# Foreword to the Fourth Edition

Without a doubt, *Bass & Stogdill's Handbook of Leadership* has been the most widely used and cited reference book in the study of leadership. Even though there has been a dramatic increase in leadership books of all kinds, including reviews of research and other handbooks, I am quite certain that the impact of this, the fourth edition of the *Handbook*, will be equal to or greater than the last edition. Why?

For leadership scholars, the *Handbook*, in its three earlier editions, has been *the* primary reference book—our bible for all things leadership. I consult the *Handbook* on a nearly daily basis, so much so that it is the only book that has a permanent place on my work desk. I will retire my third edition to a shelf and replace it with this fourth edition.

The *Handbook*, thanks to the exacting detail of Bernie Bass, is a thoroughly comprehensive and well-organized review of the voluminous (and growing) leadership literature. To grasp the enormity of this task, two-thirds of all psychological and management research on leadership has been published since the last edition of the *Handbook*. The comprehensive nature of the *Handbook* means that scholars can find reviewed here research on nearly every leadership topic imaginable.

The longevity of *Bass & Stogdill's Handbook of Leadership*, third edition, provided a bridge between the earliest research on leadership and the research that was being conducted at the time it was published. All too often, researchers are unable (or unwilling) to search the archives for elusive copies of early leadership research. This fourth edition of the *Handbook* covers the research history and brings it up to date. The fact that Bernie Bass has lived (and published in) the past seven decades means that scholars can use the *Handbook* as a tool to trace modern research from the present back to its earliest roots.

Finally, the *Handbook* is well written and arranged and provides a coherent structure to leadership. Leadership is a topic that has been studied from many perspectives by scholars from a myriad of disciplines. While the greatest contribution of the *Handbook* has been the sheer volume of information packed between its covers, it is Bass's thoughtful organization and structure that help organize and define what is known about leaders and leadership.

Bernard M. Bass, one of the founders of the social scientific investigation of leaders and leadership, left us in 2007. Although he made enormous contributions to the field, this edition of the *Handbook* is Bernie's most impressive gift to the leadership community.

As someone who has followed Bernie around at conferences, as he scurried from one leadership session to another, collecting copies of presentations and making connections with leadership scholars, I know firsthand that Bernie Bass's heart and soul are in this handbook. His home office was crammed with copies of leadership books, journals, and papers, with his wife Ruth providing good organization to what otherwise would have been a mountainous clutter. It is very fitting that Ruth Bass, who contributed so much to Bernie's life and his work, be a recognized co-author on this edition.

Bernie's knowledge of leadership and related topics were truly encyclopedic. The knowledge of leadership research and theory that was inside Bernie Bass's head could fill a dozen or more volumes the size of this *Handbook*. He had a very difficult time deciding what should be included, and he regretted greatly all that had to be left out. There are, after all, only so many pages that fit between a single cover.

Although I have consulted the *Handbook* countless times in my work, I also have had the good fortune of being able to consult Bernie directly on particular leadership topics, and he always had the answer. Those of us who study leadership and the many more who are deeply concerned about the practice of leadership in the world owe an incalculable debt to Bernie Bass.

As you get to know this edition of the *Handbook*, I am sure you will appreciate Bernie Bass's legacy, and this final gift, as much as I do.

Ronald E. Riggio  
Kravis Leadership Institute  
*Claremont McKenna College*

# In Memory of Bernard M. Bass

On October 11, 2007, during the final stages of the production of the fourth edition of the *Handbook of Leadership*, Bernard M. Bass passed away. Bernie, who was 82 years old, was distinguished professor emeritus in the School of Management at Binghamton University (State University of New York) and a member of the academy of Senior Professionals at Eckerd College in Florida. He was also the founding director of the Center for Leadership Studies at Binghamton and founding editor of *The Leadership Quarterly* journal. In the seven decades after 1946, he published over 400 journal articles, book chapters, and technical reports; plus 21 books and another ten books that he edited.

He was a consultant involved in executive development for many of the Fortune 500 companies and delivered lectures and workshops in over 40 countries. He also lectured and conducted workshops pro bono for wide variety of not-for-profit organizations, including religious organizations, hospitals, government agencies, and universities. His work has been cited thousands of times and he received millions of dollars in research grants. Translations of his work have appeared in French, German, Spanish, Portuguese, Italian, and Japanese.

In addition to authoring the *Handbook of Leadership*, Bernie focused for 25 years on research and applications to management development of transformational leadership. Bernie was honored with many awards for lifetime achievement by several professional organizations, including the Distinguished Scientific Contributions Award from the Society for Industrial and Organizational Psychology and the Eminent Leadership Scholar Award from the Leadership Network of the Academy of Management. A Festschrift in his honor was held in 2001.

He is survived by his wife, Ruth, who was instrumental in the completion of the *Handbook of Leadership*; his daughter Audie; his daughter Laurie and her husband, Steve; his son Robert and Robert's wife Maryanne and their three daughters, Rebecca, Megan, and Lauren; his son Jonathan and Jonathan's wife Patricia, with their three sons Joshua, Jeremy, and Jonathan Jr., and Jonathan Jr.'s wife Christie and their two children.

"Bernie was first and foremost a great scholar, scientist, and researcher—the greatest leadership scholar of the last 50 years—but he was also a generous, kind, and humorous human being. The field has lost a great scholar; I have lost a friend, colleague, and mentor."

Francis J. Yammarino, Ph.D.

SUNY Distinguished Professor of Management

Director, Center for Leadership Studies

School of Management

State University of New York at Binghamton

"Bernie was a giant in advancing the field of leadership for over seven decades. He was also a close friend to many colleagues around the globe, a mentor of the highest caliber, and an extraordinary thinker. The field of leadership would not be as advanced as it is today without his enormous contributions to theory, research, and of course the *Handbook of Leadership*."

Bruce Avolio, Ph.D.

Clifton Chair in Leadership

Director, Gallup Leadership Institute  
Department of Management  
College of Business  
University of Nebraska–Lincoln

“For me, leadership is social influence, and therefore Bernie Bass was my leader. Without knowing it, he played a major role in my becoming a leadership scholar 20 years ago, the most significant and fruitful move in my professional life. In the 1980s, the field of leadership studies was half dead and badly needed invigoration. We were lucky that a scholar of Bernie’s caliber was around to provide the needed invigoration. He is perhaps the person most responsible for the thriving of the field in the last 25 years. He was truly a luminary.”

Boas Shamir, Ph.D.  
Dean, Faculty of Social Sciences  
The Hebrew University  
Mount Scopus  
Jerusalem, Israel

“Bernie was a fabulous mentor. The opportunity to work with him shaped my career in many positive ways. I continue 25 years later to pursue leadership research. This interest started with Bernie’s passion for transformational leadership.”

Leanne Atwater, Ph.D.  
Chair, Department of Management  
School of Global Management and Leadership  
Arizona State University

“I harbor most pleasant and appreciative memories of Bernie. His intellectual depth, the broadness of his interest in organizational issues, the strict scientific approach to the study and analysis of these problems have always struck me. Also, his organizational and editorial energy and care were conspicuous.”

Pieter J.D. Drenth, Ph.D.  
Emeritus Professor, Work and Organizational Psychology  
Vrije Universiteit  
Amsterdam, The Netherlands

“Long before I met Bernie Bass, I was very aware of the fact that he had an enormous impact on my discipline of industrial/organizational psychology and on the particular area of leadership. His *Handbook* was really the “bible” for leadership scholars. It was the source for all things leadership, and it has always had a very special place on my bookshelf.”

Ronald Riggio, Ph.D.  
Henry R. Kravis Professor of Leadership and Organizational Psychology  
Director of the Kravis Leadership Institute  
Claremont McKenna College

“I currently teach a history of management thought class and we have people we study whom we call ‘giants.’ Bernie was certainly one of these and has served as a giant role model for my students and for me. His work on transformational leadership has transformed the field, and, I feel confident, has brought many young scholars into it. His work on the various *Handbook* revisions is the gold standard of the field + I have also been impressed with the many other innovative contributions he made to the leadership, management, and

psychology fields. He was always ahead of the curve. Along with these accomplishments, he has mentored a number of doctoral students and young professors who have gone on to make major contributions in their own right.”

Jerry Hunt, Ph.D.

Horn Professor of Management

Founding Director, Institute for Leadership Research

Texas Tech University

“To me, Bernie represents the model of a true scholar: interested in the content, thorough, clear. I’ve seen people attack relentlessly if their work is at all questioned—not Bernie. True scholar that he was, he was always more interested in furthering the development of the field than ‘defending his personal glory,’ if I can put it that way. He really has made a tremendous impact on our field.”

Deanne N. Den Hartog, Ph.D.

Professor of Organizational Behavior

University of Amsterdam Business School

Amsterdam, The Netherlands

“He opened a new and truly scientific way to look at what I was doing that has served me very well in my 40-year career in my field. To my way of thinking, that is the role of true scientist, scholar, and leader.”

Fred Dansereau, Ph.D.

Professor of Organization and Human Resources and

Associate Dean for Research

School of Management

State University of New York at Buffalo

“Of course the pinnacle of his career was the development of Transformational Leadership, including the articulation of the conceptual space and the development of measures to tap these concepts.”

Martin G. Evans, Ph.D.

Professor Emeritus

Rotman School of Management

University of Toronto

# Acknowledgments

Many fellow scholars, colleagues, staff, and students helped in the planning of and data collection for this fourth edition of the *Handbook of Leadership*, beginning in 1989 at the Center for Leadership Studies (CLS), School of Management at Binghamton University (State University of New York). Leading scholars of leadership research such as Chet Schriesheim and Fred Fiedler, as well as Robert Wallace, former senior editor of Free Press, reviewed Bass and Stogdill's third edition to suggest ways of improving the fourth edition, along with updating the literature. My faculty colleagues at CLS—Bruce Avolio, Fran Yammarino, David Waldman, and Leanne Atwater—also made useful suggestions and helped frame the decision to maintain and expand the single reference list. Over the 18 years during which the fourth edition was in preparation, I received useful feedback from readers. One example stands out: Native American readers pointed out that in the third edition, Native Americans were seen as a severely impoverished group, when in fact by the 1990s, they had overcome much adversity and were making important economic, educational, and cultural strides. The opening of gambling casinos on Native American lands became a major source of revenue and enabled extensive investments. Much had changed for the good in their lives. Google was another source of unpublished ethnic information.

Secretarial staff and students helped greatly in locating and copying articles and technical reports. Particularly important was CLS secretary Wendy Kramer.

When it came time to finish the final draft of the manuscript of the fourth edition. I was aided immensely by two CLS professors at Binghamton University, Kim Jaussi and Shelly Dionne and their Ph.D. students, Becky Jestice, Jung Hwan Kim, Betsy Carroll, and Mike Palanski, as well as my wife, who all put a great deal of energy into locating and completing fully and partly missing references. They were an important source of support in preparation of the final reference list.

Writing was expedited by my ability to work directly on the computer. It was a new experience trying to get the results to the publisher using the exacting format and instructions I was required to supply. But thanks to Ruth Bass, my wife of 61 years and a self-taught computer buff, it was possible to do this. I remain deeply grateful for her efforts in this regard as well as for her editorial suggestions for the text and her encouragement as the final manuscript unfolded. Without her assistance, the task would never have been completed.

Bernard M. Bass

# Preface to the Fourth Edition

What's new in the fourth edition? Much has happened on the world scene over the past 18 years in international relations, politics, psychology, science, and technology, which is reflected in the leadership and leadership research that have appeared during these years. Increasingly, imaginative leadership is required. Globalization, climate change, and a single superpower, the United States, have become salient issues, along with the expansion and consolidation of the European Union. China and India have joined Japan as major economic powers and contributors to science and technology. The Arab world and the Middle East are now major players in international political life. Militant Islamists have spawned terrorism, civil wars, and massacres like the World Trade Center catastrophe of September 11, 2001, as well as overreaction by governments, particularly that of the United States. In reaction, national security has been strengthened with some loss to individual freedom. But a successful war on Al-Qaeda, the largest and best-organized network of terrorism, has been fought, reducing the network to small splinter groups still pursuing a philosophy of terrorism but lacking a central base and stripped of the means to easily communicate or coordinate their efforts.

In the 18 years since the publication of the third edition, the study, application, and practice of leadership have burgeoned. Business, government, and nonprofit agencies, plus community, education, military, and health organizations have increasingly made leadership a core concept in meeting the challenges of the last decade of the twentieth century and the first decade of the new millennium. There was a 100% increase in leadership research and applications in the United States and a 300% increase in management consultants during this period. Academic courses and curricula on leadership proliferated. In 1990, the same year that the third edition of the *Handbook of Leadership* appeared, the *Leadership Quarterly* was first published, followed over the next 10 years by almost 200 new articles. Also new during the 1990s were the *Journal of Leadership Studies* and other new sources on leadership research, applications, and practice. The domination in leadership research and theory by the United States and Britain has changed, spawned by a growing diversity of publications from Holland, Sweden, Spain, and Russia. Japan, China, Korea, Singapore, and India have become other rich sources, along with Canada, Australia, New Zealand, and South Africa.

The subject index of the fourth edition reflects the emergence of new terms and concepts, some likely to be fads but others likely to survive as important innovations. Cognitive models of leadership have become as important as behavioral ones. Personal traits of leadership are back in vogue, bolstered by innovations in genetics. Leaders are both born and made. But situational differences remain of consequence. The "new leadership" of vision and transformation has become as important to leadership as the conception of leadership as an exchange of reward for following the leader. Also new are concentrations on strategic and virtual leadership.

In the last quarter of the twentieth century we saw a rise of interest in the charisma of those in everyday affairs and leadership positions join the interest in world-class figures, politicians, and CEOs. There was a spin-off and application to transformational, visionary, and value-based leadership. Empirical work was greatly expanded as a consequence of Robert House's 1976 theory of charisma and James Burns's 1978 exposition on transformational leadership.

Ralph Stogdill conceived the *Handbook of Leadership* and published its first edition in 1978. Soon after, he asked me to collaborate on the second edition but died before the work could begin. I carried on alone with the second edition, published in 1981 as the *Stogdill's Handbook of Leadership* and the third edition in 1990, published as the *Bass & Stogdill Handbook of Leadership*. This fourth edition still includes some of Ralph's work in two of its 36 chapters. In the final preparation, my wife, Ruth Bass, assisted editorially and

applied her skills at research and use of the computer.

Illustrating the new developments are three new chapters added to the *Handbook*. [Chapter 9](#) is dedicated to the ethics of leadership. [Chapter 22](#) deals with transformational leadership. [Chapter 24](#) focuses on strategic and executive leadership. In the same way, in addition to the updated chapters, many new sections address topics like heritability, accountability, authenticity, and virtual leadership. At the same time, space limitations required some reduction in pre-1990 content and details, but generally theories, conclusions, comments, and citations from the earlier literature have been maintained in the text and endnotes. Reflecting the changes in leadership research over the years, the fourth edition proportionally involves fewer short-term studies of leaders and follower relations at the micro level. More is presented at the macro level, of leaders as senior executives and heads of organizations, and the meta level of leaders of societies. Here, more effort has been made to include findings from political science, sociology, and history. As in the third edition, I have included content from prepublished and unpublished manuscripts and an increased number of paper presentations, especially from the annual meetings of the Academy of Management and the Society for Industrial and Organizational Psychology. Books used tend to be limited to those that have some research base and are not just anecdotal accounts.

Most compendiums on leadership like the *Encyclopedia of Leadership* (2004) are collections of essays from many authors selected by the editors. These have the advantage of having been prepared and published quickly; they present many different points of view. They are disadvantaged, however, by duplication and a lack of integration. The *Handbook of Leadership* has a single author, who hopefully has avoided duplication, included a sufficient number of alternative points of view, and provided a continuing integration of the literature. Unfortunately, much more time has been required for data collection, review, and writing.

The third edition, published in 1990, was handwritten, then typed and printed as galley pages and eventually page proofs. This fourth edition was written more efficiently on a personal computer. The file was sent to the publisher on CDs to provide the page proofs for publication.

## Plan of the Fourth Edition

---

The fourth edition of 36 chapters is in nine parts. In [Part I](#), the *Handbook* expands the beginning chapters from the previous editions, addressing the history, definitions, and concepts of leadership. These are followed by taxonomies, theories, models, and methods of leadership research. In [Part II](#), the *Handbook* takes up the personal traits of consequence to leadership, including activity level, authoritarianism, orientation to power, and Machiavellianism. [Part II](#) concludes with an examination of the values and ethics of leaders along with their feelings of self-esteem and well-being.

Part III deals with the externalities that affect the personal performance of a leader. These involve the leader's accorded status and power. How the power is distributed, how conflicts are resolved, and the leader's authority, accountability, and responsibility are considered. The leader's use of reinforcement in the instrumental exchange with followers and the follower's impact on the exchange conclude [Part III](#).

[Part IV](#) reviews the alternative styles of leadership and their effects on individual, team, organizational, and societal performance.

[Part V](#) is about the "new leadership" of charisma and transformational leadership. Managerial work and executive and strategic leadership begin [Part VI](#). Situational conditions that affect the manager and leader follow. They include the impact of the environment and organization, the immediate team, the task and technology, stress, physical distance and closeness, virtuality, substitutes for leadership, and the transfer of leadership and executive succession.

[Part VII](#) concentrates on women and minorities as leaders, as well as leadership across countries and cultures.

Previous editions concentrated on African Americans, but the fourth edition has expanded to examine leadership among many other minorities, ranging from what has become the largest group, Hispanics, to another large group, Italian Americans, for whom less leadership literature exists.

[Part VIII](#) is concerned with development, training, and education of leaders and their assessment, appraisal, and selection.

[Part IX](#) concludes the *Handbook*, with extrapolation from the previous chapters of trends, likely environmental changes, and speculation about the future of leadership and leadership research.

I have used many secondary sources in my research. These include books, reviews, commentaries, technical reports, unpublished manuscripts, and theoretical papers. I also benefited from early drafts of prepublication manuscripts sent to me before a lot of the good ideas they contained were edited out in the publication process. I indicate in the references both the secondary sources and original publications from which the secondary sources are derived. Many of these references are presented in the footnotes, though they are by no means exhaustive. By 2008, there could be as many as 100 different citations of a popular research replication. I have tried to credit all the primary and secondary sources and have also included in the references some works which were not cited directly in the *Handbook*. The earlier seminal studies of 1950 to 1980 were not followed by numerous replication. Rather, I have tried to cover many of the meta-analyses of these replications, which continue to appear into the twentieth century.

I began collecting and reading for the fourth edition in 1989 and worked fairly steadily on the project. I never expected that it would take almost 20 years to complete. The first draft of the third edition was handwritten and took nine years to reach publication in 1990. It provided a substantial background and history of leadership research and practice, particularly from the 1940s onward; much of it is included in the fourth edition, along with additional work I found for the era. This material should help to defray the opinion that the only good leadership research is that which recently appeared. I have been privileged to contribute to the leadership literature dating back to 1946, and some of my early work is as valid and applicable today as it was then.

## PART I

---

# Introduction

## CHAPTER 1

---

# Concepts of Leadership

A definition is a sack of flour compressed into a thimble.

RÉMY DE GOURMONT (1858–1915)

The evidence is all around us. It is in our daily lives—in our schools, businesses, social groups, religious organizations, and public agencies. It is in our local community, in our more distant state government and national government, and on the international scene. Leadership makes the difference. Leadership can be good, as when your sales manager calls his department together to point out that last month's quotas have been met but that a new competitor is starting to make inroads. It can be better, as when a political party leader sums up what she and her team feel will be needed to win an election. It can be best, as when a community activist senses and articulates the community's pressing needs and mobilizes the community into effective action.

Leadership has been built into the human psyche because of the long period we need to be nurtured by parents for our survival. Early on, we learned to follow the leadership of parents and their proxies for satisfaction of our needs for food and comforting. Our mothers or their surrogates became our leaders in early childhood. They still are. Fathers came next when they were recognized. With socialization, as we grew, peers and other significant people gradually took the place of parental leadership. How we think and behave as leaders and followers when we reach adulthood is still likely to be affected by our earlier relations with our parents, as well as by our genetic makeup. So it is not surprising that leadership is a universal phenomenon. The importance of parenting for human development and survival makes leadership the world's oldest vocation. Parenthood makes for ready-made patterns of leadership.

During the period of hunting and gathering, leaders had to be independent and strong to defend the sovereignty of their group of followers against marauders and natural disasters (Lipman-Blumen, 1996). The study of leaders advanced with the rise of civilization. All societies have created myths to provide plausible and acceptable explanations for the dominance of leaders and the submission of subordinates (Paige, 1977). The greater the socioeconomic injustice in a society, the more distorted the realities of leadership—its powers, morality, and effectiveness—in the mythology.

The patterns of behavior that are regarded as acceptable in leaders differ from time to time and from one culture to another, although we will find some surprising commonalities. Citing various anthropological reports on primitive groups in Australia, Fiji, New Guinea, the Congo, and elsewhere, H. L. Smith and Krueger (1933) concluded that leadership occurs among all people, regardless of culture, be they isolated Indian villagers, nomads of the Eurasian steppes, or Polynesian fisherfolk. Lewis (1974) determined, from an anthropological review, that even when a society does not have institutionalized chiefs, rulers, or elected officials, there are always leaders who initiate action and play central roles in the group's decision making. No societies are known that do not have leadership in some aspects of their social life, although many may lack a single overall leader to make and enforce decisions. Such shared leadership is now representative of many scholarly and practical ideas about organizational life in the twenty-first century, the age of information, when no one member of a group has all the expertise and experience to help the group to reach its goals.

## Myths, Legends, and religious texts

---

Myths and legends about great leaders were important in the development of civilized societies. According to Joseph Campbell, early myths about heroic leadership had much in common. The hero went forth and brought back something of great value. Prometheus brought back fire. Moses went up Mount Sinai and brought back God's Ten Commandments. Myths mature into legends. Legendary heroes figure prominently in the Hindu *Upanishads* and in the Greek and Latin classics. In the *Iliad*, higher transcendental goals were emphasized: "He serves me most, who serves his country best" (Book 10, line 201). The *Odyssey* advised leaders to maintain their social distance: "The leader, mingling with the vulgar host, is in the common mass of matter lost" (Book 3, line 297). Plato's ideal leader was the philosopher-king. Exploits of individual heroes were central to the Babylonian *Gilgamesh* and the Hindu *Ramayana*. Leadership was of much interest to Aśoka, Confucius, and Lao-tzu. Leadership was the focus of certain medieval classics of western literature such as *Beowulf*, the *Song of Roland*, and the Icelandic sagas. According to Gemmill and Oakley (1992), the social concept of leadership is a myth that maintains a belief in the need for hierarchies and organizational leaders in society. This myth results in alienated, intellectually and emotionally deskilled employees and the magical desire for an omnipotent leader.

Religions offer many accounts of leaders as prophets, priests, chiefs, and kings. Such leaders served as initiators, symbols, representatives, and examples to be followed. In the Old Testament, Moses led the Hebrews out of Egypt, and Joshua led them to the promised land. Leaders such as Abraham, Moses, David, Solomon, and the Macabees were singled out in the Old Testament for detailed expositions of their behavior and relations with God and their people. God was the supreme leader of his chosen people; he clarified, instructed, and directed what was to be done through the words of his prophets and arranged for rewards for compliance with and punishment for disobedience to the laws and rules he had handed down to Moses. The gospels of the New Testament are filled with stories about how Jesus led his small group of disciples as well as large audiences. Saint Paul was the initiator of a multinational organization of churches. To the leadership of Saint Peter is attributed the founding of the Roman Catholic Church. In Islam, religious law provided the basis for the leadership of the ideal caliphate (Rabi, 1967). The Koran still undergirds the legal systems of Islamic republics. Gautama Buddha led his movement by his precepts and example.

### ***From Myths and Legends to Early Histories of Leaders***

From its infancy, much of the study of history has been the study of leaders—what they did and why they did it. What would the first histories of Herodotus, Thucydides, or Xenophon, written before 400 B.C.E., have been like without discourses about leaders, leadership, and followers? Over the centuries, the effort to formulate principles of leadership spread from the study of history and philosophy to all the developing social sciences. In modern psychohistory, there is still a search for psychoanalytical generalizations about leadership, built on the in-depth analysis of the development, motivation, and competencies of prominent leaders, living and dead.

### ***Early Principles of Leadership***

Written principles of leadership go back nearly as far as the emergence of civilization, which shaped its leaders as much as it was shaped by them. Written principles of leadership can be found in Egypt in the *Instruction of Ptahhotep* (2300 B.C.E.). Confucius and Lao-tzu of the sixth century B.C.E. discussed the responsibilities of leaders and how leaders should conduct themselves. Like J. M. Burns (1978), Confucius said that leaders must set a moral example. Like Argyris (1983), Lao-tzu declared that leaders must participate in and share ownership

of developments. In developing their ideas about imperialism and public service, leaders of the British Empire turned for inspiration to the classics, such as the works of Cicero and Marcus Aurelius. Roman and Greek authors such as Caesar, Cicero, Seneca, and Plutarch, to name just a few, wrote extensively on the subject of leadership and administration. For instance, in his *Parallel Lives* of around 100 C.E., Plutarch (1932) tried to show the moral similarities between 50 Greek and Roman leaders: for each Greek leader there was a Roman counterpart. The mythical founder of Athens, Theseus, was matched with the mythical founder of Rome, Romulus. The lawgiver of Sparta, Lycurgus, was matched with the lawgiver of Rome, Numa Pompilius. Alexander the Great was matched with Julius Caesar.

The classical Greek and Roman writers had considerable influence during the medieval, Renaissance, and early modern periods, when many people looked back to the classics for guidance. The Greeks and Romans influenced Machiavelli in *The Prince* (1513), for instance, and Montesquieu in *The Spirit of Laws* (1748). In his *Two Treatises on Government* (1690), John Locke wrote that what we would now call leadership had to reach beyond institutional authority to create and maintain a liberal society (Weaver, 1991).

America's founding fathers were well versed in all these texts and were aware of how autocratic and democratic leadership had succeeded or failed in the Roman, Venetian, Dutch, and Swiss republics. Plato's *Republic* and Aristotle's *Politics* figured strongly in their deliberations at the Constitutional Convention in 1787. The constitutional checks and balances among executive, legislative, and judicial powers owe much to these writings.

### ***Written Concepts and Principles of Leadership***

Written concepts and principles of leadership emerged early. [Figure 1.1](#) shows the Egyptian hieroglyphs for leadership (*seshemet*), leader (*seshemu*), and follower (*shemsu*), which were being written 5,000 years ago. In 2300 B.C.E., in the *Instruction of Ptahhotep*, three qualities were attributed to the pharaoh: "Authoritative utterance is in thy mouth, perception is in thy heart, and thy tongue is the shrine of justice" (Lichtheim, 1973).

Chinese classics written as early as the sixth century B.C.E. are filled with hortatory advice to leaders about their responsibilities to the people. Confucius urged leaders to set a moral example and to manipulate rewards and punishments for teaching what was right and good. Lao-tzu emphasized the need for a leader to work himself out of his job by making the people believe that success was due to their own efforts.

The Greeks' concepts of leadership were exemplified by the heroes in Homer's *Iliad*. Ajax symbolized inspirational leadership and law and order; Agamemnon, justice and judgment; Nestor, wisdom and counsel; Odysseus, shrewdness and cunning; and Achilles, valor and activism (Sarachek, 1968). Later, Greek philosophers, such as Plato, in the *Republic*, looked at the requirements for the ideal leader of the ideal state. Plato's philosopher-king was to be the most important element of good government, educated to rule with order and reason. In *Politics*, Aristotle was disturbed by a lack of virtue among those who wanted to be leaders. He emphasized the need to educate youths for such leadership. Plutarch, concerned with prosocial ideals about leadership, compared the traits and behavior of actual Greek and Roman leaders to support his point of view in *Parallel Lives* (Kellerman, 1987).

SOURCE: Author

A famous Renaissance work was Machiavelli's (1513/ 1962) *The Prince*. Machiavelli's thesis that "there is nothing more difficult to take in hand, more perilous to conduct, or more uncertain in its success, than to take the lead in the introduction of a new order of things" is still a germane description of the risks of, and resistance to, leadership. Machiavelli was the ultimate pragmatist. He believed that leaders needed steadiness, firmness, and concern for the maintenance of authority, power, and order in government. It was best if these objectives could be accomplished by gaining the esteem of the populace; but if they could not, then craft, deceit, threats, treachery, and violence were required (Kellerman, 1987). Machiavelli is still widely quoted as a guide to an effective leadership of sorts, and he was the basis for a modern line of investigation using a "Mach scale" (Christie & Geis, 1970). In 1987, a survey of college presidents reported that they still found *The Prince* highly relevant.

Other famous works of the Renaissance include Shakespeare's plays, such as *Richard II*. As king of England, Richard made many mistakes in judgment, especially in his judgments of people, which alienated his nobles and ultimately led to his forced abdication and imprisonment (Payne, 2000).

Philosophy continued to contribute to principles of leadership. Thus a fundamental principle of leadership at West Point today can be traced back to Hegel's *Philosophy of Mind* (Hegel, 1830/1971), which argued that by first serving as a follower, a leader subsequently can best understand his followers. Hegel thought that this understanding was a paramount requirement for effective leadership.

## The Modern Study of Leadership

---

Among the landmarks in the modern study of leadership are Terman's (1904) investigation of the psychology and development of leadership, Kohs and Irle's (1920) predictions of the promotion of U.S. Army officers, Freud's (1922) work dealing with group psychology, Weber's (1927/1947) introduction of charismatic leadership, Cox's (1926) analysis of the biographies of leaders, Moreno's (1934/1953) invention of sociometry, and Benne and Sheat's (1948) classification of roles in small groups. Leadership assessment centers began in 1923 in Germany (Ansbacher, 1951); they were initiated in Britain during World War II (Garforth, 1945) and by the Office of Strategic Services (1948) in the United States. By 1948, Stogdill (1948) was able to locate 128 studies of leadership, which he classified according to the traits of importance to leadership: capacity, achievement, responsibility, participation, and status. There were 124 articles, books, and abstracts on leadership published in English and four in German up to 1947 in the half-century preceding Stogdill's (1948) review of the literature (see [chapter 4](#)). In contrast, 188 articles on leadership appeared in just one journal, *Leadership Quarterly*, between 1990 and 1999.

In determining the leadership that emerged, Stogdill also found it necessary to consider the situation and the

nature of the followers—their objectives and their need for leadership. After Stogdill, there was a paradigm shift away from research on the traits and personalities of leaders to an emphasis on the situation and context in which the leadership occurred. Stogdill himself maintained that the personal traits associated with leadership were still important, though their effects were modified by the needs of the situation. But most empirical researchers up to 1975 abandoned the search for traits and turned their attention to the situation. Another paradigm shift occurred in the late 1970s, with a rising interest in charismatic, visionary, and transformational leadership (Hunt, 1999) and a perspective that both personal traits and situations (including followers) were important in determining the emergence, success, and effectiveness of leadership. By the 1980s, traits had again become important for research, along with context.

### ***Influence of Leadership Research on Popular Books and Management Techniques***

Leadership is a widely discussed and popular topic. In mid-1999, 55,172 publications on leadership could be found in the Online Computer Library Center (OCLC). As of April 14, 2005, Amazon.com listed 18,299 books for sale on leadership in English, French, and Spanish. Google Scholar listed 16,800 books on leadership, 95,500 publications on leadership, and 386,000 citations related to leadership.

In the past, popular books on leadership consisted of hortatory advice to leaders based on a mixture of “arm-chair analysis” and unproven generalizations. The best seller *How to Win Friends and Influence People* by Dale Carnegie (1937) is illustrative, and is still used for confidence building, especially in workshops for public speaking and salesmanship. Dickson, BeShears, Borys, et al. (2003) selected 30 popular books on business leadership mainly written in the past 30 years such as *The One Minute Manager*, *The 7 Habits of Highly Effective People*, and *First, Break All the Rules*. Two reviewers prepared a summary of key points in each book. Much in common was found with the academic research literature on leadership. (This was confounded to some extent because some of the authors of the popular books were primarily academics.) Staw and Epstein (2000) looked at the effects during five annual periods on the largest 100 U.S. firms (in sales) of introducing three popular management programs: Teamwork, Total Quality Management (TQM), and Employee Empowerment. The firms’ reputations were enhanced in news reports of the programs by the business press. The CEOs’ salaries and bonuses also reflected the use of the three programs, but the firms’ profitability remained unaffected.

## Universality of Leadership

---

Leadership is a universal phenomenon in humans and is also observed in many species of animals, such as matriarchal elephants and patriarchal gorillas. Allee (1951) maintained that all vertebrates living in groups exhibit social organization and leadership. Koford (1963) observed that the relative dominance of two bands of monkeys encountering each other at an eating place was usually determined by the relative dominance of the leaders of the bands. Zajonc (1969) suggested that primate groups learn norms for the different status of members and their leadership. The norms are learned by group members, are stable but can be changed, and are complied with by the majority of members. Experimentation and observation in natural settings suggest that many groups of mammals learn strongly differentiated status hierarchies, which their members recognize and comply with. In primate groups, leaders obtain privileges that tend to bolster their dominance. Their presence is an advantage to the group in gaining possession of a desired territory and in expanding the area of free movement for the group. Whether these findings and similar results reported for packs of wolves and hyenas, elephant matriarchies, bands of gorillas, and pods of whales are relevant to understanding the human condition remains controversial.

## ***Theory versus Problem Orientation***

The earliest social science literature on leadership was concerned predominately with theoretical issues. Theorists sought to identify different types of leadership and to relate them to the functional demands of society. In addition, they sought to account for the emergence of leadership by examining either the qualities of the leader or the elements of the situation. Earlier theorists can be distinguished from more recent ones in that the former did not consider interactions between individual and situational variables. Also, earlier theorists tended to develop more comprehensive theories than do their more recent counterparts. Between 1945 and 1960, students of leadership devoted more of their efforts to empirical research and, as a consequence, ignored various issues that earlier theorists regarded as important. But research on leadership became theory driven again from the 1970s on, although the theories involved tended to focus on a few phenomena and were less ambitious than those of the past. Empirical research increasingly tested hypotheses derived from a theoretical model. By the 1990s, advances in statistical analysis had made possible testing of multivariate models of leadership involving interactions contingent on leaders' and followers' traits and situational variables.

Empirical research on leadership in some segments of the population (students, military personnel, and business managers) was heavy, but sparse in other segments such as leaders of volunteer agencies, police officers, and health administrators. Because of growing employment in health, social services, and protection, there was an upsurge in studies of leadership among nurses, social workers, and the police. In the same way, the increase and upgrading of minorities in the U.S. labor force has resulted in an examination of leadership among women and minorities. Cross-cultural studies of leadership have burgeoned as well.

The emerging propositions about leadership maintain their validity over time in strong cultures. Nonetheless, they also are subject to change because of cultural changes. Thus, over 50% of more than 1,000 students from eight U.S. universities who were surveyed about their attraction to the television series, *MASH*, dealing with a medical unit in the Korean War, indicated that watching the program had modified their attitudes or behavior about organizational life. All but 5% considered *MASH* a realistic portrayal of organizational values and processes. The respondents felt an increased desire to work with superiors who treat subordinates with understanding and respect (Dyer & Dyer, 1984). Most of the coercive, tough, autocratic, bullying leaders in organizations of 1905 had been replaced by 2005 with leaders who may still be as highly concerned about getting the work done but also have concern for their followers. Much of the work itself has changed from unskilled labor to the application of knowledge, from repetitive tasks to more meaningful work, from individual work to teamwork, from functional to project-based work, from single-skill to multiskill work. Coordination from above has decreased while coordination among peers has increased (Stein & Pinchot, 1995).

## ***The Need for Leadership***

Napoleon expressed his feeling about the importance of leadership in his quip that he would rather have an army of rabbits led by a lion than an army of lions led by a rabbit. Surveys of job satisfaction from the 1920s on illustrated the importance of leadership.<sup>1</sup> They uniformly reported that employees' favorable attitudes toward their supervisors contributed to the employees' satisfaction. In turn, employees' favorable attitudes toward their supervisors were usually found to be related to the productivity of the work group (see, for example, Lawshe & Nagle, 1953). Since then, countless surveys can be cited to support the contention that leaders make a difference in their subordinates' satisfaction and performance. For example, Becker (1992) found that compared with their commitment to the organization, employees' commitment to their

supervisors and to top management was more highly related to their job satisfaction, their intention not to quit, and their prosocial behavior. Again, Becker, Billings, et al. (1996) showed that commitment by employees to their supervisors was more strongly associated with the employees' performance than was their commitment to the organization. Leaders also can make the difference in whether organizations succeed or fail. In the public sector, local government managers must be able to lead when angry, single-issue, negative minorities wish to take over public policy making about issues ranging from abortion rights to protective services (Abels, 1996).

Typically, efforts to estimate the number of leaders in the United States use census data on proprietors and officials. But Gardner (1986) noted that although owners, managers, and officials are in a position to do so, they do not necessarily act as leaders. Cleveland (1985) estimated the number of opinion leaders in the United States and how this number grew between 1955 and 1985. In 1955, he estimated that there were 555,000 opinion leaders; in 1971, he guessed that at least one million Americans could be classified as opinion leaders. He considered 7 out of 10 public executives to be opinion leaders—policy makers in public, philanthropic, voluntary, and large-scale private enterprises. By 1985, he estimated the number to have multiplied to one out of every 200 Americans. In the age of information—with the ever-present need for change to stay ahead of the competition, for learning from timely feedback, for teamwork, and for the introduction of new technology—the need for leadership at all organizational levels is apparent. On the basis of a field study of 12 large organizational reengineering attempts. Jaffe and Scott (1998) pointed out that without engaging the firm's leadership, efforts to reengineer, the operations will fail. Large-scale redesign requires leaders' and employees' commitment.

*Need and Importance.* It was the leadership of Robert E. Lee that enabled the Confederate forces to defeat the larger, better-equipped Union forces in many of the battles of the Civil War. It was the leadership of Henry V and longbow technology that produced the victory at Agincourt of 15,000 Englishmen over the 45,000 more heavily armored Frenchmen (Fiedler & Garcia, 1987). De Vries, Roe, et al. (1998) developed and validated a scale of "need for supervision" that can differentiate between conditions when employees need to be supervised and conditions when they do not. However, the effect of the need for leadership on the outcomes of leadership, though positive, is small (De Vries, Roe, and Taillieu, 2002). Supervisors do make a difference in employees' sense of equity in the workplace and are more important than issues of pay and long working hours (Porter, 1997). Leaders' vision, empowerment, and enabling of subordinates makes possible a highly adaptive, learning organization (Johnson, 1998). The Gallup Organization Workplace Audit, administered to 2 million employees in 61 countries, and supported by focus groups, identified five statistical factors associated with high-quality work environments. Two of these factors were one's immediate supervisor and the overall leadership in the firm (Gallup, 1995, 1998). Leadership was central to the success of Total Quality Management (TQM), which requires the support and commitment of top management (Shea and Howell, 1998). Some of the performance of football teams is beyond the control and ability of the coach's leadership, but the coach can turn a consistently losing team into a consistently winning team—as Vince Lombardi did with the Green Bay Packers. Around the globe, leadership is widely required because of two antithetical forces: interdependence and diversity (economic, political, and social). But despite the importance of leadership, Conger (1999, p. 145) lamented, "A more competitive world forced many firms to reinvent themselves + (but) rarely did companies possess the courage to change management skills needed to orchestrate large-scale transformations. + The leadership talent necessary for such undertakings was + in short supply." Lipman-Blumen (1996) conceived a need for "connective" leaders who can bring divisive parties together by developing a sense of self-sacrifice, community, and common causes. Leadership is needed to change organizations. However, when De Vries, Roe, and Taillieu (2002) questioned 958 Dutch employees about how much they *individually* needed their supervisor to set goals, to decide what work should be done, etc., they found only modest effects on the relationship between the need for leadership and job satisfaction,

commitment to the organization, stress of work, role conflict, and self-rated performance.

