunities should be given for the child and family to ask questions and consider options whenever possible. Decisions that must be made in a short time frame or in moments of crisis may be more likely to lead to decisional regret. Providing opportunities for parents to process these decisions might be helpful. It is essential to help parents know that they and the team made the best decisions they could given the child's critical condition and available information.[1]

Yosida et al.[7] identified 23 barriers to end-of-life discussions with children with cancer and their families (Table 61.1). The age of the child and developmental capacity influence the legal obligation to be involved in decision-making.[8,9] Previous experience with healthcare may also impact children's TDM preferences. Children who have had medicalized lives, with frequent hospitalizations, medical tests, and treatments may prefer to be more or less involved in decision-making based on their own values, preferences, and experiences. Most children 8 years of age and older and many children 5–7 years are able to contribute to decision-making by reporting their symptoms and experiences during treatments and their views of QOL to inform decision-making.[23] Children may choose to be actively involved in decision-making or designate a trusted surrogate to make decisions in their best interests based on these experiences. Healthcare providers must consider the preferences of the child to be or not to be involved in decision-making, as informed by the ethical principle of autonomy.

Parents may be influenced by their own previous experiences in healthcare or those of other family members. Parents are more likely to opt for chemotherapy (42/77, 54.5%) compared with healthcare professionals (20/128, 15.6%; $p < 0.0001$).[26] Healthcare professionals present options related to the likelihood of disease control, usually in terms of percentages. Parents then interpret any possibility of disease control as positively influencing a choice of disease-directed therapies. Even in the context of a very small chance of disease control, if only for a limited amount of time, parents may view palliative chemotherapy as worthwhile. Research is needed to better understand how best to present treatment options to parents and children that result in decisions that are consistent with the family's values and preferences and that are not regretted.

Healthcare providers also come with their own values, preferences, experiences, and unconscious biases in relation to decision-making. Physicians are ethically responsible for providing accurate and timely information to the child, as developmentally appropriate, and to parents to aid in decision-making. Some clinicians report that prognostic information can take away hope or cause increased emotional distress for patients and/or families, resulting in conscious or unconscious biases regarding the effect of prognostic information on families from different racial, ethnic, and/or religious backgrounds.[27] Providers must be mindful that parent preferences about how and how much information to receive regarding diagnosis and prognosis is variable, not only between differing backgrounds, but between any given individual within any particular culture, race, ethnicity, or religion.[28] This is further complicated by the fact that accurate prognostication is difficult for even the very experienced clinician. Conversations can therefore be vague, leading to ambiguity for families in weighing treatment options. In some cases, parents may not be offered all treatment options due to the unconscious biases of clinicians. Clinicians may feel certain therapies have little chance of disease control, and, rather than specifically offering their opinion, they do not offer the option to the family at all.[1] At the other end of the ethical debate is whether physicians should offer options they do not feel have a reasonable chance of helping the child.

Pediatric End-of-Life Decisions

The types of end-of-life decisions that families face will vary depending on the underlying medical condition. For the preborn, parents may be faced with decisions about elective termination of pregnancy and/or preferences for birth plans that include end-of-life care when the underlying condition is not compatible with life for longer than hours to days. Parents whose child has a genetic, metabolic, neurologic, or other congenital condition which is likely to contribute to death in childhood or young adulthood may be faced with multiple decisions throughout the child's life regarding invasive supports, such as tracheostomy, ventilatory supports, and/or aggressive surgical interventions depending on the child's condition. Considerations of perceived QOL and the degree to which the child can give and receive joy in his or her life often factor heavily in decision-making in these cases.[29]

Decision-Making in Pediatric Oncology

Most children diagnosed with cancer have normal lives with relatively few medical issues until the time of diagnosis. Parents are faced with multiple decisions about their child's medical care as soon as symptoms manifest; for example, when and where to take their child for medical care. Parents are asked to give consent for diagnostic testing, such as bone marrow aspirate/biopsy, lumbar puncture, magnetic resonance imaging (MRI) scans, other radiology studies, surgical biopsy, and others depending on the suspected diagnosis. Once the diagnosis is made, parents are presented with complicated treatment options such as phase III randomized clinical trials, which in turn contain multiple treatment arms and other decision points. This all occurs at a time when parents are struggling to cope with and understand the diagnosis itself and the impact for the child and family. When there are no clear evidence-based treatment options for cancers with very poor prognoses phase II or phase I clinical trials may be the only options (Box 61.2).

Relapse or Refractory Cancer Decisions

At relapse or when initial treatments fail to achieve the desired results, the child and family are faced with increasingly difficult decisions. Parents must balance their understanding of the underlying condition; information regarding treatment options; cultural, spiritual/religious perspectives; and their innate sense of knowledge of their child with hoping for a cure and at the same time knowing that their child now has a terminal illness. Options are often limited to phase II or phase I clinical trials when available or tailored treatment plans deemed to be best options by the treating oncologist. Some view the recommendation of bone marrow transplant, which is considered as curative-intent treatment for relapsed or refractory cancers, as a "phase II" approach given cure rates between 25% and 50% depending on the type of cancer being treated.[30]

There is a continuum of knowing where the hope for cure transitions to planning for the end of their child's life. For some, this

Box 61.2 Clinical Trials in Pediatric Cancer Treatment

Clinical trials are the gold standard in pediatric cancer care. Most children newly diagnosed with cancer will be treated on a phase III trial where the best-known standard therapy is compared against promising alternative therapies. Efficacy against the specific type of cancer, as well as anticipated side effects, is generally well known. The clinical trial is evaluating two or more treatment options thought to have a reasonably good chance at long-term disease control. Phase II clinical trials test drugs that have been evaluated in phase I clinical trials to evaluate toxicity profiles, but now are being evaluated for efficacy in certain cancer populations. Phase I clinical trials evaluate new drugs to determine dosages and toxicity and to determine the maximum tolerated dose in a variety of types of cancers.[51]

fulcrum of decision-making moves from cure to comfort sooner, while other parents opt to continue disease-directed therapies until the child is actively dying. The healthcare team plays a pivotal role in providing anticipatory guidance so that this change is as gentle and seamless as possible, and the family feels supported in their decisions, thus minimizing crises. Physicians rank the child's QOL as the priority in guiding decisions, where families most often identify hope being of utmost importance.[26]

Parents and/or the child may view this transition as "giving up" or abandoning hope. It is therefore important to support the child and family to maintain hope, yet redirect that hope from cure to optimizing QOL for whatever time the child has left to live. Understanding that parents want to ensure that their child feels loved is important for the healthcare team to align goals of care and recommendations for treatment options. Options for care, including palliative chemotherapy, palliative care, and hospice care should be presented with an understanding of the unique attributes of each specific family. Respecting choices in light of what matters most may also lessen moral distress for healthcare providers as they move from curative intent recommendations to palliative recommendations for care.

Being a Good Parent to My Seriously Ill Child

Hinds and colleagues identified important reasons that influence parent EOL treatment decision-making. In interviews with more than 100 parents of children with incurable cancers across several studies, the majority of parents (approximately 80% within each study) identified their definition of being a good parent as influencing their EOL decision-making on behalf of their very ill child.[31,32] Key characteristics of their definition of being a good parent to a seriously ill child are listed in Box 61.3.[33] These characteristics did not differ by type of EOL decision made or by diagnosis.[35] Parents also identified clinician behaviors that helped them to achieve their definition of being a good parent before their child died.

This research has been replicated in the pediatric intensive care unit (PICU), documenting the most common factor in being a good parent to their seriously ill child including "focusing on their child's QOL, advocating for their child with the medical team, and putting their child's needs above their own."[35] Engaging parents in a discussion of what it uniquely means to them to be a good parent to their child may illuminate the things that matter most to the child and family.[36]

Box 61.3 Parent Themes from Their Definition of Being a Good Parent to Their Seriously Ill Child

Parent themes	Clinician strategies
Doing right by my child	All that can be done is being done
Being there for my child	Staff respect me and my decisions
Conveying love to my child	Staff continue to comfort my child and me
Being a good life example	Staff know our special needs
Being an advocate for my child	Staff like our child
Letting the Lord lead	Staff are pleasant
Not allowing suffering	Staff coordinate care
Making my child healthy	Staff ask about our faith
	Give us the facts
	Staff tell us we are good parents
	Do not quit on us

Decisions for Hospice and Location of Death

Trusted healthcare team members should begin discussions early about what may be expected if the cancer does not respond favorably to treatment so that the child and family have time to consider options and ease transition to hospice and palliative care.[5] Often a family identifies one or two healthcare team members whom they view as most important in their child's care and with whom they will be most comfortable having these treatment discussions. Members of the healthcare team should also frequently discuss the course of a child's cancer experience, including the family's responses, to help recognize when goals of care are shifting. EOL decision-making should include discussion of care issues outlined in Box 61.4.

Box 61.4 Key Considerations in End-of-Life Decision-Making Discussions

Pain and Symptom Management

- What symptoms are most concerning to the child and parents?
- Anticipated symptoms that may occur as disease progresses
- Strategies for pain and symptom management (pharmacologic and nonpharmacologic) with identified processes for problem-solving when a strategy does not produce relief of symptom distress
- Use of opioids in children, with careful assessment of child and parents' fears, worries, and concerns about use of these medications and likelihood of need to titrate dose for pain control in the face of developing tolerance
- Options for palliative sedation in cases of extreme, unrelieved symptom distress, including that the child will likely remain sedated through end-of-life
- Consultation with palliative care specialists, if not already involved, to assist in pain and symptom management

Child and Parent Perspectives

- Manifestations of anticipatory grief and loss
- Managing daily life with some degree of normality
- The importance of parental and family presence
- Experiencing joy in the midst of sadness as acceptable
- Maintaining and fostering communication
- Maintaining connection with the primary oncology team
- Receiving clear, consistent, and honest information about preparing for end-of-life
- Parents preference for early end-of-life discussions with anticipatory guidance provided
- Communicating prognosis

(*continued*)

Box 61.4 Continued

Patterns of Care

- Discussion of preferred location of death (i.e., hospital, oncology unit, ICU, home, inpatient hospice, other settings)
- Discussions of nonbeneficial life-sustaining supports including recommendations for initiation or no initiation of CPR, intubation, noninvasive ventilatory support (BiPAP/CPAP), use of vasoactive medications, use of medically administered fluids and hydration including total parental nutrition, use of antibiotics, diagnostic testing, and other supports that may be anticipated
- Availability and acceptance of home hospice supports
- Completion of state Medical Order for Life-Sustaining Treatments (MOLST), Physician Order for Life-Sustaining Treatment (POLST), Durable Do Not Resuscitate Order (DNR) or other appropriate out-of-hospital form indicating resuscitation status decisions[5]

Decision-making for parents at the end of their child's life relates to perceived or actual suffering. Suffering can take many forms, physical, psychosocial/emotional, spiritual, and environmental. Action and assurances to mitigate suffering impact the QOL of the child and family.[5,33] Agreement on goals of care is paramount to address divergent perceptions of suffering from the parent and healthcare provider perspectives.[5] The child and/or family make decisions based on understanding the information they have received, their wish to help others, trust in their healthcare providers, and individual preferences in care. Outcomes of decision-making about end-of-life care are influenced by parent's perception of being a good parent to their child, perception of QOL for their ill child, and presence and engagement of the healthcare team. Parents who experienced these in a positive way reported less depression and less complicated grief and bereavement.[1] In most cases, parents and healthcare providers prefer home as the location of death for children with cancer.[37] With careful attention to symptom management, child and parent preferences, adequate discussion of EOL care choices, and effective anticipatory guidance, most children with cancer can be well cared for at home. This does not mean that every family will choose home as the preferred location for their child's death. Kassam et al.[37] noted that 30% of parents do not want their child to die at home, but may prefer in-hospital care with specialty palliative care services. Advance care planning will assist with anticipatory guidance and appropriate planning for EOL care (Table 61.2).

Advance Care Planning

Advance care planning is a discussion of values and preferences in care to inform EOL decision-making. It should be distinguished from an *advance directive,* which is a legal document for patients 18 years of age and older that typically names a surrogate decision-maker if the patient is unable to make informed decisions themselves, with preferences for cardiopulmonary resuscitation (CPR) and life-sustaining supports.[13] Advance care planning should be a series of conversations regarding care preferences, often revisited over time as the clinical condition changes, and may or may not result in completion of a written advance directive.

AYAs have unique experiences, unlike those of children or adults. They are experiencing life transitions, such as moving into high school or college or beginning their first postsecondary education job at the same time that they are dealing with serious illness. In a large retrospective cohort study of 663 AYAs who had died from progressive or refractory cancers, it was found that two-thirds of these AYAs had intensive treatments, such as emergency room visits, chemotherapy, or admission to intensive care units within the last 14 days of life.[38] High rates of aggressive medical interventions may reflect poor communication with AYAs about their values and preferences.

Healthcare providers are often uncomfortable with facilitating advance care planning conversations, and parents struggle with initiating these conversations with AYAs. Lyon et al.[39,40] have consistently demonstrated that facilitated conversations by specially trained personnel do not cause undue harm and are desired by parents and AYAs. This facilitator can be the physician or another trusted member of the healthcare team, but trained facilitators who are not part of the AYA's care team may have less unconscious biases which could influence the discussion.[41] Parents and AYAs should be asked for their preferences regarding who is best to facilitate advance care planning discussions for them. Nurses may be in a unique position to provide anticipatory guidance throughout the process of advance care planning (Table 61.3).[13]

Table 61.3 Nurses' role in advance care planning

Clinical practice
◆ Advance care planning is essential to family-centered, person-centered care. ◆ Children and their families have the same rights as adults to honor their values and preferences in care. ◆ Nurses should advocate for the child's and family's voices to be heard, valued, respected, and included in care. ◆ Nurses should honor the child's and/or family's decision not to engage in advance care planning.
Education
◆ Nurses should be educated on the tenets and processes of advance care planning for children with serious illness and their families at any stage of illness. ◆ Nurses should be provided with opportunities for training in the skills to facilitate advance care planning discussions with children and their families. ◆ Nurses must respect and attend to preferences for advance care planning discussions related to culture, ethnicity, spirituality/religion, and other factors unique to each individual child and family.
Institutional policies
◆ Institutions must incorporate advance care planning as a key initiative in quality care for all children with serious illness. ◆ Policies and standards for implementing advance care planning as a standard of care should be developed for all adolescents and young adults 18 years of age and older, and should be thoughtfully considered for younger children with capacity, as well as for certain high-risk medical conditions or procedures with high risks of morbidity and/or mortality (i.e., bone marrow transplant, heart failure, etc.).

Source: From Reference 13.

Involvement of the Child or Adolescent in End-of-Life Decision-Making

Children as young as 7 years can articulate their preferences for treatment, as well as EOL care.[8,10,23] The child's voice is important to decision-making, however, not every child will want to participate in these discussions. The purpose of having this discussion with the child should be reviewed with the parent prior to having the conversation, unless the child is of legal age to make independent decisions.[43] If a child declines to participate in advance care planning discussions, then those wishes should be respected. It is usually very helpful to ask a child who he or she would like to make decisions for them. In most cases, this is a parent, but it may not always be.

There are a variety of tools to facilitate conversations with children. No one tool or one approach will be best for all children. Some examples of advance care planning tools for children are listed in Table 61.4. Capacity to have this conversation should be assessed at the time of the discussion and what exactly is to be discussed. For example, a child may have capacity to name a surrogate decision-maker, but may not have the mature insight to have discussions about choices for life-sustaining supports. Another factor to consider is who should facilitate the advance care planning discussion with a child. It may be the parent(s) or a trusted member of the healthcare team or a trained facilitator. Care should be taken to assess who has a trusted relationship and is best able to ascertain the child's values and preferences. In some situations, the child may prefer a teacher, child life specialist, social worker, chaplain, or another psychosocial team member. In other situations, this may be a physician, advanced practice nurse, or registered nurse. There is no prescriptive way to conduct advance care planning with a child. What works best for one child and family may not be the best for another. Regardless of when, who, and how the advance care planning conversation is implemented, the child's preferences, values, and choices should be respected and honored. Care must be taken to provide adequate time for discussion and reflection of choices and to avoid any possibilities of perceived coercion by a parent, members of the healthcare team, or others. Information obtained from advance care planning discussions should be appropriately documented and communicated to all medical teams caring for the

Box 61.5 Guidelines for the Healthcare Team to Use in Assisting Pediatric Patients with End-of-Life Decision-Making

1. Seek input of parents as to the timing and extent of information that should be offered to the patient about diagnosis, treatment options, and the likely response to treatment.
2. At the time of diagnosis and throughout treatment, actively seek opportunities to provide information to the child or adolescent that is appropriate to his or her developmental stage.
    a. For a child, ensure parental presence during such discussions.
    b. For an adolescent, ensure a discussion that includes the parents, but offer to discuss with the patient alone as well.
3. Be available to discuss and rediscuss decisions and related concerns in a manner appropriate to the developmental stage of the patient.
4. With parental agreement, encourage the patient to interact with other pediatric oncology patients.
5. Convey verbally and nonverbally the recognition that the patient is trying his or her best and that the healthcare team is committed to the patient's well-being before, during, and after decision-making regardless of decision made.
6. Provide assurances that everything that can be done to help the patient is being done and being done well.
7. As a patient's disease progresses, provide clear verbal (and written, if desired by the patient) explanations of the patient's status. Consider visual explanations, such as showing MRI scans, if developmentally appropriate.
8. With parental agreement, inform the patient of treatment options as they become available in the treating institution or elsewhere.
9. Assess patient suffering and the need to change interventions to relieve such suffering.
10. When end-of-life options should be discussed with the patient, consult parents about the appropriate depth and timing of such discussions.
11. After receiving input from the parents and exploring the patient's readiness for information, discuss the end-of-life options, with
    a. A strong emphasis on the team's commitment to the patient's comfort and to providing expert care at all times.
    b. Professional recommendations.

(*continued*)

Box 61.5 Continued

   c. Descriptions about how the patient is likely to respond to each option (physical appearance, ability to communicate, etc.).
   d. Information about other support resources such as chaplains and ethicists.
12. Include more than one healthcare team member in end-of-life discussions with the patient.
13. Ask the patient what he or she is hoping for now.
14. Allow the patient private time to consider the options with his or her parents.
15. Reassess the appropriateness of the chosen end-of-life options on an ongoing basis, remaining aware that patients will
    a. Vacillate between certainty and uncertainty about the decision.
    b. Need clarification and additional information to resolve uncertainties.
16. Convey respect for the patient's right to change decisions when such changes are clinically feasible.
17. When appropriate to the patient's comprehension level, explain to the patient the availability and value of an ethics and/or palliative care consult for the patient.
18. Maintain sensitivity to any specific ethnic, cultural, or religious preferences during the terminal stage.
19. Demonstrate continued commitment to providing symptom management, support of quality of life, and assurance of the parents' well-being.

child. Permission should be obtained to share this information, not only with the medical teams, but also with the child's parents and/or named surrogate decision-makers in a compassionate manner that respects and honors the child's voice (Box 61.5).

Involvement of the Parent in Decision-Making

Parents usually have the ethical and legal responsibility to make decisions in the best interest of their child. If a parent is unwilling or unable to make decisions regarding their seriously ill child, then careful assessment should be done to evaluate if adequate and appropriate information was provided in a language or format the parents can understand, if the parent understands this information, and if they desire more information or other opinions about options for care, and to discover if any other underlying factors exist that may be influencing decision-making.

In the same manner as for the child, there is not one prescriptive way to have a conversation with a parent regarding advance care planning for their seriously ill child. The same tools that are used for conversations with the ill child may be helpful in facilitating conversations with parents. Another helpful tool is Choices for My Child, which is a document from the United Kingdom originally developed for parents of children with neurological conditions where the child is unable to communicate his or her own treatment preferences.[43] This tool can be used as a way to consider where the child is now on the spectrum of a wide variety of domains of physical, emotional, spiritual, and psychological function and then compare this status over time at multiple time points to establish a trend of decline, stability, or improvement. Often reflecting back over time allows parents to have a "picture" of the trajectory of their child's illness. This may also be accomplished by asking the parents to describe what the child was doing in those domains of function at different time points (i.e., 1 week ago, 1 month ago, 3 months ago, 6 months ago, 1 year ago, etc.). Facilitating a conversation about the noted changes over time can lead the parents to better understanding (Box 61.6).

Box 61.6 Guidelines for the Healthcare Team to Use in Assisting Parents with End-of-Life Decision-Making

1. At the time of diagnosis and throughout treatment, actively seek opportunities to provide information to the parent about treatment and the patient's response to treatment.
2. At the time of diagnosis and throughout treatment, involve the parent in treatment-related discussions and decision-making. Be available to discuss and rediscuss decisions and related concerns.
3. Ask parents if they would like to talk with parents of other pediatric oncology patients.
4. Verbally and nonverbally reassure the parents that they are "good" parents who are committed to the well-being of their child and that they have made good decisions for the child all throughout the child's treatment course.
5. Provide assurances that everything that can be done to help the patient is being done and being done well.
6. As the child's disease progresses, provide clear verbal (and written, if desired by the parent) explanations of the child's status. Provide visual sources of evidence such as actual scans, with appropriate interpretations.
7. Inform parents of treatment options as they become available in the treating institution or elsewhere.
8. At each treatment juncture, ask the parents what they are hoping for and anticipate that they will have more than one hope.
9. Include more than one healthcare team member in end-of-life discussions with the parents.

(*continued*)

Box 61.6 Continued

10. When discussing end-of-life options with parents,
    a. Strongly emphasize the team's commitment to the patient's comfort and to providing expert care at all times.
    b. Offer professional recommendations.
    c. Describe how their child is likely to respond to each option (the child's physical appearance, ability to communicate, etc.).
    d. Give information about other support resources (ethics committees, social services, other healthcare professionals, etc.).
11. When discussing end-of-life options with parents, anticipate
    a. Parents' vacillation between certainty and uncertainty about the decision.
    b. Parents' need for clarification and additional information to resolve their uncertainties.
    c. Parents' need for practical information about ways to explain the end-of-life decision to other family members.
    d. Being asked to give personal advice (i.e., what you would do if this was your child).
12. Allow parents private time to consider the options.
13. Maintain sensitivity to any specific ethnic, cultural, or religious preferences during end-of-life care.
14. Convey respect for the parents' right to change decisions when clinically feasible.
15. Consider seeking an ethics consultation for the family and/or the healthcare team as a whole.
16. Consider seeking consultation from palliative care experts.
17. Demonstrate commitment to maintaining the child's comfort and dignity and to affirming the parents' role.
18. Do not question the parents' decision after it has been made.
19. Carefully document the end-of-life treatment or care decision once it is made so that all clinicians can be fully informed of this decision.

The Role of the Nurse in Decision-Making

Nurses are in a unique position to provide education and anticipatory guidance for the decisions that children and their families face throughout the trajectory of the cancer diagnosis and other serious illnesses. Nurses develop trusting relationships with children and families at the bedside, which creates an environment that empowers parents to make informed decisions and helps the child and family to transcend the experience of end of life with a peaceful death.[44] Accurate family education about side effects and interventions is essential to clarifying realistic expectations.

Nurses provide support for children and families at all stages of the cancer experience, from diagnosis through survivorship, end of life, and into bereavement. Providing empathetic listening, presence, and supportive care enhance the trusted relationship. Allowing children and families time to express their feelings and providing empathy for the family's point of view will aid the family in processing the information about the child's condition and in making immediate, as well as future, decisions. Nurses also provide realistic information about prognosis based on the clinical evidence, as well as their experience, to gently inform the family that a child is unlikely to survive. Hearing this information from a trusted member of the healthcare team may support the family's decision to forgo more aggressive medical and life-sustaining interventions. The expertise of nurses in facilitating and advocating for EOL decision-making conversations is helpful to elicit the child's and parents' voices in goals of care. The impact of nursing involvement in EOL conversations with patients and families may help families realize the patient is dying and make informed decisions regarding treatment options.

Support of Professional Nursing Organizations of the Nurse's Role in Decision-Making

The American Nurses Association (ANA) Code of Ethics[45] supports the nurse in advocating for the rights, health, and safety of all patients and families. Guidelines to support members of the healthcare team may be helpful to frame discussions with families and between the healthcare team (Box 61.6). The ANA has published position statements to guide nurses in participating in EOL decision-making, including "Nursing Care and Do Not Resuscitate (DNR) and Allow Natural Death (AND) Decisions"[46] and "Nurses' Roles and Responsibilities in Providing Care and Support at the End of Life."[47] These statements are not specific to pediatrics, however they do endorse developing an adequate skill set to facilitate discussions and encourage patients and families to actively participate in decision-making. The HPNA[13] advocates for a dynamic process in a series of conversations with families over time, beginning before anticipated health crises. The ANA and HPNA Palliative and Hospice Nurses Professional Issues Panel endorses the role of the nurse in facilitating informed decision-making for all patients with serious illness, including pediatric patients.[48] Advocating, supporting, and facilitating decision-making for children with cancer and their families is not only a professional obligation supported by key nursing organizations, but it is ethically our responsibility in providing high-quality child and family-centered care (Box 61.7).

Box 61.7 Guidelines for the Healthcare Team to use in Assisting Each Other with End-of-Life Decision-Making

1. Know the guidelines offered by specific disciplines regarding roles in end-of-life decision-making (i.e., the ANA's official statements on what the nurse is expected to do to help parents and patients make decisions) because it is possible that the guidelines differ from expectations held by others outside the discipline.
2. Before initiating end-of-life discussions with patients[a] and parents, all members of the healthcare team should discuss and agree on
    a. The need for such a discussion.
    b. Which options are appropriate and available.
    c. Whether outside consultants, such as an ethics committee, palliative care specialists or an external oncology expert, are needed to identify which options are in the best interest of the patient.
    d. Which other team members will participate in the discussion with the parents and patient.
    e. The time of the discussion and specific staff members who will participate.
    f. Which staff member will document the discussions in the medical record.
    g. Availability of the appropriate staff time and resources to address any questions parents and patients may have. Communicate to the team members who were not present at the patient-and-parent discussion what specific language was used to provide support to the parents and patient in making this decision.
3. Be available to team members and to the patient and parents to discuss and rediscuss decisions and related concerns.
4. Explore with the team all appropriate options to ensure that all that can be done is being done and being done well.
5. Consider consulting an ethics and/or palliative care expert on behalf of the entire team.
6. Inform other team members if feedback from or assessment of the patient, parents, or both indicates that any decision needs clarification or reconsideration.
7. Directly approach other team members regarding aspects of decision-making rather than seek such information from the parents.
8. Make certain that decision-making is fully documented in the healthcare record and accessible for all members of the team.

[a] When considering whether the patient should be present during such discussions, evaluate the developmental stage of the patient and the severity of illness and symptoms at the time of the discussion.

Conclusion

Decision-making in pediatric oncology is complex and dynamic, from the time of diagnosis throughout the trajectory of disease into survivorship or death and bereavement. Children and parents should be actively engaged in conversations that elicit their unique values and preferences. Healthcare providers must provide accurate and timely information to inform decision-making in a developmentally appropriate manner. This information should be reviewed frequently, framed in terms of the child's stable or changing clinical condition, and respect the opinions of parents as experts on their child. The child and family should be provided with opportunities for advance care planning, beginning before health crises. Nurses are key to advocating, initiating, and facilitating discussions with family that educate, inform, and elicit goals of care that honor the values and preferences of the child and family.

CHAPTER 62

Palliative Care in the Perinatal Setting

Neonatal Intensive Care Unit, Labor and Delivery Unit

Cheryl Ann Thaxton, Diana Jacobson, Heather Murphy, and Tracey Whitley

Key Points

- Palliative care in labor and delivery (L&D) and the neonatal intensive care unit (NICU) is an integral component of family-centered care and patient-focused care. Palliative care gives nurses the opportunity to provide support for the infant and family unit at a time of tremendous stress. Care for an infant, either prenatally or postnatally, with a life-limiting or life-threatening condition is one of the most intimate times that a nurse can share with a family.
- Palliative care incorporates comfort care and pain and symptom management for the infant, as well as emotional, psychosocial, and spiritual support for the infant and family members. Family is defined by the parents or caregivers and may include other children, grandparents, and extended family members. Palliative care measures should be initiated early in the hospitalization and must be provided with cultural sensitivity and while supporting the developmental aspects of neonatal care. Palliative care is provided when a condition is life-threatening; this condition may or may not result in death. Palliative care can be provided along with curative treatments.
- Palliative care involves a dynamic exchange of information among an interdisciplinary team and the family and promotes the implementation of care that is aimed toward treatment of pain and distressing symptoms that interfere with the infant's and family's quality of life. The nurse has a compelling role in both prenatal and neonatal palliative and end-of-life care.
- In 2015, the infant mortality rate in the United States was 5.9 deaths per 1,000 live births and more than 23,000 infants died; the five leading causes of infant death were birth defects, preterm birth, sudden infant death syndrome, maternal pregnancy complications, and injuries.[1]
- Palliative care interventions and end-of-life care should be a part of the nurse's sphere of practice and requires that the nurse develop competencies in providing supportive and compassionate nursing care measures which can provide relief from emotional and physical suffering and bring about a peaceful death experience for the patient and family.[2]

Introduction

Substantial effort has been made to adequately address the need for perinatal and neonatal palliative care for patients and families. According to the American Academy of Pediatrics (AAP), pediatric palliative care (PPC) includes "relieving suffering, improving quality of life (QOL), facilitating informed decision-making, and assisting in the care-coordination between sites of care."[3] Due to technological advances in the past 30 years in diagnosing fetal anomalies and genetic disorders during the prenatal period, parents may face months of anguish and uncertainty as they prepare for the birth of an infant with a life-limiting, life-threatening, or lethal condition.[4,5] The sudden delivery of a prematurely born infant also may pose existential reflections within the family unit.

The anticipated delivery of a healthy term baby with a planned, predictable, and healthy future suddenly can become uncertain and overwhelming when the fetus is diagnosed with a life-limiting condition or the infant is delivered early or outside the viable gestational limits of medical and nursing knowledge and care.[6] Grandparents and extended family members often feel helpless and search for the "right things to say" to support the mother and father. Siblings often experience a deep sense of confusion during a time that was supposed to be filled with happy anticipation.[7] As the time draws near for the birth of the baby, each family member will individually transition through thoughts that pose more questions than answers, as they come to understand the long-term consequences of the infant's underlying condition, poor prognosis, and/or poor QOL.[8] The nurse is in the key position to provide support to bring the needed aspects of care together during this challenging time.

Early empathetic communication with parents to give detailed information prior to the birth of extremely premature infants or neonates with life-limiting conditions or uncertain prognoses is difficult but necessary in order to provide supportive care for the infant and family.[9] After delivery, the baby may receive care in the neonatal intensive care unit (NICU) or remain in the labor and delivery (L&D) unit in order for the mother and baby to receive care if the infant's death is more imminent, was a fetal demise, or died during delivery. Most neonatal deaths occur after the family and interdisciplinary team (IDT) decide to withhold or withdraw life-sustaining treatment.[10] Structured, evidence-based bereavement programs in NICUs have demonstrated efficacy and parental acceptance in many intervention studies. A longitudinal, prospective study incorporated parent interviews to explore the bereavement process of parents with critically ill infants; the findings support measures such as early intervention in preparation for the possible death of an infant and establishment of resources to prospectively support parent bereavement, including memory-making.[11] Nurses should recognize the sensitive nature of this subject and use language to promote a culturally sensitive, patient- and family-centered approach to the care of the infant during this difficult time for the family.

Parents are often faced with challenging decisions and even some uncertainties regarding the impact of shifting their focus from curative therapies to palliative care measures.[12] Providing a seamless transition into palliative care measures requires an interdisciplinary effort and support of the entire healthcare team. The focus of the team should be to provide optimal conditions for the infant's life and death, including interventions to prevent and relieve suffering.[12] Implementing a palliative care protocol involves tremendous individual planning that supports a variety of choices, which may include various aspects of active life-sustaining measures, up until the end of the infant's life. The nurse has a vital role in ensuring that communication with the family is not fragmented and that parents are reassured that the best effort will be made to support their wishes throughout the uncertainty of the journey. Dignity of the infant and family should be maintained at all costs.

Patient- and family-centered care measures seek to ensure that the final hours of a dying infant are spent in a peaceful environment and in the presence of the family. This chapter presents the core values of perinatal and neonatal palliative care nursing within the context of providing culturally appropriate, compassionate, individualized, family-centered developmental care (IFCDC) and patient-focused care for infants receiving care in the L&D as well as in the NICU environment. To illustrate use of palliative care with the neonatal population, the following case study was supplied by a parent.

Case Study: Just Breathe: Graham's Story

by Christy McGurgan

"Our son Graham was born by emergency C-section at 24 weeks, weighing 1 pound 2 ounces. When I entered Graham's room for the first time, I couldn't find him among the tubes and tangle of wires in the incubator. I couldn't believe how fragile he looked. His body was so thin, I could have wrapped my thumb and middle finger around it. His chest pulsed up and down with each heartbeat. I tried to catch my breath, I had to remind myself just to breathe.

"The next day, Graham had a pulmonary hemorrhage, and was placed on the high-frequency jet ventilator. He looked like he was having a constant seizure, his entire body was shaking. It was hurtful to look at my baby that way, I found myself holding my breath again as I watched. His nurse suggested that I take some of my pumped milk and put it on Graham's tongue, and with that simple suggestion, she empowered me to take care of my baby. After 2 days of helplessness and crying, this was the first thing that I could do to help him, and I was extremely grateful.

"When Graham was about a week old, he developed an unidentified black spot on his back. Before it could be diagnosed, it spiraled out of control, and, in just a couple of days, it had spread through his skin, muscle, tissue, and bone. After several days, it was diagnosed as an extremely rare and invasive fungal infection. It was so rare that only 70 cases had been seen in 50 years. We couldn't amputate because the infection was in Graham's back. At that point, the neonatologist took us into a quiet room. He was very patient, slow, and respectful. He told us, "We don't know how much time you have left: maybe a couple hours, maybe a couple days." He paused, then added quietly, "I recommend you spend as much time with him as you can." No words could come out of my mouth. We had no idea what to do. Fortunately, the doctor's quiet demeanor, his patience in allowing us to take in the information, and his recommendation gave us a place to feel safe and gently guided us to our next step. From that point on, we didn't focus on anything except being with Graham. Our goals were bonding with Graham, giving him love, and making him part of our family. Despite what the doctors told us, when his wound was covered, he looked like a "regular" micro-preemie. We vowed that we would follow Graham's lead. If he showed us that he was ready to die, we would let him go. If he showed us he wanted to live, we would support his fight for life.

"Medical staff orchestrated a plan for me to hold Graham while he was on the high-frequency jet ventilator, despite NICU policy. The reason was clear: they didn't want Graham to die without me ever having a chance to hold him. Knowing this broke my heart, but I was intensely grateful for the opportunity to hold my precious baby for the first time at almost a month old. While the policy had been no holding babies on the high-frequency jet ventilator, the benefit that it brought to Graham and to me was huge, and I was extremely grateful to staff for overlooking the policy for the benefit of our family.

"Once we started medically treating Graham's infection, its progress halted significantly. Once I began holding Graham, he began to improve, and the neonatologist made a standing order that we could hold him as much as we wanted. We held him constantly, when we weren't in rounds or providing hands on care, and the hours that we were told Graham had left to live turned into days, then to weeks, then to months. The nursery let my husband and me take care of Graham in any way that we could, and helped his sisters participate in his care by allowing them to change Graham's clothes, hold his pacifier in his mouth, and even help with his physical therapy.

"Graham's nurses showed caring in many other ways: after I went home at night, they played a recording of me reading to him, sometimes put a blanket over me while I slept in a chair by his incubator after late nights at the hospital, and even sent Graham postcards in the NICU when they went on vacation. Despite the prognosis that he would die at 2 weeks, Graham spent 7 months in the NICU. He eventually overcame the infection. However, complications from the infection caused Graham to develop pulmonary hypertension (PPHN) and prevented his lungs from growing large enough to oxygenate his body as he grew.

"The night Graham's vitals started going downhill, we knew it was the beginning of the end. His nurse called our primary nurses, nurse practitioners, and parent support staff. They were our family, Graham's family. They had been with us all day every day for the last 7 months. They had taken care of him, laughed with us, cried with us. When we knew it was time to let him go, they left us alone with Graham, to say goodbye in private. My husband and I held Graham together, crying and comforting him, as he peacefully drifted off to join the NICU angels. Our NICU family helped us with hand and footprints, cut a lock of hair, helped us bathe him, and neatly packed away his treasures. They allowed us to move at our pace, to care for our baby in death as we had in life, to spend all the time with him we needed.

"That night, my husband and I said the hardest goodbye that we'll ever have to say, but what we gained from that time with Graham is so much more than we lost, and we couldn't say that without the support of Graham's medical team. With their support, we did every single thing we could to save our baby, we loved him intensely, we bonded with him, and we understood Graham enough to know when it was time to let him go. Every bit of support that we got changed all of our lives for the better forever, and my gratitude for that will never be enough to say thank you for what they did for Graham and for our family."

Summary of Graham's Case

The nurse must be present at the most difficult time for the family, to be fully attentive to the infant and family and to separate personal values regarding birth, life, and death from those of the family. Nurses must adapt and individualize the care so that there is as much support for positive development as possible for the infant and family. It is only after the parental role is solidified that parents can become caregivers to a child that may or will die. The main obstacles to good palliative care are the inability to appropriately communicate with grieving parents and a lack of knowledge about evidence-based pain management.

Standard of Care for Neonatal Patients

The care of the neonatal palliative care patient is not setting-specific. Care can be provided within the L&D unit, NICU, a newborn special care unit, or through a perinatal home hospice program.[4] Integration of perinatal and neonatal palliative care services in tertiary care centers is increasing in the United States and other developed countries. Importantly, early identification and referral of patients to palliative care teams are encouraged to provide comprehensive care.[8] For example, extremely premature infants with multiple comorbidities are potential candidates for early and consistent perinatal or neonatal palliative care. The nurse is instrumental in providing goal-directed support through care that integrates potential curative therapies with palliative measures. All patients may benefit from the palliative care goals of reducing suffering, minimizing symptoms, and improving QOL.[8]

Nurses work with the IDT to ensure that the patient and family have all needs addressed. To deliver care that is interdisciplinary, as well as patient- and family-centered, nurses work collaboratively with neonatologists, nurse practitioners, social workers, chaplains, child life specialists, geneticists, respiratory therapists, pharmacists, and many subspecialists.[8] The nurse often leads communication with the family and should participate in palliative care discussions as part of the palliative care team because the nurse spends the most time with the infant and family. A study reported the strengths and weaknesses perceived by parents in their communication with physicians and nurses in the NICU. The findings noted that communication with nurses was described as a source of emotional support more often than communication with physicians and that nurses, because of the nature of their job, are more often physically present at the bedside and thus more available for emotional contact with families.[13]

Parents and caregivers often voice concerns to the bedside nurse as they process difficult information about the infant's medical status. The neonatal nurse, with the support of the IDT, should be prepared to provide palliative care within the context of the infant's uncertain life trajectory. There are six key roles for nurses in providing palliative care. These are pain and symptom management, prenatal palliative care consultations, end-of life care, discharge to hospice, communication and conflict resolution, and collaboration in the care of the medically complex infant.[9] The nurse should work in collaboration with the IDT to support the needs of the family and utilize knowledge of standard ethical principles to provide a patient-focused and family-centered care (Box 62.1, Table 62.1).

Cultural Influences on Care

For culturally competent care to reflect the complexity of care that is much broader than ethnicity, the nurse must be sensitive to cultural, ethnic, and religious values. Importantly, parents must be asked whether they have personal cultural or religious preferences for the goals of care for their child. The terms "healing" and "suffering" have various meanings within the cultural belief system of each individual family. The nurse should not assume that because the family is of a particular race, ethnicity, or religious sect that their reactions or requests are reflective of all individuals of that race, ethnicity, or religious sect.[4] For example, bereavement

Box 62.1 Core Concepts of Patient- and Family-Centered Care

- *Dignity and respect.* Healthcare practitioners listen to and honor patient and family perspectives and choices. Patient and family knowledge, values, beliefs, and cultural backgrounds are incorporated into the planning and delivery of care.
- *Information sharing.* Healthcare practitioners communicate and share complete and unbiased information with patients and families in ways that are affirming and useful. Patients and families receive timely, complete, and accurate information in order to effectively participate in care and decision-making.
- *Participation.* Patients and families are encouraged and supported in participating in care and decision-making at the level they choose.
- *Collaboration.* Patients, families, healthcare practitioners, and leaders collaborate in policy and program development, implementation, and evaluation; in healthcare facility design; and in professional education, as well as in the delivery of care.

Table 62.1 Palliative care medications for neonatal patients

Medications	Usual dose	Special considerations
For pain		
Morphine	0.02–01 mg/kg IV q2–4h PRN	Opioid. Medication of choice for pain management in palliative and end-of-life care
	0.2–0.4 mg/kg PO/SL q2–4h PRN	May use in combination with benzodiazepine
	Infusion: 0.02–0.1 mg/kg/hr	More frequent doses may be needed to assure patient's comfort.
Fentanyl	1–3 mcg/kg IV or Intranasal q1–2h PRN	Fast onset and short-acting opioid
	Infusion: 1–3 mcg/kg/hr	Use injection form to administer intranasally. Bioavailability is almost 90%.
		Preferred in patients with renal failure
Methadone	0.05–0.2 mg/kg IV or PO q4–24h	Long-acting opioid
		Usual starting frequency is every 8–12 hours scheduled.
		Peak onset is delayed and may require breakthrough pain medication for 48 hours after initiation or dose escalation.
Acetaminophen	10–15 mg/kg PO/IV q4–6h PRN	Analgesic. Antipyretic
	20 mg/kg PR q6h PRN	May give IV form undiluted over 15 minutes
	7.5–10 mg/kg IV q6h PRN	
Oral sucrose 24%	<1 kg: 0.1 mL PO PRN	Analgesic. May administer directly into mouth or apply on pacifier
	1–2 kg: 0.5 mL PO PRN	
	>2 kg: 1–2 mL PO PRN	
For pain/sedation		
Clonidine	1–3 mcg/kg PO q6–8h	Alpha agonist. Has mild analgesic and sedating properties. May cause hypotension and bradycardia. Avoid use of patch in neonates.
For sedation		
Midazolam	0.05–0.1 mg/kg IV q1h PRN	Very short-acting benzodiazepine
	0.2 mg/kg PO/SL or Intranasal q1h PRN	Anticonvulsant, sedating, produces amnesia. Rapidly penetrates the CNS.
	Infusion: 1–2 mcg/kg/min	During end-of-life care, more frequent doses may be needed to ensure patient's comfort.
Lorazepam	0.05–0.1 mg/kg IV/PO/SL q2–4h PRN	Benzodiazepine
		Reduces anxiety and agitation. Anticonvulsant
		Consider adding to opioids for sedation
Diazepam	0.05–0.25 mg/kg PO or PR q4–12h	Long-acting benzodiazepine. Peak onset is delayed and may require breakthrough with shorter-acting benzodiazepine for 24–48 hours after initiation or dose escalation.
		Reduces anxiety and agitation. Anticonvulsant.
		Consider adding to opioids for sedation.
For secretions		
Glycopyrrolate	2–10 mcg/kg IV/SC q6h 20–100 mcg/kg PO q6h	Decreases oral secretions through anticholinergic activity. Increase slowly to effective dose. Consider reducing dose if signs of tachycardia noted.
For constipation		
Glycerin suppository	1/8–1/4 suppository PR q12–24h PRN	Osmotic laxative. Consider using with opioids to reduce constipation.

Source: References 36–45.

interventions such as mementos (i.e., hand and footprints; lock of hair) or photographs of the deceased infant may not be acceptable in all cultures.

In an example of a nurse working with a Native American family, the nurse must consider how to combine healing ceremonies from tribal rituals, if that is what the family desires, with Western medicine to alleviate suffering. In this instance, ethnic and religious beliefs are intertwined. But, in other instances, religious and ethnic values must be differentiated and incorporated into individualized care. It must be remembered that not every family that identifies with an organized religion strictly adheres to all principles of that faith. The entire healthcare interdisciplinary palliative care team must guard against prescriptive, generalized, and oversimplified views of different cultures' and ethnicities' beliefs and practices concerning illness, suffering, and death.[14] Thus, individualized nursing care must include considerations of cultural assimilation, healthcare literacy and language barriers, educational attainment, health insurance status, and socioeconomic factors. Evidence demonstrates that, due to misunderstandings, lack of communication, and healthcare provider bias, racial and ethnic minorities (Asians, African Americans, Latinos) may have a delay in the initiation of palliative care services and pain alleviation as compared to white patients.[15] This delay or underutilization of palliative care measures may increase the infant's and family's pain and emotional suffering. The nurse needs to examine his or her own beliefs and biases because these personal constructs will influence the delivery of culturally sensitive palliative care.[14]

Neonatal Palliative Care Guidelines

The National Association of Neonatal Nurses (NANN) in 2016 published a position statement no. 3015 entitled "NICU Nurse Involvement in Ethical Decisions, Treatment of Critically Ill Newborns."[16] This position statement reiterates the importance of the contribution of the neonatal nurse on the palliative care team. In addition, the American Academy of Pediatrics published its recommendations in a guideline for care of infants, children, and adolescents in need of PPC and hospice care.[17] The guideline emphasizes the goals of PPC and the importance of collaboration among the IDT. Standards of care for patients in the NICU must be followed, and protocols for the implementation of palliative care should be guided by evidence-based practices.

Advocacy for Support Services

Nurses can serve as an advocate to ensure that comprehensive support is being offered to the family. The benefit of providing these services is crucial for the family unit to maintain a sense of "wholeness" as they journey through this challenging time. In order to best support parents in their role of decision-making, eliciting their values and goals is imperative; asking questions that explore a family's values, their understanding of the newborn's meaning and QOL, and their experience in the medical journey help build a relationship based on trust and caring. These measures support the need for adequate services during the neonatal end-of-life (EOL) care period.[16]

The nurse should not underestimate the impact that palliative and EOL care discussions can have on each member of the healthcare team. The nurse can feel torn between spending quality time with a dying child and family and caring for other patients. The emotional strain associated with end-of-life and bereavement care not only affects a nurse's health but can also affect relationships at home and with coworkers.[18] In the past decade, more attention has been paid to the role of the nurse and the sense of moral distress that can exist when a nurse is providing care for infants as they continue to decline clinically. The most commonly reported cause of distress for nurses is reported as having to follow orders to support patients at the end of their lives with advanced technology when palliative or comfort care would be more humane.[19] Parents may sense the moral distress when the nurse is not receiving adequate peer support during the delivery of intensive care measures. Initial distress involves feelings of frustration, anger, and anxiety when a person is faced with institutional obstacles and conflict with others about their own personal culture and values.[20] It is vital that nurses have a forum where they can process their concerns within a confidential and professionally supported environment.

The implementation of debriefing sessions or clinical case reviews for difficult neonatal cases can be helpful.[21] Team support can also come in the form of relief or "emotional rest" periods for the neonatal nurse; for example, a nurse who has experienced a recent neonatal EOL care case may benefit from having patients with more stable clinical trajectories for the next few patient care assignments. Education and support in nursing practice could be enhanced by supporting nurses to attend workshops and seminars on the topic of perinatal loss and bereavement care; incorporating discussions on supporting families, patients, colleagues, and oneself in bereavement care during orientation to the unit and ongoing education; debriefing after perinatal loss; and providing staff with a bereavement mentor.[21]

Perinatal Loss and Palliative Care in the L&D Unit

Perinatal palliative care includes the needs of parents who are faced with a life-limiting fetal condition that may present as death in utero or quickly following birth.[22] Perinatal loss encompasses loss during pregnancy through the neonatal period. Intrauterine fetal demise (IUFD) is commonly called a *stillbirth,* although birth of an infant at 20 weeks or greater gestation is considered a neonatal death in the L&D setting. "Perinatal death, although not always fitting the traditional palliative care referral criteria, results in grief and bereavement unique in human relationships. Regardless of the circumstances that surround the loss, parents are often devastated and heartbroken."[23] In the United States, according to 2013 vital statistics, fetal mortality at gestations of 20 weeks or greater occurs at a rate of 5.96 per 1,000 births.[23] *Perinatal mortality*, defined as fetal death at 20 weeks of gestation or greater *and* neonatal death at 28 days or less after birth, occurs at a rate of 9.98 per 1,000 births.[24] Given the incidence of perinatal mortality in the United States, it is imperative to have an understanding of palliative and perinatal bereavement care.

When first learning of a life-limiting condition or fetal death, parents are faced with multiple decisions to make in a relatively short amount of time. Patients experience overwhelming stress, shock, and grief as they must make decisions with many implications.[24] Decisions should be made with full knowledge and understanding of the situation as well as of options that may exist. When parents are given the poor prenatal diagnosis, the option of a perinatal palliative care program should be offered.[25] For families with a perinatal life-limiting condition or for those going through unexpected loss, the L&D unit becomes a palliative care unit. The goals of care in these circumstances are to help families face the diagnosis, listen to and discuss options as the family is ready, and facilitate communication with providers and other ancillary team members, as well as being present while the family experiences a situation like no other.[25] The parent may learn of the life-limiting condition at a prenatal visit and have months to plan and anticipate the birth of the baby. In the months leading up to birth, time can be spent deciding on wishes for the pregnancy and birth. Birth plans can be developed outlining specific wishes related to L&D

care (both antepartum and postpartum) and palliative care photography.[25] Parents often make statements such as, “just let my baby be born alive,” with a desire to spend every second possible with the newborn regardless of how short life may be. Others have unexpected complications and have minutes to hours to work through decisions that can impact the life trajectory of the newborn. For those with unexpected complications, the same decisions must be made quickly and are often made while in a state of disbelief.

Perinatal palliative care involves caring for the mother, her unborn child, and the family during the antepartum, intrapartum, and postpartum periods and actively participating in bereavement care planning prior to and after birth.[25] Flexibility is needed when working with families experiencing perinatal loss because parental decisions can change. Nurses are on the front-line and are with the parents at time of diagnosis and delivery, as well as providing bereavement care. Focusing on the L&D setting, an overview of perinatal palliative care and bereavement support will be discussed as we follow a family that experienced an IUFD.

Case Study: Perinatal Palliative Care

Crystal and EJ were expecting their third child. Crystal (an L&D nurse) was 36 5/7 weeks pregnant, and she named the baby Norah Raine. After working her 12-hour night-shift, Crystal did not feel Norah moving like “normal.” She went to L&D triage for evaluation prior to going home. Per routine, the L&D nurse in triage placed Crystal on the fetal heart monitor. No heartbeat was detected. The physician was notified and came to Crystal’s bedside, where an ultrasound showed that Norah no longer had a heartbeat.

Crystal Shares Her Inner Experience

“There is a feeling as mothers that we want to protect our children from harm. I felt profound powerlessness, guilt, and defeat. I had never had an epidural with my previous deliveries but decided to get one because I wanted to somehow distance myself from the birth. I felt so strong and connected to the process of delivering my boys. This time, I felt weak and powerless. I hoped the doctors were wrong. I hoped the moment I held her in my arms a miracle would happen, and she would begin to cry. Norah Raine was delivered at 1:15 P.M. in a room full of silence after two easy pushes. I will never forget the doctor who delivered her, holding her lifeless body and looking at me to say, ‘I am so sorry,’ before he laid my daughter on my chest. Those first moments seem a blur, busy with activity to complete the delivery. My placenta was delivered, the bed was reassembled, all the while I held and took in every corner of her face. We laid her on the bed and admired every tiny detail, as I wanted to never forget how perfect she was. There were minor imperfections of peeling skin which I knew was to be expected, but in my eyes, all I saw was my beautiful, perfect first-born daughter. My nurse was instrumental in leading us through next steps. We gave Norah a bath, brushed her soft brown hair, and dressed her in the nightgown and blanket we had planned to bring her home in. It felt good to care for her in a way that felt normal. We created footprints, handprints, and took a lock of hair for her memory box. A photographer was called from a local organization and arrived to take precious photos of Norah and us together. Later we invited our other children and parents to meet and hold their sister and granddaughter for the first and last time. We chose to keep Norah with us through the night. We were placed on the gynecology unit. Once we released Norah to the funeral home, I was discharged home, with empty arms. The days and weeks after the loss of Norah seemed to drag on endlessly. My doctors called me to check on us, my friends from the unit called and visited, and many sent cards and flowers to our home. The outpouring of love from family and friends kept us from drowning in those early days. Local support groups and friends who were willing to listen were all instrumental in helping me to walk through the journey after the loss.”

Summary of Crystal and EJ’s Experience

Supporting parents as they find out their baby has died or will die immediately after birth can become a humbling experience for the nurse. The nurse may have a sense of powerlessness while seeking to become empowered to help support the patient and family. It is the nurse’s role to help the mother through labor and to remain present when the parents face the challenge of saying goodbye to the newborn. Many parents hope that the diagnosis is wrong and that their baby will live. For those patients with previous knowledge of life-limiting conditions, a L&D plan is created with a multidisciplinary team.[25] Questions are centered on the labor process, what to expect, and fear of the unknown.[26] For those in preterm labor or diagnosed with an IUFD, decisions are often made quickly. Preterm labor may lead to several stressors; for example, the patient may be transferred to a large tertiary care center that is located many miles from home and away from their usual care provider as well as from family and friends. The patient hopes that her labor will not happen prematurely; however, that hope often turns to sadness as delivery becomes inevitable.

A vaginal delivery is preferred since a cesarean section is major abdominal surgery with its attendant increased risk, including for patients who have had a previous cesarean delivery.[26] The focus of fetal monitoring changes to observing contractions. If the fetal heart rate is monitored and there are signs of fetal distress, there can be preparation for cesarean section. In the case of an IUFD or a baby with a life-limiting condition, induction of labor can occur with cervical dilation and delivery. Induction options may include cervical ripening with medication, a mechanical option such as a cervical balloon, or induction without cervical ripening. Time in labor can vary greatly and may be prolonged up to several days depending on the dilation of the cervix at the beginning of the process and the normal variables of labor.

The pain of labor is always challenging; however, without the hope of a “normal” baby, the pain often seems intensified. Patient teaching and perinatal palliative and bereavement care begins with admission and continues through discharge and beyond. Answering questions about the labor and birth process and what the baby will look like becomes the focus during labor. During labor, patients who have a fetus with a deformity or IUFD are often waiting anxiously and have fears about the appearance of the baby. Nurses should create a supportive and open environment for questions, concerns, and fears. After delivery, the teaching focuses on self-care, family grief, community resources, and infant disposition.[26] Some parents and family members fear seeing a deceased, damaged, or deteriorated body.[27]

Nurses should be honest and compassionate when explaining what parents should anticipate. An IUFD, for example, may have peeling skin and pale skin tones. Blankets and clothing can cover any area of the skin that may not be intact. Deformities and congenital syndromes often have characteristic traits that can be described to prepare the parents and family for the baby's appearance. Prior to delivery, the patient and family should discuss their expectation about social media posts, photographs on cell phones, video, cultural rituals, or desires with their caregivers, family, and friends. The focus of the nurse includes medical care such as induction medication management, pain control, and comfort measures, as well as encouragement and reassurance.

At times, the delivery room can become chaotic as staff prepare for possible resuscitation and parents hold on to hope that their baby will live and will have the option for transport to the NICU. Once the baby is born, decisions are made quickly whether to start, continue, or discontinue life-saving measures. Anxiety can be overwhelming for the family. After members of the delivery team have completed the delivery process, there is a plan in place to allow for the family to have privacy. It is the nurse who remains with the patient and family, giving care to the dying or deceased infant as well as to the mother. The birth of a baby with life-limiting conditions in which parents have chosen to avoid resuscitation or an IUFD requires consistent interdisciplinary support. Family presence is at the discretion of the parent(s). The delivery room is often somber and peaceful, with hushed voices. There is a silence in the room as the baby delivers without that hallmark cry of a normal newborn. Parents may weep quietly and hold their baby or they may not appear sad at all; while looking at the baby they may talk about any familial features of the baby while enjoying their moments together.

Parents experience several first moments with the baby, the first moments of life and/or death, the first look, touch, bath, and dressing, as well as the last moments including the last look, touch, bath, and dressing. All the hopes, dreams, anxieties, and anticipation of the possibilities that will come with new life are changed to a new set of fears, anxieties, hopes, and heartbreak. The nurse is often present with parents around the time of the death.[28] The nurse must help the patient and the family navigate through this time while displaying compassion, understanding, presence, and patience. It is common for families to ask the same questions repeatedly. The nurse becomes the mediator, giving families privacy, having side conversations (with permission) with the extended family, answering questions, listening, and being present. Care should emphasize the importance of the baby. The nurse role-models the handling of the deceased baby for the patient and family, which can help the patient and family to feel more comfortable in handling the baby. The nurse should call the baby by name if possible and point out all the good things about the baby (i.e., cute nose, perfect hands, etc.).[29] If agreed to by the parents, collect and create mementos like a lock of hair, pictures, footprints, molds of the hands or feet, and allow the parents to take as much time as they desire.[30]

Postpartum care for the patient is the same from a medical standpoint. Perinatal loss resources and education on what to expect are imperative in the postpartum period. The loss of a baby does not shorten or change the physical and emotional changes that occur after pregnancy ends. Nursing assessments include observations of the perineum, fundus level, bleeding, and breasts. Postpartum care should be taught and reinforced.[26] Lactation support should also be discussed, as some women may choose to suppress their milk supply while others may choose to donate their milk to a milk bank in memory of their baby.

The family members are also grieving. The nurse may encounter fathers in hallways and waiting rooms seeking to regroup emotionally. The nurse should be open to listening and comforting. Fathers can also develop posttraumatic stress disorder (PTSD) and depression.[31] Siblings can handle grief differently, and their developmental stage impacts their ability to comprehend the situation. Not acknowledging the death and the subsequent grief of the sibling may complicate that child's grief. Grandparents are often struggling with their own grief. Discussions need to occur with the patient and family as to how the patient wants to handle the potential newborn nursery at home and baby shower gifts, as well as funeral arrangements. Notification of friends and acquaintances may or may not happen due to the extent of grief, and, in turn, family friends may unknowingly ask about the deceased baby weeks later.

Perinatal loss resources should be given to the patient and family that allow connection to others experiencing the same loss.[26] The nurse forms a bond with the family that is rarely forgotten and is often celebrated at annual events to remember those who were born silent or had a very limited life.[31] For some patients, the pregnancy and birth will be their first or only pregnancy. For those who decide to have another child after loss, pregnancy and delivery can be challenging. The patient may experience an uncomplicated pregnancy the next time or could have miscarriages and experience loss again. Anxiety has been found to be higher in pregnancies after a perinatal loss, as well as increased rates of PTSD and depressive symptoms.[32–34] Formal and informal support networks from friends, families, and groups such as a church congregation often increase the resilience of mothers and lead to decreased symptoms of PTSD and depression.[34] Patients react differently to loss, and some may choose a different obstetrical provider, hospital, and nurses, while others might want everything to stay the same.

New Trends

In 2003, the End-of-Life Nursing Education Consortium (ELNEC) developed a neonatal/PPC curriculum.[35] To date more than 1,800 pediatric/neonatal nurses have received this education in the United States and abroad http://www.aacn.nche.edu/elnec.

More institutions are interested in neonatal-specific content to start their own palliative care teams. Despite support from the AAP and the World Health Organization (WHO) for the provision of palliative care, there are still many barriers. Some barriers to neonatal palliative care include formal educational needs on the part of staff, a feeling of failure (especially by the physicians), difficulty in communicating bad news to the parents, and ethical conflicts among the team members.[23] The ability of the nurse to deliver care to the dying newborn is impacted by many barriers to and inconsistencies in such care. There is demonstrated evidence through the interest in ELNEC that nurses around the world wish to provide good palliative care as a standard part of neonatal and pediatric care.

Conclusion

Neonates with a life-threatening anomaly or illness and their families will benefit from timely and interdisciplinary palliative care. The nurse should focus on providing care when the prognosis is uncertain, and this may challenge existing healthcare system structures. The neonate's illness trajectory can be unpredictable, and the nursing focus needs to be on excellent pain and symptom management while promoting developmental care of the infant as well as maintaining culturally competent emotional, psychosocial, and spiritual support for the family. Families and healthcare professionals have the difficult task of helping the infant live as fully as possible with complete dignity and comfort while preparing for and accepting that the infant may not live a long time. This requires a committed IDT with referral to community resources as appropriate. Nurses new to palliative care practice should have the support of more senior nurses and staff because the first experience of infant death can cause a considerable amount of anxiety and emotional distress for the nurse.

Regardless of the length of life or the place where that life is lived, excellent palliative care includes optimum symptom relief for the neonate, honoring the parents' wishes, providing ongoing support to parents and family, planning for the death, and honoring the life by creating memories of that life. The nurse should avoid phrases such as "withdraw care" or "nothing more can be done." There are always interventions that can be done to promote comfort during the EOL care for infants with complex, life-limiting, or chronic conditions, such as supporting comfort measures, managing secretions, minimizing sleep disturbances, administrating medications for agitation, and optimizing the time the infant can spend peacefully with the family. Table 62.1 lists common medications used for the palliative and EOL care period for infants. The use of a neonatal scale should continue during EOL care.[16] Supportive care should continue throughout the bedside postmortem care and incorporate options for obtaining mementos. The website www.PerinatalHospice.org is an important international clearinghouse of information for providers and parents. The website was started in 2006 by Amy Kuebelbeck, a journalist and parent advocate. To date, 280 PPC programs representing 22 countries are listed on the website.[36]

In some areas, there are bereavement photography specialists who can assist with providing compassionately developed photographs of the deceased infant, such as the Now I Lay Me Down to Sleep organization (https://www.nowilaymedowntosleep.org/find-a-photog/).

Acknowledgments

We would like to acknowledge Christy McGurgan and her family for sharing their journey and experiences with the death of their beloved son, Graham. We would like to acknowledge Crystal and EJ for sharing their journey and experiences with the death of their beloved daughter, Norah. We would also like to acknowledge Chi Dang Hornik, Neonatal Pharmacist, Duke Children's Neonatology Division, for support with the medication chart in this chapter.

CHAPTER 63

Grief and Bereavement in Perinatal and Pediatric Palliative Care

Rana Limbo, Kathie Kobler, and Betty Davies

Key Points

- Bereavement care for all family members is an integral component of perinatal and pediatric palliative care.
- Grief assessment begins at the time of diagnosis of a child's serious illness, applies to all family members, and continues into the bereavement period following the child's death.
- Grieving after a death is a normal process because grief is experienced from the loss or alteration of a close relationship; however, some grief reactions become complicated, and nurses must assess for factors that put family members at risk for such reactions.
- Nurses have a responsibility to create supportive relationships in which family members feel free to express their grief.
- Caring for children at end of life requires nurses to attend to their own personal and professional responses to death, dying, and bereavement as a basis for providing optimal care to families.

Grief and Bereavement Overview

Effective and compassionate care for children with life-threatening conditions and their families is an integral part of care from diagnosis through death and bereavement follow-up.[1] The progression of such care has been summed up this way: "Grief flows from relationship. Relationship forms a bridge from suffering to hope. Hope transforms."[2] Guidelines and standards outlined by the National Consensus Project on Palliative Care, the American Academy of Pediatrics, and the Institute of Medicine emphasize the importance of providing interdisciplinary bereavement support to families experiencing the death of a child.[3–5]

Medical science has contributed significantly to the treatment of life-threatening illnesses or conditions, but children still die as a result of disease progression, extreme prematurity, trauma, and more. Grief can arise at any point in care for all connected in relationship with the child, even well before death occurs. Regardless of the cause, the death of a child is a tragedy, an incomparable life event that affects all family members, friends, and their community. A child's death also affects the physicians, nurses, social workers, and other healthcare professionals who provide care through the child's living and dying.