*Caveat—Leadership is a Figment of the Imagination.* Agency theorists (Meckling & Jensen, 1976) argued that an organization is a legal fiction that serves as the connection for contracts among parties. An organization is simply a network of individuals who exchange according to market conditions, rewards, resources, time, and skills. There is no distinction between leaders and followers. If there are no followers, there is no need for leadership (Arnott, 1995). Some critics have argued that all the effects of leadership are a romantic fiction, existing only in the eye of the beholder. Followers attribute to leadership effects that in fact are due to historical, economic, or social forces. Meindl, Ehrlich, and Dukerich (1985) presented five empirical studies of their concept of the “romance of leadership.” In the first study, they demonstrated that among a total of 33,248 titles of articles in *The Wall Street Journal* between 1972 and 1982, 34 business firms in various industries, leadership was more likely to be emphasized in those years when the firms did well but not when they did poorly. Leadership also appeared much more often in the titles in the years that industries performed well rather than poorly. A second study showed that the percentage of leadership topics between 1929 and 1983 in social science doctoral dissertations was greater after poor rather than good economic times. A third study found that the number of articles about leadership in business periodicals was also affected, but in the opposite way. The fourth and fifth studies demonstrated that students given various business scenarios were more likely to attribute large changes, up or down, to leadership rather than to alternative reasons for company success. Middling changes generated the least effect.

Other critics, such as Pandey (1976), have regarded the concept of leadership as useless for understanding social influence. Calder (1977) argued that the objective contributions of the “leader” to outcomes were possibly more interesting than true. Some critics attributed organizational outcomes primarily to other factors, but held that after the fact, leaders were credited with what happened. Organizational leaders who were perceived to be exerting leadership on organizational performance were merely the subjects of misperceptions. That is, organizational outcomes were objectively determined by environmental and organizational factors in which leadership, at best, could play only a minor role. For instance, M. C. Brown (1982, p. 1) concluded that “once other factors influencing effectiveness are accounted for, it is likely that leadership will have little bearing on organizational performance.” Pfeffer (1977) took a similar but less extreme position: leadership is a sense-making heuristic to account for organizational performance and is important primarily for its symbolic role in organizations. Leaders are selected or self-selected to fulfill the fate of the organization and are highly constrained by organizational and external factors. Therefore, compared with external factors, they can have only a limited impact on organizational outcomes. Leaders are able only to react to contingencies, to facilitate the adjustment of the organization in its context, and to alter the environment to some limited extent. Also, they have no control over many factors that affect organizational performance. Typically, they have unilateral control over few resources.

Salancik and Pfeffer (1977) showed that the mayors of 30 U.S. cities had real influence on a just a few budgetary issues, such as libraries and parks, that were not in the domain of important special-interest groups, such as the police, firefighters, and highway maintenance personnel. Seemingly influential leaders—political party officials, lobbyists, and contractors—often are followers, not leaders. Pfeffer concluded that since people want to feel they are in control of their environment, they find it useful to attribute their group and organizational performance to leaders rather than to the complex internal and external environmental forces that actually are most important. Meindl and Ehrlich (1987) showed that if performance outcomes of firms were attributed to the leadership of top management rather than to the employees, to market conditions, or to the government, evaluators gave better evaluations of the outcomes. Meindl and Ehrlich attributed this finding to the evaluators’ assumption that leaders have a reliable and potent impact on outcomes. Even when the true causes of outcomes were logically not determinable, Meindl, Ehrlich, and Dukerich (1985) showed that there was a tendency to view leadership as the likely cause. This study and the one by Meindl and Ehrlich (1987)

were thought to demonstrate that leadership is more of a romantic notion than a phenomenon that truly affects group and organizational outcomes. Support for the idea that leadership is a fiction was the evidence that would-be followers, subordinates, and groups of employees are so constrained by technology, rules, job requirements, and organizational policies that there is little discretionary room for a superior or leader to make much of a difference in how things get done (Katz & Kahn, 1966). Furthermore, subordinates may have much more effect on the behavior of their superiors than vice versa (Goodstadt & Kipnis, 1970).

Miner (1975, p. 200), a prominent scholar of leadership, was ready to abandon the concept of leadership, stating that “the concept of leadership itself has outlived its usefulness. Hence, I suggest that we abandon leadership in favor of some other, more fruitful way of cutting up the theoretic pie” (Hunt, 1999, p. 129). Miner (1982a) later recanted this statement but still maintained that the concept had limited usefulness because so much of the empirical research had been on emergent leadership in small groups rather than within more complex organizations. For Miner, the fragile, distressed leadership that arises in the small, temporary group to develop, maintain, and enforce the norms of the group may have little relevance for leadership in the impersonal “task system” of the traditional organization. Cronshaw and Lord (1987) found in a laboratory study that participants used simple cognitive rules of thumb to form their impressions of leadership. Bass (1949) showed that in an initially temporary, initially leaderless group discussion, ratings of members’ leadership correlated as high as .90 with how much they talked in the discussion.

*Leaders Do Make a Difference.* Historians such as Arthur Schlesinger (1999) are mindful of how the course of history might have been changed by chance events in the lives of individual leaders. On a visit to New York in 1931, Winston Churchill was hit by an automobile while crossing Fifth Avenue. Suppose his injuries had been fatal. Would Britain have rallied in 1940 under Neville Chamberlain in the face of impending defeat by the Nazis? What if in 1932, an assassin’s bullet intended for Franklin Roosevelt had killed him instead of Mayor Cermak of Chicago, who was beside him on the speakers’ platform? Would his more conservative replacement, Vice President John Garner, have launched the New Deal? Would the country have shifted from isolationism to interventionism? Suppose Lenin had died of typhus when he was exiled to Siberia in 1897 or Hitler had been killed on the western front in 1916. Would the twentieth century have been the same?

Although there is some validity in Meindl’s proposition that we wrongly attribute to leaders the success or failure of their groups, leaders do make a difference. It is not an all-or-none matter. An experienced expert group has less need for close leadership than a group of inexperienced novices. Posner and Kouzes (1996), after analyzing several thousand cases and surveys over a dozen years, found a consistent pattern of exemplary leadership practices. Leadership is not a “mystical or ethereal concept.” Rather, leadership is an observable, learnable set of practices. Certainly leaders make a difference. There is no question about it. But, as noted by Henry Mintzberg, leaders often make a difference because they stimulate others (McCarthy, 2000).

*The Role of Followers.* Proponents of the follower theory of leadership of social and political movements, such as Rost (1993), argue that leaders find the parade of followers and get in front of it. These critics oversimplify. Social and political leaders discover what their followers need or should need, but the followers have not been able to articulate and mobilize for what they want. Leaders give voice and words to capture what is needed and mobilize others to follow. Despite skepticism about the reality and importance of leadership, all social and political movements require leaders to begin them. As Tucker (1981, p. 87) put it, “In the beginning is the leadership act. A ‘leaderless movement’ is naturally out of the question.” This does not mean that *formal, institutionalized* leadership is required. Informal leaders can stir up a rioting mob. Organized slave revolts were initiated informally by leaders like Spartacus (70 B.C.E.) in Rome and Toussaint-Louverture (1792) in French Haiti. In fact, no leader in an institutional form appeared in the numerous peasant revolts from the sixteenth century to the nineteenth century in southern Germany. The same was true of journeymen’s strikes during the eighteenth century. Leadership remained informal and egalitarian. Only in

the middle of the nineteenth century did definite radical leaders like Ferdinand Lassalle emerge. Lassalle placed himself at the head of the German workers' movement and developed its explicit ideology along with the myth that he had founded the movement (Groh, 1986). This behavior is consistent with most cases of institutional development: Leaders determine the direction they will take. The early historical records of the British Royal Society in the seventeenth century illustrate that its secretaries were responsible for who joined the society and what kinds of science were sponsored (Mulligan & Mulligan, 1981).

*Leadership May Be Critical to Organizational Success.* Indeed, leadership is often regarded as the single most critical factor in the success or failure of institutions. For instance, T. H. Allen (1981) argued that the principal's leadership is the most important factor in determining a school's climate and the students' success. Sylvia and Hutchison (1985) concluded that the motivation of 167 teachers in Oklahoma depended considerably on their perception of the quality of their relationships with their superiors. And Smith, Carson, and Alexander (1984) found that among the 50 Methodist ministers they studied, some were more effective leaders than others. The effectiveness of these ministers was evidenced by the differential impact that their ministries had on church attendance, membership, property values, and contributions to the church.

In the business and industrial sector, leaders' effectiveness is measured objectively by their organizational units' profit, profit margin, sales increase, market share, return on investment (ROI), unit productivity, cost per item produced, and cost relative to budgeted cost. Objective measures of effectiveness (and employees' satisfaction) also include safety records, absenteeism, voluntary turnover, grievances, complaints, requests for transfers, work slowdowns, and incidents of sabotage. Superiors', peers', subordinates', and customers' ratings and attitude surveys provide subjective measures of the effectiveness of unit leaders and their contribution to the units' processes. Product quality can be gauged by amount of required rework, number of rejects, and customers' complaints or subjective ratings (Yukl, 1998). Maccoby (1979, p. 313) concluded, from his observations of the manager as a game-playing politician, that the need of firms to survive and prosper in a world of increasing competition, technological advances, changing governmental regulations, and changing attitudes of workers requires "a higher level of leadership than ever before." Strong support for this proposition came in a study by Andersen Consulting's Institute for Strategic Change, which found that the stock price of firms seen as well-led increased 900% over a 10-year period. Stock prices of firms seen as poorly led increased only 74% (Bennis, 2000). When an organization must be changed to reflect changes in technology, the environment, and the completion of programs, its leadership is critical in orchestrating the process (Burke, Richley, & DeAngelis, 1985). Mintzberg and Waters (1982) examined the evolution of a retail firm over a 60-year period and found that a senior executive could successfully reorient the firm by intervening to change previous strategies and organizational structures. This finding was corroborated by Thomas (1988), whose data showed that over 60% of the sales and profits of British retail shops were due to changes in the top executive.

*Leadership and Various Organizational Outcomes.* Management and leadership do seem to have a substantial effect on some organizational outcomes. Thus when Lieberman and O'Connor (1972) examined the effects of top management on the success of 167 firms over a 20-year period, they found that these effects depended on which outcomes were considered. Senior managers had the greatest effect on profit margins but the least effect on sales; they also were of less consequence in capital-intensive industries. In the same way, Day and Lord (1986) noted that when confounding errors are controlled in studies of the effects of executive succession, differences in executive leaders can account for as much as 45% of their organizations' performance. Agreeing with Chandler (1962), they stated that historical analyses of changes of leadership over significant periods, demonstrated that leadership had a profound influence on an organization. Concurrent correlational analyses of a sample of executives and their organizations at the same point in time reach similar conclusions, although the effects are not as strong. Barrick, Day, et al. (1991) analyzed 15 years of data in 132 industrial organizations and found that high-performing executive leaders had a positive impact on their firms' new income, earnings per share, and return on equity. In a review of experiments in the United States on the

productivity of workers between 1971 and 1981, Katzell and Guzzo (1983) concluded that supervisory methods seemed particularly effective in increasing output. In Sweden, Westerlund (1952a) observed that the high-quality performance of supervisors improved the attitudes and performance of telephone operators. Also in Sweden, Ekvall and Arvonen (1984) found that leadership styles accounted for 65% of the variance in organizational climate in the 25 units they studied. Virany and Tushman (1986) stated that the senior managers of better-performing minicomputer firms were systematically different from those of firms that performed poorly. The senior managers in the better firms had previous experience in the electronics industry and were more likely to include the founder of the firm, who still served as chief executive officer. Although most attention has been paid to industrial leaders as developers and builders, Hansen (1974) pointed out that the success with which a firm, such as the Ford Motor Company, closed a plant without much human dislocation depended on effective leadership.

Leadership has been considered a critical factor in military successes since records have been kept; that is, better-led forces repeatedly have been victorious over poorly led forces. Thus, not unexpectedly, morale and cohesion among Israeli and U.S. enlisted soldiers correlated with measures of the soldiers' confidence in their company, division, and battalion commanders (Gal & Manning, 1984).

Personnel of the Mississippi Cooperative Extension reported that they felt less job stress if they saw their supervisors displaying more leadership in structuring the work to be done and showing concern for the subordinates' needs (Graham, 1982). In a study of 204 innovations in state programs, Cheek (1987) found that the governors came up with 55% of the innovations and the agencies with only 36%.

*Effects of Presidential Performance.* Studies by Tucker (1981), Hargrove and Nelson (1984), and Hargrove (1987) concluded that the style and performance of a U.S. president makes a big difference in what happens to legislation, policy, and programs. Successful presidents are more sensitive to the inherent politics of policy making. They define and publicize the policy dilemmas facing the country and earn widespread public and congressional support for their positions. They construct their policy agendas with the felt needs of the country in mind and create political support for their agendas; they also realize that timing is important (Tucker, 1981). But, like Jimmy Carter, they can fail if they push for what they deem to be right but what is not politically feasible and if they favor comprehensive integrated solutions, rather than incremental steps (Hargrove, 1987). Presidents can make decisions that are not implemented because they or their assistants do not follow them up. For example, as part of the agreement to resolve the Cuban missile crisis, President Kennedy ordered the removal of U.S. missiles from Turkey on the border of the Soviet Union. Six months later, he was astonished to learn that the missiles were still in place (Manchester, 1988). Although presidents spend relatively little time trying to make major re-orientations in policy, they have an important impact on the smaller substantive decisions that affect larger overall strategies (Neustadt, 1980). History may be drastically altered by a sudden change in presidents. Before leaving Washington, D.C., for his fateful trip to Dallas, Texas, where he was assassinated in November 1963, Kennedy signed the first order for a phased withdrawal from Vietnam. On assuming office after Kennedy's assassination, Lyndon Johnson rescinded the order. The war continued for another decade.

According to Richard Nixon's "Silent Majority" speech in 1969, presidents may have to take an unpopular stand, but when they do, they can strengthen acceptance by explaining their reasons, soliciting support, and winning approval (Safire, 1975). Presidents also provide symbolic support for the development of norms, values, and beliefs that contribute to subsequent national and organizational development (Sayles, 1979). As Gardner (1988a) noted, for a society to function, its people must share beliefs and values regarding the standards of acceptable behavior. Bill Clinton, a popular president, was almost removed from office for violating standards of sexual propriety. Leaders can revitalize those shared beliefs and help keep the values fresh. "They have a role in creating the state of mind that is the society" (Gardner, 1988a, p. 18). They conceive and articulate goals that move people from their own interests to unite for higher ends.

*Indirect Effects of Leadership.* Often, the effects of leadership are indirect. For example, Katzell (1987) showed that although supervisors' direct influence on their subordinates was modest, they exerted indirect influence and improved the employees' morale by providing rewards, relating rewards to performance, and treating employees equitably. By increasing morale, these supervisors improved the employees' performance. Jongbloed and Frost (1985) modified Pfeffer's (1977) reasoning to argue that leaders still have an important general role to play. What leaders really manage in organizations is the employees' interpretation or understanding of what goes on in the organizations. The leaders manage meanings and, therefore, exert a strong impact on organizational outcomes. Jongbloed and Frost compared the laboratory director in one Canadian hospital with another director in a second hospital. The two had the same formal assignments, and neither of them had control over issues; but the first director successfully lobbied for the importance of pathology and persuaded the hospital administrators to allocate more funds for operations and budget than were allocated in the second hospital.

*Relation to Development, Training, and Education.* The importance of leadership is attested to by academics' and lay people's interest in leadership as a subject for development, training, and education (Campbell, 1977).<sup>2</sup> Although U.S. college presidents believe that our educational institutions are reluctant to incorporate leadership education into their curricula (Cronin, 1984), the college landscape is not bleak. Quite the contrary. Gregory's (1986) survey of all known U.S. degree-granting institutions of higher learning found 53 that offered an academic course on leadership, 70 that made it possible to major or concentrate in the subject, and 181 that incorporated the study of leadership into an academic course or a student-affairs program.<sup>3</sup> These numbers increased during the 1990s. Undergraduate schools of leadership, such as the Jepson School, appeared—along with concentrations and certifications in leadership and research, such as those offered at Claremont McKenna College and Binghamton University. By the 1990s, leadership research and training centers such as the Center for Creative Leadership, the Center for Leadership Studies, the Kravis Institute, and the Drucker Foundation had appeared, as did journals such as the *Leadership Quarterly* and the *Journal of Leadership Studies*. The Alliance for Leadership Development promotes research on and the teaching of leadership and serves as a clearinghouse of information on leadership programs at universities and secondary schools, leadership development programs in the community, development programs for corporate executives, and continuing education programs for professionals.

### ***Leadership as a Subject of Inquiry***

The understanding of leadership has figured strongly in the quest for knowledge. Purposeful stories have been told through the generations about leaders' competencies, ambitions, and shortcomings; leaders' rights and privileges; leaders' roles, duties, and obligations; and leaders' successes and failures.

The importance of leadership is also demonstrated by its place in social science research. According to DeMeuse (1986), leadership has been a frequent subject of empirical research concentrating on the antecedents of leaders' behavior and the factors that contribute to its effectiveness. Leadership is a featured topic in almost every textbook on organizational behavior (McFillen, 1977). Scholarly books on leadership and scholarly articles, reports, and essays form a considerable number of the total publications on leadership, as noted earlier.

Many schools of thought have existed, some simultaneously, since leadership first was studied. The early theorists explained leadership in terms of either the person or the environment. Later theorists viewed leadership as an aspect of role differentiation or as an outgrowth of social interaction processes. More recently, theories of leadership have focused on the mutual influence of leaders and followers. All this is as it should be. Theory and empirical research should move forward together, each stimulating, supporting, and modifying the other. Neither can stand alone. An elegant theory with no prospect of elegant data gathering is likely to be a

sketchy theory. Early in a line of investigation, crude data and theory may be useful. Later, as understanding develops and practice improves, more stringent standards for theorizing are required (Bass, 1974).

The subject of inquiry has been changing over the years (Knights & Morgan, 1992). Small-group analysis of leadership has been giving way to organizational and strategic studies. Increasingly, empirical studies are about leaders and their strategies that create particular norms and values affecting organizational performance. The studies discussed in the chapters that follow are based on a wide variety of theoretical assumptions, methods, participants, and venues. Despite differences in the philosophies that guide them and the research methods used, there is considerable convergence of findings on many problems. This convergence, when it occurs, may be regarded as convincing evidence of the validity of the findings.

*Caveat—Too Much Rehashing.* An almost unanswerable question is the extent to which we pour old wine into new bottles when we propose “new” theories. For instance, Julius Caesar’s descriptions of his leadership style in the Gallic wars in the first century b.c.e. are clear, succinct endorsements of the need for what Blake and Mouton (1964) conceived as 9, 9 style—a style that Fleishman (1953a) described in terms of strong initiation and consideration, and that some theorist will rename in the year 2050. When does a field advance? Are we beyond Caesar’s understanding of how to lead infantry shock troops? In 1975, an unknown scholar of leadership declared, “Once I was active in the field. Then I left it for ten years. When I returned, it was as if I was gone only ten minutes” (Hunt, 1999, p. 129). Shortly after this pessimistic comment appeared, the new paradigms of neocharismatic and transformational leadership were introduced in the seminal publications of House (1977) and J. M. Burns (1978). They proved to be giant leaps forward for the study of leadership, as will be documented in chapters 21 and 22. Contrary to the criticism, according to House and Aditya (1997), the study of leadership has been truly cumulative.

*Integration of Theories.* The study of the dynamics of leadership was dominated by two broad themes. First, leadership was conceived as an exchange between the leader and the followers in which following the leader was rewarded and disciplinary action was avoided. Second, leadership was exerted through the leader’s personality. Within this framework, emphasis was placed on traits, behaviors, and contexts. As we shall see, these have been integrated into many modern theories of leadership with practical applications to the assessment, development, and training of effective leaders, as will be described in Chapters 34 and 35.

My hope in this book is to catalog much of what is known about leadership and to suggest some of what we do not know and should try to find out. Although I agree with Burns (1978, p. 2) that “leadership is one of the most observed phenomena on earth,” I disagree with Burn’s statement that “it is one of the least understood.” His position has probably become more optimistic since 1978, with the introduction into a good deal of leadership research of his original concept of transforming leadership.

*More on the Meaning of Leadership.* The word “leadership” refers to a sophisticated modern concept. In earlier times, words meaning head of state, military commander, princeps, proconsul, chief, or king were common in most societies; these words differentiated the ruler from other members of society. A preoccupation with leadership, as opposed to headship based on inheritance, usurpation, or appointment, occurred predominantly in countries with an Anglo-Saxon heritage. Although the *Oxford English Dictionary* (1933) noted the appearance of the word “leader” in the English language as early as the year 1300, the word “leadership” did not appear until the first half of the nineteenth century, in writings about the political influence and control of the British Parliament. What was considered appropriate leadership changed as a consequence of the industrial revolution, first in the nineteenth century in England, and then in western Europe and America. Before the Industrial Revolution, shops were small and owner-managed, and relations were personal. The owners tended to be paternalistic authority figures. In the large factory system of the Industrial Revolution, the owner might be absent, the manager might be distant from the employees, and power over the employees rested in the shop foreman, who was likely to “rule his little kingdom as a tyrant, hiring, helping, firing and frustrating as he pleased. + The owners (and shareholders) were + impervious to the

impact of factory life upon their workers, to the alienation and uncertainty, and degradation bred in these impersonal establishments” (Wiebe, 1967, p. 20). Economic rationality provided the rules of management and supervision, eventually softened by organized labor, progressive politics, and the Human Relations Movement. After the Industrial Revolution, in the age of information, concern for followers’ interests by the leadership became mandatory in most establishments, large and small, in the developed world.

## Defining Leadership

---

Different definitions and concepts of leadership have been presented in countless essays and discussions. Often, a two-day meeting to discuss leadership has started with a day of argument over the definition. Rost (1993) found 221 definitions of leadership in 587 publications he examined. Furthermore, the distinction between leadership and other processes of social influence such as coordination and control was blurred. Ciulla (2004) argued that Rost confused the issue further by conceiving theories about how leadership works as definitions. The many dimensions into which leadership was cast and their overlapping meanings added to the confusion. Representative of definitions of leadership in the 1920s was impressing the will of the leader on those led and inducing obedience, respect, loyalty, and cooperation. In the 1930s, leadership was considered a process through which the many were organized to move in a specific direction by the leader. In the 1940s, leadership was the ability to persuade and direct beyond the effects of power, position, or circumstances. In the 1950s, it was what leaders did in groups and the authority accorded to leaders by the group members. In the 1960s, it was influence to move others in a shared direction. In the 1970s, the leader’s influence was seen as discretionary and as varying from one member to another. In the 1980s, leadership was considered as inspiring others to take some purposeful action. In the 1990s, it was the influence of the leader *and* the followers who intended to make real changes that reflected their common purposes. In the first decade of the twenty-first century, the leader is seen as the person most responsible and accountable for the organization’s actions. McFarland, Senn, and Childress (1993) considered six themes of leadership most appropriate for the twenty-first century: (1) Leadership is no longer the exclusive domain of the top boss. (2) Leadership facilitates excellence in others. (3) Leadership is not the same as management. (4) Leadership has a sensitive, humanistic dimension. (5) Leaders need to take a holistic approach, applying a variety of qualities, skills, and capabilities. (6) Leadership is the mastery of anticipating, initiating, and implementing change.

Hughes, Ginnett, and Curphy (1993) attributed the confusion over defining leadership to a lack of agreement about the major questions in the field of leadership and about the answers to them. There is a surfeit of definitions of leadership. Nonetheless, there is a useful body of knowledge about the subject, which can be applied (Church, 1998). Fleishman, Mumford, et al. (1991) identified 65 systems for classifying definitions of leadership, and there is sufficient similarity among definitions to permit such classification. The definitions most commonly used tend to concentrate on the leader as a person, on the behavior of the leader, on the effects of the leader, and on the interaction process between the leader and the led.

### ***“Leadercentric” Definitions of Leaders and Leadership***

“Leadercentric” definitions are about one-way effects due to the leader as a person. According to these definitions, the leader has the combination of traits necessary to induce others to accomplish a task (Tead, 1929).

*The Leader as a Personality.* The concept of personality appealed to several early theorists, who sought to explain why some persons are better able than others to exercise leadership. A. O. Bowden (1926) equated leadership with strength of personality: “Indeed, the amount of personality attributed to an individual may not

be unfairly estimated by the degree of influence he can exert upon others.” Bingham (1927) defined a leader as a person who possesses the greatest number of desirable traits of personality and character.

*Leadership as an Attribution.* Leadership may be conceived solely as a romantic figment of the imagination, used to explain why a group, organization, community, or nation has been successful. Or leadership may be conceived solely as the observable reason for outcomes that have occurred. The truth lies somewhere in between. André Maurois noted that the most important quality in a leader was to be acknowledged as a leader. Such acknowledgment is a matching of the traits and behaviors thought implicitly to be the characteristics of leaders (the prototype) and the traits and behaviors observed in the person acknowledged as a leader. Most people carry around in their heads implicit theories about what qualities leaders should have and what behaviors leaders should exhibit. When 378 undergraduates were asked what characteristics were needed for acceptance of a new leader by a group, topping the list were learning the group’s goals, taking charge, and being a nice person (Kenney, Blascovich, & Shaver, 1994). For more than 15,000 respondents, the first four of 20 characteristics chosen to describe admired leaders were being honest, being forward-looking, being inspirational, and being competent (Kouzes & Posner, 2002).

*Leaders as the Foci of Group Processes.* Early on, definitions of leadership tended to view the leader as a focus of group change, activity, and process. Cooley (1902) maintained that the leader is always the nucleus of a tendency, and that any social movement, closely examined, will be found to have such a nucleus. E. Mumford (1906–1907) observed that “leadership is the preeminence of one or a few individuals in a group in the process of control of societal phenomena.” Blackmar (1911) saw leadership as the “centralization of effort in one person as an expression of power in all.” For M. Smith (1934), “the social group that expresses its unity in connected activity is always composed of but two essential portions: the center of focal activity, and the individuals who act with regard to the center.” For Redl (1942), the leader was a central or focal person who integrated the group. As a nation develops, it needs a centralized locus for its operation, which can be achieved only by a single leader (Babikan, 1981). All important decisions and their implementation center on the cult of the leader, even when, as in parliamentary democracies, actual decision making is diffuse. The leader embodies the collective will. This single leader sorts out the essential problems, offers possible solutions, establishes priorities, and launches developmental operations.

J. F. Brown (1936) maintained that “the leader may not be separated from the group, but may be treated as a position of high potential in the field.” Following in the same tradition, Krech and Crutchfield (1948) observed that the leader “by virtue of his special position in the group + serves as a primary agent for the determination of group structure, group atmosphere, group goals, group ideology, and group activities.” For Knickerbocker (1948), “when conceived in terms of the dynamics of human social behavior, leadership is a function of needs existing within a given situation, and consists of a relationship between an individual and a group.” In his book *If I’m in Charge Here, Why Is Everybody Laughing?* David Campbell (1992) suggested that no matter how competent and motivated a group is, it cannot be effective collectively without a central focal leader.

Chapin (1924b) viewed leadership as a point of polarization for group cooperation. According to L. L. Bernard (1927), leaders were influenced by the needs and wishes of the group members; in turn, they focused the attention and released the energies of group members in a desired direction. This emphasis on the leader as the center or focus of group activity directed attention to group structure and group processes in studies of leadership. On the one hand, some of the earliest theorists, such as Cooley and Mumford, were sophisticated in their concept of leadership. On the other hand, several of the definitions placed the leader in a particularly fortuitous, if not helpless, position, given the inexorable progress of the group. Leaders were thought to have to stay one step ahead of the group to avoid being run over. Centrality of location in the group could permit a person to control communications, and hence was likely to place him or her in a position of leadership, but centrality in itself is not leadership.

*The Leader as a Symbol.* Leaders serve a symbolic function and serve as representatives of their group to outsiders. They provide a way to simplify and find meaning in the group's external environment (Katz & Kahn, 1978). In doing so, leaders invoke symbols to reinforce the meaning of events and circumstances (Gronn, 1995).

*Leadership as the Making of Meaning.* Leaders provide understanding and meaning for situations that followers find confusing, ambiguous, unclear, vague, indistinct, or uncertain. They define reality for followers. Leaders provide credible explanations, interpretations, stories, parables, and accounts about what has happened, what is happening, and what will happen. They make sense of a situation for their followers. Leaders talk about values that are acceptable to the followers and that can guide their subsequent action (Gronn, 1995).

*Leadership of Thought.* This leadership is exerted through lectures, writing, or discovery by people like Darwin, Marx, and Einstein, whose original intellectual activities are profound and exciting (Clark & Clark, 1994).

*Leadership as Purposive Behavior.* One school of theorists preferred to define leadership in terms of activities or behaviors. These are the particular activities in which a leader engages in the course of directing and coordinating the work of group members. They may include acts such as structuring work relations, praising or criticizing group members, and showing consideration for members' welfare and feelings. For L. F. Carter (1953), "leadership behaviors are any behaviors the experimenter wishes to so designate or, more generally, any behaviors which experts in this area wish to consider as leadership behaviors." For Shartle (1956), a leadership act is "one which results in others acting or responding in a shared direction." Hemphill (1949a) suggested that "leadership may be defined as the behavior of an individual while he is involved in directing group activities." Fiedler (1967a) proposed a somewhat similar definition. For Heifetz (1994), leadership is adaptive work, the activity of mobilizing a social system to face challenges, clarify aspirations, and adapt challenges faced.

For Jacobs and Jaques (1987), leaders give purpose to others to expend and mobilize energy to try to compete. Outcomes are attributed more readily to the leader: thus when things go wrong, the leader is likely to be blamed and even removed (Hollander, 1986).

*Leadership as Persuasive Behavior.* Presidents Eisenhower and Truman emphasized the persuasive aspect of leadership. According to Truman (1958, p. 139), "a leader is a man who has the ability to get other people to do what needs to be done and what they don't want to do, and like it." According to Eisenhower, "leadership is the ability to decide what is to be done, and then to get others to want to do it" (Larson, 1968, p. 21). And for Lippmann (1922), such persuasiveness is long-lasting: "The final test of a leader is that he leaves behind him in other men the conviction and the will to carry on."

Several theorists defined leadership as successful persuasion without coercion. Followers are convinced by the merits of the argument, not by the coercive power of the arguer. Neustadt (1960) concluded, from his study of U.S. presidents, that presidential leadership stems from the power to persuade. Schenk (1928) suggested that "leadership is the management of men by persuasion and inspiration rather than by the direct or implied threat of coercion." Merton (1969) regarded leadership as "an interpersonal relation in which others comply because they want to, not because they have to." According to Cleeton and Mason (1934), "leadership indicates the ability to influence men and secure results through emotional appeals rather than through the exercise of authority." Copeland (1942) maintained that leadership was the art of influencing a body of people by persuasion or example to follow a line of action. It was never to be confused with drivership—compelling a body of people by intimidation or force to follow a line of action. Odier (1948) differentiated between the value and the valence of a leader. Valence is the power of one person to strengthen or weaken the values of other persons—the influences exerted on others. Koontz and O'Donnell (1955) regarded leadership as "the activity of persuading people to cooperate in the achievement of a common objective."

Persuasion is one form of leadership. Much of what has been learned from studies of persuasion can be incorporated into an understanding of leadership. Persuasion is a powerful instrument for shaping expectations

and beliefs—particularly in political, social, and religious affairs. The definition of leadership as a form of persuasion tended to be favored by students of politics and social movements and by military and industrial theorists who were opposed to authoritarian concepts. It was also the province of rhetoricians and communications theorists. Research on persuasion, persuasability, and communications paralleled research on leadership (W. Weiss, 1958).

*Leadership as the Initiation of Structure.* Several commentators viewed leadership not as passive occupancy of a position or as acquisition of a role but as a process of originating and maintaining the role structure—the pattern of role relationships. M. Smith (1935a) equated leadership with the management of social differentials through the process of providing stimuli that other people respond to integratively. Lapiere and Farnsworth (1936) observed that situations may be distinguished from one another by the extent to which they are organized by one member of the group. Such organizing is usually spoken of as leadership, with its nature and degree varying in different social situations.

Gouldner (1950) suggested that there is a difference in effect between a stimulus from a follower and one from a leader. A stimulus from a leader has a higher probability of structuring a group's behavior because the group believes that the leader is a legitimate source of such stimuli. Gouldner disagreed with C. A. Gibb (1947) regarding the notion that once the group's activity is dominated by an established and accepted organization, leadership tends to disappear. Thus Bavelas (1960) defined organizational leadership as the function of "maintaining the operational effectiveness of decision-making systems which comprise the management of the organization."

Homans (1950) identified the leader of a group as a member who "originates interaction." For Hemphill (1954), "to lead is to engage in an act that initiates a structure in interaction (pattern of relations) as part of the process of solving a mutual problem." And Stogdill (1959) defined leadership as "the initiation and maintenance of structure in expectation and interaction." Hemphill and Stogdill defined leadership in terms of the variables that give rise to the differentiation and maintenance of role structures in groups. Such a definition has greater theoretical utility than definitions that are more concrete and descriptive to a layperson: it leads to the basic processes involved in the emergence of the leadership role. Again, what must be kept in mind is that leadership is more than just the initiation of structure. As Gouldner (1950) noted, we need room for acts of leadership in the completely structured group. Stogdill's (1959) inclusion of maintenance of structure is important. Furthermore, if structure is a consistent pattern of differentiated role relationships within a group, we must also be sure to consider persons, resources, and tasks within the differentiated roles. Much of [chapter 20](#) is dedicated to initiation of structure.

*Leadership as the Exercise of Influence.* The concept of influence was a step in the direction of generality and abstraction in defining leadership. J. B. Nash (1929) suggested that "leadership implies influencing change in the conduct of people." Tead (1935) defined leadership as "the activity of influencing people to cooperate toward some goal which they come to find desirable." Stogdill (1950) described leadership as "the process of influencing the activities of an organized group in its efforts toward goal setting and goal achievement." The influence may be direct or indirect (Hunt, 1991). Shartle (1951a, b) proposed that the leader be considered an individual "who exercises positive-influence acts upon others" or "who exercises more important-influence acts than any other members of the group or organization." Similarly, Tannenbaum, Weschler, and Massarik (1961) defined leadership as "interpersonal influence, exercised in a situation and directed, through the communication process, toward the attainment of a specified goal or goals." This definition was expanded by Ferris and Rowland (1981), who conceived of the influence process in leadership as contextual influence that has an impact on subordinates' attitudes and performance through effects on their perceptions of their jobs.

The interactive aspect became apparent as leadership was linked by definition to influence processes. Haiman (1951) suggested that "direct leadership is an interaction process in which an individual, usually

through the medium of speech, influences the behavior of others toward a particular end.” According to Gerth and Mills (1953), “leadership + is a relation between leader and led in which the leader influences more than he is influenced: because of the leader, those who are led act or feel differently than they otherwise would.” For Cartwright (1965), leadership was equated with the “domain of influence.” Katz and Kahn (1966) considered “the essence of organizational leadership to be the influential increment over and above mechanical compliance with routine directions of the organization.” They observed that although all supervisors at the same level of an organization have equal power, they do not use it with equal effectiveness to influence individuals and the organization. In the same way, Hollander and Julian (1969) suggested that “leadership in the broadest sense implies the presence of a particular influence relationship between two or more persons.”

According to Hemphill (1949a), an individual’s effort to change the behavior of others is “attempted” leadership. When the other members actually change, this outcome is “successful” leadership. If the others are reinforced or rewarded for changing their behavior, this evoked achievement is “effective” leadership. The distinctions between attempted, successful, and effective leadership are important because the dynamics of each are quite different. *Effective leadership* is *successful* influence by the leader that results in the attainment of goals by the influenced followers. Defining effective leadership in terms of attaining goals is especially useful because it permits the application of reinforcement theory to understand leader-follower behavior (Bass, 1960). “Emergent” leadership is a more widely used catch-all term for what occurs when leadership is attempted but may or may not be successful or effective.

The concept of influence recognizes the fact that individuals differ in the extent to which their behaviors affect the activities of a group. It implies a reciprocal relationship between the leader and the followers, but one that is not necessarily characterized by domination, control, or induction of compliance by the leader. It merely states that leadership, if successful, has a determining effect on the behaviors of group members and on activities of the group.

There is reciprocal influence between leaders and followers. In a dyad, if A influences B more than B influences A, A is leading B and B is following A (Bass, 1960). With regard to a larger group, Simonton (1994) suggests that the leader is the member whose influence on the group’s attitudes, performance, or decision making greatly exceeds that of the average member. The definition of influence also recognizes that by their own example, leaders can influence other members of a group. The Israeli lieutenant leads with the call, “Follow me.” Leaders serve as models for the followers. As Gandhi suggested, “Clean examples have a curious method of multiplying themselves” (Paige, 1977, p. 65).

*Leadership as Discretionary Influence.* Numerous theorists have wanted to limit leadership to influence that is not mandated by the leader’s role. As noted before, Katz and Kahn (1966) defined leadership as an influential increment over and above compliance with the routine directives of an organization. J. A. Miller (1973a) saw leaders as exerting influence “at the margin” to compensate for what was missing in a specified process and structure. Jacobs and Jaques (1987) conceived of and viewed leadership in complex organizations as “discretionary action directed toward dealing with unanticipated events that otherwise would influence outcomes of critical tasks at the actor’s level.” Osborn, Hunt, and Jauch (1980) focused attention on discretionary leadership as influence over and above what is typically invested in a role and typically required of a position. It is influence beyond what is due to formal procedures, rules, and regulations. Thus managers are leaders only when they take the opportunity to exert influence over activities beyond what has been prescribed as a requirement of their role.

*Leadership as the Art of Inducing Compliance.* Munson (1921) defined leadership as “the ability to handle men so as to achieve the most with the least friction and the greatest cooperation. + Leadership is the creative and directive force of morale.” According to F. H. Ailport (1924), “leadership + is personal social control.” B. V. Moore (1927) reported the results of a conference at which leadership was defined as “the ability to impress the will of the leader on those led and induce obedience, respect, loyalty, and cooperation.”

Similarly, Bundel (1930) regarded leadership as “the art of inducing others to do what one wants them to do.” According to T. R. Phillips (1939), “leadership is the imposition, maintenance, and direction of moral unity to our ends.” Warriner (1955) suggested that “leadership as a form of relationship between persons requires that one or several persons act in conformance with the request of another.” For Bennis (1959), “leadership can be defined as the process by which an agent induces a subordinate to behave in a desired manner.” According to Barker (1994), this definition is traceable to Machiavelli’s ideas about leadership as a matter of controlling others.

The “compliance induction” theorists, perhaps even more than the personality theorists, tended to regard leadership as a unidirectional exertion of influence and as an instrument for molding the group to the leader’s will. They expressed little recognition of the rights, desires, and necessities of group members or of a group’s traditions and norms. This disregard for the followers and the group was rejected by various other theorists, who sought to remove, by definition, any possibility of legitimating an authoritarian concept of leadership. Yet, regardless of the sentiments of some behavioral scientists, one cannot ignore that much leadership is authoritarian, directive, and even coercive. Its effects are seen in public compliance but not necessarily in private acceptance. Nonetheless, compliance with the leader’s point of view may be reinforced by identification with the leader and internalization of the perspective by the followers.

### ***Defining Leadership as an Effect***

*The Leader as an Instrument of Goal Achievement.* Numerous theorists have included the idea of goal achievement in their definitions. Several have defined leadership in terms of its instrumental value for accomplishing a group’s goals and satisfying needs. According to Cowley (1928), “a leader is a person who has a program and is moving toward an objective with his group in a definite manner.” Bellows (1959) defined leadership as “the process of arranging a situation so that various members of a group, including the leader, can achieve common goals with maximum economy and a minimum of time and work.” For Knickerbocker (1948), “leadership exists when a leader is perceived by a group as controlling [the] means for the satisfaction of their needs.”

Classical organizational theorists defined leadership in terms of achieving a group’s objectives. R. C. Davis (1942) referred to leadership as “the principal dynamic force that motivates and coordinates the organization in the accomplishment of its objectives.” Similarly, Urwick (1953) stated that the leader is “the personification of common purpose not only to all who work on the undertaking, but to everyone outside it.” K. Davis (1962) defined leadership as “the human factor which binds a group together and motivates it toward goals.” Cattell (1951) took the extreme position that leadership is whatever or whoever contributes to the group’s performance. To measure each member’s leadership, Cattell noted, remove him or her from the group, one at a time, and observe what happens to the group’s performance. In a similar vein, as noted earlier, both Calder (1977) and Pfeffer (1977)<sup>4</sup> stated that leadership is mainly influence and is even attributed to participants after the fact. The attributions may be based on implicit theories of leadership (Rush, Thomas, & Lord, 1977). Implicit theories of leadership are what we expect leaders to say and do, the traits and behaviors we attribute to the stereotype of a leader. Offerman, Kennedy, and Wirtz (1994) reviewed the content, structure, and generalizability of implicit leadership theories.