The purpose of this chapter is to discuss grief as a life-long, relational process. The trajectory of grief reflects how survivors of loving relationships maintain closeness and connection, cherishing dear ones, from those not yet born through adolescence, who are no longer physically present. Practical strategies for grief assessment and supporting bereaved parents and children are highlighted. Also included are the experiences of healthcare professionals as they maintain relationships with the child, the family, and team members and are affected by loss.

Grief as a Process

Death is a part of each individual life, something we all must face as we contemplate our own mortality. The expectation is that children will outlive their parents; the death of one's child is outside of that hoped-for pattern. The grief associated with a child's serious illness can begin at diagnosis, as parents and family members grapple with the possibility that the illness cannot be cured while also simultaneously hoping for a good outcome.[6] The Integrative Model of Curing and Healing[7] in Figure 63.1 shows bereavement and hope as intertwining experiences throughout a serious illness, accompanying the moments that make up each day. As a serious illness progresses, a realignment of goals occurs (termed "regoaling" by Hill and colleagues[8])—a result of shifting hopes and preferences in response to a child's deteriorating condition.

When a child transitions to dying, grief responses intensify, and family members' grief continues long past the child's death. Many parents feel that they never recover from the death of their child. They may resume daily activities, adjust to life without their child's presence, and find new pleasures in life, but most parents feel vulnerable and that they are not the same people they were before the child's death.[2] The death of a child, or any beloved person, is not something one gets over; rather, as time unfolds, one learns to integrate the loss into one's life. Indeed, grief is a process that is not always orderly and predictable; each individual's unique experience of loss is manifested in diverse ways.

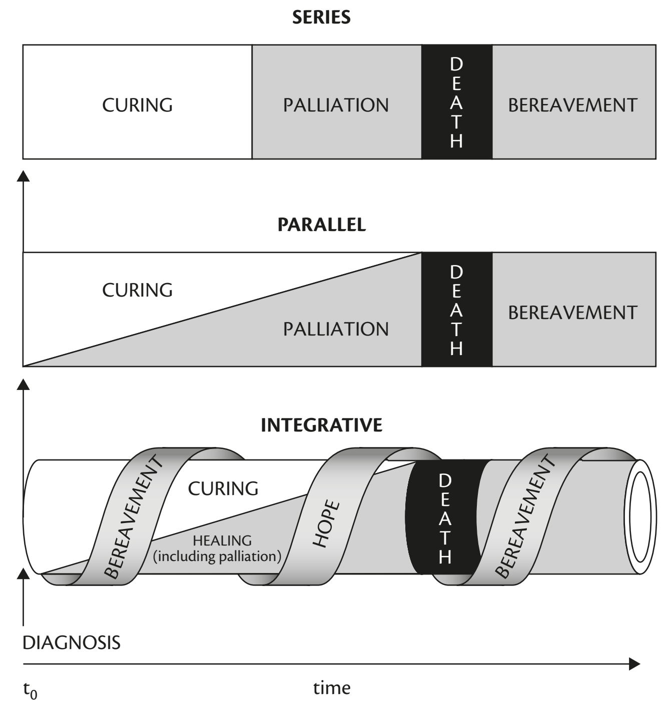

Figure 63.1 Integrative model of curing and healing (with bereavement and hope).

Grief, Bereavement, and Mourning

The term *grief* is used to refer to the emotional response to a loss.[9] But grief is much more than emotion. It is an overwhelming and acute sense of loss and despair. It is the personalized feeling and response that an individual makes to real, perceived, or anticipated loss or death. Grief encompasses every domain of human life: physical, emotional, psychological, social, and spiritual. Sadness, anger, numbness, sleep and eating disturbances, inability to concentrate, fatigue, existential angst, and tension in interpersonal interactions are among the responses to a loved one's death. Please refer to Table 63.1 for a summary of types of grief.

Grief occurs when an individual experiences a loss that he or she deems personally significant. To a certain degree, who or what we consider to be personally significant is culturally defined. For example, in the contemporary United States, the death of one's child is expected to result in profound grief.[13]

The term *bereavement* refers to the state of being bereaved or deprived of something. The word derives from the Old English word *reave*, which means to plunder, spoil, or rob.[9] This meaning implies that the lost object is a valued one (i.e., why someone who is bereaved feels deprived). This definition is especially apt for bereaved parents, who often report feeling as though a part of them has been torn away or that a part of them is missing. As the bereaved mother of a 22-month-old who died following a brain aneurysm sighed: "When my son died, it was as if my heart had been stolen from my breast, and my arms that held him ripped from their sockets."

Please refer to Table 63.2 for a summary of terms and phrases that help to understand grief and bereavement.

Mourning refers to the outward, social expression of grief—often through ritual—and sometimes to the psychological process of adapting to loss.[17-21] Expression of loss is dictated by cultural norms, customs, and practices, including rituals and traditions. Some cultures are very emotional and verbal in their expression of loss, while others appear stoic and businesslike. Religious and cultural beliefs and customs may also dictate how long one mourns and how one behaves during the bereavement period. In addition, outward expression of loss may be influenced by the individual's personality and life experiences.[22]

Grief in the Context of Relationship

Without relationship, there would be no grief; we grieve because we are connected in meaningful ways through relationship, which death significantly changes.[2] Parents, grandparents, siblings, healthcare providers, and all who cared about the child are affected when death occurs. These next sections reflect the ways relationship influences and is influenced by grief, no matter the child's age.

Child and Parent

Parent–child relationships are sacred, unique, and complex. The connectedness between parent and child has its roots in the biological and emotional bonds that precede birth. It grows as the parent begins to know and care for the child. The child is a parent's

Table 63.1 Characteristics of various types of grief

Type of grief	Characteristics
Anticipatory	Most commonly refers to situational factors that lead to grief for what might happen. A life-threatening diagnosis may lead to grief for a "normal" life. Thinking in terms of lost expectations helps one understand anticipatory grief. Often results in an "emotional roller coaster." Anticipatory grief is often accompanied by changing hopes.[9]
Disenfranchised	Acknowledges social context of grief. May overlook someone who has a close and intimate relationship with the one who receives bad news or dies. Often accompanies grief around stigmatized circumstances such as suicide, termination of pregnancy, or an early pregnancy loss (miscarriage). Young children or those with cognitive challenges may also experience disenfranchised grief if they are not expected (and therefore not allowed) to grieve.[10]
Complicated or Troubled	Complicated grief refers to a response to loss that is more intense and longer in duration than usual. It may also include prolonged searching and yearning. Examples of causes include chronic, suppressed, child death; stigmatized death; ignored response; a difficult relationship; multiple losses occurring close to each other; absent or very weak social support.[11]
Traumatic	"Traumatic" depends on individual perceptions and experiences; however, these types of death are generally more traumatic than others: death of a child (at any age), homicide and other violence, suicide, severe accident, disaster-related (terrorism, weather-related, fire). These examples are not prescriptive, but research findings show that traumatic deaths resulted in different ways of finding meaning and making sense of the death and the world than did deaths for which one could prepare.[12]

Table 63.2 Terms and phrases that help understand grief and bereavement

Terms and phrases (including theories, models, concepts, and other)	Explanation or description
Concept of perinatal bereavement	Groundbreaking work that expands the field of perinatal bereavement (PB). The authors conclude the following points: (a) phenomenon is universal, (b) follows perinatal loss, (c) lacks conceptual clarity, (d) addresses the need for scholarly study to clarify and extend perinatal bereavement as a concept. PB is a practice-based concept and may be confabulated with grief and bereavement. One clear meaning of the definition is that it follows *death*. Therefore, the authors concluded that the meaning of PB is "loss of a pregnancy or loss of an infant through death" (p. 4) (e.g., excluding infertility, traumatic birth, adoption).[14]
Caregiving theory	Comprised of four crucial functions in the area of perinatal bereavement: Nurturing, protecting, socializing, final acts of caregiving.[15]
Continuing bonds	The concept of continuing bonds addresses the idea that death does not end a relationship. In fact, the feeling of connection and affection remains forever in healthy grief.[16]
Regoaling	In their chapter on hope, hopefulness, and pediatric palliative care, Hill and Feudtner link hopeful thinking to goals. Specifically, they hypothesize that parents whose child has a life-threatening condition who hope for positive adaptation revise or establish new goals or set of goals (i.e., regoaling).[6]
Pridham's Guided Participation (GP) theory	GP is a theory of relationship-based teaching and learning researched over approximately 40 years specially bringing participatory learning into pediatric nursing. It has been adapted for use by interprofessional disciplines in clinical care by Karen Pridham, PhD, RN, FAAN.[18]
Dual-process model of grief	The authors suggest that grieving is a dual process of coping: restoration-oriented and loss-oriented. Some may describe this process using the metaphor of a roller coaster: at times, one may feel "normal," with merely a faint hint of the suffering following the death of a loved one (restoration-oriented coping). At other times, one is overtaken by grief, and memories of the person's life and death flood one's being, leading to loss-oriented coping. As time passes and the loss becomes more fully integrated into a person's life, suffering is less common.[19]
Empty space phenomenon	Parents were interviewed 7–9 years after the death of their child to cancer. They all identified an empty space and used three principal ways of filling it, with one example given for each type of responding: (a) getting over the loss (view themselves as not significantly changed), (b) filling the emptiness (periodically experience the empty space, but focus is about moving on to other activities and thoughts), and (c) keeping the connection the (definition and what the empty space constitutes changes over time). Findings suggest the experience of having a child die from cancer is dynamic over time and bears a conversation when the nurse has future contact with the couple.[20]

link to the future.[23] Tributes to the parent–child relationship appear regularly on social media. Recently, young parents whose first baby was diagnosed with several life-threatening conditions wrote so lovingly about the joy their unborn daughter already brought them at 20 weeks' gestation. She had a name, a place in their family, and their post was filled with descriptions of her movements and fighting spirit. They wrote of welcoming her to their family, whether she was alive at birth or not.

Watching a child become sick and die is a crisis of meaning for families, and it is through their cultural understandings and practices that families struggle to explain and make sense of this experience.[24] Results from one study[25] showed that parents whose child died of a nonviolent cause were more likely than those whose child died in a violent way to come to an understanding and make sense of the child's death more quickly. Gender, culture, temperament, and a variety of other factors influence grieving styles. Many parents whose child is receiving palliative care are likely having their first experience with illness, hospitals, medical technology, dying, and death. Consequently, they may have few practiced skills for dealing with significant loss.

Parental grief is all-consuming, affecting every aspect of the parents' existence. Parental bereavement after a child's death involves a level of suffering for both parents. Caution is advised against assuming that mothers express their grief one way and their partners in another. Both parents should be assessed individually to determine how they make sense of their loss. Parents often struggle with guilt throughout their child's illness and following death because of deep-rooted feelings of responsibility for their child's welfare. Parents are responsible for protecting and sustaining their children[26] and shielding them from all danger; many parents feel they should have protected their child from illness and death. When children die from an inherited disease, such as cystic fibrosis or sickle cell anemia, parents know that their child's condition results from their unknowingly passing on the genetic material.[27] When the child dies, parents may still carry the burden of knowing that their genetic makeup is responsible for their child's terminal illness. Parents whose child dies from an accident may also feel guilty for abdicating their protective role.

Bereaved parents may cling to irrational guilt because it is often easier to accept blame, with its fantasy of control, than it is to accept the total loss of control with which they must grapple. For example, one young mother's intense guilt was rooted in her belief that her baby's premature birth and eventual death was caused by her eating too many spicy foods early in her pregnancy. Parents may also blame someone else for their child's death. Sometimes this guilt is targeted toward a partner or spouse, or toward another child or family member. Nurses should be aware of these dynamics and help parents find an appropriate place for their anger and blame.[26]

Professionals who support bereaved parents are attuned to parents' own descriptions of being different after their child died. Gilmer and colleagues[28] found that changes in bereaved parents occurred primarily in two realms: in their personal lives (e.g., emotions, beliefs, work habits) and in relationships. Parents themselves reported changes in priorities, while their surviving children noted the intensity of their parents' sadness. Davies and Limbo[29 (p.78)] share the story of a mother who asked her college-age son, "Did I change?" Her son was in grade school when his brother—and, a year later, his sister—were stillborn. Her son was flabbergasted that she was not aware of how different she was from the way she had been before the loss of her babies. He responded, "You were never happy, you stopped being a room mother or participating with any of our sports teams. You cried all the time."

Researchers have found that the loss of a child affects the parents' relationship. Odds of divorce are higher in couples after miscarriage or stillbirth,[30] and the rate of relationship dissolution after such a loss increases for both married and cohabiting couples.[31] Researchers have also highlighted unique interpersonal dynamics between partners. Stroebe and colleagues[32] found that bereaved parents who attempted to hold in their own grief in order to spare their partner increased their own and their partner's grief over time (at 6, 13, and 20 months post-death), a phenomenon they refer to as "partner-oriented self-regulation (POSR)."[32 (p. 395)] Nurses who work with bereaved parents often hear one parent or the other make a comment such as, "I feel like I need to be strong for her" or "If he sees how I'm hurting, I don't think he can deal with it." The paradoxical nature of the findings from this study provides nurses with insight into couple dynamics, follow-up interventions, and potential support group topics.

Nurses must also be cognizant of the special needs of those bereaved parents who cope with additional stressors in their everyday lives. Moreover, nurses should pay attention to the indirect grief of parents who witness or co-experience the death of other terminally ill children in the same clinical setting as their child. Single parents or same-sex parents may not have as many options for support as married parents in a heterosexual relationship. Black and Fields[33] provided several clinical practice guidelines for nurses and others caring for lesbian couples who experience perinatal loss. Examples included recognizing the complexity of always needing a third party to get pregnant; understanding the financial, legal, and social ramifications of achieving the pregnancy; and considering that the couple may feel disenfranchised in their bereavement by those who judge their lifestyle choices. Same-sex couples whose baby dies appreciate being treated as any bereaved couple, not considered "different" or "unusual" as they navigate factors associated with their pregnancy and subsequent loss.

Child and Grandparents

The grief of grandparents is twofold: they grieve the loss of their grandchild, but they must also bear witness to the grief of their own child, the parent of the deceased child, a phenomenon termed "double pain."[34] In addition, grandparents experience cumulative pain.[34(p. 170)] Gilrane-McGarry and O'Grady identified three sources in addition to the double pain: pain from their own past losses, pain common to all grief, and witnessing negative changes in their child. Grandparents identified two factors highly relevant to nursing care that helped them with their grief: having their loss acknowledged and being considered a part of the bereaved family.[35] Nurses should hold in mind that grandparents will have their own unique needs in the moments surrounding their grandchild's end-of-life (EOL) care, especially if they experienced the death of another of their own children many years prior.

Grandparents can be a source of considerable strength for parents and siblings, or they can be an additional source of stress. Their advice may be sought but then ignored; often their practical help is accepted, but their own grief is barely acknowledged.[1] Grandparents may experience considerable helplessness and frustration; they question the meaning of life as they struggle with the lack of order they feel in having their young grandchild precede them in death.

Impact of Family Dynamics on Relationship

Families have characteristic ways of being in the world, of solving problems, of managing crises, of interacting with one another, and of relating to those outside the family. When a child is seriously ill and dies, families respond in the ways that are typical of how they manage other life events. These ways of coping are more or less functional. Past experiences with death and the learned response to loss also affect how each family member will grieve a child's death. Other deaths of a similar nature may have occurred in the family, such as when more than one child suffers from the same life-threatening genetic disorder or when grandparents experienced the death of their own baby years ago. How previous losses were handled in the family will influence the current situation.

Researchers of families with adult patients[36] and with pediatric patients[37,38] documented eight dimensions of family functioning: communicating openly, dealing with feelings, defining roles, solving problems, using resources, incorporating changes, considering others, and confronting beliefs. These dimensions occur along a continuum of functionality, so that family interactions tend to vary along the continuum rather than being positive–negative or good–bad.[37]

In families where thoughts and opinions are expressed freely without fear of recrimination, where a wide range of feelings is expressed and differences tolerated, where roles are flexible and problem-solving instead of blaming is the pattern for dealing with challenges, where families are able to ask for and receive assistance from others, and where beliefs and values are confronted and examined, the children and all family members are better able to manage their grief and support one another. Through establishing relationships with a child and family, nurses have the opportunity to bear witness to the family's functioning in both happy and difficult moments, which in turn provides important insight into supportive measures that would best honor their grief and bereavement.

Child and Siblings

Histories among siblings are closely intertwined because siblings often develop special bonds that are unlike any other. The closer two siblings are to one another before death, the more behavior problems the surviving sibling may have following the death.[37] Siblings may be forgotten as grievers; even teenagers may feel overlooked. Their needs can be ignored when a brother or sister dies—not for lack of parental concern, but because their parents are so overcome with grief that they have little energy for the needs of their surviving children. The impact of a child's death on surviving siblings is manifested in four general responses, best characterized in the words of the children themselves: "I hurt inside," "I don't understand," "I don't belong," and "I'm not enough."[37,39] Not all bereaved siblings experience all four responses, but most children through to adolescence demonstrate all responses to varying degrees.

"I Hurt Inside."

This first response includes all the emotions typically associated with grief—sadness, anger, frustration, loneliness, fear, guilt, restlessness, and a host of other emotions that characterize bereavement. Unlike adults, who are able to talk about their responses, children manifest their responses in various behaviors, such as withdrawing, seeking attention, acting out, arguing, fear of going to bed at night, overeating, or undereating. In response to children who are hurting inside, nurses need to allow, and even encourage, the expression of the hurt the children are feeling. Nurses can share their own thoughts and feelings with the children to let them know that they are not alone in this situation. If adults in the child's life do not allow for or facilitate expression of feelings, children learn that there is something wrong with such feelings and may suppress what is on their minds and in their hearts.

"I Don't Understand."

Children's difficulty in understanding death is greatly influenced by their level of cognitive development. However, once children know about death, their cognitive worlds are forever altered. Without guidance by adults in helping them to understand the death in clear, simple, and age-appropriate ways, children make up their own explanations, which usually involve taking responsibility for their sibling's death and their parents' distress. Without explanations, they can become more frightened and insecure. Nurses working with siblings should have a solid grasp of children's cognitive development, provide appropriate explanations for events that happen, and be open to supporting the family as questions from siblings arise.

"I Don't Belong."

A death in the family tears apart the usual day-to-day activities and patterns of living. Parents are overwhelmed with their grief, with making arrangements, and with caring for their other children. Surviving children are overwhelmed with the flurry of activity and the depth of emotion surrounding them. They often feel uncertain about what to do; they may want to help, but they don't know how, or, if they try, their efforts are often not acknowledged by grieving family members. Bereaved siblings may feel as if they are in the way or as if they are not a part of what is happening. They feel different from their peers as well and begin to feel that they don't belong anymore. Nurses play a critical role in encouraging parents to include siblings in illness- and care-related events, such as inviting the child to participate in certain treatments (for example, by holding their sibling's hand or blowing bubbles together for distraction during procedures). After death, the nurse can help the parents by modeling or guiding exploration of what to say to the surviving siblings.

"I'm Not Enough."

Assuming that they are somehow responsible for their parents' distress, surviving siblings may feel as if they are not enough to make their parents happy ever again. They may feel that their deceased brother or sister was the favorite child and that they should have been the ones to die instead. Some siblings respond by striving to be as good as they can be, trying to prove that they are worthy. Bereaved siblings benefit from feeling accepted just for being themselves and not from being compared with their deceased brother or sister. Moreover, surviving siblings may not want to burden their parents with their own feelings and may keep the depth of their grief private. Nurses can assist siblings to feel special by asking questions about their lives and acknowledging their unique characteristics or abilities.

Children and Adolescents at End of Life

Assessing and responding to a child's experience of serious illness is the very essence of palliative care provision.[40] Children experience their own disease progression and impending death within their cognitive and emotional capabilities, and they communicate such feelings to others as they are able.[41] They live and die as children, but often with much apparent wisdom, sometimes seeming to surpass that of their adult caregivers. In one of the earliest studies of seriously ill children, researchers found that very ill children are indeed aware of death and are more anxious than children hospitalized for nonserious illnesses or nonhospitalized children.[42] While remembering that there are individual variations within these patterns, this work provides nurses with background for understanding terminally ill children, such as this 14-year-old boy whose death is imminent:

> My mother used to go to church to pray for me early every morning. I also prayed in my bed for my mother to stop her soundless sorrow. We were all sad and we pray separately in different places. Now, I am getting more worried about how sad she will be after my death, and she will feel lonely without me. How can I express my sorrow for her and thank her? She has lost so many things . . . money, time, and smiles, all because of me . . .

Adolescents with a terminal disease struggle against physical pain, are sensitive to their parents' reactions, and have a strong desire to maintain relationships with their friends, regardless of their illness status: "I couldn't say anything with my Mom. She pretends to smile to me, but I know how she feels so sad whenever looking at me. I want to come out and share my emotions with my friends at least. But, now there is nobody around me."

Children and teens with terminal illness often wish to please their parents, and parents may want their child to maintain hope and not give up, resulting in barriers to honest communication.[43,44] In such cases, nurses are in a position to honor the feelings of all involved while helping family members to open to the possibility of truthfully sharing perspectives, hopes, and grief.

Child and the Healthcare Team

Professionals who care for children with serious illness are constantly reminded of the frailty and preciousness of life. When a child dies, healthcare professionals experience their own grief and also miss the relationship once shared through daily communication with the child and family.[45] *Caregiver suffering* is a contemporary term that includes moral distress and grief[46] and encompasses bearing witness to the suffering of another.[47–49] In one study of nurses' experiences following the death of a child,[50] participants described two types of distress: (1) *moral distress* resulted when the nurses knew the child's death was imminent and were required to carry out painful treatments they perceived as unnecessary, and (2) *grief distress* occurred in response to the child's death. Both types of distress resulted from lack of open communication within the care team and lack of consideration of the nurses' viewpoints.[50]

Working with children at end of life can also trigger nurses' awareness of their own personal losses and fears about their own death, the death of their own children, and mortality in general.

The process is complicated by cumulative loss—that is, a succession of losses experienced by nurses who work with patients with life-threatening illness and their families, often on a daily basis.[51] Nurses who work in settings where death occurs frequently seldom have time to grieve one child before the next death occurs on their unit.

Papadatou[52] described a framework for how professionals manage grief that entails fluctuating between both experiencing and avoiding intense emotions. An expert in the care of dying children, she notes that professional caregivers are profoundly affected by what is required of them in working with bereaved parents, other family members, and children and that they learn to regulate their grief.[52] For example, to manage the experience, a nurse may cry at a child's bedside and be fully present to a father who has just watched the removal of his child's ventilator. Later that day, the same nurse may avoid the intensity of the emotions garnered from the child's death to engage in a dinner out with her family.

Understanding the normalcy of the grief responses provides caregivers with an awareness of how they can simultaneously support families and themselves. Papadatou proposes that meanings are attributed to death and dying through grieving, that grief complications occur when there is no fluctuation, and that grief provides opportunities for personal growth.[52] Other researchers have found that caring for children at end of life provides opportunities for such growth and transformation, as healthcare professionals report finding meaning and enhanced life views through their work.[53,54]

Assessing Grief throughout the Trajectory of Care

Bereavement care is interdisciplinary in nature, with all team members collaborating to understand the experiences of each individual's grief, as well as those of the family as a whole.

Grief assessment begins when the child is diagnosed with serious illness and continues throughout disease progression, transition to end of life, death, and aftercare.

Five questions serve as a simple way for pediatric palliative teams to learn more about parents' perception of their child's needs and key issues:

- Who is your child as a person?
- What is your understanding of your child's illness (or condition today)?
- What are your hopes?
- What are your worries?
- What sustains you or gives you strength?[55,56]

These questions—followed by respectful probes such as, "What are the most important things we should address for you and your child right now?"[57] or "What do you think should happen next?[56]—can help to elicit what is weighing heaviest on parents' minds and also serve as a bridge to learning more about their feelings. In addition, statements such as, "This feels so difficult," or "Other parents/children have told me . . . it sounds like this is similar to you," can aid in acknowledging the experiences of another and open a way for eventual sharing of tender feelings.

During such interactions, nurses should also be mindful of periods of extended silence because there may be much that the child or parent is holding deep inside that cannot yet be spoken aloud.[41] Honoring silence in a compassionate manner offers the child or parent the opportunity to focus on these private thoughts or grief that may eventually be spoken aloud and shared with a trusted healthcare professional.[57]

Family Assessment

The nurse's role is to assess each family's way of functioning and to realize that some families are more challenging to assess and work with than others. For example, some families may not wish to share information in the presence of their children, others do not wish to discuss matters with any relatives in the room, while other families include everyone in most discussions. Thus, it is important for the nurse to gather information over time and to talk with more than one family member to appreciate the varied perspectives. As trusted relationships are established with the child and family, the nurse can assess family functioning with questions such as, "What have you done in the past when you had a difficult decision to make?[56] or "Help me to know how your family found their way through previous losses (or deaths)." Responses to such questions can help the nurse identify strategies that will honor and facilitate the family's grief work.

Factors Affecting the Grief Experience

In assessing grief, the palliative team should keep in mind the range of factors that affect the grief of family members while noting those factors that put individuals and families at risk for disenfranchised or complicated grief. The passage of time is not a useful consideration in assessing grief responses; instead, one should assess the degree of grief's intrusiveness into each individual's life and the extent to which family members can carry out their usual activities.

Where or when a child died, decision-making about the death, memories of sights and sounds, degree of medical intervention, and the cause of death are all subjects that families discuss while exploring their grief during bereavement. Ideally, the location (home or hospital) of a child's death is based on the family's specific needs and requests, but circumstances (insurance issues, nursing shortages, transportation issues) may preclude achieving this goal. Long-term outcomes for bereaved parents and siblings suggest an early pattern of differential adjustment in favor of home-care deaths.[58,59]

Decisions made at the end of life, such as withdrawal of life support, may have left parents second-guessing or wondering afterward about their choices. Lasting images or smells may be comforting or concerning to families, depending on their associations. In fact, pain or other distressing symptoms the child might have experienced provide powerful material for families to struggle with during their grief. A full code that ends with the child's death is very different from a death in which the child slips away from an unconscious state. Death following years of treatment is experienced very differently from a death that happens quickly.

When families are less functional, practitioners may want to explore their experiences and offer potential resources one at a time, with considerable attention paid to the possible disruption that would result from each suggestion. In more functional families, a list of possible options can be presented and considered all at once. Most families value the opportunity to tell their story. Thus, listening becomes a central aspect of assessing and caring for all grieving families.

Perinatal Considerations

Parents who experience perinatal death suffer deeply—yet, in the midst of suffering, there are moments in which human kindness and exemplary professional practice can make a difference. Perinatal palliative care allows professionals to demonstrate the deepest of human responses and to understand that the meaning of life is embodied by the very youngest in our world.[60] As the team and family "hope for the best while preparing for the worst,"[61] the act of therapeutic birth planning allows expectant parents the emotional space to discuss their needs with one another, express their grief, and plan for the anticipated death of their child.[7,62] Munson and Leuthner[63] outline a framework for perinatal palliative birth planning that includes engaging families in the exploration of their wishes, providing options, and allowing choice. Families vary in their ability to communicate effectively about their distressing thoughts and feelings. In order to make decisions collaboratively when planning for their baby's birth and death, they may need support from staff.[64] Perinatal palliative care teams can gently inquire about the meaning of the pregnancy and the baby's prognosis to help parents both acknowledge their feelings and discern those things that they find most important for their baby's care.[63]

Interventions and Supporting the Bereaved

Nurses, in particular, play a central role in a family's initial bereavement experience, holding in mind the family's sense of loss while pursuing with interdisciplinary team members care that best addresses the bereaved family's well-being. Most children's deaths still occur in the hospital; nurses are most often present at the time of death. If not with the child at the moment of death, the nurse is usually the first one called to the child's bedside. The nurse's words and actions at that time leave indelible imprints upon family members. This next section explores strategies for supporting bereaved individuals as they grieve the loss of a beloved baby or child.

Guided Participation

Pridham's *Guided Participation Theory* is an example of a teaching/learning relationship-based practice adapted for clinical intervention through approximately three decades of research by Karen Pridham and colleagues.[65,66] Table 63.3 shows the three components of guided participation: processes, competencies, and issues. The focus of guided participation is the caregiving of children, applied here for families and healthcare professionals caring for families in perinatal and pediatric palliative care settings.

Table 63.3 Framework of guided participation in perinatal and pediatric palliative care

Processes	**Competencies**	**Issues** (Examples of the many potential issues that arise in perinatal and pediatric palliative care)	**Notes on potential ways of guiding the parent**
Getting and staying connected	Being with	Parent expresses that he does not understand the MD's explanation of baby's condition	Process: **Structure the learning** by using drawings, brochures, explaining small pieces of information. Note whether **joint attention** is achieved by having parents describe what they have learned. Competency: **Communicating**
Joining and maintaining attention	Knowing and relating to the other as a person	Deciding how to tell others about a baby's prenatal diagnosis	Process: Create a **bridge** from this need to another: "How have you told someone distressing news before? How did it go? Is there anything you would do differently? Assess **shared understanding and transfer responsibility** by guiding the parent through practice time. Competency: **Problem solving/Decision-making; Communicating and engaging**
Sharing understanding	Communicating and engaging	Determining when a baby's suffering is a burden that outweighs potential life-saving interventions	Process: **Achieving joint attention and sharing understanding** with parents and healthcare team Competency: **Knowing and relating to the baby; problem solving and decision-making**
Bridging	Doing the task	Figuring out how to engage an uninterested health care professional in creating a perinatal and/or pediatric palliative care service	Process: Work toward **getting and staying connected (i.e., develop a relationship)** and move toward **joining and maintaining attention** Competency: **Knowing and relating; communicating and engaging; problem solving and decision-making**
Structuring the task/learning	Problem solving/ decision-making	How to assess whether a parent needs further intervention for potentially complicated grief	Process: **Structuring the task/learning** about symptoms, parent's emotions and cognitions; **Transferring responsibility** for mental health assessment as needed Competency: **Regulating emotion**
Transferring responsibility	Regulating emotion	Determining best practice for supporting a mother whose baby was diagnosed with anencephaly at 19 weeks gestation	Process: **Getting and staying connected; joining and maintaining attention; sharing understanding** Competency: **Being with the HCP and baby; knowing and relating to both as persons; sharing understanding**

Caregiving theory, reciprocal to attachment, involves nurturing, protecting, and socializing a child. Researchers have found that caregiving is central when a diagnosis of a life-threatening condition in the fetus is made during pregnancy.[15] Mothers receiving perinatal hospice support expanded caregiving theory by talking poignantly in interviews about their long-lasting grief and bereavement and the importance of final acts of caregiving.[15] They provided a new understanding of the caregiving relationship with a child who may not have been seen and touched until after death. Examples of caregiving during pregnancy included speaking lovingly to the baby (nurturing), being cautious about diet and activity (protecting), and describing the baby by explaining his or her movements and showing an ultrasound photo (socializing).

Caregiving for a child from infancy through adolescence may include lying in bed with a child who is ill (nurturing), instructing family members and friends about health precautions when visiting a child whose immune system is compromised (protecting), or placing a child who lacks mobility in a wheelchair and taking her to the rooftop deck of the hospital to feel sunshine on her face (socializing). Acts of normal parental caregiving, such as reading a story, bathing the child, or bedtime hugs take on a new layer of meaning when shared within the context of EOL care.

To aid in understanding the key points of guided participation and its applicability to grieving families, several examples are included in Table 63.3. In addition, Figure 63.2 provides a visual depiction of guided participation, which can begin at any point (represented in the figure's triangular shape). For example, one may first identify an issue (e.g., the nurse assessing a family's preferences for being with their child who is dying), the need for a competency (e.g., the parent articulating EOL care choices that would be meaningful), or the focus for a process (e.g., joining attention).

Teaching and learning are often bounded by the idea that the expert provides information and the other learns by taking in the information, remembering it, and changing or enhancing behavior accordingly.[82] Such a definition is far too narrow. The most important component of guided participation is that it is based on the relationship between the teacher or guide (typically the one with more knowledge and experience) and the learner (the one who has a need for specific learning or information). In perinatal and palliative care situations, healthcare professionals should be mindful that they are not always the teacher because parents and the child are experts in their own values, goals, and expectations for the child's care.[67]

When using guided participation in palliative care situations, it is helpful to reflect, to take a step back, and mindfully examine all that is going on. This helps the guide to begin guided participation, which always has relationship as its center. Since guide and learner are both teachers and learners (participatory learning), it is common to use the process of getting and staying connected to begin. The process has as its goal fostering the competencies of being with and knowing and relating to the other (see Table 63.3). For example, when a young boy with terminal cancer shared quietly that his Lego superhero figure could "probably fly up all the way to heaven, too," his palliative nurse used this interest in his toy figures to establish rapport that eventually led to the boy disclosing how he would miss his family and toys when he died.

Salient features of relationship "are trust in sensitive responsiveness and respectful confidence in engagement in the process."[66] Gaining trust includes both mind and emotion. One child mental health specialist highlights the role of "being held in mind"[68]—that is, being thought about in one's absence—as a strongly motivating factor for the clinician in developing trust. This could be conveyed simply as, "I've thought about what you asked me yesterday before I left" or "I smiled this morning as I was getting ready for work, thinking of Jeremy's smile." Being in relationship may also mean sitting together quietly in the child's room, with both parents and the healthcare professional realizing that gaining trust and being with can also occur in moments of silence, especially at painful times when words are difficult to utter aloud.

Using guided participation in daily practice, specifically in the context of grief and bereavement, requires the guide to be alert to nonverbal cues such as looking away, silence, tears, or even being absent from the child's bedside. To understand how the parent defines the issue at hand requires observation and likely sensitive questioning. The guide is interested in what is on the parent's mind that led to the observed behavior. Being in relationship with the parent can lead to the nurse saying, "You seem a bit quieter than you did this morning. I'm wondering if you have identified

something for your child or yourself that we should talk about." Another example could be an acknowledging invitation such as "It is important to me to know more about what you expect of yourself in relation to your children at home. Would you like to talk about that? I notice you are holding their photo."

The process of joining and maintaining attention, also referred to as "joint attention" requires that guide and learner understand whatever the issue is in a like manner—that is, that they share understanding.[66] Numerous potential issues could result in lack of shared understanding, such as navigating the complex needs that arise for the grieving family as a child's condition significantly deteriorates. In such moments, both the family and the child's team will experience a shift from familiar interactions to new, more uncertain situations.[67] The relationships that support a guided and participatory approach to teaching and learning can result in a shared understanding between family and team that results in choices, such as facilitating a beloved family pet's visit to a child's bedside at end of life or securing access to the hospital fitness center so a father can use a punching bag to physically work through intense feelings as he anticipates his daughter's impending death.

To summarize, guided participation depends on sustaining a relationship, and such relationships are strengthened through holding another in mind. Key issues for the child's care and the family's grief support can be addressed through establishing joint attention and creating shared understanding.

Being Present for the Bereaved Family

Healthcare professionals may fear saying the wrong thing to a family member, or they may worry about not knowing what to say in the midst of such profound sadness and grief. A compassionate presence can be conveyed through thoughtful words acknowledging a family's love for their child, by holding them in mind,[68] and by bearing witness to their experience. A nurse can sit or stand quietly, close to the family, let them know that they can stay with their child for as long as they would like, comment on the child's special qualities, and acknowledge his or her own sadness about the child's death. Offering to help in practical and concrete ways is also helpful.

Most family members have a need to share their story, telling and retelling anecdotes about the child and the events of his living and dying. Listening to their stories is probably the most helpful action. For some families, reviewing what happened with their child with the care providers is critical. Meert and colleagues' innovative parent–physician bereavement meetings provide parents the opportunity to review the events surrounding their child's dying and death in the pediatric intensive care unit.[69] Bereaved parents report that such meetings helped them to understand the biomedical reasons for the death and to review their decision-making, resulting in making sense, finding benefit, staying connected with their child, and reconstructing their parental identity.[69]

Follow-up telephone calls or visits with the team members who cared for the child are much appreciated by families. This is especially true for those parents who, over the many years of their child's care, developed close relationships with their child's team members. Such families worry that the team will forget their deceased child; some families want to maintain an ongoing connection with those who cared for their child.[70] Thus, during the transition after the child's death, families and staff must navigate the changing relationship.

Preparing Bereaved Parents for Their Grief Experience

Many parents who are unaware of the normal manifestations of grief can find some comfort in knowing that their experience is normal. Providing information about the common facts of grief can be helpful; having written materials to send home with families is even better. Understanding that each person's grief experience is unique helps parents understand that there is no single right way to grieve. It also helps them realize that they are not bad or crazy if they do not express their grief in the same ways that other family members do.

Team members should identify any need for additional assistance and make referrals as necessary. For example, a family member may have spiritual concerns that would be best addressed by the spiritual care provider (e.g., "We just cannot understand how this could happen to us"), or a social worker may assist with funeral arrangements or financial concerns (e.g., a father apologizes for not being at his child's bedside more, stating, "We just don't have the money for bus fare").

Parents, as individuals, may have different styles of grieving. Nurses can help by acknowledging the normality of a variety of grieving styles and encouraging parents to understand each other's ways of grieving. Differences in bereavement response also may lead to a strain on the couple's sexual intimacy. Again, pointing out that such reactions can be expected may help couples realize that their reactions are normal.

Supporting Bereaved Grandparents

Grandparents, like their adult children, benefit from compassionate bereavement support. Healthcare professionals should be especially attentive to those grandparents who were actively involved in their grandchild's daily care. In one study, researchers found that grandparents who provided childcare for their grandchild experienced more intense symptoms of grief, depression, and posttraumatic stress disorder than grandparents who were not directly involved in caregiving.[71] Grandparents report valuing the opportunity to participate in intergenerational perinatal bereavement programs, receiving support with the entire family following a perinatal death.[72]

Grandparents can also benefit from an individualized approach to bereavement support that takes into account and honors their life experiences. For example, in the R family, when Grandfather R was 10 years old, his older brother was killed in a car accident. At that time, no one explained what had happened, he was not allowed to attend the funeral, and, following the death, he regretted that he had not been the one to die because he felt his brother was so much smarter than he. As a young boy, he decided unconsciously that he would hide his pain behind a wall of silence; he seldom displayed or talked about emotions. When Grandfather R's grandson died from cancer at age 11 years, Mr. R was flooded with memories and sadness about his older brother's death. His previously learned coping through silence and withdrawal resulted in his being unprepared to help either himself or his distraught son with the current loss. A healthcare team sensitive to the entire family's grief could provide a healing balm for Mr. R's aching heart by encouraging him in a loving and compassionate way to share his story. One suggested way of opening conversation would be: "We've learned over the years that it is not uncommon for grandparents to have experienced past losses that are triggered by this one. Does that sound familiar to you?"

Grief Support for Children and Teens

Given the family focus that is central to perinatal and pediatric palliative care, healthcare professionals are also present to siblings whose brother or sister is seriously ill. Still, bereaved siblings may harbor lingering questions and concerns along with the normal manifestations of grief. Thus, siblings can be at risk for negative long-term outcomes of a brother's or sister's death. How adults and other providers respond to children's and adolescents' grief has the potential to intensify the risk of problem behaviors or, conversely, to promote healing and health. Adults' ability to optimally support grieving siblings depends in large part on their understanding of the typical or normal reactions that characterize siblings' grief and siblings' reactions as an attempt to make sense of a senseless situation and to act out their distress.

Grief is a human response. Children and adults alike feel denial, anger, sadness, guilt, and longing in response to the loss of a loved one. They may experience lack of sleep, lack of appetite, and difficulty concentrating and maintaining usual patterns of interaction with others. However, most children have limited ability to verbalize and describe their feelings; they also have limited capacity to tolerate the emotional pain generated by open recognition of their loss.[73] Moreover, children's cognitive developmental levels interfere with their ability to understand the irreversibility, universality, and inevitability of death and to understand the reactions of their parents. They also deeply fear being different in any way from their peers and, therefore, are often unable to find comfort, as adults do, in sharing their discomfort with their friends.

Play is the work and the language of childhood, so children are often able to express their feelings through their play, as well as through music and art. Bereaved children will benefit from spending time with art therapists, music therapists, or child life specialists who can foster creative avenues for children to process their experiences and grief. During an art therapy session with clay, a young girl carefully and quietly made a creation, then smashed it flat. After observing her repeat this action, the art therapist inquired what she was thinking about. Following more silence, the girl eventually confided that she heard when someone dies they get a new body, so she was trying to figure out what her new body would look like. This confession was the first time she expressed an understanding of her terminal condition and opened the door for honest communication among the child, her parents, and team.

Self-help support groups for teens, either in person or via the Internet, often prove valuable to grieving adolescents. Adolescents are often open to writing, art, or music. Adults may come along on such journeys or share the results, but they should take care to follow the adolescents' lead, respecting confidentiality and permitting them to interpret the significance of their grief work in their own way.

Bereavement Support Groups for Siblings

Peer support groups can often help siblings in ways their parents may not be able to because they are overwhelmed with their own grief.[74] Parallel support groups for parents can offer them support, as well. In the past nearly four decades, the number and types of peer support groups have grown considerably and are offered in nearly every state within the United States. In response to the ongoing development of such groups in the United States, the National Alliance of Grieving Children was formed in 2004, serving as an umbrella nonprofit organization to provide resources and education for the many children's bereavement programs and models.

The principles that underlie the Dougy Center's bereavement support program for children have been widely accepted and expanded by numerous other programs.[75]

- Grief is a natural, normal, and healthy human reaction to loss, so the goal of support groups is to normalize children's grief experiences.
- Within each child is the capacity to heal, but this does not happen within a vacuum. Their resilience is enhanced by such factors as strong social connections that are facilitated by having children meet individuals in similar situations.
- The duration and intensity of grief are unique for each child despite sharing broad developmental similarities with peers of similar ages. Programs do vary in structure and format (depending on the setting, resources, and intent), with some being time-limited and others ongoing, and with some being curriculum-based and others nondirective. This variety helps match children with the group most suitable for them.
- Caring and acceptance assist in the healing process. Thus, efforts are directed toward providing a safe, contained environment in which bereaved children can share their experiences and can ably chart their own course through grief, rather than simply accommodating the wishes of others.

Bereavement support groups provide children with opportunities to express their emotions, including the hurt, sadness, and pain associated with grief. Art supplies, musical instruments, outdoor and indoor play equipment, quiet corners, rituals—all serve this purpose. Being with others in similar circumstances, children can listen to and learn from them about their experiences with death and grief. From the adult leaders, siblings also can learn such things as the facts about various illnesses, treatments, or dying and death, thus helping to clarify any misunderstandings they might have.

Groups are not for everyone. Depending on their individual preference, preexisting mental health, behavior, or family system challenges, some grieving siblings and/or their families might benefit more from individual or family therapy. Thus, orientation sessions about support groups must be conducted prior to children joining a peer support group to assess the fit between each child and the program.[75,76]

Supporting Grieving Healthcare Professionals

Caring for dying children requires nurses to explore, experience, and express their personal feelings regarding death. Reflection is a key process for pediatric palliative care nurses in being with the child and family before, during, and after death.[77–79] The PRAM model incorporates reflection and self-awareness as one *P*auses, *R*eflects on what is happening, *A*cknowledges one's feelings and thoughts, and is *M*indful when starting a new encounter with others.[2] When using the PRAM while working in perinatal or palliative care settings, the nurse may consider these questions:

- What is happening in my personal life right now that may affect my interactions with this child and family?
- What personal thoughts, feelings, values, or biases come to mind as I engage with this family?

- What expectations do I have for the care of this child and the child's family?
- What have I learned from team members that I should either hold in mind or place aside as I enter into relationship with the family?
- How does this family remind me of past experiences with other children? What did I learn from them that I might carry with me or lay aside at this time?[74]

Self-awareness about one's own history of loss and one's own beliefs about death, dying, and the afterlife is essential to ensure that our personal preferences do not interfere with the experience of the family. Personal death-awareness activities and exercises, discussion of belief systems about death/afterlife with friends and colleagues, self-exploration, and reflection may promote an understanding and acceptance of death as part of life. After significant interactions and patient death, a nurse can also engage in self-awareness by honest reflection through these questions:

- What affected me the most from this case?
- What went well?
- What surprised me?
- What hurt the most?
- What do I wish I could have done differently?
- What did I learn from this child that I will carry with me to my next patient?

Nurses have responsibilities for acknowledging their own personal and professional limitations, seeking assistance, and engaging in self-care activities. They must give themselves permission, space, and time to process feelings when a beloved patient dies and to regulate when and how to become connected in relationship again with the next child and family. Free-writing, journaling, poetry, music, art, ritual—all have a place in processing professional experiences of grief.[79–81]

When the death of a child resonates throughout the child's entire team, opportunities for group reflection can be helpful to process the impact of the loss together, especially if the death occurred unexpectedly or was traumatic to the team.[82] In such situations, facilitation of team processing should be offered using differing strategies over time to meet the unique needs of each grieving healthcare professional.[82–84]

Hospital Bereavement Programs

Development of interdisciplinary perinatal and pediatric bereavement programs in healthcare institutions has increased notably in the past decade despite budget and resource concerns.[85–89] A bereavement program within a pediatric palliative care program, or as part of an agency or system-wide initiative, can be of considerable service to both families and staff. These services typically include staff with specific training in bereavement care and a follow-up component.[7] An interdisciplinary bereavement team ensures that all families are educated on and supported in their grief and are made aware of available services, such as support groups, memorial services, or grief workshops. Bereavement program leaders facilitate family referral to grief therapists as needed and may also help bereaved families to be with one another as a source of support. Parents report feeling supported by staff through hospital bereavement programs and value the opportunities offered by such programs to grieve and stay connected with their deceased child.[86–92]

The existence of a bereavement program gives a clear message that an institution and its staff are committed to the care of families. In 2015, Advocate Healthcare, the largest health system in Illinois, formed a perinatal and pediatric bereavement council with interdisciplinary representatives from the system's 12 hospitals, with the goal of standardizing bereavement support care across all sites. This system-wide initiative has been successful in streamlining bereavement care processes, ensuring equity of resources across sites, and promoting high-quality, compassionate care for all families experiencing the death of a baby or child. Key initiatives to date have included organizing events for both families and staff and raising awareness of the needs of the bereaved.

In addition to helping bereaved families, institutional bereavement programs also serve the needs of staff. Programs can be structured to offer help in debriefing after a death, validating staff feelings, offering support groups, and encouraging informal support through the one-on-one sharing of experiences with coworkers, peers, or pastoral care workers.[82–85]

Ritual and Meaning-Making

Ritual is used by people across all time and cultures to mark or acknowledge significant life events,[90] providing opportunities for meaning-making and transformation.[2,91, 92]

According to Limbo and Kobler,[2] ritual creates a bridge from suffering to hope and reminds all involved of the importance of moments in the care of bereaved families. Ritual can also play an important role in helping healthcare professionals process their experiences and reconnect to the purpose in their work.[82,91]

Nurses can aid in co-creating ritual with both families and interdisciplinary team members. Discussions about ritual often begin when a nurse notices a parent letting out a deep sigh or sharing a poignant memory. In such moments, a nurse can inquire, "What is most important to you right now?" or "Holding in mind what you are thinking and feeling right now, what would be meaningful to do next?"[93] Answers can provide insight into ways that a ritual could honor all that is unfolding. For a mother whose baby was dying in the neonatal ICU, the idea of holding her baby over her heart was very important. Together, the mother and nurse decided to pause in silence, with the nurse letting the mother decide when and how to lift up and snuggle her baby close. The mother later shared how important it was to decide when and how she was ready for the ritual; for the nurse, this moment became a treasured reminder of trusting parents as experts in their children's care and in discerning their own grief support needs.

Children are intuitively drawn to ritual and are adept at co-creating ritual when invited to participate.[2] One young boy, standing at his sister's gravesite burial ceremony, noticed all of the flowers nearby. When the chaplain finished speaking, the boy asked aloud what would become of the flowers. The chaplain wisely asked the little boy to share more what he was thinking about, which led the boy to declare that he wanted to give his sister one last flower. With his parents' tearful permission, the boy carefully took out a single white rose from a nearby arrangement, knelt down before the open grave, and reverently tossed the flower in. Without spoken word, his parents followed their son's action, and eventually all present chose a flower and knelt to honor the boy's sister one last time . . . a ritual that arose out of the moment and connected all participants together in a meaningful way.

Box 63.1 Resources

Membership Organizations

- *Pregnancy Loss and Infant Death Alliance (PLIDA)* (www.plida.org).

As the only perinatal bereavement member organization, PLIDA offers numerous evidence-based position statements, a biennial 3.5-day conference, member online forum, and best-practice research. The organization includes healthcare professionals and parent advocates.

- *Hospice and Palliative Nurses Association* (HPNA) (http://hpna.advancingexpertcare.org/).

HPNA offers education, a research scholars program, numerous opportunities for certification (e.g., perinatal bereavement and pediatric palliative care), and publications.

- The *National Association of Neonatal Nurses* (NANN) (www.nann.org)

NANN is a membership organization including a community of registered nursing professionals who care for infants born with a variety of health challenges and surgical problems.

Education (Writings, Websites, and Conferences)

- *Children's Project on Palliative/Hospice Services* (ChiPPs) newsletter, published by the National Hospice and Palliative Care Organization (NHPCO) (https://www.nhpco.org/chipps-e-journal). The November 2017 issue was on perinatal and pediatric palliative care. Visit the website to sign up for the newsletter, published quarterly.
- *PerinatalHospice.org* (http://www.perinatalhospice.org/) is a clearinghouse of information about perinatal hospice and palliative care, including many resources for parents and caregivers as well as an international list of programs.
- *Blueprint for a Perinatal Palliative Care Program Toolkit*. Available from Resolve Through Sharing at https://glbereavement.dcopy.net/product/rts-2025-perinatal-palliative-program-tool-kit. The kit is divided into four sections: (1) organizing your work, (2) communication and documentation, (3) educational resources for parents, and (4) educational resources for staff. The kit includes handouts, sample forms, algorithms, and more.
- *Palliative and End-of-Life Care for Newborns and Infants Position Statement #3063* (2015). Drafted by Anita Catlin, DNSc, FNP, FAAN; Debra Brandon, PhD, RN, CCNS, FAAN; Charlotte Wool, PhD, RN; and Joana Mendes, PhD, RN. Reviewed by Brenda Barnum, MA, RN. Approved by the NANN Board of Directors. Downloadable from the National Association of Neonatal Nurses (www.nann.org).
- Limbo R, Toce S, Peck T. *Resolve Through Sharing (RTS) position paper on perinatal palliative care* (Rev. Ed.). La Crosse, WI: Gundersen Lutheran Medical Foundation, Inc.; 2008–2016. Downloadable from www.resolvethroughsharing.org.
- Wilke J. *Investing in Resolve Through Sharing Creates a Culture of Compassion, Enhances Quality, Improves Patient and Staff Experience, and Supports National Standard Benchmarks.* La Crosse, WI: Gundersen Lutheran Medical Foundation, Inc.; 2014. This white paper includes industry standards and where you can find them; the latest research on caring for someone after perinatal, pediatric, and adult death; public education that emphasizes conversations within families focused on the elements of advance care planning (e.g., medical facts, goals, values, and beliefs); timely facts on Accountable Care Organization (ACO) and Electronic Healthcare Records (EHRs); and perinatal loss certification.
- Resolve Through Sharing (www.ResolveThroughSharing.org) is a provider of interprofessional bereavement education since 1981, including training in perinatal death (including perinatal palliative care) and training in neonatal/pediatric death (including pediatric palliative care). Training for those who want additional program implementation, leadership, and education skills is offered through Resolve Through Sharing Coordinator training (offered since 1985).
- *End-of-Life Nursing Education Consortium* (ELNEC) has provided nursing education since 2000. Courses include a core course, pediatric palliative care, and, new in 2018, ELNEC Communication, in addition to numerous other offerings. For more information, visit http://www.aacnnursing.org/ELNEC.

Certification

- Certification in perinatal bereavement (Certified in Perinatal Loss Care) and as a pediatric nurse (Certified Hospice and Pediatric Palliative Nurse) is available through the *Hospice and Palliative Credentialing Center* (http://hpna.advancingexpertcare.org/).

Specialized Bereavement Products for Family Support When an Infant or Young Child Dies

- Memory boxes, the presentation and handling system (Preshand System), and the Keepsake Impressions Kit for infants and toddlers are unique products designed by the team at Memories Unlimited. Available at http://www.gundersenhealth.org/resolve-through-sharing/shop-our-products/ (for purple products) or call Memories Unlimited at 360-491-9819.

Conclusion

Healthcare professionals bear witness to the impact of a child's serious illness and death on all who love and care for the child. Providing compassionate bereavement care when a baby or child dies begins with honoring the relationship and requires a willingness to be present, to listen carefully, and to offer individualized strategies to support those who grieve. Through the children and their families, healthcare professionals are reminded of the fragility of life and that hope and love are everlasting. See Box 63.1 for additional resources.

CHAPTER 64

Pediatric Pain

Knowing the Child Before You

Juliana H. O'Brien and Maggie C. Root

Key Points

- Infants and children experience pain.
- Pediatric pain assessment is specific to age and developmental level and includes both observational and self-reporting tools and strategies.
- Pain management plans are individualized based on the pain source and physiology (acute vs. chronic, somatic vs. neuropathic), the patient's history (past pain experience), and the patient's goals for pain management.
- Children and their families should be engaged in assessment and management of pain.
- Pediatric medication dosing is based on the child's age and body weight, and potentially on hepatic or renal function.

Introduction

Children and infants, like adults, experience pain as a serious complication of disease and injury. Unfortunately for this vulnerable patient population, it is only recently that clinicians have come to understand that children experience pain, due to a surge in publications on neonatal and pediatric pain in the 1980s.[1] Previously, it was thought that infants were unable to perceive pain due to early neurodevelopment. Exposure to painful injury is associated with psychological consequences in children, including posttraumatic stress symptoms.[2] Pain exposure in infancy impacts future neurodevelopment of babies and is associated with increased anxiety and cortical dysfunction in childhood.[3] In seriously ill infants, pain may be associated with increased morbidity and mortality.[4] In older children, untreated pain can lead to decreased functioning, social isolation, sleep disorders, and mood changes. Children may have exaggerated future responses to painful or nonpainful stimuli based on past painful experiences. Prevention and relief of pain for this vulnerable population can help them to grow as children.

Pain assessment and management in infants and children require that palliative care nurses understand the developmental stages of childhood. A child's response to pain may differ based on his or her developmental stage. Careful attention should be paid to eliciting the child's and family's perspectives about pain, including past pain experiences, cultural and social perspectives on pain, and individual behaviors around pain. Children and families should be engaged as a part of the healthcare team, with their input being important in the management of pain. The pediatric pain experience can be influenced by emotional, psychological, and existential distress, just as in adults.

Pediatric Pain Assessment

Taking a Pain History and Self-Reporting Pain Scales

Self-report of pain is an integral part of the pediatric pain assessment whenever it is developmentally and clinically feasible. At the same time, self-report is not the only aspect of the pain assessment; it is considered along with behavioral observations, parental report, and clinical data.[5]

Children can affirm or deny pain at a young age. The ability to describe pain will correlate with the child's expressive language and vocabulary. The interviewer should be mindful to use a word for pain that the child is familiar with such as "hurt," "owie," or "ouchie." Toddlers can begin to communicate pain location either with words or by pointing but may not always be consistent or reliable. A preschool-aged child (>3 years) begins to be more reliable and can utilize a self-reporting pain scale such as the Faces Pain Scale – Revised: six cartoon faces that depict varying levels of pain severity. The child is asked to "point to the face that shows how much you hurt right now."[6] A school-aged child (>8 years old) may be able to provide a more detailed pain history, and the interviewer can use similar questions to those utilized in obtaining a pain history from an adult (Box 64.1). School-aged children with numerical processing skills (about age 8) can make use of the Numeric Rating Scale. See Table 64.1 for examples of pediatric self-reporting pain scales. If a child's self-report when using a validated scale does not correlate with the clinical observation and/or pain behaviors exhibited, the nurse should clarify the child's understanding of the pain scale and potentially utilize a different scale. This is an opportunity for "teach back," having the child explain the pain scale to the nurse. It is important for the interviewer to be mindful of the motivations to underreport or overreport pain (see Table 64.2 for examples). The nurse could also use reflective listening to clarify his or her understanding of the child's report, "I hear you say that you are not having any pain, but then again you are not wanting to get out of bed or move around. What do you feel in your body?"

Box 64.1 OLDCARTS Mnemonic for Obtaining Pain History

O: Onset: When and/or how did your pain start? Did it happen all of a sudden?

L: Location: Where is your pain? Can you point to where you hurt on the stuffed animal?

D: Duration: How long does your pain last? All day vs. comes-and-goes?

C: Characteristics: How would you describe your pain? What does it feel like?

A: Aggravating factors: What makes your pain worse? What makes it hurt more?

R: Relieving factors: What makes your pain better? What takes the "ouch" away?

T: Treatments: What treatments have you tried to help make it better? Play, movement, being held by parent?

S: Severity: Rate your pain using a given pain scale. How much is your pain affecting your life (mood, sleep, daily functioning)? Can you play/sleep/eat/move with the pain?

Physical Exam and Observational Assessment of Pain Intensity

For children who cannot self-report either due to age (infants and toddlers), developmental disability, or medical intervention (i.e., intubation), the caregiver must rely on observational signs of pain and parent/caregiver report. Examples of age-appropriate observational pain scales are listed in Table 64.3 [7–9] For those children who can self-report pain, it is still important for the examiner to also observe the child's behavior for signs of pain as part of his or her physical exam. Examples are listed in Table 64.4. The nurse should note congruence between the self-report of pain and presence of pain behaviors. If there is a positive self-report of pain *and* pain behaviors are observed, this congruence supports the child's pain experience. Incongruence between self-report and behavior does not invalidate the pain report; for example, a child may report no pain on the numeric scale but have limits to function and grimacing during activities of daily living. The examiner should first ensure that the child understands the self-reporting pain scale to avoid misinterpretation and then, once again, be mindful of motivations to underreport pain. Conversely, children who suffer from chronic pain, such as with rheumatoid arthritis, sickle cell disease, or chronic pancreatitis, may report a significant amount of pain but may not exhibit pain behaviors. For these children, assessment of daily functioning may better indicate their level of impairment from pain.

Just as in adults, some children can articulate what is an acceptable or tolerable level of pain and what are acceptable or intolerable side effects from pain treatments. When children decline pain treatment, caregivers and clinicians should seek to better understand the child's reasoning. Children may misunderstand the purpose, effects, or risks of the treatment or medication. If children do not like the taste or side effects of a given treatment, other therapies or medications can be trialed. Children and adolescents may prefer to tolerate pain as opposed to feeling lethargic or impaired from pain medications. This can become distressing for caregivers and clinicians caring for children and adolescents, particularly for those at the end of life. Care should be respectful and honor the wishes and values of the child or adolescent with respect to pain management. Consider further assessment of cultural or religious beliefs around the experience or presence of pain.

Case Study: A Pediatric Patient with Pain

Brian was an 8-year-old boy with end-stage metastatic rhabdomyosarcoma who was receiving oral palliative chemotherapy. He reported generalized body pain (3–5 out of 10 on numeric scale, sore with deep aching feeling) and described it as tolerable (reports that tolerable is up to 6/10 on numeric scale). He was using heat packs, gentle massage, and distraction with movies, as well as scheduled acetaminophen and ibuprofen for pain management. Brian described "the worst pain imaginable" was after he had a thoracotomy to resect pulmonary lesions, which was several months ago. On your assessment, Brian was observed to be cachectic and weak, moving gingerly and wincing when turning over in bed, he preferred to be carried in and out of clinic by his dad as opposed to using a wheelchair. The oncology team wanted to trial long-acting opioids in the hopes of improving his pain control, but Brian refused, stating he didn't like the way opioids "made him feel in his head," that they made him sleepy and not himself. Brian had trialed oral oxycodone, oral morphine, oral hydromorphone, and methadone, each one with a similar intolerable side-effect profile. While oncology and palliative care teams continued to work with Brian and his family to find alternative methods of improving pain control, they respected Brian's desire to avoid sleepiness to maximize time awake with family and friends. Brian was discharged to home with recommendations for continued use of nonpharmacologic and nonopioid therapies, as well as a prescription for an as-needed oral opioid should pain progress to more than tolerable.

Table 64.1 Pediatric self-reporting pain scales

Age	Scale	Parameters	Comments
4–12 years old	Faces Pain Scale – Revised	Uses six cartoon faces showing increasing signs of pain/distress	Complete instructions and translations may be downloaded at www.iasp-pain.org/FPS-R
>8 years old	Numeric Rating Scale (NRS)	Uses a 0–10 scale where 0 denotes no pain and 10 signifies the worst pain. *Hint*: It is helpful to note what the child considers to be "the worst pain imaginable." The "anchor effect" may lead to misinterpretation or skewed pain report (e.g., whether a "10" to an individual child is a stubbed toe vs. multiple broken bones)	Requires language skills and numerical processing To reduce failure rates, consider use of a visual analogue scale (a 10 cm visual scale) or Faces Pain Scale – Revised in children 8–12 years of age who do not seem to understand the NRS

Table 64.2 Children's motivations for underreporting and overreporting of pain

Underreporting	Overreporting
Fear of being admitted to the hospital or having to stay in the hospital longer Desire for healthcare provider to leave the room Fear of needles or procedures that might come if pain is reported Fear of what admitting pain means (cancer returning, disease progression, becoming sicker) Social construct (boys/big kids don't cry) Lacking language to articulate pain Feelings that providers do not believe reports of pain	School avoidance Not wanting to be discharged from hospital Liking the way pain medicine makes one feel Getting more attention from parent/caregiver Not wanting parent/caregiver to leave bedside Fear of future pain

Assessment of Pain in Child with Severe Neurologic Impairment

Children with severe neurologic impairment who are nonverbal are at risk for the underrecognition and undertreatment of pain.[10] A child may be severely neurologically impaired from an anoxic or traumatic brain injury or from a specific disease, such as a congenital anomaly, brain malformation, or metabolic disorder. The revised FLACC is a pain scale to aid in the assessment of the nonverbal, neurologically impaired child.[9–10] When pain behaviors are observed, common sources of acute pain in the severely neurologically impaired child such as spasticity, dental caries, constipation, fracture, subluxation, and urinary retention should be considered and addressed.[10] If pain behaviors persist without any findings of tissue injury or inflammation indicating an acute pain source, then some experts propose that it may be reasonable to trial neuropathic pain agents, arguing for the empiric treatment of a central neuropathic pain syndrome in this population.[10]

Procedural Pain Management

Procedural pain is the most commonly experienced pain event of hospitalized children.[11] Hospitalized children experience painful procedures including venipuncture, intramuscular injections, lumbar puncture, heel lancet, subcutaneous port access, urinary catheterization, feeding tube placement, wound dressing change, and chest tube placement. Children who experience unrelieved or severe pain from procedures may in the future have a worse pain response to the same procedure or be avoidant of medical care altogether.[12]

In infants, procedural pain management includes caregiver education and preparation for the procedure (anticipated duration, steps prior to painful part of intervention, how to position infant, anticipated infant response), skin-to-skin contact with caregiver in position of comfort, and preemptive analgesia with sucrose and non-nutritive sucking or breastfeeding.[13]

In children, developmentally appropriate procedural preparation is important to help reduce pain perception. This includes counseling parents or caregivers on how to respond to their child in pain and how to support their child's positioning and coping during the procedure. Children should be offered guidance on what to expect from the procedure, with attention to how the child will be supported and what role the child will have in the procedure (i.e., counting, taking deep breaths, holding caregiver's hand, staying still). Children may benefit from medical play prior to the procedure to destigmatize the tools and environment (i.e., water play with needleless syringes, tour of casting room or lab draw station prior to procedure time). Child life specialists may be helpful in supporting the child's coping in a developmentally appropriate manner.

Children should be allowed to help with determining their positioning for the procedure in a way that supports comfort and safety. For toddlers, a hug position with arms and legs wrapped around parents may allow one arm free for intramuscular injection or phlebotomy procedure. School-aged children may prefer to sit on a parent's lap or in a chair facing away from the affected body part. For procedures around the eyes or face, children may prefer their head supported by a caregiver. Children should be allowed to hold a support object (stuffed animal or blanket) if desired and safe. When possible, avoid painful procedures in the child's hospital bed to allow this to be a safe space. Procedure rooms or sitting outside of the bed are alternative settings.

Children may benefit from visual stimulus such as pictures or moving lights. Distraction techniques include video games, having children identify objects in a book, singing a song, or listening to music. Hypnosis techniques may also reduce children's perception of pain.[14] Application of cold and vibration stimulus has also been shown to reduce pain during intravenous line starts.[15]

Preemptive analgesia is appropriate for procedures when pain is expected. This may include topical analgesia (lidocaine-based creams EMLA, LMX-4) or a needleless injection of lidocaine (J-Tip). Pharmacologic therapies are similar to those used in acute pain management, noting that onset and duration of action are

Table 64.3 Observational pain scales for infants, toddlers, and children

Age	Scale	Parameters	Comments
Infants (0–6 months)	CRIES	Assess *C*rying, *R*equired oxygen, *I*ncreased vital signs, *E*xpression (facial) and *S*leepiness. A score of 0–2 is given for each parameter based on changes in the patient's baseline	Score out of 10
Infants and Toddlers	FLACC	Assesses *F*ace, *L*egs, *A*ctivity, *C*rying, and *C*onsolability	Score out of 10
Developmentally Delayed/ Cognitively Impaired	Revised –FLACC	Uses same parameters as FLACC but allows for the addition of individualized pain behaviors	Score out of 10 Engage caregivers to help individualize this scale

Table 64.4 Observed pain behaviors

Age	Pain behaviors
Infant (0–12 months)	High-pitch crying Facial grimacing Furrowed eyebrows Difficulty sucking Frequent hiccupping Frequent yawning Avoidance of eye contact or inability to console Change in level of activity Irritability/Restlessness
Toddlers (12 months–4 years)	Facial grimacing Furrowed eyebrows Sleep difficulties Guarding area of discomfort Crying/moaning Decreased interest in play Irritability/restlessness Loss of appetite Needs to be held more than normal
School-aged and Adolescent (5–17 years)	Facial grimace Furrowed eyebrows Difficulty sleeping Crying Guarding area of discomfort Decreased activity level Withdrawn Irritability Anger Change in eating habits Breath holding

important to match with the expected duration of the procedure and resulting pain.

Acute Pain

Acute pain typically lasts less than 30 days and is associated with tissue injury, with improvement of pain as the tissue heals. Pain persisting more than 3 months and after the complete healing of tissue damage is then considered chronic pain. Examples of acute pain include postoperative pain, chemotherapy-induced mucositis pain, and sickle cell vaso-occlusive pain crisis.

Acute pain management includes nonpharmacologic and pharmacologic approaches. Medications should be used in addition to nonpharmacologic interventions—not instead of them. See Table 64.5 for examples of age-appropriate nonpharmacologic interventions for pain management. Updated in 2012, the World Health Organization (WHO) guidelines provide clinicians the basic tenets for the use of analgesics for pediatric pain management[16]:

1. Use a two-step strategy for pain medications, also referred to as "by the ladder."
2. Dose medications at regular intervals: "by the clock."
3. Use the least invasive route of administration: "by the mouth."
4. Adapt the treatment to the individual child: "by the individual."

Table 64.5 Nonpharmacologic interventions for pain management

Age	Nonpharmacologic interventions
Infant (0–12 months)	Cuddle/swaddle infant Skin-to-skin care Massage Dim lights Lower voices/noise Non-nutritive sucking (pacifier, bottle) Music Breastfeeding Physical therapy
Toddlers (12 months–4 years)	Positioning for comfort and control Distraction (storytelling, reading favorite book, games, play with toys) Art and music therapy Massage Guided imagery/visualization Physical therapy Relaxation through deep breathing (using bubbles or pinwheel) Heat or cold therapy
School-aged and Adolescent (5–17 years)	Positioning for comfort and control Environmental changes to promote safety Dim lights Procedural preparation Relaxation through deep breathing Guided imagery/visualization Distraction (television, reading a book, video games, board games) Art and music therapy Acupuncture (>8 years) Massage Hypnosis Aromatherapy Heat or cold therapy Physical therapy Biofeedback

Using a Two-Step Strategy

The pediatric two-step strategy replaces the three-step analgesic ladder introduced by the WHO in 1986. Like the three-step ladder, the two-step strategy outlines medications to be used based on the child's pain severity, but no longer recommends the use of weak opioids (e.g., codeine) for moderate pain. For mild pain, Step 1 treatments are nonopioids including acetaminophen and/or ibuprofen (or an alternative nonsteroidal anti-inflammatory); see Table 64.6 for Step 1 medications and dose recommendations. If the child has moderate to severe acute pain related to tissue injury, then Step 2 treatments are strong opioids, and these should be used in conjunction with Step 1 treatments. See Table 64.7 for Step 2 medications and dose recommendations.

Table 64.6 Treatment of acute pain Step 1: Mild pain, nonopioids

Medication	Route	Term neonate–6 months	6 months–12 years	>12 years	Maximum daily dose	Comments
Acetaminophen	PO, IV, PR	10–15 mg/kg/dose q4–6h	10–15 mg/kg/dose q4–6h	650–1,000 mg q4–6h	75 mg/kg/day or 3,000 mg	Avoid use in hepatic impairment; requires dose adjustment in renal impairment
Ibuprofen	PO		5–10 mg/kg/dose q6–8h	400–800 mg q6–8h	40 mg/kg/day or 2,400 mg/day, whichever is less	Chronic use increases risk of thrombotic events, gastrointestinal (GI) bleed, and renal impairment; may impair platelet aggregation
Naproxen	PO		5–7 mg/kg/dose q8–12h	250 to 375 mg q12h	1,000 mg/day	Chronic use increases risk of cardiovascular thrombotic events, GI bleed, and renal impairment
Ketorolac	IV		0.5 mg/kg q6–8h	15–30 mg q6h	120 mg/day	Increases risk of bleeding, stroke, GI bleed, cardiovascular events, and renal impairment Maximum duration of use 5 days
Celecoxib	PO		10–25 kg: 50 mg q12h	100–200 mg/day	400 mg/day may be used short term	Chronic use increases risk of cardiovascular thrombotic events, GI bleed, and renal impairment

Table 64.7 Treatment of acute pain Step 2: Moderate to severe pain, opioids

Medication	Route	Pediatric starting dose	Adult starting dose	Comments
Fentanyl	IV	0.5–2 mcg/kg IV bolus every 5 minutes–1 hour, 0.5–3 mcg/kg/hr continuous infusion	25–50 mcg/dose IV bolus every 5 minutes–1 hour, 25–200 mcg/hr continuous infusion	Skeletal muscle and chest-wall rigidity can be seen with rapid intravenous dosing Has no active metabolites and is considered relatively safe to use in patients with renal failure
	Intranasal	1.5 mcg/kg once (maximum: 100 mcg/dose); may repeat 0.5 mcg/kg every 5 minutes to a max of 3 mcg/kg given	100 mcg/dose	Use IV preparation
	Transdermal patch			Not intended for opioid–naive patients Half-life 20–27 hours, steady state reached after 2 sequential 72–hour patch applications Refer to Duragesic patch package insert for dose recommendations when converting from another opioid to a fentanyl patch
	Transmucosal (i.e., sublingual, buccal)	Not approved for use in children, could consider for adolescents receiving end-of-life care	100–200 mcg	Available as a lozenge, dissolving tablet, buccal film, sublingual spray Onset of action 5–15 minutes
Hydromorphone	Oral	0.03–0.08 mg/kg/dose q3-4h as needed	1–4 mg/dose q3-4h as needed	Use with caution in renal impairment (inactive metabolite accumulation can lead to neurotoxicity)
	IV	0.01 mg/kg/dose q3-6h as needed Continuous IV infusion: 0.003 to 0.005 mg/kg/hour	0.2 to 1 mg q2-3h as needed	

(*continued*)

Table 64.7 Continued

Medication	Route	Pediatric starting dose	Adult starting dose	Comments
Methadone	Oral	0.1 mg/kg/dose q4h for 2–3 doses, then q6-12h	Initial 5–10 mg; dosing interval may range from 4–12 hours during initial therapy; decrease in dose or frequency may be required (~2–5 days after initiation of therapy or dosage increase) due to accumulation with repeated doses	Not recommended for opioid naive patients Long and unpredictable half-life of 5–100 hours Used in management of opioid dependence and weaning
	IV	0.1 mg/kg/dose q4h for 2–3 doses, then q6-12h as needed; maximum dose: 10 mg/dose	2.5–10 mg q8-12h; titrate slowly to effect	Helpful in treatment of neuropathic pain given its NMDA receptor activity and has some inhibitory effect on the reuptake of serotonin and norepinephrine Use with caution in hepatic impairment, metabolized primarily by liver QTc prolonging drug, consider checking EKG prior to initiation and with dose titration
Morphine	Oral	0.2–0.5 mg/kg/dose q3-4h as needed	5–15 mg q4h as needed	Use with caution in renal impairment (inactive metabolite accumulation can lead to neurotoxicity)
	IV	0.05–0.2 mg/kg/dose q2-4h as needed continuous infusion: 0.01–0.04 mg/kg/hr	2–5 mg q2-4h as needed continuous infusion: 1 mg/hr	
Oxycodone	Oral	0.1–0.2 mg/kg/dose q4-6h as needed	5–15 mg/dose q4-6h as needed	

Opioids with Limited or No Use in Pediatrics

Medications that have limited uses in pediatrics include nalbuphine (Nubain), a mixed opioid agonist-antagonist. Nalbuphine can be helpful for an opioid-naive, postoperative patient whose acute pain is expected to get better quickly or to treat opioid-induced itching. Nalbuphine is not recommended for patients with pain that is expected to get worse before getting better (if it is expected to get better at all); in this case, a strong opioid is recommended.

Combined opioid and acetaminophen products should only be used with caution in children given the risk of dosing errors with both opioid and acetaminophen contents[17] and risk of hepatotoxicity with acetaminophen overdose. In pediatrics, it is preferred that the medication components be dosed and administered separately, even in acute surgical pain. For some children, surgical pain may be well-controlled with acetaminophen taken together with a nonsteroidal anti-inflammatory drug (NSAID). Others may benefit from having an opioid available as a separate third-line agent for breakthrough pain. This depends on the anticipated pain severity and recovery time. For children with disease-related pain that is expected to worsen over time, fixed opioid and acetaminophen combination products limit the flexibility for opioid titration at home since the dose is limited by the recommended daily acetaminophen maximum. If the opioid and acetaminophen are separated, the patient can take the same opioid scheduled around the clock and as needed for breakthrough pain.

The US Food and Drug Administration recommends against the use of codeine and tramadol in children and adolescents given the risk of oversedation with associated respiratory depression and potential death.[18] Both codeine and tramadol are prodrugs and must be metabolized by the body into their active metabolite to produce analgesia. There is genetic variability in metabolism: those persons who are ultra-rapid metabolizers will have too much of the active metabolite in their body too quickly and potentially suffer the side effects of opioid-induced respiratory depression.

Dosing at Regular Intervals

When pain is constantly present, analgesics should be administered at regular intervals, not simply on an as-needed (PRN) basis. With as-needed dosing, the risk is undertreatment and uncontrolled pain. The addition of as-needed or "rescue dose" to scheduled analgesia is appropriate for breakthrough pain.[19] This can be achieved by using one or more routes of medication administration.

Case Study: A Patient in Pain Crisis

Molly is a 12-year-old admitted to the hospital for acute vaso-occlusive pain crisis secondary to sickle cell disease. For the 48 hours prior to admission, she had been taking oxycodone 7.5 mg orally every 4 hours, with an additional oxycodone 5 mg orally every 1 hour as needed for breakthrough pain. She typically began this regimen at the onset of acute pain crisis symptoms. On admission, Molly and her father reported that she had taken 17.5 mg of oxycodone in the prior 4 hours with only minimal pain relief. She received heat packs to apply to painful sites, distraction with movies, intravenous hydration, and scheduled intravenous ketorolac, and was started on a patient-controlled analgesia (PCA) pump (morphine 1 mg/hr plus a 1 mg demand dose every 10-minute lockout) since she was complaining of upset stomach and was unable to tolerate any more oral medications. After several hours, she had improved pain control and was using her demand dose on average once per hour.

By the Appropriate Route

Analgesics should be administered by the simplest, most effective, and least painful route making oral analgesics preferred if possible. The intramuscular route is to be avoided given its painful administration. Alternative routes of administration, including buccal, intravenous, intranasal, subcutaneous, rectal, or transdermal, should be used when the oral route is not available or based on clinical judgment and patient preference.

Case Study: Varying the Route of Medication Delivery

Heather is an 8-year-old with spinal muscular atrophy who was preparing for hospital discharge following spinal fusion surgery. She had been hospitalized for 4 weeks and required high-dose opioids for pain control during her intensive care stay. The critical care unit had been reducing her intravenous hydromorphone doses over time to avoid withdrawal symptoms, without need for breakthrough dosing. Heather had severe gastroparesis at baseline and was dependent on total parenteral nutrition. She had a gastrostomy tube, but her mother reported that medications appeared to "just come right back out" when her gastrostomy tube was vented. The team decided to transition her from her intravenous hydromorphone to buccal concentrated morphine for home use and expected her to continue her opioid wean as an outpatient.

Treatment for the Individual Child

Consideration should be given to other sources of nonopioid-responsive pain and distress (emotional, existential, spiritual) and non-pain symptoms that children may report as pain (constipation, spasticity, gastrointestinal upset). Analgesic regimens should be multimodal, including both nonpharmacologic and pharmacologic strategies; combination therapy of nonopioids, opioids when necessary, and adjuvant medications for neuropathic pain may be utilized.[16] Analgesic regimens should target the primary source and pathophysiology of the individual child's pain. The child's age and ability to metabolize medications should also be considered. Opioid regimens should be tailored and titrated on an individual basis, taking into consideration a child's previous opioid exposure and response. There is no absolute maximum dose of opioids; the appropriate dose achieves desired pain relief with side effects tolerable to the patient and caregivers.

Neuropathic Pain

Neuropathic pain occurs when there is damage to a nerve either by chemical damage, nerve compression, or prolonged excitation. On physical exam, there may be autonomic changes to the affected area including changes in skin color, skin temperature, or edema. There may be sensory abnormalities (Box 64.2) and motor function changes (as evidenced by decreased strength or diminished reflexes). A child may describe a burning sensation, "prickling," numbness, tingling, "pins and needles," shock waves, or shooting pain. Some children may not have the vocabulary to describe neuropathic pain characteristics. Neuropathic pain can be constant or intermittent. Common causes of peripheral neuropathic pain in pediatrics include medications (i.e., chemotherapy), metabolic conditions, tumor compression of the nerve root, and nerve compression caused by musculoskeletal abnormalities such as scoliosis in neuromuscular disease. Recent surgery can be a risk factor for peripheral neuropathic pain. *Central pain syndromes* can occur as a result of a malformation or damage to the central nervous system. Children with severe neurologic impairment are at risk for neuropathic pain.[10] Severe neurologic impairment may result from injury (severe anoxic brain injury), congenital brain malformation (schizencephaly or lissencephaly), or metabolic disorders (mitochondrial cytopathy, Leigh's syndrome).

Box 64.2 Sensory Abnormalities Seen in Neuropathic Pain Syndromes

- *Paresthesia*: An abnormal (not unpleasant) sensation, whether spontaneous or evoked
- *Dysesthesia*: An unpleasant abnormal sensation, whether spontaneous or evoked
- *Allodynia*: Pain due to a stimulus that does not normally provoke pain
- *Hyperalgesia*: Increased pain from a stimulus that normally provokes pain

Neuropathic pain treatment is focused on decreasing the firing of the ascending pathways and increasing the descending or inhibitory pathways of the peripheral and central nervous systems. Gabapentin is most commonly used in pediatrics as it is available in liquid formulation and has a limited side-effect profile. In pediatric orthopedic surgery patients, gabapentin and clonidine have been shown to decrease postoperative opioid use, decrease hospital length of stay, and improve functioning postoperatively.[20] Serotonin norepinephrine reuptake inhibitors may be helpful for patients with neuropathic pain and comorbid depression. Methadone and ketamine (oral or intravenous) may be indicated when patients are experiencing severe neuropathic pain requiring opioids with minimal relief.[21] Table 64.8 details medications used to treat neuropathic pain; medications are listed in what would be a stepwise approach. The medications used to treat peripheral neuropathic pain and central neuropathic pain syndromes are the same. Concurrent treatment with physical and occupational therapy supports improved functioning and reduction in pain over time.[22]

Case Study: A Pediatric Patient with Peripheral Neuropathy

Brittany was a 17-year-old girl with leukemia who was hospitalized for continued chemotherapy. She had severe chemotherapy-induced peripheral neuropathy in her hands and feet. She cried when her hands or feet were lightly touched by her bed sheets. On exam, she was sedated, her hand grasp was extremely weak, and she was unable to stand due to pain and lethargy. She was receiving hydromorphone PCA of 1.5 mg/hr plus a 2 mg demand dose with every 20-minute lockout. Brittany was engaging in a function-focused rehabilitation plan with desensitization through physical and occupational therapy. Meditation, animal-assisted therapy and art therapy supported her coping with pain. She was receiving scheduled acetaminophen, oral gabapentin 1,200 mg three times a day, and clonidine 0.3 mg/24 hr transdermal patch. She had pancytopenia following chemotherapy and was thus unable to take NSAIDs. She was started on a ketamine infusion and achieved improved pain control within 24 hours. Over the course of the next week, the hydromorphone PCA was able to be weaned with

Table 64.8 Medications used in the treatment of neuropathic pain and chronic pain syndromes

Medication or drug class	Route	Dose	Titrations	Comments
Gabapentin (Neurontin)	PO	Start 2–5 mg/kg/dose qHS	Titrate every 1–4 days by 5 mg/kg/day until effective analgesia Minimum effective dose for children <5 years 40–60 mg/kg/day; children >5 years 30 mg/kg/day Maximum dose 50–75 mg/kg/day (2400–3600 mg/day) divided tid Children with severe neurologic impairment may require higher doses	Monitor for side-effects: nystagmus, sedation, tremors, ataxia, swelling May see increase fatigue/sleepiness when initiating or titrating May give 50% of total dose in evening if symptoms occur mostly overnight
Pregabalin (Lyrica)	PO	Start 0.3 mg/kg qHS Adults: 150 mg divided bid–tid	Titrate every 3 days to 1.5 mg/kg/dose bid (max 6 mg/kg/dose) Adults: titrate in 1 week to 300 mg divided bid–tid, max daily dose 600 mg	
Clonidine	PO, TD	Day 1–3: 0.002 mg/kg qHS	Day 4–6: 0.002 mg/kg bid; Day 7–9: 0.002 mg/kg tid	PO and TD daily dosing is equivalent, but TD patch takes 2-3 days to reach full effect Monitor blood pressure
Tricyclic antidepressants	PO	Nortriptyline: Start 0.1 mg/kg qHS, titrate up to 0.5 mg/kg, max 1 mg/kg		Nortriptyline has less anticholinergic effect than amitriptyline Given at night can help with sleep
		Amitriptyline: Start 0.1 mg/kg qHS, titrate up to 0.5 mg/kg, max 1–2 mg/kg		
Serotonin norepinephrine reuptake inhibitors	PO	Duloxetine: 20 mg qHS, titrate up to 60 mg QD, max 60 mg bid, cannot be crushed		
		Venlafaxine: 12.5–37.5 mg daily ×1 week, then bid, then increase by 12.5–37.5 mg every week, max 225 mg/day; immediate-release tabs can be crushed		
Methadone	PO, IV	0.1 mg/kg/dose q6-12h		Strong opioid with NMDA receptor channel blocker Long and variable half-life, 3–60 hours, requires prescriber to be skilled in methadone use
Ketamine	PO, IV	PO: 0.2–0.5 mg/kg/dose tid–qid[19] IV: 0.06–0.3 mg/kg/hr	PO: can titrate to 1 mg/kg/dose	NMDA receptor channel blocker Ketamine may reduce opioid tolerance allowing for opioid dose reduction
Cannabinoids	PO	Dronabinol (Marinol) 2.5 mg PO bid, max 20 mg/day		In some states, medical marijuana has been approved for use in pediatric patients

Source: Adapted from J. Hauer's "neuro-pain" ladder described in Reference 10, as well as the adjuvant analgesics recommended in Reference 23.

continued pain control, less sedation, and improved functioning. She was eventually transitioned off her hydromorphone and ketamine infusions and onto scheduled oral methadone, which was continued after hospital discharge and then slowly weaned over the next 3 months as her neuropathy resolved. She continued outpatient physical therapy and psychotherapy for support of her symptoms.

Chronic Pain

Pain is considered chronic if present for more than 3 months. It is often divided into two subcategories: *cancer pain* and *chronic nonmalignant pain*. Examples of chronic nonmalignant pain conditions seen in pediatric patients include avascular necrosis, musculoskeletal pain secondary to neuromuscular deformities, and abdominal pain in patients with inflammatory bowel disease. In chronic nonmalignant pain, pain persists even after the tissue injury has healed.

Treatment of chronic pain in children should use a multimodal approach, including interventions to address the physical and emotional impacts of chronic pain, such as pharmacotherapy, physical therapy, and psychotherapy.[23] The goals of treatment are primarily to improve function and coping because pain frequency may not change.[24] Improvement in daily functioning, mood, and sleep may occur over weeks to months with adherence to medication, exercise, and psychotherapy.

Opioids are appropriate for chronic use in cancer patients who have clear tissue injury or malignant disease. Opioids are not indicated for use in nonmalignant chronic pain and should be avoided given their limited benefit long-term, risk of side effects, and risk of abuse.[25] In nonmalignant chronic pain, pharmacologic treatment should target neuropathic etiologies[23] (refer to Table 64.8 for recommended medications). Children should be empowered to continue daily functioning despite pain and encouraged to maintain a healthy lifestyle with good sleep hygiene, daily exercise, and good nutrition. Appropriate referrals to physical therapy, occupational therapy, psychotherapy, and psychiatry should be made as needed. Comorbid depression and anxiety are commonly seen in patients who experience chronic pain and should be treated accordingly. Psychotherapy can be especially helpful for patients to learn and practice coping techniques such as guided imagery, self-hypnosis, cognitive-behavioral reframing, and progressive muscle relaxation. Grief support may be helpful if children have experienced a loss or an anticipated loss due to illness (e.g., loss of independence or functioning, amputation of limb, loss of normal childhood experiences, death).

Case Study: A Pediatric Patient with Chronic Pain

Alice was a 15-year-old girl (45 kg) with Charcot-Marie-Tooth disease and subsequent scoliosis and muscle weakness. She complained of several months of constant pain to her low back and right hip (sore, with shooting and tingling) and an intermittent shooting pain down her right leg. She took oral gabapentin 600 mg three times a day and diazepam at bedtime because pain limited her restful sleep. She also took oral oxycodone 5 mg every 4 hours as needed and as prescribed by her orthopedist; she used on average 1 dose per day. Alice was referred to outpatient physical and occupational therapy, massage therapy, and a psychologist for support in coping with her chronic illness and chronic pain. She was also started on oral amitriptyline 25 mg at bedtime to help with chronic neuropathic pain secondary to scoliosis, and the team hoped the anticholinergic effects of amitriptyline would also help Alice sleep. She was seen a month later in follow-up and stated that she saw an improvement in her sleep with the first dose and that her pain improved over the next few weeks in alignment with functional improvements brought on by concurrent physical therapy. She continued to take her gabapentin in addition to her amitriptyline but had not needed to use any diazepam or oxycodone in the past month.

Medical Marijuana in Pediatrics

Many states have adopted laws legalizing the use of medical marijuana, but it remains illegal based on federal law in the United States. Given this, there is a lack of research on the risks and benefits of medical marijuana in the pediatric population. Medical marijuana for children became popularized by case reports of its benefit in the treatment of epilepsy.[26] The use of medical marijuana for the management of pain is uncertain, and there are insufficient data to strongly support or refute its use for pain.[27] Parents whose children are suffering from refractory symptoms such as pain, muscle spasms, and seizures may be open to trying anything that may help. The nurse should know the status of the medical marijuana laws in his or her state, eligibility criteria, and the process to obtain medical marijuana. The patient and the family may want to consider consultation with a pain or palliative care specialist. Nurses should remain open to the conversation with parents/families as together we learn more about medical marijuana.

Conclusion

The plan of care for assessment and management of pain in children should be individualized, with an understanding of developmental and behavioral norms taken into consideration. Children and families facing serious illness desire to be engaged and empowered in their care, and the palliative care clinician should include them in order to best manage the child's pain. The common conditions seen in pediatric palliative care are different from the adult population: however, children still experience the same types of pain.

CHAPTER 65

Supporting Adolescents with a Parent in Hospice

Denice Sheehan, Pamela Stephenson, M. Murray Mayo, Diane Snyder Cowan, and Dana Hansen

Key Points

- Parentally bereaved adolescents are at higher risk for emotional and psychosocial distress than their nonbereaved peers.
- Family communication and support are critical to the adolescent during this time.
- The work of assisting adolescents with spiritual issues during and after the death of a parent will often fall to providers who must be able to recognize and assist adolescents in spiritual crisis.
- Despite the challenges of meeting and establishing rapport with adolescents, teens are interested in being involved with the hospice team.

Introduction

The National Hospice and Palliative Care Organization reported that approximately 175,000 people between the ages of 34 and 64 years died while in hospice care in 2012[1]; many had adolescent children. Adolescents struggle to process their "new world" that includes a dying parent during the final months of a parent's life, making this an especially stressful time for them.[2] Although parentally bereaved children may experience long-term effects, including greater rates of early mortality,[3] they are likely to show the greatest distress just prior to the parent's death.[4]

Adolescent Development

Adolescents whose parents are near the end of their lives are a unique population. While they experience the normal challenges of adolescent development, including rapid physical changes and concerns about their appearance, as well as developing their identity, establishing autonomy, seeking independence from parents, and focusing on peer and romantic relationships,[5] they are also experiencing the stressors of having a parent who is dying. Their homes are often transformed into "death's waiting room."[6] Other stressors include caretaking responsibilities, restrictions on time spent on school activities and socializing with friends,[2,7] witnessing the parent's symptoms and physical decline,[2,4,7] fear of abandonment and family dissolution,[2] isolation from peers, and attempts to maintain normalcy by suppressing or minimizing feelings of distress.[2,8]

Bereaved children are at a greater risk for emotional and psychosocial distress than nonbereaved children. Some of the most common psychological problems among youth facing parental death during the first year and persisting into the second year after the death are anxiety, depression, personality disorder, and posttraumatic stress disorder.[9,10] Gender and age have been associated with parental bereavement, with the highest rates of problems being reported by younger boys. Approximately 31% of bereaved youth exhibited increased grief reactions 9 months after a parent's death; the rate decreased slowly over time.[11] Children and adolescents with complicated grief or prolonged grief reactions showed higher levels of functional impairment.

Prolonged grief in youth and in the surviving caregiver predisposed the children and adolescents to an increased incidence of depression. Parentally bereaved children and adolescents were found to be at higher risk for major depression and alcohol or substance abuse 21 months after the parent's death compared to the normed group.[9] Bereaved youth with a history of depression were at increased risk of depression during the first 9 months following the death and at 21 months post death. Depression in the second year was found to be associated with losing a mother, blaming others, low self-esteem, negative coping, and complicated grief. Youth experienced more difficulties at work, less well-elaborated plans for career development, lower peer attachment, and diminished educational aspirations at 62 months post parental death.[12] When parentally bereaved children were not given clear and honest information during appropriate time points throughout their parent's illness and at the time of death, relevant to their understanding and experience, they experienced distress as children and adults.[13] When children and adolescents feel included and supported through their social network, distress is minimized.

Adults commonly want to protect children and adolescents from the pain of death, dying, grief, and loss. Western culture promotes the perception that if death is not discussed, the loss has less impact. However, death is a constant in the lives of adolescents. They are aware when plants, pets, and people die. Movies, television, video games, and books in school include themes and images related to death, which can reinforce illusions and misinformation about the topic by the teen years. Grief needs to be validated, and adolescents need to be supported. Often adults' hesitancy to discuss death with grieving adolescents isolates the adolescent from his or her own experience and from others.

Becoming independent, developing and maintaining friendships and relationships, and determining a focus for the adult world are paramount during adolescence.[14] Although teens have the ability to talk about their emptiness, pain, and hurt, they are often unwilling or unable to share these feelings with others. Feelings of grief may be intense and changeable, and the adolescent may fear these feelings. It is common for a grieving adolescent to experience decreased motivation or the ability to concentrate for long periods of time, making school work more challenging.

Teens have a cognitive understanding of and a philosophical, speculative interest in death. However, they are only beginning to grapple with it spiritually and often ask theoretical questions about what happens after death. They are able to distinguish between body and soul and engage in discussions about the deceased but often do not literally believe the dead go to heaven. Teens preoccupied with questions about life after death are sometimes skeptical of the existence of an afterlife. The death of a parent or someone close adds another dimension, as the teen might have just begun to appreciate this person from the perspective of a young adult like him- or herself. Furthermore, the death of the parent includes the loss of a personal history, continuity in their lives, and someone with whom the adolescent talked to and shared ideas, thoughts, and feelings.[15]

Adolescent Grief

The Harvard Child Bereavement Study followed 70 families for 2 years after the death of one parent. While the study has never been replicated, it is widely accepted among grief counselors. The study's findings include teens' increased levels of social withdrawal, anxiety, and social problems 2 years after the death. Mother loss was associated with more emotional and behavioral issues, especially for teenage girls. Children who adapted better were from cohesive families in which there was open conversation about the deceased parent. The most powerful predictor of adjustment was the functioning level of the surviving parent. Support, nurturance, and continuity were identified as three needs of the adolescent after the death.[16]

Anticipatory grief is often present when the parent is dying in hospice or is in palliative care. It can be present in the face of a chronic illness, where there is a continuum of losses including physical, functional, and cognitive decline as the disease progresses. Anticipatory grief does not take away or lessen the pain of grief after the death, but it does allow time for the family to come together. Thus, it can be a time for parents to talk about the anticipated death, address questions, and hopefully empower one another for when death occurs. It's a time to share feelings and concerns, and talk about and solve problems, as well as acknowledge that the death is not preventable.

Disenfranchised grief is not publicly acknowledged or socially sanctioned. The grief of adolescents is often disenfranchised, and they are frequently referred to as "invisible" or "forgotten mourners." The fear of social disapproval, of losing control, and peer perception of grief reaction impacts how adolescents express their grief. Parents create the social norms for the grief experience. Their belief or lack thereof about the impact of the loss can disenfranchise the grief.[17]

Secondary losses, which are physical or psychosocial losses resulting from the initial loss, occur with the death of a parent. These losses include not only relationship roles (confidant, companion, caregiver, etc.) but also intangible losses (dreams, hopes, self-esteem, meaning, and purpose). Sometimes the adolescent was the caregiver for the parent or played a smaller but still critical role in the household by engaging in chores, meal preparation, and care of younger siblings.[2,18] Teens may grieve the loss of that role. In addition, there are losses that occur over time. Adolescents revisit the meaning of their parent's death as they give away the parent's clothing, as memories fade, and as they experience their physical absence at significant events (prom, graduations, college selection, weddings, etc.). Each secondary loss results in its own grief reaction and needs to be mourned.[18] When others don't understand this grief process or reaction, the adolescent often feels unsupported.

Gender differences play a role in grief reactions. Males seem to be concerned with loyalty and solidarity, whereas females are more involved with meeting each other's needs. There are also differences in societal expectations about how children should behave. Early on, children learn their family's scripts and messages on how to react to a death. Girls are frequently given more leniency in expressing their feelings than boys, who may try to be more rational and logical. With traumatic loss, males may manifest their grief in expressions of anger and rage, whereas females typically turn their anger inward.[19] Regardless of gender and parental expectations, adolescents will grieve in their own way. Box 65.1 lists examples of the ways adults can support grieving adolescents.[20]

Telling Adolescents about a Parent's Life-Limiting Illness and Death

Telling adolescents about a parent's life-limiting illness and death is very difficult, especially when the family members struggle with communicating with each other.[21] Protecting the child from the potentially harmful effects of bad news is often a dilemma.[22] Worry and concern about the child's emotional reaction to a parent's imminent death may be a reason for lack of communication.[23] Healthy adaptation to parental loss is more likely to occur when families share information and openly express feelings of anger, guilt, and sadness about the deceased person.[20,24,25]

Parents communicate with their children in a variety of ways, ranging from neither parent talking about the impending death to both parents actively preparing the children for the death.[21] Limited communication often results when the well parent follows the lead of the ill parent until the imminence of death necessitates disclosure. Reasons for lack of communication between teenagers and their parents about a parent's imminent death include one or both parents and their teenage child pretending that the illness was not that serious and parents being unaware that death was imminent.[26] The spectrum of disclosure, covering ways in which adolescents were told about the parent's prognosis, ranges from saying nothing to saying the parent may die. However, often, adolescents speculate that their parent might die no matter what prognostic information they are given.[6,21]

Sheehan and colleagues[21] found that parents disclosed information about the progression of a parent's life-threatening illness and death that was intended to inform the adolescent and ease his or her distress. The process remained fairly consistent throughout the

Box 65.1 Ways to Help Adolescents Who Have Lost a Parent or a Loved One

- *Ongoing assessment*: Adolescents at high risk for complicated grief should be identified and monitored. Due to the prolonged and lingering effects of grief and grief triggers, reactions can manifest at any time.
- *Grieving adolescents need to share their story*: Adults can look for opportunities to listen to their story.
- *Peer support groups*: Because peers and friends are so important in this stage of development, adolescent peer support groups are very valuable. Members discover that their feelings are normal and that they are not going crazy. Hearing suggestions and receiving support from fellow teens has more power than from well-intentioned adults.
- *Literature*: Many books and movies focus on death and dying. Literature studied in high school classes frequently includes the death of a central character, thus presenting an educational opportunity for coping with grief and loss.
- *Writing may serve a therapeutic purpose for some adolescents who put their grief in words*: Putting thoughts and feelings in journals, letters to the person who has died, poems, and stories give grieving adolescents an avenue to express feelings.
- *Rituals*: Participating in a ritual that becomes a focus for the grief is helpful. Adolescents often incorporate music and slideshows into elaborate memorials. Rituals should be meaningful and are useful to help "say goodbye."
- *Legacies*: Maintaining a relationship with the deceased is valuable. By living a legacy of the deceased, teens not only remember their parent, but also feel they will be remembered themselves.
- *Music plays an important role in the lives of adolescents*: Communicating through music can enhance our understanding of grieving adolescents. Certain songs elicit feelings, thoughts, and memories related to the person who has died. Music can help adolescents share what they are experiencing with someone else and break through the defenses of grief. Adolescents may want to write original music as a tribute to the person who has died or select music that reminds them of their loved one and discuss the lyrics.
- *Art provides a creative outlet for grieving adolescents to create a visual image of their feelings and their story of grief*: They may want to create a legacy, such as a quilt or a memory box. These visual images can encourage communication and support a healthy grieving process.
- *Social media and technology*: Adolescents are high-volume users of social media networks. Learning about deaths in the community as well as sharing information about their own loved one's death is instantaneous in social media and through technology. Online condolences can be both helpful and hurtful. Monitoring the adolescent's usage has advantages and disadvantages. Adults need to be cognizant of the importance of social networks in this stage of development. Good information and support is available online, and more apps are constantly being developed to specifically address grief and loss, suicide ideation, anxiety, and other issues important to teens. Adolescents need to be reminded that information found online may be inaccurate and that anonymity may expose them to painful comments and predators.

Source: From Reference 20.

illness and after the death. Parents shared information in one of four ways in an attempt to make the illness and death "easier to swallow" for adolescents: measured telling, skirted telling, matter-of-fact telling, and inconsistent telling.

Measured telling. Measured telling occurred when the parent told the adolescent about the death in a way that was thoughtfully considered. Parents considered the adolescent's age and emotional state before carefully and rationally determining the nature, the amount of information shared, and the timing of the disclosure. Adolescents felt well-informed but not overwhelmed. The outcomes of measured telling were generally positive.[21]

Skirted telling. Skirted telling occurred before the death, when parents told their adolescents about the illness and imminent death of the parent in an indirect or ambiguous way. Parents did not lie or hide the truth from the adolescents, but they avoided revealing information directly. Parents bypassed difficult information to make the disclosure easier for their adolescent children. Adolescents acted as if the parent was not seriously ill and dying, and told their parents they did not want to discuss the illness. Parents and adolescents agreed about this way of communicating; they did not experience discord in relation to disclosure. Parents thought they were allowing their children to live as normally as possible, and adolescents were satisfied with the information they received. Outcomes for skirted telling were generally positive.[21]

Matter-of-fact telling. Matter-of-fact telling occurred when parents told the adolescent about the parent's life-limiting illness and death in a way that was unemotional and factual. These disclosures focused mainly on practical issues, such as caregiving needs, the death, and making funeral arrangements. These disclosures were described as everyday conversations, rather than as specific incidents in which parents "broke the bad news" to adolescents. Before the death, neither the parents nor adolescents specifically recalled the disclosure, because they were embedded in daily conversations. However, parents and adolescents vividly remember telling and being told of the death.[21]

Inconsistent telling. Inconsistent telling occurred when the parent told the adolescent about the death in ways that were changing and unpredictable. Inconsistent telling before the death involved a mixture of not telling, telling very directly, telling practical information, delays in telling, and telling information that was not true. No consistent patterns of disclosure could be discerned for these families.[21]

The quality of parenting by the surviving parent is one of the most influential resources for helping bereaved children adjust positively to the parent's death.[27] Clinicians can assist bereaved families with disclosure by tailoring strategies in accordance with the family's communication style. For example, families who disclose in inconsistent ways may need help in designing interventions to promote their parenting communication skills and coping. Creating group sessions for bereaved families could assist them in maintaining emotional stability to cope effectively with the stress related to informing their adolescent children about a parent's death.

Living in Two Worlds

Adolescents and their parents have described "two worlds" that constitute the lives of adolescents while their parents were seriously ill and shortly after their death: the well world and the ill world. The worlds had no physical boundaries; they were spheres in which the adolescents carried out practical, daily activities. Adolescents lived their "normal" lives in the "well world," attending school, spending time with peers, and engaging in social activities. They dealt with the life-limiting illness and death of their parents in the "ill world," spending time with their ill parents, visiting them in the hospital or hospice facility, providing care for them in the home, and taking on additional family responsibilities such as household tasks and caring for siblings.

They managed the two worlds in common ways across the duration of the parent's illness and death by keeping the ill world and the well world separate, having the ill world intrude into the well world, moving between the ill world and the well world, being immersed in the ill world, and returning to the well world having been changed by the ill world. They tried to keep their two worlds apart when the ill parent was initially diagnosed with a life-limiting illness. Adolescents wanted life to be "normal" and did not want to be seen as different from their peers.[2]

Keeping the two worlds separate. One strategy they used to keep the two worlds separate was staying busy with well-world activities to keep themselves from worrying about their parent's declining health. One 17-year-old daughter explained, "Being at school is a distraction because it gives me other things to do instead of worry about home, what is making me sad. At school it is like, school mode, [at home it is] home mode." Adolescents distracted themselves from the ill world by going to school, going out with friends, participating in sports, listening to music, writing, playing video games, sleeping, and maintaining their privacy. They also kept the ill world out of their well world by not revealing or discussing their parent's illness and by keeping their friends away from their ill parent. Adolescents who lacked a close relationship with the ill parent found it easier to separate the two worlds.[2]

When the ill world intrudes into the well world. The ill world intruded into the well world as the ill parent's health declined and the adolescent observed the parent getting weaker, changing in appearance, receiving more intense medical treatment, and becoming less able to accomplish daily tasks. Adolescents were especially distressed after a difficult incident, such as when the parent was brought to the hospice facility or something happened at home. During this stage, some adolescents began to accept support from concerned family and friends.[2]

Moving between the two worlds. Moving between the two worlds involved a sense of being vigilant as to when one needed to move from one world to another. The adolescents knew they may be called home from school or from a friend's house to help their ill parent. This was especially true in single-parent families.[2]

Becoming immersed in the ill world. As the health of their ill parents declined further and they grew closer to death, adolescents focused more on their ill parents and their families and gave up many of their well-world activities. They became immersed in the ill world by taking on caregiving responsibilities and spending more time with the ill parent.[2]

Caregiving responsibilities undertaken by adolescents of ill parents were in many cases considerable. Some did extensive household tasks, provided personal care for the ill parent, and cared for siblings. Although some adolescents appreciated the opportunity to care for dying parents and to "help out" their families, caregiving responsibilities could occupy a significant amount of time and feel burdensome. The responsibilities of having a parent near death were especially taxing for adolescents in single-parent families and for those in which the well parents worked outside of the home. Adolescents also became more immersed in the ill world as they spent more time with their families, often choosing to stay home just to "hang out" with their ill parents as they realized there was little time left. During these times, adolescents would offer emotional support and express affection toward the ill parent.[2]

Returning to the well world having been changed by the ill world. The final stage occurred after the ill parent's death and funeral, when adolescents fully resumed their well-world activities. Several adolescents emphasized, however, that they were fundamentally changed by the loss of their parent, and the well world was no longer the same. The well world was different because most others in the well world knew of their parent's death and therefore freely offered support and condolences. Feelings connected to others in the well world were now a comfort for most of the adolescents. Some connected through social media such as Facebook.[2]

Adolescents continued to feel the presence of their deceased parent, and thus many well-world activities were dampened by their sense of loss. They were painfully aware of the parent's absence at home and at athletic activities. Although adolescents continued to mourn the loss of their parents, several expressed a readiness to return fully to the well world, having grown through their loss. These adolescents had a sense that this is what their deceased parents would have wished for them.

Healthcare professionals can use the two-world model as a springboard to initiate conversations about how adolescents are managing their two worlds, explore which stage they are in, and help them decide how they wish to manage the tensions they experience in managing the demands of each world. The role of healthcare professionals and other adults who seek to help bereaved adolescents may change over time; adolescents may reject adult help when they are trying to keep the ill world out of their well world but welcome it when the ill world intrudes.

Adolescent Spirituality

Despite the fact that everyone undergoes spiritual development, spirituality itself is difficult to understand. Nearly every scientific manuscript about spirituality begins with the warning that spirituality has not been suitably defined for research.[28] Understanding spirituality as a phenomenon experienced by adolescents is no less challenging and is further complicated by competing demands of other cognitive, social, and physical developmental processes occurring at the same time.[29]

It is important for providers to understand that spirituality and religion are not equivalent and should not be used interchangeably.

Spirituality is a personal, unique, and subjective experience, and religion is a collection of dogmatic rituals and practices shared with others belonging to a specific community.[29] Viewing spirituality as religion risks alienating those who do not adhere to a particular religious view. This is especially true for adolescents who have not fully formed their religious beliefs. According to a recent Pew Poll,[30] Christianity is the predominant religion in the United States with 70.6% of those polled self-identifying as Christian, 20.8% of whom were Catholic. The same survey reports that 22.8% self-identified as having no religious affiliation and included atheists (3.1%) and agnostics (4.0%). Findings that those without a religious affiliation outnumbered the proportion of American Catholics underscores the importance of recognizing spirituality as an expansive phenomenon that consists of more than just religion. Stephenson and Berry[28] conducted an in-depth review of 40 original research articles to identify the common attributes that researchers used to describe or define spirituality for research. Five common attributes emerged from the data that overlapped to form the essence of spirituality. These attributes—meaning, beliefs, connections, self-transcendence, and value—will be used to frame spirituality for this discussion.

Adolescent Spiritual Development

Erikson described adolescence as a time when youth begin to think abstractly about transcendence.[5] This period aligns well with what Cobb, Kor, and Miller called a period of "spiritual surge"[31(p. 863)]—when adolescents reflect on the meaning and purpose of life events, the development of deep and sometimes romantic connections with others, and the exploration of religiosity. It stands to reason that children in the early stages of adolescent development will have reached fewer spiritual milestones and may struggle more with spiritual insight and expression.[31] This is generalized spiritual development, however, and should be weighed against the maturity and experiences of an individual adolescent.

Benson and Roehlkepartain[32] described adolescent spiritual development as dynamic, interactive, and difficult at times. Specifically, they described three nonlinear processes that adolescents undergo: an awakening to the larger universe around them, realization of their interconnectivity and identity within that universe, and eventual integration as an authentic member of the world around them. This explains how considerably the world changes from an adolescent's perspective of a limited and largely concrete viewpoint to recognition of an expansive and abstract universe in which they must somehow find their place. This shift in perception can be an overwhelming process that becomes more complicated with the death of a loved one.

Adolescent Exposures to Death

More than 2 million children under the age of 18 have experienced the death of a parent. As many as 90% of adolescents will experience what they consider to be a significant death.[29] Early experiences with death are especially challenging for adolescents who are still in abstract cognitive development. Witnessing the death of a loved one produces questions about God, meaning, and religion. Adolescents striving to find meaning in a loss can feel supported or distressed by thinking about spirituality, depending on their spiritual views at the time. Spiritual reflections about a loving God can have a calming influence for some adolescents, while others may feel anger, betrayal, or abandonment by the very God they are trying to understand.[29] Other variables are also associated with spirituality, including previous experiences, family traditions, and available support mechanisms.[32,33] King, Abo-Zena, and Weber[34] documented the importance of key relationships with others as being influential to adolescent spiritual development (e.g., parents, families, peers, community).

What happens, then, when an adolescent's significant relationship is disrupted, as occurs with the death of a parent? Hansen and colleagues[35] described how adolescents remained connected with their deceased parent after the parental death. The ways that adolescents preserved their continued bonds included using memories of their parent as an "inner guide" to help them navigate life after parental death, embracing opportunities to encounter their deceased parent through dream-like states, and collecting mementos of objects previously belonging to the parent. This supports other research showing how spirituality can offer protective benefits for youth at risk for problems associated with a significant death.[36–38] Additional research is needed to understand the role of and extent to which spiritual interventions can mitigate adolescent risky behaviors.

Assisting Adolescents with Spirituality

The spiritual literature describing the benefits of spirituality for adolescents is similar to that of adults. Adults and adolescents can reach out to religious and transpersonal authority figures when life becomes difficult. Dill[37] interviewed 20 urban African American adolescents about their spiritual and religious beliefs and found that participants used prayer to ask God to intervene on their behalf by correcting what they saw as being wrong with their life at the time. This presents new questions for adolescents who ask for divine intervention only to find that their prayers are not answered in the ways they expect. In research conducted to examine how adolescents managed having a parent in hospice a 17-year-old boy who was a self-proclaimed atheist admitted to experimenting with prayer to help his dying father.[33] The question of how this experience will impact the adolescent who already doubts the existence of God should be considered. What short- or long-term behaviors might manifest in response to his grief and disappointment? Holmes and Kim-Spoon[39] found that, among adolescents, a greater belief in an afterlife was associated with less participation in cigarette, alcohol, and marijuana use. Could this adolescent's disbelief in religion and afterlife forewarn the potential of future behavioral risks because of the loss of his father?

Many parents feel ill-prepared to help adolescents with issues they may not understand themselves, particularly when they are immersed in their own grief and suffering. Therefore, the work of assisting adolescents with spiritual issues during and after the death of a parent will often fall to providers who must be able to recognize and assist adolescents in spiritual crisis. Unfortunately, current evidence shows that dimensions of spirituality are often neglected by providers caring for families with adolescent children. Punziano and colleagues[24] conducted focus groups with hospice providers and found several challenges with delivering spiritual care to adolescents, such as the unique needs of adolescents depending on their spiritual development, views of an unacceptable death in a death-denying culture, the emergence of overwhelming negative feelings from the crisis to which the provider had to respond, and the long-term effects of loss. Deterrents from the family perspective included conflict between adolescents who wanted to do more for their parent while they were ill and parents who wanted to protect adolescents from the burden of care.

Adolescents' Interactions with Healthcare Providers

It is well-documented that adolescents with a parent in hospice are under stress and need ongoing support to cope with changing family dynamics and impending losses. In such cases, however, both the parents and patient's hospice/palliative healthcare team (HPHT) must face and overcome a number of obstacles in order to foster the kind of communication that helps teens survive and thrive during and after these pressing times. Researchers are now just beginning to report on some strategic approaches and training programs to help the HPHT reach out to teens in need as well as support parents to understand and respond to the emotional needs of their sons and daughters. In order to help refine these recommendations and ensure a good fit with what teens really need, it is important to hear how teens "size up" the HPHT and, as a result, either make themselves available and amenable or not to assessment and therapeutic interventions. Doing so may help formulate interventions that respond to teens' pressing concerns and counter any resistance they might have to working with the HPHT.

To better understand how adolescents "size up" and respond to the HPHT, researchers[38] interviewed adolescents (n = 30) with a parent in hospice and identified four types of teen–HPHT interactions: (1) no interactions (40%), (2) in-passing interactions (20%), (3) engaged interactions (20%), and (4) formal interactions. Analysis of each interaction type revealed different attitudes toward and appraisals of the HPHT.

No interactions. The most common type of interaction among teens and the HPHT was no interaction. Most indicated that they were away from home, either at school or busy with additional duties (working part-time or catching up on missed assignments due in part to adjusting to their parent's illness) during HPHT visits. When they were home, teens avoided the interaction, assuming that the HPHT's job was to take care of the sick parent and not knowing how to start a conversation and express themselves in order to get the support they needed.[38]

No interactions were a product of other factors as well. Parents may be motivated to protect their children from knowing too much about the severity of a parent's illness and may withhold both information and access to those with information to make the situation appear normal and thus more manageable. Also, teens may present themselves as doing fine in order not to worry and burden the sick parent, despite their potential need for additional care and support. Furthermore, hospice/palliative consults and care requests are often late referrals, leaving little time to assess and work with other family members in addition to the patient. HPHT daily schedules are often full, which forces individual visits to be time-limited and almost by default exclusively patient-focused. Additionally, HPHT members report that they do not have the skills nor do they understand how to assist grieving adolescents and, as a result, fear that they will not have the time to adequately assess and provide needed therapeutic support given the ever-pressing time constraints.[38,40]

In-passing interactions. One step further than no interaction, in-passing interactions occurred when teens were present for at least a brief period of time when the HPHT was providing clinical care to their dying parent. Like the "no interaction" group, teens often left early or arrived late due to conflicting schedules and had little-to-no time to connect with the HPHT provider. Conversations that did result were often brief updates on how the parent was doing or about changes to their status or care. Despite the brevity and lack of focus characterizing many of these encounters, adolescents were often left with the impression that the HPHT was approachable and could be called upon later if needed.[38]

Engaged interactions. In contrast to in-passing interactions, engaged interactions were typically ongoing and of longer duration. Teens and HPHT members were able to find and build on common ground and/or perceived shared similarities. With this foundation in place, teens reported being more relaxed as they developed trust in and felt they could rely on the HPHT member to provide guidance on how to cope with as well as support their dying parent.[38]

Formal helping interactions. The final group reported that the HPHT referred them to healthcare professionals to help with adjustment problems to their parent's illness. These professionals included art therapists, bereavement specialists, and counselors. To the degree that these referrals were on target to meet teens' needs, it appears that the HPHT was able to arrange a sufficient number of interactions to develop a workable relationship to conduct an assessment and develop enough trust to encourage teens to follow through on their recommendations.[38]

Facilitating and Improving Adolescent–HPHT Interactions

Despite the challenges of meeting and establishing rapport with adolescents, teens are interested in being involved. Alvariza et al.[41] report that teens want "1) to be seen and acknowledged; 2) to understand and prepare for illness, treatment, and the impending death; 3) to spend time with the ill parent, and 4) to receive support tailored to the individual teenager's need."[40(p. 313)] To begin, it is important to strategize how to initiate contact and maintain ongoing interactions with adolescents in order to allow the HPHT the time to make assessments and provide whatever therapeutic interventions and/or referrals are needed. Some preliminary work is needed to identify when teens are available to allocate sufficient time to meet and get to know them. Learning about their interests as well as concerns beforehand from parents or other adults in the family helps establish some common ground that may be used to "break the social ice" and ensure a good first impression that the HPHT member is approachable and available.

In addition to establishing and building rapport with teens who have a parent receiving hospice services, HPHT members must have proper training to ensure that the interactions are of sufficient quality to engender the trust needed to provide therapeutic support. The HPHT needs training to be able "to understand normal development, appreciate common grief responses and identify deviations" as a prerequisite for decisions regarding which supportive strategies and resources are appropriate for this age group.[41(p. 275)]

For the HPHT to support grieving adolescents, it is important to understand the psychosocial development of teens in a larger context. According to Erik Erikson's stages of psychosocial development,[5] teens are at the "identity vs. role confusion" stage in which individuating and establishing an independent sense is of primary importance. Losing a parent at this time can be particularly troublesome and anxiety-provoking as teens lose the "mirror" formerly provided by the parent to reflect back to them a sense of self.[42] HPHT must provide support to help teens cope with the loss and, at the same time, engage in the process of reconstructing a new life. In helping with this process, HPHT members will encounter a number of issues that teens will need to confront. Punziano et al.[24] conducted focus group interviews with health professionals to understand their experiences of providing supportive care to teens who lost a parent. Eight therapeutic themes were reported, including the reality of the loss as unthinkable, the loss generating negative emotions, the loss freeing up resources, the loss taking time to process, the loss becoming a catalyst for change, an authentic relationship as central to the loss, being present in the loss, and competent help for dealing with the loss. Navigating these issues with the teens requires the HPHT to strike a balance between addressing the impending loss while encouraging the adolescent to develop an independent sense of self. Attainment of these goals has been shown to improve both the teen's current and future mental health and psychosocial functioning.

CHAPTER 66

Use of Social Media as a Communication Tool for People with Serious Illness and Their Families

Dana Hansen, Amy Petrinec, and Nidal Harb

Key Points

- Social media provides a modern venue for people with advanced serious illness to tell their illness stories.
- Social media provides a venue for people with advanced serious illness to receive support from others.
- Social media provides another way for people with advanced serious illness to communicate with others.

Brief Social Media History and Impact of Social Media

With Web 2.0 came the creation of user-generated content and web-based interaction,[1] which has led to the development of a variety of social media platforms. The advent of this technology has influenced human interaction for individuals and communities; we now interact in ways we could not comprehend just 15 years ago. As the technology evolved, we developed algorithms that facilitated social networking sites to create an interconnection of platforms, which has led to our culture of connectivity.[2] Families with a loved one with serious advanced illness seek support, and social media provides this venue.

Over the past 15 years, use of the Internet and social media has skyrocketed. Today, around 32% of the world's population has Internet connection; in 1995, it was less than 1%. The first billion Internet users were reached in 2005.[3] At the time of this writing (December 2017), more than 4 million blogs and 570 million tweets were written or sent, and close to 2 million people were active on Facebook.[3] Current examples of social media are Twitter, Facebook, YouTube, Tumblr, and Pinterest.[4] To further define social media, the categories listed in Table 66.1 have been offered by Carrigan[4] and van Dijck.[2] In addition, Hootsuite, a social media management platform, offers categories to facilitate our understanding of these sites and why they are used.[5] It is important for the palliative care team to be aware of the types of social media available to patients and families because of their importance as a method for communication during advanced serious illness.

Social media affects multiple aspects of our lives, including the words we use and the meanings they have. Most people know what is meant by social media, Googling, or tweeting. Words like "friending," "sharing," and "liking" have newly understood meanings.[4] The term "well-connected" used to refer to a person of a certain social status; now, it could refer to many followers on one's Facebook page. On social media, these followers indicate "connections" or "friends" and do not discriminate between a close friend versus an acquaintance. For example, a Facebook "friend" may be an acquaintance from high school with whom there is very little interaction in real time. In addition, many close friends and family may also be denoted as "friends" on a Facebook page. In this way, there is no differentiation between family, close friends, and acquaintances with whom there is no face-to-face interaction.

Social media is changing the nature and structure of communication and interpersonal connectivity and serves as a method for obtaining social support, especially during times of crisis or difficulty. The Internet allows for interpersonal, participative, and interactive exchanges of information in a variety of ways, including blogs, Facebook, and Twitter.[6] A theoretical view provides more insight into the evolution of social media related to health and healthcare.

Theoretical View

Researchers have adopted many different theoretical frameworks to study the impact of social media on our everyday lives.[7] Frequently cited theories in this category include Social Aspects Theory, Social Capital Theory, and Social Power Theory. Mass communication theories try to explain the influence of social media on people's behavior. Para-social Interaction, Uses, and Gratification Theory (UCT) highlights this category. However, Social Capital Theory will be examined in depth to understand the role of social media in illness, including research of serious illness such as cancer.

Table 66.1 Categories of social media

Category	Purpose	Examples (not an exhaustive list)
Social network sites	One of the oldest forms of social media Promotes interpersonal contact between individuals or groups Often personal, professional, and geographical connections	Facebook, Twitter, and LinkedIn
User-generated content or media sharing networks	Supports creativity and exchange of amateur or professional content Provides a place to find and share media	YouTube, Instagram, Snapchat, Vimeo, and Flickr
Discussion forums	Older type of social media Used to find, discuss, and share news, information, and opinions	Reddit, Quora, and Digg
Blogging and publishing networks	Regularly updated website or web page Maintained by an individual or small group Can be personal updates and reflections, photos, etc. Often written in a diary style (blogs)	Wordpress, Tumblr, and Medium
Book marketing and content curation networks	Discover, save, share, and discuss new and trending content and media	Pinterest and Flipboard
Trading and marketing sites or social shopping networks	Exist to exchange products Provide comments and experiences from other shoppers	Amazon, Fancy, and eBay
Interest-based networks	Connect with others around a shared hobby or interest	Goodreads, Houzz, Last.fm
Consumer review networks	Find, review, and share information about brands, products, and services as well as restaurants and travel destinations	TripAdvisor, Yelp
Play and game sites	Host games that are social	Angry Birds, Farm Ville

Social Capital Theory

Broadly speaking, *social capital* is the amount of resources accumulated through relationships among people.[8] In Social Capital Theory, *bridging* and *bonding* social capital is discussed. The *bridging* social capital is the weak tie, and the *bonding* social capital is the strong tie. Finally, *linking relationships* refer to the relations of respect and trust between people who interact across power or authority differentials, such as the relationship between teacher and student or physician and patient.[9(p. 655)] Ultimately, the more social capital one has, the more resources and personal relationships one enjoys. Social capital refers to "features of social life—networks, norms, and trust—that enable participants to act together more effectively to pursue shared objectives."[10(p. 56)] The underlying idea of social capital is based on forming social networks. Therefore, people join social networks to form systems, such as social support during serious illness, which they were unable to attain on their own.[11(p. 1)]

In the case of palliative care, people with serious illness may build their social capital by seeking support through social media. Later in this chapter, we will discuss the benefits of people with serious illness connecting with others through illness blogs or other forms of social media such as Facebook. This type of social support is emerging as a valuable resource for the ill person and their family.

The influence of social capital relies on the ability to access and use resources within a social network. This, in turn, facilitates flow of information, influences decision-making, and provides different forms of support for an individual as a member of a social group sharing similar interests and resources.[11] Therefore, the more people one knows and the more relationships and connections one has within a social network, the more resources one can access to, consequently, achieve higher levels of social capital. More importantly, quality matters more than the number of relationships and resources available within a social network, consistent with the proverb, "It's not what you know but who you know that counts."[12(p. 264)] The dynamic interactions of Social Capital Theory can offer insight into the capabilities of a social structure to influence people's behavior within a social network.[13]

Social Media and Social Capital

Social media usage for enhancing personal relationships is a remarkable revolution of the modern era.[14] More importantly, it provides another venue for people with an advanced serious illness and their family to receive support, and it provides new ways to experience intimacy, friendship, and identity in which people can share their experiences with each other in a public display.[14] Social media provides a rich venue for people to share and exchange their experiences, interests, or views regardless of their racial, sexual, or religious identities.[15] Many Internet-based social media applications are available such as Facebook, blogs, Twitter, or Instagram. These applications allow people to share and exchange information using different platforms from texting to photo- or video-sharing.[15] Therefore, social media can be beneficial in building social capital via social networking. Social media has the potential to develop social capital by allowing people with a serious illness to establish and form new social relationships with others or to strengthen preexisting relationships within a social network.[8] This will lead to greater levels of social connectedness,[16] social support,[16–19] self–esteem,[20] experience-sharing,[21,22] management of burdens,[21,23] fostering of awareness,[24] decision-making,[25] and life satisfaction,[26] all of which are important outcomes for both the ill person and family.

The Power of Storytelling

Human beings are storytellers by nature, and the benefits of storytelling in healthcare are increasingly being recognized.[27–29] Storytelling as a fundamental component of nursing knowledge is a long-standing tradition.[30] Social media, in its various forms, also provides a venue to tell a story. In the case of a serious illness, the patient and family receive supportive and often useful comments from their social network in response to the story they are publicly writing on social media. As a narrative communication strategy, storytelling is useful in understanding experiences and communicating health information in an understandable manner with therapeutic health benefits for the teller and the listener.[21,27,31] Therapeutic benefits of storytelling in palliative and hospice care include being heard and creating a shared sense of purpose and connection to others. The sense of purpose (or sense-making) comes through the sharing of the story, and the ill person and family find a new purpose, sometimes described as new self.[32–34]

Social Media and Illness Key Characteristics

Social media expert danah boyd[35] describes the characteristics of social media: persistence, visibility, spreadability, and searchability. Hansen, Sheehan, and Stephenson[36] conducted a phenomenological study exploring the family caregivers of people with a serious advanced illness and their experience with illness blogs. Exemplars from this study demonstrate the following characteristics as described by boyd.

Persistence means that the content of social media is not forgotten. Conversations linger and provide a written history. For example, one participant commented about keeping her loved one's blog "alive" after he died. The content is not forgotten and is a powerful comfort to the surviving loved ones:

> I don't spend quite as much time on it . . . I kind of got it [the blog] at a stage where it gets regular traffic. . . . I guess that ties in with just grieving and wanting to keep things going. When he was doing it [writing the blog] I was kind of like his assistant and it was a team thing and I'm still part of the team, and I'm here, and I'm gonna keep it going.

Visibility refers to the accessibility of the content. In terms of communication of one's illness over social media, the accessibility of these sites increases the ill person's social network. Hansen, Sheehan, and Stephenson[36] found that many family caregivers commented on how their loved one's blog gained support from all over the country or sometimes even the world:

> Well, I think it has a benefit for me [the caregiver]; I feel the support and love she has out there with people I don't even know, that she doesn't even know. I mean, she's got over a thousand followers all over the world and I would say most of them don't know her but they've come across her blog. I think for me, it gives me a sense of hope that you know, she's on a mission.