For Burns (1978), Bennis (1983), Bass (1985a), and Tichy and Devanna (1986), leadership can transform followers, create visions of the goals that may be attained, and articulate for the followers the ways to attain those goals. Luis Muñoz Marín, former governor of Puerto Rico, said; “A political leader is a person with the ability to imagine non-existing states of affairs combined with the ability to influence other people to bring them about” (Paige, 1977, p. 65).

Envisioning goals involves intuition, fantasy, and dreaming, not just analytical, systematic, conscious thought processes. For Jack Sparks, the chief executive officer who transformed the Whirlpool Corporation, “the vision came after years of mulling over the kind of organization that Whirlpool could be, and after his constant interaction with people in other organizations and academics. The vision was his; and the strategic planning process became the vehicle for implementing that vision, not its source” (Tichy & Devanna, 1985, p. 138). Tucker (1981) observed that most current politicians must focus the attention of their constituents on short-term goals and programs. More statesmanlike opinion leaders are necessary to arouse and direct a democracy toward achieving longer-term goals, such as stabilization of the population, improvement of the environment, and arms control.

*Leadership as an Effect of Interaction.* Several theorists have viewed leadership not as a cause or control but as an effect of group action. Bogardus (1929) stated that “as a social process, leadership is that social inter-stimulation which causes a number of people to set out toward an old goal with new zest or a new goal with hopeful courage—with different persons keeping different places.” For Pigors (1935), “leadership is a process of mutual stimulation which, by the successful interplay of individual differences, controls human energy in the pursuit of a common cause.” For H. H. Anderson (1940), “a true leader in the psychological sense is one who can make the most of individual differences, who can bring out the most differences in the group and therefore reveal to the group a sounder base for defining common purposes.” The theorists in this group were important because they called attention to the fact that emergent leadership grows out of the interaction process itself. It can be observed that leadership truly exists only when it is acknowledged and conferred by other members of the group. Although these authors probably did not mean to imply it, their definitions suggested that this quality amounts to little more than passive acceptance of the importance of one’s status. An individual often emerges as a leader in consequence of interactions within the group that arouse expectations that he or she, rather than someone else, can serve the group most usefully by helping it to attain its objectives.

### ***Defining Leadership in Terms of the Interaction between the Leader and the Led***

*Leadership as a Process.* This definition of leadership as a process is becoming increasingly popular. It concerns the cognitions, interpersonal behaviors, and attributions of both the leaders and the followers as they affect each others’ pursuit of their mutual goals. For Northouse (2001), leadership is a process in which an individual influences a group of individuals to achieve a common goal. Leadership is not one-way but rather an interactive two-way process between a leader and a follower. Homans (1950) and Dansereau, Graen, et al. (1975) among many others, conceived the process as an exchange or transaction between the leader and the led. Such leadership can be enacted by any member of the group, not only the formally elected or appointed leader. Leaders and followers can exchange roles during the process. Yukl (1994) defined leadership in organizations as influence processes that interpret events for followers, the choice of objectives for the group or organization, the organization of work to accomplish the objectives, the motivation of followers to achieve the objectives, the maintenance of cooperative relationships and teamwork, and the enlisting of outsiders to support and cooperate with the group or organization.

*Leadership as a Power Relationship.* Most political theorists, from Machiavelli through Marx to the academic political scientists of the twenty-first century, conceived of power as the basis of political leadership. For Machiavelli, leaders had to concentrate on what was under their control, not on what was controlled by others. Leadership was an effort to create and maintain power over others (Barker, 1996). The social psychologists J. R. P. French (1956) and Raven and French (1958a, b) defined leadership in terms of differential power relationships among members of a group. Power may be referent, expert, reward-based,

coercive, or legitimate (see [chapter 11](#)). Power is “a resultant of the maximum force which A can induce on B minus the maximum resisting force which B can mobilize in the opposite direction.” Similarly, Janda (1960) defined “leadership as a particular type of power relationship characterized by a group member’s perception that another group member has the right to prescribe behavior patterns for the former regarding his or her activity as a member of a particular group.”

M. Smith (1948) equated leadership with control of the interaction process. Thus, “the initiator of an interaction, A, stimulates a second participant, B. A asserts control by interfering with B’s original course of action.” The use of power is regarded as a form of influence relationship. Some leaders tend to transform any opportunity for leadership into an overt power relationship. In fact, the very frequency of this observation, combined with the often undesirable consequences for individuals and societies, induced many theorists to reject the notion of authoritarian leadership. Nevertheless, many of those, like Bennis (1970), who were most committed at one time to openness, participatory approaches, and building trust, faced the world as it is, not as they would like it to be, and came to acknowledge the importance of power relations in understanding leadership. The power relationship may be subtle or obscure: “a power relation + may be known to both leader and led, or unknown to either or both” (Gerth & Mills, 1953). Myths and symbols about the master-slave relationship may unconsciously influence superior-subordinate relationships in modern organizations (Denhardt, 1987).

*Leadership as a Differentiated Role.* According to role theory, each member of a society occupies a position in the community, as well as in various groups, organizations, and institutions. In each position, the individual is expected to play a more or less well-defined role. Different members occupying different positions play different roles. Birth and class may force the differentiation of roles. According to the leader of Ponape, Heinrich Iriarte, some Micronesians are born to rule while others are born to serve (Paige, 1977, p. 6R).

Leadership may be regarded as an aspect of role differentiation. H. H. Jennings (1944) observed that “leadership appears as a manner of interaction involving behavior by and toward the individual ‘lifted’ to a leadership role by other individuals.” Similarly, C. A. Gibb (1954) regarded group leadership as a *position* emerging from the interaction process itself. For T. Gordon (1955), leadership was an interaction between a person and a group or, more accurately, between a person and the group members. Each participant in this interaction played a role. These roles differed from each other; the basis for their difference was a matter of influence—that is, one person, the leader, influenced; and the other persons responded.

Sherif and Sherif (1956) suggested that leadership is a role within the scheme of relations and is defined by reciprocal expectations between the leader and other members. The leadership role, like other roles, is defined by stabilized expectations (norms) that, in most matters and situations of consequence to the group, are more exacting and require greater obligations from the leader than do those for other members of the group. The recognition of leadership as an instrument of goal attainment, as a product of interaction processes, and as a differentiated role adds to the development of a coherent theory that fits most of the facts available to date. Leadership as a differentiated role is required to integrate the various other roles of the group and to maintain unity of action in the group’s effort to achieve its goals. Newcomb, Turner, and Converse (1965) observed that members of a group made different contributions to the achievement of goals. Insofar as any member’s contributions were indispensable, they could be regarded as “leader-like”; and insofar as any member was recognized by others as a dependable source of such contributions, he or she was leader-like. To be so recognized was equivalent to having a role relationship to other members. Much of the research on the emergence and differentiation of roles pertains equally to leadership. As Sherif and Sherif (1956) indicated, roles are defined in terms of the expectations that group members develop in regard to themselves and other members. Thus the theory and research pertaining to the reinforcement, confirmation, and structuring of expectations applies also to leadership. Of all the available definitions, the concept of leadership as a role is most firmly buttressed by research.

*Recognition of the Leader by the Led.* Matching of the leadership prototype of traits and behaviors with face-to-face contact is required for a more controlled cognitive process. The matching is based on socially communicated processes (Lord & Maher, 1991). These implicit theories or social representations of leadership vary in different professional groups, as was shown when 257 French professionals were asked to define a person they thought best suited to lead a work group (Francois, 1993). Lord and Maher (1991) found a correlation of .83 between prototypes of leadership in business and finance but a correlation of only .18 between prototypes of leadership in business and sports. Similarly, they found a correlation of .80 between religious prototypes and educational prototypes but no correlation between religious prototypes and prototypes of leadership in the media.

*Identification with the Leader.* There is an emotional connection between the leader and the led. The leader provides an example to be imitated by followers. The aspirations of the leader become the followers' own aspirations (Shamir, 1991).

*Leadership as a Combination of Elements.* Naturally, some scholars combine several definitions of leadership to cover a larger set of meanings. Bogardus (1934) defined leadership as "personality in action under group conditions. + not only is leadership both a personality and a group phenomenon, it is also a social process involving a number of persons in mental contact in which one person assumes dominance over the others." Previously, Bogardus (1928) described leadership as the creation and setting forth of exceptional behavioral patterns in such a way that other persons respond to them. For Jago (1982), leadership is the exercise of noncoercive influence to coordinate the members of an organized group in accomplishing the group's objectives. Leadership is also a set of properties attributed to those who are perceived to use such influences successfully. Other definitions, such as Barrow (1977), have combined interpersonal influence and collective efforts to achieve goals into the definition of leadership. Dupuy and Dupuy (1959) added to this combination of definitions that leadership also involved obedience, confidence, respect, and loyal cooperation from followers. Still others defined leadership as a collection of roles that emerge from an interactional process. For Tichy and Devanna (1986), the combination of power with personality defined the transformational leader as a skilled, knowledgeable change agent with power, legitimacy, and energy. Such a leader was courageous, considerate, value-driven, and able to deal with ambiguity and complexity.

To summarize, the search for the one and only proper and true definition of leadership seems to be fruitless. Rather, the choice of an appropriate definition should depend on the methodological and substantive aspects of leadership in which one is interested. For instance, if one is to make extensive use of observation, then it would seem important to define leadership in terms of activities, behaviors, or roles played; its centrality to group processes; and its compliance with observed performance—rather than in terms of personality traits, perceived power relations, or perceived influence. But if an extensive examination of the impact of the authority of leadership is the focus of attention, then it would seem more important to define leadership in terms of perceived influence, control, and power relations. Nonetheless, 84 social scientists from 56 countries meeting in Calgary, Canada, in 1994 for the Globe Project (House, Hanges, Javidan, et al., 2004), despite their linguistic and cultural diversity, could agree on a combination of elements regarded as universal and elements more specific to cultures. They concluded that *leadership was the ability to influence, motivate, and enable others to contribute to the effectiveness and success of the organizations of which they are members.*

## Leadership, headship, and Management

---

The concepts of leadership, headship, and management need to be distinguished from each other although the same person may be a department head and a leader of his or her department. The head or manager who is not a leader will plan but won't envisage an attractive future for the department. The head or manager who is not a leader will organize and structure the department, but won't enable its members to improve their performance. The head or manager will control what happens in the department but won't empower employees to make decisions. In 1950, a major complaint about leadership studies was that they concentrated on student leaders; in 2000, the complaint was that too many leadership studies focused on CEOs, managers, and administrators who were heads but might not be leaders.

Holloman (1986) conceived headship as being imposed on the group but leadership as being accorded by the group. C. A. Gibb (1969a, p. 213) distinguished leadership from headship as follows: (1) Headship is maintained through an organized system, not by group members' spontaneous recognition of an individual's contribution to group progress. (2) The group goal is chosen by the head person. (3) In headship, there is little sense of shared feeling in pursuit of the given goal. (4) In headship, there may be a wide social gap between the group members and the head. (5) The authority of the head derives from some power, external to the group, which he or she has over the members of the group. (6) The leader's authority is spontaneously accorded by fellow group members and particularly by followers.

Managers, executives, and agency officers must be both leaders and heads (Kochan, Schmidt, & de Catus, 1975). In its conception, leadership can include headship. Defined more broadly, leadership includes the many ways it is exerted by leaders and heads and the various sources of power that make it work (Bass, 1960). With the broader definition, *heads* lead as a consequence of their status—the power of the position they occupy. Without such status, *leaders* can still gain a commitment to goals and can pursue arbitrary coercive paths with their power if their esteem—their accorded value to the group—is high. But then their esteem is likely to suffer. Status and esteem are not all-or-none qualities. In any group, members are likely to vary in both. Therefore, leadership may be distributed among them in similar fashion.<sup>5</sup> Although there is usually one head of a group, we cannot ordinarily attribute all leadership that occurs in a group to just its head.

## An Evolving, Expanding Conceptualization of Leadership

---

It is not surprising that concepts and definitions of leadership have been evolving and expanding. In the first several decades of the twentieth century, leadership was considered a matter of impressing the will of the leader and inducing obedience. Currently, in the age of information, leadership is seen more as consulting and shared decision making. House (1995) noted a progressive broadening of the definition of leadership to include “contributing to social order, introducing major change, giving meaning and purpose to work and to organizations, empowering followers, and infusing organizations with values and ideology” (Clark & Clark, 1994, pp. 355–356).

Definitions can be used to serve a variety of purposes. The appropriate definition for a study of leadership depends on the purposes of the study (Bass, 1960). Yukl (1981, p. 2) concluded that “leadership research should be designed to provide information relevant to the entire range of definitions, so that over time it will be possible to compare the utility of different conceptualizations and arrive at some consensus on the matter.” Either by explicit statement or by implication, various investigators have developed definitions to serve different purposes: (1) to identify the object to be observed, (2) to identify a form of practice, (3) to satisfy a particular value orientation, (4) to avoid a particular orientation or implication for a practice, and (5) to provide a basis for the development of theory. (The hope is that the definitions will provide critical new insights into the nature of leadership.)

The definitions indicate a progression of thought, although historically many trends have overlapped. The

earlier definitions identified leadership as a focus of group process and movement—personality in action. The next definitions considered it the art of inducing compliance. The more recent definitions conceive of leadership in terms of influence relationships, power differentials, persuasion, influence on goal achievement, role differentiation, reinforcement, initiation of structure, and perceived attributions of behavior that are consistent with what the perceivers believe leadership to be. Leadership may involve all these things. Ciulla (1998, p. 11) noted that “... the problem of definition is not that scholars have radically different meanings of leadership. Leadership does not denote radically different things for different scholars. One can detect a family resemblance between the different definitions. All of them discuss leadership as some kind of process, act, or influence that in some way gets people to do something. A roomful of people, each holding one of these definitions of leadership, would understand each other. ... The definitions differ ... in their implications for the leader-follower relationship ... [and] how leaders get people to do things ... and how what is to be done is decided.”

*Applicability.* Leadership research faces a dilemma. A definition that identifies something for the production supervisor or an agency director is not necessarily the most useful one for the development of a broad theory. Thus a definition that enables the researcher to identify a group leader—the person whose behavior exercises a determining effect on the behavior of other group members—may not provide much insight into the processes and structures involved in the emergence and maintenance of leadership in specific situations and conditions. But if the results of research are to be applied by the production supervisor, the agency director, or the military officer, then the definitions must be as close as possible to their ways of “wording the world” (Van de Vail & Bolas, 1980). A definition should do more than identify leaders and indicate the means by which they acquire their positions. It should also account for the maintenance and continuation of leadership. Thus few groups engage in interaction merely for the purpose of creating leaders and dropping them as soon as they emerge. For the purposes of this handbook, leadership must be defined broadly.

The introduction of the concepts of goal attainment and the solution of problems in certain definitions recognizes the fact that leadership serves a continuing function in a group. But the definitions do not account for the continuation of leadership. The concepts of role, position, reinforcement of behavior, and structuring expectation serve better to account for the persistence of leadership. For the purposes of theory development, it would seem reasonable to include variables in the definition of leadership that account for the differentiation and maintenance of group roles. Finally, room is needed for a conception of leadership as an attribution that is consistent with the implicit theories about it that are held by the individuals and groups who are led.

Manz and Sims (1980, 1987) expanded the concept of leadership to “super-leadership” and “self-leadership.” Super-leaders lead others to lead themselves. Teams are organized for production or service, and the former supervisors and technical staff serve as outside consultants to these teams. The teams decide what is to be done and how it is to be done. Leadership is shared among team members.

Finally, room is also needed for a concept of leadership as an attribution that is consistent with the implicit theories about it that are held by the individuals and groups who are led. As Ciulla (1991) suggests, definitions of leadership can be regarded as more like theories. Some of these, such as servant leadership, leadership as shared vision, and transformational leadership, will be introduced in the discussions of theories of leadership in later chapters.

As we will see, some principles of leadership are universal. They have been validated across different tasks, groups, organizations, and countries. Others depend on circumstances. A definition that is relevant for research on a broad theory may not be applicable to specific leadership—say, that required by a factory manager, prison warden, or priest.

## Summary and Conclusions

---

The study of leaders and leadership is coterminous with the rise of civilization. Leadership is a universal phenomenon. It is not a figment of the imagination, although there are conditions in which the success or failure of groups and organizations will be incorrectly attributed to the leaders, rather than to environmental and organizational forces over which the leaders have no control. In industrial, educational, and military settings, and in social movements, leadership plays a critical, if not the most critical, role, and is therefore an important subject for study and research.

The years during and since World War II have seen increasing numbers of empirical studies of formal organizational leaders, in contrast to studies of informal leaders of small groups. Also, there has been less dependence on students as subjects. The period began with a primary focus on first-line supervisors. The focus then moved up to middle managers and administrators; and the twentieth century ended with substantially increased studies of senior executives. Again, as woman and minorities were increasingly appointed, elected, or self-selected to positions of leadership, studies of their performance as leaders increased, as did studies in health care, protective services, and other services in the past half century.

How to define leadership can generate long-drawn-out discussions, and such discussions have dominated the opening deliberations at many a scholarly meeting on the subject of leadership. Until an “academy of leadership” establishes an accepted standard definition, we must continue to live with both broad and narrow definitions, making sure we understand which kind is being used in any particular analysis.

Leadership is an interaction between two or more members of a group that often involves a structuring or restructuring of the situation and of the perceptions and expectations of the members. Leaders are agents of change, whose acts affect other people more than other people’s acts affect them. Leadership occurs when one group member modifies the motivation or competencies of others in the group. Leadership can be conceived as directing the attention of other members to goals and the paths to achieve them. It should be clear that with this broad definition, any member of the group can exhibit some degree of leadership, and the members will vary in this regard.

There are many possible ways to define leadership. However, the definition of leadership should depend on the purposes to be served. Leadership has been conceived as the focus of group processes, as a personality attribute, as the art of inducing compliance, as an exercise of influence, as a particular kind of activity, as a form of persuasion, as a power relation, as an instrument in the attainment of goals, as an effect of interaction, as a differentiated role, and as the initiation of structure. Definitions can be broad, including many of these aspects; or they can be narrow.

A distinction may be made between headship and leadership. One complex definition that has evolved, particularly to help us understand a wide variety of research findings, delineates effective leadership as the interaction among members of a group that initiates and maintains improved expectations and the competence of the group to solve problems or to attain goals. Types of leaders can be differentiated according to some of these definitions, more often on the basis of role, function, or context.

<sup>1</sup> See also Viteles (1953).

<sup>2</sup> Recognition of the importance to the notion of leadership and its development for all types of organizations is witnessed by the Alliance for Leadership Development, which includes the following members: American Leadership Forum of Houston; Association of American Colleges of Washington, D.C.; Association of Governing Boards of Universities and Colleges; Center for Creative Leadership of Greensboro, N.C.; Coro Foundation of St. Louis; International Leadership Center of Dallas, National Association of Secondary School Principals of Reston, Va.; and the National Executive Service Corps of New York. The Alliance's programs include the promotion of leadership-related conferences and publications.

<sup>3</sup> Details about these can be found in Clark, Freeman, and Britt (1987).

<sup>4</sup> Different definitions and conceptions of leadership have been reviewed briefly by Morris and Seeman (1950), Shartle (1951a, 1951b, 1956), L. F. Carter (1953), C. A. Gibb (1954, 1969a), Bass (1960), Stogdill (1975), and Schriesheim and Kerr (1977b).

<sup>5</sup> More will be said later about defining the effects of leadership.

### Types and Taxonomies

A simple model of leadership may be a list of different types of leaders grouped according to one or more characteristics about them. Taxonomy classifies them according to their mutual relationships, similarities, and differences. The model or taxonomy describes but does not explain the relationships, as would a theory. U.S. presidents, state governors, and city mayors form a threefold taxonomy. If the three categories are divided into Republican and Democratic, we obtain a more complex sixfold classification or taxonomy of Republican and Democratic presidents, governors, and mayors. This classification can be used to show how the different types of political leaders react, say, to pressures from their respective constituencies. A taxonomy is formed. Taxonomies are classifications in an ordered arrangement of types.

After defining leadership, earlier scholars usually developed a handy classification. This was either a simple typing of leaders or a multilayered taxonomy with formal rules for classifying the leaders by their roles, perceptions, cognitions, behaviors, traits, characteristics, qualities, and abilities. In *The Republic*, Plato offered three types of leaders of the polity: (1) the *philosopher-statesman*, to rule the republic with reason and justice; (2) the *military commander*, to defend the state and enforce its will; and (3) the *businessman*, to provide for citizens' material needs and to satisfy their lower appetites. This early taxonomy has been followed by a long line of taxonomies of leadership, some of which are probably being formulated at this moment by popularizers of the subject for sale in airport bookstores or for presentation in the popular press. A respite from new leadership typologies is unlikely in the foreseeable future, for although typologies lack rigor, they are appealing, convenient, and easy to discuss, comprehend, and remember.

One typology that continues to survive is formal versus informal leaders. *Formal* leaders are in positions that provide them with legitimacy and the power to lead. *Informal* leaders influence others as a consequence of their personal attributes and the esteem they are accorded. Compared with formal leaders, informal leaders are seen to be somewhat more communicative, relations-oriented, authentic, and self-confident (Pielstick, 2000). Informal leaders may emerge in newly formed small groups without structure—in street gangs, in small groups of friends, and in organizations independently of their positions (Bryman, 1992).

Different types of leaders have been studied. Many attempts have been made to extrapolate conclusions from one special type of leader and organization studied to leadership in general. The types of leaders studied have included task and team leaders as well as emergent, elected, or appointed small-group leaders. Early on, leaders of informal crowds and demonstrations were described. Some of the leaders studied in larger organizations have included college presidents, chief executive officers, military officers, school principals, student leaders, technical leaders, hospital and nursing administrators, and religious leaders—and have included leaders of revolutionaries, juvenile delinquents, criminals, and terrorists. Managers at all levels of business and industry, consumer-opinion leaders, work teams, minority leaders, women leaders, public officials, athletic leaders, child and adolescent leaders, leaders of social movements, political leaders, and administrators at all levels of various public agencies and private institutions have also been considered. Taxonomies have been created within and among these types.

### Types of Leadership in Small Groups

---

Leaders of small groups have been classified in many ways, according to their different functions, roles, and behaviors. Pigors (1936) observed that leaders in group work tend to act either as masters or as educators. Cattell and Stice (1954) identified four types of leaders in experimental groups: (1) *persistent, momentary problem solvers*, who have a high rate of interaction; (2) *salient* leaders, who observers think exert the most powerful influence on the group; (3) *sociometric* leaders, who are nominated by their peers; and (4) *elected* leaders. Bales and Slater (1955) observed that the leader performs two essential functions; the first is associated with productivity, and the second is concerned with the socioemotional support of the group members.

Benne and Sheats (1948) proposed that group members who exert leadership play three types of functional roles: (1) group-task roles, such as *initiator*, *gatekeeper*, and *summarizer*; (2) group-building and group-maintenance roles, such as *harmonizer*, *supporter*, and *tension reducer*; and (3) individual roles, such as *blocker*, *pleader*, and *monopolizer*. Bales (1958a) noted that the first two roles are the major functions of leadership in small experimental groups. For Hemphill (1949a), the leader's behavior could be typed according to how much he or she set group goals with the members, helped them to reach the goals, coordinated their efforts, helped them fit into the group, expressed interest in the group, and showed humanness.

From another point of view, Roby (1961) developed a mathematical model of the functions of leadership that was based on response units and information load and developed the following classification of leadership functions: (1) to bring about congruence of goals among the members; (2) to balance the group's resources and capabilities with environmental demands; (3) to provide group structure that would focus information effectively on solving the problem; and (4) to make certain that all needed information is available at a decision center when required.

According to Schutz (1961b), the functions of leadership could be classified as follows: (1) to establish and recognize a hierarchy of group goals and values; (2) to recognize and integrate the various cognitive styles that exist in the group; (3) to maximize the utilization of group members' abilities; and (4) to help members resolve problems that involve adapting to external realities as well as the fulfillment of interpersonal needs.

S. Levine (1949) identified four types of leaders: (1) the *charismatic* leader, who helps the group rally around a common aim but tends to be dogmatically rigid; (2) the *organizational* leader, who emphasizes effective action and tends to drive people; (3) the *intellectual* leader, who usually lacks skill in attracting people; and (4) the *informal* leader, who tends to adapt his or her style of performance to the group's needs.

Clarke (1951) proposed three types of leaders applicable to small groups: (1) *popular* leaders, who wield influence because of their unique combination of personality traits or ability; (2) *group* leaders, who, through their understanding of personality, enable group members to achieve satisfying experiences; and (3) *indigenous* leaders, who arise in a specific situation when group members seek support and guidance.

Getzels and Guba (1957) offered three types of leadership, two of which are associated with separate dimensions of group activity: (1) *nomothetic* leadership, which is involved with the roles and expectations that define the normative dimensions of activity in groups; (2) *ideo-graphic* leadership, which is associated with the individual needs and dispositions of members that define the personal dimensions of group activity; and (3) *synthetic* leadership, which reconciles the conflicting demands that arise from the two contrasting subgroups within a group. Bowers and Seashore (1967) maintained that the functions of leadership are support of members, facilitation of interaction and of work, and emphasis on goals. Cattell (1957) observed that the leader performs the following functions: maintaining the group, upholding roles and status satisfaction, maintaining task satisfaction, keeping ethical (norm) satisfaction, selecting and clarifying goals, and finding and clarifying means of attaining goals.

Using a factor analysis of behavioral ratings, Oliverson (1976) identified four types of leaders in 24 encounter groups: (1) *technical*, (2) *charismatic*, (3) *caring-interpersonal*, and (4) *peer-oriented*. The *technical leader* emphasizes a cognitive approach; the *charismatic* leader stresses his or her own impressive attributes; and types 3 and 4 accentuate the facilitation of interpersonal relations with caring and friendship.

After observing 16 group-therapy leaders of various theoretical persuasions, Lieberman, Yalom, and Miles (1973) formulated three types of group leaders: (1) *charismatic energizers*, who emphasize stimulation; (2) *providers*, who exhibit high levels of cognitive behavior and caring; and (3) *social engineers*, who stress management of the group as a social system for finding intellectual meaning. Three other styles—*impersonal*, *manager*, and *laissez-faire*—were variants of the initial three. Therapeutic change in participants was highest with providers and lowest with managers. Casualties were highest with energizers and impersonals and lowest with providers. Again from observations of therapy groups, Redl (1948) suggested that the leader may play the role of *patriarch*, *tyrant*, *ideal*, *scapegoat*, *organizer*, *seducer*, *hero*, and *bad* or *good influence*.

Komaki, Zlotnick, and Jensen (1986) provided a sophisticated and rigorous approach to classifying the behavior of leaders on the basis of a minute-by-minute time sampling of coded observations in a small-group setting. Their taxonomy, which was constructed to provide observers a way to categorize specific supervisory behaviors, includes seven categories. The first three categories are derived from operant-conditioning theory; they are related to effective supervision: (1) consequences of supervisees' performance, indicating knowledge of performance; (2) monitors of performance, involving collecting information; (3) performance antecedents, providing instructions for performance; (4) "own performance," referring to the supervisor's performance; (5) "work-related," referring to work but not performance; (6) "non-work-related," not pertaining to work; and (7) solitary, not interacting with others. The categories are linked, as shown in [Figure 2.1](#).

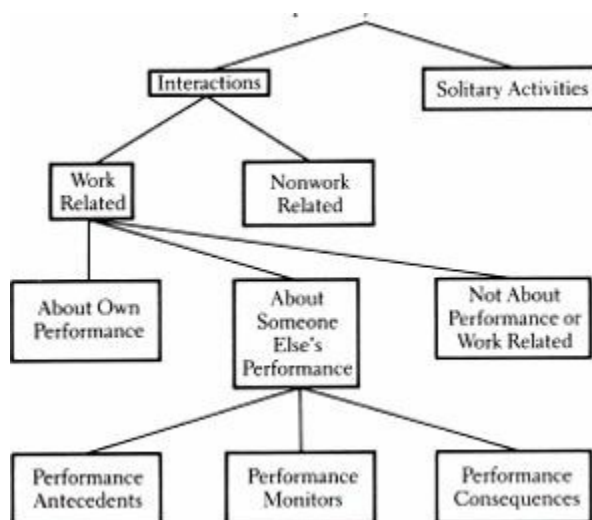

Analyses of the behavior of leaders have also produced many other categorizations of such behavior in small groups (e.g., Reaser, Vaughan, & Kriner, 1974). Much of the leadership in small groups has relevance for groups within larger organizations and institutions.

## Types of Leadership in Organizations and Institutions

Presentations of types of leaders in organizations and institutions coincided with the appearance of essays on effective management. J. H. Burns (1934) proposed the following types: the *intellectual*, the *business* type, the *adroit diplomat*, the leader of small groups, the mass leader, and the administrator.

Bogardus (1918) distinguished four types of organizational and institutional leaders: (1) the *autocratic* type, who rises to office in a powerful organization; (2) the *democratic* type, who represents the interests of a group; (3) the *executive* type, who is granted leadership because he or she is able to get things done; and (4) the *reflective-intellectual* type, who may find it difficult to recruit a large following.

Figure 2.1 Operant Taxonomy of Supervisory Behavior

SOURCE: J. L. Komaki, S. Zlotnick, and M. Jensen, "Development of an Operant Based Taxonomy and

Observational Index of Supervisory Behavior,” *Journal of Applied Psychology*, 1986. Copyright 1986 by the American Psychological Association. Reprinted by permission of the publisher and author.

Sanderson and Nafe (1929) proposed four types of leaders: (1) the *static* leader is a professional or scientific person of distinction whose work influences the thoughts of others; (2) the *executive* leader exercises control through the authority and power of position; (3) the *professional* leader stimulates followers to develop and use their own abilities; (4) the *group* leader represents the interests of group members.

Chapin (1924a) differentiated *political-military* from *socialized* leaders. Political-military leaders imbue the masses with their personality; socialized leaders influence their followers to identify themselves with the common program or movement.

In Bartlett’s (1926) threefold classification: (1) *institutional* leaders are established by virtue of the prestige of their position; (2) *dominative* types gain and maintain their position through the use of power and influence; and (3) *persuasive* types exercise influence through their ability to sway the sentiments of followers and to induce them to action.

In seminal German publications in 1921 and 1922, Weber (1947) delineated three types of legitimate authority in organizations and institutions, each associated with a specific type of leadership: (1) *bureaucratic* leaders operate with a staff of deputized officials and are supported by legal authority based on rational grounds. Their authority rests on belief in the legality of normative rules and in the right of those who are elevated to authority under such rules to issue commands; (2) *patrimonial* leaders operate with a staff of family relatives rather than officials. They are supported by traditional authority that rests on the sanctity of immemorial traditions and the legitimacy of status of those who exercise authority under them; (3) *charismatic* leaders operate with a staff of disciples, enthusiasts, and perhaps bodyguards. Such leaders tend to sponsor causes and revolutions and are supported by charismatic authority that rests on devotion to the sanctity, heroism, or inspirational character of the leaders and on the normative patterns revealed or ordained by them. House and Adidas (1995) equated *charismatic* with *transformational* leaders; but Bass (1985a) suggested that charismatic and inspirational leaders formed a single factor differentiated from the transformational factors of *intellectual stimulation* and *individualized consideration*. Jennings (1960) typed these charismatic and patrimonial leaders differently. The great men who break rules and value creativity are *supermen*; those who are dedicated to great and noble causes are *heroes*; and those who are motivated principally to dominate others are *princes*. Princes may maximize the use of their raw power, or they may be great manipulators. Heroes come in many varieties, including heroes of labor, consumption, and production; risk-taking heroes; and war heroes. Supermen may or may not seek power to dominate others.

Several commentators have noted that types of leadership are classifiable according to the model of organization in which the leadership occurs. Golembiewski (1967) proposed that the *collegial* model of organization permits leadership to pass from individual to individual at the same level in the organization. The *traditional* model implies that leadership is retained within the positions established by a hierarchy of authoritative relationships.

Influenced by Burns and Stalker (1961), Sedring (1969) suggested that political leaders in the adaptive, *organismic* model of organization are characterized by inter dependence, evolutionary change, and domination by factors that involve the whole organization of which their unit is a part.<sup>1</sup> In the rule-based *mechanistic* model of organization, leaders are classified by a lack of integration, by conflict in relationships, and by dominance by factors in their own units. Morrow and Stern (1988) typed managers according to their performance in assessment programs.<sup>2</sup> The *stars* were smart, sensitive, social, self-assured, sustained self-starters. The next best in assessments were the *adversaries*, who were able, analytic, argumentative, adamant, abrupt, and abrasive. The least adequate, according to their assessment, were the persevering, pain staking *producers* and the *phantoms* (polite, passive, and perturbed).

On the basis of John Dewey's philosophy and a search of the literature, Lippitt (1999) proposed six types of leaders of organizations, according to their priorities: (1) *inventor* (developing new ideas, products, and services); (2) *catalyst* (gaining market share and customers); (3) *developer* (creating systems for high performance); (4) *performer* (improving processes for effective use of resources); (5) *protector* (building a committed workforce and supporting values, identity, and culture); (6) *challenger* (identifying strategic options and positioning the organization for the future).

Maccoby (1979) posited three ideal types of leaders of business and industry in a longer view of production in the United States in the past 200 years: (1) *craftsman*, (2) *jungle fighter*, and (3) *gamesman*. These types matched the ideals of the prevailing social character of the time, which was linked to the mode of production then dominant and the leaders' functions in production and service. The independent craftsman was the prototypical social character in Jefferson's idealized democracy of farmers, craftsmen, and small businessmen. Leaders were independent lawyers, physicians, small businessmen, and farmers. They espoused egalitarian, autonomous, disciplined, and self-reliant virtues. After the Civil War, the paternalistic empire builder came to the fore, reflecting the rags-to-riches entrepreneurial spirit of Horatio Alger's stories. In this post-1865 social and economic environment, "ambitious boys had to find new fathers who had mastered the new challenges. The *paternalistic* leader ... appealed to the immigrant ... in need of a patron. ... The still independent craftsmen ... were forced into increasingly routinized factory jobs [and] struggled [by unionizing] against the paternalistic *jungle fighter*" (Maccoby, 1979, p. 308). The second ideal leader, the empire builder, the lionlike jungle fighter with patriarchal power, gave way to the third ideal, the *gamesman*. The gamesman emerged in the twentieth century when social character became more self-affirmative and the spirit more meritocratic. Adventurous and ambitious but fair and flexible leadership became the dominant ideal. "With a boyish, informal style, ... [the gamesman] controls subordinates by persuasion, enthusiasm, and seduction rather than heavy and humiliating commands. Fair but detached, the gamesman has welcomed the era of rights and equal opportunity as both a fair and an efficient climate for moving the 'best' to the 'top' " (Maccoby, 1979, p. 309). The gamesman enjoys challenges and is daring, willing to innovate and to take risks (Maccoby, 1976). But the gamesman can become a liability to a firm when one person's gain can be another person's loss. Leadership is needed that values caring and the assurance that no one will be penalized for cooperation. Both sacrifice and reward need to be shared equitably (Maccoby, 1981).

In U.S. industry, *task-oriented* leaders dominated production in the 1940s, when everything that was produced could be easily sold. In the 1950s, these leaders gave way to *relations-oriented* leaders, who had to find markets for what was produced in an "other-oriented" nation of conformists. For a nation that next turned inward, *self-oriented* leaders emerged in the late 1960s and 1970s during the "me too" generation of drugs and flower children. Between 1980 and 2005, increased task-orientation was reflected in the start-ups in electronics and biotech firms coupled with increased relations-orientation to family and increased scandalous self-oriented, self-serving behavior in business and government, and then a turning inward toward spirituality and religiosity.

*Executive Characteristics.* Zaccaro (1996) used job analyses and psychological assessments to categorize required characteristics and skills for the executive position: *cognitive capacities and skills* (intelligence, analytical reasoning, ability to integrate complexities flexibly, verbal skills, writing skills, and creativity); *social capacities and skills* (social reasoning, behavioral flexibility, and skills in negotiation, persuasion, and conflict management); *personality traits* (openness, curiosity, self-discipline, flexibility, willingness to take risks, and inner locus of control); *motivation* (self-efficacy, need for achievement, need for socialized power); *expertise and knowledge*, and *metacognitive skills* (the ability to construct problems, encode information, specify categories, combine and reorganize best-fitting categories, evaluate ideas, implement, and monitor) were required. Also required was the need to know when to apply these skills (Mumford, Zaccaro, Harding, et al.,

1993).

*Leaders of Crowds.* Leaders of mobs and crowds were the first to be given social psychological classification. LeBon (1897) described the crowd leader as a persuasive person of action whose intense faith and earnestness resist all reasoning and impel the mob to follow. Influenced by LeBon (1897), Conway (1915) observed three types of crowd leaders: (1) the “crowd-compeller” inflames followers with his or her point of view; (2) the “crowd-exponent” senses what the crowd desires and gives expression to it; and (3) the “crowd-representative” merely voices the already formed opinions of the crowd.

Since these early views about leadership of a crowd, spontaneous crowds have frequently been replaced by organized demonstrations complete with television reporters. In such demonstrations, the leader must add considerable administrative effort to this overall performance; usually, the leader here is Conway’s third type—the crowd-representative—speaking to the already converted. Advanced planning as to time and place are important for the mobilization to be effective.

*Student Leaders.* As a result of observations and interviews, Spaulding (1934) classified elected student leaders into the following five types: (1) the social climber, (2) the intellectual success, (3) the good fellow, (4) the big athlete, and (5) the leader in student activities. From then on, the typing of student leaders as social, political, athletic, or intellectual became a common practice.

*Educational Leaders.* Typologies of educational leaders have included teachers, principals, and staff members in elementary, middle, and high schools. Likewise, studies have been completed of students, faculty members, department chairs, deans, presidents, and administrative leaders in colleges, universities, and technical schools. Harding (1949) distinguished 21 types of adult educational leaders: (1) autocrat, (2) cooperator, (3) elder statesman, (4) eager beaver, (5) pontifical type, (6) muddled person, (7) loyal staff person, (8) prophet, (9) scientist, (10) mystic, (11) dogmatist, (12) open-minded person, (13) philosopher, (14) business expert, (15) benevolent despot, (16) child protector, (17) laissez-faire type, (18) community-minded person, (19) cynic, (20) optimist, and (21) democrat.

Benezet, Katz, and Magnusson (1981) classified college presidents as founding presidents, explorers, take-charge presidents, standard-bearers, organization presidents, and moderators. A *founding* president fulfills many assignments until a regular staff has been assembled. The *explorer* brings on new programs and risky new plans; the *take-charge* president holds together an institution that is facing great difficulties; the *standard-bearer* leads an institution that has “arrived”; the *organization* president is a pragmatic administrator; and the *moderator* is an egalitarian administrator who consults with and delegates a great deal to faculty members and student leaders.<sup>3</sup>

Birnbaum (1988) typed college presidents as bureaucratic, collegial, political, or symbolic. They differed in their orientation toward their college’s faculty, administrators, students, alumni, and finances. Looking to the future, Weber (1995) saw a need to replace the traditional bosses of command-structured organizations with leaders who were mentors, guides and cheerleaders.

*Public Leaders: Statesmen, Politicians, and Influential People.* Credit is due to Plato for the first taxonomy of political leaders. Plato classified such leaders as *timocratic*, ruling by pride and honor; *plutocratic*, ruling by wealth; *democratic*, ruling by popular consent on the basis of equality; and *tyrannical*, ruling by coercion (Shorey, 1933). This classification fits well with much of what will be analyzed in later chapters about the bases of influence and power. Plutocratic, democratic, and tyrannical leaders remain in the popular lexicon of political leadership.