Spreadability refers to acts of sharing that frequently occur on social media platforms, thus creating a situation known as "going viral."

> Many of them read her blog; either they found it on a Google search or learned about it through the forums [on websites], and it [the blog] became quite well known within the forums. There's not a comment about her, especially at the end, that didn't mention her blog and how it helped them.

Finally, *searchability* simply means the user-generated content on the Internet is searchable; therefore, even if the content has not spread, the content can be found. Hansen, Sheehan, and Stephenson[36] found this was true among their study participants:

> It [the blog] seemed to come up very easily on searchable indexes or Google; searching for some keywords with ovarian cancer and certain treatments seemed to come up with her blog all the time.

Understanding these characteristics as described by boyd helps explain why communicating with family and friends about a serious illness while in palliative and hospice care can be so powerful. The key characteristics of social media allow for sharing of information, mobilizing social support, and fostering self-expression, which are particularly important to individuals with severe illness. Social media can address feelings of isolation as well as reduce the experiences and symptoms of loneliness and depression for some adults facing a serious illness.[37] While any social media forum can be used to communicate one's illness, the following content focuses on illness blogs, Facebook, and Twitter. There are similarities and differences among these venues; however, blogs and Facebook are most similar when used to tell an illness story (Table 66.2).

Types of Social Media Used in Illness

Illness blog. The use of social media in healthcare has also grown rapidly among patients and caregivers.[38] A quick Google search for cancer blogs elicited 51,000,000 results, indicating that even difficult and stressful conversations are occurring on social media. Blogs initiated by patients or caregivers during treatment of a serious illness have increasingly become a way for individuals to give voice to their unique experiences as well as seek support from others in similar circumstances.[39] An illness blog is the story of one's illness posted on a social media platform which, when read and/or responded to by the family, has the potential to increase the social network and support for both the patient and family by increasing their social capital or resources.[40] Although an "illness blog theory" has not been posited in the literature, Heilferty[41] advanced the science with a concept analysis of illness blogs focusing on their applicability to nursing research and the interaction between family and patients. The author reported a theoretical definition of an illness blog as "an online expression of the narrative of illness."

Writing about one's illness on a blog has shown positive results for bloggers, including increased connection with others, decreased isolation, and more opportunities to tell their illness stories.[36] In addition, illness blogs have been found to promote accountability (to self and others) and create opportunities for making meaning and gaining insights from the experience of illness, nurturing a sense of purpose, and furthering understanding of their illness.[42,43] Furthermore, there are potential benefits to family caregivers who interact with their loved one on the illness blog in addition to their daily activities. According to Hansen, Sheehan, and Stephenson,[36] the illness blog, for the family caregiver, becomes a tool for communication and connection with the ill person, which leads to face-to-face conversations and comfort and hope for positive outcomes.

Facebook. Facebook is a Web 2.0 interface designed as a gathering place for its subscribers, where people who may be no more than acquaintances or even strangers become friends. For example, Gage-Bouchard, LaValley, Mollica, and Beaupin[44] reported that interaction on Facebook provided a venue to express cancer-related stories, promote advocacy, and obtain social support. Interestingly, Facebook social support was significantly related to general social support.[18,19] Participants valued the support they received from

Table 66.2 Examples of posts from select platforms

Illness blog, mother of four, breast cancer Published with permission, 10/26/2017	NED!!!! No! Evidence! of Disease! Cancer-Free! Complete Pathological Response! These were the words we heard today from our Super Surgeon, PRAISE GOD!!! The pathology came back clean. Clean lymph nodes. Clean margins. Clean breast tissue. *Chemo did its job! Cancer is nowhere to be found!* These are the words I have dreamed of hearing. And hearing them caused a wave of emotion in me – relief, happiness, thankfulness, awe, and then of course, the tears. Everyone was just happy today. Our doctor said this is the best kind of news to deliver. She looked so happy. Amazing Nurse Practitioner stopped in to say hi and share in the joy. The nurses were all so cheery. Our oncologist is in the Philippines for the next two weeks so I couldn't run up to him and give him the big bear hug that I imagined doing in my mind. At one of our appointments, as our doctor marveled at my shrinking tumor, he said there is a 30% (my husband heard 32% so that's still up for debate) chance that the tumor would shrink to nothing. Nothing. He said we wouldn't know until surgery, but the way he smiled, I knew he was hopeful. I heard him say these words and all I could think of was *there is a chance that the tumor could shrink to nothing. NOTHING.* In that moment, hearing him say those words, I told myself that would be ME. God willing, I would be part of this 30% club. Let's DO THIS! It's been an *awesome* week. It's been a surreal week. I am thanking God for carrying me through the toughest parts of this journey. There were many, many days when I know there was one set of footprints in the sand because I could no longer walk and he was carrying me. We have more decisions, and big ones at that, coming up regarding radiation and some genetic information that we are just learning about. This journey is far from over. I am healing from surgery. Tonight I am going to enjoy watching my girls do a little hip hop number at the high school basketball game. I am also anxiously awaiting joyful news of a new niece or nephew. Most of all, I am smiling from ear to ear that I am officially *NED*! December 3, 2013 has been added to the list of my all-time favorite dates! *Rejoice in the Lord!*
Illness story on Facebook, child with stage IV neuroblastoma With permission, 10/26/2017	I'm watching my son sleep for what we hope and pray is his last night ever on the Hematology/Oncology/Transplant HOT unit. If all goes well, we can leave on Fri night after he is unhooked from his final infusion. My husband came by tonight and the three of us hung out, played, and finally snuck out into the halls after his pca (pain meds) were done for the night. We reflected on how different things are now from our first night here on HOT. That day 14 months ago my son came out of day surgery for his cvl placement and we were taken directly up here. My husband and I were terrified. Still in shock of the diagnosis. Wondering what in the world we were getting into. Scared for the future. Feeling certain there had been some kind of mistake. This couldn't be happening to us. To him. To our baby boy. That night the nurses came in and hooked up his brand new cvl to lines and a pole. Our vocabulary quickly expanded to include words like "tubies," commode, Insuflon, dressing (not the salad kind), the hard to pronounce names of various medications, and more. It became commonplace to see nurses in the big "Cookie Monster" chemo gowns. Sleepless nights. Vitals. Beeping machines. At the end of that first week and still glazed over, we were scared to go home after our initial week-long hospital stay, because now *we* would suddenly be in charge of flushing lines, administering medications, and watching for fevers. It was like the terrifying feeling of bringing home your firstborn, only worse. And yet over time, this place became comfortable in a weird way. We got more efficient with packing each hospital stay as we learned what we wanted and needed in our room to make the tiny space home. The nurses became friends and then family we looked forward to seeing. We found playmates and buddies whom we looked forward to seeing on the floor when our stays coincided. We became experts at pushing around giant iv poles, stepping over a million iv lines, moving furniture 100 times a day to accommodate tents and toys in our small space. Eli stopped crying when we told him it was time to come back to stay at the hospital for a while. Instead, he started planning what he would take and what he would like to do while he would be there. . . .
Illness-related content on Twitter (Diddy & Lundy, 2017)	Does anyone feel like they are running up a sand pile, trying to push awareness to action during October? Just me? #bcsm"

Facebook friends and followers as much as the support received by family and friends in their daily lives.

Facebook has also been used to support bereaved caregivers through a hospice online support group[45] in which caregivers sought help for healing from their loss. Online support was found to be useful and as effective as face-to-face support groups. Furthermore, social support in many forms has been found to benefit cancer patients. Valle and colleagues[46] found that Facebook is a beneficial way for young cancer survivors to exchange health information and receive support, especially in promoting physical activity.

Twitter. Seeking health information and online support is commonplace and has been studied from numerous perspectives, including health information-seeking behaviors, predictors of eHealth usage, and the use of Twitter to disseminate health information.[47–49] Twitter is considered "microblogging" because it allows only short messages; therefore, the stated content is often simple. However, a good tweet invokes both emotion and information.

Research on social support through Twitter focuses on health outcomes and behavior change interventions such as weight loss[50,51] and smoking cessation.[52–55] Research examining serious illness, such as cancer, on Twitter is sparse. However, some studies focus on cancer patients. In a social support intervention through Twitter for cancer patients, Nam[56] discovered that bonding social capital had a strong, positive influence on achieving positive health outcomes. In addition, the Twitter-based social network system intervention had a significant direct effect on achieving positive health outcomes.[57] Based on current health-related Internet research, Twitter is a rich source of health information used by its members to seek health information, change health behaviors, and engage in illness-related discussions.

Social Media and the Family

Social media connects families in many ways. There is some evidence that social media can be a mechanism to enhance certain aspects of family interaction. Discussion about one's serious illness over social media can help open doors for difficult conversations, provide a charted course of what has happened over the duration of the illness, and lead to new avenues of support for and from others.

> And so it was just like oh, you know, that's my man, you know, and that was one of the most amazing things about it was that in that dark time when he was being stripped of everything, there was this one thing that had grown (his writing); it wasn't going away, it was coming, this new skill had been created or discovered.[36]

Enhancing Family Communication

Healthcare providers often think of difficult conversations taking place between the patient, family, and provider. However, difficult conversations also occur between patients and the family caregiver. When loved ones write about their own fears regarding their illness, it can invoke the same emotion in the family caregiver. Examining communication as a factor in the patient–caregiver dyad is crucial to the patient's and caregiver's quality of life.[58,59] However, the illness story also opens doors for further communication, as illustrated by the following participant comments.[36]

> Reading about his fear kind of made that more real for me; there was something about reading when he would write about this thought makes me really scared and would clue me into what was really bothering him if he hadn't been able to articulate it to me.

Reading a loved one's comments on a blog allows the family caregiver to reflect on the message before reacting to the written words, unlike a face-to-face conversation in which an immediate response is usually required. Other interpersonal behaviors, such as the involvement of the family caregiver with the ill loved one, may also affect how difficult conversations are initiated and continued throughout the illness trajectory. Some research suggests that when communication and sharing occur among family members, there is a sense of relief from emotional turmoil or even the desire to rebuild a crumbled relationship.[60,61] Hansen and colleagues[61] found that patients valued family members who were involved and reported high levels of comfort with that involvement. Furthermore, low-energy activities are better tolerated and appreciated by patients with a serious illness; therefore, interacting through social media may be well-accepted as an intervention.[61]

Difficult conversations are filled with a variety of emotions that are challenging, albeit critical, to the patient and family caregiver's well-being. When a family caregiver is first able to get a glimpse of how his or her loved one is coping with the illness or approaching decisions that lie ahead, it can open a door for further face-to-face conversations. One participant shared that "sometimes it is easier to write it than to talk about,"[36] indicating that the written story makes problems related to the illness easier to talk about later, after both the patient and the caregiver have a chance to think about what was written. Another participant remarked how his wife would write about her "feelings, fears, and what was going on" which they would discuss after her posts.[36] This interaction is comforting and presents one way for family caregivers to feel like part of the team.[36]

Facilitating Sense-Making

The written word detailing the illness story on social media is a document that tracks events in addition to experiences. These stories offer a method for developing interpretations of events.[62] The development of interpretations facilitates sense-making through a sequential interlacing of past, present, and future events.[62] The stories also facilitate dialogue around the meaning and purpose of the illness.[34,36,38] Hansen and colleagues[36] found that participants appreciated the written "track record" as a valuable aspect of the illness blog. The following exemplars demonstrate this phenomenon.

> She went through the standard National Comprehensive Cancer Network (NCCN) guidelines for treatment, and we were very on top of things, reading, and learning about stuff and in particular, that was sort of my primary role, coming up with ideas with the doctors and talking to other people, patients. What it ended up being [the blog] was a record of the treatment. She had about 27 regimens during her treatment, many did not work and most of them were outside of standard care.
>
> For her, it [the blog] was kind of cathartic to write what's on her mind, how she's feeling but also how she's approaching things and how she's approaching uncertainty with regimens or new regimens or vacations or stresses with family and life.

Family caregivers can also find clues in the illness story about how their loved one wants the illness and corresponding situations handled. In this way, social media can offer insights and clarification to the family caregiver's role.[36] For example, one man commented on how the blog provided a better understanding of how his wife wanted things handled,[36] explaining ". . . it let me have a glimpse into how she would like things handled and clearly, gloom and doom were not in our playbook."

When faced with uncertainty, the ability to create meaning or make sense out of a difficult situation becomes paramount.[63] As the patient and family caregiver navigate their way through the disease trajectory, they face uncertainties ranging from initial diagnosis to the prognosis, treatment, and side effects. When they use their stories to make sense of what is happening, they gain clarity and meaning.

Garnering Social Support

Typically, the end of life is thought to be shadowed by isolation and loneliness; however, caregivers find that, through social support, a balance of caregiving and burden is found because the ability to cope is improved.[32,36,58,59] In addition, research on social support demonstrates that close personal relationships assist in improving well-being, even in the absence of stress.[58,59] One method of support is through sharing an experience via social media. For example, a participant communicated about how she and her husband with a serious illness shared moments.[36]

> And then, start up in the middle of the night came all the comments. He got loads and loads of comments, and he loved . . . he kind of fed off those. . . . And that was something that we shared together. . . . I might wake up and he'd go oh, I've got five comments and we read them

> together and so it's kind of sharing the process with him and because we did it together it felt like it was support for both of us.

This statement exemplifies how communication through social media (in this case an illness blog) provides support for both the ill person and his or her family.

Support can also be derived through social media from others who have shared similar experiences. For example, one family caregiver stated, "the most important thing I think captured on this blog is how it helped other cancer victims and patients."[36] Kim and colleagues[64] reported the experiences of young adult cancer patients as described through online narratives via the website Planet Cancer. Over a 1-month period, 168 posts from blogs written by 12 males and 34 females were collected and analyzed. Ten main themes were reported: topics ranged from physical and psychological isolation to cancer survivorship. Researchers concluded that the online blogs provided a venue for sharing stories with those of similar ages and situations. Additionally, blogs served as a medium to combat social isolation when faced with physical disfigurement. A study using a sample of young women with cancer examined the use of complementary therapies.[65] Through analysis of the illness blog content, the authors reported the emergence of positive themes regarding complementary therapy use for symptom burden. This method of online communication provided an avenue to share information about complementary therapies and glean social support from women of similar ages with a cancer diagnosis.

Another study examined 24 illness blogs from Australia, Canada, the United Kingdom, and the United States written by men and women of different ages and with a range of cancer diagnoses.[66] One of the most distinguishing features of the blogs was the production and management of personal affect through self-expression about the impact of illness on the body and everyday life. The authors also describe the value of the blogs not only as a "communicative labor" but as a "network-enabling and social" labor. Bloggers generate online spaces where experiences can be shared, which ultimately impacts the broader social understanding of their illness.

Leaving a Legacy

As another means for support, social media may serve as a living memorial after a person dies, also known as a *continued bond*. Continued bonds assist those mourning the death of a loved one with creating meaning out of their loss and adjusting to life without their beloved family member or friend.[59] This is illustrated by a man discussing his wife's blog, who reported that "This [the blog] was helpful; her life was important and it's like a living memory or memorial for her."[36]

Pennington[67] discusses how students who have lost a loved one use Facebook as a living memorial. The author highlights the importance of Facebook in facilitating a continued bond with the deceased loved one and supporting sense-making and coming to terms with continuing the ties versus letting go, facilitating the grieving process, and moving forward. Keim-Malpass, Adelstein, and Kavalieratos[68] also found posthumous responses on illness blogs. The blogs in their study served both legacy-making and grief-processing functions. They found that posthumous responses included expressions of grief such as videos, obituaries, and communication via Twitter. Other studies support the use of social media in maintaining a continued relationship with the deceased loved ones. Degroot[69] found that written communication on deceased individuals' Facebook pages serve the function of sense-making and continued bonding for family members.

Social Media and Healthcare Providers

Healthcare providers use social media for both personal and professional objectives, with usage rates approaching 90%.[70] Although there is a great deal of variability in the use of and engagement with social media in the course of their professional duties, a smaller majority of providers (67%) use social media in a professional capacity.[70] The driver of professional use has been online professional communities aimed at sharing domain knowledge, keeping up with new developments, communicating with colleagues, or listening to experts.[71] This type of professional interaction and sharing was formerly reserved for regional and national professional meetings that occurred infrequently and required travel. The use of social media for professional education and collaboration has diminished geographic and time restrictions for dissemination of knowledge, collegial discussions, and networking.

Attitudes of healthcare professionals toward the use of social media in communicating with patients and families vary. In general, younger practitioners are more likely than older practitioners to have a favorable view of social media and use it to interact with patients.[72,73] Furthermore, there is some discordance in the motives for using social media in healthcare of professionals and patients.[71] Professionals tend to use social media for communicating with colleagues and marketing, whereas patients tend to access social media for healthcare information, advice, and social support. Regardless of usage motives, a majority of healthcare providers perceive social media as beneficial to their patients.[71] Some of the identified benefits of social media use include increased interactions with others, easily accessible and tailored information, social and emotional support, and public health surveillance.[74]

The nature of social media involvement by healthcare professionals can vary from direct engagement with patients for the purpose of communication to participation in online health networks dedicated to specific health and wellness issues.[70] Additionally, providers can guide patients and families to use social media during the illness trajectory in order to maximize the benefits of their use.[43,75] A systematic review of the effects of social media on patients and their relationships with healthcare professionals concluded that patient empowerment through the use of social media equalized the power imbalance between patient and healthcare professional, leading to increased quality of clinical decision-making.[76] Furthermore, social media interventions have shown some promise for cancer prevention and management by providing combinations of targeted, reliable information and social support.[77] Social media may also be a source of feedback to clinicians. For example, a study conducted in Japan in 2015 concentrated on Japanese men and women with a diagnosis of lung cancer in various stages.[78] Through analysis of 100 blog posts, the authors identified several themes. In general, the content focused on feelings of dissatisfaction and anxiety in cancer patients and their families, as well as on relationships with medical staff, insights not assessed in previous surveys. Most notably, researchers concluded that, when comparing the illness blog content to voluntary records from previous surveys conducted by the healthcare institution, the illness blog was predicted to be more representative of the patient's true thoughts and feelings.

Ethical Considerations

The adoption of social media use among healthcare professionals also carries ethical and professional implications.[79] Concerns have arisen about the blurring of professional and personal lines, inadvertent discussion of protected health information, financial conflicts of interest, advertising, and exploitation of patients. Various professional organizations have published recommendations to guide ethical social media use by healthcare practitioners.[79] Additionally, clinicians have a duty to counsel patients and families about the potential pitfalls of social media use, such as difficulty in establishing the reliability of information on social media as well as risks of confidentiality and privacy breach.[74] Organizations have an obligation to verify the accuracy of information presented on their sites and disclose conflicts of interest. Healthcare professionals have an obligation to maintain appropriate professional boundaries and protect patient privacy. Chretien and Kind[79] have published guidelines examining the ethical considerations for healthcare providers engaging with social media. The authors concluded that providers who successfully incorporate the use of social media while maintaining trust and integrity "will be poised to lead this social revolution in healthcare."[79(p. 1419)]

Conclusion

Social media provides many opportunities for individuals to connect with one another. These connections are important in leveraging social capital, especially during an illness experience. Current research supports the use of social media as a medium for public storytelling with many benefits to the ill person and family members. Benefits for the ill person include mustering social support, combating isolation, comparing and sharing information with others in similar circumstances, and providing a venue for self-expression. Family members may benefit in terms of facilitating sense-making, garnering social support, enhancing family communication, and, in the event of death, leaving a legacy.

CHAPTER 67

Access to Pediatric Hospice and Palliative Care

Lisa C. Lindley and Jessica Keim-Malpass

Key Points

- Access to high-quality pediatric hospice and palliative care is becoming increasingly important as the prevalence of children with serious illness grows and the complexity of their health at end of life rises.
- State and federal policies have influenced access to care for children and families.
- Ongoing research has provided evidence on the distinctive profile of community-based pediatric hospice and palliative care providers.
- For many children and their families, community factors influence care utilized, whereas for other children it is their health conditions or complexity of their health.
- Nurses can advocate to expand access to hospice and palliative care for children.

Introduction

Access to high-quality pediatric hospice and palliative care is becoming increasingly important as the prevalence of children with serious illness grows and the complexity of their health at end of life rises.[1,2] The American Academy of Pediatrics[3] articulated its commitment to equitable access to pediatric hospice and palliative care, and the Standards of Practice for Pediatric Palliative Care and Hospice state the importance of accessible care for children and their families.[4] However, many children at end of life lack access to these care models, especially in the community. Statistics on the location of death suggest that home is the preferred place for children and families[5]; yet recent evidence suggests that fewer than a third of community-based hospice and palliative care providers deliver care for children, and less than 10% of children and their families utilize the services.[6,7]

Pediatric hospice and palliative care is end-of-life (EOL) care focused on enhancing the quality of end of life for the child and the family, preventing and/or minimizing suffering, optimizing function, and offering opportunities for personal and spiritual growth.[3,4] This care focuses on effective management of pain and other distressing symptoms, along with psychosocial and spiritual care. Hospice care is often distinguished from palliative care as EOL care provided in the last 6 months of life as certified by a physician or nurse practitioner. Community-based care is care accessed outside the inpatient setting and provided in the home, dedicated-hospice facility, or long-term care facility.[8]

This chapter addresses access to pediatric hospice and palliative care services in the community by examining the roles of healthcare policy, delivery of care, utilization of care, and quality of care. Research findings are used to illustrate the current evidence on access to care for children and their families. The chapter concludes with nursing recommendations on ways to improve access to pediatric hospice and palliative care.

Access Definition and Framework

Access to healthcare is a complex notion with varying definitions.[9] Access to pediatric hospice and palliative care is defined as EOL care that is available, accessible, accommodating, acceptable, and affordable for children with serious illnesses and their families. The conceptual framework created for this chapter was modified from the classic work of Aday and Andersen,[10] which conceptualizes access as a multidimensional process proceeding from health policy through the characteristics of the healthcare delivery system to the utilization of healthcare services and culminating in quality of care accessed (Figure 67.1).

Using this framework, access to healthcare is considered in a political context.[10] Federal and state laws guide access to services by defining financing and eligibility criteria. Next, the characteristics of the healthcare delivery system influence what care is available and accessible to patients.[10] There is a distinctive profile of providers who deliver care for children. Additionally, accessing care depends on whether or not the patient population utilizes healthcare.[10] For children at end of life, hospice and palliative care utilization is influenced by their health. Finally, the framework indicates that accessing care should result in quality care that is accommodating and acceptable to patients.[10] Accessed pediatric hospice and palliative care must be child- and family-centered care that reduces symptom burden and meets the needs of the child and family to their satisfaction. In summary, the framework provides a guide for this chapter on the dimensions of access to pediatric hospice and palliative care.

Health Policy

Due to reimbursement structures, delivery models, and financing, it is critical to first understand access to pediatric hospice and palliative care within the lens of health policy. An

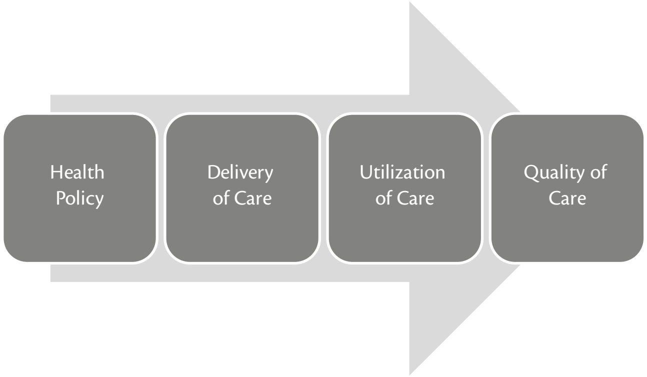

Figure 67.1 Framework of access to pediatric hospice and palliative care.

estimated 17,000 pediatric deaths each year are associated with chronic, complex conditions, and the vast majority of these children are enrolled in Medicaid due to their disability status, severity of disease, or overall level of functioning.[11] Additionally, private insurance does not usually cover in-home nursing care, so, in essence, Medicaid is the primary public financing structure for pediatric hospice care services.[12] Medicaid and most private insurers originally followed the Medicare hospice eligibility criteria that require a patient to be in the last 6 months of life and forgo any curative treatment. Families often had to choose between continuing curative therapies or receiving hospice care services. For many children with complex, chronic conditions, curative therapies include routine regimens such as antibiotics, antispasmodic drugs, and other therapeutics that promote optimal symptom management and functional status. In the 1990s and early 2000s, pediatric hospice care advocates recognized that making the decision to stop ongoing curative therapies to enroll in hospice care was a pervasive barrier to enrollment for many families.[13] Advocates argued that the either/or nature of the Medicaid hospice eligibility criteria was amenable to state-based policy because of the decentralization of Medicaid provision.

State Policies

Several states met the challenge of the early pediatric advocates and began to explore and test alternative pediatric hospice and palliative care models under their Medicaid programs. States such as Florida, California, and Massachusetts were early innovators in Medicaid hospice policy and developed programs and legislation to expand hospice enrollment for children with life-limiting conditions.[14] One way states are able to operationalize these programs and policies is through 1915 Medicaid waivers. These waivers allow states to offer benefits to home- and community-based services to promote children remaining in their home and community. Florida was among the first states to publicly finance concurrent curative and hospice care through a 1915 Medicaid waiver program, which waived many of the reimbursement rules.[15] Challenges to implementation in Florida in the early days of the program included identification of eligible children, workforce constraints, and billing complications.[15] Upon implementation of the Florida program, Medicaid was the primary funding source, covering 92% of the expenses of those enrolled.[15] As the program matured, there was a significant increase in the number of children enrolled, and families were highly satisfied with the care provided.[15]

California also was an early leader in alternative eligibility criteria and financing for pediatric hospice and palliative care. With the aid of their engaged pediatric hospice community, California advocates were successful in lobbying and enacting legislation such as the *Nick Snow Act*.[14] Nick Snow was a young man with a life-limiting condition who "failed" hospice twice (e.g., outlived his 6-month prognosis window) because his condition improved so much through the help of hospice. He was himself an advocate for expanded hospice access for children and adolescents.[13] California enacted concurrent care through the Nick Snow Act (Assembly Bill 1745) and later expanded their 1915 Medicaid waivers to incorporate this legislation.

In 2006, Massachusetts funded a Pediatric Palliative Care Network as a part of the overall state Healthcare Reform Act.[14] The Massachusetts Health Reform law included a one-time $800,000 financial appropriation for the training and implementation of expanded pediatric hospice access across the state, with the majority of money going directly to hospice contracts.[16] A key difference with the Massachusetts approach was that eligibility and financing were separate from Medicaid and did not include medications, durable medical equipment, home health aides, or other services that were covered through Medicaid.[12,16] In general, states that were early pediatric hospice and palliative care innovators established feasible models of care that loosened traditional hospice eligibility requirements and were well-received by the families of children who enrolled.[14]

Federal Policy

Recognizing the success of early state adopters of pediatric hospice and palliative care models, hospice advocates continued to garner bipartisan support for legislation on the federal level. Section 2302 of the Affordable Care Act (ACA) offered the first federal legislation aimed at modifying hospice eligibility criteria nationally for children enrolled in Medicaid or the Children's Health Insurance Plan (CHIP). Under Section 2302, children were eligible for concurrent curative therapies and hospice care upon the signing of the ACA on March 23, 2010.[17] The legislative intent of Section 2302 care included (1) expanded access for children with chronic, complex, life-limiting conditions; (2) enhanced child and family quality of life; and (3) earlier enrollment/longer length of stay in community-based hospice instead of frequent hospital admissions.[14]

Even though enactment of ACA Section 2302 made great efforts in uniformly offering access to pediatric hospice care across all states from the legislative context, there are several policy concerns remaining, including abilities of states to implement policies, solvency of state Medicaid budgets, limitation to Medicaid enrollees, lack of economic data suggesting overall return on investment, and shortage of trained pediatric hospice and palliative care workforce. For example, states that faced economic and budget concerns are less likely to implement Medicaid legislation (e.g., those facing Medicaid/CHIP budget crisis).[18] Additionally, there has been a dearth of economic and policy research focused on this provision and the cost-effectiveness of pediatric hospice as a whole, which impacts sustained policy engagement in the topic.[18] Finally, due to the continued political uncertainty of the ACA, many fear that uprooting this landmark legislation will adversely impact children with life-limiting conditions.

Delivery of Care

Who Delivers Care

Along with health policy, access to pediatric hospice and palliative care is influenced by the providers that deliver care for children and their families. Over the past decade, a distinctive profile of community-based, pediatric hospice and palliative care providers has emerged. Less than a third of all hospices provide care for children, and only a fraction of these have a special pediatric program.[19–21] Pediatric hospice providers are often small or medium sized and have been in operation for more than 8 years.[19,20,22,23] Most are nonprofit, nonaccredited organizations.[19,21–24] They are frequently free-standing and are not affiliated with a hospital or a home-health agency.[19,21–23,25] Pediatric hospices are often reimbursed by private insurance, followed by Medicaid and charity.[26] Most of their costs are in nursing labor, and their balance sheets typically indicate a positive trend with higher revenues than expenses.[26] Generally, pediatric providers are located in the South, and they commonly serve an urban community.[6,19,24,26–28]

In addition, our understanding of the nurse workforce within pediatric providers is expanding. Registered nurses (RNs) constitute more than three-quarters of the staff, with one full-time-equivalent (FTE) RN for every two patients in pediatric hospices.[23] Less than a quarter of organizations have advanced practice registered nurses on staff, such as nurse practitioners or clinical nurse specialists.[23,29–32] However, a majority of organizations have RNs on staff with a baccalaureate degree as the highest RN degree, while approximately 75% of nurses have a specialty certification.[19,23,30–34] Among pediatric hospices, RNs maintain one of the lowest caseloads while providing the most visits compared to other staff members.[22,24]

Factors that Influence the Delivery of Care

The characteristics of hospices influence the care delivered for children and their families. Emerging evidence has begun to identify key factors within the organization that may act as barriers or facilitators in the delivery of pediatric hospice and palliative care. Several of these characteristics have been investigated and are presented in detail here.

- *Company policies*: Some community-based hospice and palliative care providers do not deliver care for pediatric patients because of company policies. In a recent study, researchers explored hospice and palliative care delivered in rural Appalachia.[29] Through key informant interviews, they discovered that providers sometimes have specific corporate policies that do not allow them to deliver care for children and their families. Therefore, company policies may be a barrier to hospice and palliative care for children.
- *Clinical pediatric knowledge*: Community-based hospices commonly care for elderly patients and lack clinical knowledge of children, especially at end of life. In a study of North Carolina organizations, researchers identified important clinical barriers to providing care, such as a lack of pediatric-trained staff, lack of pediatrician consultation, and lack of pediatric pharmacy.[21] Although partnership with pediatricians and/or those skilled in providing pediatric EOL care has been suggested,[27] there are relatively few examples of partnerships or mentorship programs available. Thus, staff discomfort with providing care for children is a critical barrier to the provision of pediatric hospice and palliative care.
- *Educational environment*: The educational environment in the hospice has a positive impact on the delivery of pediatric care. Studies among providers that provide highly specialized pediatric hospice and palliative care show that the organization's teaching status, presence of advanced practice registered nurses, RN certification, and BSN education levels are important facilitators to the availability of services for children and their families; these factors include complementary and alternative therapies (CAM) and culturally sensitive care (i.e., interpreter services, materials translated, multilingual staff).[23,30,32] These organizations may encourage their staff and students to explore new methods of delivering care (e.g., CAM), and RNs with higher education levels may be more receptive to meeting the needs of diverse patient populations (e.g., translated materials). Studies show the importance of an organizational climate that supports nursing education in facilitating the delivery of care for children and their families.

In summary, a profile of the pediatric hospices suggests that providers have distinctive characteristics that influence the delivery of care for children and their families. Identifying the factors that influence the delivery of care suggests that there are barriers and facilitators to access, many of which are amenable to organizational change.

Utilization of Care

Who Utilizes Care

Another component in the access of pediatric hospice and palliative care is whether or not children and their families utilize these services at end of life. We are just beginning to understand who utilizes pediatric hospice and palliative care services. Although all age groups use hospice and palliative care, adolescents have the highest utilization.[24,27,35–37] Most of these children have serious health conditions (e.g., neuromuscular, congenital, cancer)[24,38,39] and cognitive impairments.[24] They often require the use of medical technology.[4,40] Almost 80% of children with serious health problems have a need for medical technology that includes feeding tubes, central lines, and tracheostomies.[40,41] These children also have high medication needs and average at least nine medications daily.[40] Finally, they suffer with multiple morbidities along with their primary diagnosis[7,24,42] and significant symptom burden.[25] At the end of life, these children typically experience uncontrolled pain, shortness of breath, and fatigue.[43]

There is also recent evidence on the hospice care received by these children. Studies have examined the care used by children and have found that it is often received in the home[4,25,44,45] and in an urban setting.[20,45] Children who enroll in hospice and palliative care have an average length of stay of between 1 and 24 days.[24,46] Almost all children utilize pain management and skilled nursing care.[24] Approximately half of children and families utilize pastoral and bereavement care, while less than a third use nonpharmacological pain management, intravenous therapy, wound care, and volunteer care.[24]

Factors that Influence the Utilization of Care

Physician prognosis,[47,48] community support,[48] financial hardship,[49] and the child's suffering[47] all contribute to the families' decision-making at the child's end of life. However, we are just beginning to understand the impact of a child's health on access to pediatric hospice and palliative care.[50] Listed here are some of the recent discoveries about health characteristics that influence utilization of care:

- *Cardiovascular conditions*: Children with cardiovascular conditions are significantly less likely to enroll and stay in hospice care compared to those without these conditions.[7,51]A possible explanation may be the complex care needs of children with cardiovascular conditions at end of life. Children with heart failure may have multiple providers from diverse subspecialties including cardiologists, pulmonologists, and interventional cardiologists. While these specialists may manage a portion of the care, they typically do not integrate care across the children's numerous providers. Thus, no one specialist may take the responsibility to make the referral to hospice care. Instead, families often become the primary caregivers, medical managers, and health systems navigators for their children. Thus, a cardiovascular condition is a barrier to utilizing hospice and palliative care for children and their families.
- *Cancer*: A cancer diagnosis has been linked to pediatric hospice and palliative care utilization.[39,46,52,53] One study found that 45% of children with cancer at end of life enrolled in hospice and palliative care.[54] This trend is pervasive among older adults as well[4] and is also supported by previous pediatric data, due in large part to the fact that malignancies are the leading nonaccidental cause of death in the pediatric population.[55]Aside from epidemiologic trends, it is likely that a cancer diagnosis offers more concrete ability to prognosticate compared to noncancer etiologies, which is imperative for hospice utilization.
- *Comorbidities*: Comorbidities have been examined in studies of utilization. The results of a recent analysis revealed that children with comorbidities were twice as likely to enroll in hospice compared to those without comorbidities.[7] Children with comorbidities may enroll in hospice and palliative care in order to manage pain and other complex symptoms at end of life. Children with comorbidities present with unique clinical challenges for EOL care in hospice and may benefit from hospice care. For example, enrolling in hospice may enable children to receive a thorough initial assessment, assessment of medications, and provision of other psychosocial services. It also suggests that hospice clinicians may be able to provide effective pain and symptom management or engage social work services or pastoral care. Comorbidities may act as a facilitator to hospice and palliative care utilization.

Special Populations

Utilization of pediatric hospice and palliative care has also been examined among special populations of children. Information on their unique patterns of utilization is described here.

Hispanic children: In the pediatric Hispanic population, community characteristics have been associated with hospice and palliative care utilization.[56,57] Approximately 11% of Hispanic children utilized hospice care at end of life, with the most common health condition being neurological and the least common congenital anomalies. Being home at end of life is important for Hispanic families.[38,57] Pediatric hospice and palliative care services located in the Hispanic neighborhood were positively related to hospice enrollment.[56] In addition, Hispanic children who resided in communities where they could receive palliative care early in the disease trajectory were more likely to utilize hospice care. This evidence points to the importance of community for Hispanic children and their families at end of life.

Adolescents: A profile of adolescent hospice and palliative care utilizers is also emerging, with a usual source of care playing an important role.[52,58–60] Among the 10% of adolescents who utilize hospice and palliative care, about half of them have a neurological diagnosis, with cancer and cardiovascular etiologies following in equal percentages. Almost half of these adolescents have comorbidities. An important predictor of hospice utilization among adolescents is having a usual source of care. Adolescents who were an established patient with an identified primary care provider were more likely to enroll in hospice and had longer length of stays compared to those adolescents without a usual source of care. A usual source of care may have long-term knowledge of the adolescent's health, which can assist the adolescent and the family in navigating the decision to use hospice. This evidence suggests that a usual source of care provider may enable adolescents to utilize pediatric hospice and palliative care at end of life.

Children with an intellectual disability: Children with an intellectual disability at end of life have complex health needs that influence their utilization of hospice and palliative care.[46,61] Studies have shown that children with an intellectual disability aged between 6 and 14 years most frequently use hospice and palliative care. Children with an intellectual disability at end of life experience epilepsy, suffer with multiple comorbidities, and have congenital anomalies. One recent study found that having an intellectual disability was negatively related to hospice enrollment and length of stay.[46] However, when children had both an intellectual disability and comorbidities, there was a positive association with enrolling in care. Therefore, the health complexity of children with an intellectual disability was a significant predictor of hospice and palliative care utilization.

These special populations' studies highlight the importance of understanding the unique features of children at end of life. For some children, community influences care utilized, whereas, for other children, it is their health conditions or the complexity of their health. These findings suggest that future research among these groups is clearly warranted to ensure access to high-quality pediatric hospice and palliative care for all children and their families.

Quality of Care

Pediatric palliative and hospice care must be viewed through the lens of equitable access to quality care for children and their families.[62] Patient- and family-centered care is a cornerstone of both pediatric palliative and hospice care that is often operationalized through care of siblings,[3] family-centered advance care planning/goals of care,[63,64] and bereavement support in the community.[65] Parent/caregiver and sibling involvement in care planning and various transitions in care have been the focus of recent research to date, but there is still a dearth of research focused on perspectives of the children or adolescents themselves. Lyon and colleagues[63,66,67] have led family-centered research endeavors involving advance care planning among children with HIV and cancer and have demonstrated that adolescents want to engage in care planning themselves and make decisions regarding their own care trajectories along with their family supports.

Many have expressed the recommendation of initiating palliative care as a standard of care early in the illness trajectory for certain diseases like cancer,[68,69] but those guidelines have not been uniformly accepted among all children with chronic, complex conditions and they are rarely implemented in practice. One reason that hospice and palliative care have not become routine among pediatric populations is the difficulty in demonstrating efficacy (symptom control, utilization) and cost-effectiveness. A recent systematic review assessed pediatric publications that focused on the end-of-life period and found only 15.4% assessed any patient-reported outcome and only 23.1% assessed a parent-reported outcome.[69] Much of what we know about the impact of accessing pediatric hospice care on quality outcomes has been based on Medicaid claims data.[35,36,51,53,59] Like palliative care outcomes, there have been very few opportunities to assess the impact of hospice on quality care outcomes and patient- or family-reported outcomes. It is imperative to elicit patient-reported outcomes from both children and adolescents themselves (when developmentally able) and from parents/caregivers if we are to better understand the impact palliative and hospice care have on symptom control and patient–family well-being from a large, generalizable population.

Even though there are very few patient- or family-reported outcomes among children who access either palliative care, hospice care, or both, several investigators have demonstrated that early initiation of palliative and/or hospice care for children with chronic, complex conditions yields high family satisfaction and acceptance.[15,16,70] From the policy perspective, it was feasible to implement the early state models of the hospice care provision that led to the concurrent care Section 2302 in the ACA, and families responded with high satisfaction.[13,16] Clinicians, researchers, and advocates must urge families to share their palliative or hospice care experience within their clinical and social networks and within larger media perspectives to more fully engage with policymakers. There should also be a sustained effort made to embed patient- and family-reported outcomes within electronic health records and utilization data to yield a more robust perspective on the potential impacts of early access and initiation of palliative and hospice care.

Recommendations for Nurses

How nurses can advocate for health policies that expand access to hospice and palliative care for children?

Listen and share patient stories (in a way that protects their identity). Humanizing patient's stories and experiences are a natural way that nurses can become involved in advocacy efforts. Nurses have many incredible stories to tell, and we are present with families during their most vulnerable moments. By speaking on behalf of patients or writing their stories in a meaningful way, nurses can add to the shared understanding of their experiences and struggles. As an example, the popular column, "Narrative Matters," in the journal *Health Affairs* gives clinicians the opportunity to share stories that have relevant and timely policy implications. It is often the case that politicians use these stories to advocate for certain health policies because stories provide an easier way of connecting to a cause. Statistics and numbers can highlight certain aspects, but the narrative-based approach to patients' stories allows the cause to have a face and greater meaning. Along with journals that have these types of columns, there are also opportunities to publish for newspapers, magazines, and online through blogs. Understanding how to advocate for individual patients and populations of interest, how to communicate about health policy, and how to apply advocacy to the role of the nurse needs to be introduced and taught as early as possible in schools of nursing, both theoretically and in clinical practice applications.

Use evidence-based practice and join pediatric practice committees that are committed to enhancing quality symptom management and family-centered end-of-life care. Some might not associate evidence-based practice with advocacy, but getting involved in practice committees and striving for the provision of the highest quality of nursing care is a natural fit for advocacy efforts. Always approaching evidence-based nursing as the gold standard in pediatric care delivery allows nurses to provide quality care while staying informed on issues specific to the populations of interest. By continuing to acquire this knowledge, nurses can effectively translate that knowledge and care to patients and families.

Network with those interested in pediatric palliative and hospice care through social media or nursing organizations. It has become easier to connect with other nurses, clinicians, and policy advocates through social media sites online such as Twitter, Instagram, and Facebook. Professional organizations often present a natural place to connect and learn about various advocacy efforts. The National Hospice and Palliative Care Organization has an advocacy section with current legislative agendas, and the Hospice and Palliative Nurses Association (HPNA) has numerous position statements easily found online through the organization's website. The American Academy of Hospice and Palliative Medicine (AAHPM) both includes policy goals and hosts an advocacy center on its website, which also includes connections to both federal and state policy initiatives, a quality workgroup, and a regulatory issues workgroup.[71] It is critical for nurses to see what is on the agenda in terms of policy and advocacy efforts and find a way to join a cause that works for them.[72] Additionally, there are opportunities to connect and learn through various health policy online courses and tools. For instance, the Oncology Nursing Society (ONS) has a long-standing online course entitled "Advocacy 101" so nurses can gain access to a basic understanding of the legislative process and health policy advocacy.[73] For family advocacy efforts to continue to be a component of nursing practice, a sustained integration of health policy and advocacy within nursing education is critical. Content about advocacy, legislation, health policy, and nursing needs to be tailored and introduced into the curricula for nursing students at every level, with various advanced applications included within graduate nursing requirements.

SECTION VII

Special Issues for the Nurse in End-of-Life Care

CHAPTER 68

The Advanced Practice Registered Nurse

Clareen Wiencek and Alexander Wolf

Key Points

- Palliative care relieves suffering and improves quality of life for patients with serious or life-threatening illness and their families by offering symptom management, care coordination, and psychosocial and spiritual support from the time of diagnosis through the period of bereavement.
- Advanced practice registered nursing builds on the strong foundation of nursing practice by incorporating advanced knowledge and expertise in assessment, diagnosis, and management of persons with serious or life-limiting illness.
- The palliative care advanced practice registered nurse (APRN) demonstrates skilled communication and the ability to drive treatment plans based on the goals and preferences of the patient and family.
- The APRN Consensus Model, released in 2008, provides the regulatory model to standardize licensure, accreditation, certification, and education of all APRNs and enables APRNs to practice at their full scope, ensuring greater impact on patient, service, and system outcomes.
- Palliative care APRNs contribute to the financial viability of palliative care programs by providing cost-effective care and contributing to billing and reimbursement processes.

Introduction

Numerous initiatives and studies over the past two decades have identified the critical need for better care of persons with serious or life-threatening illness and for their families.[1–4] Palliative care has grown as a discipline in response to that critical need. Palliative care means patient- and family-centered care that optimizes quality of life by anticipating and treating suffering. Palliative care addresses the physical, emotional, social, and spiritual needs of patients and facilitates patient autonomy and choice whether or not the patient chooses to be treated simultaneously with life-prolonging therapies.[5]

Within a changing healthcare environment, advanced practice registered nurses (APRNs) have demonstrated their ability to adapt to the challenges posed by an aging population and by the increasing prevalence of chronic and life-limiting diseases concomitant with aging. Additionally, APRNs can help patients and families navigate an increasingly complex and fragmented healthcare system. A systematic review of APRN outcomes from 1990 to 2008 found that outcomes for APRNs are similar and in some cases better than those produced by physicians alone and that APRNs provide effective and high-quality patient care.[6] Similar findings were reported by Stanik-Hutt and colleagues in their 2013 systematic review of 11 aggregated outcomes of care provided by nurse practitioners when compared to physician care.[7]

Historical Perspective: APRN Practice and Regulation, the APRN Consensus Model, Academy of Medicine Reports

In the early twentieth century, nurses who had completed postgraduate coursework or who had extensive expertise in a particular clinical area were called *specialists*.[8] They were the predecessors of today's APRNs. In 1954, the first clinical nurse specialist (CNS) program was created at Rutgers University, and, in 1965, the first nurse practitioner (NP) program was established at the University of Colorado.[8,9] Initially, these roles were described as extending beyond the scope of nursing due to the inclusion of some practices and procedures from the discipline of medicine. It was not until the 1980s that the term "advanced practice" was adopted after growth within graduate nursing education allowed nurses to obtain advanced expertise within the field of nursing.[8] As defined by Hamric and colleagues in their textbook on the advanced practice role, APRNs have advanced knowledge and expertise in performing histories and physical examinations, ordering and interpreting diagnostic tests, and prescribing medications and other therapies appropriate for the management of particular symptoms or diseases.[9] But the rapid growth in APRN programs and practitioners during the 1980s led to concerns among the members of the National Council of State Boards of Nursing (NCSBN) about the lack of clear practice standards, inconsistency among state regulations that impacted APRN portability, and variation in educational programs.[10] These concerns led the NCSBN to develop and release the Consensus Model for APRN Regulation: Licensure, Accreditation, Certification, and Education (LACE) in 2008.[11] Since 2008, more than 44 nursing organizations have endorsed this regulatory model.[11] The LACE regulation is the vehicle responsible for the full implementation of the APRN Consensus Model, and representatives from each of the LACE constituencies continue to work toward this goal. As of 2017, many state boards of nursing have adopted portions of the Consensus Model, but there remains significant variation by state. The NCSBN's Campaign for Consensus website provides an interactive map that illustrates the adoption of the Consensus Model in each state.[11]

The APRN Consensus Model endorses a uniform model of regulation for the legal status of advanced practice registered nursing designed to align licensure, accreditation, certification, and education and to support a full scope of practice by all APRNs. It provides a definitive foundation for nurses who choose or plan to pursue advanced practice and has impact on licensing boards, certification corporations, schools of nursing, and accreditation entities.[10] The definition of each element of advanced practice is central to the Model. *Licensure* is the granting of authority to practice. *Accreditation* is the formal review and approval by a recognized agency of degree or certification in nursing. *Certification* is the formal recognition of the knowledge, skills, and experience identified by a professional association and with the intent to protect the consumer. Finally, *education* is the formal preparation in graduate-level or postgraduate certificate programs.

The APRN Consensus Model has two main components: APRN roles and population foci with additional APRN specialties, such as palliative care.[11] "Advanced practice registered nurse" or "APRN" is the new legal title and recognized credential to be used by any nurse licensed in any of these four roles: certified nurse practitioner (CNP), certified registered nurse anesthetist (CRNA), certified nurse-midwife (CNM), and clinical nurse specialist (CNS). The Model has helped to bring consistency to all four roles. Now, graduate-level education in an accredited program; completion of the core courses of advanced physiology, pharmacology, and assessment; and national certification in the provision of direct care to a patient population are required.[11]

The other main component of the APRN Consensus Model is the population of focus. The Model asserts that the APRN is educated in at least one of six population foci: family/individual across the life span, adult-gerontology, neonatal, pediatrics, women's health/gender-related, or psychiatric-mental health. An important element of the Model is that there must be congruence between the educational program and degree and the certification exam. Finally, the top tier of the Model refers to APRN specialties such as palliative care, oncology, and cardiology. While these specialties provide depth and reflect expertise in a specific area, these specialties have no prescribed educational criteria, no requirement for accredited certification or education, and do not require Board of Nursing regulation. Thus, APRNs may specialize in the care of these populations but cannot be licensed solely within these areas of specialty. The implication for hospice and palliative APRNs is that hospice and palliative care is no longer a primary practice but rather specialty only, necessitating preparation and certification in one of the six population foci.[11,12]

It is important that the palliative care APRN understands the basis for the APRN Consensus Model and the legislative and regulatory changes occurring at the state level. The overarching goal is to support the full scope of APRN practice and to improve access to APRN care by healthcare consumers, thus driving better outcomes for the entire population. Peer-reviewed research conducted over the past four decades has demonstrated the quality and safety of APRN practice,[6,7] and certifying agencies are working to ensure consumer protection through the adoption of the Model's regulatory language.[10] An individual state would demonstrate full implementation of the Model by passing these statutes: the APRN title, role delineation of the four roles, educational requirement at the master's or doctoral level, required certification, licensure in the APRN role, practice autonomy for the APRN, and full prescriptive authority. As work continues across the country toward full implementation of the Consensus Model, each APRN should stay abreast of the progress and refer to his or her state board of nursing for the most current regulations related to licensing and scope.[11,13] It is the APRN's responsibility to be familiar with relevant state law and to maintain a practice that is guided by legal, ethical, and professional practice standards. The 29th Annual Legislative Update on the licensing and regulation of APRN practice in all 50 states is an excellent resource.[13]

In addition to the APRN Consensus Model, two influential reports have been issued by the National Academy of Medicine (NAM), formerly known as the Institute of Medicine. The NAM's 2010 report *The Future of Nursing: Leading Change, Advancing Health* and the 2015 report *Dying in America: Improving Quality and Honoring Individual Preferences Near the End-of-Life* are both of important historical note in the development and growth of the APRN role.[4,14]

NAM's *Future of Nursing* report strengthens the argument for the APRN role and the new regulatory structure to meet some of the challenges in the American healthcare system and includes four key messages relevant to advanced practice in all specialties and population foci:

1. Nurses should practice to the full extent of their education and training.
2. Nurses should achieve higher levels of education and training.
3. Nurses should be full partners with physicians and other health professionals in redesigning healthcare in the United States.
4. Effective workforce planning and policymaking require better data collection and improved information infrastructure.

Highly relevant to the practice of APRNs in hospice and palliative care, NAM's *Dying in America* provides a historical update on the challenges and progress in end-of-life (EOL) care over the past 20 years. Challenges include the increasing number of elderly; structural barriers to access, especially in marginalized groups; increasing cultural diversity in the country, which necessitates individualized care; and the imbalance between the palliative care workforce and need.[4] The NAM report outlines the three major barriers to changing the culture of care through education: curriculum deficits, lack of interprofessional education, and inattention to building communication skills. In the five major recommendations for change, NAM specifically recommends that all accrediting organizations require palliative care education for all specialties, that clinicians across every discipline should be competent in basic palliative care, and that nursing-, medical-, and social work-certifying bodies require competency in palliative care.[4] The findings and recommendations in this report by the National Academy of Medicine position all APRNs, especially hospice and palliative care APRNs, to drive solutions to fill the gaps in optimal care of those who are seriously or terminally ill.

There is evidence that the APRN Consensus Model, the NAM reports, and the efforts of nurses at the state level are having a positive impact on advanced practice. In 2016, 16 states adopted regulations to improve the practice environment for APRNs.[13] New Jersey now requires APRNs to pursue education in EOL care and includes APRNs in the definition of "physician" when completing physician orders for life-sustaining treatment (POLST) and includes APRNs in Hospice Licensing Standards. New York passed legislation that requires prescribing clinicians to complete an approved 3-hour course in pain management, palliative care, and addiction management within 1 year of obtaining a Drug Enforcement Administration registration. In addition, some states are reporting improved legal statutes related to APRN roles in pain management clinics.[13] Given the current opioid crisis, many states are passing statutes that regulate opioid prescribing and prescription monitoring programs, and APRNs should keep abreast of legislative actions in their individual state.[13]

In summary, the APRN Consensus Model is the accepted regulatory model that supports practice to the full extent of scope. When fully implemented, the Model will allow APRNs to meet provider shortages across the United States.[10,11] The overarching goals are to achieve uniformity in education and licensure, remove barriers to interstate endorsement, and promote common understanding of the APRN role for optimal impact on healthcare outcomes.[11] The intent of the Model is not to disenfranchise practicing APRNs, but, as graduate nursing programs, state boards of nursing, and certification corporations adjust to the Model's recommendations, some impact on existing programs and individual APRNs is expected to occur. Though grandfathering is a provision in the regulatory model and should exempt those already practicing within the state of their current license, it is recognized that the requirement for current, national certification in the role and population focus may impact some APRNs.[11] Of note, the APRN Consensus Model does not require or preclude the Doctorate of Nursing Practice (DNP) as an entry-level degree for APRNs, a point that has caused confusion for some in the APRN community.[11] The APRN should refer to the original position statement on the practice doctorate by the American Association of Colleges of Nursing.[15]

Developments in Palliative Care: National Consensus Project, National Quality Forum, and Joint Commission's Advanced Certification for Palliative Care

Three significant developments within the past decade reflect a period of growth and standardization in the discipline of palliative care and have implications for the hospice and palliative care APRN. First, the National Consensus Project (NCP) for Quality Palliative Care published the first edition of the *Clinical Practice Guidelines for Palliative Care* (NCP Guidelines) in 2004.[5] The NCP was originally a partnership of five national palliative care organizations: the American Academy of Hospice and Palliative Medicine (AAHPM), the Center to Advance Palliative Care (CAPC), the Hospice and Palliative Nurses Association (HPNA), the Last Acts Partnership, and the National Hospice and Palliative Care Organization (NHPCO). Several other organizations have since joined the NCP. The NCP Guidelines were intended to aid the development of palliative care programs, establish definitions of palliative care, set goals for access to quality palliative care, reduce variation, foster performance measurement and quality improvement, and promote continuity of palliative care across settings. The guidelines cover eight domains of palliative care: structure and process; physical aspects; psychological and psychiatric aspects; social aspects; spiritual, religious, and existential aspects; cultural aspects; care of the patient at the end of life; and ethical and legal aspects.[5] The third edition of the NCP Guidelines reflects current practice and is consistent with the two previous editions except that the title of Domain 7, "care of the patient at the end of life," was changed from "care of the imminently dying patient." The publication of the third edition reflects the maturation of the discipline, the changes in practice, the continued growth in the palliative care evidence base, and the impact of national seminal events such as the healthcare reform mandated in the Patient Protection and Affordable Care Act.[5] The essential underlying tenets found throughout the NCP Guidelines include patient- and family-centered care, comprehensive palliative care across care settings, early introduction of palliative care at time of diagnosis of serious illness, interdisciplinary teams, expertise in clinical and communication skills, relief of suffering, and focus on quality.[5] While the first three editions of the NCP Guidelines largely applied to hospice and specialty palliative care programs in hospitals, the fourth edition of the NCP Guidelines will have an increased focus on optimizing palliative care delivery across all healthcare settings and provided by all clinicians who care for patients with serious illnesses. The fourth edition of the NCP Guidelines is expected to be released in October 2018.[16]

While publication of the NCP Guidelines helped establish the definition and scope of palliative care, the National Quality Forum's National Framework and Preferred Practices for Palliative and Hospice Care Quality (NQF Preferred Practices) was also an essential step in the acceptance and implementation of those guidelines by the larger healthcare community.[17] The NQF is a nonprofit, public–private partnership focused on improving the quality of healthcare through the establishment of voluntary consensus standards. The NQF Preferred Practices are based on the NCP Guidelines and identify 38 preferred practices that will improve the quality of palliative and hospice care. Additionally, in 2012, the NQF endorsed 14 palliative care performance measures focused on symptom relief in acute illness and at the end of life; patient- and family-centered care that addresses psychosocial needs; and patient, caregiver, and family experiences of care. The NQF framework creates a quality measurement and reporting system that may be used to support improved reimbursement for palliative care services.[17] Taken together, the NCP Guidelines and the NQF Preferred Practices set the performance standards for new and existing palliative care programs.

The third development occurred in 2011, when the Joint Commission (TJC) launched advanced certification for palliative care.[18] This certification recognizes inpatient palliative care programs, in Joint Commission-accredited hospitals, that provide the full range of palliative care services and demonstrate exceptional patient- and family-centered care. More than 40 standards in program management, provision of care, information management, and performance improvement are included. TJC used the NCP Guidelines to develop this certification program, which can help APRNs and their teams to build the infrastructure needed for high-quality outcomes. This 2-year certification is also a recognition of the importance of palliative care to quality healthcare outcomes and is recognized as a major landmark for the specialty.[18]

There are several reasons why these national guidelines and TJC certification are indispensable to the professional practice of palliative care APRNs. First, the guidelines establish standards for program development and for clinical outcomes and serve as a nationally accepted benchmark of quality. Both Guidelines set the standard that palliative care teams must be interdisciplinary and that patients and families must have access to palliative care expertise 24 hours per day, 7 days per week. At the level of patient outcomes, the NQF advocates for screening and assessment of symptoms using standardized scales,[17] and the NCP Guidelines call for prompt response to psychological symptoms and regular documentation of response to treatment.[5]

Second, the NQF Preferred Practices and NCP Guidelines set standards for educational preparation for APRNs and members of the palliative care team.[5,17] APRNs are ideally suited to take a leadership role in providing experiences for all team members in the range of settings where patients receive care. The consensus guidelines should be used by graduate faculty to identify basic skills and knowledge that should be integrated into curricula and ensure that palliative care programs help advanced practice students develop specialist-level competency in all domains.[5]

An additional benefit to the use of the NCP Guidelines and NQF Preferred Practices and attainment of TJC advanced certification for palliative care is to conduct meaningful performance improvement activities using these national benchmarks. APRNs, as leaders on their teams, can use individual standards to form the core of performance improvement measures and plans, thereby elevating the quality of the structure, processes, and outcomes at the program and patient-family levels. Finally, the NCP Guidelines and the NQF Preferred Practices serve as useful frames for palliative care research. Any APRN conducting research should review the recommendations made in these publications. For example, the NCP Guidelines call for new research methods to overcome the shortcomings of randomized controlled trials in palliative care, demonstration projects and multicenter research to test some of palliative care's central tenets, and more detailed studies analyzing reasons for late referrals to hospice.[5] The NQF Preferred Practices identifies gaps in palliative care's knowledge base and has extensive notes on directions for research in each of the domains and in cross-domain issues.[17]

Competency, Education, and Certification

Competency

The APRN's expertise is built on the strong foundation of skills possessed by the generalist registered nurse. Compared with the generalist, the APRN has broader and deeper education and expertise in the areas of assessment, diagnosis, and treatment of disease as well as in prevention, health maintenance, and provision of comfort. Additionally, the APRN must hold a graduate degree in nursing, is nationally certified at the advanced practice level, and has a practice focused on care of patients and families.[9] The APRN is expected to engage in more complex problem-solving and has broader responsibility for patient care than the generalist nurse.

The HPNA, as the nursing association representing this specialty, has developed educational standards and competencies. The *Scope and Standards of Hospice and Palliative Nursing Practice, 5th edition*,[19] which includes standards for advanced practice, and the second edition of *Competencies for Advanced Practice Hospice and Palliative Care Nurses*[20] should be utilized by the APRN to assess personal congruence with these standards and by undergraduate and graduate nurse educators to assess program-level congruence. In the Scope and Standards, eight competencies are outlined for the generalist hospice and palliative nurse: clinical judgment, advocacy and ethics, professionalism, collaboration, systems thinking, cultural competence, facilitation of learning, and communication.[19] In the HPNA's companion publication on APRN competencies, the same eight competencies, plus a research competency, are defined and include details of additional criteria for the APRN's expanded scope of practice.[20] For example, both the generalist and APRN use the nursing process to address the multidimensional needs of patients and families, but the APRN assumes greater responsibility for the evaluation, communication, and documentation of care across healthcare settings.

Education

The NCP Guidelines call for improved education for all clinicians as a priority in palliative care. More than a decade ago, surveys confirmed that undergraduate and graduate nursing programs paid little attention to palliative care topics.[21] Recent reports from the National Academy of Medicine, the American Association of Colleges of Nursing, and HPNA indicate that there are significant gaps in education across disciplines and across undergraduate and graduate programs.[2,4,12] A seminal work by Ferrell and colleagues, in which 50 frequently used nursing textbooks were reviewed, found that only 2% of all pages had any EOL content.[22] In 2015, the National Academy of Medicine's report, *Dying in America: Improving Quality and Honoring Individual Preferences Near the End of Life,* highlighted the insufficient attention given to palliative care in nursing and medical education and recommended that palliative care training and education be considered as a licensing requirement across healthcare professions. Increased palliative care content has been endorsed by HPNA,[12] American Association of Colleges of Nursing (AACN),[2] and the NCSBN.[23] At the generalist level, palliative care content has already been successfully integrated into the National Council Licensure Exam for RNs (NCLEX-RN).[23] The most recent NCLEX-RN test blueprint includes content on EOL care, pharmacological and nonpharmacological approaches to pain management and comfort, advance directives, ethical practice, aging, and grief and loss.[23]

At the master's level, there has also been progress in palliative care programs. The first graduate nursing programs specifically designed for training palliative care APRNs were created in the 1990s. The first palliative care nursing master's program for clinical nurse specialists was established at the Breen School of Nursing of Ursuline College in Pepper Pike, Ohio, and for nurse practitioners at New York University College of Nursing.[24] The APRN is directed to the HPNA website for the current listing of graduate-level palliative care programs.[25] In 2004, the AACN endorsed the Position Statement on the Practice Doctorate in Nursing[15] recommending that all advanced practice graduate nursing programs transition to DNP programs by 2015. At this time, there is variability in the implementation of the Consensus Model, and, as stated previously, the DNP degree is not a required component of the APRN Consensus Model, and no state board of nursing is requiring the DNP for APRN licensure. However, DNP programs are growing at a considerable rate, with the promise that nurses with the practice doctorate will be able to drive urgently needed and meaningful change at the patient-family and system levels. Thus, the registered nurse or the APRN considering graduate education should refer to the AACN,[15,26] NCSBN,[11] or HPNA[25] sites for the most current recommendations regarding the required educational degree for advanced practice.

HPNA's standards for clinical education of hospice and palliative nurses provide guidance for registered nurses, APRNs and for educators.[27] The standards clearly define primary palliative nursing practice from specialty palliative practice. Because goal-directed care and relief from suffering in the face of serious or life-threatening illness are fundamental to nursing, all nurses practice aspects of primary palliative care. Specialty palliative nursing skills include knowledge of advanced pathophysiology, pain and symptom management, counseling, and communication skills; advanced knowledge about care of persons with serious or life-threatening illness and those who are imminently dying; management of complex pain and symptoms using complex regimens; utilization of expert communication skills; care coordination across settings; provision of psychosocial and emotional support to patients and families along the illness trajectory; and integration of cultural and spiritual dimensions of care into the treatment plan for all patients. In 2017, HPNA and the American Nurses Association issued a joint call to action that nurses need to lead and transform palliative care. The call for every nurse to provide primary palliative care for any patient with serious or life-limiting illness or injury is at the center of that call to action.[28]

The Clinical Education standards also define the categories of clinical experiences for APRNs: observership, preceptorship/practicum, internship, residency, fellowship, and immersion courses.[27] These experiences are defined as follows:

- *Observership*: The purpose is to introduce the nurse to palliative care, assumes the nurse is a novice, and may be a formal requirement or informal shadowing format.
- *Preceptorship/practicum*: These are academic clinical experiences required for degree completion and eligibility to sit for certification exams.
- *Internship*: A temporary position in which a nurse exchanges services for experience between the student and the organization, lasting for weeks to months.
- *Residency*: A period of advanced education and training that should be at least 12 months in length and normally follows graduation from a nursing program.
- *Fellowship*: A postgraduate experience that offers specialty role and skill development for the APRN. This is a structured program of didactic and clinical instruction directed toward specialty practice.
- *Immersion courses*: Typically 1- to 2-week intensive courses on palliative care with or without clinical content.

Continuing education is essential for the APRN to keep current in evidence-based practice that can be accomplished through self-study, clinical in-services, and professional conferences. APRNs should become active members of national, regional, and local professional organizations so they will have access to continuing education opportunities and provide mentorship to nonspecialists. In 1999, the AACN and the City of Hope National Medical Center formed the End-of-Life Nursing Education Consortium (ELNEC) to design a curriculum for teaching palliative care to nurses.[29] ELNEC has been a successful model for improving palliative and EOL education for nurses across all practice specialties including pediatrics, critical care, and geriatrics.[29,30] Such train-the-trainer programs can be particularly impactful because they have the potential to reach a much larger audience through the participants' efforts to replicate the training in other settings.

Certification: The Advanced Certified Hospice and Palliative Nurse

With the growth of APRN roles in hospice and palliative care, the National Board for Certification of Hospice and Palliative Nursing (NBCHPN), in partnership with the American Nurses Credentialing Center, initiated specialty certification for the APRN in 2001. The first examination was offered in 2002, and the NBCHPN became the full proprietor of the exam in 2005. There are several benefits to obtaining national certification as an advanced certified hospice and palliative nurse (ACHPN). Certification is a marker of professional competence and assures that care meets the established standards for quality and safety. In addition, certification validates the specialty, protects the consumer, and is necessary for APRN billing and reimbursement.[9,10]

The ACHPN exam tests knowledge in five domains of practice: clinical judgment; advocacy, ethics, and systems thinking; professionalism and research; collaboration, facilitation of learning, and communication; and cultural and spiritual competence. APRNs who wish to sit for the exam must meet eligibility criteria including graduate-level education and a minimum of 500 hours of clinical practice in palliative care.[31] The Core Curriculum for the Advanced Practice Hospice and Palliative Nurse, published in 2007 and revised in 2013, provides the foundation of knowledge for APRNs who practice palliative care and is an excellent resource for exam preparation.[31]

APRNs: Outcomes across Practice Settings

The positive outcomes of the care provided by APRNs across specialties and settings are well-substantiated.[6,7,32] Studies of the impact by nurse practitioners on quality and financial outcomes in the acute and critical care setting have shown a reduction in resource use and length of stay and no difference in 90-day survival or mortality when compared to care by resident teams.[33–35] Evidence shows that clinical nurse specialists drive cost-effective outcomes.[36]

Although palliative care as a specialty is relatively new and the number of certified APRNs in palliative care is less than those in primary or acute care, still, evidence shows their impact on positive patient- and program-level outcomes in acute and community settings. Additionally, APRNs have the opportunity to reduce the fragmentation of care that can occur during transitions from one care setting to another and for specific patient populations. The provision of expert symptom management by palliative care APRNs early in the course of cancer may improve quality of life and, in some cases, patient survival.[37,38] Home-based palliative care consults by nurse practitioners reduced total hospitalizations, total hospital days, and the probability of 30-day readmissions in a study of 369 persons with advanced complex illness.[39] Likewise, benefits of APRN-driven outcomes in pediatric populations have been shown.[40,41]

Billing and Reimbursement

APRN billing and reimbursement is an essential part of a palliative care program's business model, and it is easier to demonstrate and to understand the value that APRNs bring to a program through documentation of revenue generated by reimbursement from government and third-party payers. The following guidelines apply to reimbursement for APRN services provided in inpatient hospital settings, outpatient clinics, skilled nursing facilities, and at home. Hospice will be covered separately at the end of the section. Medicare, the federally administered health insurance available to those aged 65 years and older or who have end-stage renal disease or meet disability criteria, will be covered in some detail because it represents a large proportion of total reimbursement for hospital- and office-based care and because other third-party payers often follow Medicare's lead.[42]

Under the Omnibus Budget Reconciliation Acts of 1989 and 1990, APRNs were first granted limited ability to bill Medicare in rural areas and in skilled nursing facilities.[42] Prior to this legislation, APRNs could bill "incident to" physician services, but this applied only to patient encounters in which the physician provided direct personal supervision by being in the office suite at the time of the encounter and APRNs could not bill for new patients or new problems.[42] In the 1997 Balanced Budget Act, APRN billing was expanded significantly. APRNs in all geographic areas and practice sites were allowed to be reimbursed at 85% of the physician fee schedule under Medicare Part B.[42] "Incident to" billing continues to be an option, but applies to only a small number of encounters and is subject to numerous restrictions.[43] To qualify for Medicare reimbursement, APRNs must satisfy a variety of requirements. They must have a master's degree in nursing, advanced certification from a nationally recognized certification body, and a National Provider Identifier. The APRN must satisfy all of the state's practice requirements, including state RN and APRN licensure, and must document a collaborative arrangement with a physician even if the state does not have a collaborative practice law. The service being submitted for reimbursement must be a service for which a physician would be reimbursed, and the state must recognize the APRN's legal authority to perform that service. In addition, the practice cannot be owned by the hospital and the APRN's salary cannot be on the hospital nursing department's cost report because the hospital is reimbursed under Medicare Part A for those services.[42] The APRN who satisfies these requirements can bill Medicare Part B. These rules apply to both nurse practitioners and clinical nurse specialists, but clinical nurse specialists may have a more difficult time meeting the requirements either because of limits to or silence at the state level on their scope of practice.[42]

To be eligible for Medicare reimbursement, a service must be defined as a "physician service" and assigned a current procedural terminology (CPT) code to document the procedure done or the service provided.[42,43] The evaluation and management (E&M) CPT codes are the most frequently used in palliative care because, rather than describe procedures (which make up a small part of palliative care practice), they describe cognitive services such as history-taking, conducting the physical exam, decision-making, and counseling.[42] There are different sets of CPT codes for different practice settings, and each set comprises a range of numbers reflecting distinct levels of service. The level of service may be determined on the basis of either complexity or time. If greater than 50% of a clinician's time is spent in coordination and counseling, then the clinician may bill based on time. This can be an effective way to document the intensity of work in palliative care, especially if the physical exam is limited. For billing on the basis of complexity, the level of service is supported by documentation of the extent of the history, physical exam, decision-making, and counseling.[42]

Of particular import to palliative care APRNs, the Centers for Medicare and Medicaid Services now allow physicians and APRNs to bill specifically for time spent performing voluntary advance care planning.[44] Although there is reportedly no limitation on the number of times advance care planning can be reported and billed for a Medicare beneficiary within a specific time period, these services should be supported by documentation of changes to a beneficiary's health status or to their wishes for medical treatment and EOL care.[44]

A second set of codes for diagnoses is necessary to qualify a service for reimbursement. International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10) codes are used to describe the disease or symptom that is treated.[45] Examples include acute respiratory failure, pain, and nausea. Compared to previous revisions, however, the ICD-10 mandates greater specificity in the diagnosis and reporting of many conditions. It is important to note that a payer will not reimburse more than one clinician per day for the same indication. For example, a palliative care APRN who consults on a patient on a ventilator in an ICU and who helps manage the patient's dyspnea should avoid submitting the ICD-10 for acute respiratory failure because the critical care clinician or pulmonologist is likely to use that code. A better choice for the APRN in such a case would be to use the ICD-10 code for dyspnea. If two clinicians submit bills listing the same ICD-10 code on the same day, only the clinician whose bill is processed first will be reimbursed. It is possible to bill for concurrent care, even if the clinicians are from the same specialty, as long as each clinician is providing a different service and can bill for a different diagnosis.

In addition to Medicare reimbursement, APRNs may be eligible for reimbursement from other third-party payers including Medicaid, commercial insurers, and managed care organizations (MCOs).[42] Although many of the billing and reimbursement guidelines for Medicare are applicable to these other payers, the Medicaid plans have considerable state-to-state variation, and each commercial insurer and managed care plan has its own policies.[42] All APRNs should refer to their respective Board of Nursing for the current status of reimbursement for services.

The 2003 Medicare Modernization Act specifies that a nurse practitioner can directly bill Medicare Part B for services provided to hospice-enrolled patients, but only if she or he is the patient's attending, and only if she or he is not a paid or volunteer employee of the hospice. A nurse practitioner must be the patient's attending of record in order to bill, and, while nurse practitioners may complete hospice face-to-face encounters, they may not certify or recertify terminal illness or serve as physician replacements on hospice teams.[46,47] Nurse practitioners may order physical therapy, speech therapy, and occupational therapy but cannot order the initial referral to hospice.[46,47] Obviously, this statute remains a barrier to full scope of practice for the palliative APRN and contributes to fragmented transitions for patients and families.

Conclusion

The past decade has brought many changes for the APRN in palliative care. The growth in palliative care programs across the United States has provided more opportunities to provide care to patients with serious or life-threatening illnesses or injury across the age spectrum. Palliative care APRNs have the skills and knowledge to address healthcare challenges by contributing to interdisciplinary patient care; providing education to patients, families, and colleagues; serving as consultants; conducting research; and taking on leadership roles. In addition, reducing psychosocial and spiritual distress is a basic nursing role that palliative care APRNs fulfill by addressing symptoms and responding to suffering through compassionate presence.[48] The implementation of the APRN Consensus Model and responses to the National Academy of Medicine's recommendations are expected to promote and increase the optimal impact of advanced nursing practice. Each APRN must keep abreast of the regulatory changes and national and state progress during this time of transition as the APRN Consensus Model is fully implemented and federal healthcare reform continues. Fortunately, the NCP Guidelines, NQF Preferred Practices, and TJC Advanced Certification for Palliative Care are excellent resources for APRNs as they lead their palliative care programs toward optimal outcomes—for patients and their families, for palliative care programs, and for healthcare systems.

Case Study: A Patient in the Care of a Palliative Care APRN

PB is an 87-year-old Italian American woman, a retired schoolteacher, who had a medical history notable for Alzheimer's dementia, aortic stenosis, hypertension, and hypothyroidism. Although she was confused and demonstrated forgetfulness and word-finding difficulty, PB was participatory in activities of daily living and able to make her basic needs known.

Following her husband's death, PB moved in with her daughter. Over the following 2 months, PB experienced a rapid decline, punctuated by increased forgetfulness, confusion and agitation at night, and several falls. PB's daughter contacted her primary care physician, who recommended placement in an assisted living facility and a referral to a community-based palliative care program.

The palliative care APRN made a home visit and met with PB, her two children and their spouses, and one adult grandchild. When the APRN inquired about the family's knowledge of palliative care, the daughter stated it was like hospice and would keep her mother comfortable, but her son commented that they were not ready for this level of care as "it's not like she's dying or anything. Dad just died, I can't imagine losing mom, too." The APRN acknowledged the family's recent loss, allowed time for the family to ask questions, and learned more about PB. Due to concern for PB's safety, the APRN recommended a referral to the team's social worker. PB's family agreed that palliative care may help prevent trips to the hospital as well as to "plan for the future." The APRN reviewed PB's advance directive and noted that the patient had a signed durable do-not-resuscitate order. PB's family agreed that she would want to be kept free of pain if her heart or breathing stopped.

The team social worker made a visit the following week. With guidance from the social worker, PB's family was able to arrange for her to be placed in assisted living 6 weeks later, but PB had difficulty adjusting to another new living environment. The staff reported that PB was becoming severely confused at night, was occasionally combative, and was anxious and tearful during the day. The APRN made a visit to the facility and reviewed the patient's medications. A bedtime dose of melatonin 5 mg was added, and escitalopram 10 mg daily, which was escalated to 20 mg daily after several weeks. Additionally, the APRN contacted PB's family and her primary physician to discuss discontinuation of several potentially unnecessary medications, namely pantoprazole and atorvastatin. These medications were subsequently discontinued.

Over the next month, PB's anxiety and agitation gradually improved. During the following 6 months, PB was seen by the APRN every 6–8 weeks and was treated for several acute problems, including a urinary tract infection and volume overload. However, she did not require hospital transfer during that time. Her speech was notable for worsening confabulation and word-finding difficulty, and at times she required hand feeding. The APRN communicated with PB's family by phone to discuss her condition, and they expressed understanding that her dementia was progressing. They agreed that maintaining PB's comfort was the priority goal of treatment. With this goal in mind, the APRN recommended hospital transfers only if her comfort could not be maintained at the facility.

Two months later, PB was found unresponsive and dyspneic in her wheelchair. She was transferred by rescue squad to the emergency department, where she was found to be in acute hypoxic respiratory failure. A chest x-ray revealed a large right middle lobe infiltrate concerning for aspiration pneumonia. She was placed on high-flow oxygen and was started on a course of antibiotics.

The palliative care APRN was able to see PB the following morning. Although her work of breathing and oxygen requirement had improved, PB was obtunded and unable to participate in her care. PB became increasingly weak and deconditioned over the course of the week. The unit case manager recommended nursing facility placement for PB, but her family members strongly disagreed. PB's children felt that she had been through too much change and returning to a familiar setting would be most congruent with honoring her comfort. Since the APRN knew PB's current condition would exceed the level of care at the assisted living facility, hospice was recommended and family agreed. The APRN contacted the assisted living facility and confirmed that PB would be reaccepted at discharge with hospice support.

PB received hospice care at her assisted living facility for 1 month and continued to decline. She died 1 month later, with her family members present.

The case illustrates the significant impact that a palliative care APRN can have across the continuum of care when using expert communication skills and comprehensive approaches to symptom management. PB suffered unfortunate but common complications of Alzheimer's dementia, yet the APRN was able to build and maintain trust with her family, collaborate effectively with other team members to provide care across settings, cultivate shared decision-making, and honor the patient's preferences through the end of her life.

CHAPTER 69

Self-Care

Kathy G. Kravits

Key Points

- Happiness is a key component of well-being.
- Well-being has a survival advantage.
- Well-being can be created through thoughtful and disciplined practice.

A Personal Perspective

Self-Care, a Journey of Discovery

> I was approximately 6 weeks out of high school when I started nursing school at a large public institution. My education was wonderful, but right from the beginning I was challenged by the suffering that I saw.
>
> At that time in our profession, we were counseled to remain "professional" when providing care, which meant not to display how we were affected by the suffering we saw. We were caught in a paradox consisting of expectations for caring and compassion for our patients while at the same time creating a façade of "professionalism" that denied our experience of suffering, especially of suffering we were helpless to stop.
>
> I graduated from school and spent the first 6 months as a registered nurse working on a general medical unit at the same facility where I trained. I chose to stay at that facility because I knew that I was committed to stopping at least some of the suffering I saw, and the patients who sought care there had very few resources to obtain relief.
>
> I was accepted into a critical care training program and worked in critical care for the first 15 years of my career. I thought the critical thinking and problem-solving would distract me from the suffering and help me to manage my increasing compassion fatigue. Wrong. The new layers of complexity in the actual caregiving only added to my distress. I became increasingly irritable and negative. My distress became unbearable. I was probably fully involved in burnout at this time, but did not recognize it. My distress became so unbearable that I changed jobs, thinking that that would help. Wrong. For the next 5 years, I changed jobs every year, never really improving. I descended more quickly with every job into burnout.
>
> My recovery did not start until I began to teach new critical care nurses about the biological basis of the stress response as proposed by Hans Selye.[1,2] Understanding that what I was experiencing was a normal biological response to exposure to stressors associated with professional caregiving including the suffering of others relieved me of the shame that I had been feeling. Shame associated with my belief that I was not good enough.
>
> I began to learn about self-care and how to create a fulfilling life. This process of self-discovery and healing is an ongoing one. I continue to evolve my understanding of what it means to care for myself. Every new practice that I implement in my life with self-compassion, self-reflection, and a holistic perspective helps me to grow to be a better person and a better nurse, less vulnerable to the challenges of being a compassionate caregiver.
>
> —*Kate Kravits*

Introduction

Palliative care providers, by the nature of their work, are exposed to patient care situations that require the expenditure of intense emotional energy (i.e., end of life, physical suffering, emotional distress, psychological pain, moral distress, etc.).[1,2] This chapter describes the vulnerabilities commonly associated with palliative care that put palliative care providers at risk for compassion fatigue and burnout. Evidence-based, self-care strategies that promote wellness are discussed, as is a process for developing a personalized wellness plan. The long-term, physiologic impact of body stressors are reviewed. Strategies for responding to stress are reframed as opportunities for gaining new awareness to promote resilience and allow for adaptation and growth. Well-being is defined, and the impact of well-being on quality of life and long-term survival is discussed.

Stress and Stressors

Hans Selye was one of the first researchers to study the response to stress in an organized and rigorous manner. He coined the term *general adaptation syndrome* (GAS) to describe the stages of the stress response.[1] In 1946, Selye not only described the GAS, but developed evidence to support the role of the endocrine system in the stress response and the role that stress plays in the development of chronic illnesses (i.e., cardiovascular disease, hypertension, diabetes, etc.).[2] Building on Selye's work, researchers have developed a detailed view of the stress response and have confirmed Selye's belief that the stress response can play a role in the development of chronic illness and organ dysfunction.[3] Individuals who either personally or professionally experience frequent, intense, and/or uninterrupted stressors must develop effective strategies for preventing and managing their exposure and response to those stressors in order to protect their long-term health and well-being.[4]

Biological Systems Supporting the Stress Response

Three important systems that mediate the stress response are the sympathetic adreno-medullary system (SAM), the hypothalamic-pituitary-adrenocortical axis (HPA), and the polyvagal system.[3]

These systems mediate the processes necessary for the individual to respond to threat.[5]

The SAM system consists of sympathetic nerve fibers that release norepinephrine (NE). NE, a neurotransmitter, increases respiratory rate, heart rate, and blood flow to voluntary muscles. Activation of the SAM system creates the earliest response to threat. It redistributes oxygen and glucose to the muscles and organs necessary for "fight or flight."[5]

The HPA is an endocrine system that functions during the stress response to promote the release of glucocorticoid. Glucocorticoid plays a significant role in metabolizing glucose from liver glycogen and in releasing the glucose into the bloodstream.[5]

The polyvagal theory suggests that the branches of the vagus nerve perform unique functions, including facilitating heart rate variability in response to changing environmental conditions and self-regulation.[6] The dorsal vagal complex (DVC) branch of the vagus nerve promotes survival by conserving resources through behavioral strategies such as immobilization and avoidance. Freezing and fainting may be triggered in response to actual or perceived loss of oxygen.[6] When people say, "I nearly passed out with fright," they may, in fact, be speaking the literal truth. In the face of extreme threat, when resources are insufficient to meet the threat, the body protects itself from suffering by freezing or fainting.

Initiation of the Stress Response

Sensory information is brought to the brain, and two pathways relay the sensory data to the limbic system and the prefrontal cortex for processing and action. The two pathways are known as the "quick" and "slow" paths. The "quick" path delivers sensory information to the limbic system, where threat is immediately determined and action taken, if necessary, through the activation of the SAM.[7] The "slow" path delivers sensory data to the prefrontal cortex and is designated as "slow" because, compared to the "quick" path, many more neurons are involved in the transfer of data and thus require a longer period of time to deliver information.[7] Cognitive processing of response strategies lags behind the more immediate responses of the sympathetic system.

Intentional choices to behave in a specific manner in the face of threat require activation of the prefrontal cortex. Deep breathing is an ideal behavior for retarding the sympathetic response through activation of the vagus nerve, allowing cognitive processing to take place. Many self-care practices include some form of breathing practice. Yoga and meditation are two examples.

Palliative Care and Emotional Labor

Palliative care, regardless of the discipline involved, relies on emotional labor to accomplish many of its goals. Unfortunately, emotional labor often is not recognized as a component of professional caregiving, nor is its impact acknowledged.[8,9] Emotional labor involves managing emotion and emotional displays in the professional caregiving environment. Emotional labor requires the use of personal energy and resources. It is an essential element of authentically attending to the patient, family, and caregiving team. Overuse of personal energy and resources in the pursuit of providing care without rest and renewal may be associated with role stress.[8]

Compassion Fatigue

Compassion, a vital component of emotional labor, is a feeling of profound sympathy that arises from witnessing the suffering of another and prompts the desire to intervene in that suffering.[10] Emotional labor requires that the professional healthcare provider be capable of experiencing compassion and use it in the context of delivering patient care.[8] *Compassion fatigue* describes a progressive decline in the ability to feel compassion and/or to act on those compassionate feelings.[11] The healthcare environment exposes providers to multiple sources of human suffering. Repeated, diverse, and intense exposures without reasonable opportunities for emotional recovery over time can lead to compassion fatigue.[12]

Compassion fatigue that occurs as a consequence of professional experiences can invade all domains of life, frequently impacting personal resources and relationships (i.e., spouses, family, friends etc.), making it increasingly more difficult to recover.[12] Presented in Table 69.1 are the signs and symptoms associated with compassion fatigue that are consistent with emotional exhaustion and the coping strategies used to manage the exhaustion.[12]

Table 69.1 Examples of signs and symptoms associated with compassion fatigue

Physical domain	Psychological/Emotional domain	Social/Relational domain	Spiritual domain	Professional practice domain
Alterations in sleep patterns	Irritability	Withdrawal from family activities	Loss of meaning and purpose	Avoidance
Changes in eating patterns	Episodes of tearfulness	Lack of interest in pleasurable activities	Hopelessness	Increased absenteeism
Unplanned fluctuations in weight	Impaired concentration	Conflict in personal relationships	Overwhelmed with uncertainty	Inability to meet obligations in a timely manner
Episodes of pain	Alterations in judgment	Isolation		Disengagement
Decrease in self-care activities	Emotional emptiness			Errors and other safety violations
Substance use	Feeling removed from self			Conflict in work relationships
	Feelings of helplessness			Frequent changing jobs

Secondary Traumatic Stress Symptoms

There has been a great deal of confusion in the literature about *secondary traumatic stress symptoms* and whether this is the same syndrome as compassion fatigue. The evidence suggests that they are different experiences with different etiologies that may present with some of the same signs and symptoms.[13] Secondary traumatic stress symptoms occur in the context of an individual who has experienced adversity historically and is traumatized by experiences in the present that are similar enough to the original experience(s) to reactivate the feelings and memories associated with the original trauma.[13]

The coping behaviors and associated resultant signs of individuals who are experiencing secondary traumatic stress symptoms may overlap with some of the signs of compassion fatigue. Healthcare providers may suffer from both syndromes. Management is different for secondary traumatic stress symptoms and requires professional assistance. If proactive, positive self-care measures fail to bring relief, working with a mental health professional may be appropriate to create a successful remedy.

Burnout

Burnout has been investigated for more than 20 years. It is considered an occupational risk for individuals working in human service professions including healthcare. Maslach is one of the seminal researchers in the area of burnout and one of the creators of the most frequently used instrument for measuring it, the Maslach Burnout Inventory.[14]

Maslach defines burnout as "a psychological syndrome occurring in response to prolonged interpersonal stressors at work."[14] In the original conceptualization of burnout by Maslach and her colleagues, burnout included three subcategories: emotional exhaustion, depersonalization, and personal accomplishment. The subcategories have been reconsidered to be emotional exhaustion, cynicism, and inefficacy. Replacement of depersonalization with cynicism acknowledges the influence of negative attitude on the development of burnout. Inefficacy emphasizes the impact of feelings of helplessness on the development of burnout.[14,15]

In recent years, *engagement* has emerged as an important concept with regard to work environments. Engagement is the subjective experience of being fully absorbed. While engagement is defined in different ways, researchers agree that engagement is an important, positive, accomplishment-affirming factor in the workplace. The evidence indicates that engagement is composed of the qualities of vigor, dedication, and absorption, and it serves as a counterbalance to the circumstances that promote burnout.[16]

Engagement is influenced by both personal and contextual factors.[16] There is evidence to suggest that engagement improves well-being and health.[16,17] Gander and colleagues conducted a randomized, placebo-controlled online trial of interventions addressing pleasure, engagement, meaning, positive relationships, and accomplishment as strategies to increase well-being and reduce depressive symptoms.[17] The results of this study of 702 individuals suggest that engagement has a beneficial effect on well-being and depressive symptoms. However, the degree of distress present when enrolling in the study may have influenced the degree of response found.

Gander and colleagues developed an intervention that relied on attending to personal experiences that meet the definition of engagement.[17] The intervention instructed: "Remember three things you have experienced today where your attention was particularly focused and you were not aware of your surroundings. Write these three things down and describe how you felt." This intervention identifies and describes both the circumstances of the experience and the feelings associated with those circumstances, which are then documented, thus creating a journal of "engaged" moments. The material is then available for intentional choice as the individual works to create a more enriched life and better well-being.

Antecedents of Burnout and Compassion Fatigue for Palliative Care Providers

The work environment is the context within which burnout and compassion fatigue most commonly occur. Some of the personal vulnerabilities identified in the literature include genetic predispositions, transgenerational histories of trauma, insecure attachment, childhood adversity, historical trauma, maladaptive coping such as substance abuse, and personal losses including divorce and death.[18–20]

There is well-documented evidence of vulnerabilities that predispose a palliative care provider to develop burnout or compassion fatigue. Many of the risk factors are associated with providing service to patients at end of life. They include the providers' feelings of helplessness that come with the inability to relieve the suffering of their patients, psychological challenges that are part of assisting a patient's adaptation to catastrophic illness, and navigating with the patient those losses that are part of the illness and treatment experience, including the loss of meaning and purpose.[20,21]

Professional expectations and behaviors that may contribute to the development of these syndromes include overinvolvement (blurry professional boundaries), unrealistic personal expectations of the caregiving experience, attempting to meet personal needs through work, and work not a fit for the personality.[10] As noted in Box 69.1, there are five organizational characteristics commonly identified with increasing the risk of burnout and compassion fatigue.[14]

Organizations can create systems and structures that intensify the potential for staff to develop compassion fatigue. Rotating shifts is one of the factors identified in many work environments that contributes to the risk of burnout and compassion fatigue and diminishes workplace safety.[16] Workloads perceived by staff as impossible to manage and lack of management support are organizational factors that also contribute to compassion fatigue and burnout.[14] Workplaces that successfully construct management structures that incorporate, in a meaningful manner, employee contributions to the development of work routines reduce rates of burnout and compassion fatigue within their organization.[10,22]

Consequences of Burnout and Compassion Fatigue

Burnout and compassion fatigue can be associated with negative interpersonal, physical, and professional consequences.[14] Some of the consequences are declining work performance, safety violations, errors in judgment, inability to concentrate, disruption of relationships, and diminished participation in recreational activities. Additional signs and symptoms associated with burnout and compassion fatigue are noted in Table 69.1.

Box 69.1 Sample Wellness Plan

Intention Statement(s)

An intention statement is an "I" statement phrased in the present tense using action-oriented verbs. It represents an action, pattern of behavior, and/or thought process that the individual intends to incorporate into his or her life. For example:

1. I am healthy and energetic.
2. I practice random acts of kindness.
3. I count my blessings daily.

Action Matrix

Domains	Action/ Frequency	Resources	Re-evaluation
Positive emotion	Daily counting of blessings	None	Weekly review
Engagement	Weave with absorption and passion	Weaving materials	At the end of each session
Meaning	Practice daily meditation	None	Did I practice?
Positive relationships	Make cookies for the toddlers in the neighborhood	Cookie mix	Ongoing contact with the family
Accomplishments	See patients one day a week	Group practice	Full schedule

Qualities that Protect the Palliative Care Provider from Burnout and Compassion Fatigue

There are individual and organizational qualities that may decrease the likelihood that the individual will develop burnout and compassion fatigue. Individual qualities include feelings of self-efficacy, optimism (ability to frame experience in terms of opportunity and learning), hardiness (triumph of hope over experience), and resiliency (recognition of internal and external resources).[22,23] These qualities provide an emotional foundation that encourages the individual to reframe challenging experiences and to learn new, adaptive strategies for managing these challenges in the future.[2] Organizational factors that promote engagement and inhibit the development of burnout and compassion fatigue are outlined in Table 69.2. Each of the qualities protects feelings of self-efficacy and communicates that the organization values the healthcare provider.[14]

Creating Well-Being through Self-Care

Well-Being

Well-being is a model for creating a fulfilling life.[23] It is composed of five aspects of life: positive emotion (comprised of life satisfaction), engagement (vigor and absorption); meaning ("belonging to and serving something larger than yourself"[25]), positive relationships (well-being occurs in the context of relationship), and accomplishment (success not for gain but for the pursuit of a goal).[23–26] Cross-culturally defined personal qualities associated with well-being include kindness, fairness, authenticity, gratitude, and open-mindedness.[24] Well-being has been shown to be associated with improved physical health as well as improved mood and feelings of happiness.[23–26]

Self-Care

Effective self-care creates well-being.[18] Mill, Wand, and Fraser conducted a self-care survey of 372 palliative care practitioners including physicians and nurses. They reported that "most respondents regarded self-care as very important (86%) and less than half (39%) had received training in self-care. Self-care plans had been used by a small proportion of respondents (6%), and over two-thirds (70%) would consider using self-care plans if training could be provided."[18] These findings highlight that while the desire to practice positive self-care exists, there is a demonstrable lack of ongoing education and follow-up available for many healthcare providers. Dorociak and colleagues identified professional support, professional development, life balance, cognitive awareness, and daily balance as some of the key categories for effective professional self-care strategies.[24]

There are barriers to self-care that can be seen in a wide range of populations. Some of the barriers described in the literature are low levels of self-efficacy, beliefs that self-care can't be sustained or won't work, lack of knowledge, financial constraints, and lack of social support.[27,28]

Elements of Self-Care

Positive, proactive self-care requires both "a will and a proper way."[25] Positive, proactive self-care also requires an expectation that things can get better. It is important that self-care is attached to meaning-based activities and it requires active self-discipline.[25] The process for creating positive, proactive self-care strategies includes self-reflection, positive self-efficacy, body monitoring, planning, and action.[28]

Self-Reflection

Self-reflection examines expectations for positive outcomes. The self-reflection should be conducted with compassion and should be nonjudgmental. The self-reflection is beneficial when it includes past failures as well as past successes.[29] Making use of experiences arising from less than desirable situations requires that the individual reframe them from negative experiences into learning opportunities.

Reframing negative experiences is easy when it is started by asking oneself, "What did I learn from this situation?" This question refocuses the self-reflection from a negative self-judgment expressed in negative self-talk like, "I am so stupid" to an analysis of the experience as a new opportunity for learning new lessons and creating new, more effective coping strategies. These learning opportunities have the ability to fuel adaptation and growth.[29,30]

Self-Efficacy

Positive self-efficacy is an individual's knowledge that he or she is capable. Without an individual's believing that he or she can be the agent of success and growth, there will be no positive self-care.[23] Believing in oneself is sometimes extremely hard to do. Martin Seligman, in his book, *Flourish,*[23] offers an exercise for developing a broader and more enduring belief that one is capable. He suggests the following steps: take a moment in a peaceful, quiet environment and reflect on one's strengths. Then, make a list of those strengths and the situations in which they most commonly manifest. This can be done as a written list, but may be done through the use of a more nonverbal medium such as visual art-making. Then, select one strength and imagine how that strength could be used differently. Make a plan for using that strength in a new way, write the plan down, and commit to a timeline for doing it. Once the plan has been implemented, reflect on it. Remember to reframe and recreate if the results were less than desirable and do it again. He counsels that sometimes a single attempt is not enough. Regardless of one attempt or several, this exercise takes abilities that are often unappreciated and brings them to conscious awareness, employing them in new and creative ways that cement the belief in one's self-efficacy.[29]

Body Monitoring

Body monitoring, in its most basic sense, is regular assessment of bodily processes through intentional redirection of attention to the body, without the use of external sensors and/or surveillance using sensors (i.e., blood pressure monitors, blood glucose monitors, etc.). Body monitoring is frequently used as one element of self-care strategies to manage chronic illnesses such as heart failure and diabetes.[31–33] It is also a valuable process to use when needing to assess an emotional response as expressed by bodily sensations and symptoms.[30,34] Successful positive, proactive self-care requires that ongoing monitoring of bodily responses be carried out and used to provide feedback that supports the self-care plan and/or modification of it.

Bodily sensations are frequently discounted as valuable data about our well-being, and yet our most powerful forms of communication are frequently nonverbal. Ignoring bodily sensations is learned through life experience, especially when it is important not to feel an emotional response.[30] Healthcare providers are particularly vulnerable to this because regardless of how they "feel" when they are in professional situations, they learn to ignore their feelings in service of their brain in order to provide safe and effective care. It is important to reacquaint ourselves with our body's voice in order to achieve well-being.

Begin to familiarize yourself with your body by placing yourself in a quiet, restful environment without external distractions. Pay attention to your breath, progressively allowing it to become deeper and slower. As your breath slows, beginning at your toes, notice which muscles feel relaxed and which feel tense. Gradually move your attention up your body, noticing how the right and left sides of your body feel. Do they feel the same? Where is the tension in your body held? Is there any tension? Continue this surveillance for a minimum of 2–3 minutes and make a note of your bodily sensations and any feelings that go with them. Continue this as a regular nightly ritual. Over time, your bodily sensation will communicate how you feel on a subtle level, and you will begin to be able to use this information to create new strategies for well-being. An excellent resource for learning more about how to communicate with your body is *Sensorimotor Psychotherapy: Interventions for Trauma and Attachment,* written by Ogden and Fisher.[33]

Self-Care Planning

Writing plans down increases the likelihood that they will be accomplished.[34] For example, writing down a daily schedule for exercise reinforces the intent to exercise and results in a greater likelihood that exercise will take place. Wellness plans may take any form that is useful. Regardless of format, two essential elements of a wellness plan help to establish expectations and to create a comprehensive plan of action. They are a statement of intention and a matrix of actions organized by areas of well-being. Box 69.1 presents Sample Wellness Plan, as a suggested model for creating a comprehensive self-care plan.

An *intention statement* is an "I" statement phrased in the present tense using action-oriented verbs. It represents an action, pattern of behavior, or thought process that the individual intends to incorporate into his or her life. The intention statement should be phrased as if it were already true. By doing this, the intention is taken in and stored as if it were already the manner in which the individual behaves. It is recommended that a maximum of three intentions are documented in the wellness plan. Any more may dilute focus and are more challenging to track. Examples of several intention statements are presented in Box 69.1, Sample Wellness Plan.

A comprehensive well-being plan is created by identifying behaviors that will support the intention statement(s) and that address creating positive emotions, engagement, meaning, positive relationships, and accomplishments.

Positive Emotions

Creating positive emotions can be accomplished many different ways. One way is described by Seligman (2011) as "Imagining a best possible self."[23] Every evening before retiring, write down a minimum of three things that went well during the course of the day. On the same page, write down an affirmation (positive intention statement) that supports some aspect of those positive occurrences. Over time, the number of things that go well in the course of a

day will grow. Alternatively, one may become more proficient at noticing the positives as they happen.

Expressing gratitude is very effective in helping to create positive emotions. Once again, writing helps to make the experience of gratitude more lasting, and it allows the gratitude to be shared. Write a letter of gratitude. Mail it or not, but by writing it the experience has a profound impact.[23] A woman once reported that she began to work on her experience of gratitude by counting her blessings while walking her dog. In the beginning, she would run out of blessings before she left her yard. At the time she was describing her experience, her walk had grown to 90 minutes, and she was still counting blessings after returning home. Her experience is an example of the maxim, "We grow that to which we pay attention." The other benefit was that she was able to monitor her progress toward well-being by counting her blessings while performing a specific activity.

Performing an act of kindness can increase positive feelings. Seligman (2011) describes an exercise in his book, *Flourish,* designed to expose the impact of random acts of kindness on mood. He recommends identifying one unexpected kind thing to do and do it. He then suggests, "Notice how you feel."[23]

Meaning

Meaning is defined by Martin Seligman in his book, *Flourish*, as "belonging to and serving something bigger than the self."[23] Meaning is not entirely a subjective experience of the individual, but may be specific to the individual. Cultural biases and values may define what is meaningful for a group or society and therefore influence individuals' understanding of meaning. Meaning is an autonomous element of well-being and is measured separately from positive emotions, engagement, positive relationships, and accomplishments.[23]

Gander and colleagues used an intervention in their 2016 study to increase awareness of meaningful experiences. The intervention was framed in a manner similar to others in that the study used the following injunction, "Remember three things you have experienced today that were personally significant and meaningful. Write these three things down and describe how you felt."[17] Being able to identify what is truly meaningful to an individual promotes effective coping in times of uncertainty and bolsters feelings of hopefulness.[17]

Positive Relationships

Positive relationships have been identified as an important adult developmental milestone. In the pursuit of well-being, positive relationships and the ability to sustain one is a key indicator of good health, optimism, and well-being.[30] Comfort, safety, and support can occur in the context of a positive relationship. As with many of the other elements, it is important to be aware of your relationships and whether your partner, family, and community help you achieve the things that are most meaningful.

Accomplishments

This chapter has already addressed self-efficacy. A related but separate construct is accomplishment. Recognition of accomplishment helps to reinforce self-efficacy and has value in its own right.[24] Awareness of accomplishment is important. Using the same model as with the other elements, "Remember three things you have experienced today where you were successful or where you had the impression that you did something really well. Write these three things down and describe how you felt."[24]

Conclusion

Well-being protects physical and emotional health.[23] Following the road map laid out by Seligman enhances well-being. Practice gratitude, count your blessings, take action, and believe better things are on their way.

CHAPTER 70

Ethical Considerations in Palliative Care

Maryjo Prince-Paul and Barbara J. Daly

Key Points

- What constitutes "extraordinary care" will be almost entirely contingent on the values and clinical situation of the patient.
- Effective palliative care that rests on a sound ethical foundation requires ongoing discussions about patient and family values and preferences.
- Decisions regarding ethical dilemmas and the choices that are necessary require thoughtful discussion and critical communication skills.
- The ethical duties of all healthcare providers include the obligation to respect diversity in the views of colleagues as well as patients.
- All healthcare professionals have the right to and responsibility for maintaining their own ethical integrity.

Ethics and Moral Reasoning

Ethics, broadly defined, is the branch of philosophy that is concerned with the study of human conduct, with the rational analysis of how human beings ought to behave, and the methods by which we can identify good and evil, right and wrong.[1] In contrast, the term "morality" is conventionally used to refer to accepted and rational codes of conduct governing behavior, aimed to promote good and minimize evil.[2] As can be seen, these terms are closely related and are often used interchangeably.

Much of this text is concerned with the practical sense of nursing—that is, the application of natural and behavioral sciences in designing and implementing effective processes of care. This chapter will address what Bishop and Scudder refer to as the "primary sense of nursing practice," the moral sense.[3] The focus will be on the most common issues faced by nurses in palliative care. Our objective is to prepare the nurse for identifying, addressing, and resolving the complex questions that arise in caring for individuals and families facing life-limiting illnesses.

In confronting ethical questions, nurses may experience varying levels of moral quandaries. Given the complexity of the healthcare system and individual patient situations, nurses often are uncertain about the right or most ethically sound action. *Moral uncertainty* can produce discomfort, but it is the hallmark of a morally sensitive agent. It signals doubt or confusion about values or rules, but it can usually be resolved with careful analysis, as we will illustrate with case studies. In contrast to uncertainty, *moral dilemmas* are more troublesome and occur when the nurse finds her- or himself in a situation with conflicting demands or one in which every possible action seems to involve violating an ethical duty. Dilemmas may be associated with significant stress and anxiety; resolution may require assistance of others to sort through the conflicts involved. *Moral distress* is the most damaging state and occurs when the nurse perceives a moral duty but is unable, often because of external constraints, to fulfill that duty. Persistent moral distress can lead to disillusionment, moral apathy, and eventual resignation.

Dealing with ethical questions before moral distress occurs requires knowledge and skill in ethical reasoning. While thorough exploration of ethical theories is beyond the scope of this chapter, a brief review of the major theories that are the basis for the commonly accepted principles of autonomy, beneficence, nonmaleficence, and justice will be helpful. Following this review, specific issues that the palliative care nurse is likely to face will be explored, with particular attention paid to analysis of the problems.

Moral Reasoning

As mentioned, ethics as a discipline has its roots in philosophy. There are many ethical theories that have been developed over the years, each with its own justification. The best known of these are deontological theories and consequentialist theories. *Consequentialist theories* evaluate the justification for actions by examining consequences. The action that produces the best consequences for the greatest number is the preferred or "right" action. *Deontological theories*, in contrast, argue that actions are right or wrong according to their adherence to duties and obligations, not by virtue of the consequences of the actions. Both types of theories generate principles, such as autonomy (the right of self-determination), beneficence (the duty to promote good), and nonmaleficence (the duty to do no harm). From principles, in turn, more specific moral rules can be derived. For example, the general duty to respect autonomy and the right of self-determination is the basis of the specific rule that we obtain informed consent before interventions.

Both deontological and consequentialist theories are forms of a *principlist approach* to ethics. Principlist approaches, although they may rest on differing theoretical premises, all use general and relatively universal principles as the central tool for ethical analysis. Universal principles play a key role in developing mature ethical agency, provide reliable rules of thumb for responding quickly in real-life dilemmas, and reflect the considered wisdom of decades of philosophical analysis. Nevertheless, abstract and somewhat rigid principles can be insensitive to the nuances of specific clinical situations and conflict with the deep intuitions of experienced clinicians. More recently, appreciation for the importance of context has grown.

Feminist ethics, an *ethic of care*, and *narrative ethics* are relatively new approaches to ethical analysis. The development of feminist ethics, an outgrowth of the feminist movement, was encouraged by the work of Carol Gilligan, who studied moral reasoning in children and found that boys typically relied on a rule-oriented, justice-based approach, while girls tended to analyze situations in terms of relationships and context, seeking resolution in the details of the story or narrative.[4] Consistent with Gilligan's work, caring as a basis for ethics rests on the assumption that morality is rooted in human relationships and feelings. Nel Nodding, recognized as the originator of this theory, argues that morality must stem from the caring instinct and that the ethical ideal is located in the reciprocal caring relationship between and among persons.[5]

Narrative ethics uses the stories of patients and health professionals as the unit of analysis. In seeking understanding of ethical dilemmas from a narrative perspective, the elements of the situation are viewed as components of the story, and aspects such as the relation among participants, predominant voices, intentions of the actors, and consideration of whose voices are heard and not heard are central to developing understanding of the ethical dimensions.[6] As with the ethic of care and feminist ethics, understanding the relationships among all participants, the meaning of what is stated and unstated, and the motives of all involved is key to the evaluation of how best to respond in ethical dilemmas. Sara Fry has argued that the traditional approach to medical ethics, which centers on application of objective principles and simply evaluating which principle takes priority, is no longer adequate as a foundation for nursing ethics.[7] She points out that caring, as an ideal, is a more comprehensive basis for the traditional values of autonomy and doing good for patients. Rather than relying on moral theory, Fry suggests that nursing ethics rests on a moral view of persons. Thus, in the discussion that follows, we will attempt to evaluate issues and illustrative cases with reference to the usual moral principles, but will also consider the moral obligations that may stem from the caring relationship that nurses have with their patients.

Regardless of the theoretical underpinnings of ethical analysis, the nurse who identifies ethical issues or questions will need to use a systematic process to examine the situation and reach a decision about what action to take. There are many suggested models for analyzing ethical dilemmas, and any thoughtful, deliberative process can be helpful. One approach that is similar to the problem-solving steps most nurses have learned is illustrated in Box 70.1. The process begins with identifying the issue or question; this step helps to focus the ethical issue, clarify what aspect of a complex patient care situation is raising concerns, and differentiate the ethical dilemma from clinical problems. The second step, a review of facts and assumptions, directs the nurse to be clear about relevant data and to be sensitive to assumptions that may not be based on adequate data. The third step, to list all options, is intended to prompt the nurse to think carefully about all possible actions, rather than fall into the temptation to dichotomize the possible answers (e.g., withdraw all treatment or continue all treatment, accept the patient's decision or do not accept it, etc.). The fourth step is the point at which the nurse must bring to bear considerations related to ethical principles, relevant professional norms, laws, policies, and personal values. In this step, each option is evaluated against these touchstones or criteria. Finally, having evaluated each option, the final decision is made as the fifth step. Most ethical dilemmas are multifaceted, with conflicting demands. The case studies that follow in this chapter will demonstrate the complexity of these challenges, the need to address them in a methodical and logical process, and the essential caring role of the nurse in responding to such dilemmas.

Box 70.1 Steps of Ethical Problem-Solving

1. Define the Problem

   Differentiate clinical problems, such as uncertainty or disagreement about prognosis, from ethical problems, such as determining how to balance duties to provide benefit and duties to respect autonomy. Assure that everyone identifies the same issue.

2. Clarify Facts and Assumptions

   Differentiate known facts from assumptions about the situation, such as presumed motives of family members; assure that all parties have access to the same facts.

3. Develop a List of All Options

   Differentiate known facts from assumptions about the situation, such as presumed motives of family members; assure that all parties have access to the same facts.

4. Evaluate All Options

   Consider relevant laws, policies, and ethical principles; address rights, duties, and interests of all involved.

5. Choose the Optimal Option and Implement

Common Ethical Dilemmas

Case Study 1: Determining Decisional Capacity

A 75-year-old woman with a 15-year history of coronary artery disease, hypertension, diabetes, and heart failure entered the hospital with a left-sided cerebrovascular accident (CVA) that has left her partially aphasic, hemiparetic, and causes her to aspirate food of any consistency. Seven days after the stroke, her mental status was unclear, and there was a disagreement as to whether or not she had decisional capacity. She was able to answer "yes" and "no," although the responses were inconsistent. The attending physician was convinced that the patient lacked decision-making capacity while two family members (her daughter and younger sister) were equally convinced that she had decisional capacity. The patient did not have an advance directive. The patient's husband stated that they never held specific or detailed conversations about preferences for life-sustaining treatment. Until her stroke, she was active in her retirement and enjoyed gardening. He believed that she would not want to live in a condition that would not allow her to function as fully as she was prior to the CVA, but he was ambivalent about the placement of a feeding tube. The patient's family (daughter and sister) insisted that a feeding tube be placed because not doing so was "killing her." The attending physician and the rest of the interdisciplinary healthcare team were opposed to placing the feeding tube. In fact, several nurses who cared for this patient during previous hospitalizations for heart failure claimed that the patient told them that she did not want to be sustained by artificial means. The neurological consultant verified that, at this point, further significant recovery was unlikely due to dense damage to the cerebral cortex. The team believed placing a feeding tube was "potentially inappropriate." The advanced practice registered nurse was concerned about whether the patient would have wanted it and whether it would serve her best interests in the long term. She needed help to resolve this conflict.

Goal-Setting and Advance Care Planning

Patients with advanced disease or near the end of life, their families, and healthcare providers may encounter a variety of ethical dilemmas and subsequent choices. Although moral questions can arise about any aspect of nursing practice, including informed consent and duties to colleagues, the issues most frequently encountered in palliative care center around end-of-life (EOL) decisions. These include withholding or withdrawing treatment (e.g., mechanical ventilation, hemodialysis, cardiopulmonary resuscitation, and cardiac assist devices), concerns about use of medically administered nutrition and hydration (MANH), requests for hastened death, and palliative sedation.

For the most part, ethical analyses of these issues are grounded in patient choices, goals of care, preferences, prognosis, and communication. However, there are many important social, cultural, professional, and legal influences that have made these choices complex. The continual expansion of technological options and biomedical interventions, particularly over the past few decades, has enabled the medical profession to prolong life through sophisticated interventions before adequate bioethical norms have been established. As a consequence, it is usually more helpful to focus on patient preferences for *outcomes* of treatments rather than preferences or choices for *specific treatments*.[8] Clearly, this requires careful and repeated discussions with patients and their families. As can be seen in Case Study 1, it would have been much more helpful to know the patient's feelings and attitudes about what states or conditions would have been acceptable to her rather than general statements about use of "artificial means."

The pace and demands of healthcare today add to the challenges of addressing ethical issues in the clinical setting and may lead to hasty and arbitrary decision-making. According to Levine-Ariff, "It is only with a thrust toward preventive ethics that decisions can be thoughtful and beneficial to patients and families."[9(p. 169)] "Preventive ethics" can be thought of as standards and norms that, when adhered to, can minimize the frequency with which difficult conflicts and dilemmas occur. The use of advance care planning is an example of a "preventive ethics" intervention that nurses can implement on an individual level.

Because of the many difficult decisions that will be faced by most people as they age and experience serious illnesses, assuring that thoughtful discussions take place before serious illness occurs can be quite helpful in preventing later uncertainties and dilemmas (see Case Study 1). *Advance care planning* is a process of communication and documentation to identify patients' preferences about goals of care and to identify an authorized proxy who can provide competent, confident, and informed representation for choices when the patient is unable to express wishes. *Advance directives* are written instructions to healthcare providers that are established before the need for medical intervention. Advance directives have three major purposes: to provide a mechanism to enable providers to respect patient autonomy in situations in which the patient cannot express his wishes, to provide guidance to healthcare professionals and family members regarding how to proceed with decision-making about life-sustaining interventions, and to provide immunity for professionals from civil and criminal liabilities when certain stated conditions are met.

A *living will* is one type of advance directive which is often accompanied by a *durable power of attorney for healthcare* (DPAHC) or *healthcare proxy*. Living wills are used to declare wishes to refuse, limit, or withhold life-sustaining treatment under such circumstances that the individual is incapacitated or unable to communicate, while the DPAHC authorizes the agent or proxy to make all healthcare decisions, presumably acting as the patient would have. A living will, as the patient's own treatment preference, takes precedence over the DPAHC if there are conflicts. However, in many states, the living will statute specifies that this document is only in effect when the patient is terminally ill, as determined by a physician, and thus it may not be helpful in situations such as major cerebrovascular accident, significant dementia, coma, or other serious illnesses that are not considered inevitably terminal. Unfortunately, because predicting and outlining all possible choices regarding healthcare scenarios is difficult, advance directives are rarely specified as precisely as needed,[10] especially when a disease progresses and the context of the situation changes. Despite their shortcomings, advance directives are the best instruments we have to ensure that an individual's goals and preferences for care are met.[10]

It has been more than two decades since the Patient Self-Determination Act (PSDA) was made law in 1990, and empirical studies reporting effectiveness of advance directives continue to produce mixed results. In a systematic review and meta-analysis of the efficacy of advance care planning, Houben and colleagues[11] found that none of the studies limited to completion of advance directives explored the impact on preferences for EOL care and the actual receipt of end-of-life care. However, meta-analysis of those studies that included advance care planning discussions with completion of an advance directive yielded an increased likelihood of receiving EOL care that was in concordance with patient preferences. To that end, Johnson and colleagues[12] suggest that, in order to have a solid foundation of evidence of clinical effectiveness of advance care planning and completion of advance directives, conceptual clarity regarding "concordance," adequate attention to statistical methods, and valid and reliable measures must be considered at the onset of any research study. Nonetheless, advance care planning is an essential process that should begin to take place at the point of diagnosis and be revisited throughout the course of the disease trajectory to ensure that patients' preferences for care are honored.

Other forms of advance directives include out-of-hospital *do-not-attempt-resuscitation* (DNAR) orders and the *Five Wishes*,[13] a detailed guide for discussions of preferences for EOL care. The Five Wishes document helps individuals who are seriously ill and unable to speak for themselves express how they want to be treated from a medical, personal, emotional, and spiritual perspective. In addition, this unique document helps patients discuss their wishes with family and the healthcare team prior to loss of capacity and can be used in all 50 states and in all countries around the world (available in 28 languages); however, it meets the legal requirements for an advance directive in only 42 states and the District of Columbia. In the other eight states, the Five Wishes document can be included with the state's required form.

Healthcare advance directives differ widely in format and content, making the already complex issues that palliative care nurses face even more difficult. Additional barriers exist when patients transfer from one care facility to another and the requirements change or the previously existing document is not incorporated or honored. In addition, some advance directives are not sufficient to direct care in many healthcare institutions until a physician's order is written in the medical record. These barriers have led to an attempt to remedy these problems through the creation of other methods such as *physician orders for life-sustaining treatment* (POLST)[14] and *medical orders for life-sustaining treatment* (MOLST).[15] The overall aim of these forms of advance directives is to improve the communication of personal wishes about life-sustaining treatments, resulting in higher quality medical care that is consistent with patient choice.

The POLST Paradigm, as the concept is called, was originally developed in Oregon to improve EOL care by overcoming many of the shortcomings and pitfalls of advance directives. Because the POLST document is designed to translate shared decision-making into actionable medical orders and be long-lasting and portable across treatment settings, it can be posted on the patient's refrigerator or on the front of the patient's medical record, where it can be easily located by emergency medical personnel and other healthcare providers. The POLST form provides specific treatment orders for mechanical ventilation, antibiotics, cardiopulmonary resuscitation, and MANH and is recommended for persons who have a life-limiting disease, who might die in the next year, or who want to further define their preferences for care and treatment in order to help prevent initiation of unwanted, disproportionately burdensome, and extraordinary treatment.

Other states have adopted similar programs with different names although all share the same core elements with similar forms (e.g., medical orders on scope of treatment [MOST]; physician's orders on scope of treatment [POST]; and transportable physician orders for patient preferences [TPOPP]). The National Consensus Project for Quality Palliative Care's third edition of the *Clinical Practice Guidelines for Quality Palliative Care*[16] recommends that the POLST model be adopted nationwide because it more accurately reflects treatment goals and ensures that the information is transferable and applicable across all healthcare settings. Unfortunately, many state statutes require modification before this goal can be reached. Evidence, however, continues to support the implementation of POLST form completion and its relationship with preference concordance for less life-sustaining treatment.[17]

Nursing responsibilities related to advance care planning include initiating conversations about patient overall goals and specific wishes related to hospitalization, use of cardiopulmonary resuscitation, and other forms of advanced life support. These discussions will be most helpful if they focus on values rather than specific treatments. Patients and families should be asked about the existence of advance directives and be educated about the formal documents, their completion, and the process of advance care planning.

Do Not Attempt Resuscitation Orders

As noted, decisions about the level and type of interventions to be used must stem from consensus about the goals of care. For patients in acute care settings and those who have not yet elected to focus on comfort rather than cure, the specific issue of resuscitation status is a frequent source of distress for clinicians as well as for patients and families. In addition to discomfort and inexperience with the topic, there continues to be widespread misunderstanding about the efficacy of cardiopulmonary resuscitation (CPR) efforts and the meaning of decisions to withhold CPR in the event of an arrest.

Although survival rates following in-hospital cardiac arrest have improved over the past decade, currently, approximately half of all adult patients achieve return of spontaneous circulation following an in-hospital cardiac arrest, and less than 20% survive to hospital discharge.[18] This success rate has changed little in the 50 years since the technique of CPR was first developed. The relative ineffectiveness of CPR reflects the inappropriate widespread use of resuscitation efforts in situations in which multiple preexisting chronic illnesses have led to an irreversible state and death is inevitable. Unfortunately, the public has little understanding of what actually occurs in CPR, the limited benefit except in situations of single-organ disease and immediate intervention, and the potential for cognitive impairment if circulation is restored.[19]

Clinicians, too, may inadvertently contribute to misunderstandings about this issue in several ways. In addition to the tendency to avoid discussions of goals of care, too often the topic of resuscitation status is raised in the form of a question to patients, or more commonly to families, as "What do you want us to do if his heart stops?" (see Table 70.1). This approach reflects a well-intentioned but misguided attempt to identify patient and family preferences. It is misguided in that it places full responsibility for decision-making on the shoulders of family members and implies that it is possible to restore circulation through CPR.

As part of improving the standard of care in any institution, nurses can encourage providers to adopt the newer acronym, "DNAR." The American Heart Association, the recognized experts in emergency cardiac care, converted to the acronym "DNAR" (do not attempt resuscitation), rather than the former "DNR" in their 2005 standards,[20] signaling recognition that CPR, with its current wide application, more accurately is an *attempt* to restore cardiac function. This attempt is most often unsuccessful, and this change in language will hopefully facilitate recognition that a DNAR order does not entail a decision to allow a preventable death to occur. Rather, a DNAR order indicates a decision to withhold a very invasive and aggressive intervention that has little chance in promoting survival to hospital discharge.

Clarification of resuscitation status is best done as part of overall care planning. All nurses can play a key role in raising this topic, encouraging sensitive but straightforward communication and facilitating discussion. Because the intention to use CPR in the event of an arrest is the default in virtually all healthcare settings today, resuscitation status must be addressed in every situation of life-limiting or serious illness. This is particularly important when patients change care settings or begin care with new providers, such as occurs with admission to a long-term care facility, home healthcare, or home hospice.

Although use of DNAR orders is the standard method to indicate to healthcare personnel that CPR is not to be used, these orders are only effective within the facility in which they are issued.

Table 70.1 Phrases to avoid and phrases that can be more helpful

Do not say	Do say
"What do you want us to do if your loved one's heart stops?"	"We need to talk about where we go from here if your loved one's condition continues to worsen."
"Would you want us to do CPR if your loved one's heart stops?"	"There are many things we can do, but it's very important that we talk together about what your loved one would want done in this situation. Have you and he/she ever known anyone who was this ill . . . did he/she say anything about what he/she would want in a situation like this?"
"We need your permission to do a (tracheostomy, PEG, angiogram, etc.)."	"Given what we've discussed about your loved one's situation and the most likely benefits and burdens of the procedure, we need your help to know if he/she would want us to proceed with the (tracheostomy, PEG, angiogram, etc.)."
"We'll do whatever you want us to . . . it's your decision . . . we'll support whatever you decide."	"We have to make some decisions about where to go from here. It's our job to give you information about the medical facts and our recommendations, and we need you to help us know what would be important to your loved one now. Then, we need to talk and come up with a plan together."
"We need to withdraw care."	"We recommend stopping the dialysis based on your husband's goals of care. We will not abandon you or your husband and will still use everything we can to make sure he is comfortable."

The need to have portable orders and valid indicators of DNAR status for patients moving between facilities or patients being cared for at home has led to the creation of out-of-hospital forms and identifiers. In some cases, this has been specific clauses in the living will, and, in other cases, a specific out-of-hospital standard order form has been developed. Unlike most advance directives, the out-of-hospital DNAR document is a valid physician order that takes effect as soon as it is signed; it is not limited by the patient's diagnosis or terminal status. When available, these forms should be initiated when the decision to forego CPR is first made so that patients can take them with them as they are discharged or transferred between facilities.

A frequent challenge nurses face is how to manage situations in which they perceive the patient's condition is deteriorating and no one has addressed the issue of resuscitation status with the patient or family. Common concerns are that initiating such a discussion is outside the boundaries of the nursing role, that physicians will be angry if the nurse raises the topic, or that patients or families will be upset. It is important for nurses to recognize that it is within the professional role of nursing to identify the need to develop consensus as to goals of care and treatment plans and to facilitate discussions surrounding difficult decision-making.

Proxy Decision-Making

Because patients with serious illness frequently lack cognitive capacity at some point during the illness, professionals must rely on family or friends to represent their wishes and participate in decision-making. This creates a number of possible areas of conflict and uncertainty, including the need to make careful assessments of capacity, questions about the moral authority of family and friends to make decisions for patients, and, in some cases, the need to manage conflicts among and between families and the care team, as occurred in Case Study 1.

"Incompetency" refers to a status that is conferred by a court, establishing the inability of an individual to act as an autonomous and legally responsible person. Only the court can make a determination of *competence*; clinicians provide evidence to the court regarding the *capacity* of the individual, including data about diagnosis, cognitive and functional ability, and likelihood of recovery. The elements of a clinical determination of decisional capacity include the patient's ability to understand what decision is being made; to understand the alternative to the proposed intervention; to understand the relevant risks, benefits, and uncertainties related to each alternative; to maintain consistent reasoning; and to clearly communicate the desired decision.[21] An individual who has been deemed "incompetent" loses the right to make all decisions, including healthcare decisions, and must have a guardian appointed by the court to manage all affairs. Clinicians, therefore, cannot establish competency, but instead do have an ongoing responsibility to assess the capacity of the patient to participate in decision-making.

When patients are not able to express their wishes or make decisions and do not have a designated healthcare agent, family members are asked to act as proxies. Although this is common practice, states vary in the extent to which this is authorized by law and the precise specification of which family members have priority in decision-making. The moral basis for allowing one adult to make decisions for another is the assumption that family members are committed to furthering the best interests of the patient and that family members who share background, experiences, religion, and culture with the patient are well-equipped to represent the preferences and values of the patient. These assumptions are usually quite valid, but there are situations in which nurses question the ability of the family member to act as a valid proxy for the patient. These situations are difficult, and nurses must be prepared to seek guidance from the hospital ethics committee or hospital legal counsel, as well as collaborate with physicians and social workers on the care team.

Proxy decision-making, even under the best of circumstances, can be very burdensome to families already stressed by the realization of the seriousness of their loved one's illness. Several studies have demonstrated that family members are not able to consistently identify the preferences of their ill relative even when an advance directive is in place.[22,23] As mentioned earlier, this is related to reluctance to discuss EOL issues before a crisis and, when discussion does occur, the likelihood that the discussion was of a general nature and does not necessarily apply to the very specific decisions that have to be made in situations of prognostic uncertainty. An additional common occurrence is lack of consensus among family members about specific decisions, such as limiting treatment, DNAR status, or referrals to hospice.

In the absence of formal advance directives, intrafamily conflict, as exemplified in Case Study 1, is not uncommon. In that case, the patient's husband seemed to be leaning against use of MANH, but the patient's daughter and sister felt compelled to provide MANH. Even if the patient had completed a DPAHC that established the husband's authority as a decision-maker, the nurse can provide significant assistance to the family, as a unit, in providing education, as discussed in the next section, and helping the family come to consensus.

There are several steps the nurse can take in an effort to prevent or minimize concerns related to proxy decision-making, particularly when initiating palliative care services. First, all patients who have a serious illness and do not have a DPAHC should be asked to identify a proxy to make decisions if they should become unable. This can be done on admission to the hospital or any other healthcare delivery system in a nonthreatening manner, simply pointing out that sometimes patients become too ill or too sleepy due to medication. This will enable the team to know, if there are disagreements later, who has the strongest claim to the decision-maker role. Second, the time to obtain information about the patient's lifestyle, values, and preferences is before specific decisions about pursuing invasive diagnostic tests or procedures are needed. Talking with family members about what the patient was like, what he or she enjoyed, and what was important, can be helpful in later discussions. Third, when it is necessary to ask a family proxy to provide input into the plan of care, it is essential to address the task as one of helping the clinicians to know what the patient would have wanted. This can be done by referring back to earlier discussions about what was most important to the patient. The goals here are twofold: to minimize the burden of responsibility the family member might feel and to remain focused on the ethical mandate to act according to the patient's wishes, not the family members' wishes. In addition to Table 70.1, which provides some examples of ways to phrase questions that are not helpful and some ways that can be more useful in supporting family decision-making, there are a number of more detailed communication suggestions that have been published.[8]

Medically Administered Nutrition and Hydration

A fundamental caregiving task is to provide food and fluids. The provision of nutrition and hydration symbolizes the essence of care and compassion, and eating serves as a symbol of health. In most societies, celebrations involve eating, and through these traditional social events we communicate sharing and well-being. Clearly, human life is represented as social and communal through the provision of food.[24] When a loved one has an advanced illness, these opportunities wane, and, when one is dying, they are often lost. However, providing MANH is not synonymous with eating or feeding another person. In health, people eat in a socially acceptable form, with others, in a social setting. MANH do not share these social characteristics. The technology of feeding tubes was developed to address specific temporary medical problems (e.g., postsurgical gastric motility issues, swallowing impairment following a stroke in a patient expected to recover). However, the use of feeding tubes and medically provided nutrition and hydration has become widely used in patients with very poor prognoses and for those with little likelihood of regaining functional abilities. Few decisions are more value-laden than those to withhold or withdraw a medical intervention that is thought to be able to prolong life. As with all decisions about the use of any medical device or treatment, this decision should be based on the patient's goals of care, the medical need, and the burdens and benefits of the treatment.