Beckhard (1995) put public leaders into six commonly used categories: (1) *political* leaders, (2) leaders of *social change*, (3) leaders in *social science*, (4) leaders in *applied social thought*, (5) leaders of *business*

*organizations*, and (6) leaders of *nongovernmental agencies*. What they all have in common is ego strength, strong convictions, and political astuteness. They need to use their power for efficiency and for the largest good.

Wills (1994) covered a much broader array of 16 representative archetypes of leaders, as well as their antitypes. The taxonomy mixed leadership roles, personality traits, cognition, styles, and behaviors. Many of the types overlapped considerably. These are common defects in many taxonomies, particularly those in popular books for the layperson. To illustrate, Wills's taxonomy comprised the democratically elected leader as the archetype versus the also-ran as the antitype, the radical leader versus the reactionary, the reform versus the conservative leader, the diplomatic versus the undiplomatic leader, the successful versus the unsuccessful military leader, the charismatic versus the bureaucratic leader, the effective versus the ineffective business leader, the revisionist of tradition versus the traditional leader, the constitutional versus the unconstitutional leader, the intellectual leader with consideration for others versus the intellectual without consideration, the church organizer versus the nonorganizer, the sports organizer with and without consideration for others, the artistic leader versus the exploiter, the rhetorical leader versus the nonuser of speeches, the opportunistic versus the inflexible leader, and the saintly versus the self-centered leader.

With respect to public leadership, Bell, Hill, and Wright (1961) identified *formal* leaders (who hold official positions, either appointed or elected), *reputational* leaders (who are believed to be influential in community or national affairs), *social* leaders (who are active participants in voluntary organizations), and *influential* leaders (who influence others in their daily contacts).

Haiman (1951) suggested that five types of leaders are needed in a democracy: (1) the executive, (2) the judge, (3) the advocate, (4) the expert, and (5) the discussion leader.

Hermann (1980) categorized political leaders, such as members of the politburo in the Soviet Union, according to whether they were generally sensitive to the political context and whether they wanted to control what happened or be an agent for the viewpoints of others.

Kaarbo and Hermann (1998) presented a taxonomy concerning political leaders' style of involvement in foreign policies according to their degree of interest and experience (high, moderate, low) and focus (developing policy or building support). Managing information was classified into those who interpret or filter sources of information (or do both). Additionally, managing conflict was categorized with the leader as advocate, consensus-builder, or arbitrator and as locus of decision (exclusive or inclusive, and balancer or bridge).

*Prophets.* For Kincheloe (1928), prophets were leaders without offices. Although prophets may arise in times of crisis, they create their own situation. Their real ability is to arouse their followers' interest so that the followers will accept prophetic goals and support these goals enthusiastically. Prophets become a symbol of the movement they have initiated, and their authoritative words tend to release inhibited impulses within their supporters. Kiernan (1975) clustered leadership patterns in African independent churches into two types: (1) preachers and prophets; and (2) chiefs, prophets, and messiahs.

*Local Government Leaders.* Parry (1999) coded respondents in interviews to study processes of social influence in local government authorities during times of turbulent change. Leadership strategies were seen as deliberate plans or emergent perspectives. Other categories of response included resolving uncertainty, clarifying roles, and enhancing adaptability.

Kotter and Lawrence (1974) subdivided city mayors into categories on the basis of the agendas set by the mayors, the networks they built, and the tasks they accomplished. *Ceremonial* mayors set short-run agendas of small scope; they were individualistic and had a personal appeal but no staffs. *Personality-individualistic* mayors also had no staff, but the scope of their agendas was greater and the time involved in them was longer.

*Caretakers* set short-run agendas of large scope, had loyal staffs, and were moderately bureaucratic. *Executive* mayors set agendas of large scope and of longer range, had staffs, were bureaucratic, and had a mixed appeal. *Program entrepreneurs* set the agendas of the largest scope, had staff resources, and built extensive networks with mixed appeals.

*World-Class Political Leaders.* As an example of an empirical approach, Bass and Farrow (1977a) identified six types of world-class political leaders according to their leadership styles as revealed in an inverse factor analysis. Pairs of judges independently completed a 135-item questionnaire to describe the leaders on 31 scales after they had read considerable amounts of biographical literature written mainly by the immediate subordinates of the leaders. The 15 leaders were intercorrelated according to their scores on the 31 scales through use of the Bass and Valenzi systems model (Bass, 1976). An inverse factor analysis generated six clusters in relation to the behavior of leaders and subordinates, with the highest loadings for clustered figures as follows:

*Autocratic-submissive:* Adolf Hitler, Joseph Stalin, Nicholas II, Louis XIV.

*Trustworthy subordinates:* Hirohito, Alexander the Great, Franklin Delano Roosevelt.

*Clear, orderly, relationships:* Winston Churchill. *Structured, sensitivity to outside pressures:* Fiorello La Guardia, John F. Kennedy, Franklin Delano Roosevelt.

*Satisfying differential power:* Lenin.

*Egalitarian, analytic:* Thomas Jefferson.

*Revolutionary versus Loyalist Leaders.* Rejai and Phillips (1988) discriminated between 50 well-known revolutionary leaders such as Fidel Castro, Thomas Jefferson, and Ho Chi Minh; and 50 who remained loyal to the existing government such as Fulgencio Batista, Thomas Hutchinson, and Nguyen Van Thieu. *Revolutionaries* were statistically more likely to abandon their religion and become atheists; they had fathers who had *not* been officials in government, the military, banking, or industry, or members of the landed gentry. They had an optimistic view of human nature but fluctuated in their attitudes toward their own country. By contrast, *loyalists* remained steadfast in their religious beliefs and had fathers who were more likely to be government officials or in the military, banking, and industry. They themselves were more likely to be in government service, and pessimistic about human nature but optimistic about their own country.

*Legislative Leaders.* J. M. Burns (1978) classified legislative leaders as ideologues, tribunes, careerists, parliamentarians, or brokers. *Ideologues* speak for doctrines (economic, religious, or political) that may be supported widely throughout their constituency but more typically are held by a small though highly articulate minority. *Tribunes* are discoverers or connoisseurs of popular needs; defenders of popular interests; or advocates for popular demands, aspirations, and governmental actions. *Careerists* see their legislative careers as a stepping-stone to higher office, provided they do a job that impresses their constituents and other observers. *Parliamentarians*, as political technicians, either expedite or obstruct legislation. They bolster the legislature as an institution of tradition, courtesy, mutual forbearance, and protection of fellow members. *Brokers* mediate among antagonistic legislators, balancing interests to create legislative unity and action.

*Military Leaders.* The military hierarchy is classified from general officer to private soldier. An example of a statistically sophisticated taxonomy of army leaders was created by Mumford, Zaccaro, Johnson et al. (2000). Their taxonomy of seven types of U.S. Army officers was based on matching profiles of abilities, personalities, and motivational characteristics with the requirements of their positions. A  $d^2$  indexed the similarity of each profile to each officer's positional requirements. The officers were then clustered according to how well their profiles matched or failed to match the requirements for junior officer, either lieutenant or captain. Seven types of the 786 junior officers emerged; these types could also be applied to classifying 275

senior officers (captains to colonels) in the same way. The percentage of junior and senior officers of each type is shown below.

	Junior Officers	Senior Officers
Concrete Achievers	20%	11%
Motivated Communicators	17	40
Limited Defensive	15	12
Disengaged Introverts	10	16
Social Adapters	12	30
Struggling Misfits	13	3
Thoughtful Innovators	11	26

*Stereotypes of Woman Leaders.* Influential women have been classified in a number of ways, some fitting stereotypes about women in the workplace.<sup>4</sup> Women in a community have been classified as *fashion leaders* and *trendsetters*, in contrast to those who are content to *accept, ignore, or resist change*. For example, in determining opinion leadership among women in a community, Saunders, Davis, and Monsees (1974) found it useful to classify 587 women who attended a family planning clinic in Lima, Peru, as *early* or *late* adopters and as *pre-* or *postaccepters* of family planning.

Hammer (1978) described four stereotypes of women leaders in the workplace. The *earth mother* brings home-baked cookies to meetings and keeps the communal bottle of aspirin in her desk. The *manipulator* relies on feminine wiles to get her way. The *workaholic* cannot delegate responsibility. The *egalitarian* leader denies the power of her leadership and claims to relate to subordinates as a colleague. Similarly, Kanter (1976, 1977a, 1977b) discerned four stereotypes of women leaders who work primarily in a man's world: The *mother* provides solace, comfort, and aspirin. The *pet* is the little sister or mascot of the group. The *sex object* fails to establish herself as a professional. The *iron maiden* tries too hard to establish herself as a professional and is seen as more tyrannical than she actually is.

### ***Sociopsychological Classifications***

Nafe (1930) pioneered the classification of leaders according to social or psychological dynamics of leaders and subordinates. Nafe presented a perceptive analysis of the *dynamic-infusive* leader who directs and redirects followers' attention to the perceptual and ideational aspects of an issue until thought has been transferred into emotion and emotion into action. According to Nafe "the attitude of the leader toward the led and toward the project is found to be a problem in name only. The leader needs only to have the appearance of possessing the attitude desired by the followers." The real problem is the attitude of the led toward the leader. The attributes of leadership exist only in the minds of the led: "The leader may be this to one and that to another, but it is only by virtue of having a following that he or she is a leader." The *adhesive* leader (who seems to share the followers' attitudes) is opposite in every respect to the *infusive* (inspiring and influential) type, according to Nafe, who added the following additional categories to his taxonomy: static versus dynamic, impressors versus expressors, volunteer versus drafted, general versus specialized, temporary versus permanent, conscious versus unconscious, professional versus amateur, and personal versus impersonal.

Using analogies with genetics, Krout (1942) identified the *social variant* leader, who arises out of the group's need to agree about its goals and what to do about its lagging forms of behavior. Krout also described *hybrid* leaders, who seek to change the social structure through discontinuous methods to achieve the group's goals; and *mutants*—innovators who redefine the cultural patterns of their group and may set new goals to

achieve their objectives for the group.

Jones (1983) described the ranges of leadership in terms of the kinds of control leaders exert that affect a follower's reactions. The leader can control (1) the *process* or the *output*, and can be (2) *obtrusive* or *unobtrusive*, (3) *situational or personal*, and (4) *paternalistic or professional*. This taxonomy can be used to explain how groups can be both satisfied with their situation and yet unproductive.

*Psychoanalytic Taxonomies.* From a psychoanalytic perspective, Redl (1942) suggested that instinctual and emotional group processes take place around a member whose role may be patriarch, leader, tyrant, love object, object of aggression, organizer, seducer, hero, bad example, or good example. Continuing in the same vein, Zaleznik (1974) contrasted charismatic leaders with consensus leaders. *Charismatic* leaders are inner-directed and identify with objects, symbols, and ideals that are connected with introjection. They are father figures. *Consensus* leaders "appear" to be brothers or peers, rather than father figures.

Kets de Vries and Miller (1984b, 1986) presented a sixfold psychopathological classification of executives to account for their dysfunctional performance: (1) persecutory, (2) preoccupied, (3) helpless, (4) narcissistic, (5) compulsive, and (6) schizoid-detached.<sup>5</sup>

Narcissists, "resentfuls," and "highly likable low achievers" were the three types of flawed managers described by Hogan, Raskin, and Fazzini (undated). The transference pattern of leaders' and followers' emotional relations were seen by Pauchant (1991) as depending on the self-development of the leader and follower.

## **Personality Types**

*Strengths and Signature Themes.* These self-ratings fall into three domains of leadership: (1) relating, (2) striving, and (3) thinking. The eight themes of *relating* include the most effective ways to work with others individually and in groups: (1) arranging; (2) developing; (3) empathizing; (4) individualizing perception; (5) caring for people and building rapport with them; (6) accepting responsibility and ownership of projects with accountability, dependability, and ethics; (7) radiating enthusiasm and creating fun; and (8) enjoying working together with associates as a team. Types of *striving* are achieving, activating, competing by measuring oneself against others, increasing determination in the face of resistance and obstacles, maintaining discipline and establishing structure in one's own life and environment, and being focused and goal-oriented. The domain of *thinking* encompasses concepts, strategic thinking, constant measurement to improve performance, and a perception of how systems can improve performance (Clifton, 2000). At Gallup management seminars, participants are encouraged to focus on further improving their strengths and not to be as concerned about their weaknesses (Clifton & Nelson, 1992).

*Character Types.* According to Pitcher (1997), there is a continuing crisis in management and organizational leadership; this is due to managers' and leaders' technocratic mentality and character, in contrast to those managers and leaders who are artists or craftsmen. *Technocrats* lack emotion, imagination, good judgment, and vision. They are analytical, intense, methodological, and detail-oriented. They are put into power to try to ensure rationality in decision making. They drive out of the organization those whom they perceive as emotional. *Artists* are people-oriented, entrepreneurial, bold, intuitive, and imaginative. They are visionary leaders who talk in metaphors rather than specifics. *Craftsmen* are dedicated, reliable, realistic, and knowledgeable. They appreciate the past and near future in their thinking. They have a realistic strategic vision. They have "people skills" and generate loyalty from subordinates. Technocrats downgrade artists and craftsmen, whereas artists and craftsmen admire and cooperate with each other.

Lewis, Kuhnert, and Maginnis (1987) sorted military officers into three character types. *Operators* have a personal agenda that they pursue without concern for others; they lack empathy and cannot be trusted. *Team*

players are highly sensitive to how others feel about them and value decisions according to what others will think or say, rather than according to the merits of the case. In contrast, *self-defining leaders* are personally committed to ideals and values and pursue what they regard as the right and most worthy solutions.

*Myers-Briggs Types.* Jung's (1971) psychoanalytic conceptualization was the basis of the popular Myers-Briggs fourfold classification of the thought processes of leaders and managers faced with decisions and problems. The Myers-Briggs Type Indicator (Myers & McCaulley, 1985) sorts leaders into four types and 16 subtypes based on their responses to the indicator. Leaders are: (1) *extroverted* or *introverted*, (2) *sensing* or *intuitive*, (3) *thinking* or *feeling*, and (4) *judging* or *perceiving*. The extrovert prefers the outer world of people, things, and activities, whereas the introvert prefers the inner world of ideas and concepts. The extrovert is gregarious and people-oriented; the introvert seeks accomplishment working with just a few key colleagues. The sensing type of leader is oriented toward facts, details, and reality; the intuitive leader is focused more on inferences, concepts, and possibilities. The thinking types prefer analysis, logical order, and rationality and are seen as "cold" by feeling types. The feeling types, who value feelings and harmony, are described as too "soft" by the thinking types. The judging types prefer to make decisions rapidly and move on to the next issue, but the perceiving types seek to delay decisions.

A sample of 875 U.S. managers who were tested by the Center for Creative Leadership (Osborn & Osborn, 1986) between 1979 and 1983 were distributed as follows: extroverts (50%), introverts (50%), sensors (52%), intuitives (48%), thinkers (82%), feelers (18%), judges (70%), and perceivers (30%).

The four Myers-Briggs types, as noted above, generate 16 subtypes of managers. The 875 managers were concentrated in four of the subtypes: ISTJ (introverted-sensing-thinking judges), ESTJ (extroverted-sensing-thinking judges), ENTJ (extroverted-intuitive-thinking judges), and INTJ (introverted-intuitive-thinking judges). Delunas (1983) showed that for 76 federal executives and managers from private industry, the Myers-Briggs types (sensors-perceivers, sensors-judges, intuitives-thinkers, and intuitives-feelers) were significantly linked with their most or least preferred administrative styles.

Data from almost 7,500 managers and administrators showed that the majority were types like judges who reached closure, rather than perceivers who missed nothing. They were more likely to be impersonal, logical, and analytical thinkers than to be more concerned with personal feeling and human priorities. The subtypes that were most likely to be concerned with enhancing human performance, the intuitive-feelers, were underrepresented except in human resources departments. Those who were involved in the production of tangible products or in following established procedures tended to be practical sensing types. Those who provided long-range vision tended to be imaginative, theoretical, intuitive types (McCaulley, 1989).

*Other Examples of Personality Types.* Other taxonomies of leadership based on personality have developed around scores that subjects obtain on various assessments of their personalities. For instance, using scales developed for the California Personality Inventory (CPI), Gough (1988) described four types of individuals who are found in diverse samples of students and adults: (1) *leaders*, (2) *innovators*, (3) *saints*, and (4) *artists*. Leaders and innovators are extroverts, but leaders are also ambitious, enterprising, and resolute, while innovators are adventurous, progressive, and versatile. Saints and artists are introverted, but the saints are steadfast, trustworthy, and unselfish whereas the artists are complex, imaginative, and sensitive. Leaders and saints accept norms; innovators and artists question norms. Although only 25% to 30% of the general population of students and adults were classified by the CPI as leaders, 66% of cadets at West Point were so typed. Leaders and innovators at West Point had a higher aptitude for military service than the saints or artists.

## Taxonomies of Leaders according to their Functions, roles, Perceptions, and Behavior

---

Many attempts have been made to categorize organizational leaders and managers specifically according to the kinds of functions they perform, the roles they play, of the behaviors they display, and their cognitions and perceptions. Numerous classification schemes have appeared. Many of them prescribe functions for the ideal organizational leader. Others are derived from empirical job analyses or factored behavioral descriptions of the actual work performed by managers and administrators. For example, both approaches have concluded that the organizational leader may play the role of final arbitrator, the superordinate whose judgment settles disputes among followers. This function was often considered critical for the avoidance of anarchy in political units and societies. The maintenance and security of the state, it was believed, depended on the existence of a legitimate position at the top, to which all followers would acquiesce to avoid the continuation of conflict among them.

## ***Functions***

Classical theories of ideal management indicated that the primary functions of managers and executives could be neatly characterized as planning, organizing, and controlling. Although coordinating, supervising, motivating, and the like were added to the list, they were seen merely as variations managers' and executives' function of organizational control. On the other hand, behavioral descriptions of the functions of actual managers and executives included defining objectives, maintaining goal direction, providing means for attaining goals, providing and maintaining the group structure, facilitating action and interaction in the group, maintaining the cohesiveness of the group and the satisfaction of members, and facilitating the group's performance of tasks.

The functions identified by the behavioral descriptions grew out of research on basic group processes and on the emergence of the leadership role and its contribution to the performance, interaction, and satisfaction of members who are engaged in a group task. The classical functions of planning, organizing, and controlling were concerned with the rationalized processes of formal organizations. Although these functions are generalized and abstract, they are by no means unreal; however, they tend to ignore the human nature of members of the organization and the limited rationality with which the manager must operate. Yet organizations strive for rationality. Understanding the purposes of a leader in an organization requires a consideration of his or her planning, directing, and controlling. However, many more behaviors emerge in large-scale descriptive surveys and interviews with leaders.

Mooney and Reiley (1931) identified the three functional processes in any organization as being the same as in any governmental entity: legislative, executive, and judicial. Coffin (1944) suggested that the three functions of organizational leadership were formulation (planning), execution (organizing), and supervision (persuading). Barnard (1946b) identified the functions of organizational leadership as (1) determination of objectives, (2) manipulation of means, (3) instrumentation of action, and (4) stimulation of coordinated effort. Davis (1951) was in agreement with many others in declaring that the functions of the business leader are to plan, organize, and control an organization's activities. In a study of leadership in Samoa, Kessing and Kessing (1956) identified the following leadership functions: consultation, deliberation, negotiation, the formation of public opinion, and decision making. Gross (1961) proposed these functions: to define goals, clarify, and administer them; to choose appropriate means; assign and coordinate tasks; to motivate; create loyalty; represent the group; and spark the membership to action.

Selznick (1957) suggested that the functions of organizational leadership include: (1) definition of the institution's mission and goals; (2) creation of a structure to achieve the institution's purpose; (3) defense of institutional integrity; and (4) reevaluation of internal conflict.

Katz and Kahn (1966) advocated three functions for organizational leadership: (1) policy formation (the introduction of structural change); (2) the interpretation of structure (piecing out the incompleteness of the

existing formal structure); and (3) administration (the use of a formal structure to keep the organization in motion and operating effectively).

Wofford (1967) proposed the following functions of management be selected: setting objectives, organizing, leading, and controlling. For Krech and Crutchfield (1948), a leader could be an executive, planner, policy maker, expert, representative of the external group, controller of internal relationships, purveyor of rewards and punishments, arbitrator and mediator, exemplar, symbol of the group, surrogate for individual responsibility, ideologist, father figure, and scapegoat.

T. A. Mahoney (1955, 1961) and colleagues (Ma-honey, Jerdee, & Carroll, 1965) typed managers according to their main functions. According to a survey of 452 managers in 13 firms, supervising was the main function of 51% of lower-level supervisors, 36% of middle managers, and 22% of top managers. Top managers were more likely than lower-level managers to be generalists and planners. [Figure 2.2](#) shows how managers could be typed according to their main function. As can be seen, the type of manager depended on the organizational level.

Williams (1956) focused on dealing with knowledge, decision making, interaction with others, character, organization over person, policies, and records. Koontz, O'Donnell, and Weihrich (1958) wrote about planning, organizing, motivating, and controlling. McGrath's (1964) fourfold classification concerned monitoring, forecasting, taking direct action, and creating conditions. For Bennett (1971), the taxonomy included deciding, planning, analyzing, interacting with people, and using equipment. For Hemphill (1950a), who used factor analytical approaches of leaders, the functions of supervisors, managers, and executives were initiation, representation, fraternization organization, domination, recognition, production, integration, and communication down<sup>6</sup> and communication up (in the organization).<sup>7</sup> For Hemphill (1960), supervisors, managers, and executives dealt with the following: providing staff services; supervising work; controlling business, technical markets, and production; human, conducting community, and social affairs; engaging in long-range planning; exercising broad power and authority; maintaining one's business reputation; meeting personal demands; and preserving assets. For Fine (1977), who employed job analyses, the functions were analyzing, negotiating, consulting, instructing, and exchanging information. For Dowell and Wexley (1978), they included working with subordinates, organizing their work, planning and scheduling work, maintaining efficient and good-quality production, maintaining equipment, and compiling records and reports.

Figure 2.2. Distribution of Assignments Among Job Types at Each Organizational Level

Low (N = 191)		Middle (N = 131)		High (N = 130)	
Planner	15%	Planner	18%	Planner	28%
Investigator	8%	Investigator	8%	Investigator	6%
Coordinator	5%	Coordinator	7%	Coordinator	8%
Evaluator	2%	Evaluator	2%	Evaluator	8%
Supervisor	51%	Supervisor	36%	Supervisor	22%
Negotiator	6%	Negotiator	8%	Negotiator	3%
Multispecialist	6%	Multispecialist	8%	Multispecialist	5%
Generalist	9%	Generalist	10%	Generalist	20%

(NOTE: Totals do not add up to 100 percent because of rounding.)

SOURCE: Mahoney, Jerdee, and Carroll (1965).

An outstanding example of a large-scale long-term analysis of management functions was Tornow and Pinto's (1976) taxonomy which involved long-range thinking and planning; the coordination of other organizational units and personnel; internal control; responsibility for products, services, finances, and board personnel; dealing with public and customer relations, complexity, and stress; advanced consulting; maintaining the autonomy of financial commitments; service to the staff; and supervision.<sup>8</sup>

The categorizations were fine-tuned and became more numerous. Winter (1978) generated 19 possible functional leadership competencies, ranging from conceptualizing to disciplining. They were expanded to 66 competencies by D. Campbell (1991). Metcalfe (1984) came up with 20 classes of leaders' behavior, ranging from proposing procedures to shutting out other persons' efforts to participate. Van Fleet and Yukl (1986a) emerged with a detailed breakdown of 23 functions, ranging from showing consideration to monitoring reward contingencies. Subsequently these were combined by Yukl (1998) into 14 functions, reworked from a previous list of 15 functions (Yukl, 1989): (1) networking; (2) supporting; (3) managing conflict and team building; (4) motivating; (5) recognizing; (6) rewarding; (7) planning and organizing; (8) problem solving; (9) consulting; (10) delegating; (11) monitoring; (12) informing; (13) clarifying; (14) developing and mentoring.

## Roles

On the basis of his observations of managers at work, Mintzberg (1973) created a taxonomy in which managers were seen to engage in three sets of roles: interpersonal, informational, and decisional. Within each of these sets, specific roles were conceived. The interpersonal set included the *figurehead*, *leader*, and *liaison*. Within the informational set were the *monitor*, *disseminator*, and *spokesman*. Within the decisional set were the *entrepreneur*, *disturbance handler*, *resource allocator*, and *negotiator*.

Javidan and Dastmalchian (1993) described five leadership roles: *mobilizer*, *ambassador*, *driver*, *auditor*, and *servant*.

Kraut, Pedigo, et al. (1989) delineated seven leadership roles: (1) managing individual performance, (2) instructing subordinates, (3) planning and allocating resources, (4) coordinating independent groups, (5)

managing group performance, (6) monitoring the business environment, and (7) representing one's staff. Baehr (1992) proposed 16 leadership roles ranging from setting organizational objectives to handling outside contacts.

Wells (1997) proposed nine roles for organizational leaders driven by values: (1) *Sages* develop wisdom through gaining knowledge about the organization's history and future prospects, and can deal with complexities, ambiguities, and contradictions; (2) *Visionaries* push to go beyond what has been previously accomplished and stimulate others to share in pursuit of the vision; (3) *Magicians* coordinate change by balancing the organization's structures, systems, and processes; (4) *Globalists* build bridges across cultures and find common ground on productive work can occur; (5) *Mentors* motivate others to advance their careers by helping people to learn and work to their potential and to find new perspectives and meaning in their jobs; (6) *Allies* build partnerships by seeking mutually beneficial collaborations that can improve performance; (7) *Sovereigns* take responsibility for the decisions they make and empower others with significant authority; (8) *Guides* use clearly stated principles to direct tasks toward goals important to the whole organization, are action-oriented, and are excited by the challenge of moving things forward; (9) *Artisans* are devoted to the mastery of a craft and the pursuit of excellence, concerned with the aesthetic as well as the practical to provide the customer with maximum value by continuous improvements. The same leader can perform a number of different roles.

Quinn's (1984) competing values framework is a taxonomy of management roles to indicate conditions under which enacting them would be most conducive to effectiveness. The patterns observed gave rise to seven types of managers. The same managers could play roles conceived to be opposite in value, and the roles could be placed at two ends of a continuum. The four bipolarities were: (1) mentor versus director; (2) facilitator versus producer; (3) coordinator versus innovator; and (4) monitor versus broker (Quinn, Dixit, & Faerman, 1987).

Mentors and facilitators are flexible and internally focused. Coordinators and monitors are internally focused and controlling. Directors and producers are externally focused and controlling. Innovators and brokers are flexible and externally focused. Mentors are particularly caring, empathetic, and concerned about individuals. Facilitators are interpersonally skilled and particularly concerned about group processes, cooperation, and cohesiveness. Producers are task-oriented, action-oriented, energetic, and specifically concerned about getting the work done. Coordinators are dependable, reliable, and concerned with maintaining continuity and equilibrium in the group. Innovators are clever, creative, conceptually skillful, and searching for better ways and opportunities. Monitors are well-prepared, well-informed, competent, and technically expert. Brokers are resource-oriented, politically astute, and especially concerned about influence, legitimacy, and acquiring resources. Effective leaders are typed as masters, conceptual producers, aggressive achievers, peaceful team builders, long-term intensives, and open adaptives. *Masters* are high in all eight opposing roles. *Conceptual producers* are almost like masters, except that they are lower in monitoring and coordinating. *Aggressive achievers* are high in monitoring, coordinating, directing, and producing but are lower in the other roles, particularly facilitating. *Peaceful team builders* are high in six of the roles but lower in the roles of broker and producer. *Long-term intensives* are high in the roles of innovator, producer, monitor, and facilitator and fall nearer the mean on the roles of mentor and director. *Open adaptives* are much less likely to monitor and co-ordinate. Ineffective managers were typed with the same kind of analysis of management roles into *chaotic adaptives*, *abrasive coordinators*, *drowning workaholics*, *extreme unproductives*, *obsessive monitors*, *permissive externals*, and *softhearted indecisives* (Hooijberg & Quinn, 1992). Hooijberg and Choi (2000) demonstrated that the effectiveness of managerial leadership was greater if the subordinate leaders saw themselves resembling their supervisors and managers in taking the effective roles of innovator, broker, monitor, mentor, producer, and facilitator.

*Special Organizational Leadership Roles.* According to Senge (1995), to lead learning organizations, organizations dedicated to continuous improvement and adaptation, three types of leaders are needed: (1) *executive leaders*, (2) *local line leaders*, and (3) *internal networkers or community leaders*.

Schein (1995) called for four kinds of leadership that were required in different stages of the development of an organization's culture: first, the *animator* was needed to build the culture; second came the *maintainer*; third came the *sustainer*; and fourth came the *change agent* to help promote necessary revisions.

As a strategic manager for General Electric and as a consultant, Rothschild (1993) developed a taxonomy of the types of strategic leader needed at different stages of an organization's life. As the organization starts up and grows rapidly, the strategic leader has to be a *risk taker*. When growth slows, a disciplined *caretaker* is needed to maintain stable long-term growth. If the organization must cope with significant declines, a *surgeon* leader is needed to act quickly. When there is no hope of turnaround, an *undertaker* leader is needed to dispose of the organization's assets compassionately and decisively.

## ***Cognitions and Perceptions of Leaders***

Compared with leaders' functions, roles and behaviors, their cognitions and perceptions have received much less research. Lord (1985) advanced the study of the structures underlying the cognitive categorization of leaders, which determined how they were perceived by others. The perceiver is seen as an active selector and organizer of stimulus information to provide cognitive economy. Categorizing information allows similar but nonidentical leaders to be seen as equivalent in a perceptual structure.

Hunt, Boal, et al. (1990) provided a fourfold categorization of leadership prototypes: (1) *Heroes* are leaders perceived as experts in both content and process. (2) *Technocrats* are perceived as experts in content but not process. (3) *Ringmasters* are perceived as experts in process but not content. (4) *Illegitimate leaders* are perceived as experts in neither content nor process.

Bimbaum (1988) organized a taxonomy of how college and university presidents differed in their frames of reference: bureaucratic, collegial, political, or symbolic. According to Bensimon (1990) *bureaucratic* presidents control by being active in making decisions, resolving conflicts, solving problems, evaluating performance and outputs, and distributing rewards and penalties. They are likely to be authoritarian, decisive, and results-oriented. The *collegial* president views the members of the establishment as the most important resource. Collegial presidents favor goal achievement and define priorities through teamwork, collective action, building consensus, loyalty, and commitment. Presidents with a *political* frame of reference see their institution as consisting of formal and informal constituencies competing for power to control the college's processes and outcomes. Decisions are the result of bargaining and coalition building. The president serves as a mediator who must be persuasive, diplomatic, and able to deal with shifting power blocs. The president with a *symbolic* frame of reference focuses on his or her institution as a culture of shared meanings and beliefs. Rituals, symbols, and myths are sustained to provide a sense of the college's purpose and order by interpretation, elaboration, and reinforcement of its culture. The 32 college and university presidents who were interviewed by Bensimon (1990) described themselves as most symbolic in their frames of reference and least political. This was quite different from descriptions by their 80 trustees, deans, directors, and department heads, who described the presidents as most bureaucratic and least symbolic in their frames of reference. For presidents with a strong bureaucratic orientation, campus leaders saw little of the other types in the president.

## **Leaders' Styles and Patterns of Behavior**

---

Leadership and management styles are alternative ways that leaders and managers pattern their interactive

behavior with those they influence.

*Transactional versus Transformational Leaders.* As Buckley (1979) noted, the successful political leader is one who “crystallizes” what people desire, “illuminates” the rightness of that desire, and coordinates its achievement. Such leadership can be transactional or transformational. This distinction has become of considerable importance to the study of leadership since Burns’s (1978) work (Bass, 1985a; Bennis & Nanus, 1985; Tichy & Devanna, 1986; Bryman, 1992; Curphy, 1992). In exchanging promises for votes, the transactional leader works within the framework of the self-interests of his or her constituency, whereas the transformational leader moves to change the framework. Forerunners of this distinction are to be found in Hook’s (1943) differentiation of the *eventful* man and the *event-making* man. The eventful political leader is swept along by the tides of history; the event-making political leader initiates the actions that make history. President Lincoln’s predecessor, Buchanan, was content to stand by and allow the Union to disintegrate slowly; Lincoln was determined to hold the Union together and to reverse what seemed at the time to be the inexorable course of southern secession.

Downton (1973) discussed the leadership of rebels in terms of this distinction between the transactional and the transformational leader. And Paige (1977) concluded that it would be useful to classify political leaders according to the changes they sought and achieved, as conservative, reformist, or revolutionary. *Conservative* leaders tend to maintain the existing political institutions and policies, *reformist* leaders promote moderate changes in institutions and policies, and *revolutionary* leaders (as well as *radical* leaders) strive for fundamental changes in existing institutions and policies. *Reactionaries* want to revert to institutions of the past.

For Burns (1978, p. 3), who provided a comprehensive theory to explain the differences between transactional and transformational political leaders, transactional leaders “approach followers with an eye to exchanging one thing for another: jobs for votes, or subsidies for campaign contributions. Such transactions comprise the bulk of the relationships among leaders and followers, especially in groups, legislatures, and parties.” Burns noted that the transformational leader also recognizes the need for a potential follower, but he or she goes further, seeking to satisfy higher needs, in terms of Maslow’s (1954) need hierarchy, to engage the full person of the follower. Transforming leadership results in mutual stimulation and elevation “that converts followers into leaders and may convert leaders into moral agents.” If the follower’s higher-level needs are authentic, more leadership occurs. Burns went on to classify transactional political leaders as *opinion leaders*, *bargainers or bureaucrats*, *party leaders*, *legislative leaders*, and *executive leaders*. Transformational leaders were categorized as *intellectual leaders*, *leaders of reform or revolution*, and *heroes or ideologues*.

Until the 1980s, most experimental research focused on transactional leadership (see, for example, Hollander, 1978), whereas the movers and shakers of the world are transformational leaders. Although both types of leaders sense the felt needs of their followers, it is the transformational leader who raises consciousness (about higher considerations) through articulation and role modeling. Through transformational leaders levels of aspiration are raised, legitimated, and turned into political demands.<sup>2</sup> The transformational/transactional classification has been used to study leaders in many sectors, including health care, the military, business, sports coaching, politics, government service, and nonprofit agencies (Bass & Riggio, 2005). Confirmatory factor analyses by Avolio, Bass, and Dong (1999) of 14 surveys that used the Multi-factor Leadership Questionnaire concluded from the best-fitting model that *transformational* leaders are inspirational, intellectually stimulating and/or individually considerate; *transactional* leaders practice contingent reward and active management by exception (contingent negative feedback). On the basis of ratings of CEOs by 253 senior executives, and of middle managers by 208 supervisors, Pearce, Sims, Cox, et al. (2002) found that a four-factor model of leadership fit the data best in comparison with other models: *directive leadership* (instruction and command, assigned goals, contingent reprimand); *transactional leadership* (contingent material reward,

contingent personal reward); *transformational leadership* (stimulation and inspiration, vision, idealism, challenge to the status quo); and *empowering leadership* (encouraging thinking in terms of opportunities, encouraging self-reward and self-leadership, setting goals participatively, and encouraging teamwork).

*Relations-Oriented and Task-Oriented Leaders.* Blake and Mouton (1964) studied the dimensions—from one (low) to nine (high)—of task-and relations-oriented leadership by using a grid. Five styles could be generated from the dimensions. These will be detailed in [Chapter 19](#). Reddin (1977) advanced this popular taxonomy of management in relation to eight types, each of which is a consequence of being low or high in Blake and Mouton’s two dimensions of relationships and task orientation and a third dimension—effectiveness. Managers are characterized as various combinations of this three-dimensional typology, as shown in the table here.

Managers Typed by their Leadership Styles

<i>Type of Leadership</i>	<i>Relationship Orientation</i>	<i>Task Orientation</i>	<i>Effectiveness</i>
Deserter	Low	Low	Low
Autocrat	Low	High	Low
Missionary	High	Low	Low
Compromiser	High	High	Low
Bureaucrat	Low	Low	High
Benevolent autocrat	Low	High	High
Developer	High	Low	High
Executive	High	High	High

An equally compelling typology of managerial styles was developed by Tannenbaum and Schmidt (1958), focusing on the issue of who shall decide—the leader or the follower. Their types were arranged along an authoritarian-democratic continuum: the leader who announces the decision, the leader who sells the decision, the leader who consults before deciding, the leader whose decisions are shared, and the leader who delegates decision making.<sup>10</sup> Hersey and Blanchard (1969a) made extensive use of this typology.

Bradford and Cohen (1984) categorized styles of managers: the manager as *technician*, the manager as *conductor*, and the manager as *developer*. The manager as technician relates information to subordinates who are committed to the leader because of the leader’s technical competence and who depend on the leader for the answers to problems. The manager as conductor is a heroic figure “who orchestrates all the individual parts of the organization into one harmonious whole” (p. 45) with administrative systems for staffing and work flow. The manager as developer “works to develop management responsibility in subordinates and ... the subordinates’ abilities to share management of the unit’s performance” (pp. 60–61).

Sorting managers in terms of their stylistic emphasis on rationality and quantitative analysis, Leavitt (1986) identified three types of managers. *Pathfinders* are creative and visionary; they use instinct, wisdom, and imagination to meet their goals and know how to ask questions and search out problems. *Problem solvers* are analytic, quantitative, and oriented toward management controls. Implementers are political and stress consensus, teamwork, and good interpersonal relationships.

Cribbin (1981) classified effective managers into the following types: *entrepreneur* (“We do it my way and take risks”), *corporateur* (“I call the shots, but we all work together on my team”), *developer* (“People are our most important asset”), *craftsman* (“We do important work as perfectly as possible”), *integrator* (“We build

consensus and commitment”), and *gamesman* (“We run together, but I must win more than you”).

Har-Even (1992), developed four models of leaders: (1) *charismatic* (“Believe in me”); (2) authoritative (“We will act according to the laws and rules”); (3) *role model* (“Follow me, I have knowledge and personal experience”); and (4) *facilitator* (“Let’s get together, and I will help to resolve our differences”).

Fleishman, Mumford, Zaccaro, et al. (1991) reviewed 65 taxonomies of leaders’ behavior published between 1944 and 1986. Three communalities were seen in these 65 taxonomies: (1) facilitating group social interaction and pursuing task accomplishment; (2) the occurrence of management and administrative functions; and (3) emphasis on leader-group interactions. Differences in taxonomies were due to the differences in the purposes of their creators; for instance, the purpose might be to focus on leaders’ behavior or on leaders’ effectiveness. The taxonomies also differed because of differences in methods, theoretical frameworks, and intended applications. Four dimensions emerged from the biographical review: (1) “information search and structuring” (acquiring, organizing, evaluating, feedback, and control of information); (2) “information use in problem solving” (identifying needs and requirements, planning, and coordinating and communicating information); (3) “managing personnel resources” (obtaining, developing, allocating, motivating, utilizing, and monitoring personnel resources); and (4) “managing material resources” (obtaining, allocating, maintaining, utilizing, and monitoring material resources).

Manz and Sims (1993) proposed four types of leaders, based on their different kinds of behavior: strong man, transactor, visionary hero, and super-leader. The *strong man* assigns goals, intimidates, and reprimands his followers. The *transactor* uses contingent reinforcement in interactive goal-setting to reward and reprimand followers. The *visionary hero* communicates his or her vision; emphasizes his or her values; and exhorts, inspires, and persuades followers. The *super-leader* models self-leadership and develops it in followers, creates positive thought patterns, develops self-leadership in followers through contingent rewards and reprimands, promotes self-leading teams, and facilitates a self-leadership culture. “Leaders become ‘super’—that is, possess the strength of many persons—by helping to unleash the abilities of the ‘followers’ (self-leaders) that surround them.”

*Types of Strategic Leadership.* Strategic leadership is behavior that depends on combining perceptions of threats, opportunities, cognitions, analyses, and risk preferences. Some strategies of leaders are emergent perspectives that evolve. Other strategies result from deliberate planning (Mintzberg & Jorgenson, 1987). These may be only implicit in the minds of the leaders (Lewis, Morkel, et al., 1993). To classify strategic leaders, Lord and Maher (1993) applied the same taxonomy of four organizational strategies posited by Miles and Snow (1978)—defenders, prospectors, analyzers, and reactors: *Defenders* stress efficiency and product stability; *prospectors* focus on product innovation and development; *analyzers* produce and market products developed by other organizations; *reactors* fall behind their industry in adopting new products. Organizations are more likely to be successful when their type of strategy matches the leaders’ requisite personality; thus, for example, defender organizations are more successful if led by executives who stress efficiency and product stability.