In general, patients (or their surrogates) have the right to withhold or withdraw MANH if they believe that the burden or risks outweigh the benefits. There is widespread agreement in ethics and law[25–27] that patients or their surrogates have a right to choose or refuse MANH. All decisions about nutrition and hydration should be made in light of patient's goals and outcomes of care. These goals of care may change during the course of the disease or as the disease progresses and the patient's cognitive and physical functioning decline. Consequently, nurses should create opportunities for discussion and negotiation of goals and priorities of care with the patient and family/surrogate on an ongoing basis.

MANH requires the placement of a temporary or permanent feeding tube or the initiation of intravenous access. These interventions are associated with risks, including bleeding, tube displacement, and infection, as well as the potential need for repositioning and replacement.[28] In patients with impaired renal function, intravenous fluids may promote peripheral or pulmonary edema and increase the need for suctioning.[28] Tube feedings do not appear to prevent aspiration pneumonia and may increase the risk as compared to those patients who do not take anything by mouth.[28] Other potential side effects of tube feeding include diarrhea, nausea, and vomiting.[28] Teno and colleagues concluded that feeding tubes are not associated with prevention or improved healing of a pressure ulcer.[29] In fact, hospitalized nursing home residents who received a percutaneous endoscopic gastrostomy tube (PEG) were 2.7 times more likely to develop a new pressure ulcer and those with a pressure ulcer were less likely to show healing of the ulcer when they had a PEG tube inserted. Similarly, there is particularly strong evidence confirming the failure of PEGs and tube feeding to prolong survival in states of advanced dementia.[30–32]

Many patients and family members have deep concerns about the issue of "hunger" and "starvation." Contrary to what many believe, a patient with a terminal disease, who is often anorexic from the effects of the disease, is unlikely to be bothered by hunger.[33] In fact, many patients in whom the disease is progressing tend to report a complete lack of hunger. Evidence suggests that natural physiological processes that accompany the cessation of food and fluid intake naturally suppress both hunger and thirst. In addition, there is strong consensus among palliative care clinicians and oncology professionals that use of parenteral hydration in terminally ill patients is most often associated with unpleasant symptoms of fluid retention and overload.[28] Nursing interventions that can assist with the palliation of symptoms associated with dry mouth or thirst include small sips of oral intake, ice chips, meticulous mouth care, and lubrication of the lips. Involving caregivers, family members, and loved ones in this activity may replace the family's desire and need to feed with another caregiving activity that can provide the family with the opportunity to provide physical comfort.

Financial implications of these decisions and implications for discharge planning and home care also need to be considered. Some hospice programs cover the cost of MANH based on the individual plan of care and the goals of care, but others do not. Some extended-care facilities (i.e., nursing homes) mandate medically provided nutrition and hydration when a person stops eating and/or drinking, often related to misunderstanding and concern about state regulations or related to philosophy and religious missions. Consequently, discussions with families about decisions to use ANH, as in Case Study 1, should include consideration of these factors. In Case 1, the nurse would have several responsibilities, including clarifying the facts about the patient's previously stated wishes, educating all family members regarding the likely benefits and burdens of tube feedings, and focusing discussions with physicians and family members on what was known about the patient's values and preferences.

Despite the lack of proven benefit in states of irreversible and advanced illness, MANH will remain an emotionally laden topic and one of the most difficult decisions to make. There is a persistent widespread belief that healthcare professionals have a moral duty to feed all patients and that the benefits of ANH always outweigh the burdens. This misunderstanding, in combination with concerns about causing suffering, is a significant barrier to careful ethical evaluation of the decision to use or withhold ANH. Assuring informed decision-making about this aspect of the care plan often must begin with addressing the concerns of the care team and providing the necessary education about this issue.

Case Study 2: Withdrawal of Life Support in the Intensive Care Unit

Mrs. Black is a 40-year-old, divorced Caucasian woman who had been diagnosed with metastatic colorectal adenocarcinoma 2 years ago. She had undergone three cycles of adjuvant chemotherapy and radiation to reduce tumor burden and had successfully survived a colorectal resection with ileostomy placement. Over the past 2 years, she described her quality of life (QOL) as meaningful due to her relationship with her two college-aged children. Unfortunately, her liver metastasis progressed, and the last imaging revealed widespread lung metastasis with mediastinal involvement. While at home over Spring Break, her sons found her having difficulty breathing and called 911. Upon arrival to the emergency department (ED), additional imaging revealed the thoracic lesion was now compressing her bronchus, and she was taken to the operating room for stent placement as a palliative measure. This was able to be done, and she was transferred to the intensive care unit (ICU)_, intubated, and placed on mechanical ventilation. Several attempts, over the course of the next 2 weeks, were made to extubate her, but she was unable to maintain a patent airway without the positive pressure of the ventilator. Each time the ventilator support was reduced, Mrs. Black became anxious and fearful, even with the use of increasing doses of morphine and lorazepam. She was awake and alert, able to write notes, and wanted to see her sons. On rounds, the ICU physician mentioned to the team that it was time to consider performing a tracheostomy since Mrs. Black could not be intubated, and, after all, she was young. Her nurse Camille was concerned that this would just subject Mrs. Black to another procedure that would not change the eventual outcome. Camille was also uncertain whether anyone on the healthcare team had discussed Mrs. Black's condition with her and her sons and the high probability that she would never be able to leave the ICU. On the other hand, Mrs. Black was awake and oriented and withdrawing life support (e.g., extubating her) felt cruel—how could this be done without causing pain and suffering to not only the patient but her family?

Hastening Death

A central issue in decision-making in states of serious illness is the moral acceptability of actions that can be seen as hastening death. As has been noted throughout this chapter, it is well-established in Western bioethics that competent patients have an almost unlimited right to accept or refuse medical interventions, regardless of the established efficacy of the intervention or its necessity for survival. Supporting and advocating for this right is a critical function of the nurse and one which has been identified as a frequent source of ethical distress.

The recognized right of the individual to elect to stop life-sustaining technology, such as mechanical ventilation or hemodialysis, has been used by some as the basis for arguing that there is no difference between this act and acts that intentionally hasten death, including both euthanasia and assisted suicide. Arguments that there is a difference usually rely on the distinction between allowing a death caused by disease (allowing natural death to occur) as occurs when removing unwanted or ineffective life-prolonging therapies such as mechanical ventilators and dialysis, and killing, which entails being the direct cause of death (see Case Studies 1 and 2). There is ongoing debate in the bioethics community about whether this is a morally relevant distinction, and each nurse who cares for patients with life limiting disease will have to carefully identify his or her own beliefs.

Euthanasia is defined as an intentional act performed for the purpose of causing the death of another for reasons of mercy, whereas *assisted suicide* is the provision of assistance in some form (e.g., supplying lethal medications or instructions) to an individual who then acts to take his or her own life. Euthanasia in all forms is illegal in the United States and is condoned by none of the professional associations (see Box 70.2). However, assisted suicide (also termed physician-aid-in-dying [PAD], medical aid-in-dying [MAID], and physician-assisted suicide [PAS]) has been legalized in Oregon since 1997. Since this time, Death with Dignity laws are now recognized in the states of California, Colorado, Vermont, Washington, and the District of Columbia.[34] Given that PAD/PAS is legally sanctioned in these states and that legislation in additional states is anticipated, guidelines to assist palliative and hospice nurses on how to respond when hastened death is requested are germane to the delivery of comprehensive hospice and palliative care. At this time, professional nursing organizations do not condone nurses actively participating in assisted suicide/MAID (Box 70.2). In 2017, the Hospice and Palliative Nurses Association developed guidelines for the role of the registered nurse and advanced practice registered nurse when hastened death is requested.

Recent data report that typical patients who seek PAS/MAID are older, white, well-educated, and have cancer; most of these patients state that impending loss of autonomy is the primary motivation for requesting PAD/PAS.[35] Since the law passed in Oregon in 1997, a total of 1,749 terminally ill adult patients have had prescriptions written and 1,127 patients have died from ingesting the medication.[36] In 2016, most patients seeking PAD/PAS were enrolled in hospice care. In Oregon, 133 died ingesting medication (88% enrolled in hospice); in Washington, 192 died (77% enrolled in hospice).[37]Although no healthcare professional is obligated to engage in PAS, PAD, or MAID, all members of the interdisciplinary healthcare team will need to determine how to balance patients' rights with personal values and professional obligations.

Box 70.2 Position Statements from Recognized Professional Organizations

Medically Administered Hydration and Nutrition

- Hospice and Palliative Nurses Association (HPNA). *Position Statement: Artificial Nutrition and Hydration in Advanced Illness*. Pittsburgh, PA: Hospice and Palliative Nurses Association, 2011.

- National Hospice and Palliative Care Organization. *Position Statement: Palliative Sedation in Hospice and Palliative Care*. Alexandria, VA: National Hospice and Palliative Care Organization; 2012.

Given the legal status of specific actions related to PAD/PAS, ethical conflicts can arise among those individuals who support the actions permitted in the statute and those who may hold a different moral position. In an attempt to improve professional tolerance around such discussions, healthcare providers should not lose sight of serving the good of the patient, including patient preferences and religious and cultural values. These situations require very careful attention from the nurse, awareness of legal and ethical considerations, and a well-developed and collaborative plan for responding.

The first, and perhaps most important, responsibility of the nurse is clarification and assessment. The expression of thoughts of hastening death may be an accurate report of a serious intention, it may be a relatively off-hand comment, it may be an expression of distress prompted by unrelieved symptoms, or it may be intended as a test of the nurse's views about hastening death. In addition to clarifying the meaning of the patient's statements, the desire for hastened death should always prompt a thorough evaluation of the adequacy of symptom management, reassurance about commitment to address future problems, advance care planning, and hospice. There are a number of guidelines developed by professional associations and groups to assist the clinician in responding to requests for hastened death (see Box 70.2). Reassessing and focusing on palliative care efforts to relieve distress are essential. Assessment of the emotional state of the person is necessary when the request for hastened death is affected by depression, anxiety, or delirium.

Cardiovascular Implantable Electronic Devices (CIEDs), Palliative Sedation, "Nonbeneficial Interventions," Voluntary Stopping Eating and Drinking

There are some specific issues that present particularly challenging questions in palliative care. These are the acceptability and methods of withdrawing life-sustaining interventions that consist of cardiac assistive devices (pacemakers, automatic internal cardio-defibrillators [AICD], left ventricular assistive devices [LVAD]), concerns about requests for potentially inappropriate treatments or nonbeneficial interventions (formerly known as "futility"), palliative sedation, and voluntary stopping of eating and drinking (VSED).

Cardiovascular Implantable Electronic Devices

One of the most concrete examples of the complexities created by advancing technologies is the situation of patients who have elected to forego continued use of cardio-assistive devices in order to allow a peaceful death. There are a number of implantable mechanical assistive devices intended to either support or replace normal cardiac electrical and mechanical function, including LVADs, right ventricular assistive devices (RVADs), total implantable hearts (TIH), internal AICDs, and pacemakers. Each of these raises unique issues.

Internal automatic cardio-defibrillators are very commonly used in the United States as treatment of recurrent ventricular fibrillation. Pacemakers have been a long-standing therapy for bradyarrhythmias and combined AICD-pacemakers are recommended for some forms of heart failure. Hundreds of thousands of patients in the United States have cardiovascular implantable electronic devices (CIEDs), primarily due to the nearly 600,000 individuals who have end-stage refractory heart failure.[38] It is therefore very likely that palliative care nurses will find themselves caring for patients with either or both of these devices. In most cases, both AICDs and pacemakers are on-demand therapy; that is, they are programmed to deliver therapy only on demand (when heart rate decreases or a lethal arrhythmia develops). Therefore, their function should be disabled when the plan of care is based on a goal of allowing a peaceful death with no further intervention. AICDs should be turned off so that they will not deliver a shock as the heart rate falls or ventricular arrhythmias occur. Demand pacemakers can have the rate and sensitivity decreased so they do not prolong the dying process. Cardiologists or cardiac technicians usually must be called and requested to make these changes using the device programming magnets.

When cardiac function is dependent on active device operation, as is the case with some pacemakers and most cardiac assistive devices, there are more difficult challenges and unresolved questions. Some argue that discontinuing a cardiac assistive device, with the expectation that death will follow, is no different, morally, than discontinuing mechanical ventilation for a patient who has elected (or family has elected) to have life-sustaining therapy discontinued. However, others believe that the act of deactivation constitutes euthanasia or PAS.[39] The crucial difference lies in the primary intention: termination of a life versus termination of a therapy. Thus, death that follows withdrawal of LVAD support occurs from the underlying heart failure. As the burden of these devices may outweigh benefits when patients' goals and preferences change, patients have the right to request deactivation.[40,41] This right is well-accepted and supported by the American College of Cardiology Foundation (ACCF) and the American Heart Association (AHA).[42] In fact, the Heart Rhythm Society[43] issued a consensus statement that asserts that "withdrawal of a treatment is a personal right of the patient" and is ethically and legally permissible.

Since 2002, LVADs have been considered "destination therapy" for patients who are ineligible for transplant or for those patients whose estimated 1 year mortality is greater than 50% with medical therapy.[44] LVADs will alter EOL trajectories. Although intended to prolong survival related to heart failure, LVADs have the potential to decrease the overall QOL of these patients because of serious infections, neurological complications, and device malfunction.[45] Numerous research studies[44,46,47] have shed light on the importance of the ethical obligations clinicians hold to provide significant emotional support to these patients and their families.

When caring for the patient with an implanted cardiac device, the nurse has several responsibilities. First, the exact status of the device's operation has to be determined. As with all components of the palliative care plan, the plan for adjusting the device should stem from a clear understanding of the patient's goals of care. If, for example, the goal is to make the most of whatever time is left and there is hope for more time, all cardiac devices should remain active and in place. On the other hand, if the patient is actively dying or has expressed an informed desire to remove any therapy that could interfere with the dying process (whenever that might occur), the devices should be inactivated (or turned to an inactive setting). Each of these decisions, of course, must be made in collaboration with the care team. If there is consensus about discontinuing a device on which cardiac function is entirely dependent, extra care must be taken to assure that the patient, family members, and the entire care team are in agreement. The timing of the discontinuation must be carefully considered and a plan to address likely symptoms put in place.

Palliative Sedation

There are a very small number of situations at the end of life in which patient symptoms cannot be adequately relieved despite multiple pharmacologic regimens. Despite the provision of evidence-based, state-of-the-art palliative care, some patients will continue to experience protracted, intense suffering toward the end of life. In these cases, the option of palliative sedation is sometimes raised. *Palliative sedation* refers to the use of medications to induce sedation, either intermittently or continuously, for the purpose of providing relief of intractable symptoms and suffering. The intention is not to cause death, but to provide symptom relief for a dying patient when all other efforts have failed.

In an effort to clarify the different types of palliative sedation and how each may be used, Quill and colleagues[48] outlined three definitions of sedation: ordinary, proportionate (PPS), and palliative sedation to unconsciousness (PSU). Although these definitions have helped to clarify the types of sedation, there remains great fear that access to these practices may become too easy. However, in a systematic review of the literature regarding palliative sedation and survival, Barathi and colleagues[49] found no evidence to suggest that palliative sedation has any detrimental effect on survival of patients with advanced cancer. In fact, they suggested that it is a medical intervention that should be included in the list of interventions to relieve suffering.

Despite these views and data, the wide variation in the reported use of palliative sedation and limited research evidence about best practice is likely a reflection of ambivalence and uncertainty about the ethical acceptability of the practice.[50] Perhaps the most common objection to palliative sedation is the belief that PPS and PSU will directly hasten death. Nevertheless, use of PPS and PSU does require also addressing other interventions, such as the continuation of oral medications and the administration of food and fluids.[50] In general, these other decisions should be made separately and before palliative sedation is begun. If there are adequate reasons to stop food, fluids, and other medications (i.e., if the patient is in the final stages of dying, has been refusing food and fluids, and other medications are not needed for promotion of comfort), there is no reason to insist they be used when palliative sedation begins. On the other hand, if nutrition and hydration were indicated before sedation, there may be good reason to continue their use or sedation should be stopped or lightened intermittently to offer food and fluid.

Case Study 2 is an example of a situation in which palliative sedation might be necessary. If Mrs. Black, who retained decisional capacity, chose to have ventilatory support withdrawn, it might be necessary to sedate her to the point of unconsciousness in order to prevent suffering. This act certainly would shorten her survival, compared to continuing mechanical ventilation. However, this act would be morally permissible and supported by the *principle of double effect*. This principle, well-established in bioethics, asserts that acts that are intended to achieve a "good" effect (in this case, respecting autonomy and preventing suffering) are permissible even if the act also carries with it an unintended "bad" effect (hastened death). In addition to intending only the good effect, this principle requires that the good not be achieved by means of the bad (i.e., the relief of suffering is achieved by the sedation, not by causing death), and the weight of the good achieved must be greater than the bad effect.[24]

Although many professional organizations (see Box 70.2) support the use of palliative sedation in carefully selected situations, all emphasize the importance of clarity in the intended objective (relief of suffering) and the need for thorough discussion and informed consent from the patient. In addition, all healthcare institutions providing palliative and EOL care should have a written policy about palliative sedation and the types of sedation that will be offered to patients if requested. This policy should be provided to patients or their proxies who ask about the possibility of having PSU in the future or request it when other interventions have failed to relieve intractable suffering. Moreover, if the healthcare institution offers PSU but an individual physician objects to its provision, the providers must make alternative arrangements for the care to be transferred to another provider or institution.

Given the importance of communication in the final stages of life, use of palliative sedation should be reserved for those few situations in which all other interventions have been ineffective and the patient finds continued consciousness to be intolerable. Clinicians have an obligation to describe as clearly as possible the likely scenarios for a patient who is considering palliative sedation and should work with patients, families, and the interdisciplinary team to establish a clear plan of care before sedation is initiated. This should include discussion about what life-sustaining treatments will be continued or withdrawn after the patient has been sedated.

Futility and Alternative Terminology

"Futility" is a term that refers to the inability of a specific intervention to lead to its intended outcome (e.g., prolonged survival, discharge from the hospital, shrinkage of tumor). Although the term "futility" continues to have widespread use in the medical community, several alternative terms have more recently been proposed to accurately reflect the medical judgment that there is no realistic likelihood of benefit to the patient based on the existing scientific evidence and a high likelihood of harm or suffering. These terms include: "withdrawing and withholding of nonbeneficial medical interventions," "potentially inappropriate treatments," and "not indicated interventions." Each of these descriptors, however, offer little assistance when confronting a disagreement about providing a particular treatment, where the other side in the argument sees the treatment as indicated and appropriate because it might offer some benefit.

Most recently, the American Thoracic Society, American Association for Critical Care Nurses, American College of Chest Physicians, European Society for Intensive Care Medicine, and the Society for Critical Care issued a policy statement regarding how to respond and manage requests by patients or surrogates for treatments that clinicians believe should not be administered.[51] This multidisciplinary statement recommends that the term "potentially inappropriate" be used rather than the term "futile" to describe treatments that have some minimal possibility of accomplishing the goal sought by the patients, but clinicians believe that competing ethical considerations justify *not* providing them. This collaborative statement goes on to assert that the term "futile" be restricted to rare situations where surrogates request interventions that simply cannot accomplish the intended physiological goal, such as continued ineffective chemotherapy. And, finally, it is recommended that clinicians not provide such futile interventions.[51]

Today, potentially inappropriate intervention disputes occur frequently with patients with advanced illness and their families and are one of the primary reasons for hospital ethics consultation. In fact, one large academic medical center estimates that 20% of patients in its ICU are receiving "futile treatment."[52] An example of a potentially inappropriate treatment is prolonged use of mechanical ventilation in a patient who has widely metastatic and incurable cancer (see Case Study 2). Over the past decade, clinicians have increasingly encountered situations in which patients and families request or demand therapies that the clinician believes have no meaningful chance of prolonging life or improving well-being. Over the years, there has been a growing consensus that the right of patients and families to accept or refuse therapies does not entail the right to demand therapies which the physician does not believe are medically justified. This stems from the principle of autonomy, which establishes the duty to refrain from interfering in the life choices of competent persons.

The gradual move away from the paternalism of the past and a commitment to supporting patient autonomy has unfortunately led to a tendency to shift the responsibility for decision-making entirely to patients and families. This is sometimes seen in the reluctance of clinicians to advise or guide patients and families in decisions and, instead, to present options in a completely impartial fashion. Not infrequently, families will express the wish to have "everything" done for their loved one. When this is said, the nurse or physician should respond by assuring the patient and family that they are heard and that their wish to receive all therapies that have any meaningful chance of maintaining or improving the patient's condition will be used. The use of shared decision-making should be emphasized from the start. As the condition of the patient deteriorates and it becomes apparent that continued interventions will not be helpful, it is best to set the stage for later decisions by affirming that the clinicians will provide honest and direct information and will identify when there are no further curative options, with assurances that the plan of care will always be discussed before changes are made. When the situation is such that CPR or other interventions are no longer indicated, this should be stated; patients or families should not be asked to give permission to withhold an ineffective intervention. If consensus appears to be unreachable, other resources, such as clergy or ethics consultants should be utilized. Although seeking guidance from the court may be required in intractable disputes, in general this should be viewed as a last resort, and thoughtful, interdisciplinary procedural approaches are preferable.

In Case Study 2, the nurse, Camille, may have believed that performing a tracheostomy on Mrs. Black would indeed be futile. Although the procedure could be safely performed, it would not save the patient's life or even allow her to recover enough to leave the ICU—she would always require mechanical ventilation. To address this issue, Camille would need to first validate her assumption about the location of Mrs. Black's tumor and the ineffectiveness of a tracheostomy to relieve the obstruction. Next, a care conference with the entire multidisciplinary team would have to be arranged to develop consensus about the best approach. If the team reaches agreement about the lack of any effective treatment options for the cancer, a plan would have to be developed, including who would talk with Mrs. Black and her sons, what recommendation would be offered, what options would be acceptable, and how to manage her symptoms when she was ready to discontinue mechanical ventilation.

Although it is becoming increasingly recognized that clinicians have not only the right but the professional duty to refrain from interventions that are harmful, it is essential to be cautious in judging interventions as "futile" or medically inappropriate. There are many treatments or therapies that offer neither cure nor improvement in patient condition, but which are effective in supporting survival, such as mechanical ventilation following anoxic brain injuries. Today, the claim of "futility" should not be used to justify withholding therapies in situations in which the clinician believes that the proposed therapy would accomplish its intended purpose but the resulting QOL would be undesirable. Judgments such as this reflect the subjective opinions and values of clinicians and are not a valid basis for withholding therapy against the wishes of patients and families.

Voluntary Stopping Eating and Drinking

Voluntary refusal of food and fluids is another option to hasten death and anecdotally seems to have increasing prevalence, specifically in states where PAS and MAID have not been legalized.[53] Persons with a terminal illness who retain decisional capacity may elect to stop eating and drinking; it is both legally and morally permissible. In contrast to PAS, VSED requires no action by a physician and requires no physical action by the patient. Persons who elect this approach usually die within 7–21 days.[53] In contrast, VSED in a non–terminally ill patient is usually considered a form of suicide and must be evaluated as such. The American Nurses Association (ANA) recently published a favorable position statement regarding VSED (see Box 70.2), yet almost no medical association, either in the United States or in Europe, has formally supported or taken a neutral position on the subject. Institutions should have established policies in place that address VSED and include educational offerings for the staff and family, safeguards for the patient (e.g., psychiatric evaluation), and ethics committee consultation when requested.

Nursing Issues, Moral Distress, and Compassion Fatigue

Decisions regarding ethical dilemmas and the choices that are necessary require thoughtful discussion and critical communication skills. Stemming from the priority of the principle of autonomy or self-determination, decisions about care should be made in accordance with patients' preferences for care, beliefs, and values. With increased medical technology, the advances in science, and conflicting interests of patients and families, nurses stand in a pivotal position to lead the way in assuring patient access to quality palliative care. This charge does not come without the risk of the nurse feeling like he or she is "in the middle," trying to provide the best possible care to the patient and supporting the family members while preserving personal values.

Nurses and other members of the interdisciplinary healthcare team daily face ethical and legal issues in decision-making related to EOL care in clinical practice. These dilemmas have a strong potential to provoke conflict among those involved in patient care, sometimes between professionals and sometimes between patients, families, and professionals. The ANA Code of Ethics states that nurses have the right to withdraw from providing care to patients when their own values conflict with that of patients so long as the patient's care can safely be transferred to another care provider. The ANA goes on to discuss the importance of "preservation of integrity." Specifically, Provisions 5 and 6 of the ANA Code of Ethics discuss moral self-respect and the influence of the environment on ethical obligations, moral virtues, and values. According to these provisions, nurses have a duty to remain consistent with both their personal and professional values and to possess character strengths such as compassion and patience. Although simply stated, these behaviors may be challenged when faced with ethical and moral dilemmas.

Close, personal relationships are often formed with patients and their families as palliative care nurses care for them over a prolonged period of time. Moral and ethical dilemmas, often associated with patient/family situations and healthcare environments, may leave the hospice and palliative care nurse feeling physically, emotionally, and spiritually drained. As nurses continue to be exposed to patients with greater healthcare needs, staff shortages, heavy and intense workloads, an aging workforce, and a lack of resources to work effectively, the opportunity to develop moral distress, moral fatigue, burnout, and compassion fatigue is a real possibility.[54]

Compassion fatigue is a term used to describe a stress response in a healthcare provider; it has been widely studied and is pervasive within the nursing profession.[54] Compassion fatigue is a state in which the compassionate energy that is expended by nurses outweighs the restorative processes and the ability to recover has been lost; it is the negative aspect of helping that can be related to the actual provision of care, the environment, colleagues, and/or beliefs about self.[55] *Burnout*, on the other hand, relates to work-related hopelessness; it is the inability to cope with job stress that produces feelings of inefficacy.[56] *Moral distress* is a phenomenon in which an individual knows the right action to take but is constrained from taking it.[57] Moral distress arises when one must act in a way that contradicts personal values and beliefs; *moral fatigue* is the consequence of continued moral distress.[57] For example, nurses might act in a way that is contrary to personal and professional values or be unable to translate moral choices into action. This creates anguish, and the consequences can be profound and have lasting effects.[58] Although nearly all healthcare professionals experience some moral distress during their tenure in caring for those who are ill, nurses seem to be at a higher risk.[59] Nurses who appear to be at a higher risk for compassion fatigue include those who are younger, who have a history of personal trauma and have not worked through issues related to that trauma, nurses working with large caseloads and/or long hours, those already experiencing professional burnout; nurses with inadequate training in effective communication or those less competent in communication, and nurses without adequate collegiate and personal support systems.[60]

According to Potter and colleagues,[61] the risk and incidence of compassion fatigue among nurses could largely be decreased with education regarding its existence, prevention, and coping strategies. Coping strategies, including self-care, are key to prevention of compassion fatigue. Integrating self-care activities, including self-compassion and mindfulness-based strategies, into professional workloads is not typically part of professional training, nor is it explicitly part of one's job description. One of the most crucial elements in dealing with moral distress is knowing *what* support is available and *how* to navigate the system in place. Ethics Committees are one source of support and serve to assist in resolving complicated ethical problems that affect the care and treatment of patients within healthcare organizations. Just as preventive ethics should be used before an ethical dilemma arises, so should they be used to guide nursing practice before a crisis occurs.

Conclusion

There will always be new ethical dilemmas that require decision-making, and the answers to those dilemmas will not always be obvious or easily identified. It is often in states of uncertainty that serious wrongs occur. As partners in the care of patients and families with advanced illness who must make difficult decisions, nurses must be empowered to facilitate discussion and to be heard by all parties involved. The challenge today is to ensure that all nurses acquire attributes of leadership, excellent communication skills, and self-reflection that enable them to fulfill the crucial role of nursing.

CHAPTER 71

Palliative Care and Requests for Assistance in Dying

Carey T. Ramirez, Kathleen Fundalinski, Judy Knudson, and John Himberger

Key Points

- Assistance in dying is now available in 6 states and the District of Columbia, is being considered in 27 more states, is available with euthanasia in 5 countries, and is available without euthanasia in 3 more countries, making it increasingly likely that palliative clinicians will encounter a request.
- Assistance in dying is highly controversial due to the ethical, legal, and clinical issues it brings to the forefront.
- Although assistance in dying is not a palliative intervention, palliative clinicians are uniquely prepared to field requests without judgment, assess the concerns underlying the request, and ameliorate most of them.

Introduction

Requests for assistance in dying are becoming increasingly common due to legislation in Colorado (2016), California (2015), and the District of Columbia (2016) permitting people with terminal illness to request physician aid in dying (PAD).[1–3] These states join Oregon (1997) and Washington (2009), which enacted Death with Dignity Acts by referendum, followed by Vermont (2013).[2,4,5] In a landmark 2009 ruling, the Montana Supreme Court became the first and only judiciary to authorize physician-assisted suicide by reversing an earlier district court judgment, thus protecting a right to pursue PAD and effectively shielding from prosecution those physicians who choose to honor a person's request.[6] These six states and the District of Columbia make up 16.4% of the US population.[7] Outside the United States, assistance in dying is legal in Canada, the Netherlands, Belgium, Luxembourg, Switzerland, Colombia, and Victoria, Australia. Though highly controversial due to the ethical, legal, and clinical issues it brings to the forefront, it is being debated in 27 other states in 2018. For many nurses, it is only a matter of time before they are confronted with this highly sensitive and personal topic.[8,9]

Assistance in dying is not a palliative intervention. However, Radbruch et al. point out that, "individual requests are complex in origin and may include personal, psychological, spiritual, social, cultural, economic, and demographic factors."[10] Palliative nurses are uniquely trained to assess the hopes, fears, and concerns underlying patient requests for PAD without agenda or judgment. Patients will have individual goals and values deserving of respect, even when they differ from the values of those providing their care. As a result, some may request assistance in dying despite reception of expert palliative care. To ensure palliative specialists are prepared to handle requests for assistance in dying, this chapter will explore the issues and concepts surrounding such requests.

Definitions

The nomenclature surrounding assistance in dying is often value-laden, intended to sway the reader for or against it depending on the perspective with which the author writes. Furthermore, the literature elucidates evolution not only of the nomenclature, but also the underlying philosophy of this topic. Therefore, it is necessary to cite important definitions as a foundation for this chapter.

- *Euthanasia*: A physician (or other person) intentionally kills a person by the administration of drugs at that person's voluntary and competent request.[10]
- *Physician-assisted suicide (PAS)*: A physician intentionally helps a person to terminate his or her life by providing drugs for self-administration at that person's voluntary and competent request.[10]
- *Physician aid in dying (PAD), medical aid in dying (MAD); physician assisted dying*: A physician provides, at the patient's request, a prescription for a lethal dose of medication that the patient can self-administer by ingestion with the explicit intention of ending life.[8]

History

Although legislation and contemporary debate regarding assisted dying and euthanasia have heightened over the past few decades, discussions date back to ancient Greece and Rome, when attitudes toward euthanasia were more tolerant. Medical practice often supported voluntary death requests from patients with intractable suffering, indicating value on the quality of one's life. This contradicted the traditional Christian and Jewish value of life and strict condemnation of suicide in any form as a violation of God's plan and authority. Global consensus opposing assisted death prevailed until the late nineteenth century, when the development of analgesics like morphine marked a pivotal shift in the debate.

Practice changed from prolonging life at any cost to increasing focus on ameliorating suffering and palliation at end of life.[11]

Use of medications to intentionally end life was controversially first proposed in 1870 by Samuel Williams, a nonphysician, thus fueling a global ethics debate. The American Medical Association responded in 1885 with vehement opposition of Williams, likening his proposal to an act of execution.[12] Perspectives shifted again in 1915, when Chicago physician Dr. Harry Haiselden recommended against surgery for a baby boy with severe deformities, thus inciting public discussion on physician responsibility. He argued that infants with severe disabilities were at risk for suffering and could be a potential burden to broader society.[13] In 1906, legislation to legalize euthanasia was defeated in Ohio, followed by defeat of a bill introduced in the British House of Lords in 1936.[14] Throughout the twentieth century, public attitude fluctuated as concurrent global advancement in end-of-life (EOL) care increasingly focused on patient rights and self-determination, bringing right-to-die options to the forefront of a fiercely contested issue.

World View

As of 2016, assisted dying and euthanasia are legal in six countries, and assisted dying without euthanasia is legal in three.[2] The terms "assisted dying" and "euthanasia" will be used separately to distinguish between the two acts. As legislation is introduced worldwide, increased research related to practice, geographic attitudes, and the role of palliative care will occur. Many countries require voluntary consent, mandatory reporting, physician involvement, and a second opinion. These requirements aim to protect against impropriety in euthanasia and assisted death practices. Despite these safeguards, data indicate nonreported or nonconsented cases remain prevalent, which calls into concern potential ethical violations.

Europe is in the vanguard of policy development regarding assisted dying and euthanasia. Swiss law dates to the first federal penal code of 1918 holding that suicide not be considered a crime if motivated by altruistic reasons.[15] In 1942, assisted suicide was decriminalized, although the law does not recognize euthanasia as legal.[16] The law uniquely permits assisted suicide by nonphysicians. Article 115 of the Swiss penal code stipulates that persons assisting suicide are only committing a crime if the motive is selfish and otherwise condones the act for altruistic considerations.[15] Swiss citizens and foreigners need not have a terminal medical condition to request assistance.[10] Due to leniency in foreign participation, Switzerland has seen an influx in "suicide tourism," with increasing requests from visitors with chronic, nonterminal diagnoses.[17]

Elsewhere in Europe, assisted dying was legalized in the Netherlands (2001), Belgium (2002), and Luxembourg (2009).[10] Legalization of euthanasia and assisted suicide was sanctioned in the Netherlands through the Termination of Life on Request and Assisted Suicide Act. Minors, aged 12–16, can also access the law if the requirement for obtaining parental consent is met.[10] There is also consideration for people with dementia.[18] Data from 2014 showed that patients in the Netherlands requesting euthanasia or assisted dying accounted for less than 4% of total deaths and for around 4.5% in Belgium.[16] Increased percentages of euthanasia over assisted suicide in countries where both are legal postulate a preference for patients to have providers perform the procedure when given a choice.[19]

Belgium legalized euthanasia in 2002 as a voluntary act by lethal injection for patients with similar qualifications as the Netherlands. The condition need not be "terminal," but additional process and time requirements are imposed if the person is not terminally ill. The law was extended in 2014 to include minors with parental consent and in certain cases when criteria is met for patients with mental suffering.[18] This accounts for a small percentage of total reported cases.[20] Case totality increased significantly between 2007 and 2013, from 1.9% to 4.6% of deaths. Palliative services were provided concurrently in 73.7% of cases in 2013.[21] A comparison of palliative development between 2005 and 2012 in the Benelux countries, where assisted dying is legal versus those where it is not permitted showed that, despite theories that palliative development would be stunted, services and spending expanded.[22]

In 2015, the European Association for Palliative Care (EAPC) published a follow-up white paper on assisted dying/euthanasia to provide an ethical framework for the palliative care field.[10] The paper supported palliative care involvement for people considering assisted dying/euthanasia, yet stipulated that the practice should not be a part of palliative care.[10] The paper refocused core palliative care tenets as a benefit to comprehensively assess and understand the rationale behind an individual requesting assisted dying.[10]

Canada legalized euthanasia and assisted dying in 2015, via unanimous decision by the Supreme Court of Canada (*Carter v. Canada*), which followed years of consideration by parliament (aside from Quebec, which passed legislation in 2014). The court ruled that prohibition of assisted dying was in violation of the Canadian Charter of Rights and Freedoms and spurred legislative development to support assisted dying.[21] Eligibility criteria include mental capacity, voluntary request, and a "grievous and irremediable medical condition" that causes intolerable suffering. Canadians overwhelmingly supported the ruling, with 78% of those polled in agreement.[23] Canadian law also broadens the role of medical providers who can provide care to include both physicians and nurse practitioners in certain provinces.[24]

In 2015, the Colombian Ministry of Health formalized the process for euthanasia. The Colombian Constitutional Court initially permitted mercy homicide in 1997, but took almost two decades to develop specific instructions on how the process could take place.[18] Australia passed legislation in 1996 legalizing both assisted dying and euthanasia in the Northern Territory. It was overturned the following year by Parliament.[10] In late 2017, the Australian state of Victoria passed legislation legalizing assisted dying.[25]

United States

The movement toward assisted dying has gained momentum in the United States following inception of Oregon's Death with Dignity Act (1994), with 51% of voters in favor of the law. Implementation was delayed by legal injunction until 1997, when voters again retained the act with approval of 60%.[26] Passage demonstrated a landmark change in attitude and legislation regarding the "right to die" debate in the United States. At that time, the US Supreme Court ruled that PAD should be determined at a state level.[27] Prescriptions are permitted based on safeguard criteria allowing adults with mental capacity who have a prognosis of 6 months or less to provide informed and voluntary consent. Moreover, consultation with a second medical provider is required, and follow-up with mental health professionals is recommended if there are concerns of psychological or psychiatric disorders.[18]

Brittany Maynard, a 29-year-old volunteer in a national right-to-choose advocacy organization who suffered from terminal cancer, brought EOL discussions into the national spotlight in 2014, when she moved from California to Oregon for access to assisted dying. Her movement sparked controversy and brought a new perspective to a contentious issue that had been primarily associated with the elderly.[28]

Hospice is commonly provided concurrently to patients who utilize assisted dying. Reports from 2009–2011 demonstrated that in Oregon 96% and in Washington 81% of patients received hospice. As of 2017, 1,749 prescriptions were written, and 1,127 people died from ingestion since initiation of the law. This accounted for 37.2 per 10,000 total deaths in 2016.[4] The state of Washington (2015) reported 938 prescriptions and 917 deaths since 2009.[5] Numerous states have assisted dying legislation pending, and public debate continues on the legal and ethical implications of PAD.

Ethics

The ethical deliberations encompassing PAD are based predominantly on the four pillars of medical ethics: autonomy, beneficence, nonmaleficence, and justice.[29] *Autonomy* in medical decision-making can be defined as a patient's ability to make independent decisions related to his or her well-being.[30–32] Often, this is further defined as a patient's ability to make a decision without coercion or untreated mental illness and with the ability to rationalize a decision.[33] This is the foremost ethical concept supporting PAD requests. It is essential to ensure the patient's autonomy in relation to his or her decision to request aid in dying.[34] There are a number of threats to autonomy, including but not limited to metabolic disturbances, brain metastasis, unmanaged symptom burden, and poorly understood complex care plans. In addition, religious influence and family perception of the medical situation affect decisions around PAD.[35] Family beliefs can guide patients to make a decision contradicting their personal choices. If care decisions are made based on family preference, autonomy may be sacrificed.[36] This warrants consideration at end of life; however, there is currently little impact around PAD because of the requirement of capacity and the inability of surrogate decision-makers to elect PAD on behalf of their loved one in most locales.[37]

The autonomy of the care team is also valued. The nurse may object to participation in what he or she views as the termination of a patient's life and should have the right to do so.[21] Conscientious objection can also be found among other care team members and, if encountered, should be respected.[38] Transfer of care to other staff should be encouraged.

Beneficence is benefit to the patient, which in PAD is a major point of contention.[29] Proponents argue that PAD is beneficial to the individual with a terminal disease by allowing the patient control of his or her dying process, hence preventing degradation of quality of life (QOL). Opponents argue that improved medical technologies such as palliative surgery, radiation, or medication management could provide improved QOL. Furthermore, they posit that the availability and engagement of palliative and hospice care invalidates the benefit of PAD. The palliative care and hospice healthcare team provide the standard of care during terminal illness and are recognized as experts in symptom management, with the primary focus on improving QOL. It is important to recognize that where PAD has been legalized, the prevailing view of the legal system and public opinion are that PAD provides benefit to the patient.[21,31,39]

Nonmaleficence means "first do no harm," another source of debate regarding PAD.[29] Supporters indicate that, by respecting autonomy, the patient dictates his or her own medical course and decline, choosing the time of death in relation to the disease process. PAD prevents the patient from being harmed by uncontrolled or underaddressed symptoms while avoiding prolonged suffering and loss of dignity or respect. Opponents argue that PAD brings harm by ending life, potentially depriving people of valuable experiences that illness may bring, both personally and with loved ones.

Justice is viewed as providing what is fair and equitable to a patient.[29] This can be viewed on an individual level as related to patient choice or on a systems level based on resources available. The issue of justice is partially addressed in states and countries where PAD is legal by making it available to all residents. Unfortunately, socioeconomic status may preclude some from accessing PAD due to the exorbitant cost of filling certain prescriptions. In addition, PAD is not available in every state, and residency requirements restrict those from requesting it who do not live within the jurisdiction in which it is legal.

Another concern about justice described in the literature is that physicians are providing EOL care and, at times, hastening the end of life of patients who, in their view, are suffering.[35] Timothy Quill, in his writing on "The Graying of America," argues this point: whether through withdrawal of treatments, failure to offer treatments, or adjustment of medications with the understanding of the dual effect of these medications with palliative intent, he believes that hastening of death is occurring, although it appears to be "unevenly and unpredictably available."[40] Quill supports legalization of PAD and making it available to all only after expert palliative care has been obtained and patients have failed to respond adequately with treatment.[40] A study completed in European intensive care units indicated that physicians caring for patients who had treatments withdrawn would intentionally accelerate the dying process in up to 18% of cases. While this supports Quill's concern regarding the justice of PAD, it also demonstrates the concept of double effect. While these clinicians were attempting to alleviate symptoms, they accelerated the patient's death.[35]

Autonomy, beneficence, nonmaleficence, and justice, however, cannot be applied to a question without considering the surrounding context. For example, the question is "Should physicians be allowed to assist patients with dying?" Traditionalists would argue that the Hippocratic Oath defines and limits the physician role to that of healing and curing disease while bringing no harm.[35] Without context, the immediate morally intuitive response would be "no"; however, when the context of the question is defined, then the ethics considerations become more complex.[31] Asking whether physicians should be allowed to assist patients with terminal illness who are at risk for unbearable suffering to die comfortably and with dignity may lead to a more robust conversation and perhaps a different outcome.

Throughout the medical and legal literature related to PAD, the terms "suffering" and "dignity" are often referenced.[34,41,42] Each individual is responsible for defining what suffering and dignity mean, and these definitions underlie an individual's narrative and therefore cannot be interpreted by another without exploring the individual's definitions.[32,42,43] For the sake of this discussion, we will discuss and define these terms based on current literature.

There are various types of suffering—physical, emotional, and spiritual, with the latter two characterized as existential.[41,44] Physical suffering is addressed with direct management of the identified source of suffering. For example, mixed pain with bone and nerve components secondary to compression fracture may be treated with analgesics and/or kyphoplasty. Existential suffering, on the other hand, can lead to significant treatment challenges due in part to a lack of training for providers.[44] Existential suffering may include but is not limited to loss of dignity, purpose, or meaning. There are validated screening tools available to assist the medical team in this area. Unfortunately, the resources allocated to the treatment of existential suffering are often overtasked and understaffed, thus highlighting the importance of a team approach versus an individual one. The palliative care interdisciplinary team will focus on emotional, social, physical, and spiritual aspects of suffering, otherwise known as *total pain*, and treat them accordingly.

The palliative provider will strive to understand the person's individual narrative and how it can modify how he or she relates to or defines suffering.[32] One's narrative is not only generated individually, but is shaped by surrounding influences. In the past, the question was asked whether those who pursue PAD are doing so secondary to depression. Today, it is fair to consider whether it represents an autonomous choice to forego living with a disease and its burden. If one demonstrates the ability to understand a disease and its outcome and can rationalize the result of one's action independently and without coercion, this may be considered a valid decision.[33,45,46]

Like suffering, dignity is inherent to the topic of PAD. Soren Holm, in "Undignified Arguments," notes the frequent use of the term in the medical, ethical, and legal literature, as well as in rulings associated with medical cases.[21,32,34,47] Dignity often relates to the ethical principle of autonomy, which is a direct reflection of an individual's choices. This may be subdivided to include inherited dignity (being a human being) and personal dignity, as well as identifying key areas of focus for dignity, including respect, spiritual peace, and hope.[32,48] The patient is not the only one experiencing the dying process. Family, friends, and the healthcare team of the patient will also perceive the event through the lens of their own individual influences, each determining whether it was a dignified death. Whether PAD is applied or not, it is vital to understand the individual's values and beliefs that inform treatment. Consideration should be given to involving palliative care or hospice, usually well-equipped both in training and skills, to meet the needs and goals of the patient and family.

Informed consent in PAD is also an area of concern. Informed consent, including for alternatives, must exist if the patient is to exercise autonomous decision-making in treatment choices.[37,40] As the complexity of treatment plans increase, the issue of what the patient understands about treatment is often less clear.[43] Within each locality where PAD is legal, there are various criteria in place, including second opinions, psychiatric evaluation, and documentation of the ability to rationalize the choice, to ensure that the patient is fully capable of consent and fully understands what is being requested.[21] There has been concern around ensuring that these criteria are being met and true informed consent is obtained.

Legal

One of the first legal cases bringing attention to QOL issues and prolonged dying was the Karen Ann Quinlan case in the 1970s, which became an impetus for discussion around PAD and withdrawal of life-prolonging interventions. From there, a number of subsequent treatments that prolonged life began to be addressed.[31] Several cases have been heard by the US Supreme Court, with favorable rulings for patients' or surrogates' right to refuse life-sustaining therapies as well as the state's rights to individually address issues of PAD.[31,49] Today, these questions continue to be encountered, particularly in the presence of advancing technologies. Although less litigious, these questions become the charge of local palliative care or ethics teams to address within healthcare systems.

The legalization of PAD has been accompanied by safeguards to prevent potential misuse of the laws and to protect not only patients but also providers. There are concerns that some of the safeguards are not being monitored or enforced with regularity and that the procedure of PAD is being carried out in violation of acceptable standards of care. The *Michigan Law Review* completed a medical review of the Oregon PAD program and found that compliance with the Death with Dignity Act was not being followed and therefore that it was not possible to ensure that safety guidelines were enforced.[50] This substantiates the concern for a "slippery slope."[19,35] These safeguards to define the procedural component of PAD did not address clinical criteria for its use. Medical experts, including supportive services, came together to define clinical guidelines and criteria for PAD.[37] The most recent revision of criteria was completed in 2012, with the formation of the Physician Aid in Dying Committee. By ensuring that safeguards and defined clinical criteria are followed, it is possible to protect both the patient and provider.

Continued high visibility around the issue of PAD has resulted in a rapid acceleration of attempts and successes in introducing legislation at the state level.[49] This is being driven by public opinion and awareness, as well as by legal action.[21,39,43,51] A majority of the state laws being passed—and, in fact, country laws in the case of socialized medicine—are the result of legal action.[39,52]

Case Study: A Patient Requesting Physician Aid in Dying

Kathy, a 68-year-old married female, was diagnosed with metastatic ovarian cancer 3 years ago. She held a master's degree and owned an art and dance studio. She completed standard treatment for her cancer followed by a clinical trial, but she developed disease progression leading to recurrent partial bowel obstructions and generalized edema rendering her bedbound. Kathy was recently rehospitalized with a recurrent bowel obstruction.

She and her husband met with the palliative care team. During the initial consultation, she inquired about the physician aid in dying (PAD) process. With her husband at her side, she was very calm and rational as she discussed this option, explaining why PAD appealed to her. She shared that she had lost control and noted the lack of further disease-modifying treatment options making a further decline and death inevitable. She worried that she was only prolonging the burden of caring for her and did not see a purpose in continuing to live with a progressive decline. She reminded us that PAD had been on her mind for the past 3 years and that, now that this choice was legal in her state of residence, she wanted to proceed with this option.

Characteristics of Those Who Request PAD

Most who request PAD are individuals who are facing a life-limiting situation. A conversation may be initiated by a patient shortly after hearing the news of having a limited prognosis, sometimes as short as weeks or days. Requests for information about PAD may occur for several reasons including but not limited to curiosity, contingency planning, and fear of lingering or suffering. Requests may also be made as a planning measure to ensure control and provide options for individuals with terminal illness who are fearful of potential physical or emotional suffering. Finally, other requests are carried out with the intent to move forward with PAD.

A 2003 study of physician descriptions of patients requesting PAD found that the majority were nearing end of life and suffered a high degree of pain or symptom burden.[53] Patients making requests were primarily male, between 46 and 75 years old, and of European descent, and approximately half had a terminal cancer diagnosis.[53] Similarly, data from Oregon show patient characteristics as aged 65 years or older, white male, college-educated, and with a cancer diagnosis.[54] Reasons cited for the request included loss of autonomy (93%), diminished ability to participate in activities that bring joy (88.7%), and loss of dignity (73.2%).[54] A retrospective study of experiences of families of patients in Switzerland cared for by a palliative team who died after assisted suicide found that existential distress and fear of loss of control were predominant reasons for the request.[55]

Responding to Requests

Regardless of a provider's personal position or whether it is legal within the jurisdiction in which the interaction occurs, it is vital for the provider to listen to the patient without judgment while offering support.[56] Exploration of the hopes, worries, and concerns of the patient will assist in clarifying the intent of the request while identifying opportunities for palliative intervention with the goal of relieving distress. Providers who are willing to listen to the patient and openly discuss the option of PAD denote respect, thus fostering a therapeutic relationship between the provider and patient at a critical juncture.[56]

The conversation will offer insight into whether the patient possesses decision-making capacity, is adversely affected by psychiatric illness, or is suffering emotional distress, thus allowing for screening and appropriate referral to a mental health professional when appropriate.[50,51] Finally, the provider should attempt to ascertain how the request correlates with the patient's goals and values.[56] Consistency over time may lend credence to a request whereas inconsistency may alert the clinician to the need to further explore the request.

Alternatives to Physician Assistance in Dying

Patients who request PAD may recognize barriers blocking access to PAD. Some barriers may include but are not limited to locating a prescriber, enduring the 2- to 3-week time period required by law, insufficient finances to purchase the medications, and lack of family support. As a result, patients may need to consider alternative options to allow for a more natural dying process. It is possible to meet most patients' needs, resulting in a natural death rather than utilization of PAD.[40]

Various alternatives include the right to refuse or withdraw treatments. For example, a patient with myelodysplastic syndrome converting to acute myeloid leukemia who is transfusion-dependent may opt to forego further transfusions. In cases during which the patient demonstrates refractory symptoms creating uncontrolled suffering, palliative sedation may be employed. This procedure titrates sedation to symptom relief.[57] Some view this as the most intense method of symptom management, carrying with it the recognition that it truly represents the end of the patient's life unless it is utilized for respite.[58] Finally, voluntary stopping of eating or drinking (VSED) is an alternative that is gaining more attention in the literature. This method allows the patient to stop consuming any food or fluids in order to hasten death.

In all aforementioned situations, patients with a prognosis of 6 months or less may benefit from hospice care. Hospice offers supportive assistance and should be encouraged for every person facing the end of life, whether the patient chooses PAD or not. The hospice team provides the highest quality of pain and symptom management with a focus on the social, emotional, spiritual, and physical aspects that may improve the patient's QOL while allowing the natural failure of the body from disease.[59] The benefit also offers 13 months of bereavement care to the family, thus allowing for grief support.

Conclusion

PAD is a controversial subject encompassing clinical, legal, and ethical issues. Though not a palliative intervention, palliative clinicians are uniquely prepared to assess the multiple sources of physical and existential suffering that lead to its consideration, thus leading to appropriate treatment resulting in improved QOL. Some, however, may not be palliated despite expert intervention or may consider PAD for personal reasons. They may also benefit from consideration of palliative consultation as a means of exploring their options without judgment or agenda and with empathy and kindness.

CHAPTER 72

Nursing Education

Pam Malloy and Andra Davis

Key Points

- There is a need for palliative care nursing education.
- Practice guidelines and competencies for palliative care provide direction for nursing faculty, students, and practicing nurses.
- Updates to prelicensure education and changes in advanced practice registered nursing (APRN) will promote improved palliative care.

Introduction

There has never been a more exciting time to be a nursing educator, promoting palliative care education, practice, policy, advocacy, and research. Opportunities are unprecedented to provide this education to the next generation of nurses, as well as to clinicians, educators, and researchers. The National Institute of Nursing Research (NINR) included end-of-life (EOL) and palliative care in its strategic plan and noted that this care is truly a "science of compassion."[1] This inclusion aligns with the core of nursing practice: contribute to, organize, implement, and assess the interprofessional plan of care for those with serious, complex illness/injury in clinics, acute care facilities, and community settings. Nurses play a key role in providing holistic palliative care to those with serious illness because they recognize it is "fundamental to health and human dignity and is a basic human right."[2]

Nurse educators and leaders promote standards of palliative care, supporting healthcare systems to integrate this care throughout community settings. While hospitals provide care to the sickest, the majority of those with serious illness are generally at home, "neither dying nor in the hospital."[3] Numerous documents from national and international organizations provide position statements, standards, and guidelines for promoting excellent palliative care education.[1, 3–10] Students' clinical experiences and didactic instruction are often based on a curative-oriented perspective. Nursing faculty have a responsibility to integrate palliative care principles into both the classroom and clinical arenas, enabling students to learn and practice comfort-oriented care and communication as equally important nursing competencies. Future employers will demand they have this expertise. With the *Competencies and Recommendations for Educating Nursing Students* (CARES) document, nursing faculty has a blueprint of necessary entry-level competencies.[5]

Today, more than 90% of hospitals with 300 beds or more provide palliative care services.[11] The Joint Commission is now recognizing the importance of palliative care in the healthcare system and is promoting opportunities for hospitals to obtain Advanced Certification in Palliative Care.[12] Because of the increased focus on palliative care and growing numbers of palliative care teams there is a continuing need and commitment to promote and provide such nursing education.

While a variety of healthcare providers care for patients and their families from the time of diagnosis of a serious illness through the end of life, nurses are the constant presence and spend the majority of time listening, bearing witness, facilitating patient-directed goals, coordinating, and implementing care. Just as education is vital to safely bringing new life into the world, it is equally critical to commit to education and experiences that promote holistic, compassionate, and sacred care for those at the end of their lives. Therefore, palliative care education should begin at the entry-to-practice level; extend to advanced, specialty nursing practice; and be available for practicing nurses through clinical in-services, continuing education courses, annual competencies, and professional conferences.

History of Palliative Care Nursing Education

Nurses have a long history of leading the efforts in developing policies and guidelines regarding palliative care. Leading the way were visionaries such as Dame Cicely Saunders, who began her career as a nurse and went on to found the first free-standing hospice in London, England, in 1967. Following in 1974, the first US hospice was founded by Florence Wald. Jeanne Quint Benoliel examined the nurse's role in caring for the seriously ill from a psychosocial standpoint with her research, directing healthcare providers to include families in decision-making and caregiving.[13,14] The American Association of Hospice and Palliative Medicine (AAHPM) included several nurses in its first cohort of visionaries, recognized as being among the most influential leaders in hospice and palliative care. Serving their profession for at least 25 years as leaders in palliative care, these nurses included Nessa Coyle, PhD, ANP, FAAN; Patrick Coyne, MSN, APRN, ACHPN, FPCN FAAN; Betty Ferrell, PhD, RN, MA, CHPN, FPCN, FAAN; Sister Mary Giovanni, RN; and Nancy Hinds, RN.[15]

These visionaries have been role models, particularly in education. Faculty cannot teach and nurses cannot practice what they do not know. Because of long-standing gaps in EOL content in curricula, nurses practiced with limited knowledge of how to attend to the suffering of patients and their families facing EOL issues.[16]

A chain of events began with the 1998 publication of the American Association of Colleges of Nursing's (AACN) *Peaceful Death* document. This document outlined 15 palliative care nursing competencies and was followed by a ground-breaking review of nursing school curricula that confirmed the severe paucity of palliative and EOL care concepts.[17,18] An early analysis of nursing textbooks revealed that only 2% of overall content was related to EOL care, and much of the information was inaccurate and/or outdated.[18] Pain and symptom management were virtually absent, and information about communication at the end of life was also lacking. There was minimal information about the roles and needs of family caregivers and issues of policy, advocacy, ethics, and law, as well as scarce information about death awareness, anxiety, imminent death, and preparation of families for the death. Grief was described, but there was little information about nursing interventions or the nurse's personal experience of loss. Pharmacological information was either mentioned briefly or absent.[18] Graduate nursing faculty also reported, in a 2006 research survey, that although they believed EOL education was important, they saw their own programs being only moderately effective in promoting and providing the content.[19] With the development and dissemination of the End-of-Life Nursing Education Consortium (ELNEC) advanced practice registered nurse (APRN) curriculum in 2013, practicing APRNs can now receive further education as they begin or continue to practice palliative care, and graduate nursing faculty can obtain resources to embed in master's and doctoral nursing programs.[20]

Other opportunities to promote palliative nursing education involved collaborating with the National Council of State Boards of Nursing (NCSBN) to improve EOL content in the national nursing licensure examination for registered nurses (NCLEX-RN).[21] NCLEX began incorporating EOL issues beginning in 2001, resulting in an increase in evidence-based practice and the expansion of EOL and palliative care. The *Peaceful Death* document was updated and expanded in 2016, and is known as the CARES document.[5]

These efforts have increased palliative care content in nursing curricula, culminating in 2017 with a call to action released jointly by the American Nurses Association (ANA) and Hospice and Palliative Nurses Association (HPNA) recommending that nurses lead and transform palliative care.[22] In this directive, ANA president Pamela F. Cipriano called for every level of nurse to "have the knowledge and ability to facilitate healing and alleviate suffering through the delivery of safe, quality, and holistic, person-centered, primary palliative care."[22(para 2)] First among the 12 recommendations is the standard use of the ELNEC curricula available for general and specialty practice, as well as the recently released online undergraduate modules.[23]

Curriculum Developed to Assist Nurse Educators

Nursing faculty, continuing education (CE) providers, and staff development educators (SDEs) have long looked to the ELNEC curriculum, originally funded by the Robert Wood Johnson Foundation (RWJF) in 2000, as the primary evidence-based curriculum to teach the next generation and practicing nurses about this vital care.[16,18,24,25] The curriculum, updated annually since ELNEC-Core debuted in 2001, centers around eight content areas listed in Table 72.1. Education is provided through lectures, case study reviews, role plays, and videos. Individuals attending the ELNEC course learn content and obtain skills to teach that content. Since its inception, ELNEC has broadened both in scope of specialty content and international adaptation. Table 72.2 summarizes various curricula that have evolved since 2000.

More than 1,600 nurses attended one of the first eight RWJF-funded ELNEC train-the-trainer courses and reported 1-year post-course that they had provided ELNEC training to more than 19,000 student nurses. Forty-nine percent of the CE providers and SDEs stated that they were able to disseminate ELNEC-Core to clinical settings and CE programs throughout their community.[26,27] These data reflected successful adaptation across many settings. Several factors contribute to this effective dissemination: nursing faculty had long cited difficulty in adding new content to an already robust curriculum; and CE providers and SDEs are responsible for maintaining and addressing quality improvement issues, orienting new staff, often overseeing nursing internships/residency programs, providing CEs, preparing for Joint Commission visits, maintaining Magnet status, and attending to annual competencies. Each of these was an opportunity to promote palliative care education.

The ELNEC project continues to provide annual national and international train-the-trainer courses. The most recent figures reflect continued momentum and expansion, with 214 ELNEC

Table 72.1 End-of-Life Nursing Education (ELNEC)—Core Consortium modules

Module	Description of content
1. Introduction to Palliative Nursing	Creates an overview of the need to improve palliative care and the role of the nurse as a member of an interdisciplinary team in providing quality care.
2. Pain Management	Reviews basic principles of pain assessment and management in patients with serious illness/injury.
3. Symptom Management	Builds on Module 2: Pain Management, by addressing other symptoms common in advanced disease and the role of the nurse in managing these symptoms.
4. Ethical/Legal Issues	Discusses key ethical issues and legal concerns in palliative care and resources to address these in practice.
5. Cultural/Spiritual Considerations	Reviews dimensions of culture, which influence care in advanced disease.
6. Communication	Emphasizes the importance of good communication in palliative care and provides "the words" to improve care.
7. Loss/Grief/Bereavement	Addresses the challenging aspects of grief, loss, and bereavement of patients and families as well as the loss experiences of nurses.
8. Final Hours	Focuses on care at the actual time of death, emphasizing the preparation necessary to insure the best care at this critical event.

Table 72.2 Various ELNEC curricula developed

ELNEC curricula/date of presentations	Overview of participants	Funder
Current Curricula		
ELNEC-Core (2001–Present)	Staff nurses, APRNs, nursing students and faculty, staff development educators, unit-specific educators, community educators, administrators, researchers who work in acute care settings (i.e. medical-surgical and oncology units, clinics, homecare, hospice and palliative care settings)	RWJF, 2000–2004 Stupski Foundation (2016–2017)
ELNEC-Pediatric Palliative Care (2003–Present)	Nurses described in ELNEC-Core are also targeted for this course. Those working in pediatric units, pediatric (PICU) and neonatal intensive care units (NICU), hospice, homecare, clinics, and schools	Aetna Foundation (2005–2006)
ELNEC-Critical Care (2006–Present)	Those working in intensive care (ICU), coronary care (CCU), burn, dialysis, transplant units, emergency departments, etc	Archstone Foundation (2007–2010) Milbank Foundation (2014–2016)
ELNEC-Geriatric (2006–Present)	Geriatric nurses working in long-term care and skilled nursing facilities, nursing homes, undergraduate and graduate nursing faculty, hospice, community, and acute care nurses	California HealthCare Foundation (2008–2010)
ELNEC-APRN (2013–Present)	APRN nurses with 2 tracks to choose from: Adult and pediatric tracks	Cambia Health Foundation (2012–Present) Milbank Foundation (2014–2016)
ELNEC-International (2006–Present)	Presented in 96 countries worldwide to nurses and other interdisciplinary team members.	Open Society Foundations (2005–2017) Oncology Nursing Foundation (2013) American Association of Colleges of Nursing (AACN) (2015)
ELNEC-Undergraduate (2017– Present)	This online, interactive palliative care curriculum, is designed to meet the recommendations of the 2016 document and assists nursing students to successfully meet the 17 competencies and nurse residency programs, as they enter practice.	Cambia Health Foundation (2017–2019)
ELNEC-Oncology APRN (2017–Present)	Oncology APRNs to be prepared as generalists in palliative care.	National Cancer Institute (NCI) (2017–2022)
Integrating Palliative Oncology Care into Doctor of Nursing Practice Programs (2013–2018)	Doctor of Nursing Practice (DNP) faculty in an effort to integrate palliative care content into DNP program curricula.	National Cancer Institute (NCI) (2013–2018)
Past Curricula		
ELNEC-For Veterans (2009–2012)* ELNEC-For Veterans/Critical Care (2012) ELNEC-For Veterans (2017)	Nurses who work in Veteran-specific facilities, representing over 200 institutions **Note*: This 2017 curriculum is available on-line at no cost at https://www.wehonorveterans.org/elnec-%E2%80%93-veterans-updated-curriculum	The US Department of Veterans Affairs (2009–2012) Milbank Foundation (2012)
ELNEC-For Public Hospitals (2011–2013)	This course was presented to nurses in 16 public hospitals throughout California in November, 2008.	The California HealthCare Foundation (2011–2013)
ELNEC-Oncology (2003–2007)	Nurses belonging to an Oncology Nursing Society (ONS) chapter, working in inpatient, outpatient bone marrow transplant settings	National Cancer Institute (NCI) (2003–2007)
ELNEC-Graduate	Graduate nursing faculty in Schools of Nursing throughout the US	National Cancer Institute (NCI) (2003–2007)
TOTALS = 13 curricula		11 Funding Sources

train-the-trainer courses held nationally and internationally in the first 17 years of the project, with more than 22,300 educators completing the curricula and returning to their communities to provide ELNEC education to more than 668,000 healthcare professionals.[28]

One of the most recent expansions of the ELNEC curricula, ELNEC-Undergraduate, addresses the scarcity of undergraduate nursing education in palliative care.[18,29] In 2015, funded by Cambia Health Foundation, the ELNEC project assessed the current state of palliative care education in undergraduate nursing programs and began to develop an online prelicensure ELNEC curriculum. Using the original 1998 EOL competencies and the *Peaceful Death* document as a template, the new *Competencies and Recommendations for Educating Undergraduate Nursing Students* (CARES) was developed and unanimously approved by AACN in 2016.[5] CARES summarizes the educational needs of nursing programs, makes recommendations for how to incorporate the competencies in core nursing courses, and lists the 17 competencies needed for all students to achieve by graduation.[5] Box 72.1 lists these competencies.