Gupta and Govindarajan (1984) typed organizations as pursuing a *build* strategy of increasing market share rather than a *harvest* strategy of cash flow and short-term profits. For success, the *build* strategy requires risk-taking executives with a tolerance for ambiguity. The *harvest* strategy, by contrast, needs executives with little propensity for risk and little tolerance for ambiguity.

Using facet and smallest-space analysis of data from 27 business cases, Shrivastava and Nachman (1989) empirically established four patterns of strategic leadership behavior: *entrepreneurial* (a confident, charismatic chief executive singularly guides strategy and controls others with direct supervision); *bureaucratic* (strategy is based on rules and the way the bureaucracy interprets rules, policies, and procedures); *political* (coalitions of organizational managers with different functions, but in reciprocal interdependence, interact as colleagues to

decide on strategies); and *professional* (small groups, dyads, or individuals control the requisite information in an open system and provide strategic direction with new rules).

On the basis of their experience as consultants, Farkas and De Backer (1996) enumerated five strategies that could be pursued by the chief executive to manage for success: (1) Act as the organization's top strategist, systematically envisioning the future and planning how to get there; (2) Concentrate on the organization's human assets—its policies, programs, and principles about people; (3) Champion specific expertise to focus the organization's human assets; (4) Create a "box" of rules, systems, procedures, and values to control behavior and outcomes within well-defined boundaries; (5) Act as a radical change agent to transform the organization from a bureaucracy into an adaptive organization that embraces what is new and different.

An important executive function is to remain alert to trends in one's own and other relevant industries, and one's own and other organizations, regarding the possibilities and expected utilities of insourcing and outsourcing. Parry (1999) conducted a qualitative study of local government administrators in New Zealand. From interviews with and responses of senior, middle, and operational leaders, it was possible to categorize their strategies. Social influence enhanced adaptability and resolved uncertainty. These leaders developed strategies to enhance their own and their followers' adaptability to the uncertainties of change.

## Commonalities in types and taxonomies

---

Despite the plethora of diverse types and taxonomies of leadership, five common themes appear: (1) The leader helps set and clarify the missions and goals of the individual member, the group, or the organization; (2) The leader energizes and directs others to pursue the missions and goals; (3) The leader helps provide the structure, methods, tactics, and instruments for achieving the goals; (4) The leader helps resolve conflicting views about means and ends; (5) The leader evaluates the individual, group, or organizational contribution to the effort. Many of the taxonomies include certain styles: authoritative, dominating, directive, autocratic, and persuasive. Common types are democratic, participative, group-developing, supportive, and considerate. Other types include intellectual, expert, executive, bureaucrat, administrator, representative, spokesperson, and advocate.

It is possible to encapsulate many of these types into the dichotomy of autocratic versus democratic. The autocratic type correlates with the directive type, and the democratic type correlates with the participative or considerate type. The executive is not regarded as a separate type but is classified as either task-oriented (autocratic) or relations-oriented (democratic). The persuasive pattern of behavior is a subclass of task-oriented or initiating behavior. However, in many situations the representative (spokesperson's) pattern of behavior is independent of task orientation and relations orientation. The intellectual type, the expert, often ignored early on, was soon seen to be required for any comprehensive theory of leadership.<sup>11</sup> Yukl (2002) validated a hierarchical model of leaders' behavior as best fitting using *change* in addition to *task* and *relations* as second-order metacategories. *Change* included the first-order factors of visioning, intellectual stimulation, risk taking, and external monitoring. *Relations* encompassed developing, supporting, consulting, recognizing, and empowering. *Task* included the primary categories of clarifying, monitoring, and short-term planning. Goodness of fit and other tests of the model came from 275 questionnaire descriptions of the behavior of supervisors and middle managers by their immediate subordinates.

Yukl (1987a, 1989) found strong similarities across these types and taxonomies of the behavior of leaders, dealing with leadership in the small group and the large organization, as provided by other investigators including Bowers and Seashore (1966), House and Mitchell (1974), Luthans and Lockwood (1984), Mintzberg (1973), Morse and Wagner (1978), Page (1985), and Stogdill (1963). Yukl also demonstrated that the descriptive scales of his taxonomy when used by subordinates to describe their leaders were highly reliable

and discriminated accurately among the supervisors being described (Yukl, 1987b).

*An Integrated Model.* Mumford, Fleishman, Levin, et al. (1988) summarized and integrated these efforts in a single taxonomic model. Their summary classification included: (1) the search for and structuring of information (acquisition, organization, evaluation, feedback, and control); (2) the use of information in problem solving (identifying requirements, planning, coordinating, and communicating); (3) managing personnel resources (acquisition, allocation, development, motivation, utilization, and monitoring); and (4) managing material resources (acquisition, maintenance, utilization, and monitoring). Information is acquired and then organized and evaluated to identify needs and requirements for planning and coordinating to obtain, allocate, and maintain material and personnel resources. For their utilization, personnel need development and motivation. Feedback and control loop back to the acquiring of information. Winter (1978, 1979b) created a similar model for tests and measures of leadership competencies that will be discussed in [Chapter 23](#).<sup>12</sup>

## Summary and Conclusions

---

Early in the scientific process, efforts were made to classify phenomena. Investigators have focused on classifications of leaders of crowds, institutions, industry, education, politics, legislative opinion, and communities. They have made an important distinction between transactional leaders, who concentrate on an exchange relation of what they and their followers want; and transformational leaders, who strive to arouse and satisfy the higher-level needs of their followers. Various sociopsychological classifications of small-group leaders are also available. Many of these classifications can be seen in terms of either a task orientation or a relations orientation.

<sup>1</sup> See glossary for definition of organismic.

<sup>2</sup> See [Chapter 35](#).

<sup>3</sup> See also Astin and Scherrei (1980) for an empirical classification of college presidents based on factor analysis.

<sup>4</sup> See [Chapter 31](#).

<sup>5</sup> These will be discussed more fully in [Chapter 8](#).

<sup>6</sup> Downward in the organization.

<sup>7</sup> Upward in the organization.

<sup>8</sup> More about this taxonomy will be discussed in [Chapter 23](#).

<sup>2</sup> Transformational leadership is discussed in detail in [Chapter 22](#); transactional leadership in Chapters 15 and 16.

<sup>10</sup> See [Chapter 18](#).

<sup>11</sup> As detailed in [Chapter 27](#).

<sup>12</sup> This taxonomy will be discussed in detail in [Chapter 23](#).

# Models and theories of Leadership

Theories of leadership attempt to explain its emergence or its nature and its consequences. Theories of management focus on its governance and consequences. Models show the interplay among the variables that are perceived to be involved; they are replicas or reconstructions of reality. Both theories and models can be useful in defining research problems for the social and political scientist and in improving prediction and control in the development and application of leadership. In this chapter we will introduce briefly the most prominent theories of leadership. Many will be discussed in more detail in later chapters as appropriate.

Until the late 1940s, most theories of leadership focused on the personal traits of leaders. According to these theories, leadership depended on leaders' abilities and personality characteristics. Then, up to the late 1960s, personal styles of leadership rose in prominence. From the late 1960s to the early 1980s, leadership studies became contingent on a mix of leaders' and followers' traits and situations. Leadership theories of inspiration and transformation emerged in the early 1980s and became prominent in the 1990s and at the turn of the twenty-first century. Theories of management paralleled the rise of civilization, and management practice was exemplified in the rules of planning, organizing, and controlling. Theories of management became more sophisticated in the twentieth century and were strongly influenced by the advent of computerization, information science, and globalization.

Before 1970, there were many complaints about a lack of theory to provide hypotheses for empirical research to test. Since then, diverse theories and models have been abundant as a source of hypotheses. However, relatively few of these models and theories have dominated the research community, and many have been restatements of the obvious. On the other hand, progress has been made when the models and theories have been built on astute observations and on assumptions that are the result of insightful observations. Good theories are disciplined imagination (Weick, 1995). They are internally consistent and consistent with a more general body of propositions from the social sciences. For instance, theories about reinforcement leadership have been built from what is generally known about reinforcement theories. Transformational leadership theory has similarly benefited from motivational theory.

## Good and Bad theories

---

Diagrams, speculations, and hypotheses are not theories; nor are cited references, data, and variables that are used in place of theory (Sutton & Staw, 1995). Rather, good theories usually start from one idea or a small set of ideas. They make possible a logically detailed case characterized by simplicity and interconnectedness. Predictions are presented with underlying causal logic: "The process includes abstracting, generalizing, relating, selecting, explaining, synthesizing, and idealizing." Good theories explain how and why (Sutton & Staw, 1995, p. 389). DiMaggio (1995) adds that good theories provide "categories and ... assumptions that ... (clear) away conventional notions to make room for artful and exciting insights" (p. 391). Good theories emerge from various experiences. Observations and inferences from frequent contact with leaders and followers help. Connections are identified between observations and concepts that heretofore were not seen to be connected. There is a convergence of several interests and activities at the same time. Intuition and feelings supplement logical analysis. There is a desire to explain, understand, and find meaning in the real world. Ideas are

confronted and confirmed or disconfirmed. Conventional wisdom may be revised or reversed. Research is restated in alternative ways. Established value judgments are challenged. Above all, to be good, theories need to be grounded in assumptions that fit the facts. Theorizing and modeling are now commonplace in providing the rationale to justify and test empirical hypotheses. These will be discussed more fully as they become relevant to the topics of later chapters.

Nothing is supposed to be as practical as a good theory (Lewin, 1947), but nothing seems more impractical than a bad one (Bass, 1974). A theory is supposed to be a way of trying to explain the facts. Unfortunately, theories about leadership sometimes obscure the facts. Much effort then has to be expended in coping with the obscurity. Poor research derives from poor theory. Poor research is often expedient, quick, and convenient. Klimoski (2005) notes that bad theory is dangerous. And according to Ghoshal (2005), bad management theories are destroying good management practices. Examples are agency theory (Jensen & Meckling, 1976) and transaction costs theory (Williamson, 1975). *Agency theory* assumes that managers are bent on maximizing their own interests at the expense of all the other constituencies of the organization. *Transaction costs theory* assumes that managers are in deadly competition with each other. Monitoring and tight control of their opportunistic behavior are needed. They cannot be trusted. To gain a comparative advantage requires a company to compete not only with other companies but also with its own suppliers, customers, employees, and regulators (Porter, 1980). These “ideologically inspired” amoral theories are being preached in many business schools and management development programs. They free future organizational leaders from any sense of moral responsibility for their decisions. and encourage rather than inhibit their opportunistic behavior (Ghoshal & Moran, 1996). Scientism rather than science makes these bad theories appealing, for their derived propositions can be reproduced with mathematical models. They would be good theories if their assumptions about human behavior were correct. In fact, governance based on the assumption that managers are self-aggrandizing and cannot be trusted results in less trustworthy managers (Osterloh & Fry, 2003). Deductions from these economic theories that control of managers requires more independent boards of directors, and that corporate performance is improved if the positions of board chairman and CEO are separated, are not supported empirically (Dalton, Daily, Ellstrand, et al., 1998). But the same could be said about cognitive, behavioral, and social theories based on faulty assumptions about human and social behavior. There was a long-held theory that efficiency increased if work was divided into parts so each worker could specialize; but the effects on the workers’ motivation were ignored.

Ferraro, Pfeffer, and Sutton (2005) point to a further complication and effect of bad theory and practice. They cite evidence that corporate managers are less interested in first evaluating whether a new fad increases effectiveness and profitability, and more interested in showing that they have adopted the latest popular theory or practice without really finding out its effects. They treat the effects as self-fulfilling prophecies. And political leaders have done the same thing, according to Keynes (1936), with damaging long-term effects on the economy and society.

## Sources of Current Models and theories

---

With the growth of cognitive psychology we have seen cognitive theories and models of leadership added to the earlier behavioral and social theories. Zaccaro (1996) has combined cognitive, behavioral, and social approaches in a “Leaderplex Model” of executive leadership (see also Hooijberg, Hunt, & Dodge, 1997). Theories of leadership with extensive empirical support of effects on followers’ effectiveness and satisfaction can be broadly classified as instrumental, inspirational, and informal. *Instrumental* theories focus on the leader’s orientation to the task or to the person, on leaders’ direction or followers’ participation, on leaders’ initiative or consideration of their followers’, and on leaders’ promises and rewards or threats and disciplinary

action. *Inspirational* theories of leadership include charismatic, transformational, and visionary theories. These focus on emotional and ideological appeals, displaying exemplary behavior, confidence, symbolism, and concentrating on intrinsic motivation. *Informal* leadership theories deal with the emergence and service of effective leaders who lack formal positions and authority (House, 1995).

## ***Cognitive Theories***

*Implicit Theories of Leadership (ILTs)*. Implicit theories of leadership (ILTs) are the concept of “leader” that different people have in mind. These implicit leadership theories about leaders and followers affect the relations between them. An ILT may be about instrumental, inspirational, or informal leadership. ILTs are beliefs about how leaders behave, in general, and what is expected of them (Eden & Levitan, 1975). Such theories are naive concepts of leadership, revealed (for instance) when people are asked to list a number of traits that come to mind when they think of the term “leader.” Although respondents may be affected by individual, gender, social, organizational, and cultural differences, ordinarily their similarities outweigh their differences. Therefore, it is possible to determine a generalized image or “prototype” of the concept of a leader. We can then compare prototypes that may emerge from markedly different samples, such as Americans and Chinese. In the same way, different prototypes can be discriminated among the concepts of 11 types of leaders: business leaders, sports leaders, etc. (Lord, Foti, DeVader, 1984). There is little difference between the prototype of a “leader” and that of an “effective leader.” However, the term “supervisor” receives somewhat less favorable trait ratings from college students than the terms “leader” and “effective” leader (Offerman, Kennedy, Wirtz, 1999).

For college students, T. Keller (1999) found ILTs for “leader” comparable to those of Offerman et al. (1999). In addition, she obtained modest correlations of selected ascribed traits of “leader,” self-rated personality using the NEO five-factor personality inventory, and perceived parental traits. For instance, the extent to which respondents perceived *sensitivity* as a characteristic of a “leader” correlated significantly (.20) with the respondents’ self-rated “openness.” Dedication as a trait of a leader correlated .23 with their self-rated “conscientiousness” and .31 with their perceived “paternal dedication.” A number of other such correlations were found, suggesting to Keller that individuals perceive a leader as mirroring traits of themselves and their fathers.

Another application of implicit leadership theory was a study to determine 378 undergraduates’ idea of characteristics required for a new leader to be accepted by a group. The list of 16 expectations formed four abstract categories: (1) taking charge, (2) learning the group’s goals, (3) being nervous, and (4) being a nice person (Kenny, Blascovich, & Shaver, 1994).

Increased interest in implicit leadership has paralleled a cognitive revolution in psychology and developments in information processing. Lord and Maher’s (1991) book, *Leadership and Information Processing: Linking Perceptions and Performance*, is illustrative.

In organizations, these are—in contrast to implicit theories—concepts espoused in formal documents, memorandums, and executives’ speeches. These state intentions, goals, objectives, and desired relationships of leaders and managers with their various constituencies. Or they may be *theories in practice*, theories actually guiding the behavior of members of the organization that can be observed, expressed, or inferred in interviews with members (Argyris, 1982).

*Grounded Theory*. Grounded theory is closely allied to implicit leadership theory. If a theory of leadership is to be used for diagnosis, training, and development, it must be grounded in the users’ concepts, assumptions, language, and expressions. The users include emergent leaders and followers in informal

organizations as well as managers, administrators, and officials in formal organizations (Glaser & Strauss, 1967; Strauss & Corbin, 1990). Qualitative research is often grounded. But such grounding requires conceptual rigor. There may be a loss of generality and less opportunity to apply standardized measurements. Grounded research generates rather than tests theory (Parry, 1998).

### ***Biological-Genetic Theories***

“He was born to lead.” “She instinctively knew how to take charge.” “The coach was a natural leader.” Such comments assume that nature has been more important than nurture in the emergence of a particular leader. But until recently a majority of social scientists considered nurture more important than nature. Nonetheless, *leaders are both born and made*. The importance of health, physique, and energy in the emergence of leadership has long been recognized. Additionally, with advances in genetics and neuropsychology, as well as speculations about evolution and recognition of the biological differences between the sexes, has come an appreciation of inborn traits and the expression of genes.

As Spinoza said, “Man is a social animal.” Lawrence (1997) has enumerated four built-in evolutionary survival factors in humans that affect their organizational life, and therefore leader-follower relations: (1) a need to acquire; (2) a need to bond; (3) a need to learn; and (4) an inborn reflexive mechanism to avoid pain. They involve strong emotions and a strong motivation toward goal-oriented behavior. The acquisitive needs of followers are helped by instrumental and transactional leadership. Social-bonding needs are fulfilled by considerate and charismatic leaders. Learning needs of followers are fulfilled when leaders clarify purposes. Followers’ pain is avoided when coercive, ruthless leadership is avoided.

*Great-Man Theories.* Jennings (1960) reviewed the “great man” theory. For many commentators, history is shaped by the leadership of great men. Without Moses, according to these theorists, the Jews would have remained in Egypt; without Winston Churchill, the British would have given up in 1940; without Bill Gates, there would have been no firm like Microsoft.

The eighteenth-century rationalists felt that to determine the course of history, luck had to be added to the personal attributes of great men. The Russian Revolution would have taken a different course if Lenin had been hanged by the old regime instead of being exiled. For romantic philosophers such as Friedrich Nietzsche, a sudden decision by a great man (Thomas Jefferson’s decision to purchase Louisiana, for example) could alter the course of history. William James (1880) believed that certain mutations of society were due to great men, who initiated movement and prevented others from leading society in another direction. According to James, the history of the world is the history of great men, who determined what the masses could accomplish. Carlyle’s (1841) essay on heroes reinforced the concept of the leader as a person endowed with unique qualities that captured the imagination of the masses. The hero would contribute somehow, no matter where he was found. History was created by the acts of great leaders. Leaders molded the masses. (Despite the examples of Joan of Arc, Elizabeth I, and Catherine the Great, great women were ignored.) Dowd (1936) maintained that “there is no such thing as leadership by the masses. The individuals in every society possess different degrees of intelligence, energy, and moral force, and in whatever direction the masses may be influenced to go, they are always led by the superior few.” Although one of many civil rights leaders, Martin Luther King, Jr., was considered the great man whose leadership inspired the civil rights movement. The great-man theory of leadership was espoused to show how faltering or threatened organizations could be turned around by business executives like Lee Iacocca, military leaders like Douglas MacArthur, and political figures like Margaret Thatcher.

Influenced by Galton’s (1869) study of the hereditary background of great men, several early theorists attempted to explain leadership on the basis of inheritance. Woods (1913) studied 14 nations over periods of

five to ten centuries and found that the conditions of reign approximated the ruler's capability. The brothers of kings (as a result of natural endowment) also tended to become men of power and influence. Woods concluded that the man makes the nation and shapes it in accordance with his abilities. In line with the eugenics movement, Wiggam (1931) proposed that the survival of the fittest people and intermarriage among them produces an aristocratic class, which differs biologically from the lower classes. Thus an adequate supply of superior leaders depends on a proportionally high birthrate among the abler classes.

*The Warrior Model of Leadership.* This variant of the great-man theory appeared in several classics: Suntzū's *Art of War* (c. 400 b.c.), Aristotle's *Politics* (324 B.C.), Machiavelli's *The Prince* (1513), Gratian's *The Art of Worldly Wisdom* (1643), and Clausewitz's *On War* (1833). General George Patton exemplified the warrior model. Wars are won or lost, according to this theory, depending on the leadership of the opposing forces. Thus, Napoleon's and Julius Caesar's tactics often spelled the difference between victory and defeat in battle. President Lincoln had to replace the commanding general of his Union army numerous times before he found, in Ulysses Grant a commander who was able and willing to use his forces, superior in size and logistics, to take the initiative and accept the casualties needed to wear down Robert E. Lee's Confederate forces. Victorious warrior leaders win fame and power. They control flows of information. The means justify the ends for them, even if they must resort to deception, betrayal, violence, and other morally questionable acts. These acts may be delegated to subordinates so that the leaders are held blameless. Planning and preparation assume that the world is a dangerous place (Nice, 1998).

## ***Trait Theories***

The great-man theories drew attention to the specific qualities of leaders and their identification (Kohs and Irle, 1920). L. L. Bernard (1926), Bingham (1927), Tead (1929), Page (1935), and Kilbourne (1935) all explained leadership in terms of traits of personality and character. Bird (1940) compiled a list of 79 relevant traits from 20 psychologically oriented studies. Similar reviews were done by Smith and Krueger (1933) for educators, and by W. O. Jenkins (1947) for military leaders.

Until the 1940s, much research about leaders and leadership focused on individual traits. Leaders were seen as different from nonleaders in various attributes and tested personality traits. Two questions were usually posed: (1) What traits distinguish leaders from other people?; (2) What is the extent of the differences? The pure trait theory eventually fell into disfavor. Stogdill's (1948) critique concluded that both person and situation had to be included to explain the emergence of leadership. But as will be seen in [Chapter 5](#), traits are still considered of great importance in the study of leadership.

*Charismatic-Transformational Leadership Theory.*<sup>1</sup> Max Weber (1924/1947) introduced a religious concept—charisma—into the social sciences to describe leaders who are perceived as endowed with extraordinary abilities. Charismatic leaders are highly expressive, articulate, and emotionally appealing. They are self-confident, determined, active, and energetic. Their followers want to identify with them, have complete faith and confidence in them, and hold them in awe. Generally, charismatic leaders have strong positive effects on their followers. House (1977) presented a theory of charismatic leadership that specified the expected behavior of charismatic leaders and their followers, stimulating renewed interest in empirical studies of this subject.

According to Hunt (1999), for the empirical study of leadership, transformational leadership was a new paradigm (Kuhn, 1964)—a change of views, preferred methods, acceptable findings, interpretations of findings, and important areas to study. Transformational leadership was first mentioned by Downton (1973) and first formalized as a theory by Burns (1978). In contrast to transactional leaders, transformational leaders

were said to motivate followers to go beyond their own self-interests for the good of the group, organization, or society. Followers' interests are raised by transformational leaders from concerns for security to concerns for achievement. Followers are encouraged to meet the challenges they face, to excel, and to self-actualize. Bass (1985a) presented models of the factors in transformational and transactional leadership. House and Aditya (1997) viewed transformational leadership as close in meaning to charismatic leadership. Bass (1985a) found that charismatic leadership was the largest factor in transformational leadership but only one of several other empirical factors with which it correlated, including inspirational leadership, intellectual stimulation, and individualized consideration. Transactional leadership encompassed contingent reward, management by exception, and passive or laissez-faire leadership. This was confirmed empirically by Avolio, Bass, and Jung (1999), among others.

By 1960, the dominant paradigm for the study of leadership had evolved from research on the traits and situations that affect leadership to something more dynamic. Leadership was now seen as contingent on traits and situations involving a *transaction* or exchange between the leader and the led (Hollander, 1986). In this view, leaders promise rewards and benefits to subordinates in exchange for the subordinates' fulfillment of agreements with the leader. Even the psychoanalysts conceived of followers as complying with the leader to obtain the leader's love. But Freud (1922) suggested that there was more to the concept of leadership than a mere exchange: the leader embodied ideals with which the follower identified. Barnard (1938) noted that personal loyalty was more powerful than "tangible inducements." But along with Downton (1973), Burns (1978) presented the new paradigm of the transformational as opposed to the transactional leader. The transformational leader asks followers to transcend their own self-interests for the good of the group, organization, or society; to consider their long-term need for self-development rather than their need of the moment; and to become more aware of what is really important. Hence, followers are converted into leaders. Among 90 transformational leaders who were interviewed, Bennis (1984) found evidence of competence to manage attention and meaning, to articulate visions of what was possible, and to empower the collective effect of their leadership.

Burns's conceptualization of leadership as either transforming or transactional was modified by Bass (1985a, 1985b), who proposed that transformational leadership augmented the effects of transactional leadership on the efforts, satisfaction, and effectiveness of followers. Many great transformational leaders, including Abraham Lincoln, Franklin Delano Roosevelt, and John F. Kennedy, did not shy away from being transactional as well as transformational. Lincoln, Roosevelt, and Kennedy were able to move the nation as well as play petty politics. Waldman and Bass's (1985) analysis of surveys of senior military officers and business managers confirmed the fidelity of the model. Tichy and Devanna (1986) described the hybrid nature of transformational leadership. According to them, transformational leadership is not due just to charisma. It is "a behavioral process capable of being learned and managed. It's a leadership process that is systematic, consisting of purposeful and organized search for changes, systematic analysis, and the capacity to move resources from areas of lesser to greater productivity ... [to bring about] a strategic transformation" (p. viii).

On the basis of Kegan's (1982) theory of the evolving self, Kuhnert and Russell (1989) designed a four-stage model of how the transformational leader develops. Factor-analytic studies done by Bass (1985b) and confirmed by Avolio, Bass, and Jung (1999) have suggested that transformational leadership can be conceptually organized along four correlated dimensions: (1) charismatic leadership, (2) inspirational leadership, (3) intellectual stimulation, and (4) individualized consideration. For House (1977) and Conger (1999) all four components are contained within their concept of charismatic leadership (House & Shamir, 1993). Later chapters detail the antecedents and consequences of transformational and charismatic leadership. The components of *transactional* leadership are contingent reinforcement, expressed usually as contingent reinforcement and management by exception, which will be examined at length in Chapters 15 and 16.

According to a leader's subordinates, colleagues, and superiors, transformational-charismatic leadership

correlates more highly with the leader's effectiveness than contingent-reward leadership does. Contingent reward, in turn, correlates more highly with the leader's effectiveness than reactive management by exception or contingent punishment do. Satisfaction with the leader follows a similar pattern (Bass & Avolio, 1989). Similar results can be obtained when different sources are used to describe the leader and to more objectively evaluate the outcomes of leadership in terms of effectiveness and satisfaction (Lowe, Kroek, & Sivasubramaniam, 1996). In the same way, House and his associates (e.g., House, Spangler, & Woyke, 1991) have reported numerous studies showing positive correlations between charismatic and effective leadership. Conger and Kanungo (1998) along with Sashkin (1988) focused on the process effects of charisma on the followers and on the leader's need to articulate a vision to be accepted and followed.

Transformational leadership is closer to the "proto-type" of leadership that people have in mind when they describe an ideal leader and is more likely to provide a role model with which subordinates want to identify (Bass & Avolio, 1988). In practice, this means that leaders develop in their subordinates an expectation of high performance rather than merely spend time praising or reprimanding them (Gilbert, 1985). For Bradford and Cohen (1984), the manager must be more than a hero of technical competence and organizing skills. He or she must become a developer of people and a builder of teams.

*Servant Leadership.* Less well researched but still prominent, servant leadership was formulated by Greenleaf (1977) and was based on his experiences as an executive. According to Greenleaf, ego spurs achievement, but leaders need to curb their own egos, convert their followers into leaders, and become the first among equals. The needs of others must be the leaders' highest priority. Power has to be shared by empowering followers. Leaders should think of themselves as servants building relationships with their followers that help their followers to grow (Buchen, 1998). Servant leaders must be oriented to the future as stewards of the human and physical resources for which they are responsible. Leaders who are stewards are similar to but not the same as servant leaders. Stewards try to balance the interests of all the different constituents of their organization: shareholders, owners, managers, peers, subordinates, customers, clients, and community (Bass, 1965; Donaldson, 1990). Servant leaders are especially concerned about constituencies with less power or more need for help. Servant leadership also shares much in common with transformational leadership: vision, influence, credibility, and trust (Farling, Gregory & Stone, 1999).

Closely aligned with servant leadership is a model of organizational leadership by Choi and Mai-Dalton (1999): *self-sacrificial leaders* abandon or postpone their own interests, privileges, or welfare in the way they work with their followers. They give up or postpone rewards to which they are fairly or legitimately entitled. They voluntarily give up or refrain from using their positional or personal power. In one study that used scenarios about a self-sacrificing company president and a non-self-sacrificing president, university students and white-collar employees judged the self-sacrificing president as more charismatic and legitimate. These respondents stated that they would be more likely to reciprocate in self-sacrifice if the president was self-sacrificing.

## ***Situational Theories***

In direct opposition to trait theorists, situational theorists have argued that leadership is a matter of situational demands; that is, situational factors determine who will emerge as a leader. Particularly in the United States, situationalism was favored over the theory that leaders are born, not made. According to situationalism, the leader is a product of the situation and circumstances, not self-made and not a product of personality, drive, or ability (Stogdill, 1975).

The controversy over which is more important to leadership—situation or personality—is an ancient one.

Plutarch's *Parallel Lives* (c. a.d. 100) described how for each type of leader who emerged in Greece, one emerged under parallel conditions in Rome. Alexander the Great, for instance, had his counterpart in Julius Caesar. The great-man theorists believed that it was all a matter of personality and personality development—that Alexanders and Caesars would surface no matter what conditions surrounded them. The situationalists thought otherwise: for example, they sought to identify conditions that gave rise to the emergence of the “man on the white horse,” the dictator who appears following revolutionary upheaval, chaotic politics, social and economic distress, and a weakening of traditional institutions.

The situationalists advanced the view that the emergence of a great leader is a result of time, place, and circumstance. For Hegel, the great man was an expression of the needs of his times. What the great man did was automatically right, because he provided what was needed. The great man actually could not help what he did; he was directed and controlled by his historical environment. For example, the need for civil peace made it mandatory for Octavian to make himself sole ruler of Rome, form the Roman Principate, and destroy republicanism. If Octavian had not appeared to carry out these changes, someone else would have done the same. Herbert Spencer believed that societies evolved in a uniform, gradual, progressive manner, and no great man could change the course of this development. Engels, Marx, and their successors believed that economic necessity made history. The American Civil War was, then, an inevitable clash caused by the conflicting economic interests of North and South. Economic determinists held that obstacles to expanding production had to be overcome. The greater the obstacles, the greater this need was and the more capable the required leader had to be. But who he turned out to be was irrelevant (Hook, 1943). Mumford (1909) agreed that who emerged as a leader depended on the abilities and skills required at a given time to solve the prevailing social problems. Although these abilities and skills were innate as well as acquired, leadership, as such, stemmed from the organized phases of the social process or the habitual ways in which people adapt to each other. Thus, according to the situationalists, the national condition determined the development and emergence of great military figures. For A. J. Murphy (1941), leadership did not reside in a person but was a function of the occasion. The situation called for certain types of action; the leader did not inject leadership but was the instrumental factor through which a problem was solved. For Person (1928), any particular situation played a large part in determining the leadership qualities and the leader for that situation. Moreover, the leadership required in that situation was a product of a succession of previous leadership situations that molded the leader.

J. Schneider (1937) noted that the number of great military leaders in England was proportional to the number of conflicts in which the nation engaged. Spiller (1929) concluded that a broad survey of the field of human progress would show that 95% of the advance was unconnected with great men. Rather, a great man like Martin Luther King, Jr., would appear at a critically important point of a socially valued cause, would devote himself to it, and would profit greatly from the work of many others. Thus, time itself was an important variable for the situationalists. The passage of time changed the situation and the people involved. Thierry, Den Hartog, Koopman, et al. (1997) viewed Dutch people's preferences for leadership as a matter of Dutch history and trends. Leadership was conceived as a relational process that unfolded over time. Time might be needed for trust to develop before an individual could emerge as a leader. Time made an important addition to models and theories of leadership. Repeated measurements over time are important to analyses of leaders' performance (Hollenbeck, Ilgen, & Sego, 1994). Bogardus (1918) presented the view that the type of leadership that developed in a group was determined by the nature of the group and the problems it had to solve. Hocking (1924) went even further, suggesting that leadership resided in the group and was granted to leaders only when they put forth a program that the group was willing to follow.

*A Rational-Deductive Model.* Vroom and Yetton (1974) rationally linked some of the accepted facts about directive and participative decision making as assumptions. From these, they created prescriptions for the leadership style that was most likely to succeed in a given situation. They posed ten questions that leaders

should ask themselves in deciding whether to be directive or participative in making decisions with their subordinates and whether to do so primarily with individual subordinates or with the whole group at once. Essentially, the prescriptions were that supervisors ought to be directive when they were confident that they knew what needed to be done and when their subordinates did not have this knowledge. Furthermore, in this situation, the subordinates would accept the decision made by the supervisor. However, if the subordinates had more information than the supervisor, if the subordinates' acceptance and commitment were of paramount importance, and if the subordinates could be trusted to concern themselves with the organization's interests, the supervisor should be participative.

Vroom and Jago (1988) created an improved model. Instead of requiring yes-or-no answers to the questions, they provided a five-point scale of possible answers: (1) no, (2) probably no, (3) maybe, (4) probably yes, (5) yes. The older model used only two criteria for the decision rules: acceptance of the decision by followers, and the quality of the decision. The five-point scale made it possible for the leader to prioritize possible decisions, reducing the several feasible alternatives into a single decision.<sup>2</sup>

### ***Person-Situation Theories***

Although wars and other crises present opportunities for the acquisition of leadership by persons who would otherwise remain submerged in the daily round of routine activities, various theorists have maintained that the situation is not in itself sufficient to account for leadership. How many crises arise that do not produce a person who is equal to the occasion? A combination of personal and situational elements needs to be considered. James (1880) pointed out that the "great man" needs help. His talents need to fit with the situation. Ulysses Grant, for instance, was a failure in private life before his emergence as the Union's great military commander, and he failed again afterward as president. His rise to commanding general of the Army of the Potomac was delayed by the many political appointees who came before him and took turns displaying their ineptitude before an exasperated President Lincoln turned to him. Grant's leadership in the Vicksburg campaign brought victory, despite the orders of his superior, General Halleck, to fall back toward New Orleans. But it was Grant's persistence, and some help by congressmen, that overcame the inertia of the political appointment system; and the traits of persistence and confidence marked the style with which he hammered out his military victories (Williams, 1952).

The great man theorists and the situational theorists both attempt to explain leadership as an effect of a single set of forces, and both overlook the combined effects of individual and situational factors. In reaction, Westburgh (1931) suggested that the study of leadership must include the affective, intellectual, and action traits of the individual, as well as the specific conditions under which the individual operates. Case (1933) maintained that leadership is produced by a conjunction of three factors: (1) the personality traits of the leader, (2) the nature of the group and its members, and (3) the event confronting the group. J. F. Brown (1936) proposed five field-dynamic laws of leadership: leaders must (1) be identified as members of the group they are attempting to lead; (2) be of high interpersonal potential; (3) adapt themselves to the existing structure of relationships; (4) realize the long-term trends in the structure; (5) recognize that leadership increases in potency at the cost of reduced freedom of leadership.

Hook (1943) noted that there is some restriction in the range of traits that a given situation permits the emergent leader to have. Thus heroic action is decisive only when alternative courses of action are possible. Exiled to Elba, close to France, Napoleon had alternatives; exiled to Saint Helena, in the South Atlantic and more closely guarded, he had none.

Bass (1960) argued that controversy over the great man versus the situation was a pseudo problem. For any given case, some of the variance in what happens is due to the situation, some is due to the individual, and

some is due to the combined effects of the individual and the situation. Mao Zedong played a critical role in the Chinese revolution, but without the chaotic state of Chinese affairs under the Kuomintang, his rise to power would not have been possible. Dansereau, Alutto, and Yammarino (1984) developed the multiple-levels analysis, to be described later. It provided a complete statistical formulation of models to examine the interplay of leader, individual follower, group, and organizational situation. Personal-situational theorists argue that theories of leadership cannot be constructed in a vacuum: they must contain elements of the person as well as elements of the situation. Any theory of leadership must take account of the interplay between the situation and the individual. Barnard (1938) and many others (C. A. Gibb, 1947; Jenkins, 1947; Lapiere, 1938; Murphy, 1941) attempted to resolve the controversy over situation versus personality by suggesting that leadership behavior is a less consistent attribute of individuals than such traits as nonsuggestibility, energy, and maturity, which are empirically associated and theoretically linked with overt leadership behavior. Leaders with a strong personal tendency to be consistent will display leadership across many situations.

Stogdill (1948) concluded that leaders' traits must bear some relevant relationship to the characteristics of the followers. An adequate analysis of leadership needs a study not only of leaders, but of the situation. Stogdill's position strongly influenced the theories that followed. According to Gerth and Mills (1952, pp. 405–406), "to understand leadership, attention must be paid to (1) the traits and motives of the leader as a man, (2) images that selected publics hold of him and their motives for following him, (3) the features of the role that he plays as a leader, and (4) the institutional context in which he and his followers may be involved." C. A. Gibb (1954, p. 914) suggested that "leadership is an interactional phenomenon arising when group formation takes place." A group structure emerges. Each member of the group is assigned a relative position within the group depending on the nature of his or her relations with the other members. It is a general phenomenon and depends on the interrelation of individuals pursuing a common goal. Similarly, Stogdill and Shartle (1955) proposed that leadership needs to be studied in terms of the status, interactions, perceptions, and behavior of individuals in relation to other members of an organized group. Leadership should be regarded as a relationship between persons rather than as a characteristic of an isolated individual. Data for all the members of a group should be combined and interrelated to study leadership in terms of the structural and functional dimensions of the organized interrelationships.

Wofford (1981) presented an elaborate integration of concepts and research results from behavioral studies of ability, motivation, role perception, environmental constraints, determinants of the behavior of leaders, and environmental influences. This *leader-environment-follower interaction theory* conceived of the leader as a person who analyzes current deficiencies in the conditions that determine the performance of followers and takes corrective action. The theory appeared to concentrate on the practice of management by exception. Bennis (1961) concluded that theories explaining who emerged and succeeded as a leader in an organization had to take into account: (1) the impersonal bureaucracy, (2) the informal organization and interpersonal relations, (3) the benevolent autocracy that structures the relationship between superiors and subordinates, (4) the job design that permits individual self-actualization, and (5) the integration of individual and organizational goals.

The personal-situational approach has come to dominate the forecasting of leadership potential in prospective supervisors and managers. The effort builds on attempts to match individuals' personal history, competencies, and traits with the requirements of a job. Since the late 1970s, analyses of the inspirational, charismatic, transformational leader, and the servant leader have all looked at both the person and the situation. Crises are seen to lie behind the rise of charismatic leaders whose personal development and personality move them to succeed in taking charge. Transformational leaders are usually personally assertive. They react to their perceptions of what their followers need, but they also proactively influence what their followers want. Servant leaders are strongly service-oriented and are influenced by what their organization and followers need. A description that emerged from a conference about what was expected of senior managers illustrates the

importance of both person and situation: “Leaders should be uncommon (yet congenial, vulnerable, and accessible); capable as almost to promote awe.” A leader should be “a faultless reader of signals from the environment, a diagnostician capable of taking corrective action; ... an architect who builds an enabling organization” (Wilson, 1994).

Increasingly, behavioral theories postulate leadership as an interaction among the leader, the situation, and the led (e.g., Popper, 2001). Yammarino (1991) reasoned that a full explanation of leadership and situation requires a multiple-level approach: leaders, leader-follower pairs, groups, and organizations. At the level of leaders, whether and how much the leaders differ are examined. At the level of the leader-follower pair (the dyad), analyzed is how much the leader relates differently to each follower. At the level of groups, the question is to what extent each leader’s followers differ. At the level of organizations, the question is whether and how much differences in leadership depend on the organization—above and beyond any differences among the different groups and leaders. Many other analyses are possible across levels. These within-and-between analyses (WABAs) are appearing with increasing frequency.

### ***Psychoanalytic Theories***

Freud (1922), as well as many other psychoanalytically oriented writers such as Erikson (1964), Frank (1939), Fromm (1941), and H. Levinson (1970), addressed leadership at length, in terms of clinical studies. Favorite interpretations conceived of the leader as a source of love or fear, as the embodiment of the superego, and as an emotional outlet for followers’ frustration and destructive aggression (Wolman, 1971). Freud (1913) proposed that the beginnings of civilization required a struggle with the leader (father) of the primitive clan. A primal horde of sons slew their father and formed a society of equals, but the need for leadership resulted in the rise of totemism and religion, in which gods substituted for the murdered father. According to Freud (1922), group behavior is emotional and irrational. Groups of followers are both obedient to and intolerant of authority and require strength and forcefulness in their leaders. They are oppressed by, fearful of, and ruled by leaders. The group mind determines its cohesiveness. The followers’ identification with the leader shapes their identification with each other. However, within their personalities, they remain in a state of tension. Their ego (rationality) is too weak to resolve the conflict with their id (instincts) and superego (social and moral imperatives). But leaders are without emotional attachment to anyone. They are narcissistic, independent, and self-confident.