Box 72.1 New Competencies for Educating Undergraduate Nursing Students to Improve Palliative Care

Competencies that new nurses need to have completed by the end of their undergraduate nursing education are the following:

1. Promote the need for palliative care for seriously ill patients and their families from the time of diagnosis as essential to quality care and an integral component of nursing care.
2. Identify the dynamic changes in population demographics, healthcare economics, service delivery, caregiving demands, and financial impact of serious illness on the patient and family that necessitate improved professional preparation for palliative care.
3. Recognize one's own ethical, cultural, and spiritual values and beliefs about serious illness and death.
4. Demonstrate respect for cultural, spiritual, and other forms of diversity for patients and their families in the provision of palliative care services.
5. Educate and communicate effectively and compassionately with the patient, family, healthcare team members, and the public about palliative care issues.
6. Collaborate with members of the interprofessional team to improve palliative care for patients with serious illness, to enhance the experience and outcomes from palliative care for patients and their families, and to ensure coordinated and efficient palliative care for the benefit of communities.
7. Elicit and demonstrate respect for the patient and family values, preferences, goals of care, and shared decision-making during serious illness and at end of life.
8. Apply ethical principles in the care of patients with serious illness and their families.
9. Know, apply, and effectively communicate current state and federal legal guidelines relevant to the care of patients with serious illness and their families.
10. Perform a comprehensive assessment of pain and symptoms common in serious illness, using valid, standardized assessment tools and strong interviewing and clinical examination skills.
11. Analyze and communicate with the interprofessional team in planning and intervening in pain and symptom management using evidence-based pharmacologic and nonpharmacologic approaches.
12. Assess, plan, and treat patients' physical, psychological, social, and spiritual needs to improve QOL for patients with serious illness and their families.
13. Evaluate patient and family outcomes from palliative care within the context of patient goals of care, national quality standards, and value.
14. Provide competent, compassionate, and culturally sensitive care for patients and their families at the time of diagnosis of a serious illness through the end of life.
15. Implement self-care strategies to support coping with suffering, loss, moral distress, and compassion fatigue.
16. Assist the patient, family, informal caregivers, and professional colleagues to cope with and build resilience for dealing with suffering, grief, loss, and bereavement associated with serious illness.
17. Recognize the need to seek consultation (i.e., from advanced practice nursing specialists, specialty palliative care teams, ethics consultants, etc.) for complex patient and family needs.

CARES: competencies and recommendations for educating undergraduate nursing students: preparing nurses to care for the seriously ill and their families. http://www.aacnnursing.org/Portals/42/ELNEC/PDF/New-Palliative-Care-Competencies.pdf. Published February 2016. Accessed October 3, 2017.

In January 2017, ELNEC-Undergraduate was released online through Relias, a comprehensive, innovative service that addresses the educational needs of nurses in a variety of clinical settings. ELNEC-Undergraduate is intended to assist faculty in meeting the required competencies. The curriculum consists of six, 1-hour, interactive, online modules modeled after the ELNEC-Core modules, with Cultural/Spiritual Considerations and Ethical/Legal Aspects of Care embedded in each of the six modules. The curriculum can be used across a variety of courses or as a stand-alone course and will revolutionize undergraduate preparation in palliative care. Each module permits students not only to read text, but also to hear from national palliative care leaders, to review case studies, and to view communication vignettes. Multiple-choice questions at the end of each module are designed to provide an opportunity to evaluate learning and allow students opportunities to practice taking NCLEX-style questions. In the first 10 months since its inception, more than 100 schools of nursing across the nation had signed up more than 5,000 students to review the curricula. For more information about ELNEC-Undergraduate, visit http://elnec.academy.reliaslearning.com/.

Other ELNEC curricula are also available online through Relias. Through an online subscription, Relias administers not only

ELNEC-Undergraduate, but also Core, Pediatric Palliative Care, Geriatric, and Critical Care. Each curriculum includes vignettes and other useful resources to improve nursing education. For more information on online ELNEC curricula, visit https://www.reliaslearning.com/elnec.

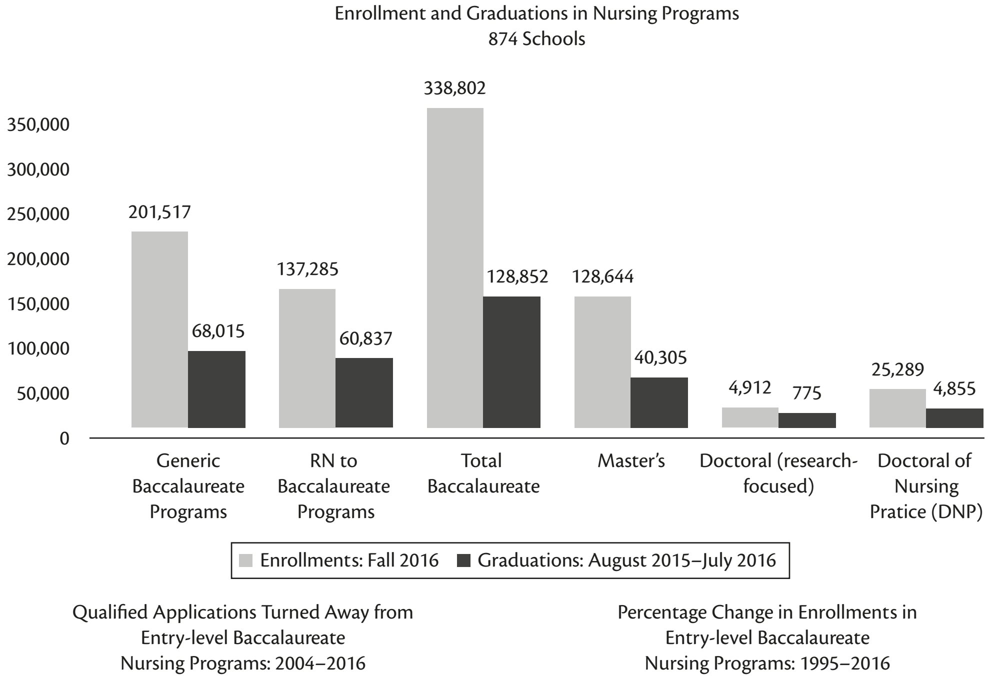
Barriers and Opportunities for Palliative Care Nursing Practice and Education

Both barriers and opportunities exist today in providing palliative care and in promoting the education required to implement that care. For example, one of the leading barriers that nurses face today are laws in many states that prohibit and prevent APRNs from practicing to the full extent of their education.[30] For nurse educators, barriers include lack of time to teach palliative care principles in an already overcrowded curriculum and lack of palliative care expertise among the faculty.[26,31–34] Nurse educators, administrators, and national organizations must be on the forefront to advocate the elimination of these practice and educational barriers so that these well-educated nurses can contribute their talents to meeting the healthcare needs of the nation. Schools of nursing must be committed to providing more generalist versus specialist education, and a greater emphasis needs to be placed on delivering care in the community rather than in acute care settings alone.[35]

Currently, the NCSBN has an initiative to assist in breaking down some of these barriers by supporting states in aligning APRN regulations with the Consensus Model for APRN Regulations. *APRN Campaign for Consensus: Moving Toward Uniformity in State Laws* promotes elements supporting the four roles of advanced practice (certified nurse specialist [CNS], certified nurse practitioner [CNP], certified registered nurse anesthetist [CRNA], certified nurse midwife [CNM]).[36]

Now that barriers have been removed in some states, nurses across the nation have a renewed interest in opportunities to advance their education—whether in obtaining their baccalaureate or graduate degree.[37] Nurses have many options for furthering their education on the graduate level (i.e., Clinical Nurse Leader [CNL], Masters of Science in Nursing [MSN], Doctor of Nursing Practice [DNP], Doctor of Philosophy [PhD], Doctor of Nursing Science [DNS/DNSc]). The demand for doctoral nursing education is growing rapidly in the United States. According to the AACN's 2016–2017 annual survey, which showcases 874/980 (89.2%) nursing programs in the United States, enrollment at the master's, research doctorate (PhD, DNSc, DNS), and doctor of nursing practice (DNP) levels were 128,644, 4,912, and 25,289, respectively.[37] Growth in baccalaureate, master's, and doctoral enrollments and graduations continue to rise (Figure 72.1).

While nurses remain committed to seeking further education, the United States continues to grapple with its complex healthcare system. Nurses have to be informed about professional issues, including political ones, and rise to be leaders in the healthcare transformation conversation to advocate for and play a major role in the years ahead because changes will affect the way patients and their families are cared for. Legislative restrictions, often supported by medical associations' political influence, have produced practice barriers for nurses even when the restrictions lack supporting data.[38] Numerous studies have been published about care provided by APRNs compared to physicians, and they conclude that patient outcomes are similar in terms of safety, effectiveness, quality, and patient satisfaction scores. In some studies, patient outcomes are better than when care is provided by a physician alone.[39] It is vital that governmental officials and policymakers understand the important role APRNs play in providing this care to the most vulnerable in our society. In 2015, approximately 8,000 primary care physicians entered the workforce, yet it is estimated that, in 2020,



Enrollment and Graduations in Nursing Programs

Percentage Change in Enrollments in Entry-level Baccalaureate Nursing Programs: 1995–2016

Figure 72.1 Key indicators and trends.
Source: Reference 37.

8,500 primary care physicians will retire, exceeding the number entering practice.[40] This is especially alarming since the US population will continue to grow and age. This presents an opportunity for APRNs to meet the monumental healthcare needs of the nation. Many APRNs have already responded to this need as they work in clinics to monitor and adjust medications to stabilize hypertension and diabetes, practice in rural settings where there are limited services, and deliver and oversee complex care in urban acute care facilities as well as in symptom management clinics. Yet while the needs and opportunities for this care exist, there are still barriers for APRNs to provide this care. For example[40]:

- Not all public or private insurance companies pay for nursing services.
- Schools of nursing provide minimal education and clinical experience in primary care.
- Salaries are generally lower in primary care versus acute care.

The need to remain updated on the complex changes in healthcare and to seek further education are responsibilities and privileges of all palliative care nurses as they "ensure that the healthcare system provides seamless, affordable, quality care that is accessible to all and leads to improved health outcomes."[35]

The Landscape of Healthcare Today: A Call to Action to Improve Education for All Nurses

Nurses, who spend more time with patients than any other discipline, assess and manage patients with increasingly complex needs. There are nearly 3 million employed nurses in the United States, representing the largest sector of the healthcare workforce.[41]

Chronic conditions are present in about half of all US adults (117 million people), with a quarter of this population having two or more chronic health diseases.[42] Of the top 10 causes of death in the United States, seven occur from chronic illnesses, including heart disease, cancer, lower respiratory diseases, stroke, diabetes, and kidney diseases.[43] Chronic illness is a personal and social burden and creates a deep economic impact, with 86% ($2.3 trillion) of the $2.7 trillion in annual US healthcare costs spent on the many challenges associated with these diseases.[44] In spite of the prevalence and scope of the problem, very little attention is given to maximizing health potential and improving quality of life (QOL) for those with chronic illness. The number of people in the 65-years-and-older category is expected to double by 2060, representing an increase from 15% to 24% of the overall population.[45]

A ground-breaking report released in 2010 and published by the Institute of Medicine (IOM), *The Future of Nursing: Leading Change, Advancing Health,* highlighted key areas for nursing transformation in an effort to meet these tremendous needs.[35] The result of a 2-year initiative by the RWJF Campaign for Action outlined four key messages that significantly affect the future of nursing[35]:

- Nurses should practice to the full extent of their education and training.
- Nurses should achieve higher levels of education and training through an improved education system that promotes seamless academic progression.
- Nurses should be full partners with physicians and other healthcare professionals in redesigning healthcare in the United States.
- Effective workforce planning and policymaking require better data collection and information infrastructure.

Two of these four key messages specifically address education as it is vital in meeting the complex needs of patients and transforming healthcare systems. In order to provide safe, "seamless, affordable, and quality care," nurses must obtain higher levels of education.[35] Contrary to this initiative, the current US healthcare system and nursing curricula focus on assessing and managing acute illnesses. A drastic change in curricula must take place in order to meet the needs of older adults, many of whom live at home and are seen by nurses in the community who assess and manage complex, chronic comorbidities, including obesity, heart disease, hypertension, and mental illness. Schools of nursing must develop and promote "leadership, health policy, system improvement, research and evidence-based practice, and teamwork and collaboration" competencies in order to provide quality care beyond acute care settings and inclusive of the community, public health, and geriatric settings.[35]

In 2015, the IOM requested an assessment of progress toward implementing *The Future of Nursing* report recommendations. The 2015 report found that significant strides had been made in educating more nurses at all levels of practice, but it also called out the need to develop and evaluate the transition-to-practice programs and the effect of such programs on patient outcomes.[46] In addition, the report recommended incentives for and expansion of programs to promote both DNP- and PhD-prepared nurses, as well as life-long learning. Finally, the report emphasized the need for interprofessional education (IPE) and professional collaboration.

A panel of experts conducted a review of palliative care nursing within the current healthcare systems and identified strategies for nurses to lead in transforming palliative care. Resulting recommendations jointly issued by the ANA and HPNA in the "Call to Action" are aimed at ensuring that "seriously ill and injured patients, families, and communities receive quality palliative care in all care settings. This is achieved by the delivery of primary palliative nursing by every nurse, regardless of setting."[23] Education-focused recommendations suggest that primary palliative care education for undergraduate (baccalaureate), graduate, and doctoral degrees, and continuing education for practicing nurses and advanced practice registered nurses, be based on the ELNEC curricula.[22] The number of employed nurses with baccalaureate degrees continues to grow and is in line to achieve the goal of 80% by 2020.[47]

Primary palliative care is distinguished from specialty palliative care in that primary palliative care contains the core, fundamental skills needed by all clinicians. Included in the *primary palliative care* scope is basic assessment and management of pain and symptoms and improving communication skills related to advance care planning and setting goals of care.[48] *Specialty palliative care* refers to providers equipped with advanced education and certification in this care, addressing more complex and refractory symptoms, possessing advanced communication and conflict-resolution skills, and providing care across settings.[49,50]

In addition to primary palliative care education, nurses are needed in advanced practice roles. The demand for doctoral nursing education is growing rapidly in the United States. Much of this is due to the increase of evidence-based practice, the complexity of patient care due to technology and multiple comorbidities, concerns about quality of care and safety issues, and a shortage of nursing faculty with a doctoral degree, and as a response to healthcare reform. There is evidence of steady increases in employed nurses with doctoral education.[51] The IOM recommendation of doubling the number of doctoral-prepared nurses by 2020 has already been achieved. For example, the number of research-focused doctoral graduates increased by 24.9% between 2012 and 2016, and graduations also increased for DNPs by 161.3% from 2012 to 2016.[51]

Nurses are leaders in providing care across the spectrum of health and illness, and they have an impact on quality, access, and delivery of affordable care. As the population ages and care grows in complexity, palliative care continues to gain momentum in the narrative of care. Nurses will continue to be well-educated and positioned to participate and lead in these changes and to promote policies that outline excellent palliative care. Educators must be poised to meet this challenge.

Interprofessional Palliative Care Education

IPE is a strategy embraced in both education and practice. Palliative care is by nature an interprofessional specialty and a well-established exemplar of team-based care. IPE is a logical platform for engaging students in discipline-specific and cross-discipline knowledge, skills, and competencies, thus fostering greater appreciation and attitudes toward the unique and synergistic contributions each profession brings to palliative care as well as posing opportunities to break down barriers. The IPE narrative began in the early 1970s by encouraging academic centers to provide team-based experiences. Head and colleagues summarized the discourse and magnitude of the imperative, which gained traction in 2010 with reports from IOM and a World Health Organization report.[52] Recent efforts have proved promising in the use and impact of palliative interprofessional training on the attitudes, knowledge, and behavior of nursing and medical students in caring for those with serious illness, although standards for such training do not yet exist.[53–55]

The new competencies (CARES) document for undergraduate nursing education twice references IPE as it relates to collaboration and communication toward quality, patient-centered outcomes in palliative care.[5] The increase in palliative and EOL education in prelicensure nursing programs, medical school curricula, and specialty journals and textbooks is promising. However, most healthcare provider programs still lack formal curricular integration of these concepts.[29,52] It will take normalizing of care and communication within the training milieu before the paradigm in practice can shift. Key leaders in palliative medicine and nursing have developed core competencies for their respective disciplines in training medical and nursing students to care for seriously ill patients and their families, but widespread integration into curriculum is still lacking.[5,56,59] As von Gunten and Ferrell (2014) remind us, "the greatest mistake in medical and nursing education and training is to view it as a cognitive exercise."[58(p. 226)] There is an imperative for academia to provide evidence-based knowledge and role-model the skill and practice of palliative care.[5,38,61]

Higher education and certificate programs are beginning to emerge, and, as stated by the ANA, nurses are "leaders in developing, promoting, implementing, and sustaining such teamwork in palliative care."[6(p. 8)] Exemplars of such initiatives are summarized in Table 72.3.

Promoting Palliative Education, Certification, and Scholarships

The 2013 National Consensus Project's (NCP) *Clinical Practice Guidelines for Quality Palliative Care* has been a roadmap used by numerous nursing educators, clinicians, and researchers to develop palliative care programs and curricula, research studies, protocols, and annual competencies.[9] Now, in its fourth edition, the guidelines expand ways to "improve access to quality palliative

care for all people with serious illness, regardless of setting, diagnosis, prognosis, or age."[59]

Because of these guidelines and their direction in practice, nurses have a clearer understanding of the importance of becoming better educated and even seeking certification in palliative nursing. Belonging to an organization where nurses can meet and learn from each other is critical to professional growth. The HPNA provides educational resources and opportunities, position statements, conferences, and support to APRNs, registered nurses, licensed practical/vocational nurses, nursing assistants, and administrators.[60] There are approximately 11,500 HPNA members in the United States and in several foreign countries.[61] HPNA provides educational opportunities through continuing education via webinars, ELNEC train-the-trainer courses, special interest groups (SIGs), online chats, and publishing resource books. In addition, meetings such as the Leadership Week-End Conference, Clinical Practice Forum, and the Annual Assembly, co-sponsored by HPNA and the American Academy of Hospice and Palliative Medicine (AAHPM), provide opportunities to network with other nurses and members of the interprofessional team. Hospice and palliative nurses can stay updated on the latest evidence-based practice through articles found in the *Journal of Hospice and Palliative Nursing* (JHPN) and through an online subscription to the *Journal of Palliative Medicine* (JPM). For more information regarding HPNA, go to www.advancingexpertcare.org.

One of two affiliated organizations within HPNA is the Hospice and Palliative Credentialing Center (HPCC), http://hpcc.advancingexpertcare.org/, the only organization that provides specialty certification for all levels of hospice and palliative nursing. There are currently seven certification exams offered by HPCC: Advanced Certified Hospice and Palliative Nurse (ACHPN), Certified Hospice and Palliative Nurse (CHPN), Certified Hospice and Palliative Pediatric Nurse (CHPPN), Certified Hospice and Palliative Licensed Nurse (CHPLN), Certified Hospice and Palliative Nursing Assistant (CHPNA), Certified Hospice and Palliative Care Administrator (CHPCA), and Certified in Perinatal Loss Care (CPLC). Currently, there are 18,809 certificants across all seven certifications (personal communication from S. L. Shafer, July 28, 2017).

The second organization affiliated with HPNA is the Hospice and Palliative Nurses Foundation (HPNF), incorporated in 1998, and it is committed to raising awareness and funding ways to support professional development of hospice and palliative nurses. As a 501(c)(3), the Foundation provided nine scholarships for education, research, conferences, and certification in 2016.[60] For further information on HPNF, go to http://hpnf.advancingexpertcare.org/.

International Efforts to Educate Nurses in Palliative Care

Each year, 40 million seriously ill children and adults around the world could benefit from palliative care, yet it is estimated that one-third of the world has no access to palliative care.[61,62] This is unfortunate because the world's aging population and cancer rates are increasing not only in the United States and other developed countries, but also in resource-poor countries. Nurses around the globe are responding to the tremendous needs to care for people who are suffering and dying, and they are becoming educated so they can provide evidence-based care. Yet there are barriers to providing palliative care education throughout the world[62,63]:

- Unawareness of and/or confusion about palliative care services.
- Poor or nonexistent support and advocacy on behalf of governments, ministries of health, and nongovernmental organizations (NGOs).
- Lack of access to opioids.
- Lack of education for healthcare professionals.

While there are tremendous needs and barriers, education is vital in responding to them. Today, there are variations in the establishment of palliative care educational programs around the world. For example, there are both stand-alone palliative care courses and courses where palliative care concepts are woven into already existing curricula in universities, seminars, workshops, and conferences in the Americas, Africa, Asia, Australia, the United Kingdom, and northern/eastern Europe, as well as in the Middle East.

Since 2004, there has been a widespread effort to expand ELNEC internationally.[28] Today, ELNEC has been presented in 96 countries, representing six of the seven continents. The ELNEC-Core curriculum has been translated into nine languages: Albanian, Chinese, Czech, German, Japanese, Korean, Romanian, Russian, and Spanish. Nursing leaders throughout these nations have led the way to make sure healthcare professionals have a thorough and up-to-date curriculum. In addition, ELNEC faculty from the United States has dedicated time to develop and deliver leadership seminars to palliative care visionaries throughout Eastern Europe, Kenya, and Asia. Efforts by several international nursing leaders in disseminating ELNEC through various educational means include[66–68]:

- Nicoleta Mitrea, PhD, APRN, MSc, is a lecturer at the Transylvania University Medical School and an APRN and researcher at the Casa Sperantei, Brasov, Romania.
- Juli Boit, MSN, RN, FNP, is the director of Living Room International and founder of Kimbilio, a 24-bed hospice and palliative care inpatient facility in Kip Karen, a rural community in Kenya.
- Joan "Jody" Ramer Chrastek, DNP, CHPN, is the pediatric advanced complex care team coordinator at the Fairview Home Care and Hospice in Minneapolis, Minnesota, and has spent many years volunteering in India to educate, translate ELNEC into Hindi, and empower nurses in palliative care.
- Sayaka Takenouchi, PhD, RN, MPH, is a senior lecturer at the Department of Ethics Support, Kyoto University Hospital, Kyoto, Japan, and, with her team, has translated ELNEC-Core, ELNEC-Geriatric, ELNEC-Critical Care, and ELNEC-Pediatric Palliative Care into Japanese.
- Hyun Sook Kim, PhD, RN, MSN, MSW, is a Professor in the Department of Nursing, Korea National University of Transportation, Jeungpyeong, Chungbuk, South Korea, and she has led the efforts to translate ELNEC-Core, ELNEC-Geriatric, ELNEC-Pediatric Palliative Care, and ELNEC-Critical Care into Korean.

For more information about ELNEC-International, go to http://www.aacnnursing.org/ELNEC/International.

Conclusion

As stated at the beginning of this chapter, there has never been a more exciting time to teach palliative care. It is rewarding to report the progress that has been made over the past 20 years in palliative care nursing, both within schools of nursing as well as across settings for practicing nurses. The science of palliative care as well as the shift in national directives and resources has contributed greatly to this progress. The literature has reported that nurses feel inadequately prepared in palliative care, and nursing faculty are on the cusp of shifting this paradigm.

Not only do patient outcomes, quality of care, and costs of care improve with palliative care, so do future practicing nurses and physicians. Many studies have reinforced the benefits of in-program training and education to their knowledge, sense of confidence, level of anxiety, and comfort in caring for those with serious illness and the dying.[53,54,69,70] Educators must foster excellence in palliative care practices through education, skills-building, and practice opportunities.

Now that palliative care has expanded from EOL care to address the QOL and symptom management needs of patients living with serious illness/injury and has demonstrated both patient satisfaction and cost-effectiveness, palliative care is being adopted rapidly in both inpatient and outpatient settings. As a result, employers are expressing the need for educated palliative care professionals. Unfortunately, there are not enough educated personnel to meet the workforce demand, and thus challenges remain.[71] Nurses must take opportunities to acknowledge and understand these challenges and work collectively to overcome them.

Teaching palliative care is not purely a cognitive exercise. Academia and professional training must provide evidence-based knowledge and role-modeling of the skill and practice of palliative care. Students and practicing nurses need to envision what excellent palliative care can look like.

Teaching and guiding students requires compassion and exquisite attention to respecting students' and practicing nurses' values, beliefs, personal experiences, and culture. It is essential that palliative care education not only incorporate knowledge and skills but also strive to teach effective ways of knowing how to best enhance compassion for those who suffer, empathy for those without a voice, and the "art" as well as the science of palliative nursing to patients and families who desperately need this care. It is a privilege to provide this education!

CHAPTER 73

Nursing Research

Terrah Foster Akard, Karen Hyden,
and Mary Jo Gilmer

Key Points

- The goal of nursing research is to improve care for patients and their families.
- Nurses have been instrumental in the field of palliative care research and are in ideal roles to be involved in or lead palliative care research.
- Palliative nursing research includes many sensitive topics such as suffering, quality of life, communication about death, and life meaning.
- Nurse researchers face many obstacles in conducting research, such as obtaining informed consent, dealing with vulnerable populations, and openly discussing end-of-life issues with patients and families.
- Palliative nursing research should utilize an interdisciplinary model that includes all supportive care disciplines.

Introduction

The ultimate goal of nursing research, and indeed of nursing knowledge, is to improve patient care. Palliative care science develops strategies to decrease suffering and enhance life for individuals living with, suffering from, and dying of life-threatening conditions and their family members. Palliative care research includes physical, emotional, social, and spiritual domains and informed decision-making support.[1] Nurses are in ideal roles not only to be part of palliative care research, but also to serve as leaders in the field to advance the science of palliative care.

Nurses led some of the earliest palliative care research contributions.[2] Pioneering work by Benoliel and others raised awareness of deficiencies in the care of the dying.[3,4] Early descriptive studies documented the influence of nursing attitudes and beliefs about death on the care provided to patients. From the earliest studies in the 1960s to the "awakening" of attention to palliative care in the late 1990s, research in palliative care has been limited. Nurse investigators have addressed aspects of palliative care such as symptom management, bereavement, communication, and care of special populations such as dying children.

Historically, there has been a lack of support for palliative care nursing research. National initiatives are increasingly supportive of palliative care research. For example, the National Institute of Nursing Research (NINR) has been designated as the lead institute at the National Institutes of Health (NIH) in the area of end-of-life and palliative care.[5] The Office of End-of-Life and Palliative Care Research coordinates NINR and NIH palliative care research efforts including (a) stimulating research opportunities in palliative care, (b) creating opportunities for collaboration, (c) facilitating interdisciplinary palliative care research, and (d) identifying opportunities for palliative care research to inform practice and policy. The Palliative Care Research Cooperative was established in 2010 to develop scientifically based methods that lead to meaningful palliative care evidence by creating a community of palliative care investigators, including nurses, who can engage in research discovery.[6] While such palliative care initiatives at the national level have improved support and funding for palliative care research, stronger support specific to nursing science in palliative care is needed. Nurses are in ideal roles to step up as leaders to further advance the field of palliative care nursing science.

Goals of Palliative Care Research

Goals of nursing research in palliative care ultimately focus on capturing evidence to improve the outcomes of patients with life-threatening or life-limiting conditions. Palliative care nursing research focuses on discovery, quantification, descriptions of phenomena, quality improvement, and problem-solving.[7]

Defining palliative care and understanding its ramifications have received increased attention but remain relatively unexplored areas, resulting in many opportunities for discovery. For example, more studies need to focus on the unique role of nursing within an interdisciplinary team and the greatest needs of patients receiving palliative care and their caregivers. Descriptive studies and epidemiological approaches can assist in quantifying advanced disease symptoms, including severity and impact. The experience of dying coupled with the subjectivity implicit in pain and terminal illness call for research methods that describe phenomena in context. Studies have identified gaps in palliative care such as end-of-life (EOL) care.[8,9] Research is needed to fill such gaps and improve the quality of care at the end of the illness trajectory.

While knowledge about the care of families receiving palliative care is expanding, current goals focus on defining populations of interest in addition to oncology patients, developing methods to measure various phenomena, and learning more about the development of patient and family indicators.[10] Oncology was understandably the discipline that received the most attention in early research in palliative care because funding was generally available and success rates of cure were relatively low. Research going forward could benefit from a focus on other populations such as those with heart conditions, autoimmune disorders, respiratory diseases, neurological conditions, and trauma.

Recent health policy changes such as the Affordable Care Act have resulted in innovative models of care. Research is needed to examine fixed components of care compared with aspects amenable to modification to achieve improved outcomes. Specifically, it is incumbent on researchers to study the infrastructure needed to maintain new models of care.

The Hospice and Palliative Care Nurses Association (HPNA), a national palliative care organization for nurse clinicians, researchers, and academics, conducted a member survey to identify goals of palliative care research. Results focused on palliative and EOL care for patients of all ages experiencing a life-threatening or life-limiting condition and included structure and processes of care, physical aspects of care, and psychological aspects of care.[7] Although the field of palliative care is developing through research, more work is needed to address the goals of professional palliative care organizations such as HPNA and the needs of this vulnerable patient population through discovery, quality improvement, and symptom management.

Benefits and Challenges in Palliative Care Research

Research in palliative care includes unique benefits and challenges. Considerable agreement about research priorities over the past 15 years is evident through systematic reviews and conference proceedings. Although a widely endorsed research agenda exists, the state of the science has progressed relatively slowly, suggesting the presence of considerable challenges in the field.[11] While even a mention of conducting research with patients who have received a life-threatening or life-limiting diagnosis raises concerns related to their vulnerability, there are also benefits to participants in research during this difficult journey.

Even when patients feel most vulnerable, having an opportunity to help others through enhancing healthcare providers' awareness and understanding of best practices, symptom management, and access to care is often very rewarding. Participating in research may offer an opportunity to derive some meaning from their experiences and to feel their suffering may even benefit others.[12] Participants may derive therapeutic benefits from telling their stories. In studies involving interviews with bereaved parents and siblings, parents frequently offered positive feedback and thanks to researchers for caring enough to listen to their stories and working toward improving the care of families after the death of a loved one.[13]

In contrast, challenges and barriers in palliative care research are widespread. The multidimensional interdisciplinary aspects of palliative care and the vulnerability of the population are two examples that pose special challenges to this area of research. Challenging areas include ethical concerns, financial/time constraints, research design questions, human resource limitations, and institutional politics (Figure 73.1).[14]

Staying true to the ethical principles of beneficence and nonmaleficence, as clinicians, nurses strive to enhance a patient's

well-being and quality of life (QOL) while, as researchers, they must be careful not to confound data. Another ethical principle, autonomy, plays into the challenges of gaining informed consent from debilitated and declining patients as nurses strive to protect patient and family independence. Potential research participants may feel obligated to agree to engage in the research, particularly when they are the recipients of high-quality care and feel indebted to providers. While all patients receiving palliative care are vulnerable, some groups, such as children, those with cognitive impairment, the poor, and the elderly, are particularly at risk.[13,14]

Funding and time limitations are often barriers to palliative care research. Telephone interviews with 61 leading researchers in palliative care identified funding and institutional capacity as barriers that limit progress in the field of palliative care.[11] Respondents described a limited number of funding sources and the review process of proposals as blocks to funding. Although community-based palliative care is growing, few outpatient palliative care services exist or have the capacity to conduct research. Palliative care services often are integrated into departments of geriatrics or oncology and may have few dedicated resources for internal research activities. Nurses often serve in roles of recruiters or data collectors for studies. A nurse may have difficulty balancing the role of a researcher with the role of a clinician, wanting to mitigate symptoms rather than assess them.

Design concerns may manifest through Institutional Review Board (IRB) proposals, informed consent of compromised patients, unwillingness to talk about the dying process, attrition, the emotions of both research staff and families, and a lack of appropriate measures. Hospital IRBs may be hesitant to approve protocols that involve families from the time of a difficult diagnosis through the illness trajectory that proceeds to end of life. Subject burden must be taken into consideration in palliative care, perhaps more than in any other field of study. As mentioned earlier in discussing the benefits of palliative care research, however, participants may welcome an avenue for communicating their needs and their successes. Potential attrition needs to be considered in determining sample sizes and becomes a real concern when longitudinal studies are proposed, which are definitely needed in palliative care research. Both qualitative[15] and quantitative[16] approaches are useful in the emerging science of palliative care.

Definitions of palliative care are disparate and may not be understood by the general population, leading to misunderstandings and potential conflicts. Another challenge is that palliative care is not generally revenue-producing, and its status may not measure up to specialties such as cardiovascular surgery. A research team with members who are passionate about palliative care, knowledgeable, caring, and insightful must be recruited to conduct the research, and burnout remains a constant threat. Interdisciplinary collaboration is a key to success with these complex patients. Finally, life-threatening conditions are shared experiences, and including families in the research enriches the benefits of palliative care research.[9,17]

Priority Research Areas in Palliative Care

In the past twenty years, palliative care research has focused on efforts to fill the gaps in knowledge identified by multiple initiatives. Palliative research has historically focused on symptom management, health systems, cultural considerations in care, QOL of patients and their caregivers, needs of caregivers, and emotional and spiritual aspects of living with a terminal illness.[18] Although these topics are relevant and important in palliative care research, it is imperative that gaps continue to be identified to address ever-changing healthcare delivery systems, care models, costs of care, and needs of patients and caregivers.

In 1997, the NIH appointed the NINR as the lead institute of end-of-life and palliative care research. With the support of the NIH, the NINR released a report of trends in scientific literature focusing on palliative care between 1997 and 2010. The results of the extensive review showed that although there was significant growth in end-of-life and palliative care nursing research during this time period, knowledge gaps remained and these persist today. The gaps were identified in the topic areas of changing demographics of patients with serious illness and EOL palliative care issues related to renal or liver disease, as well as HIV/AIDS and pediatric populations. In addition, there was a lack of literature pertaining to ethnic, cultural, and spiritual needs (Box 73.1).[19] In 2011, the NINR led The Science of Compassion: Future Directions in End of Life and Palliative Care Research Summit to assess the gaps in knowledge in end-of-life and palliative care and to further the agenda for future research. Some of the proposed future agenda items were ethical aspects of palliative care, early versus delayed access to care across disease processes, integrated models of care, improved communication, more community involvement, and a need for more longitudinal studies.[20,21]

Also during this time of tremendous growth in palliative care research, the HPNA[7] presented a 2015–2018 research agenda consisting of topics to provide direction for research: (1) provide focus for graduate students and researchers, (2) guide organizational and research funding, and (3) illustrate to other stakeholders the importance of specific research foci. As a framework for these agenda items, the *Clinical Practice Guidelines for Quality Palliative Care* released by the National Consensus Project for Quality Care provided eight domains essential to providing high-quality palliative care that are considered to be the highest priority for current and future nursing research. These domains are structures and processes of care; physical aspects of care; psychological and psychiatric aspects of care; social aspects of care; spiritual, religious, and existential aspects of care; cultural aspects of care; care of the patient at end of life; and ethical and legal aspects of care.[7]

In addition, the Institute of Medicine's (IOM) report has highlighted areas for improvement in providing quality palliative care for patients and their caregivers.[15] The report contained five recommended areas for improvement in care: delivery of care, clinician–patient communication and advance care planning, professional education and development, policies and payment

Box 73.1 NIH/NINR Identified Gaps in Nursing Research

End-of-life palliative care (EOL PC) issues related to:

1. The changing demographics of patients with serious illness
2. Renal or liver disease end-of-life palliative care issues related to HIV/AIDS
3. Pediatric populations
4. Ethnic needs
5. Cultural needs
6. Spiritual needs

Box 73.2 IOM: Recommended Areas for Research/Improvement in End-of-Life Care

1. Delivery of care
2. Clinician–patient communication and advance care planning
3. Professional education and development
4. Policies and payment systems
5. Public education and engagement

systems, and public education and engagement that can be used to help guide future nursing research in palliative care (Box 73.2).[22]

The continued interest in palliative nursing research is evidence that there is room for discovery in what nurse scientists know about palliative care and room for improvement in how the information is translated into best practice. The research focus areas suggested by the NIH/NINR, HPNA, and IOM are those areas with significant gaps in palliative care literature to date and should be used to guide future research directions. Nurse scientists and clinicians must collaborate to identify best strategies to translate findings into practice in a meaningful way if palliative care practice is to evolve and improve based on emerging research.

Palliative Care Funding Sources

Numerous organizations support palliative care and provide funding opportunities for research. Palliative care funding is available for many investigative levels, including predoctoral students, postdoctoral fellows, junior faculty researchers, and senior scientists. Researchers should consider potential internal hospital and institutional funding mechanisms in addition to external funding mechanisms such as private organizations, industry, and the NIH. Examples of funding sources that can support palliative care research are listed here.

- American Cancer Society: https://www.cancer.org/research/we-fund-cancer-research/apply-research-grant.html
- American Nursing Foundation: http://www.anfonline.org/nursingresearchgrant
- Hospice and Palliative Nursing Association: http://advancingexpertcare.org/research-grants/
- National Institute of Nursing Research: https://www.ninr.nih.gov/researchandfunding/dea/desp/oep/fundingopportunities
- National Palliative Care Research Center: http://www.npcrc.org/content/19/Funding-Opportunities.aspx
- Palliative Care Research Cooperative: http://palliativecareresearch.org/funding/funding-opportunities/

Table 73.1 Research proposal components

Specific aims	Clearly stated. Hypotheses or study questions are consistent with the study aims. All proposed study procedures and data to be collected are encompassed. Guided by a clear theoretical/conceptual framework
Significance	Research has high impact and advances the science of palliative nursing care. Research has strong potential to lead to further investigation. Research offers a unique contribution to the literature. Research is clinically relevant to palliative care. Relevant and current literature is reviewed, critiqued, synthesized, and analyzed.
Innovation	Is pioneering in the field of palliative care Seeks to shift palliative care paradigms Develops new theories, tools, approaches Accelerates or strengthens existing palliative care research or practice
Approach	Procedures are feasible. Procedures include methods for training and supervision of personnel. Procedures provide sufficient description of precisely what will be required of subjects. Statistical procedures are identified, and analysis is appropriate for the type of data and study design and answers the study questions. Well-designed tables and figures. Feasible study timeline, typically in table format.
Human subjects	Institutional Review Board approval is given or documentation of pending review is given. Investigator is clearly aware of the impact of participation in the study on the subject. Investigator addresses concerns regarding length, intrusiveness, and energy expenditure required. Investigator has acknowledged special considerations of patients with life-threatening conditions.
Investigators	Consultation is available for the less experienced researcher. Role of co-investigators or consultants is established.
Format	The proposal strictly adheres to format restrictions and page limitations.

Table 73.2 Tips for preparing research proposal

Team effort	Seek consultation and collaboration from others, especially senior palliative care researchers. Seek opportunities to involve interdisciplinary clinical palliative care team members (e.g., nurse practitioners, physicians, social workers, psychologists, child life specialists) in nursing research.
Peer review	Have peers review proposal before submission. A proposal submitted for funding is generally the product of numerous revisions.
Follow directions	Follow the directions in detail, including margins, page limits, and the use of references and appendices. Communicate directly with the funding source to clarify any directions.
Writing	State clear and concise ideas. Word economy is essential to a fine-tuned proposal.
Proofread	Proofread carefully. Do not allow grammatical errors or typos. Grant reviewers want to see that you have given attention to detail in the preparation of your proposal.
Time frame	Plan ahead and develop a time frame for completing your grant. Grant proposals cannot be written at the last minute. Strictly adhere to all deadlines, including internal deadlines within your organization.
Appendices	Use appendices to include study instruments, procedures, or other supporting materials *if allowed*.
Support letters	Include support letters from individuals who are important to the success of your study. This includes department chairs, medical staff, nursing administration, consultants, and co-investigators.
Start small	Successful completion of a pilot project is the best foundation for a larger study. Efficient use of small grant funding is influential when seeking larger scale funding for major proposals.
Be realistic	Design research projects that can be realistically accomplished within the scope of your other responsibilities and the limitations of your work setting.
Patient focus	Design and implement research that is relevant to patient care and improves quality of life and decreases suffering for patients with life-threatening conditions and their families.

Preparation of a Research Proposal

Components of a research proposal are specific to the funding mechanism, yet content is similar in the majority of proposals. Table 73.1 includes an example of guidelines for preparing a research proposal. These criteria, adapted from the NINR,[23] depict the essential elements of a research proposal: specific aims, significance, innovation, approach, human subjects, investigators, and format. Table 73.2 includes general tips for preparing a research proposal. Attention to the criteria that reviewers will use to assess and score the application can also help in preparing the proposal. Review criteria differ according to funding mechanism and organization. NIH review considerations are summarized in Table 73.3.

Conclusion

Research is essential to advance the science of palliative care to inform practice. Leading organizations highlight research agendas to help identify important areas in need of study in palliative care. Numerous opportunities are available to fund rigorous studies that will significantly impact the field of palliative care and ultimately improve patient care. The palliative care research community is interdisciplinary and collaborative in nature. We should continue

Table 73.3 Review considerations for research sponsored by the National Institutes of Health (NIH)

Significance	Does this study address an important problem? If the aims of the application are achieved, how will scientific knowledge be improved? Is there a strong scientific premise?
Investigator	Is the investigator appropriately trained and well suited to the project? Is the work proposed appropriate to the experience level of the principal investigator and other researchers (if any)?
Innovation	Does the project shift research or practice paradigms forward? Does the study use novel concepts, approaches, or methods? Are the aims original and innovative? Does the project challenge existing paradigms? Does the study develop new theory, methodologies, instruments, or interventions?
Approach	Are the conceptual framework, design, methods, and analyses adequately developed, well integrated, and appropriate to the aims of the project? Are potential problems and possible solutions addressed? Does scientific rigor ensure robust and unbiased study results? Are relevant biological variables (e.g., sex, age, weight, underlying health conditions) addressed?
Environment	Does the scientific environment in which the work will be done contribute to the probability of success? Is there evidence of institutional support? Does the project benefit from unique features of the research environment, study populations, or collaborations?
Additional considerations	Adequacy of plans to include both genders and minorities and their subgroups as appropriate for the scientific goals of the research are reviewed. Plans for the recruitment and retention of subjects are also evaluated. Rigor and reproducibility should be addressed.

efforts to support and develop the next generation of nurses to become leading independent palliative care researchers. Nurses are vital to advancing the science of palliative care research and are in ideal roles to not only support, but also to lead innovative palliative care research that will enhance life and decrease suffering for the patients and families that we serve.

CHAPTER 74

Advocacy in Palliative Nursing

A Conceptual Model

Nessa Coyle and Timothy W. Kirk

Key Points

- Nurses are ideally suited to advocate for patients and families due to their professional orientation, education, and role in patient care.
- Six components constitute a model of advocacy in palliative nursing: clinical competency, relational care, communication skills, bio-psycho-social-spiritual orientation, interdisciplinary collaboration, and a combination of confidence and humility.
- Nurse advocates respond to the strengths as well as the vulnerabilities of patients and families, building empowering relationships to support care decisions that respect the values and personhood of patients.
- Seven functional elements facilitate effective advocacy in palliative nursing: specific documentation, careful observation of patient and family interactions, assessing understanding, building rapport, eliciting care preferences, privileging patient values and preferences, teaching and sharing information.
- Advocacy is an *approach* to palliative nursing care, one which emphasizes careful attention to process over outcome.

Case Study: Advocating for a Patient—Part 1

Mr. O'Reilly is a 75-year-old retired literature professor, married with three adult children—two daughters and one son. One daughter was a writer and a stay-at-home mom; the other worked in a law firm. Both have young children. The son was in graduate school studying business management and communication. The children and their families lived nearby, and this basic family structure appeared to be a close-knit one. Mr. O'Reilly and his wife were originally from Ireland. They moved to the United States to attend university, became citizens, and have lived in the country for more than three decades. Their three children were born and educated in the United States. Mr. O'Reilly described his family as being the most important aspect of his life.

Mr. O'Reilly was diagnosed with incurable lung cancer 5 years ago, and the disease was initially controlled with multiple chemotherapy regimens. He now had end-stage disease, including newly diagnosed metastases to the brain, leptomeninges, and skeletal system. Over the past year, he had become increasingly dependent on his family for his basic needs.

His last chemotherapy treatment was 8 months ago. At the time of that visit and following a frank and open discussion with his oncologist, Mr. O'Reilly declared his preference for a do not attempt resuscitation (DNAR) code status and to allow a natural death (AND) when "my time comes." There was no note in the chart as to whether a family member was present during the code status discussion or if it was discussed with the family at a later date. At his request, Mr. O'Reilly was referred to the Integrative Medicine Service, and turned the focus of his care toward nutrition, exercise, and meditation. He was also referred to the outpatient palliative care clinic for support and ongoing management of pain and dyspnea.

Several months later, Mr. O'Reilly's final hospital admission was through the emergency department for increasing shortness of breath and hypoxia. On admission, he looked frail, cachectic, and close to death. He complained of generalized pain. Consistent with his previously stated wishes, and following a conversation with his attending physician in the emergency department, his code status was established as DNAR and AND. On the inpatient floor, his analgesic regimen was adjusted, and he was placed on high-flow nasal oxygen. His symptoms were brought under control, and he was able to communicate clearly.

After several days on the unit, Mr. O'Reilly's nurse walked into the room one morning and was handed, by the son, a handwritten note, signed by the patient and all members of his immediate family, stating that he wished to rescind his DNAR order. Goals of care became less clear. Prior to this code status change, when speaking to the nurse alone, Mr. O'Reilly expressed being tired of "the struggle" and just wanting to be kept comfortable. But when his family was present, he expressed the wish to keep fighting for as long as he could; he "had a book to finish." The request to rescind the DNAR order was strongly endorsed by the family. The staff became concerned that Mr. O'Reilly's "true wishes" were being muffled by the strong voice of the family.

Chapter Goals

This chapter addresses four questions related to nursing advocacy:

1. What does it mean for a nurse to "advocate" for a patient like Mr. O'Reilly?
2. In what way(s) is advocacy part of palliative nursing?
3. What kind(s) of communication, and with whom, is necessary for effective advocacy in palliative nursing?
4. How does a palliative care nurse develop/strengthen her skills as a nurse advocate?

The chapter is presented in four parts:

I. Literature review
II. Conceptual model of advocacy in palliative nursing
III. Functional elements of advocacy in palliative nursing
IV. Barriers to anticipate and pitfalls to avoid when advocating in palliative nursing.

A working presumption of the chapter is that *any* nurse working with a patient who has advanced illness has the obligation to provide palliative nursing at a generalist (basic) level.[1] Although it is anticipated that the model of advocacy presented here will also apply to palliative nursing at a specialist level, the chapter is intentionally written with the nonspecialist inpatient nurse in mind.[2,3]

Literature Review

While there is not a peer reviewed literature on advocacy specific to palliative nursing, advocacy is frequently put forward as a core function of ethical nursing practice generally.[4–6] Indeed, some influential nursing theorists have gone so far as to claim that effectively advocating for patients is one of the defining elements of what it means to be a nurse—what makes nursing, "nursing."[7,8] While there may be widespread agreement on the importance of advocacy in nursing, there is considerable heterogeneity on the meaning of advocacy in nursing. A review of several prominent approaches will inform development of our concept of advocacy in palliative care nursing. Readers will note that several of the sources reviewed herein were published prior to 2013. They are included to engage important conceptual work in nursing advocacy and to refer readers to primary sources rather than secondary analyses.

The most prevalent conceptual approach to advocacy in the nursing literature is to position the nurse as a defender of patient rights.[9] This "rights protection" model of advocacy sees the nurse as acting in response to the vulnerability of patients.[6,10] Conditions of patienthood create vulnerability insofar as (a) patients are weakened by illness and injury, (b) there is a significant imbalance in knowledge and experience between patients and the clinicians providing their care, and (c) the structures and practices through which healthcare is delivered are insufficiently designed to elicit patient values and ensure that care is given in alignment with informed patient choices. Actions of the nurse as advocate in this model are interventions to mitigate the threat to patient rights presented by these conditions: (a) carefully assessing patients' symptom distress and collaborating with the care team to optimize symptom management, (b) providing patients the information and understanding necessary to make informed choices, and (c) interceding with the care team on behalf of the patient.

In their mid-range theory of patient advocacy, Bu and Jezewski[11] refine the notion of "rights protection," presenting it as "safeguarding patients' autonomy," which, along with "acting on behalf of patients" and "championing social justice in the provision of healthcare," constitute the three core attributes of patient advocacy. Via a synthetic review of the nursing literature, the authors claim that these three attributes frame a conceptual definition that can be used to develop an operational concept of advocacy.

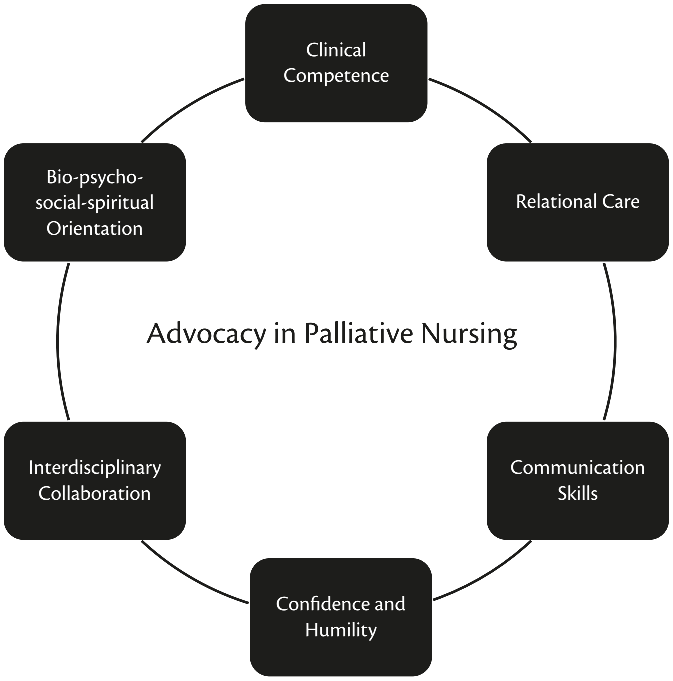
While a rights protection approach to advocacy is driven by a response to patient vulnerability, an alternate approach emphasizes empowering patients and families by engaging their strengths. Gaylord and Grace,[12] for example, describe advocacy as being embedded in multiple domains of nursing practice, manifesting in each interaction for which a nurse supports a patient to understand and adapt to the meaning of health or illness as uniquely experienced by that patient. Grace[13] further refines this approach to advocacy, one she terms "professional advocacy," by explaining that nursing advocacy attends not only to protecting the rights of patients, but also to creating a care environment in which patients can draw upon their own strengths and partner—with nurses, family members, other care team members—to create and respond to the meaning of their clinical situations in a manner that engages and expresses their personhood.

This alternate approach to advocacy resonates strongly with Gadow's concept of "existential advocacy": "that individuals be *assisted* by nursing to *authentically* exercise their freedom of self-determination."[8(p. 85)] In existential advocacy, nurses build relationships with patients and family members with the aim of empowering them as persons; it is a relational model of supportive partnership wherein the significance of clinical care is always rooted in the ability of that care to enable patients to more fully realize all aspects of who they are as persons. Existential advocacy requires what Kirk[14] calls "clinical intimacy," in which nurses partner with patients using cognitive and behavioral cues to co-create meaning through shared perceptions of the patient's illness and treatment.[15] The aim of such partnering is to offer a supportive presence that empowers patients to create the meaning necessary to (a) cope with the stress that can accompany serious illness and its treatment and (b) make care decisions consistent with their core values and preferred processes of perception and judgment.[16]

While the literature on nursing advocacy focuses primarily on advocating in particular clinical relationships between nurses and patients, some articles also address advocating—for groups of patients and the nursing profession—at an organizational and a public policy level.[11,17] This is an important kind of palliative nursing advocacy but is beyond the scope of the chapter.

Conceptual Model of Advocacy in Palliative Nursing

Six components constitute a conceptual model of advocacy in palliative nursing: clinical competence, relational care, communication skills, combined confidence and humility, interdisciplinary collaboration, and a bio-psycho-social-spiritual orientation (Figure 74.1).[18] Integration of these elements demonstrates that advocacy is a *way* of doing the things that palliative nurses do—an *approach* to care rather than a collection of discrete tasks added to an already full nursing workload. What is being advocated for is a process rather than a particular patient choice or outcome.



Clinical Competence
Relational Care
Communication Skills
Confidence and Humility
Interdisciplinary Collaboration
Bio-psycho-social-spiritual Orientation
Advocacy in Palliative Nursing

Figure 74.1 Core components of advocacy in palliative nursing.

Clinical Competence

"You can't practice what you don't know" has become a well-known mantra for those in the field. With knowledge and competency comes, for example, the ability to accurately assess symptom burden and functional status and intervene as appropriate, as well as to structure conversations and listen to patients in a way that identifies personal values and goals of care.[19–21] Knowledge of the current literature and best practice standards positions the nurse to make judgments about the significance of assessment findings and present such findings in a way that conveys their significance to other members of the team.[18,22–24]

Relational Care

A relational approach to nursing care emphasizes the power of therapeutic relationships between a nurse and care recipient to create an environment in which it is safe to be vulnerable and seek assistance in the midst of illness.[15,25] In this way suffering can be identified and addressed, meaning can be restored or created, and patients can integrate and express their personhood even in the midst of serious illness and injury.[26] Healing, in its broadest sense, can take place in the absence of cure. Hallmarks of relational care are empathy and reliability, in which a nurse creates an atmosphere of understanding and safety for her patient.[15] While frequently applied to environments such as long-term care facilities and patients with limited capacity to participate in their own care (such as persons with dementia), the conceptual framework of relational care is a useful one for advocacy in palliative nursing care. Creating an environment of safety and reliability allows patients and family members struggling with the impact of advanced and final illness to explore and express fears, hopes, inner conflicts, confusions, and disagreements—all of which need to be engaged and worked through to develop clear goals of care.

Nurses are usually on a unit for 8- to 12-hour periods of time, seeing patients and families on multiple occasions during each shift. Conversations will occur simultaneously with nursing assessments, monitoring and adjusting medication infusions, dressing wounds, and coordinating care. With such frequent and varied interactions, nurses build relationships with patients and families in which opportunities for observation, listening, teaching, and holistic assessment arise regularly and with less formality than with many other members of the healthcare team.[27,28] This is in addition to their more structured and formal routine assessments. Connecting with patients and families at the same time as the nurse is engaged with specific nursing interventions can open opportunities for intimacy which invite disclosure of important information. While a conversation with other disciplines may purposefully focus on a defined topic, interactions that occur spontaneously while specific nursing tasks are being performed can open a space for incidental exchanges that, while not specifically focused on clinical care, may nonetheless uncover important aspects of a person's life and the way he or she experiences aspects of illness and care that are important.

Although most of the literature on advocacy focuses squarely on advocating for the patient with little to no mention of the family, values and care preferences often take shape and are expressed in relationship with others.[29] A model of advocacy in palliative nursing that does not integrate the relational context in which life is lived is incomplete. The conceptual commitments in relational nursing have explanatory power for the therapeutic value of relationships between patients and family caregivers, not just patients and nurses. Establishing supportive relationships with family members empowers them, in turn, to maintain empathy and reliability in their relationships with the patient. Palliative care is patient- *and* family-centered care—not just one or the other.

Communication Skills

Well-developed and deliberately used communication skills enhance bedside nurses' ability to advocate for their patients and families.[30,31] Du Pré and Foster[15] explain one model of communication especially resonant with the aims of palliative care nursing advocacy: *transactional communication*. In this model, meaning is created in the shared spaces between a nurse, a patient, and family members—precisely the safe, supportive environment emphasized in relational care. Coyle and Kirk[9] offer an ethical framework for such communication guided by the cornerstone principles of clinical sensitivity, truthfulness, accommodation, and advocacy. In this framework, each communication transaction carries with it the possibility of enhancing (and the risk of diminishing) the therapeutic nature of the clinical relationship. This is done by reinforcing a commitment to honoring the moral agency of all parties and, especially, to understanding the values, preferences, and needs of the patient.[32] The potential for meaningful advocacy is advanced.

Nurses, in spending the kind of extensive time on a unit as previously described, have opportunities to interact with patients with and without family members present. It is also common for family members to communicate directly with nurses outside patients' rooms and for patients to speak with nurses when alone. The tenor of these conversations may be very different. They are considered as a whole, and yet our primary responsibility is to patients. This duality yet unity can be a difficult area for the bedside generalist palliative care nurse to negotiate. When a family prefers to communicate with the healthcare team without the patient's participation, despite their ability to engage in such conversations and decisions about care, the nurse can advocate for the patient (unless there is a strong contraindication) by moving the conversation back to the bedside and ensuring that the patient is a full participant in the process. When a patient communicates significantly different preferences in the presence of family members than are expressed when the family is not present, the nurse can explore these differences with the patient. When a nurse perceives that her patient is more confident and engaged in conversations about healthcare when a son or daughter is present, the nurse can request that critical conversations with healthcare professionals are scheduled when that person is able to participate. Hence, nurses can advocate by attending not only to the content of communication, but also to the circumstances in which communication occurs. Documentation of these conversations and interactions with the patient and family are an important part of good communication and advocacy work.[33]

Confidence and Humility

With competence comes the "power" to influence others. That power can take two forms: (a) it is empowering as a palliative nurse gains confidence in her own abilities and embraces the value of her clinical observations and findings to shape and implement the patient's plan of care, and (b) it enables the nurse to communicate information, observations, and assessment effectively.[34] Through her choice of words, confident tone, and application to the clinical context, the information she brings to the table is more likely to have an impact on the giving and receiving of care. Humility is the other face of confidence. It is the ability to be open to the views of others. Just as the nurse is confident in her skills and the value of a nursing perspective, she recognizes that she is only one member of the team and one discipline among several. The best care is delivered when the talents of multiple team members and disciplines are integrated together. By necessity, this requires acknowledging that each member of the team has a valuable—and partial—perspective when compared to the well-integrated complement of perspectives from all team members. Combining confidence with humility can enhance interdisciplinary collaboration.

Interdisciplinary Collaboration

Palliative care is, in its very nature, interdisciplinary care. Palliative nurses must not only build therapeutic relationships with patients and their families, but they are also in important relationships with other members of the healthcare team. Managing these multiple relationships, and facilitating the relationships between members of the clinical team and the patient and family, provide an important opportunity for nursing advocacy.[35] Nurses may be the ones to see most clearly how a patient/family decision is in tension with—or in direct opposition to—the best judgment of the care team. In the advocacy role, nurses can offer the team insight to the patient's and family's day-in and day-out experience of living with advanced illness and its treatment—a first-hand, lived experience for which no amount of clinical expertise can substitute. Bedside nurses may be privy to this information while other team members are not. Similarly, nurses can help patients and families understand the perspective of the team.

Bio-psycho-social-spiritual Orientation

The orientation and philosophy of nursing as a discipline is one that uses a bio-psycho-social-spiritual approach to health and illness and encourages an attentiveness to elements of patients' and families' lived experience. This includes implications of environmental, behavioral, spiritual, psychological, and social influences on advanced illness and its treatment. Addressing these elements of personal experience with patients and families, bearing witness to them, and ensuring that they are included in any interdisciplinary team discussion where treatment recommendations are being considered, is part of advocacy. Patients are considered primarily as *persons* who are also patients. Individuals and families have meaningful lives that, although impacted on by advanced illness, cannot be reduced to the biomedical aspects of disease and its treatment. By ensuring that the psychological, social, and spiritual impact of disease and treatment on patients' lives remain in the forefront of team discussions regarding care, nurses contribute a fuller picture to the team concerning this reality.[35] Presenting treatment alternatives that empower, rather than threaten, each patient's personhood is the goal.

Functional Elements of Advocacy in Palliative Nursing

Returning to the story of Mr. O'Reilly, his nurse was in a strong position to care for him in a way that illustrates seven functional elements of advocacy in palliative nursing (Box 74.1). They are highlighted in italics in the narrative that follows.

Box 74.1 Functional Elements of Advocacy in Palliative Nursing

1. Specific documentation.
2. Careful observation of patient and family interactions.
3. Assessing understanding.
4. Building rapport.
5. Eliciting care preferences.
6. Privileging patient values and preferences.
7. Teaching and sharing information.

Case Study: Advocating for a Patient—Part 2

The care team chart notes and the verbal hand-over when the nurse came on duty reflected a major concern—that the patient's real wishes around code status were being overridden by his family. The evidence cited for this was the following: (a) The patient's prior DNAR/AND choice—made several months ago as an outpatient when he was less frail and less dependent on his family, then confirmed in the emergency department just a week ago—had been changed to attempt cardiopulmonary resuscitation (CPR) during this hospitalization with the strong encouragement of his family; (b) Mr. O'Reilly, when alone with the nurse during the prior shift, spoke about not wanting to fight anymore but to be "just kept comfortable"—without pain or shortness of breath. *Specific documentation of these concerns in the electronic health record*, close review of the narrative notes from the prior day, and a thorough verbal handoff during the transition between nursing shifts ensured that this concern was communicated to the entire team and identified as an action item to be addressed with the patient and his family.

Because the nurse worked 12-hour shifts and rarely left the unit during those shifts, she was well-positioned to *carefully observe* *interactions between the patient and his family* at frequent intervals throughout the day. This was her fourth shift caring for Mr. O'Reilly, and over 40+ hours she had learned the following: (a) Mr. O'Reilly may have preferred not to be resuscitated if only considering himself. However, he had verbalized on many occasions that his family was what was most important to him. If attempting resuscitation was important to them then that might be his wish/choice now, too. He likely wanted this to be a family decision, and the team's concern that the patient's preferences were being overridden may not be warranted. (b) The patient and the family were in agreement on the overall goals of care: that Mr. O'Reilly be kept comfortable, with his symptoms well controlled, and that he be able to keep working on his almost completed book. (c) The team was on the same page with the patient and family regarding these overall goals. There was common ground.