Wolfenstein (1977) and Lasswell (1960) made extensive use of psychoanalytic theories to account for political and revolutionary leaders. Lasswell held that the personality of a political person compensates for feelings of inadequacy and low esteem by displacement, by a continuing pursuit of power to maintain personal integrity. This personal need is rationalized as “in the public interest” (Lasswell, 1962). According to Wolfenstein, the personality of a revolutionary leader is an externalized revolt against a parent. It is the Oedipus complex projected against society. Much of this psychoanalytic theorizing about leadership attempted to explain leaders’ political behavior by looking at their early childhood and families. Thus Freud and Bullitt (1932) said that Woodrow Wilson was obsessed with his articulate and impressive father. Wilson buried his resentment under an intense idealization of his father and publicly played out his private fantasies of Christlike greatness by attempting to become a new savior of the world.

For Freud, the father of the family defined the leader’s psychological world: “He is everyone’s own private leader, who mediates the transition ... from inner to outer, from psychology to politics” (Strozier Offer, 1985, p. 43). Fenichel (1945) held that obedience to the father provided protection; the father could become a savior in a crisis (Bychowski, 1948). Mother figures could be as important as father figures. Strong mothers or absent fathers figured strongly in the careers of Franklin Delano Roosevelt, Douglas MacArthur, and many other world leaders (as will be noted in [Chapter 34](#)).

*Psychohistory.* Psychoanalysis was the theory of choice for psychohistorians attempting to understand political leaders in terms of childhood deprivation, cultural milieu, relationships with parental authority, and the psychodynamic needs of their followers. Illustrative of this approach are the psychoanalytic treatises written about Adolf Hitler (e.g., Waite, 1977). Other biographical subjects of psychoanalysts have been Abraham Lincoln, Martin Luther, and Mahatma Gandhi (Erikson, 1969). Psychohistory went beyond psychoanalysis by looking at the personality development and dynamics of leaders in their interactions with society and history. The personal conflicts of world leaders were linked to historical developments. For instance, Erikson (1968, 1969) concentrated on the importance of Martin Luther's adolescence and Mahatma Gandhi's adult life. Historical crises were explained in terms of personal traumas of a leader.

Kernberg (1979) focused on the *schizoid*, *obsessive*, *paranoid*, and *narcissistic* character of leaders. Kohut (1976, 1977) saw charismatic leaders as narcissists, who use their followers to maintain their self-esteem. The followers' shame, jealousy, and hate are buried by their idealization of the leader. The pathology of leadership was also explored by Kets de Vries (1980, 1984), among others. But although the psychoanalytic study of leadership has accentuated psychopathological issues, "it is ... patently absurd to label all leaders as pathological" (Strozier & Offer, 1985, p. 6). There is an imbalance in the psychoanalytical attention given to the neurotic and psychotic aspects of leaders' behavior and the ignoring of what is healthy and creative in leaders. Therefore, the psychoanalytic view needs to be refocused to explain "that elusive fit between the *leader* and the *led* in the full richness of the unique moment of the past" (Strozier Offer, 1985, p. 7). For example, Alexander (1942) and Erikson (1964) considered mature leaders, in contrast to immature leaders, to have innate abilities to command attention, to be free from irrational conflicts, to be sensitive to the needs of others, and to be able and willing to relate emotionally to others.

Using the methods of psychohistory to delve deeper into questions concerning social insight, G. Davis (1975) explained how the psychodynamics of Theodore Roosevelt found expression in his affective insights as an adult leader. Personal recollections, published accounts, journalism, and biographies about Roosevelt as a child were meshed with an analysis of relevant cultural developments in the United States during his time. Davis concluded that Roosevelt's psyche resolved the childhood experiences of his generation.

*Crises and Charisma.* Psychoanalytical theory was also used by Kets de Vries (1980) and by Hummel (1975) to show how the interaction of the personalities of leaders and their situations is dramatized in times of crisis. Kets de Vries (1980) maintains that charismatic leaders arise during crises out of a sense of their own grandiosity and the group's sense of helpless dependency. Whether they serve well as leaders depends on whether they can test their "paranoid potential" and their sense of omnipotence against reality. In fragmented societies, such charisma may give rise to an integration of institutions and loyalties or it may spawn opposition movements (G. T. Stewart, 1974). For Hummel, "projection" by followers explains their intense love for a charismatic leader. Followers see the leader as a superhuman hero because they cannot become consciously aware of their unconscious projections. Zaleznik (1977) proposed that a true leader, in contrast to a manager, has resolved the conflicts of his id and superego and has developed strong ego ideals, embodied in his confidence and self-determination.

*Cognitive-Experiential Self Theory.* Freud's initial concept has been improved in the light of new clinical insights and experiments in cognition and the psycho-dynamic unconscious. Freud's single fundamental need to seek pleasure and avoid pain was replaced as a source of motivation by the need of a leader for a stable, co-herent conceptual framework (Rogers, 1959) and the need to overcome feelings of inferiority (Adler, 1954), among many other alternatives of consequence to the leader-follower relationship. Particularly relevant was Epstein's (1994) integration of the cognitive and psycho-dynamic unconscious. Epstein assumed two interacting information processing systems—rational and emotional-experiential.

Behavior is influenced by both. Four fundamental interacting needs are those (1) for pleasure, (2) to maintain coherence, (3) for relatedness, and (4) to enhance self-esteem. Both leaders and followers would be more likely to value emotional appeals based on hunches if they more often processed information on the basis of experience and emotions. Conversely, they would be moved by principles and deductions if they processed information more often by reasoning.

*Group Dynamics.* Psychoanalysis had much to say about the leader-follower development in the small group.<sup>3</sup> According to Freud (1922), group members act like siblings in developing their ego-identification. They form a common libidinal connection with their leader (father) by incorporating his image into their superego. According to Redl (1942), the central person in the group (not necessarily the group leader) becomes an object of the members' identification on the basis of love or fear, an object of aggression, and a support for their own egos. The central person can become a model to be admired—the members' *ego-ideal*. The followers may internalize the leader's standards of conduct or come to fear her or him as an aggressor. What had the most influence on the course of subsequent research on education and the practice of group dynamics was Bion's (1948, 1961) sorting of leader-member relations into four "cultures": (1) task-oriented, (2) dependent, (3) fight-flight, and (4) pairing.

Psychoanalysis also has much to say about leader-ship in therapeutic groups, although opinions differ on whether the group therapist is the group leader. For instance, Scheidlinger (1980) argued that the therapist's leadership is important to how the group will function, as well as how much the group can contribute to successful treatment by providing a climate of safety and support for the reenactment of family-child and parent-child encounters.

### ***Political Theories of Leadership***<sup>4</sup>

Political theorists, from Plato on, had explanations, either explicit or implicit, and prescriptions for leadership. Marxism-Leninism, with its focus on economic determination in history coupled with the dictatorship of the proletariat, laid out strong messages about who shall lead and what is expected of leaders. Mao Zedong's mass-line leadership was much more explicit. It incorporated operant conditioning, consciousness-raising in small groups, confession, self-criticism, and critical feedback. For Mao, the scattered and unsystematic ideas of the masses were to be studied to turn them into concentrated and systematic ideas that the leadership would take back and explain to the masses. This was to continue until the masses became committed to the ideas and then implemented and tested them (Barlow, 1981).

Nazi ideology was centered on the *Führerprinzip*, which had figured strongly in German authoritarian ideology in the nineteenth century. As propounded by the Nazi movement, unquestioning obedience and loyalty to superiors produced order and prosperity, to be shared by those who were worthy by race (the Aryans) to participate in the "new order." The other races were to be relocated, enslaved, or exterminated (Evans, 2005). Worship in Japan and fascism in Spain, Italy, and elsewhere had a similar blend of feudalistic, authoritarian, and ethnocentric ideologies. Like kings with a divine right, like the emperor of China who pursued the "will of heaven," the national dictator could do no wrong, so each successive level of leadership below him was equally infallible. Superiors' decisions were to be obeyed, not questioned (Evans, 2005). In contrast, in the leadership espoused in the democratic world constitutionally elected representatives are responsible to their constituencies and follow laws based on the legislative vote of the majority, but the rights of the minority are constitutionally respected and protected.

According to J. M. Burns (1977), political leaders is "those processes and effects of political power in which a number of actors ... spurred by aspirations, appeal to and respond to the needs ... of would-be followers ...

for reciprocal betterment ... or real change in the direction of 'higher' values. Political leadership is tested by the extent to which real and intended changes are achieved by leaders' interactions with followers through the use of their power bases. Political leadership is broadly intended "real change." It is "collectively purposeful causation" (p. 434). In established governments, "political power" refers to processes for the "authoritative allocation of values that are considered legitimate uses of power under existing ... conventions, traditions, understandings, or constitutional processes. This legitimacy is usually linked to formal authority" (J. M. Burns, 1977, p. 434). Political theories of leadership explain the rise of conservative, reform, and rebel movements; the significance of historical events and forces; the mobilization of constituencies; and the importance of the leader's personality and power. They examine the leadership of presidents, ministers, cabinets, and legislatures in democratic, authoritarian, and totalitarian states. Their focus ranges from the small community to the large urban center. They examine the results of public opinion polls and elections.

### ***Leadership of Organizations***

Chester Barnard had 40 years of experience with AT&T and eventually became president of New Jersey Bell. On the basis of his experience and observations, in his classic *Functions of the Executive* (1938), he concluded that *cooperation* was essential for an organization's survival. (At the time he wrote, command and control were regarded as more essential by management theorists.) Equally important were acceptance of purpose and the ability to communicate. The executive required the capacity for affirming decisions that provided quality and morality to the coordination of organized activities and to the "formulation of purpose." The purposes of cooperation were impossible without specialization, and the integration of the specializations demonstrated the cooperation needed for the organization to survive.

Barnard's ideas were modified by a focus on executive decision making (Simon, 1947; March & Simon, 1958), and more recently by other organizational theorists to fit with changes in society. Thus Guskin (1999) suggested that organizational instability may call for executive command and control until stable conditions are reestablished. Perloff (1999) argued that Barnard had left out the overriding importance of trust in the executive by his (or her) various constituencies (board members, managers, employees, customers, suppliers, government agents, and community). Fowler (1999) saw another factor as having been ignored: the importance to the executive of being allied with reliable advisers who tell what he needs to hear, not what he wants to hear. Among many others, Clifton (1999) added to Barnard's principles of purpose and the need for communication the psychological and humanistic need of the organization for a sense of shared mission, promoting employees' participation in decisions, matching employees' strengths and assignments, and offering incentives for measured superior performance.

*Economic Theories of Organization.* Economic theories are based on assumptions about the motivation of "economic man." For instance, according to Agency Theory (Meckling & Jensen, 1976), owners of firms aim to maximize their profits. Nonowner managers are agents of the owners and cannot be trusted to have the same interests as the owners. They are likely to be interested in maximizing their own compensation and advancement. As economic persons, they are selfish, opportunistic, and individualistic, and they may ignore what is best for the organization in favor of what is best for themselves. They will need to be monitored closely by the owners. Williamson (1975) saw the firm as a marketplace in which all members are economically motivated in competition with one another. Bargaining replaces cooperation in getting things done. The interactions between leaders and followers are negotiations influenced by their differences in resources and power. Economic theories are in marked contrast to humanistic theories, which see people as basically cooperative, as having a strong sense of responsibility, and as willing to work toward common goals

(Donaldson, 1990).

*Social Psychological Theories.* Social psychological leadership theories were influenced by the principles of American democracy and individual freedom. The human being is by nature a motivated organism. The organization is by nature structured and controlled. It is the function of leadership to modify the organization to provide freedom for individuals to realize their motivational potential for the fulfillment of their needs and to contribute to the accomplishment of organizational goals.

*McGregor.* One prominent analysis was McGregor's (1960, 1966) postulation of two types of organizational leadership—Theory X and Theory Y. Theory X assumed that people are passive: they resist organizational needs and attempts to direct and motivate them to fit these needs. Theory Y assumes that people already have motivation and a desire for responsibility: organizational conditions should be arranged to make it possible for people to fulfill their needs with efforts toward achieving organizational objectives.

*Argyris.* In his *maturity-immaturity* theory, Argyris (1957, 1962, 1964a) perceived a fundamental conflict between the organization and the individual. It is the nature of organizations to structure members' roles and to control their performance in the interest of achieving specified objectives. It is the individual's nature to be self-directive and to seek fulfillment through exercising initiative and responsibility. An organization will be most effective when its leadership provides the means whereby followers may make a creative contribution to it as a natural outgrowth of their own needs for growth, self-expression, and maturity. Most organizations pursue a one-way model of how people are supposed to relate to others. The model has a single loop or one-way link from the more powerful to the less powerful. In this model, there is preference for: (1) unilateral control; (2) a win-or-lose orientation toward others; (3) concealment of feelings; and (4) a rational censoring of information, freedom, and risk. In contrast, the model espoused by Argyris (1983) is double-looped in that it comprises: (1) a learning orientation; (2) a low-defensive, high-information environment; and (3) joint control by the more powerful and the less powerful. Choice is free and informed. This double-loop model ought to be more effective in the long run for both the individual and the organization.

Heavily influenced by Kurt Lewin (1947), Likert (1961a, 1961b, 1967) argued that leadership is a relative process because leaders must take into account the expectations, values, and interpersonal skills of those with whom they are interacting. Leaders must present behaviors and organizational processes that the followers perceive to be supportive of their efforts and of their sense of personal worth. Leaders will involve followers in making decisions that affect their welfare and work. They will use their influence to further the task performance and personal welfare of followers. Leaders will enhance the cohesiveness of the group and the members' motivation to be productive by providing followers with freedom for responsible decision making and the exercise of initiative.

*Blake and Mouton.* Blake and Mouton (1964, 1965) conceptualized leadership in terms of a managerial grid. Concern for people was represented by one axis of a two-dimensional grid; concern for production was represented by the other axis. Leaders may be high or low on both axes, or they may be high on one axis and low on the other. The leader who rates high on both axes develops followers who are committed to the accomplishment of work and have a sense of interdependence through a common stake in the organization's purposes. Relationships of trust and respect for the leader emerge as well. Misumi and Peterson (1985) reviewed a line of theory and testing by Misumi and colleagues in Japan. Called Performance-Maintenance (PM) theory, it was similar to Blake and Mouton's concern for performance and concern for production. Optimum supervision occurred when both P and M were high rather than low.

*Maslow.* Maslow's theory of "eupsychian" management (1965) was derived from his observations of people at work in industry. Maslow stressed that it is important for managers to develop their subordinates' self-esteem and psychological health and emphasized the need for self-actualization so that everyone would have an opportunity to realize his or her own capacity. Eupsychian management distinguished between the person who was trying to be a democratic superior and one who was spontaneously democratic. According to this theory, the unconscious and the depths of personality had to be probed in the search for enlightened management. On the basis of such probes, different leaders would be chosen for different situations. The Blackfoot Indians were an example. The Blackfoots gave power to a leader only on an ad hoc basis for the situation in which it was warranted. Such leadership ought not to be left to self-seekers with a neurotic need for power, but should be given to those who are best suited to be leaders for the designated situation—those who can set things straight, who can do what needs to be done.

*Hersey and Blanchard.* Hersey and Blanchard's (1969a, 1972) life cycle theory of leadership synthesizes Blake and Mouton's (1964) managerial grid, Argyris's (1964a), maturity-immaturity theory and the Ohio State leadership study with regard to concepts of consideration and initiation of structure (Stogdill & Shartle, 1955). According to Hersey and Blanchard's situational leadership model, the leader's style of behavior should be related to the maturity of the subordinates. As the subordinates mature, the leader should decrease emphasis on structuring tasks and increase emphasis on consideration. As the subordinates continue to mature, there could be an eventual decrease in consideration. Maturity is defined in terms of subordinates' experience, motivation to achieve, and willingness and ability to accept responsibility.

*Rost.* Rost's (1993) theory is at an extreme. Most theories of leadership focus on the leader. Rost argued for eliminating the distinction between leader and follower. Leadership is a process. Influenced by Maslow, Rost held that whoever had the information and motivation in a given set of informal relationships should be able to temporarily be the source of influence in the ideal group, a group without a formal distribution of power, authority, and responsibility.

### ***Interaction and Social Learning Theories***

Social psychology formed the basis of many other theories of leadership. Many other social interaction and social learning theories explain the leader-follower relationship as a consequence of the leader's interaction with the followers as well as with the circumstances involved. Interaction theories of leadership such as Gibb's (1958) study are characterized by a complex combination of the leader's personality; the followers' needs, values, attitudes, and personality; and the group's structure of interpersonal relations, character, task, and environmental setting. What happens also may be explained in terms of the leader's role and its attainment, reinforcement of change, paths to goals, and the effects of contingencies.

*Leader-Role Theories.* In *informal* groups, structure develops and roles are taken so as to permit one person or perhaps a few persons to emerge as leaders. According to leader-role theory, the characteristics of the individual member and the demands of the situation interact so that during the course of the members' interactions, groups become structured in terms of positions and roles. Leaders are expected to play a role that differs from the roles of other group members. Homans (1950) developed a theory of the leader's role based on action, interaction, and sentiments. He assumed that an increase in the frequency of interaction by group members and their participation in common activities was associated with an increase in their mutual liking and in the clarity of the group's norms. The higher the status of persons within the group, the more nearly their activities would conform to the group's norms, the wider their range of interactions would be, and the

larger the number of group members with whom they would originate interactions would become.

In *formal* organizations, leaders behave according to what their colleagues expect of them and how—in their own perception—their roles are formally defined. The leaders' and colleagues' perceptions and expectations of their roles are further influenced by the organization's formal policies and procedures, by informal communications with colleagues, by past experience, and by their own needs and values (Kahn & Quinn, 1970). There is also an effect on the ratings of their performance as leaders, which depend on whose expectations are most salient for them in defining their roles (Tsui, 1995). The expectations will change as an organization changes. New and conflicting requirements will call for changes in roles (Eggleston & Bhagat, 1993). Managers ordinarily must cope with conflicts among different sources of information about their roles. Osborn & Hunt (1975a) argued that what the organization prescribes for the managers' routine activities is not leadership; rather, leadership involves only the discretionary activities that leaders perform when the prescriptions fail to tell them what to do. Hunt, Osborn, and Martin (1981, p. 3) presented a well-supported theory to explain why some leaders act efficiently in response "to specific opportunities and problems which the unit is not designed to handle."

Rules and procedures created by an organization can make the leadership role redundant. Kerr and Jermier (1978) pioneered the analysis of the *substitutes for leadership*. Nevertheless, a wrong inference can be drawn here—that more available regulations necessarily reduce the discretionary behavior of leaders. On the contrary, Hunt, Osborn, and Martin (1981) predicted and found that leaders in units with more rules, policies, and procedures were expected to respond with more discretionary use of those rules and procedures and actually did so. Jones (1983) analyzed the leader's role in terms of controls imposed by the organization. Jones argued that such controls of the work flow, of the way a task is structured, and of the way jobs are formalized may provide supervisors with as much influence over what goes on as does their power to discipline subordinates.

*Theories on Attaining the Leadership Role.* These theories attempt to explain who emerges as a leader of a group and why. Hemphill (1954) argues that leaders emerge in situations in which components of group tasks are interdependent and are related to the solution of a common problem among group members. Fundamental to his theory is the concept of *structure in interaction* or predictable interaction activity. The role structure of the group and the office of the leader are defined by institutionalized expectations with respect to *initiation* of structure in interaction. The probability that an attempted act of leadership will succeed is a function of the members' perceptions of their freedom to accept or reject the suggested structure in interaction. When such a structure leads to the solution of common problems, it acquires value and strengthens the expectation that all group members will conform to it. Thus initiation of structure in interaction is attempted leadership. Hollander and Julian (1969) hold that an emergent leader, instead of being just another undifferentiated member of the group, is the member who has built up *idiosyncrasy credit* with his or her followers by successive successful attempts to lead.

*Role Expectations.* According to Tsui (1984), superiors, peers, subordinates, and others indicate what they expect of the manager's role. The expectations of these various constituencies can be in conflict. Superiors may expect the manager's role to be that of a monitor; subordinates may see it as that of a coach. If the expectations are met, the leader gains reputational effectiveness. Consistent with Hemphill, Stogdill (1959) developed an *expectancy-reinforcement* theory of such role attainment. This theory attempted to explain the emergence and persistence of successful leadership in initially unstructured groups. It also tried to understand what leadership is and how it comes into existence. As group members interact and engage in shared tasks, they reinforce the expectation that their actions and interactions will continue in accord with their previous performance. Thus the members' roles are defined by confirmed expectations of the performances and interactions they will be permitted in order to contribute to the group. The potential of members to be

successful leaders is the extent to which they initiate expectations and maintain structure in interaction. For Stein, Hoffman, Cooley, et al. (1979), emergent leaders are the group members who are most willing and able to perform those roles and functions that enable the group to accomplish its tasks. They guide and encourage others to contribute to the process. Such leadership will appear in phases that parallel Tuckman's (1965) stages of group development: orientation, conflict, and emergence. Some emergent leaders take charge early; others move ahead with collaborators; and still others fail to maintain their initial success as leaders.

*Path-Goal Theory.*<sup>5</sup> The reinforcement of change in the subordinate by the leader is a prominent aspect of path-goal theory. Georgopoulos, Mahoney, and Jones (1957) and M. G. Evans (1970a) suggested that the successful leaders showed followers the rewards available to them. House (1971) maintained that the leader also showed the followers what paths (behaviors) to follow to obtain the rewards. The leader clarified the goals of the followers as well as the paths to reach those goals. This clarification enhanced the psychological state of the followers and aroused them to increase their efforts to perform well. Followers achieve satisfaction from the job to be done. The leaders enhanced satisfaction with the work itself and provided valued extrinsic rewards like recommendations for pay increases, contingent on the subordinates' performance. (The leader needed to be able to control the rewards that subordinates value.)

The situation determined which behavior by the leader could accomplish these path-goal purposes. Two important situational aspects were how competent the subordinates were and how highly structured the task was (House & Dessler, 1974). To reconcile the theory with experimental results, House (1972) proposed that the effects of a leader's behavior were contingent on three kinds of "moderator variables": (1) task variables, such as role clarity, routine, and externally imposed controls; (2) environmental variables; and (3) individual differences in preferences, expectations, and personality.

*Contingency Theories.* Along with House's path-goal theory, Fiedler's contingency theory (1967a) dominated much of the research on leadership during the 1970s and 1980s. For Fiedler, the effectiveness of task-oriented and relations-oriented leaders was contingent on the demands imposed by the situation. Leaders were assessed as task oriented or relations oriented according to the way they judged their least preferred coworker. A situation was favorable to the leader if the leader was esteemed by the group; if the task was structured, clear, simple, and easy to solve; and if the leader had legitimacy and power by virtue of his or her position. The *task oriented* leader was most likely to be effective in situations that were most favorable or most unfavorable to him or her. The *relations oriented* leader was most likely to be effective in situations between the two extremes of favorable and unfavorable.

Most person-situation theorists focused on how the leader ought to be developed to adapt best to the needs of the situation. But Fiedler's research and theory emphasized that the leader ought to be placed in the situation for which he or she is best suited. Task oriented people should be selected to lead in situations that are very favorable or unfavorable to the leaders; relations-oriented people should be selected to lead in situations that are neither very high nor very low in favorability. Otherwise, leaders needed to learn how to change a situation to match their orientation. Therefore, Fiedler, Chemers, and Mahar (1976) developed a method to help a leader "match" his or her appropriate situation: the leader was helped to change the situation or to adjust better to its favorability or unfavorability. Fiedler, Chemers, and Mahar's (1976) leadership-training program consisted of first identifying the trainee's particular style—task or relations orientation—and then teaching the trainee how to analyze and classify leadership situations for their favorableness, or situational control. The next elements to be considered were the best fit of the situation and style and how to change one's style to suit the occasion or how to change the situation to fit one's style better. Fiedler's five decades of work involved a progression from empirical discoveries to the formation of the theory to the practical application of the theory and to validation of the applications.<sup>6</sup>

*Situational contingencies.* Many others have proposed that personal traits resulting in the emergence or success of a leader would be influenced by the task or goals, the followers' traits, and the organizational context of the situation (Bass, 1960).

*Additional Theories and Models of Interactive Processes.* Numerous additional elaborations have appeared to account for leadership and for leader-follower relations as an interactive process. For instance, Fulk and Wendler (1982) and Greene (1975) agreed that if subordinates (followers) perform well, the leader displays more consideration, which then leads to increased satisfaction for the followers. If the followers do not perform well, the leader displays more structuring behavior and the followers' satisfaction does not increase.

*Communication Theories.* Communications and rhetoric provide another point of departure for theories about leader-follower interactions. For example, Sharf (1978) created a rhetorical framework based on a theory by Burke (1969) to analyze the relative success of emerging leaders in small groups in obtaining cooperation from the other members and in resolving the struggle for leadership status. When applied to recorded discussions of small, leaderless task groups, the analyses revealed the importance of going beyond symbolic divisions in the emergence of leadership.

*Multiple-Linkage Model.* Yukl (1971) agreed that the leader's initiation of structure enhances subordinates' ability to cope with a situation; the leader's consideration for the welfare of subordinates enhances the subordinates' satisfaction with the situation. Then Yukl (1981) greatly expanded the interaction framework with a multiple-linkage model suggesting that the subordinates' effort and skill in performing a task, the leader's role, the resources available, and the group's cohesiveness all moderate the effects of the leader's behavior on group outcomes. The model also differentiated between leadership required for short-term effectiveness and that required for long-term effectiveness. Yukl and Kanuk (1979) provided evidence that, in contrast to performance outcomes, subordinates' satisfaction resulted from different patterns of behavior by the leader and mediating conditions.

*Multiple-Screen or Cognitive Resources Model.* Another interaction approach to understanding the relations of the leader and the led is the multiple-screen model, which attempted to explain the relationship between the leader's intelligence and the group's performance. Fiedler and Leister (1977) suggested and provided empirical support for the proposal that intelligent leaders can generate effective groups if the leaders have good relations with their bosses. If relations are poor, then experienced rather than intelligent leaders bring about more productive groups. Experience is more important to effective leadership if leader-boss relations are poor.<sup>7</sup>

## ***Exchange Theories***

Exchange theories assume that group members make contributions at a cost to themselves and receive benefits at a cost to the group, the organization, or other members. As with Burns's (1978) transactional leadership, leaders exchange rewards or the avoidance of discipline for followers' satisfactory performance. Interaction continues because leader and followers find the social exchange rewarding. Blau (1964) began with the fact that most people consider it rewarding to be elevated to a position of high status. Also, it is rewarding for members to associate with their high-status leaders. But leaders tend to deplete their power when members have discharged their obligations to the leaders. The leaders then replenish their power by rendering valuable services to the group. They benefit as much as anyone else from following their good suggestions rather than somebody else's poorer ones. Followers' compliance constitutes a surplus profit that the leader earns.<sup>8</sup>

*Vertical-Dyad Linkage (VDL) and Leader-Member Exchange (LMX) Theory.* Graen's (1976) vertical-dyad linkage (subsequently called leader-member exchange) was one of many interaction theories that were based on the assumption that social interaction represents a form of exchange. The vertical dyad of leader and subordinate (VDL) is an interaction linkage of mutual influence. It emphasizes the relationship between the leader and each individual follower rather than between the leader and the group as a whole. In corresponding LMX theory, Graen (1976) assumed that the leader behaves differently toward each follower and that these differences must be analyzed separately. This theory is in opposition to most earlier theories, which assumed that the leader behaves in much the same way toward all group members and that behavioral descriptions from group members can be averaged to obtain an accurate description of the general behavior of the leader. According to Graen, leaders categorize followers as belonging to an in-group or an out-group, and the leader behaves differently toward members of these two groups. In-group members can be more independent of the leader and receive more attention from the leader, as well as more of the other rewards. As a consequence, in-group members perform better and are more satisfied than out-group members (Vecchio & Gobdel, 1984). Numerous, extensive empirical investigations by Graen and associates of vertical-dyad effects have been published and will be discussed more fully in Chapters 15 and 16.

*Organizationally Defined Expectations.* T. O. Jacobs (1970) formulated a social-exchange theory and buttressed it with a wide range of research findings. According to Jacobs, the group provides the leader with status and esteem in exchange for the leader's unique contributions to the attainment of the group's goals. Authority relationships in formal organizations define role expectations that enable group members to perform their tasks and to interact without the use of power. Leadership implies an equitable exchange relationship between the leader and the followers. When role obligations are mutually acknowledged, each party can satisfy the expectations of the other on an equitable basis.

### ***Cue-Behavior-Reinforcement Theories***

Aaronovich and Khotin (1929) reported using differentially cued reinforcements to alter the leadership behavior of monkeys in uncovering boxes of food. Mawhinney and Ford (1977) reinterpreted path-goal theory in terms of operant conditioning. W. E. Scott (1977) saw a need to replace the concept that leadership is due to influence or persuasion with an analysis of the observable behaviors of leaders that change the behavior of subordinates. All these behavioral theories emphasized reinforcement and making the receipt of rewards or the avoidance of punishment contingent on the subordinate's behaving as required. According to Davis and Luthans (1979, p. 239), "The leader's behavior is a cue to evoke the subordinate's task behavior. The subordinate's task behavior, in turn, can act as a consequence for the leader, which, in turn, reinforces, punishes, or extinguishes the leader's subsequent behavior. Similarly, the subordinate's behavior has its own consequences, which serve to reinforce, punish, or extinguish this behavior. The consequences for the subordinate's behavior may be related to the leader's subsequent behavior [to] the work itself, and its outcomes, or [to] other organization members."

Supervisors do not directly cause subordinates' behavior; they merely set an occasion or provide a discriminative stimulus. The behavior of subordinates depends on its consequences. Environmental cues, discriminative stimuli, behaviors, and consequences form a behavioral contingency for analysis. Thus Sims (1977) conducted one of many investigations demonstrating that a leader's positive rewarding behavior will improve a subordinate's performance, particularly if the reward is contingent on the quality or quantity of the subordinate's performance.

Concentrating on the followers' reactions, Kerr and Abelson (1981) developed a model to represent

extreme, rather than ordinary, leader-subordinate interactions. The day-to-day behavior of the leader may be relatively unimportant to the supervisor-subordinate relationship, compared with the leader's behavior when a subordinate experiences an intense demand or when the leader experiences a highly unexpected response. This model shows that subordinates can become so accustomed to frequent leadership activity that the effects of this activity are minimal and even dampening.

The importance of reinforcement in the leader-follower relationship will be examined in various contexts in many of the later chapters that deal with power relationships and exchange relationships. Reinforcement is central to the operant model of supervision as well as to pathgoal theory.

*Operant Model of Supervision.* This model derives from Skinner's (1969) theories of behavioral conditioning. It describes what leaders should do "compellingly and consistently to motivate subordinates" (Komaki & Citera, 1990, p. 91). Three categories of behaviors are specified: (1) antecedents of subordinates' performance (instructions, rules, training, goals); (2) monitoring of performance (work sampling, subordinates' self-reporting, secondary sources) and; (3) consequences of performance (feedback, recognition, correcting). For an empirical example, more effective insurance managers spent more time than less effective insurance managers monitoring their agents (Komaki, 1986). Racing sailboat captains who monitored their crews hoisting their sails and provided feedback correlated (.51, .47) with the racing results (Komaki, Deselles, Bòwman, 1989).

## ***Perceptual and Cognitive Theories***

An early theoretical emphasis on the perceptual and cognitive aspects of leadership was provided by Goffman (1959), who analyzed social behavior as theater. That is, Goffman evaluated the roles, membership, and phenomena of groups in terms of actors, audience, front stage, and backstage. According to Goffman, social learning created disparities between the leader's intentions and the followers' understanding of what the leader was trying to do. As noted earlier, Quinn and Hall (1983) developed an integrated theory of leadership based on competing perceptual and cognitive dimensions such as leaders' flexibility versus their control, and leaders' internal versus external focus. Carrier (1984) constructed cognitive maps to locate traits of leadership in reference to these dimensions. For example, the trait of dominance was placed in a location that is high in both control and internal focus.

Perceptual and cognitive theories offer several advantages. They make use of advances in cognitive psychology and are immediately applicable in diagnosis and leadership education. They include theories about social and cognitive processes, attributions, integration with behavioral models, information processing, systems analysis, and rational-deductive decision trees.

*Cognitive Processes.* Before the late 1970s, empirical leadership research and theory paid little attention to leaders' behavior as a consequence of perceptions and thoughts about purposes, followers, or the task and situation. An exception was the use of *stimulated recall*, in which leaders and members of small groups were audio-taped, then listened to the tapes, and then indicated on a second tape recording what they had been thinking at the time of the original discussion (Bass, McGehee, & Hawkins, 1953). Conference videotaping would provide on a replication of the videotape sotto voce commentary by the participants about their thoughts concerning what was originally happening and what they were trying to do.

Leaders' and followers' perceptions and cognition rose in importance. Lord and Maher (1985) first showed how leadership could be best understood by attention to cognitive processes, the importance of implicit theories of leadership, and the "prototypes" or models of leadership that people form mentally. Concepts that have emerged in theories about cognitive processes include attention, encoding, attribution, memory storage,

memory retrieval, evaluations, expectations, and attributions.

To appreciate a leader's behavior, we need to understand the leader's scripts and strategies. A *script* is a conceptual structure. It is held in the memory of events, objects, roles, feelings, and outcomes. There is a sequential pattern to the script's structure of familiar circumstances and tasks. According to Wofford (1998), if a leader uses a script to confront a familiar situation and finds in feedback no discrepancies between goal and outcome, he or she will continue to process the script. The process depends on recognition and is automatic. Otherwise, the process is inferential and is based on reflection of the recent past, integration of performance information, and causal attributions (Cronshaw & Lord, 1987). The leader is likely to include alternative paths to the goal in the script, so that if feedback indicates that the original path is blocked, an alternative will be tried. If no alternative path works, the leader changes strategy. A *strategy* is an original construction of a new script formulated in a pattern to deal with a specific situation for which available scripts have not worked. Or an alternative strategy may be retrieved from memory. Experienced and trained leaders should have a greater number of available scripts. Also, they will need to change strategies less often (Wofford, 1998).

## ***Schemata***

Another cognitive concept, the schema, is an organized knowledge structure. According to Lord Emerich (2001), it is necessary to consider the difference between an individual and a collective schema. An *individual* schema, as the term implies, is in the mind of an individual; it reflects perceived networks of implicit theories of leadership and categorizations of types of leaders into prototypes. A matched prototype is selected. A *collective* schema is "a socially constructed understanding of the world derived from social exchanges and interactions among multiple individuals in a group or organization" (p. 552). Central themes include organizational performance, "sense making," and transformations.

McCormick and Martinko (2005) have combined social cognitive theory with causal reasoning to provide an understanding of a group leader's thoughts and behavior and the group's performance. McCormick and Martinko assume that people regulate their own thoughts and can control their own actions. According to Locke and Latham (1990), people actively monitor the performance environment, develop functional task strategies, implement plans, and monitor results. McCormick and Martinko hold that leaders' and followers' self-regulation is guided by attention and attributions of the causal reasoning process as well as schemata about task-relevant knowledge, skills, abilities, personal goals, action plans, and beliefs in their own efficacy.

*Self-efficacy* is a cognitive concept in Bandura's (1985) social cognitive theory. It is the belief that one has the capability to handle prospective problem situations (Bandura, 1995). A leader's choice of goals and strategies will be affected by a belief in self-efficacy (Kane & Baltes, 1998). McCormick (2001) has built on Bandura to formulate a Social Cognitive Leadership Model. Engaged in self-regulation, the would-be leader, high in self-efficacy, is likely to generate attempts to lead and persist in persuasive efforts despite resistance (Savard & Rogers, 1992). If the leader's belief is valid, the leadership should be effective (Chemers, Watson, & May, 2000).

Propositions that follow include: (1) Leaders who are *not* self-serving and are objective in their perceptions of their environment generate more efficacious behavior. (2) Leaders have an implicit model or schema that influences how they perceive their causal relationships. (3) Leaders' task schema are influenced by their beliefs about causation in their environment. (4) Leaders' self-efficacy influences their goals, task strategies, and use of task schema. (5) Lofty goals are a result of perceptions of "resource-rich" task schemata and a strong belief in self-efficacy (McCormick & Martinko, 2005).

*Attribution Theories.* DeVries (1997) constructed a model of attribution that linked impression

formation, categories, prototypes, perceptions of leadership ideals, and leadership success. Each leader and follower is perceived to have his or her own implicit theories of leadership. If we want to understand the behavior of individual leaders, we must begin by attempting to find out what they are thinking about the specific situation. Whether they are seen as acting like *leaders* depends on their own and their followers' implicit theories about leadership (Eden & Leviatan, 1975). We observe the behavior of leaders and infer that the causes of these behaviors are various personal traits or external constraints. If these causes match our naive assumptions about what leaders should do, then we use the term "leadership" to describe the persons who we observed. Thus Calder (1977) says that leadership changes from a scientific concept to a study of the social reality of group members and observers—a study in how the term is used and when it is used, and assumptions about the development and nature of leadership. For Calder, leadership is a perception of followers that caters to their perceptual needs. Attributions of leadership by observers and group members are biased by their individual social realities (Mitchell, Larson, & Green, 1977), which accounts for the low correlations that are often found between supervisors', peers', and subordinates' ratings of the same leaders (Bernardin & Alvares, 1975; Ilgen & Fugii, 1976; T. R. Mitchell, 1970a), as well as for the confounding of evaluations of the performance of subordinates and the behavior of leaders (Rush, Thomas, & Lord, 1977).

Green and Mitchell (1979) formulated a model to study such attributional processes in leaders. They explained that a leader's behavior is a consequence of his or her interpretation of the subordinates' performance. Thus a leader presented with an incident of a subordinate's poor performance (such as low productivity, lateness, a missed deadline, or disruptive behavior) will form an implicit theory about the subordinate and the situation, judging that the cause of the incident was the subordinate's own personality, ability, or effort, or an externality, such as lack of support, a difficult task, or insufficient information. Causality is attributed more to the subordinate than to the situation if the subordinate has had a history of poor performance and if the poor performance has severe outcomes (Mitchell & Wood, 1979). In such circumstances, the leader will focus remedial action on the subordinate, rather than on the situation, even if the situation was the cause of the problem. Meindl, Ehrlich, and Dukerich (1985), along with Pfeffer (1977) and Calder (1977), agreed that there is a tendency to attribute more of the cause than is actually warranted to the subordinate rather than to the situational circumstances.<sup>2</sup>

*The Romance of Leadership.* Meindl, Ehrlich, and Dukerich (1985) argued that leadership is in the eye of the follower. It is a social construction in the followers' minds and is about their thoughts of how leaders are cognitively structured and represented. Followers place more emphasis on the image of the leader than on the actual behavior or effects of the leader. They are much less under the control and influence of the leader per se than under the control and influence of "the social forces that govern the social construction process itself" (Meindl, 1995, p. 330). The object of study is not the actual personality or behavior of the leader, but personality and behavior as constructed or imagined by the followers. Ordinarily, when correlations are found between the supposed leadership and the effectiveness of an organization, the traditional interpretation is that the effectiveness was the result of the leaders' performance. But interpreted as a romantic notion, leadership is imagined by the followers. Its purpose, as noted above, is to cater to the perceptual needs of the followers (Calder, 1977). Symbols and rituals reinforce the importance of the leader (Pfeffer, 1977). Meindl (1990, 1993) found empirical support for the romantic perspective. Nonetheless, a leader does have real effects on followers, although some effects may be imagined by them. Much additional evidence in this book will attest to the objective effectiveness of leadership when measured independently of followers' opinions. For instance, Smith, Carson, and Alexander (1984) found that leaders do moderately influence the performance of their organizations. Day and Lord (1988) demonstrated that the executive leadership of organizations can account for 45% of these organizations' effective performance. But the question remains in many studies: how much is real and how much is romance, and in what circumstances?

*Integrated Cognitive and Behavioral Models and Theories.* Although attributions by followers can strengthen explanations, any explanation needs to be based on behavior. Still, Lord and Maher (1993) assume that to be a leader one must be perceived as leader. Traits are schemata, knowledge structures, and “sense makers.” Perceptions of distant executive leaders depend mainly on attributions and *inferential processing* from events and outcomes. Prototypes, scripts, implicit theories, and categories grow out of experiences. They are stored in long-term memory and are activated automatically. *Controlled processing* is intentional information processing based on short-term memory. The distinction explains a loss of charisma as followers shift from inferential to controlled processing. To solve problems, experts use *automatic processing*; novices use controlled processing. Experts use meaningful categories. Diagnosis is implicit, intuitive, or both. Solutions and evaluations are scripts and heuristics available to the expert. Novices categorize the same problems by using surface or environmental features, and solutions evaluations.

Luthans (1977) left room for cognitive processes to enter the scenario “to assign concepts to behavior and to infer relationships between events.” Luthans’s functional analysis of the leader-subordinate dynamic used his S-O-B-C model, in which S is the antecedent stimulus, O is the organism’s covert processes, B is the behavior, and C is the consequence. Chemers (1993) provided a behavioral model of leadership, which also took account of cognitive processes. The first of three dimensions of the model was relative to persons: it was the development of interpersonal relationships. The second dimension was resource utilization relevant to the task to be accomplished. The third dimension was the leader’s image management, the effort of the leader to establish and maintain a specific image in the group, such as competence or conscientiousness. As already noted, Hoojberg, Hunt, and Dodge (1997) integrated cognitive, social, and behavioral complexity into a “Leaderplex” model to generate empirical leadership research on global organizations, team-based organizations, diversity, hierarchy, and charisma.

In a mixed model proposed by Bass (1960), leadership deals with the observed effort of one member in a group to change the motivation, understanding, or behavior of other members. Change will be observed in the followers if the leading member is successful in influencing the others. Motivation is increased by changing the followers’ expectations of being rewarded or punished. Leaders acquire their position by virtue of their perceived ability to reinforce the behavior of group members by granting or denying rewards or punishments. Since the group’s effectiveness is evaluated in terms of its ability to reward its members, leaders are valued when they enable a group to provide expected rewards. The congruence of a leader’s perceived status (the value of the position held, and esteem) with the leader’s ability and value as a person regardless of the position can account for the leader’s success. Incongruence generates conflict and failure. This emphasis on congruence is also found in Halal’s (1974) general theory. A particular style of leadership is congruent with specific technologies of tasks and specific motivations of subordinates. Adaptation occurs to achieve greater congruence.

*Information Processing.* Newell and Simon (1972) focused on the problem solver’s “subjective problem space.” This “space” contains encodings of goals, initial situations, intermediate states, rules, constraints, and other relevant aspects of the task environment. Lord (1976) saw the utility of studying the shared problem spaces of leaders and followers when they tackle a common task. For example, a leader was expected to devote more effort to developing an orientation and definition of the problem or the group when the actual task lacked structure.

Social cues and symbols take on more importance for an understanding of leadership if this information processing approach is employed. In addition to encoding, information processing involves selective attention, comprehension, storage, retention, retrieval, and judgment. According to both theory and evidence, perceptions of leaders are based largely on spontaneous recognition. Moreover, the cognitive category of leadership is hierarchically organized. Perceptions and expectations of the attributes and behavior of leaders are

widely shared (Lord, 1976, 1985; Lord, Binning, Rush, et al., 1978). Recognition-based processes are dominated by automatic processing, categorizations, and implicit theories, ordinarily involved in face-to-face interactions at lower levels in the organization. Inferential processes are attributional, controlled, and inferred from events and outcomes ordinarily associated with distant executive leaders (Lord & Maher, 1991).

### ***Open-Systems Theory***

An open-systems point of view implies sensitivity to the larger environment and organization in which leaders and their subordinates are embedded. To convert inputs into outputs, flows of energy and of information must occur in the system. In open systems, the effects of the outputs on the environment are feedback and new inputs. The relations within the system grow and become more intricate with repeated input-output cycles. The cyclical conversion process can be increased in rate and intensity. Leaders or followers can import and introduce more information. Directive leaders do this alone; if followers are included, the process is participative. Energy can be increased by selecting as leaders and followers more highly motivated individuals or by increasing the reinforcements that accrue from outputs (Katz & Kahn, 1966). Agency theory (Meckling & Jensen, 1976) suggested that managers put their own interests ahead of those of owners and shareholders, as when they provide themselves with “golden parachutes.” But open-systems theory sees the manager as a good steward (Donaldson, 1990), concerned with aligning as much as possible the interests of all the constituents of the organization: owners, shareholders, management, employees, and community. The worth of the organization depends on this alignment (Bass, 1952).

Bryson and Kelley (1978) created a systems model for understanding emergence, stability, and change in organizations in which formal leaders are elected, such as cooperatives, professional associations, and legislatures. They made a list of clusters of individual, procedural, structural, and environment variables that were likely to be of consequence to each other on the basis of earlier formulations by Peabody (1976) and Van de Ven (1976).

*Change-Induction and Therapeutic Groups.* Lieberman (1976a) explained change-induction groups, such as psychotherapy groups, encounter groups, self-help groups, and consciousness-raising groups, in terms of systems analysis. Five structural characteristics of the system were seen to affect the change-induction process: (1) the psychological distance between the participant and the leader; (2) felt causes, sources, and cures of psychological misery; (3) the extent to which the group is seen as a social microcosm; (4) the degree to which members stress differentiation rather than similarity; and (5) the relationship between the cognitive and expressive behavior of the leader.

*Macro-and Microlevels.* Many models and theories of leadership have been embedded in larger organizational models and theories. For example, Bowers and Seashore's (1966) four-factor theory of leadership is part of a larger systems theory of organizations. Osborn and Hunt (1975a, 1975b) formulated an adaptive-reactive model of leadership to incorporate environmental constraints and organizational demands as antecedents of the behavior of leaders. Likewise, Bass and Valenzi (1974) used systems theory to construct an open-systems model of leader-follower relationships. According to their model, the systems are open to the outside environment and are sensitive to the constraints imposed on them from outside. The system imports energy (power) and information from outside, converts it, and exports goods and services. The Bass-Valenzi model (Bass, 1976) proposes that whether leaders are directive, negotiative, consultative, participative, or delegative depends on their perceptions of the system's inputs and the relations within the system. The leader and his or her immediate work group form an open system of inputs (organizational, task, and work-group variables), relations within the system (power and information differentials), and outputs (productivity and

satisfaction). For instance, the Bass-Valenzi model posits that leaders will be more *directive* if they perceive that they have more power and information than their subordinates. They will *consult* if they perceive that they have the power but that their subordinates have the necessary information to solve the group's problems. They will *delegate* when they perceive that their subordinates have both power and information. They will *negotiate* when they perceive that they have the information but not the power. A small-space analysis of empirical data by Shapira (1976) supported these propositions.<sup>10</sup>

Bass (1960) argued that the emergence of leadership success in influencing the group and its effectiveness (the group's actual achievement of its goals such as reward or the avoidance of punishment) depended on the *interaction potential* in the situation—the physical, psychological, and social proximity among the would-be leader and the followers. The likelihood that individuals would interact depends on the size of the group; the geographic and social proximity of the individuals; their opportunity for contact, intimacy, and familiarity; mutuality of esteem and attraction; and homogeneity of abilities and attitudes. Monge and Kirste (1975) extended the examination of proximity as a time-and-space opportunity, showing the positive association of proximity with the potential to interact as well as its contribution to satisfaction with the interaction.

Starting with open-systems theory and Jaques's (1978) general theory of bureaucratic organizations, Jacobs and Jaques (1987) formulated a theory to explain the requirements of leadership at successively higher echelons of large bureaucratic organizations such as the U.S. Department of Defense or General Motors. To operate successfully, these organizations must have an appropriate structure, which Jacobs and Jaques specified as no more than five operating echelons and two additional higher headquarters echelons. At each echelon, the complexity of the environment must be understood and clearly transmitted to the next echelon below to reduce uncertainty there. A reduction of uncertainty will add value to productivity at that echelon and define how it must adapt to remain competitive. At each echelon, the role of the leadership is to ensure the accuracy of the uncertainty reduction process and the availability of resources for the required adaptive changes. To accomplish this goal, leaders at successively higher echelons increasingly must have "the capacity to deal with more uncertain and more abstract concepts" and with longer time spans for accomplishment and evaluation.

At the lowest three echelons, leaders must focus on how they can contribute to the organization's productivity above and beyond the rules and policies that have been laid down for them by higher authority. At the next two echelons, leaders must concern themselves with how to maintain and improve their organizational arrangements. At the highest echelons, leadership involves strategic decision making in a "nearly unbounded" environment.

*Multiple Levels Approach.* It is possible to look at the same behavior at three levels of a system—individual, group, and organizational—although the operational character of a construct will change if we move from one level to another. For instance, *individualized consideration*, a component of transformational leadership, would be addressed at the individual level by a question such as, "Does the leader spend time with newcomers to help orient them to their jobs?" At the team or group level, the same issue would be addressed by, "Do the members of the team provide useful advice to newcomers?" At the organizational level, the question might be, "Are there special policies and programs for orienting newcomers?" (Avolio Bass, 1995). We need to specify at which level we are operating. For example, a leader may be described somewhat differently by each member of a team but uniformly by the team as a whole. Conger (1995) conceived a need to add a fourth level—the intrapsychic—within the leader's mentality. Data about a leader can form an additional level when they are collected during several different periods or phases. Markham, Yammarino, and Palanski (in press) found that the "leader-member exchange" had an effect on performance, which was greater in predicting performance for 25 manager's groups composed of their 110 subordinates when each leader-member dyad was taken into account, rather than each manager's group average of the exchange results.

Cognitive, behavioral, and interactional explanations are likely to be needed to account fully for leader-follower relations and the outcomes of these relations. Gilmore, Beehr, and Richter (1979) instructed leaders in an experiment to display either a lot of or a little initiative and a lot of or a little consideration. Although the participants who were subjected to the leadership failed to perceive that their leaders' behavior actually differed, a lot of actual (but not perceived) initiation, coupled with a lot of actual (but not perceived) consideration by the leaders, resulted in better-quality work by the participants. The quality of the participants' work was lower when the leaders displayed a great deal of initiative but little consideration. Evidently, under certain conditions it is more profitable to make use of behavioral theories to understand the behavior of leaders. Under other circumstances, such as when leaders and subordinates must act on the basis of their interpretations of a situation, perceptual and cognitive theories are more useful. Some theories or aspects of theories may account better for the leadership that handles short-term disturbances; other theories may deal better with the leadership that corrects chronic deficiencies over the long term.

Winter (1978, 1979a) developed a complex model that combined aspects of the trait, reinforcement, behavioral, and cognitive approaches and the feedback loops of systems analysis. Winter's model was based on a battery of tests of skills and behavioral competence measures for over 1,000 naval personnel and their leaders. [Figure 3.1](#) shows the emergent model that links various skills with particular performances. The model is based on empirical cluster analyses and subsequent regression analyses.

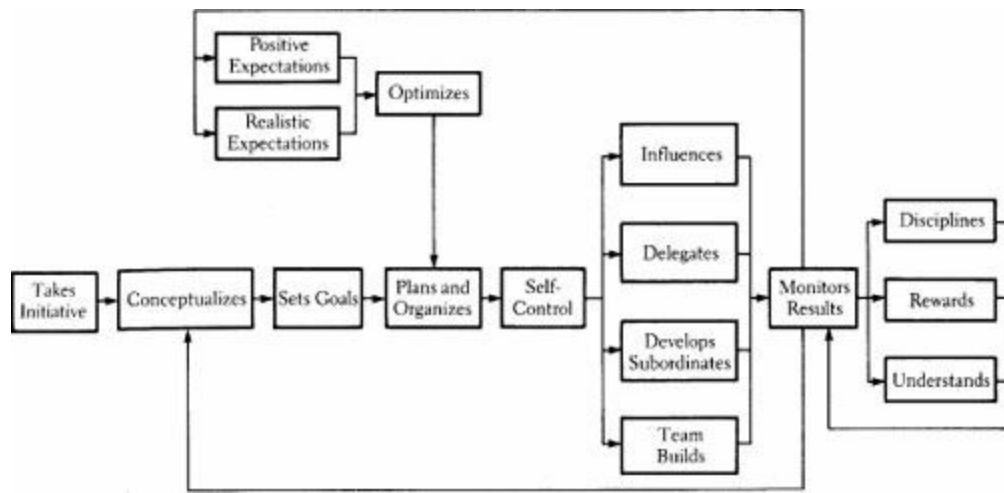

Greater optimization (assigning tasks to those subordinates who are most likely to do them well and making trade-offs between the requirements of the tasks and individual needs) and setting goals both contributed to more delegation by the leader. Increased monitoring by the leader resulted in more positive expectations, disciplining, advice, and counsel. It also contributed to more feedback, which in turn led to more disciplining and giving more advice and counsel.

Zand (1997) found that effective executives make use of knowledge, trust, and power. These three factors are needed to create an impelling vision and to direct a broad course of action. Working with their staff, the executives select a path, sharpen concepts, learn from mistakes, make adjustments, and refine their strategy and implementation as they go along. Johnston (1981) used many of the preceding theories to construct a model of a holistic leader-follower" grid. To represent the leader-follower interchange adequately, Johnston borrowed from Jung's (1968) psychoanalytic theory of life cycles, Berne's (1964) transactional analysis, McGregor's (1960) theory X and theory Y, Rogers's (1951) nondirective counseling, and Tannenbaum and Schmidt's (1958) model of decision making. Tomassini, Solomon, Romney, et al. (1982) also constructed a cognitive-behavioral model in which the leader's influence interacted with the subordinate's work behavior, and they identified situations that circumscribe what a leader can do.

## Methods and Measurements

---

Figure 3.1 Flow Chart of Navy Leadership and Management Processes in Terms of the Cross-Validated Competencies

SOURCE: *Adapted from Winter (1978).*

As noted in [Chapter 4](#), Stogdill (1948) reviewed leadership studies between 1904 and 1947 and found that they employed one of six methods: (1) observation and time sampling of behavior in group situations; (2) choice of associates by voting, naming, ranking, or sociometrics; (3) nomination by qualified observers; (4) identification of persons occupying leadership positions; (5) analysis of biographical and case history data; and (6) listing of traits essential to leadership. Research on the traits of leaders tended to rely heavily on tests and questionnaires for the collection of data. With the development of interaction models and theories, it became important to know what was happening in the group. Expert or trained observers were used to keep a running record of the behavior of group members, and the leaders and followers also might be asked to report their feelings and observations. In some cases, observers merely reported what they saw; in other cases, they were provided with checklists of behaviors or processes to be reported. Bales (1950) developed a checklist for observations of a set of behavioral categories. Carter and associates (1951); Mann (1979); and Komaki, Zlotnick, and Jensen (1986), among others, also developed observational categories and procedures. Bass, Gaier, Farese, et al. (1957) relied on the changes in correlations among members' judgments from before to after group discussion to measure how influential each member had been.

Observational studies identified behaviors that the trait theorists did not anticipate. Whereas the trait theorists were interested in the leader's personality, the interaction experimenters were more concerned with observable interactional behaviors of leaders and their followers. The two approaches could produce moderately correlated results. Jacoby (1974) was able to demonstrate substantial construct validity based on agreement among three methods of assessing opinion leadership—(1) self-designating, (2) sociometric, and (3) key informant.

Laboratory experiments and field surveys have often been the method of choice in cognitive and behavioral investigations. Experiment and survey together provided more convincing evidence. By now, it is fair to say that almost every procedure known to social science has been applied specifically to the study of leadership. These procedures have included content analysis and thematic analysis of autobiographies, biographies, and case studies; verbal protocols; individual structured interviews face-to-face and by computer; panel interviews; interview boards; news and journal reports of historical events, stories, and anecdotes; historical accounts; memorandums; minutes of meetings; speeches; biodata; sociometry, using face-to-face and electronic communication patterns; autologs; cognitive maps; observers' logs of leaders' activities; and ratings by observers, superiors, peers, subordinates, and outsiders, such as clients, customers, and suppliers. Many analyses were based on leaders' self-ratings; but to increase confidence, these increasingly were supported by investigations using two or more independent approaches. For example, Heller (1969a) first collected survey-questionnaire data from managers. After analyzing the results, he gathered the managers together in panels to interpret and confirm or refute the findings. Also, focused interviews of panels of voters provided the basic

ideas for political media campaigns that were then followed up by public opinion polls of representative samples of voters (Kerman & Hadley, 1986).

For experiments, leaders were described in fictional sketches as being reacted to by readers as if they were followers. Leaders were self-selected, appointed, nominated, elected, emergent, or simulated. Methods were quantitative or purely qualitative, but there was increasing use of each method to buttress the other. The *historiometric* approach was the oldest method, beginning with Quetelet's (1835/1968) research on leading dramatists. Historiometric research on leadership was exemplified early on by Cox's (1913) study of the influence of monarchs, and more recently by O'Connor, Mumford, Clifton, et al. (1995) on famous and infamous world leaders. Simonton (1999) enumerated psychological studies of eminent persons such as famous sports stars, Nobel laureates, and chess grand masters. Quantitative methods are used to analyze historical sources of information. *Psychometric* research applied surveys, interviews, and psychological tests to study individual leaders. Modern *psychobiographical* research began with Freud's (1910/1964) psychoanalytic study of Leonardo da Vinci. An intensive study of a single individual, Roosevelt, *The Lion and the Fox* is illustrative (J. M. Burns, 1956). Psychobiographical research can also deal with multiple cases. It has usually been qualitative. Politicians and presidents are most often the subject of investigation. *Comparative* research looks at a small sample of leaders and contrasts them according to biographies, interviews, media accounts, and other sources of information and events. Among the many quantitative and qualitative methods, some of those used more in leadership are presented briefly below.

### ***Quantitative Methods***

Of the 188 articles published by the *Leadership Quarterly* between 1990 and 1999, descriptive statistics were provided by 87%, and simple inferential statistics by 69%. From 25% to 32% of the articles made use of multivariate analyses. Less frequently employed were confirmatory factor analysis (14%), structural equation modeling (13%), and multiple-levels analyses (13%; Lowe & Gardner, 2001). The use of quantitative methods in social science such as Q sorting, confirmatory factor analysis, and structural equation modeling increased with the availability of computer analysis. Other quantitative methods in social science most applicable to studies of leadership were multiple-levels analysis, rotational designs, and designs for the avoidance of common error variance. Meta-analysis made possible valid statistical summaries of the results of replicated and similar studies using the same or comparable variables.

*Q Sorting.* Q sorts are measurements, usually rankings on a set of ratings or tests within each of the same individuals instead of the more common measurements between individuals on the same set. Individuals rather than measurements are correlated. When factor analysis is applied to the matrix of Q sorts, factor types with similar profiles usually emerge, instead of factors of measurements (Cattell, 1946). Q sorting was also applied to matching ratings in order of importance of job requirements with ratings of each candidate's profile of knowledge, skills, and abilities (O'Reilly, 1977). In a large consumer products company, the consistency of ratings of 60 statements of requirements for the position of production manager by 10 job experts was .96. The agreement among the rated manager, a peer, and the boss about the requirements was .81. The correlation of the person-job fit ranged from 2.44. to .86. A high correlation meant a very good fit; a high negative correlation signified a very bad fit. The rank order of the fits correlated .98 with the rank order of performance of the managers rated by the human resources staff and superiors. Similar findings were reported in three further investigations (Caldwell & O'Reilly, undated).

*Confirmatory Factor Analysis.* Unlike the more traditional exploratory factor analysis, which extracts underlying factors from a matrix of correlations of individuals and variables, confirmatory factor analysis

begins with a model of the assumed factors and provides several tests of the goodness of fit between the model and the factors. For instance, Avolio, Bass, and Jung (1999) determined that six factors of the “Full Range of Leadership” provided the best fit of 14 samples of data from scores on the Multifactor Leadership Questionnaire.

*Structural Equation Modeling.* This is a systematic analysis making use of partial and multiple regressions to explore or confirm causal relations between a set of predictors and a set of outcomes. The fit of the obtained model and the hypothesized model can be tested. The strengths of the relations between variables can be obtained from path coefficients similar to partial correlations. Computer programs like LISREL facilitate the analysis for exploration and confirmation.

### ***Multiple-Levels Analyses***

*WABA: Within-and-Between Analysis.* Dansereau, Alutto, and Yammarino (1984) began a continuing line of investigation of variant analyses which quantitatively shows how much of the ratings of the leader in a single study are due to different levels of analysis. The “person level” acknowledges the importance of consistent individual differences among leaders, followers, or both. The “dyad level” recognizes the importance of one-to-one relationships between a leader and each of the followers. The “group level” or “team level” takes cognizance of the face-to-face relations between a leader and a set of followers as a unit. For instance, the leader may treat the followers in the same set in the same way or different ways. The “collective level” or “organizational level” deals with hierarchically organized groups of groups, as when the same or different organizational policies apply to all groups (Yammarino, Dansereau, & Kennedy, 2001). The focus is between entities such as dyads or groups, not within them. Here, as in traditional analysis of variance, differences between entities are viewed as valid; differences within entities are viewed as random error. This is a between-units case in which the members of the unit are homogeneous and the whole unit is important. The “parts” view differs from the traditional analysis of variance in focusing within entities such as dyads or groups. Differences within entities are valid; differences between entities are considered random error. This is the within-units case in which members are heterogeneous; each member’s position relative to others is important. Dyads can be viewed as parts of a group. In this case of dyads-within-groups, leaders differ from each other in the same group, and the same pattern is repeated in the other groups. Thus each leader may form a favored in-group of subordinates and a less favored out-group. Dyads may be completely independent of the groups to which they belong. Then they are viewed as whole dyads, independent and homogeneous entities. Analysis of variance (WABA I) as well as co-variance (WABA II) can be applied to quantitatively decompose a single survey of ratings of leaders and their correlated effectiveness.

Further breakdowns may test whether there is an equitable balance of leader and subordinate, whether relations between dyads are stronger in some groups than others, and whether consensus is the same in some dyads in some groups but not others. Cross-level effects from dyads to groups can also be specified (Yammarino, 1995; Dansereau, Yammarino, & Markham, 1995). In a study of insurance and retail salespersons’ attitudes about factors controllable by management and supervisory ratings of the salespersons’ performance, Yammarino and Dubinsky (1990) found differences between the groups of aggregated ratings as well as individual differences within the groups. Some groups of supervisors and subordinates were rated higher than others across the groups; some supervisors and subordinates in the same group were rated higher than others. Castro (2002) contrasted WABA with other multi-level methods of leadership research. These included intraclass correlation ( $r_{wg}$ ), hierarchical linear modeling (HLM), and random group resampling (RGR).

*Intraclass Correlation.* The expression  $r_{wg}$  is the ratio of the difference in the variance of ratings between leaders' and followers' ratings of each of the same leaders, compared with the variance of ratings between leaders (suitably corrected for the number of leaders). This index provides the reliability of the ratings for the same and different leaders, the agreement among raters and whether aggregation of the ratings is justified (James, Demeree, & Wolf, 1984).

*Hierarchical Linear Modeling (HLM)* This is a two-level approach. First, the regression equations for the un-aggregated ratings (the individual level) and outcomes are calculated. Then, the intercepts, slopes, error, and regressions become the data for the group level of a parallel analysis. The two levels of analysis permit tests of significance of the individual ratings and the aggregated grouped ratings. HLM can be used to test moderator effects across levels and longitudinal changes, if not limited by the need to assume normality of the data, and if there are a sufficient number of cases (Bryk & Raudenbush, 1992).

*Random Group Resampling (RGR).* Based on Fischer's permutation test, proposed in 1930, RGR is related to the *bootstrap* and *jackknife* (Efron & Tibshirani, 1993). A pseudo group of the same size as the first actual group of the first followers' leadership ratings is created by sorting the data from lowest to highest and randomly forming a pseudo group without replacement. The remaining data are combined into a second pseudo group. The means of the two pseudo groups are calculated. Then, Monte Carlo techniques are applied to create a set of 1,000 pseudo groups and their distribution of differences in means. Finally, the mean group differences obtained from the actual data are tested as to whether they came from this distribution of differences of the pseudo groups and whether the average data at the group level or the individual differences in followers need to be considered. RGR can be used to test the significance of WABA II results for the covariance between predictors and outcomes (Bliese Halverson, 2002).

*Rotational Designs.* To test for personal versus situational effects, the same individuals are rotated in a systematic way through a set of conditions. An individual is placed in different groups to examine the consistency of his or her emergent leadership in each group (Kenny & Hallmark, 1992). For instance, Zaccaro, Foti, and Kenny (1991) first tested participants on selected traits. Next, participants were systematically rotated through a set of group tasks in different groups. The investigators then were able to determine that the effects of the traits on the participants' emergent leadership in the different groups was much stronger than the differences from group to group, indicating that personality was much more important than the situation in determining who would lead.

## ***Other Quantitative Issues***

*Increasing Response Rates to Survey Questionnaires.* Responses to mail questionnaires can fall to 20% or lower. One way to test whether the respondents are a valid or biased sample is to send out successive waves of the questionnaires to see if answers do not change as the numbers of respondents increase with each wave. Rogelberg and Luong (1998) listed techniques supported by research to increase the response rate: (1) Notify potential respondents in advance. (2) Follow nonrespondents with reminders. (3) Provide incentives. (4) Use appeals. (5) Keep surveys to a reasonable length. (6) Facilitate the returns by providing first-class-stamped envelopes. (7) Ask easy and interesting questions first and demographic questions last. (8) Tell who the sponsors of the research are. (9) Ensure respondents' anonymity. Telephone questioning can also increase response rates. Response rates can come close to 100% when questionnaires are handed out and completed in an assembly. According to a meta-analysis by Cychota and Harrison (2002), response rates of executives can be increased by reaching them through their social networks such as associations, professional groups, and

colleagues.

*Rating Inaccuracies.* Starbuck and Mezias (1996) reviewed 210 publications about misperceptions that are sources of inaccurate ratings by managers. These articles dealt with managerial perceptions of organizations and their internal and external environments. Ten other publications provided objective data for analysis. The authors concluded that perceptual data play an extremely important role in studies and theories about managerial behavior. Objective situations defined by perceptual data may not correlate with each other. Employees fail to agree about the properties of their organization. Perceptions may be very inaccurate. Needed in organizational and leadership research are studies to measure the errors and biases in perceptions and their determinants.

*Anonymity.* Anonymity eliminates the fear of reprisal, particularly when subordinates want to rate superiors unfavorably (Antonini, 1994). The extent to which subordinates' favorable or unfavorable ratings were reciprocated by superiors was examined in anonymous and nonanonymous conditions for 241 teams of female undergraduates in groups of six with an assigned leader. They conducted a discussion to reach decisions about the value of 15 items if they were stranded in a desert. Significant reciprocity of evaluations between the leader and the led occurred in the nonanonymous but not the anonymous condition (Haeggberg & Chen, 2000).

*Avoiding Common or Same-Source Variance.* Common methods variance is the overlap between two variables due to a common bias rather than to a relationship between the underlying constructs. For instance, a correlation between two measurements may be partially due to the fact that the measurements were obtained with the same method, at the same time, or by the same rater. Common or same-source error is greatest when two sets of data are collected at the same time, from the same respondent, on the same instrument, by the same method, and about the same trait. Campbell and Fiske (1959) suggested that each respondent be assessed on each of at least two different traits by at least two different methods to take common variance into account. This *multitrait, multimethod* procedure is one of six ways proposed to eliminate or control error. None is foolproof, according to Podsakóff and Organ (1986), who suggested applying WABA analysis in which each rater is matched with a counterpart. The first rater rates one variable—say, leadership—and the second rates an outcome. (See Avolio, Yammarino, & Bass, 1991, for a more detailed exposition.)

*Meta-Analyses.* Meta-analysis is an effort to estimate the population or true effect of an analysis from results obtained from comparable samples. Three major types of meta-analysis have been developed by Rosenthal and Rubin (1988), Hedges and Olkin (1985), and Hunter and Schmidt (1990). The basic ideas go back to the early 1930s (Johnson, Muller, & Salas, 1995). Rosenthal and Rubin convert each sample of results into standardized scores ( $Z$ 's) with one-tail probabilities for significance. *Effect sizes* derive from Fisher's conversion of correlations to  $Z$ 's. Weighted means are generated for comparing the relevant dependent variables. Hedges and Olkin convert samples of results into standard deviation units ( $g$ 's). These need correction because they overestimate the population effect size, especially with small samples. The results are combined, their consistency is tested, and their variability is explained by use of models with moderators. Hunter and Schmidt's approach is probably the best-known of the three approaches. It does not correct the biases in effect size or with moderators. Like the other approaches, it weights the means of each sample according to size. It corrects effect sizes for sampling error, attenuation due to restriction of range in each study, and the reliability of the variables used. By 2006, we were able to report numerous meta-analyses to support conclusions about many aspects of leadership and management and their effects.

*Indexes of Change.* To measure whether a change has occurred in the leader, the led, or the organization as a consequence of learning, three measures were proposed by Golembiewski, Billingsley, and Yeager (1976). *Alpha* change is a simple rise or fall in a measurement of the level of a state of affairs calibrated to reflect a one-to-one change in the concept assessed. *Beta* change is a rise or fall in the measurement where there is a recalibration to reflect systematic modification in relation to the concept assessed (see also Terborg, Howard, & Maxwell, 1960). *Gamma* change occurs if there is a change in any of these: perspective, frame of reference, or concept assessed. Factor analysis was applied to register changes in factor structures from before to after an intervention (Golembiewski et al., 1976; Schmitt, 1982).

*Critique.* MacCallum (1998) pointed to a need to correct interpretations drawn from quantitative methods in leadership and organizational research including structural equation modeling, factor analysis, analysis of variance, multiple levels of analysis, and basing measurement reliability on coefficient alpha. He also noted methodological problems in event history analysis. He favored making more use of archival data, using moderated regression, and comparing the goodness of fit of several models rather than depending for significance on the fit of a single model.

Increasingly, we are seeing efforts to use *triangulation* of quantitative and qualitative methods to reinforce conclusions from each. A quantitative survey is accompanied by a qualitative in-depth interview of selected respondents. The themes in a qualitative description of a case are categorized, counted, and content-analyzed.

## ***Qualitative Methods***

The 188 articles in the *Leadership Quarterly* in the 1990s used about half as many qualitative methods as quantitative methods. The most favored qualitative methods were content analyses (53%), case studies (45%), and grounded theory (24%; Lowe & Gardner, 2001). Results would have favored more qualitative methodology if the *Journal of Leadership Studies* or political science and sociological journals had been sampled instead of the psychology-oriented *Leadership Quarterly*.

Strauss and Corbin (1990) noted what was required to collect reliable and valuable observational data. Days and situations for observation need to be routine. Interviews need to be conducted with a cross-sectional sample representative of the population of subjects. Coding of data needs to be done through successive iterations from a smaller initial list to a more complex final list. These data need to be checked against recordings of the initial observations and interviews. From a background in cultural anthropology which depends heavily on qualitative research, Conger (1998) argued that qualitative methods, although time-intensive and complex, are the method of choice for capturing insights into contextual effects and longitudinal developments in the study of leadership. Running summaries are kept of the large amounts of the observations and data collected. General categories are refined as new data are gathered. Ideas, concepts, and theory emerge and evolve. We have already presented the qualitative endeavor of psychohistory. Psychoanalytic concepts are employed to infer the causes underlying the development and performance of individual leaders and their followers. Freud and Bullitt's (1932) interpretation of President Wilson's career is illustrative of an ideographic approach to psychohistory. Qualitative research may be idiographic or nomothetic. The *ideographic* approach is an intensive study of a single case; for example, Kofodimos, Kaplan, and Drath (1986) studied the character and development of a single manager. They included his work life and private life to try to understand why he behaved as he did. The *nomothetic* approach tries to draw inferences from a more limited exposure to a large number of cases. Most of the studies presented in this book are nomothetic.

*Interviews.* Some kind of structured or open-ended interviews begin many qualitative analyses. With a background like Conger's, Sayles (1964) applied the anthropologist's approach to interviewing. He sought to

build a coherent, chronological account of problems, cases, and issues. His interviews focused on learning about events, transitions, and conflicts. Using triangulation, he would verify or reject new information about critical interactions. He learned how events were perceived by different managers in diverse roles and was able to “reconstruct the recurring social process underpinning the tough human challenges of the organization” (Sayles, 1999, p. 9). Sayles saw the challenges of leadership as the “heart” of management. Leaders’ interventions had to be skillfully timed, sequenced, and executed.

Waldman, Lituchy, Gopalakrishnan, et al. (1998) conducted a qualitative analysis of managers. They drew themes and categorical schemes from interviews in a manufacturing plant, a hospital, and a police force engaged in quality-improvement programs. They uncovered two alternative paths of managerial commitment to the quality-improvement process. One path, following top management’s vision and commitment, was characterised by continued commitment, planned adjustments, and a cultural shift favoring quality improvement. The other path, from top management leading down, was one of wavering commitment, knee-jerk reactions, and cynicism about organizational change. From the CNN broadcast *Pinnacle*, verbatim interviews with CEOs, videotapes of 30 of 80 interviewees were randomly selected by Piotrowski and Armstrong (1989) and rated on 25 personality-lifestyle dimensions by two raters. The two raters agreed that the CEOs exhibited clear values, tolerance of frustration, and egalitarian attitudes. They were also oriented toward tasks, people, results, and compulsivity. They were workaholics and needed more social recognition and family life.

*Content Analysis.* Content analysis is often employed in qualitative studies. After identifying the research question, the text to be examined, and the unit of analysis, an initial coding scheme is tried on a pilot text. The coding scheme is purified and the observational, interview, or written data are collected. The reliability of the trained coders is assessed. Modifications of the training and the coding may be required and tried out on a second pilot. The construct validity of the categorization is determined. If reliability and validity are satisfactory, the data are coded and analyzed. Insch, Moore, and Murphy (1997) provided examples of content analyses, methods of analysis, and their strengths and weaknesses.

*Cognitive Mapping.* Sims and Siew-Kim (1993) uncovered the tension involved in simultaneously being a woman, an Asian, and a manager by asking each of nine collaborating senior Singaporean woman managers to draw a cognitive map showing issues and experiences in becoming and being an Asian woman. Subsequently, each woman provided incidents about managing or being managed. The research was grounded in the women’s own language, expressions, thought systems, beliefs, and concepts: the women explained what they thought was important and why. Nine themes emerged: (1) integrity, (2) coping with male insecurity, (3) western versus Taoist and Confucian values, (4) supporting friends and superiors, (5) female leadership, (6) fighting, (7) individual versus group rights, (8) not wishing to undermine others, and (9) high standards for oneself.

*Repertory Grid.* Although George Kelly (1955) originated this technique in the United States in the 1930s to use in counseling students, it gained more widespread use in management development and organizational research in Britain. It focused on people’s implicit constructs, concepts, and theories; and the language they used to describe cognitions, perceptions, and behaviors. In its least structured form, interviewees are asked to identify the persons in a group who are most similar to each other. Next, they are asked to use words and phrases to tell in what ways these people are similar. Then interviewees are asked to identify the person in the group who is most different from the first two chosen persons and in what ways. The process is repeated for each member of the group. Content analysis of the responses follows. (For a more structured approach to the repertory grid, see Esterby-Smith, Thorpe, & Holman, 1996.)

*Stories.* Boje (1995) gained access to the Disney studio archives of audiotapes and videotapes of Walt Disney and other Disney leaders' speeches, work interactions, documentary interviews, and conversations. Also included were television shows, films, cartoon shorts, working meetings, and stockholders' meetings, as well as many public relations films. Boje was interested in stories about this storytelling organization and was able to infer from them that Walt Disney was a tyrant. Implications will be discussed in [Chapter 17](#).

Spicochi and Tyran (2002) provided two examples of the role of leaders as story tellers and how followers made sense of the stories. These stories were attempts to communicate a vision of transformation in the health care industry, where there is need for flexibility and responsiveness to a continually changing environment. The authors suggested a number of ways leaders can make their stories effective. First, in order to learn how their stories will be interpreted by employees, they should first learn about employees' reactions to past organizational change and how their attitudes have developed. Clarify the vision. Understand how employees will see the vision as affecting them. Believe in the vision. Minimize ambiguity. Appear in person to tell the story. Incorporate a range of stories from all levels of the organization to make sense for the leadership. Empathize with your audience and focus on their understanding. Finally, be ready to listen and to further clarify the meaning in the story.

*Drawing from the Humanities and the Arts.* According to Yammarino (2002), "Leadership is part art and part science. ... An inclusive approach recognizes the complementary roles of the humanities, the arts, and the social sciences in the pursuit of leadership theory, research, and practice." History, drama, literature, and art are underutilized by students of leadership. Yet they could provide a stronger base for theory, building to avoid developing theories of leadership that are "academic amnesia" and "leadership *déjà vu*" (Hunt & Dodge, 2000). A good example of an historical source that has not been used for developing a modern theory of leadership is the *Anabasis* by Xenophon (c. 400 B.C.), whose account of the successful march of the 10,000 Greek soldiers through a hostile Persian empire illustrated the importance of cohesion, commitment, confidence, and leadership. Gordon (2002) notes that much of the emphasis on power in such historical sources and events has not been used to formulate testable concepts and theories of leadership.

### ***Combining Quantitative and Qualitative Methods***

*McNamara's Fallacy.* Camille Cavour and then Lord Curzon declared as early as the 1860s that if you can't measure something, you don't know what you are talking about. And so body counts were used invalidly to measure victory in battle in Vietnam. The need to qualify quantitative results was provided by a sophisticated view of quantitative data—"McNamara's Fallacy." This fallacy is named after Robert McNamara, who as U.S. Secretary of Defense tried to quantify military outcomes. The fallacy can be paraphrased as follows. First, measure what can easily be measured. *This is OK.* Second, disregard what can't be easily measured or give it an arbitrary quantitative value. *This is artificial and misleading.* Third, assume that what can't be easily measured is unimportant. *This is blindness.* Fourth, assume that what can't be easily measured really doesn't exist. *This is suicide.* The fallacy illustrated the need for qualitative methods to support quantitative analyses (Handy, 1994).

Among the valid methods combining quantitative and qualitative methods are the subjects of biographies assessed by personality tests and scales, triangulation, and data analyses about historical figures.

*Biographies and Personality Tests.* Biographies of political personages can become the basis for raters to complete personality tests about them. The tests are then scored to provide quantitative data about the political figures (Immelman, 1998).

*Triangulation.* Analogous to locating a target at the junction of two lines on a map, *triangulation* refers to combining results of a qualitative investigation with the results of a parallel quantitative investigation (Jick, 1979). For instance, Berson, Jung, and Tirmizi (1997) buttressed a quantitative analysis showing that light infantry platoon leaders, rated as transformational in their home station, subsequently led more effective platoons in near-combat. They also included a multi-level analysis in the process. The investigators found that the categorized responses of the observer-controllers to open-ended questions about the leaders and the platoons in action were predicted by the home station ratings, near-combat data, and U.S. Army leadership doctrine.

Modern historians with access to archival documents and data can use both to provide lessons for leaders and managers. Historians of southern history have made extensive use of data to show that slavery in the South was profitable to plantation owners. Apologists for slavery pointed to the humanitarianism of slave owners who bore the expense of caring for aged slaves who could no longer work. Mortality data show that most slaves did not live long enough to “retire.”

## Summary and Conclusions

---

Many of the most prominent theories and methods related to the study of leadership were reviewed briefly and will reappear in more detail in later chapters. The long history of reliance on greatman theories naturally led to a search for traits of leadership and theories of traits. Genetics has also increased in interest. In reaction, there arose an equally strong emphasis on environmental theories. Political, psychoanalytical, group dynamics, and humanistic theories appeared along with those built on communications and leaders' behavior, perception, cognition, and cognitive resources. Finally, syntheses were achieved in theories and methods of interacting persons and situations, built around exchanges, transformations, attributions, information processing, role attainment, reinforced change, paths to goals, contingencies of leader and situation, open-systems analysis, rational deduction, and multiple levels of analysis. Empirical research and modern theories of leadership began with studies of the personal factors that contributed to the emergence and success of a leader.