The team felt strongly that resuscitating Mr. O'Reilly was not in his best interest. They knew that resuscitation was unlikely to be successful and, at best, would result in the patient being restored to a very compromised quality of life. By carefully listening to the patient and family, and *assessing their understanding* of resuscitation and its likely outcomes, the nurse realized that their understanding of resuscitation was very different from that of the care team. To the patient and his family, resuscitation meant restoration of the patient's ability to continue work on his book—and all of the functions/capacities required to do so.

Because she had *built a strong rapport with the patient, his family members, and other members of the care team*, the nurse had participated in discussions about code status with care team members and had been in the room when the patient was discussing code status with his family, answering some of their questions. This allowed her to see that, in both conversations, discussion of code status had become decontextualized from the overall goals of care, creating a perceived tension that arose not from actual disagreement but from discussion of this intervention absent the context of goals of care. This, in turn, had led to "resuscitation" meaning something different to the patient and his family than it did to the team. There needed to be a discussion among everyone about the likely outcomes of resuscitation and the extent to which those outcomes were consistent with the goals of care.

In reflecting on what she had observed over the past few days, the nurse realized there was a different process of decision-making within the family than there was within the care team. The family, as articulated by the son who taught decision science professionally, was resistant to prospective decision-making, preferring to integrate new information (like changes in the patient's clinical status) into their decision-making as it unfolded in real time. The team, having experienced the urgency of the situation when patients decompensate quickly and enter respiratory distress, preferred prospective decision-making as they believed there would not be time "in the moment" for the family to understand and process new information about the patient's clinical status if a resuscitation decision was postponed until the patient was in the midst of respiratory distress. The nurse saw that while the team was committed to *eliciting the patient's preferences* and *privileging the patient's values*, they were not considering that the patient and family may have a strong preference regarding *how* decisions are made.[22] She understood that the team was focused on the outcome of the resuscitation discussion in a way that neglected the significance of the process of that discussion. Because the family had strong preferences about process which were not being engaged, the outcome was elusive. As such, she advocated for a discussion process consistent with the patient's and family's preferences, educating the team about the importance of process for this patient and family.

The nurse also noted that, while the team was concerned that the patient was vulnerable to having his voice drowned out by the preferences of the family, the vulnerability of the family was being overlooked by the team. The family was in a set of conditions that was stressful in multiple ways: the family patriarch was gravely ill; they were in the environment of an academic medical center with language, customs, rhythms, and background assumptions quite foreign to them; they were being asked to make decisions in a much different style, and of a much different nature, than they were accustomed to; and they were receiving the implicit message from the team that they were doing something "wrong"—inappropriately influencing Mr. O'Reilly's resuscitation preferences.

Based on these observations, Mr. O'Reilly's nurse suggested that a discussion to clarify the question of resuscitation explicitly as it related to overall goals of care be held by his bedside and include the care team and his family. By moving the discussion to the bedside, the patient and family were able to make their perspective(s) clear to the team, including how they made decisions as a family unit and what a DNAR code status implied to them. In turn, the team was able to explain Mr. O'Reilly's current medical status and the likelihood of CPR being successful, explicitly defining "success" as it related to his values and goals. It was emphasized that the team would do whatever Mr. O'Reilly wanted once they were clear what that was.

The nurse created a set of conditions—a bedside discussion—in which the patient, family, and team could have their individual voices heard. Through active listening and sometimes reframing of the communication (message) intended and the communication (message) received, the patient, family, and care team struggled to understand each other's perspectives. The nurse frequently, and respectfully, redirected discussion back to Mr. O'Reilly's stated goals of care. Reflective listening, used by the nurse as a communication strategy, is an example of how the training and disciplinary perspective of nurses positions them strongly to be advocates.

After the bedside meeting with the team, the nurse was able to reinforce key points with the patient and his family, ensure they had some written information about resuscitation, educate the family about what was going on in Mr. O'Reilly's body to cause progressive respiratory decline, and explain to them what life was like for many patients following intubation and progression toward respiratory arrest and attempted resuscitation. Because she had cultivated respectful, therapeutic relationships with the patient and his family, and because her nursing education and experience emphasized the importance of educating patients and family members, the nurse was uniquely positioned among team members to *teach and share information* effectively.

In summary, the nurse's advocacy for Mr. O'Reilly was grounded in her palliative care competencies, attentiveness to family dynamics, observation, analysis, communication skills, and carefully cultivated relationship with the patient, family, and other members of the care team. She identified where there was agreement among the healthcare team, patient, and family regarding goals of care, and she used that as a foundation for her work. The tone of advocacy was not adversarial (us vs. them), but one of collaboration and empowerment. The nurse "took on board" the information gleaned from EHR documentation, shift handoff, and team meetings about the team's perception that the family was coercing the patient into being a full-code. But, having a certain kind of presence in the life of the patient and family and trusting her own experience/perceptions, she identified a gap between the team's perception and her own perception about the nature of the relationship between the patient and the family. The nurse's recognition of the significance of her observations to this patient's care, her documentation, and her effective communication with the healthcare team provided an additional lens through which to view the situation.[16] The confidence to trust her own assessment and recognize her value as an important member of the care team was an important component of her advocacy.

Although the nurse's advocacy work surrounding the care of Mr. O'Reilly and his family was exemplary, the need for support and mentorship is clear.[36,37] Finding a compatible mentor is not easy. Where there is an opportunity for a generalist palliative care nurse to link up with a specialist palliative care nurse—to attend team meetings with that nurse, to note how she advocates for patients and their families, and to learn how she mediates when there is disagreement among members of the care team—we encourage such nurses to do so. Debriefing with a specialist nurse following advocacy work with a patient, family, and care team creates an important space for learning and reflection—especially when a bedside nurse perceives that "things went wrong" and questions her own competency. Similarly, we encourage specialist palliative care nurses to seek out opportunities to mentor nurses at the generalist level.

Challenges and Pitfalls in Nursing Advocacy

Although the model of advocacy used for Mr. O'Reilly and his family produced an outcome that successfully engaged the perspectives and values of all parties, advocating in generalist palliative care can be quite challenging and messy. The outcome will not always be satisfying to each of the parties involved. The importance of *process* rather than outcomes is therefore stressed. In some situations, the nurse will have done her work well—identifying opportunities to empower and clarify understanding, facilitating sharing of goals and decision-making, and ensuring that the patient's voice is a strong part of discussion and decision-making—yet the outcome leaves no one feeling satisfied. Reasonable expectations regarding the ability to accurately understand the wishes of another and accepting an element of uncertainty are necessary. We put together "snapshots" of "the truth" along the way; it is a quest of understanding and a challenge, and a level of humility is required.

Indicative of the challenges that a nurse may face when advocating for a patient were *three false assumptions that became clear during Mr. O'Reilly's care:*

1. Autonomy means individual decision-making, and this family is usurping the patient's autonomy and values to accommodate their own values and needs.
2. Preferences remain stable and unchanged throughout an individual's life irrespective of changes in social situation, health status, or other situations.
3. Advocating for a particular outcome is the best approach to patient advocacy at end of life.

Engaging the six constitutive components of the model of advocacy in palliative nursing—bio-psycho-social-spiritual orientation, clinical competence, a relational approach to care, communication skills, interdisciplinary collaboration, and an attitude of confidence yet humility—the nurse was able to identify and correct each of these false assumptions in the care of Mr. O'Reilly.

Although there are many examples of challenges or pitfalls that the nurse may encounter in her role as advocate, three common examples follow. The first can arise in a relational approach to care. With frequent presence at the bedside and many interactions with the patient and/or family at a time when they can be *in extremis*, strong bonds are formed and the nurse may lose her perspective of being part of a team of clinical caregivers. Intense interactions can give rise to a protective instinct, leading the nurse to believe that she is the only one who really "understands" the patient's and family's situation. An "us" (patient/family and nurse) versus "them" (other members of the healthcare team) may be the result.[37,38] In this situation, the nurse loses her perspective and ability to be clear-sighted in effectively advocating for the patient/family as a collaborative member of the care team. The second example reverses the nurse's perceived alignment. Having shared intensely emotional and clinically challenging experiences with clinician colleagues, a nurse can develop such a strong feeling of loyalty to the team that she is inhibited from advocating fully for the patient and family. The third example occurs when the palliative nurse's orientation to advocacy is strictly a "rights advocacy" model, a model that is rooted in a response to patient vulnerability (this had originally been the focus of the team working with Mr. O'Reilly). Although the vulnerability created by severe illness is acknowledged, an exclusive focus on vulnerability, insofar as it ignores the importance of identifying and engaging patient and family strengths and competencies, can be a disservice to the patient and family, distorting the nature of their personhood and failing to engage their agency. Advocacy as empowerment, rather than doing for/in place of, is what is being encouraged in this discussion and chapter. It is a relational kind of advocacy, advocating "with" rather than advocating "for."

Conclusion

This chapter has explored what it means for a nurse to advocate for a patient with advanced, serious illness and his family members. A six-part conceptual model of palliative nursing advocacy was explained, and seven functional elements embedded in this model were illustrated in an extended case study. Nurse advocates respond to the strengths as well as the vulnerabilities of patients and families, building empowering relationships to support care decisions that respect the values and personhood of patients. Finally, common pitfalls and barriers that the nurse may encounter in his or her advocacy role were reviewed.

CHAPTER 75

Global Palliative Care

Virginia LeBaron and Annette Galassi

Key Points

- The global landscape of palliative care is evolving rapidly as the world's population ages, more people are diagnosed with noncommunicable diseases, and technology transforms communication and how information is disseminated.
- Quality palliative care is an urgent global need, particularly in low- and middle-income countries where the burden of disease is significant but resources are often limited.
- Key factors that affect the development and delivery of palliative care in all countries include (1) shifting demographic and epidemiologic trends, (2) cultural barriers, (3) disparities in access, (4) healthcare policy and payment models, and (5) workforce shortages.
- All nurses have a role to play in global palliative care, whether they live and practice in a resource-constrained setting, travel internationally to train and support colleagues, conduct research with global implications, or advocate to reduce disparities within their local community.

Global Palliative Care: An Urgent, Unmet Need

Changing demographics, epidemiological trends, economic realities, and evolving cultural and societal norms all intersect to influence palliative care on a global scale. Worldwide, palliative care is growing, but too many countries still lack access. Millions of people experience serious health-related suffering each year (an estimated 61 million in 2015), but most never receive palliative care, especially if they live in a low- or middle-income country (LMIC).[1] The Global Atlas of Palliative Care[2] shows progress in the geographic expansion of palliative care, particularly in Africa, but full integration of palliative care services within overall health systems occurs in only 20 out of the world's 234 countries (Figure 75.1). Likewise, results from the Economic Intelligence Unit Quality of Death Report,[3] which ranks 80 countries on factors related to access to quality palliative care services, reveals stark disparities between high- and low-income countries. Encouragingly, palliative care and access to pain relief is increasingly recognized as a fundamental human right.[4] In 2014, The World Health Assembly (WHA) (the health-focused branch of the United Nations) passed the landmark Palliative Care Resolution, which officially urged member states to integrate palliative care into their national healthcare systems.[5]

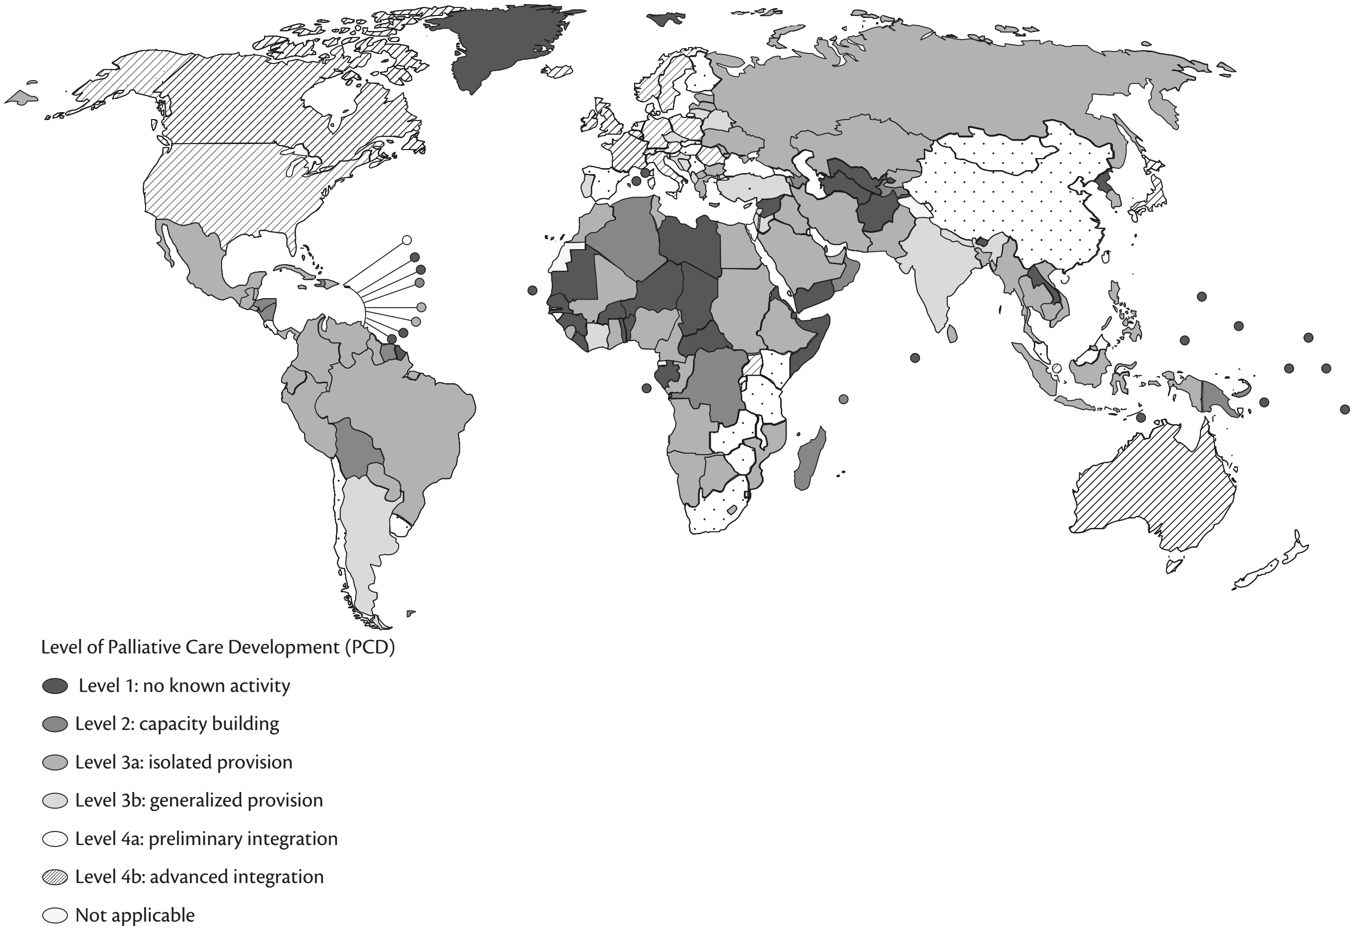
This chapter recognizes that palliative care is a critical issue for all nations, but takes a particular look at palliative care in LMICs, where the greatest burden of disease often co-exists with severely constrained health resources, and where the need for quality palliative care is arguably the most urgent. An important note regarding terminology: depending on the country, palliative care and hospice can have variable meanings and be operationalized differently. For example, in the United States, the word "hospice" typically refers to a very specific package of healthcare services for patients with a life expectancy of 6 months or less. In other countries, the terms "hospice" and "palliative care" may be used synonymously, or "hospice" may refer to a specific building or location where dying patients receive care. When engaging in global palliative care efforts, it is important to clearly understand how palliative care and hospice are conceptualized and operationalized in a specific practice setting or country. For simplicity, in this chapter, we use the term "palliative care" in its broadest sense to encompass holistic care provided to patients (and their caregivers) with serious illness that has comfort and symptom control as the primary goal.

Key Factors that Influence the Global Delivery of Palliative Care

There are five key factors that affect the development and delivery of palliative care programs and services in every country, regardless of resources or income. These include (1) shifting demographic and epidemiologic trends, (2) cultural barriers, (3) disparities in access, (4) healthcare policy and payment models, and (5) workforce shortages.

The first key theme is *shifting demographic and epidemiologic trends* leading to an increased need for palliative care globally. The proportion of older people is growing rapidly, and, by 2050, the world's population aged 60 years and older is expected to reach 2 billion[6]; in fact, people aged 60 and older are the fastest growing demographic in most countries.[7] Relatedly, the number of people diagnosed with noncommunicable diseases (NCDs), such as cardiovascular disease and cancer, is also exploding.[8] NCDs are the leading cause of death worldwide, representing almost two-thirds of all deaths annually. Thirty-eight million people died from NCDs in 2012, and this number is projected to increase to 52 million by 2030.[9] These demographic and epidemiologic realities have serious implications for global health and palliative care because more people around the world will live longer with chronic illness in the coming decades.

Second, there are *cultural barriers* that hinder the development or acceptance of palliative care (see Chapter 37, Cultural Considerations in Palliative Care). In many countries and cultures, patients are not told their diagnosis or prognosis for fear it will cause



Level of Palliative Care Development (PCD)
Level 1: no known activity
Level 2: capacity building
Level 3a: isolated provision
Level 3b: generalized provision
Level 4a: preliminary integration
Level 4b: advanced integration
Not applicable

despair and hasten death.[10] Additionally, healthcare systems and providers often emphasize "cure" without meaningful discussions regarding goals of care or quality of life. Consequently, even if palliative care services are available, they may not be initiated until the patient's last few weeks of life, if at all. For this to change, there must be a cultural shift from advocating cure-at-all-costs over comfort, greater emphasis on managing chronic illness, effective conversations about the realistic benefits and burdens of treatment, honest dialogue about prognosis, and recognition that death is an inevitable part of life.

Third, there are significant and disturbing *disparities in access to palliative care*. The vast majority of adults (approximately 80%) in need of palliative care live in LMICs; however, palliative care is underdeveloped in most of the world outside North America, Western Europe, and Australia.[11] If palliative care services do exist in LMICs, they often focus on the needs of cancer patients and may exclude patients with other chronic diseases or conditions such as congestive heart failure, chronic obstructive pulmonary disease, HIV/AIDS, dementia, neurodegenerative diseases, or drug-resistant tuberculosis. In countries where palliative care is more established, patients from racial and ethnic minority groups and lower socioeconomic status still struggle to obtain care. Palliative care also may be unavailable in rural areas, and services are often especially limited, or absent, for neonatal or pediatric patients even in high-income countries (HICs).[12]

A fourth theme affecting global palliative care development and delivery is *a country's healthcare policy and payment models*. According to the WHA, palliative care must be an essential service in a health system and part of universal health coverage of member states. A 2017 Lancet Commission report describes specific components and funding strategies for an "Essential Package" of palliative care services and urges all countries to ensure universal access by 2030.[1] In reality, only 9% of countries have advanced levels of palliative care integration into health services; all of these are HIC except Uganda.[2,11–14] When the government does not provide palliative care services, nongovernmental organizations (NGOs) such as religious institutions and philanthropic organizations often fill the void. While these groups provide momentum for the development of palliative care programs, national health systems must include palliative care as an essential service for patients with serious or life-threatening conditions in order to ensure sustainability.

Finally, perhaps the greatest obstacle to widespread implementation of palliative care services is the shortage of staff trained to provide this care. A basic working knowledge of palliative care is needed by all generalist healthcare providers (HCPs). Advanced (or specialized) palliative care skills are needed for HCPs who see a large number of patients with palliative care needs or who work in specialized palliative care settings and who train others. The attainment of basic/primary palliative care knowledge and skills can be accomplished through mandatory inclusion of palliative care in medical and nursing curricula and through continuing education programs for practicing HCPs. Programs to provide HCPs with advanced/specialist palliative care skills can be developed once basic palliative care training is established and as country or program demand requires.

Palliative care training must be adapted to the specific care context and consider available personnel and resources. HCPs in LMICs may include traditional healers, community volunteers, or community health workers (CHWs). It is vital that palliative care educational initiatives include these individuals as they may be the first, or only, HCP with whom a patient interacts. For example, CHWs in rural areas can be trained in basic palliative care skills to help identify patients in need of specialist palliative care services and then facilitate subsequent referrals.

Many small and LMIC countries cannot afford a specialized palliative care workforce, and specialty training for nurses may not exist. Barriers to training for nurses include a lack of qualified trainers, limited recognition or incentive in terms of salary or status for nurses who obtain specialization, a shortage of current and relevant print resources on palliative care, and erratic or absent Internet access which limits the utility of web-based palliative care training resources. Another key reality is the challenge of palliative care workforce "burnout," compassion fatigue, and/or moral distress, all of which can result in compromised patient care and staff attrition. Palliative care training programs and institutions should have systems in place to provide emotional support to nurses and other palliative care providers, especially in highly resource-constrained practice settings.

Many of these workforce training barriers are being addressed by international initiatives such as the End-of-Life Nursing Education Consortium Training Program (ELNEC-International) and the World Health Organization (WHO) Collaborating Centers for Palliative Care. ELNEC-International is a 5-day course that covers pain and symptom management; ethical issues; cultural and spiritual considerations; communication; loss, grief, and bereavement; and final hours of life. ELNEC-International has trained approximately 25,000 nurses and other HCPs in 98 countries.[13] WHO Collaborating Centers are designated by the WHO Director-General to carry out activities in support of WHO programs. There are currently five WHO Collaborating Centers for Palliative Care, including one nursing program, the Catholic University of Korea, College of Nursing, which is focused on the development and delivery of training in palliative care and building understanding on spirituality issues in palliative care.

Key Factors that Influence Palliative Care Implementation: Specific Challenges in LMICs

Despite the need, palliative care has only recently been recognized as a public health priority in many countries. Palliative care development using a public health framework includes four elements: (1) appropriate government policies and plans; (2) availability of essential medicines; (3) education of HCPs, policymakers, and the public; and (4) implementation of palliative care at all levels of healthcare provision.[14] Many LMICs face challenges in each of these areas.

Box 75.1 Key Elements of National Palliative Care Policy, World Health Organization (WHO)

- Service delivery through a continuum of care (through primary healthcare, community, home-based, and specialist palliative care services);
- Strategies to provide palliative care to all patients in need (noncommunicable diseases, HIV/AIDS, tuberculosis, older adults, children), with attention given to reaching vulnerable groups (poor, ethnic minorities, people living in institutions);
- Defining the government–civil society interface in establishment and delivery of care;
- Universal coverage, through financing and insurance mechanisms;
- Ensuring support for carers and families (social protection);
- Identification/allocation of resources for palliative care;
- Development of national standards and mechanisms to improve quality of palliative care;
- Identifying indicators and establishing monitoring of palliative care need and access, at national and subnational levels, including access to medicines.

Source: From Reference 16.

Appropriate government policies and plans. The provision of quality palliative care is facilitated by healthcare policies and guidelines that provide a roadmap for the development and implementation of services. Few LMICs have integrated palliative care into public healthcare policy, strategic health plans, noncommunicable disease plans, and/or cancer control plans. A national palliative care policy, whether stand-alone or part of another key health strategy, should include the essential elements outlined in Box 75.1. Government progress in addressing the palliative care needs of its citizens is often hampered by leadership changes within the ministries of health and a lack of champions able to advocate for palliative care as a healthcare priority. Another challenge is the lack of national health insurance plans in many LMICs (and in some HICs as well, such as the United States). If a plan exists, it rarely includes coverage for palliative care services.

Availability of essential medicines. National policy also affects the availability of essential medicines that are critical for palliative care. Essential medicines are defined by the WHO as medications that every country should have in adequate supply at all times, at a reasonable cost, to meet the needs of their population.[15] In 2007, the International Association for Hospice and Palliative Care (IAHPC), working in collaboration with other international stakeholder organizations, developed a list of Essential Medicines for Palliative Care (Table 75.1). Opioids are classified as essential medicines, but 80% of the world's population—the majority of whom reside in LMICs and are more likely to need palliative care due to the distribution of disease burden—lack adequate access to opioids for pain control.[1,16] In fact, more than 90% of the world's morphine supply is used by approximately 1% of the world's wealthiest countries.[17] As a result, millions suffer and die in agony without access to basic pain relief (Figure 75.2). The reasons for this are complicated but involve a combination

Table 75.1 International Association of Hospice and Palliative Care (IAHPC) list of essential medicines for palliative care

Medication	IAHPC indication for palliative care
Amitriptyline	Depression, neuropathic pain
Bisacodyl	Constipation
Carbamazepine	Neuropathic pain
Citalopram	Depression
Codeine	Diarrhea, pain (mild to moderate)
Dexamethasone	Anorexia, nausea, neuropathic pain, vomiting
Diazepam	Anxiety
Diclofenac	Pain (mild to moderate)
Diphenhydramine	Nausea, vomiting
Fentanyl (transdermal patch)	Pain (moderate to severe)
Gabapentin	Neuropathic pain
Haloperidol	Delirium, nausea, vomiting, terminal restlessness
Hyoscine butylbromide	Nausea, terminal respiratory congestion, visceral pain, vomiting
Ibuprofen	Pain (mild to moderate)
Levomepromazine	Delirium, terminal restlessness
Loperamide	Diarrhea
Lorazepam	Anxiety, insomnia
Megestrol Acetate	Anorexia
Methadone	Pain (moderate to severe)
Metoclopramide	Nausea, vomiting
Midazolam	Anxiety, terminal restlessness
Mineral oil enema	Constipation
Mirtazapine	Depression
Morphine	Dyspnea, pain (moderate to severe)
Octreotide	Diarrhea, vomiting
Oral rehydration salts	Diarrhea
Oxycodone	Pain (moderate to severe)
Paracetamol (acetaminophen)	Pain (mild to moderate)
Prednisolone	Anorexia
Senna	Constipation
Tramadol	Pain (mild to moderate)
Trazodone	Insomnia
Zolpidem	Insomnia

For complete table details, including recommended formulations and important indications for use, see: IAHPC List of Essential Medicines for Palliative Care, https://hospicecare.com/uploads/2011/8/iahpc-essential-meds-en.pdf

of restrictive regulations and bureaucracy, lack of supply, inefficient or erratic distribution and dispensing systems, limitations on prescribers, inflated medication costs, the unavailability of oral opioid formulations, and general "opioid-phobia" among HCPs and the lay public.[16,18]

At the same time opioids are unavailable in many LMICs, there is increasing alarm in some countries regarding the number of overdose deaths attributed to prescription opioids. In the United States, the so-called "opioid epidemic" has resulted in new opioid prescribing guidelines, recommended monitoring, and restrictions.[19] While it is certainly critical that safeguards exist to mitigate potential opioid-related harms, it would be a tragedy if concerns regarding the "opioid epidemic" reversed or negatively impacted decades of policy work to ensure pain relief is available to those in desperate need. A balanced approach to opioids is recommended to ensure that risks are mitigated while also ensuring access for those with legitimate medical need.[20,21]

Education of civil society. Countries need HCPs knowledgeable in palliative care to deliver services to its citizens and also to educate policymakers about the benefits of palliative care and advocate for inclusion of palliative care into health policies. Raising awareness among the lay public is also necessary to overcome stigma and misconceptions about palliative care and to create a demand for services that in turn will drive development of palliative care programs and favorable healthcare policies.

Delivery of palliative care at all levels of healthcare provision. Countries organize health services, including palliative care, at the national, provincial/state, or district level; however, services organized at the provincial or district level can result in wide variability in what is provided. In an effort to help standardize service delivery, organizations have recommended basic packages of palliative care services. One example includes the minimum package of palliative care services as recommended by the WHO[14] (Box 75.2).

It is critical that palliative care services, regardless of service delivery level, are culturally and contextually congruent. In other words, effective palliative care services must be sensitive to a country or region's societal and cultural norms; religious and spiritual practices; beliefs regarding illness, disease, and death; and expectations related to patient–family and patient–provider communication, especially regarding disclosure of diagnosis, discussion of prognosis, and delivering difficult news. Local resources, such as the availability of essential medicines, must also be taken into account. In rural areas, or in countries beginning to develop palliative care services, community-based delivery models may be more suitable and easier to implement than hospital-based models.

Implementing Evidence-Based Palliative Care Practices

The highest quality palliative care is informed by evidence and regularly evaluated. However, generating evidence and evaluating outcomes, especially in resource-constrained settings, can be hindered by a lack of trained researchers and mentors, scarce funding and resources, the inherent difficulties of conducting research with acutely ill and dying patients, lack of consensus regarding what "counts" as evidence, unpredictable infrastructure, and inadequate documentation. It is crucial that evidence used to guide palliative care practice is contextual and resource-relevant, such as when including traditional or complementary approaches to palliative care that are utilized in many LMICs. In essence, what works or is needed in an HIC, such as detailed protocols for opioid rotations or withdrawal from ventilator support, may not be feasible or helpful in a LMIC. One example of an organization actively

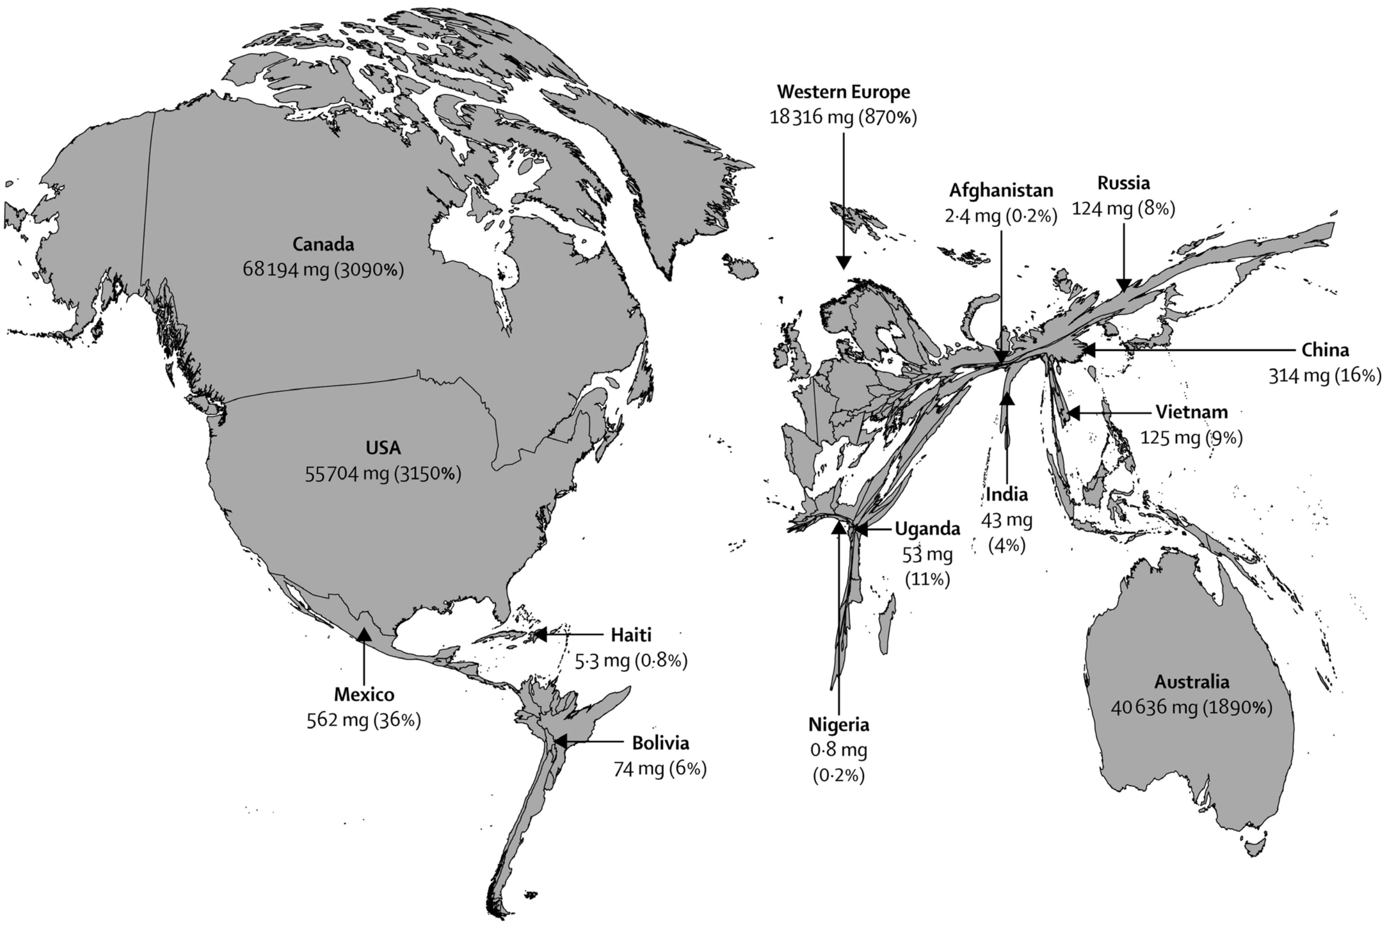

Figure 75.2 Distributed opioid morphine-equivalent (morphine in mg/patient in need of palliative care, average 2010–13), and estimated percentage of need that is met for the health conditions most associated with serious health-related suffering.

working to develop palliative care evidence specific to its region is the African Palliative Care Research Network (Table 75.2).

Specific Challenges Faced by Palliative Care Nurses in LMICs

Role expectations and the status of nurses vary tremendously worldwide. In some countries, palliative care nurses independently care for patients, prescribe opioids, and are viewed as critical members of a collaborative, interdisciplinary team. In other countries, nursing is a low-status position, and nurses are expected to take a passive role in patient management and are criticized or disciplined for questioning physician orders. This can be especially problematic in palliative care, as care delivery is seriously compromised if nurses are not taught, expected, or encouraged to advocate for quality symptom management. Similarly, professional development and advanced practice opportunities for nurses in LMICs may be limited or nonexistent.

Box 75.2 Essential Palliative Care Services, World Health Organization (WHO)

- Identify patients who could benefit from palliative care;
- Assess and reassess patients for physical, emotional, social, and spiritual distress and (re)assess family members for emotional, social, or spiritual distress;
- Relieve pain and other distressing physical symptoms;
- Address spiritual, psychological, and social needs;
- Clarify the patient's values and determine culturally appropriate goals of care.

Source: From Reference 16.

Another key challenge faced by nurses who provide palliative care in LMICs involves the reality of *limited material resources and supplies*. Government/public hospitals, where the majority of the LMIC population typically seeks care, are seriously overcrowded and underresourced. Basic supplies, infrastructure (e.g., running water or electricity), essential medicines (such as opioids), and personal protective equipment may be erratically available or completely absent. Patients typically present with late-stage disease and a very high symptom burden. For example, managing large malignant wounds and extensive lymphedema is especially relevant for palliative care nurses in LMICs, but often complicated by limited resources and training.

Nurses in LMICs often face the additional challenge of caring for seriously ill patients in unstable situations. For example, nurses in LMICs may find themselves providing palliative care in

Table 75.2 Examples of international and regional palliative care organizations and key activities

WHO region/ country	Organization	Description	Activity highlights
International	International Association for Hospice and Palliative Care (IAHPC)	IAHPC works with UN agencies, governments, associations, and individuals to increase access to essential medicines for palliative care, foster opportunities in palliative care education, research and training, and increase service provision around the globe. https://hospicecare.com/home/	Maintains a global directory of palliative care services, hospices, and organizations as well as a global directory of educational programs in palliative care. Offers travel scholarships to both palliative care workers from LMICs to attend educational activities and to individuals who are invited to teach in a LMIC.
International	International Children's Palliative Care Association (ICPCA)	ICPCA seeks to achieve the best quality of life and care for children and young people with life-limiting conditions, their families, and caregivers worldwide by raising awareness of children's palliative care, lobbying for the global development of children's palliative care services and sharing expertise, skills, and knowledge. http://www.icpcn.org/	Maintains a map locating international children's palliative care organizations and services that provide palliative care for children by trained staff.
International	Worldwide Hospice Palliative Care Association (WHPCA)	WHPCA is a network of national and regional hospice and palliative care organizations and affiliate organizations that focuses on hospice and palliative care development worldwide. http://www.thewhpca.org/	Offers a palliative care toolkit for implementation in low-resource settings. Publishes a *Global Atlas of Palliative Care*, which details palliative care development and progress globally.
African Region	African Palliative Care Association (APCA)	A pan-African organization ensuring that palliative care is widely understood, integrated into health systems at all levels and underpinned by evidence in order to reduce pain and suffering across Africa. https://www.africanpalliativecare.org/	Developed the *APCA Atlas of Palliative Care in Africa*, quality standards, a core curriculum, a framework of core competencies and an advocacy toolkit for palliative care in Africa.
Region of the Americas: Latin America and the Caribbean	Caribbean Palliative Care Association (CARIPALCA)	This organization advocates on behalf of both the region and individual countries in terms of education, capacity building, research, access to medicines, linkages to other regional and international bodies, and sharing of policy initiatives.	A recently formed regional body with both health professional and civil society representation.
Region of the Americas: Latin America and the Caribbean	Asociacion Latinoamericana de Cuidados Paliativos (ALCP) (Latin American Association for Palliative Care)	A nongovernmental organization for the development and advancement of palliative care in Latin America that unites people who work in palliative care or are interested in palliative care. http://cuidadospaliativos.org/	This organization has 7 commissions including nursing and headed the development of *The Atlas of Palliative Care in Latin America* in cooperation with IAHPC.
Region of the Americas: Northern America, Canada	Canadian Hospice Palliative Care Association (CHPCA) (Association Canadienne do Soins Palliatifs)	National association that provides leadership in the pursuit of excellence in care for persons approaching death so that the burdens of suffering, loneliness, and grief are lessened. http://www.chpca.net/	CHPCA developed *A Model to Guide Hospice Palliative Care: Based on National Principles and Norms of Care* which creates a shared vision and a consistent, standardized approach to the delivery of care, organizational development, education, and advocacy across Canada.
Region of the Americas: Northern America, United States	American Academy of Hospice and Palliative Medicine (AAHPM) Hospice and Palliative Care Nurses Association (HPNA) National Hospice and Palliative Care Organization (NHPCO)	Professional organization for physicians specializing in hospice and palliative medicine, nurses, and other healthcare providers. Since 1988, the Academy has dedicated itself to advancing hospice and palliative medicine and improving the care of patients with serious illness. www.aahpm.org Professional palliative care organization with a focus on supporting hospice and palliative care nurses. http://hpna.advancingexpertcare.org/ Largest nonprofit membership organization representing hospice and palliative care programs and professionals in the United States. NHPCO is committed to improving end-of-life care and expanding access to hospice care with the goal of profoundly enhancing quality of life for people dying in America and their loved ones. https://www.nhpco.org/	Activities focus on education and training, resources, networking, and advocacy. An annual, interdisciplinary meeting is held each year in conjunction with the HPNA (see below). Offers a large number of educational, leadership and research resources, including opportunities for specialty nursing certification in palliative care. An annual, interdisciplinary meeting is held each year in conjunction with the AAHPM (see above). Offers a large number of educational and regulatory resources, some of which are for members only.

Table 75.2 Continued

WHO region/ country	Organization	Description	Activity highlights
South East Asia Region: India	Indian Association of Palliative Care	Established in consultation with WHO and the government of India as a national forum to connect, support, and motivate individuals and institutions involved in palliative care. http://palliativecare.in/	Offers a national fellowship in palliative nursing and a distance education certificate course in essentials of palliative care. The organization's Opioid Availability Task Force is working with the Indian central government to improve opioid availability in local regions.
European Region	European Association for Palliative Care (EAPC)	A membership organization dedicated to the promotion and development of palliative care throughout Europe http://www.eapcnet.eu/Home.aspx	Developed the *EAPC Atlas of Palliative Care in Europe*. Maintains a directory of hospice and PC units in Europe by country.
Eastern Mediterranean: Lebanon	Lebanese Centre for Palliative Care -Balsam	Lebanese Centre for Palliative Care -Balsam is a NGO working in palliative care development in Lebanon and across the region through patient care, advocacy, training, capacity building, and research in PC. http://www.balsam-lb.org/index.php	Developed the *Atlas of Palliative Care in the Eastern Mediterranean Region* in collaboration with the ATLANTES Research Program.
Western Pacific Region	Asia Pacific Hospice Palliative Care Network (APHPCN)	Dedicated to promoting hospice and palliative care in Asia and the Pacific. The Network facilitates communication so that people in established hospice programs can help less experienced and more isolated colleagues. http://aphn.org/	APHPCN and the Lien Foundation (Singapore) co-developed the *Lien Collaborative for Palliative Care* to enhance palliative care leadership and capacity in developing countries. Nurses are eligible to participate.
Western Pacific Region: Australia	Palliative Care Australia	The national body for palliative care and represents all those who work toward high quality palliative care for all Australians. Aims to improve access to, and promote the need for, palliative care. http://palliativecare.org.au/	Developed *National Palliative Care Standards* to support the delivery of high quality palliative care for the person receiving care, their family, and caregivers.
Western Pacific Region: China	Chinese Association for Hospice and Palliative Care	This association offers a platform to advance the development of palliative care in China.	
Western Pacific Region: New Zealand	Hospice New Zealand	Hospice New Zealand exists to lead the hospice movement to ensure that every New Zealander has access to quality palliative care. http://www.hospice.org.nz/about-hospice-nz	Offers educational and leadership opportunities, general resources, and training scholarships for healthcare professionals with an interest in palliative care and hospice.

high-conflict settings/war zones, after devastating natural disasters, with disrupted transportation or communication infrastructure, or in the context of rapidly emerging infectious epidemics (e.g., Ebola, cholera). Each of these issues presents profound challenges and stressors for the palliative care nurse that must be acknowledged, anticipated, and managed at a systems level to ensure feasible delivery of palliative care services.

Global and Regional Palliative Care Initiatives

The Internet and mobile technology are rapidly changing the way HCPs communicate and collaborate across the globe. Palliative care providers practicing in isolated settings, or novice providers with questions, now have access to a host of resources and support, assuming they have reliable Internet service (which, of course, is not always the case). Examples of excellent, globally focused electronic palliative care resources include E-Hospice, Palliative Care Network, and Palliverse. E-Hospice (https://ehospice.com/) is a global news and information resource for those with a professional or personal interest in palliative care. Palliative Care Network (https://www.palliativecarenetwork.com/) and Palliverse (https://palliverse.com/) are interactive websites that provide opportunities to facilitate the global exchange of knowledge and ideas related to palliative care, promote collaboration among palliative care professionals, and disseminate funding opportunities.

International and regional palliative care organizations also play an important role globally by working to raise the profile of palliative care and ensure palliative care is reflected in international or regional priorities. Most of these organizations do not provide direct patient care services; instead, they focus on advancing palliative care policies, education and training, advocacy, leadership, and research. Excellent initiatives and programs have been undertaken by numerous and varied regional champions, institutions, and organizations to improve the global delivery of palliative care. It is beyond the scope of this chapter to discuss individual programs and initiatives, which are in a constant state of dynamic and rapid evolution. Instead, key international and regional palliative care umbrella organizations, summarized by WHO Regions, can be found in Table 75.2; interested readers are encouraged to explore the links for the most up-to-date detailed information and activities.

Nursing's Role in Global Palliative Care

All nurses have a role to play in global palliative care, whether they live and practice in an LMIC, periodically travel internationally to train and support colleagues, conduct research, or advocate to reduce disparities within their local community. Now, more than ever, palliative care nursing is truly a "glocal" endeavor, meaning that global issues are also local issues, and universal considerations such as access to pain relief and workforce education are interconnected and can inform each other. For example, learning about strategies to successfully deliver rural palliative care in one country can help inform effective interventions to expand palliative care services in another. This section discusses some key ways that all palliative care nurses can engage "glocally."

Training and curriculum development. The need for a nursing workforce well-versed in palliative care is paramount. At both the basic/primary level and the specialty level, nurses with palliative care and educational experience are often tapped to design and implement training programs. In many countries, palliative care education is heavily physician-/medically oriented; nurses play an essential role by creating or adapting existing curricula to ensure relevance for nursing. The most effective palliative care nursing curricula are (1) attuned to the contextual and cultural realities of practice, (2) take into account available resources and the role expectations of nurses (which can vary widely across the globe), (3) vetted by on-the-ground clinicians most familiar with the practice environment, and (4) have a plan to evaluate the impact of the training on clinical practice.

Policy and advocacy. Whether at a family or neighborhood gathering, through membership in a regional organization, or by testifying before a national legislative body, all nurses can advocate for palliative care and its crucial role within healthcare systems and institutions. Nurses contribute significantly to the advancement of palliative care each and every time they take the opportunity to dispel myths and misconceptions, advocate for its importance in policy documents (such as pain management prescribing guidelines), and accept leadership positions where they have a seat at the table to be a strong voice on behalf of palliative care and the role of the nurse.

Cultural exchange and mentorship. There are numerous opportunities for nurses to engage with palliative care providers from different countries and cultures. Traditionally, this has most often involved nurses from HICs traveling to LMICs to engage in educational or clinical practice development programs, or by partnering or "twinning" a HIC organization with an organization in another (typically LMIC) country. These experiences offer unique and potentially powerful opportunities to learn from each other, share information and strategies, and provide essential role-modeling and nurse mentorship. There is a growing awareness of the importance of the bidirectional aspect of nursing cultural exchange programs and of thoughtful participation to ensure that efforts and initiatives are optimally and mutually beneficial.[22,23]

Advocating for vulnerable populations. All nurses ideally advocate for vulnerable populations and strive to ensure equitable access to quality healthcare for all people. Perhaps nowhere is the nurse's role in advocating for vulnerable populations more vital than with patients who are seriously ill and dying. Regardless of whether nurses practice as clinicians, managers/administrators, educators, or researchers, there are many ways to alleviate suffering experienced by the most vulnerable. For example, nurses can deliver compassionate end-of-life care to populations typically unseen in healthcare systems, such as the homeless; design educational programs that include substantive content about disparities in access to palliative care and pain relief; or conduct research that aims to improve the care of seriously ill patients and their caregivers at a policy and systems level.

Conclusion

The global landscape of palliative care is evolving rapidly as the world's population ages, more people are diagnosed with NCDs, and technology transforms communication and how information is disseminated. The development of palliative care and the role of palliative care nursing, particularly in LMICs, have made significant progress in the past decade, but there is still much to be done. Too many people, especially those who are the most socially, economically, and geographically vulnerable, continue to suffer and die without access to basic palliative care services and pain relief. Continued progress will require demand from the public, advocacy from HCPs, and the political will of national governments and the global health community. Most importantly, all nurses, regardless of role or geographic location, must recognize and leverage the critical role they play in influencing palliative care on a global scale.

CHAPTER 76

The Ethos of Palliative Nursing

Mark Lazenby and Michael Anthony Moore

Key Points

- Palliative nursing has an ethos, a moral character, that builds meaning in the context of serious illness and death and dying.
- This moral character is defined by the qualities of a caring relationship.
- Trustworthiness, moral imagination, attending to the beauty of patients' humanity, creating a moral space in which patients can flourish, and being present with them are some of these qualities.

Case Study: The Ethos of Palliative Nursing

In the windowless hospital room lay a man dying of bone-rattling prostate cancer. The stars shined bright on the desert sky, but in this moment misery raked this man's soul. Between shallow, painful breaths, and the interludes of his wife wiping his beady brow, I asked this man to tell me his story. As a child, he was born and grew up a free man, but here lay in sharp contrast, a 61-year-old man in stateless adulthood. His childhood memories are of being with his siblings and friends, running and playing hide-and-seek in the olive trees in his grandparents' orchard. Trees even more ancient than his grandparents stood steady while war after war roiled through. Beneath the cover of night, the teenaged-man forcedly packed what cherished belongings he could carry with him and fled his homeland for a distant country not his own. As he started his trek, the man packed away some olive wood that had lain on the ground outside his house. This wood honored the lineage not just of his grandparents, and their parents, and their parents' parents, but also of all the olive trees that bore witness to his family's history.

The day I stepped into his story, he was dying—not just dying of prostate cancer but of a misery deep and untouchable by hormone therapy, steroids, opiates, or anything that we, as palliative care clinicians, have in our armamentarium to cure. Since I was a foreign, visiting scholar with a flexible schedule, I decided to sit with him and his wife for a few hours. I had nowhere else urgent to be—no beeping alarms, no intravenous line to change, no medications to give to lure me away; I had only time. And so, it was time I gave this man and his wife. My questions began by asking him about how he came to be in this country, the country of his adulthood but not of his childhood—the country of his fleeing-to but not of his rising-up-in. His story brought us to the olive groves that he lay under at night as a mere youth, looking up at the stars, more stars than he could count, stars that, to be sure, were biblical. Those ancient stars, he imparted, were the same stars King David had lain under after his anointing, the very stars that had guided the Magi to Bethlehem, the stars that Saint Paul used to navigate the road to Damascus, and the stars that the Damascenes used to travel to Mecca to go to the Holy Mosque for the Haj. After only a half hour of talking, the man's story arrived at what he wished for his final goodbye to this earth. He wanted to see those stars, the stars that observed biblical history and that had shown upon the olive trees of his youth. These ancient stars were calling him home, to his permanent home, a home beyond wars, borders, religions—a home where his ancestors dwell, a home in the stars.

To aid in his final goodbye, I secured clearance from the cancer center to take him and his wife up to the roof of the hospital one night. His pain notwithstanding, it was an ordeal. No elevator went all the way to the roof, so we had to devise a plan that included four of us carrying him up the last flight of stairs. Another helper worked to hold his urinary catheter as we executed the tactical operation. Prior to moving the patient, we placed a mattress for him to lie upon. We did it—we got him there on a stunning desert night when the stars smiled brilliantly at him. He lay there on the mattress with his wife, indulging in a talkative spurt of energy I had not hitherto seen in him. He looked upon the stars, and, in his native tongue, chattered to his wife. She gripped his hand tight, while tears were visible on her face. She did not wipe them. He could not see them as his eyes remained fixed on the stars. She listened, and cried, and held his hand tight. I understood his chattering enough to hear him say that he was ready to go; he wanted to see his family up there—in the stars. A few days later, the man died. It was a welcomed death as his pain had become unremitting. He had fallen into an obtunded state, but now he was with the stars.

Shortly after he had died, I came in and sat with him and his wife. Again, I was able to offer her time by being with her. She clutched a cross in her hands, and I could hear her praying while moving it between her fingers. The woman fell into deep sobs, convulsing in grief, so I continued to be with her. I spoke no words, but rather, I felt all I could do was witness her incomprehensible and ineffable sadness. And then, without words, she handed me that cross. She opened my clenched fingers and placed it into the palm of my hand. She looked up at me and said, "He carved it from the olive wood he took with him. I want you to have it. You are his child."

Here I had in my hand the cross this man had carved from the olive wood he had taken with him as he escaped his childhood homeland. During a war that had threatened him and his family, he still made it a point to pack this meaningful olive wood with the few belongings he was able to carry. I meditated on the cross of wood and the symbolism of the fallen branches from the trees that had looked upon his family through the centuries. The stars that had witnessed his familial history bore witness to his religious and biblical history and then, finally, to his death.

Caring for this man and his wife was the job of any palliative nurse. And, in a sense, no palliative nurse deserved such a special gift, but the token of the olive cross honored the relationship of the nurse with the patient's wife and with the patient himself. An ethics of caring is based on the notion that what it means to be a good person—a moral person, that is—has to do with the nature of relationships.[1–3] With this, what it means to be a good palliative nurse has to do with the nature of the relationships nurses develop with their patients and loved ones. This chapter will describe five qualities that are part of a caring relationship and, within the context of palliative care, form the ethos—the moral character—of palliative nursing. These five qualities are trustworthiness, imagination, beauty, space, and presence.

Trustworthiness

Trustworthiness cuts close to the heart of the ethos of palliative care nursing. Year after year, the public has rated nurses as members of the most trusted of professions.[4] Speculation on the potential reasons for the public's trust is possible, but the most obvious answer is that nurses are, in fact, trustworthy. The contemporary bioethicist Onora O'Neill has convincingly argued that trustworthiness has three components: competence, reliability, and honesty.[5]

Competency is essential for palliative nurses. This is why the Hospice and Palliative Nursing Association and the Hospice and Palliative Credentialing Center have established minimum experience and knowledge standards for achieving and maintaining certification as a hospice and palliative nurse. The contribution of competence to nursing's trustworthiness is so important that nurses work together as a community to ensure that each nurse practices safely. Nurses are each other's keeper, and the keeper of the public's trust, by working together to make sure that nurses do not harm patients. Competence also involves practicing according to the latest evidence. Nursing science contributes to trustworthiness by guiding practicing nurses through the results of rigorous science to help direct the most efficient ways to bring about patients' desired goals of care.

Reliability and competence are first cousins because a reliable nurse must first be competent. However, reliability differs from competence in that, to be reliable, nurses must do what they say they will do and be present when they say they will be present. The moral force of reliability is that patients and families can depend on what nurses say to them.

After listening to the man's stories in the case study, it is clear that the nurse wanted to give the patient a view of the stars before he died. But before the nurse asked the patient whether he wanted to see the stars one last time, the nurse had to have a way to make it happen. The nurse's own reliability and the reliability of the nurse's colleagues and the hospital would have otherwise been at stake. So, before the nurse proposed the idea to the patient and his wife, the nurse would have first had to check with colleagues and nursing administration. The hospital administration's embrace of the idea was dim, but administration understood the importance of the unusual plan for the patient's and his wife's wishes. If the nurse had mentioned the plan to the patient and his wife before the nurse had done this homework, the collective reliability of the nurse, the nurse's colleagues, and the hospital would have been on the line.

The palliative nurse also understands that reliability entwines with *honesty*. A nurse's word, to a large degree, verbalizes her or his reliability. In the context of healthcare, honesty, O'Neill suggests, is not just keeping one's word, but ensuring the absence of deception. When patients and families ask questions for which there is no easy, straightforward answer, it is dishonest for nurses to pretend there is an answer. No medication guarantees a relief of the patient's symptoms—remember that science traffics in probability, whereas treatment plans favor the odds, rather than guarantees, of success. Based on scientific testing, the probability of a medication's efficacy for relieving a symptom may be in the patient's favor, and that is exactly how nurses need to respond to patients' questions. However, in the end, the medication may not relieve the patient's symptom. The medication or treatment may fail to work as science suggests it does. Explaining efficacy of medical options should guide nurse–patient communication and will aid in rationalizing why a palliative care team may have to move on to other modalities to attempt symptom relief. The sake of honesty further demands not deceiving patients and their families. Nurses practice in very few certainties other than the singular idea that each human, including the nurse herself, shall one day die. Honesty with patients and their families rests in nurses' acknowledging that there are no certainties. Nurses cannot deceive patients and their families by withholding information or deceiving them with fake certainties. Rather, being present with them in the indeterminacy of pain and suffering and dying is how nurses do not deceive patients and families.

Imagination

The second quality of a caring relationship is imagination. Often, not having straightforward answers to medical and spiritual issues overwhelms those in palliative nursing. All nurses have had patients who, before they die, have one last desire that seems impossible to achieve. These situations demand imaginative thinking. The eighteenth-century philosopher, Immanuel Kant, believed that imagination takes an individual back to "first principles," meaning that imagination brings one back to what matters most and what is most fundamental.[6]

In the case study, imagination was necessary, as the nurse knew that the patient could not be taken back to his grandfather's olive trees; the patient was too sick to transport that far. Whatever the nurse could do for the patient had to be imagined right where the patient was. The nurse's colleagues, the hospital administration, and the nurse had to think new thoughts about how to take the patient back to those memories of lying under the trees and looking up at the stars. They had to use their imaginations to devise a plan to get the patient as close to that experience as possible.

Imagination as described here is deeper than just devising a creative plan to achieve a desired result. Moral imagination means that nurses can *feel with* their patients and their families. This does not mean that, through empathy, nurses must suffer the same as patients and families suffer. However, it does mean that nurses have to feel, or sympathize, with how important goals, beliefs, and practices are to patients and families. Nurses must work to feel the depth of whatever brings their patients meaning, purpose, peace, and comfort as they face serious illness and even death. This feeling—a feeling named here as *compassion*, a feeling of caring for what matters to others who suffer—gives nurses the energy to think creatively about how to help patients and families achieve their goals. Furthermore, compassion aids nurses in being faithful to patients' and families' beliefs and practices when the odds are against them. Compassionate imagination gives one's creative solutions legs, not just by thinking about innovative solutions to achieve patients' and families' goals, but compassionate imagination requires actively working to bring that solution to fruition. By engaging in imaginative solutions to seemingly intractable problems, nurses see the humanity of their patients. Humanity is, after all, beautiful.

Beauty

Beauty is another quality of a caring relationship: seeing the beauty of patients' humanity. The first way to honor patients' beauty is to listen to them. Not only is listening the process of relationships, according to the contemporary moral psychologist Carol Gilligan, but listening is the only way a provider can discover who patients are and what matters to them as they face serious illness.[7] Furthermore, what is distinctive about the beauty of humanity is that humanity can be injured. "Injury," the contemporary scholar of aesthetics, Elaine Scarry, says, is the opposite of beauty.[8] And yet, if, *per impossibile*, someone were invulnerable to injury, by definition he or she would be incapable of being beautiful. Being beautiful is being open to injury, even though injury is a wrong, as Scarry notes. Serious illness is a wrong in that it opens individuals up to injury by directly challenging their humanity. But amid the injury of serious illness, listening to patients is actively restorative. Listening is the succor that restores their humanity in face of the injury of serious illness. While actively listening, the nurse ceases to be the nurse, the healthcare provider, the medication prescriber, the Other; rather, the nurse becomes a person listening to another person, listening to the other's joys and sorrows, reminiscences and regrets, hopes and fears. When actively listening, nurses treat their patients not as patients but as people who, though sick and dying, are alive.

The man dying of prostate cancer, in a country not his own, was foreign to the nurse. The nurse could speak the patient's tongue grammatically, but only a native speaker who had shared the culture and experiences of this patient could so easily share the unspoken symbols of the language. Although the physical language was understood, the underlying humanity brought from the historical culture of the language could have been easily lost in translation without the nurse's actively listening. It was active work for the nurse to sit and listen to the patient's stories through this foreign tongue. Nurses may not immediately fully understand their patients because of a lack of shared experiences or culture. After listening to a few stories, though, surely nurses can find deep commonalities and connections. More profoundly, humanity is shared by all; this is a commonality between nurse and patient; everyone shares the same nature: human nature. When nurses listen deeply enough, they hear their own humanity in others' stories. In hearing one's own humanity in others, one can then feel the compassion that motivates imagination.

The realities of modern nursing, however, conspire against imagination. Nurses do not have time to sit and listen to patients for hours, much less minutes, on end. Nurses are busy, and the demands of the modern hospital, clinic, and hospice restrict their time. That said, nurses also know from experience that it does not take all that long to listen. A few minutes, sitting down, being attentive, not using the precious time with one's own words, but being aware of patients' words and of their emotions as they speak them: this is listening. Present, attentive listening is the kind of listening that restores beauty even as disease and death injure.

Space

In the modern medical industrial complex, patients present to nurses with their humanity injured by serious illness. Some patients present to the nurse dying. The humanity nurses aim to restore through caring relationships may be injured even more by the public spaces of the hospital, the clinic, and the hospice. This includes the machines that make it possible for nurses to deliver quality symptom management. Even when patients present in their homes, nurses bring with them the paraphernalia of the medical complex: the hospital beds and the equipment and machines that would never otherwise be in their homes.

One quality of a caring relationship is to create the space, in the context of the impersonal medical industrial complex, in which patients can still be themselves.[9] Of course, this is not simple. By being trustworthy with their patients, by imagining what needs to be done to fulfill patients' goals, by being faithful to who patients are, and by active listening, nurses open up the space for patients to be who they are—undefined by serious illness. This is part of the reason to become a palliative nurse: to treat patients as the people they are, to provide them the space to be who they are, even as serious illness imperils or takes their lives. For many palliative nurses, it is what sustains them: that moment when they see a smile shine through, a laugh, the confession of fear, the expression of hope, and the stories of a beautiful life. When nurses care that they are trustworthy, imaginative, and listen to find the beauty of their patients' stories, they then open up the space in the context of serious illness for their patients to be present as themselves.

Presence

To be trustworthy with patients, to offer imaginative responses, to listen to stories, to create the space for patients to be themselves in the clinic or their home, nurses must be present. Being present is another quality of a caring relationship. *Presence*, in the context of palliative nursing, is not nurses adopting a power pose by which to assert themselves and their desires upon patients and families. Presence is, rather, being with patients and families not as cases but as people. When in the presence of other people, nurses respect patients' capacity to make their own decisions and to be in relationships.[10]

The capacity to make decisions is essential to what it means to be a person. There are often circumstances where the nurse may not understand, or even agree with, every decision the patient makes. For instance, the patient's disease may be progressing with every evidence-based treatment already utilized, but the patient still may want to "keep going." There are infinite reasons why a patient may choose a particular decision or course of action, and the patient may need psychological or spiritual support to come to terms with said reasons. A nurse must not take away the patient's capacity and ability to make decisions about his or her own care, lest the nurse take away the patient's personhood. By taking away personhood, the nurse ceases to be in the presence of this human, and, therefore, the ability to be in a caring relationship with this person ceases. For a palliative nurse, this is simply untenable. For palliative nursing, the quality of presence is to be in the presence of a person who makes decisions about his or her own life.

The quality of presence includes respecting people's capacity to be in relationships. Patients have the capacity to choose with whom they want to be in relationship—including the nurse. Remember, patients come with their own histories around relationships, which may include traumatic relationships. Nurses must be open to patients choosing, or not choosing, to be in relationship with them. If the choice is the latter, it does not negate the role of the palliative nurse. It means, rather, that the nature of the nursing arrangement with the patient becomes more task-oriented. Yet, the nurse, through mindful presence, can still look for moments when the patient is open to relationship. It is in these moments that patients and nurses are present with each other and can make meaning in shared experiences.

The authors believe that that is what happened with the man who died of prostate cancer and with the nurse in the case study. The patient opened himself up to having a relationship with the nurse, even though he had only come to know the nurse in the last few days of his life. It is uncertain whether the patient made some meaning out of his and the nurse's relationship, but it seems as if he did. He asked his wife to give the nurse the cross the patient had carved out of the wood he had carried with him from the land from which he had long ago been dispossessed. Nor do we know whether the nurse made meaning out of her relationship with the patient and his wife. This gift of presence, however, gave the nurse the opportunity to become a better person, if only by learning to be open to having a relationship with people who seem far from one. The quality of presence is the quality of being open to the choices of patients, including their choices to make meaning out of illness with the nurse by their side. By being present to them—ready for them to choose to be in relationship—the nurse remains open to her or his own growth.

Palliative nursing demands much from nurses; it taxes emotions and spirits. However, if nurses attend to the qualities of a caring relationship through the five qualities articulated here, then the unexpected creation of meaning in the context of relationships with other people for whom nurses care becomes the ethos that carries nurses through these difficulties. These five qualities of a caring relationship—trustworthiness, imagination, beauty, space, and presence—help guide the palliative nurse to honor the humanity of his or her patients and his or her own humanity, too. There surely are other ways of articulating these and other qualities via serendipitous creativity,[11] which is an openness to the new meaning one can create in caring for the sick and the dying. But this is what the authors take the ethos—the moral character—of palliative nursing to be: that nurses are in caring relationships with their patients.