<sup>1</sup> More on theories about the charismatic leader will be found in [Chapter 21](#).

<sup>2</sup> Empirical research in support of the validity of the Vroom and Yetton model is presented in [Chapter 18](#).

<sup>3</sup> Psychoanalytic concepts of leadership and group dynamics have figured strongly in the work of Maslow (1965) and other humanistic theorists. Some of these will be considered further in [Chapter 26](#).

<sup>4</sup> More will be said about these divergent political theories of leadership in [Chapter 7](#).

<sup>5</sup> Empirical studies dealing with path-goal propositions will be discussed in detail in [Chapter 27](#).

<sup>6</sup> A section of [Chapter 19](#) is devoted to a review of research based on Fiedler's theory, and a section of [Chapter 34](#) discusses its applications.

<sup>7</sup> [Chapter 29](#) will discuss this model further.

<sup>8</sup> See also Gergen (1969), Homans (1958), March and Simon (1958), and Thibaut and Kelly (1959).

<sup>2</sup> More will be discussed about attributional processes in [Chapter 14](#).

<sup>10</sup> More will be said about these propositions in Chapters 18 and 19.

## PART II

---

### Personal attributes of Leaders

## CHAPTER 4

---

# Traits of Leadership (1904–1970)

---

This chapter is partly a revision and expansion of a longer version of a seminal publication by Ralph Stogdill (1948) concluding that leaders differ consistently in personal dispositions or traits and are propelled into leadership position if warranted by the needs of the situation.<sup>1</sup> A review of research studies up to 1948, up to 1970, then up to 2005 will follow in this and the next chapter.

## 1904–1948

---

Up to the middle of the twentieth century, leadership research was dominated by the search for the traits of leadership. In Britain in the nineteenth century, personal traits such as height, weight, health, and education had been found to correlate with leadership. But as noted by Shackleton (2001), the powerful and wealthy were better fed, clothed, and housed than factory workers and farm laborers. They could pay for an education. Smith and Krueger (1933) surveyed the preceding studies on leadership to 1933. Developments in leadership methodology, as related especially to military situations, were reviewed by Jenkins (1947).

Stogdill (1948) reviewed 128 published studies that tried to determine the traits and characteristics of leaders. The results of the survey included those characteristics and traits that were studied by three or more investigators. When contradictory evidence occurred, those studies with positive, negative, and neutral results were presented. He concluded that to some degree the traits of leadership needed to match the needs of the situation. What follows first are shortened excerpts of Stogdill's 1948 review.

### *Chronological Age*

Evidence of the relation of age to leadership in children was quite contradictory. Pigors (1933) observed that leadership did not appear in children before age two or three and then usually took the form of overt domination. Active leadership of a group seldom appeared before age nine or ten, at which age the formation of groups and gangs became a noticeable feature in the social development of children.

According to Pigors, four conditions were necessary for the appearance of leadership in children: (1) development of determination and self-control; (2) grasp of abstractions and social ideals; (3) awareness of personalities; (4) a sufficient memory span to pursue remote goals rather than immediate objectives. Arrington (1943), however, found no evidence from a survey of time-sampling experiments to support the proposition that leadership increases with age in preschool children.

Hunter and Jordan (1939) and Remmelin (1938) found leaders to be significantly younger than their followers. Bellingrath (1930) obtained results indicating that girl leaders were younger than nonleaders but boy leaders were older. However, leaders were found to be older than followers in 10 studies completed between 1915 and 1939 (Gowin, 1915; Zeleny, 1939). Correlations between age and leadership obtained in 13 studies ranged from 2.32 to .72 with an average of .21.

Gowin (1918) established that on average, outstanding executives were 12.2 years older than lower-level executives. But Ackerson (1942) and Brown (1933) failed to find leaders and followers different in age.

According to Caldwell and Wellman (1926), the relationship of age to leadership differed in various situations. Leaders in athletics were found to be close to the class average in age as were girl club leaders and student council and citizenship representatives. The correlation of chronological age with leadership appeared to depend on other variables. For instance, it was highly positive in an organization like the Roman Catholic church if policies dictated that rank was determined by age; but it was lower or negative in organizations that quickly promoted their “best and brightest” up through the ranks while their less endowed peers reached a plateau early.

## ***Stature***

Leaders were found to be taller in nine studies, shorter in two studies, and heavier in seven studies and lighter in two. No differences in height or weight were reported in four studies, and in two studies the results depended on the situation.

*Height.* Correlations between height and leadership ranged from .23 to .71. The general trend of these studies was a low positive relationship between height and leadership. The average correlation was about .30. Nevertheless, Hunter and Jordan (1939) and Garrison (1933) found student leaders to be somewhat shorter than non-leaders. Baldwin (1932) and Reynolds (1944), could find no relation at all between height and leadership in students.

*Weight.* The correlations obtained suggested a low positive relationship between weight and leadership. The average correlation was about .23. But again, Hunter and Jordan (1939) found the reverse—that leaders were significantly lighter than nonleaders. Garrison (1933) and Moore (1935) also reported leaders to be somewhat lighter than followers. Since height and weight correlated positively, the same pattern of results was obtained for weight as for height.

## ***Physique, Energy, Health***

Physique was positively associated with leadership in five studies; athletic ability and physical prowess in seven; energy in five; and health in four. Moreover, health and physical condition were found to be a factor in four of the reviewed investigations.

*Physique.* Five studies between Webb (1915) and Bernard (1928) reported that superior physique was a characteristic of leaders. The correlations of .28, .18, .11, and .23 found by Kohs and Irle (1920), Nutting (1923), Sheldon (1927), and Webb (1915), respectively, suggested that this relationship was slight but reliable. But Bowden (1926) concluded from the results of his study of college students that leadership was not the result of a dominating physique, and Baldwin (1937) found that high school leaders did not differ from followers in freedom from physical defects.

*Health.* Leaders, according to Baldwin (1932), Bell-ingrath (1930), Reals (1938), and Stray (1934), appeared to have some advantage over nonleaders in possessing better health, although Ackerson (1942) and Hunter and Jordan (1939) failed to find that health was a differentiating factor.

*Athletic Prowess.* Athletic ability and physical prowess did appear to be associated with leadership status in boys' gangs and groups. Evidence to this effect was presented in seven studies between Puffer (1905) and Flemming (1935). Correlations of .38, .62, and .40 between athletic ability and leadership were reported by

Flemming (1935), Partridge (1934), and Webb (1915), respectively.

*Energy.* According to Bellingrath (1930), Brown (1934), Cox (1926), Stray (1934), and Wetzel (1932), leaders were also characterized by high energy. But Cox (1926) found that various groups of great leaders differed markedly from each other in physique, energy, use, and athletic prowess; only military leaders were outstanding in these traits.

### ***Appearance***

Leaders presented a better appearance in 11 studies. They were better dressed in two others; but no relationship was found in one study, and appearance was negatively correlated with leadership in two studies. The results clearly depended on circumstances. Thus Dunkerley (1940) found that students who were chosen as leaders in social activities differed significantly from nonleaders in appearance and dress, but students chosen as leaders in intellectual and religious activities did not differ markedly from nonleaders in these respects. A correlation of .21 between attractive appearance and leadership in high school students was reported by Flemming (1935), but the correlation between leadership and being seen as beautiful was only .05. Yet Partridge (1934) found a correlation of .81 between ratings of appearance and leadership among adolescent boys. In Goodenough's (1930) study a negative correlation of 2.20 was found between beauty and leadership in preschool children.

Tryon's (1939) analysis suggested that appearance is more closely associated with leadership in boys than in girls. Tryon reported correlations with leadership of .49 and .06, respectively, for 15-year-old boys and girls; the correlations for 12-year-old boys and girls were .31 and .08, respectively. Ackerson (1942) obtained correlations of .12 and 2.06 between leadership and being seen as slovenly for boys and girls, respectively; a slovenly appearance and leading others into misconduct were correlated .32 and .31 for delinquent boys and girls.

### ***Fluency of Speech***

Speech was positively associated with leadership in all 12 studies that examined the relationship, although a few of the results were marginal.

*Tone of Voice.* Baldwin (1932) reported a definite trend for teachers to rate the tone of voice of leaders as confident and the tone of voice of nonleaders as lacking in confidence. Flemming's (1935) factor analysis of teachers' ratings of high school leaders revealed "pleasant voice" as one of the four factors found to be associated with leadership. The correlation between "pleasing voice" and leadership in high school students was .28. Partridge (1934) reported that boy leaders could be reliably distinguished from nonleaders when in the presence of strange boys but hidden from view, so that judgments had to be made on speech alone. However, Fay and Middleton (1943), in repeating this experiment under somewhat similar conditions, found a correlation of only .08 between leadership ratings and degree of leadership, as estimated by voice alone. Likewise, Eichler (1934) reported a correlation of only .11 between voice and leadership.

*Talkativeness.* Talkativeness and leadership were reported by Tryon (1939) to be correlated .41 and .31 for 12-year-old boys and girls, respectively; the correlations for 15-year-old boys and girls were .15 and .44, respectively. In Goodenough's (1930) study, a correlation of .61 between talkativeness and leadership was found. Thurstone (1944) did not find that highly paid administrators surpassed their lower-paid associates in scores on tests of word fluency, but he did find a significant difference in their scores on tests of linguistic

ability. Simpson (1938) also reported that verbal ability was correlated .45 with the capacity to influence others.

*Fluency.* Chevaleva-Ianovskaia and Sylla (1929) noted that child leaders were characterized by longer durations of verbal excitation. Terman (1904) reported that leaders were more fluent in speech, and Leib (1928) observed that leaders excel in speaking ability. The same skills were reported in adult leaders by Bernard (1928) and Merriam (1926). Zeleny (1939) found a correlation of .59 between leadership ratings and total remarks made in class. Interesting conversation and leadership were correlated .28 in Flemming's (1935) study. Finally, Burks (1938) and Malloy (1936) found that vividness and originality of expression and facility of conversation were associated with successful social relationships. Considering the size of the experimental groups, the competence of the experimental methods employed, and the positive nature of the evidence presented, it was apparent that fluency of speech, if not tone of voice, was a factor to be considered in the study of leadership. It has long been recognized that effective leadership cannot be maintained in an organization without an adequate system of intercommunication. Thus it does not seem surprising that some of the most searching studies of leadership should reveal the capacity for ready communication as one of the skills associated with leadership.

## ***Intelligence***

All but 5 of 23 studies presented evidence that the average leader surpassed the average member of his or her group in intelligence. However, five of the studies suggested that too great a difference in the IQ of the leader and the average member will militate against leadership. Statistically reliable differences were reported, for example, by Hunter and Jordan (1939), Rummel (1938), and Sward (1933). In most of these studies, there was considerable overlapping of the scores of leaders and nonleaders on intelligence tests, indicating that superior intelligence was not an absolute requirement for leadership. Nevertheless, the general trend of the findings suggested that leadership status was more often than not associated with superiority in intelligence. The correlations revealed a consistently positive relationship. The average of these coefficients was approximately .28.

Factorial studies demonstrated a number of points that may be of considerable significance for the study of leadership. Cattell (1946), for example, reported that the intelligence factor is heavily weighted with such elements of character as being wise, emotionally mature, persevering, mentally alert, vigorous, and conscientious. These items correspond fairly closely to the factors discussed later, which were found in the present survey to be supported by an excess of positive over negative evidence. For example, Thorndike (1936) reported a correlation of .60 for 305 male members of European royal families between their intellectual ability and their esteem (which, in turn, is related to leadership). Thus it appears that high intelligence may be associated with other characteristics that contribute to a person's value as a leader.

*Limits.* One of the most significant findings concerning the relation of intelligence to leadership is that extreme discrepancies between the intelligence of potential leaders and their followers militated against the exercise of leadership. Hollingworth (1926) found that among children with a mean IQ of 100, the IQ of the leader was likely to fall between 115 and 130. That is, the leader was likely to be more intelligent, but *not too much more intelligent than the average of the group led*. Observation further showed that a child with an IQ of 160 had little chance of being a popular leader in a group of children of average intelligence but might become a leader in a group of children with a mean IQ of 130. One of the difficulties in this connection seemed to be communication. The average child cannot comprehend a large part of the vocabulary used by a child of unusually superior intelligence to express exact meanings in relation to his or her more mature and

complicated interests. Differences in interests, goals, and activity patterns also act as barriers to joint participation, which is a necessary condition of group leadership.

Hollingworth's findings were confirmed by a number of investigations. Finch and Carroll (1932), studying groups of 66 gifted, 66 superior, and 66 average children, arrived at the conclusion that, "Given a superior group of children to lead, the leading will tend to be done by the gifted children," even though the leaders as a group tend to be younger than the group led. However, in an early study of the formation of boys' gangs, Warner (1923) found that leaders and followers differ much more in chronological age than in mental age. She observed that older boys who were mentally below normal tended to group with younger boys who had a mental age near their own and slightly higher, and that when groups of retarded delinquent boys contacted groups of brighter delinquents, the contacts were "so short and non-social that no noticeable event took place." Mailer (1925), studying cooperation and competition among children, found that homogeneity of intelligence, rather than level of intelligence, was important in cooperative behavior. McCuen (1929) studied leadership in 58 organizations of college students. He concluded that "the crowd seems to desire to be led by the average person. Evidently in a democratic society, the leader must not be too far detached from the group."

Two studies by Lehman (1937, 1942) are of interest in this connection. In the first study, Lehman determined the age intervals at which outstanding men in various professions made their best contributions. In the second study, he determined the optimal age intervals for eminent leadership. Chemists, for example, were found to make their best contributions during the age intervals 28–32 years, while the optimal ages for eminent leadership in chemistry were 45–49 years. Thus, it appears that even in science, individuals contributions and communications must be understood by, and in accord with the thinking of their contemporaries for them to rise to a position of leadership in their profession.

### ***Scholarship***

Leaders were reported to have better scholastic records in 22 studies and poorer records only once. No differences were obtained in four investigations. It is not surprising that leaders were found, with a high degree of uniformity, to have better average scholastic grades than did nonleaders, for, as was just noted, leaders had been found more intelligent than their followers. But the findings by Buttgerit (1932), Caldwell and Wellman (1926), and many others suggested that superior scholarship may not be a mere byproduct of superior intelligence, but may have direct importance for leadership when it is one aspect of a general ability to get things done. It was also suggested that superior accomplishment in areas valued by the group had prestige value, which may also contribute to leadership. At the same time, there was an abundance of evidence to indicate that a position of leadership was ordinarily not based on superior intelligence and accomplishment alone, since these two factors were present, to a high degree, in many persons who did not occupy positions of leadership. Thus, overall, the magnitude of the correlations suggests that intelligence and scholarship account for only a fraction of the total complex of factors associated with leadership.

### ***Knowledge***

The results of all 11 studies dealing with leadership and knowledge implied that persons who are chosen as leaders tended to know how to get things done. Of particular interest was Caldwell's (1920) experiment in which he asked 282 high school students to nominate boy and girl leaders for three different situations: (1) a trip to a wharf; (2) the production of a program and its presentation at a neighboring school; (3) the reorganization of a program for administering athletics in the school. The nominations revealed "a clear judgment on the part of these pupils as to the members of the group best fitted to lead them." The most

important abilities ascribed to these leaders were intelligence and practical knowledge about the situations for which they were chosen as leaders.

In this connection, it seems worthwhile to consider the findings of Baldwin (1932) and Burks (1938) in relation to the association between leadership and the ability to make constructive and creative suggestions. Burks, for example, found that the ability to present constructive ideas for difficult situations was closely associated with successful social relationships.

The studies of Cox (1926), Drake (1944), Flemming (1935), Stray (1934), and Thrasher (1927) found that constructive imagination was a characteristic of leaders. Additional evidence related to the ability to get things done was presented by Bellingrath (1930) and Dunkerley (1940). Cox (1926) and Peck (1931) reported that great leaders were characterized and differentiated from the average by a greater intensity of application and industry. In summary, the results of these various studies seemed to indicate that specialized knowledge, imagination, and the ability to get things done were factors that contributed to leadership.

### ***Judgment and Decision***

Soundness and finality of judgment were related to leadership in five studies; and speed and accuracy of thought and decision were related in four analyses. In view of the positive correlations found between intelligence and leadership, it was not surprising to find a similar relationship between judgment and leadership. Bellingrath (1932), Drake (1944), and Webb (1915) reported correlations ranging from .34 to .69 between common sense and leadership; Bellingrath (1930), Drake (1944), Flemming (1935), and Webb (1915) found correlations of .60, .34, .28, and .69, respectively, between judgment and leadership. Farsightedness and leadership were found to be correlated .55, .25, and .33 in the studies of Bellingrath, Drake, and Webb, respectively. Two of the factor-analytic studies—those of Cowley (1931) and Dunkerley (1940)—revealed that soundness and finality of judgment were common to leaders. In addition to judgment, Cowley (1931) also identified three factors that appeared to represent speed of decision. Hanawalt, Richardson, and Hamilton (1943) found that leaders used the “?”, or “undecided,” response on the Bernreuter Personality test significantly less frequently than nonleaders, and this tendency was especially noticeable on the most discriminating items. In spite of the small number of studies bearing on judgment and decision, the general competence of the methods lent confidence to the results obtained.

### ***Insight***

Leadership was found to be related to certain aspects of insight, as follows: “keenly alive to environment, alert” (six studies); ability to evaluate situations (five studies); social insight (five studies); self-insight (two studies); and sympathetic understanding (seven studies). Traditionally, insight has been regarded as one aspect of general intelligence. However, Jennings (1943) and others suggested that insight may be socially conditioned to a high degree. Brown (1931), Buttgerit (1932), Caldwell and Wellman (1926), Cox (1926), Dunkerley (1940), and Fauquier and Gilchrist (1942) found that leaders were characterized by alertness and keen awareness of their environment. The ability to evaluate situations was found to be a factor in the studies by Bowden (1926), Buttgerit (1932), Chevaleva-Ianovskaia and Sylla (1929), Merriam and Gosnell (1929), and Thurstone (1944). Less clearly defined was social insight, reported as a factor associated with leadership in the studies by Bowden (1926), Hanf-mann (1935), Jennings (1943), Pigors (1933), and Zeleny (1939). Brogden and Thomas (1943) and Guilford and Guilford (1939) found that a person who “studies the motives of others” was measured by Guilford’s T factor of being thoughtful, and was viewed as offering a kind of intellectual leadership.

The results of these various studies suggested that alertness to one's surroundings and an understanding of situations were intimately associated with leadership ability, yet little was understood about the nature of these processes. No worker who is responsible for improving the social effectiveness of individuals can fail to be impressed by the persistent blindness of maladapted individuals to the social situations to which they are attempting to adjust. From the point of view of understanding personal qualifications for leadership, one issue that still needs thorough investigation is the fundamental nature of awareness and social insight.

### ***Originality***

Although only seven studies contained data on originality, the magnitude of the positive correlations use suggested that the relationship between originality and leadership was worthy of further investigation. The correlations reported by Bellingrath (1930), Drake (1944), Flemming (1935), and Webb (1915) ranged from .38 to .70 and were higher, on average, than those for any other trait except popularity. At the same time, Cox (1926) found that great leaders rated unusually high in originality.

### ***Adaptability***

The 10 studies involving adaptability and leadership suggested that ready adaptability to changing situations might be associated with leadership, although the correlations of .13 and .21 reported by Eichler (1934) and Flemming (1935) respectively were not impressive. The ability to adjust to situations has also been regarded traditionally as an aspect of general intelligence but, as described in the investigations considered here, this factor appeared to have a large social component. This fact has long been recognized by clinical observers, who have repeatedly pointed out that persons of high intelligence may be rendered ineffectual in their vocational, social, and other adjustments through extreme self-preoccupation and inhibition to action. Such inhibition is negatively correlated with leadership.

### ***Introversion-Extroversion***

Leaders were found to be more extroverted in five studies and more introverted in three. No differences emerged in four studies. However, the only studies that reported a marked relationship between extroversion and leadership were those of Goodenough (1930) and Sward (1933). Goodenough reported a correlation of .46 between extroversion and leadership in children. Sward found that leaders scored reliably higher than nonleaders in extroversion on the Heidbreder scale. Richardson and Hanawalt (1943) observed that college leaders scored reliably lower in introversion than the Bernreuter norms and lower than nonleaders, although the difference between leaders and nonleaders was not significant. Hunter and Jordan (1939) and Remmelin (1938) also reported that introversion scores on the Bernreuter scale did not differentiate leaders from nonleaders. Middleton (1941) found that leaders scored low in extroversion. Bellingrath (1930) and Drake (1944) obtained no significant correlations between introversion-extroversion scores and leadership.

All the groups of great leaders except soldier-statesmen in Cox's (1926) study were rated as introverted, with soldier-fighters rating very high in introversion. Thurstone's (1944) study of administrators in Washington, D.C., revealed that successful administrators rated higher than less successful administrators in Guilford and Guilford's (1939) T factor, which is measured by such items as "introspective, analyzes himself"; "often in a meditative state"; "analyzes the motives of others"; and "not more interested in athletics than in intellectual pursuits." Brogden and Thomas (1943) added to this list such items as "he does not want anyone to be with

him when he receives bad news”; “he does not try to find someone to cheer him up when in low spirits”; and “he prefers to make hurried decisions alone.” These items are of interest when considered in relation to the findings on mood control. In view of the diversity of findings, it appears doubtful that leaders can be described with any degree of uniformity in terms of introversion-extroversion.

### ***Self-Sufficiency***

Much the same situation exists with regard to self-sufficiency. Hunter and Jordan (1939) and Richardson and Hanawalt (1944) found that leaders had high self-sufficiency scores on the Bernreuter test, but Dunkerley (1940), Rummel (1938), and Richardson and Hanawalt (1943) obtained no such significant results.

### ***Dominance***

The evidence concerning the relationship of dominance to leadership is somewhat contradictory. Leaders were found to be more dominant and ascendant in 11 studies; potential leaders were rejected if they were bossy and domineering in four studies; and no differences appeared in two studies.

Cox (1926) and Drake (1944) found “desire to impose will” to be associated with leadership, but Webb (1915) reported a zero-order correlation between those two factors. Ackerson (1942) reported a correlation of approximately .20 between bossiness and leadership in problem children. Leadership and bossiness were related, to some extent, in the children studied by Tryon (1939), who reported correlations of .28 and .29 between these two factors for 15-year-old boys and girls, respectively. Chapple and Donald (1946), Richardson and Hanawalt (1943, 1944), and Hunter and Jordan (1939) found leaders to be significantly more dominant than nonleaders. Small but positive differences in ascendance were reported by Bowden (1926) and Moore (1935). Eichler (1934), however, found that leaders and nonleaders did not differ in dominance. Still stronger contradictory evidence was presented by Broich (1929), Jennings (1943), and Hanfmann (1935), who concluded that bossy, domineering persons were rejected as leaders. Caldwell (1920) reported that high school pupils expressed preference for leaders who could keep order without being bossy. In all, these findings suggest that leadership cannot be defined in terms of personal dominance.

### ***Initiative, Persistence, Ambition, and Industry***

Initiative and a willingness to assume responsibility were related to leadership in 12 studies and persistence in the face of obstacles was related to leadership in 12 other inquiries. Ambition and desire to excel were of consequence to leadership in seven analyses, as were application and industry in six additional analyses.

*Initiative and Assertiveness.* All except one of the studies in which initiative was found to be a trait ascribed to leaders were investigations in which student leaders were nominated by their associates, and the traits that were thought to make them desirable as leaders were described. The study by Carlson and Harrel (1942) represented some departure from this method in that 53 Washington correspondents were asked to name the 10 ablest senators and the 10 ablest representatives in rank order and to rate them from 1 to 10 on integrity, intelligence, industry, and influence. A factor analysis of these ratings revealed Factor 1 to be heavily loaded with industry and influence and might also have been called push or assertiveness. Industriousness and leadership were correlated .55 and .16 in the studies of Bellingrath (1930) and Flemming (1935), Dunkerley’s (1940) factor analysis also revealed a trait cluster, identified as initiative, which was descriptive of intellectual

and social leaders but not of religious leaders. Finally, Drake (1944) and Sheldon (1927) respectively reported correlations of .56 and .52 between aggressiveness and leadership.

*Persistence.* Cox (1926) found that great face-to-face leaders were characterized, to an outstanding degree, by “persistence in the face of obstacles,” “capacity to work with distant objects in view,” “degree of strength of will or perseverance,” and “tendency not to abandon tasks from mere changeability.” Pigors (1933) observed that the development of determination and a sufficient memory span to pursue remote goals rather than immediate objectives were necessary conditions for the appearance of leadership in children. The remainder of the studies that presented evidence on this point represented a variety of points of view.

Pinard (1932), in an experimental study of perseverance in 194 “difficult” children ages 8–15, found that of 24 leaders, 17 belonging to the “moderate nonperseverator” group were rated as more reliable, self-controlled, persistent, and as the most constructive leaders. Drake (1944) and Webb (1915) obtained correlations of .13 and .59 between leadership and strength of will. Webb (1915) reported a correlation of .70 between leadership and “persistence in overcoming obstacles” and of .53 between leadership and persistence. In Bellingrath’s (1930) study of high school students, persistence was correlated .68 with leadership. Eichler (1934) and Sheldon (1927) found correlations of .23 and .34 between leadership and persistence. An interesting sidelight was presented in Ackerson’s (1942) study of problem children: stubbornness correlated .15 for boys and .12 for girls with leadership.

*Ambition.* Cox (1926) also presented evidence to indicate that great face-to-face leaders, such as soldiers, religious leaders, and statesmen, were characterized to an outstanding degree by a “desire to excel” at performance. Hanawalt, Hamilton, and Morris (1934), in a study of 20 college leaders and 20 nonleaders, found that the level of aspiration of leaders was significantly higher than that of nonleaders. Correlations of .47 .29 and .64 between leadership and desire to excel were reported by Webb (1915), Drake (1944), and Bellingrath (1930), respectively.

*Application and Industry.* That leadership is related to willingness to work rather than to passive status or position is suggested by the fact that a number of investigators found leaders to rate high in application and industry. Cox (1926) observed that great leaders ranked unusually high in this respect. The correlations reported by Bellingrath (1930), Flemming (1935), and Webb (1915) ranged from .16 to .55.

## ***Responsibility***

All 17 studies found responsibility to be related to leadership. Thus student leaders were seen to rate somewhat higher than followers on dependability, trustworthiness, and reliability in carrying out responsibilities in the studies by Baldwin (1932), Bellingrath (1930), Burks (1938), Caldwell (1920), Dunkerley (1940), Moore (1932), Nutting (1923), Pinard (1932), and Wetzell (1932). Trustworthiness and leadership were correlated .64 in Webb’s (1915) study, .37 in Drake’s (1944) study, and .10 in Flemming’s (1935) study. Correlations of .42, .21, and .53 between conscientiousness and leadership were reported by Webb (1915), Drake (1944), and Bellingrath (1930), respectively. Partridge (1934) observed a correlation of .87 between dependability and leadership. Jennings (1943) observed that girls chosen as leaders tended to be those who inspired confidence. Cox (1926) found that all types of great face-to-face leaders rated high in trustworthiness and conscientiousness, with religious leaders rating outstandingly high in these traits. Additionally, Broich (1929), Jennings (1943), Leib (1928), Nutting (1923), and Pigors (1933) observed that leaders tend to be able to work for the group’s welfare, and Buttgeriet (1932) noted that a sense of social responsibility is characteristic of leaders.

## ***Integrity and Conviction***

Integrity and fortitude were related to leadership in six studies, and strength of convictions was related to it in another seven analyses.

*Integrity.* Intellectual fortitude and integrity of character represent traits that are apparently associated with eminent leadership in maturity. All but one of the studies that contributed evidence on this point were concerned with outstanding adult leaders. Middleton (1941) obtained supporting evidence in college students.

Michels (1915) reported that strength of convictions was a characteristic of successful political leaders. Cox (1926) found that the great face-to-face leader was characterized to an outstanding degree by "absence of readiness to accept the sentiments of his associates." This trait was especially conspicuous in revolutionary statesmen. Webb (1915) obtained a correlation of 2.32 between leadership and acceptance of the sentiments of others. Caldwell and Wellman (1926) noted that one characteristic of high school leaders was insistence on the acceptance of their ideas and plans.

*Conviction.* Adult leaders in a community studied by Chapin (1945) appeared to hold opinions that were generally similar to those of the group, but they "expressed the trends of opinion of the rank and file more sharply, more decisively, and more consistently." Simpson (1938), in a study of those who influence and those who are influenced in discussions, found that influence scores correlated 2.41 with influenceability scores. It appears that persons in various types of groups may be valued as leaders because they know what they want to accomplish and are not likely to be swayed from their convictions.

## ***Liberalism or Conservatism***

The evidence on liberalism or conservatism suggested that the attitudes regarded as acceptable in leaders are largely determined by the nature of the situation. Hunter and Jordan (1939) found college student leaders to be somewhat more liberal than nonleaders in attitudes toward social questions. Newcomb (1943) reported that in a college where liberalism is a tradition and an ideal, women students who had the most prestige were regarded as most liberal. But Middleton (1941) ascertained that campus leaders were low in radicalism. In Thurstone's (1944) study of Washington administrators, the Allport-Vernon Study of Values was found to be the most effective of a battery of 75 tests in differentiating higher-salaried from lower-salaried administrators. Successful administrators scored significantly higher in social and theoretical values and significantly lower in economic and religious values. Drake (1944) and Webb (1915) obtained low positive correlations between leadership and interest in religion.

## ***Self-Confidence***

Almost all authors reporting data on the relationship of self-confidence to leadership, were uniform in the positive direction of their findings. Self-assurance was associated with leadership in 11 studies; absence of modesty, in six studies. The general trend of these findings suggested that leaders rate higher than their followers in self-confidence and self-esteem and slightly lower in modesty. The following correlations were reported between self-confidence and leadership: .58 by Bellingrath (1930), .59 by Drake (1944), and, .12 by Webb (1915). Cowley (1931) found self-confidence to be one of six factors possessed in common by three widely different types of leaders. Cox (1926) noted that great leaders were characterized to an unusual degree

by such traits as self-confidence, esteem of their special talents, and a tendency to rate their talents correctly. Buttgerit (1932), Moore (1932), and Zeleny (1939) also reported that leaders rated high in self-confidence. Tryon (1939) described student leaders as assured in class and as assured with adults. Richardson and Hanawalt (1943, 1944) found that college and adult leaders earned higher self-confidence scores on the Bernreuter test than nonleaders; but Hunter and Jordan (1939) and Remmelin (1938) failed to find that the self-confidence scores on the Bernreuter test differentiated between leaders and nonleaders.

*Inferiority.* Sward (1933) found that inferiority scores on the Heidbreder rating scale did not differentiate leaders from nonleaders, although women leaders rated themselves higher in inferiority attitudes than did their associates. But Ackerson (1942) reported correlations of only 2.02 and .08 between feelings of inferiority and leadership in boys and girls.

*Modesty.* The findings here suggested that leaders tend not to be handicapped by excessive modesty. Cox (1926) reported that great military leaders and statesmen were characterized to a greater than average degree by eagerness for the admiration of the crowd and desire for the limelight, although they exhibited offensive manifestations of self-esteem to a lesser degree than the average. Middleton (1941) also found leaders to rate low in modesty. A correlation of .09 between leadership and modesty was reported by Flemming (1935). Eagerness for admiration was correlated .16 with leadership in Webb's (1915) study. Drake (1944) obtained a correlation of 2.11 between conceit and leadership. Ackerson (1942) and Tryon (1939) found correlations between leadership and attention-getting and "showing off" ranging from .15 to .30.

### ***Moods, Optimism, and Sense of Humor***

In all six studies on the subject, leadership and a sense of humor were positively related. In four of six studies, leaders were controlled in mood and seldom gloomy; in two studies, leaders were happy and cheerful, but happiness was not a factor in two of the studies. The scarcity of evidence concerning the relation of mood control to leadership cannot be regarded as confirmation of its unimportance. The evidence suggests that mood control may be significantly related to effective leadership, and a sense of humor is certainly relevant. The topic appears to warrant thorough investigation.

*Mood.* Jennings (1943) stated that one characteristic of girl leaders in an institution was the ability to control their own moods so as not to impose their negative feelings, depression, and anxiety on others. Caldwell and Wellman (1926) and Malloy (1936) also found leaders to be constant in mood. Webb (1915) reported a correlation of 2.45 between depression and leadership. Ackerson (1942) and Cox (1926), however, reported some association between leadership and moods of depression, although not to a significant degree, and the extent differed with different groups.

Drake (1944), Tryon (1939), and Webb (1915) found that a cheerful, happy disposition was associated with leadership. These authors reported correlations ranging from .29 to .60 between leadership and cheerfulness. However, Ackerson (1942) did not find cheerfulness to be a distinguishing factor in leadership. Unhappiness and leadership were correlated 2.03 for boys and .06 for girls. Baldwin (1932) also found a lack of correlation.

*Humor.* Drake (1944), Flemming (1935), Tryon (1939), and Webb (1915) reported correlations ranging from .34 to .64 between leadership and sense of humor. Stray (1934) also found leaders to be characterized by a sense of humor. Goodenough's (1930) finding of a correlation of .53 between leadership and laughter was also relevant.

## ***Emotional Control***

Leaders were found to be more stable and emotionally controlled in 11 studies and less well controlled emotionally in five studies. No differences were found in three other studies.

*Self-Control.* A number of manuals that outline practical techniques for gaining friends and becoming a leader regard self-control as a very important prerequisite for attaining these goals. The evidence relating to this contention is divided. Eichler (1934) reported a correlation of .18 between leadership and self-control. Baldwin (1932), Pigors (1933), and Wetzell (1932) also found self-control to be a factor related to leadership. Bellingrath (1930) and Drake (1944) reported correlations of .70 to .38, respectively, between leadership and stability. Leaders were found by Middleton (1941) and Terman (1904) to rate low in emotionality. Bowden (1926) and Caldwell and Wellman (1926) found leaders to be well balanced and self-composed in comparison with their followers. Webb (1915) reported correlations of 2.25 between irritability and leadership, and 2.36 between readiness for anger and leadership.

*Excitability.* Despite the results above, Cox (1926) found that great face-to-face leaders rated high in excitability. This trait was present to an unusual degree in revolutionary statesmen. In problem children, Ackerson (1942) reported correlations of .12 for boys and .36 for girls between irritability and leadership. A correlation of .16 between leadership and excitability was found by Sheldon (1927). Fauquier and Gilchrist (1942) also noted that leaders were more excitable than nonleaders. According to Chevaleva-Ianovskaia and Sylla (1929), leaders were characterized by a predominance of excitation over inhibition. But Zeleny (1939) could find no difference between leaders and nonleaders in degree of emotional control, and Drake (1944) and Flemming (1935) reported correlations close to zero between leadership and excitability.

*Anger.* The data on the relationship between leadership, anger, and fighting cast further light on this subject. Cox (1926) found that great face-to-face leaders, except statesmen, were characterized by a tendency to anger and "a tendency to flare up on slight provocation." Ackerson (1942) reported that in children "temper tantrums" and "leader" were positively correlated, but "temper tantrums" and "follower" were negatively correlated. Webb (1915), however, found a correlation of 2.12 between leadership and occasional extreme anger. Tryon (1939) obtained correlations of .59, .48, .25, and .40 between fighting and leadership for 12-year-old boys, 15-year-old boys, 12-year-old girls, and 15-year-old girls, respectively. Ackerson (1942) ascertained that fighting and leadership were correlated .13 for boys and 2.17 for girls. Fighting and leading others into bad conduct were correlated .20 for boys and .36 for girls. Incurability and defiance were also positively correlated with leadership, and to a still higher degree with leadership in misconduct, while these traits were correlated negatively among followers.

These studies did not lend convincing support to the view that leaders are necessarily characterized by a high degree of self-control or an incapacity for emotional expression.

## ***Socioeconomic Status***

In 15 studies the leaders came from higher socioeconomic backgrounds, but in two studies no differences were found. Baldwin (1932) and Goodenough (1930) reported negligible differences. The differences in the social and economic status of leaders and nonleaders were usually not extreme. Only Rummel (1938) obtained differences that were large enough to be statistically reliable. Nonetheless, taken as a whole, the evidence presented in studies from a wide variety of leadership situations indicated that leaders tend to come from a

socioeconomic background superior to that of the average of their followers.

### ***Social Activity and Mobility***

Leaders participated in more group activities in all 20 studies on the subject. They also exhibited a higher rate of social mobility in five additional studies.

*Participation.* Baldwin (1932), Brown (1933), Chapin (1945), Courtenay (1938), Richardson and Hanawalt (1943), Roslow (1940), Link (1944), Merriam and Gosnell (1929), Reals (1938), Smith and Nystrom (1937), Sorokin (1927), and Zeleny (1939) all found that leaders surpassed followers in the number, extent, and variety of group activities in which they participated. Zeleny (1939) reported correlations ranging from .17 to .68 between leadership and participation in extracurricular activities. Leadership was defined by a number of authors as “occupying one or more positions of responsibility in group activities.” On the other hand, social detachment appeared to be a factor in the formation of the boys’ gangs studied by Thrasher (1927) and Warner (1923).

*Mobility.* Physical and social mobility were observed by Sorokin (1927), Sorokin and Zimmerman (1928), and Winston (1932) to be associated with adult leadership. Sorokin and Zimmerman reported that farmer leaders were characterized to a high degree by a tendency to shift from place to place and from one occupational or economic position to another. Winston (1937) observed the same tendency in inventors.

*Sociophysical Activity.* Sociophysical activities were related to leadership as follows: “active in games” (six studies); “active, restless” (nine studies); “daring, adventurous” (three studies).<sup>2</sup> Broich (1929), Brown (1931), Buttgerit (1932), and Reininger (1929) found that child leaders were more active in games than were nonleaders. In Tryon’s (1939) study, leadership and “active in games” were correlated .52 to .74 for groups of 12- and 15-year-old boys and girls. Terman (1904), Thrasher (1927), and Tryon (1939) found leaders to be more daring and adventurous than followers. Correlations of .57 to .78 between daringness and leadership were reported by Tryon (1939). Cowley (1931) ascertained that motor impulsion was a factor common to different types of leaders. Liveliness was reported by Leib (1928) and Brown (1931) as characterizing leaders. Flemming (1935) found a correlation of .47 between leadership and liveliness. Goodenough (1930) reported a correlation of .29 between physical activity and leadership. Ackerson (1942) and Tryon (1939) obtained correlations close to .20 between “restlessness” and leadership. These findings suggested that physical activity, mobility, and sociophysical activity were associated with leadership.

*Sociability.* Sociability was associated with leadership in 13 of 14 studies, and diplomacy or tact was associated with leadership in 8 others. Fairly high positive correlations between sociability and leadership were reported by Bonney (1943), Drake (1944), Flemming (1935), Goodenough (1930), Sheldon (1927), Tryon (1939), and Webb (1915). Correlations ranged from .33 to .98. But the correlation found by Eichler (1934) between social intelligence and leadership was only .10. Burks (1938), Malloy (1936), Middleton (1941), and Prosh (1928) also found that student leaders rated higher than nonleaders in sociability. Ackerson (1942) observed that belonging to a gang was correlated .26 with being a leader and .21 with being a follower. Being a leader and being within an intimate circle were correlated .39 in Webb’s (1915) study. Moore (1932) and Newcomb (1945) reported friendliness and social skills, respectively, as factors that distinguished leaders from followers. Cox (1926) also noted that, despite their higher introversion, great leaders were rated above average, but not to an outstanding degree, in fondness for companionship and social gatherings.

*Tact.* Courtesy, tact, and diplomacy were found by Bernard (1928), Wetzel (1932), Drake (1944), Flemming (1935), Hanfmann (1935), Parten (1933), Stray (1934), and Webb (1915) to be traits that distinguished leaders from nonleaders. Drake, Flemming, and Webb reported correlations of .08, .27, and .73, respectively, between tact and leadership. However, Flemming (1935) obtained a correlation of only 2.03 between rudeness and leadership for boys and girls. But the correlations between rudeness and leading others into bad conduct were .24 and .40 for boys and girls, respectively. Ackerson determined that both bashfulness and seclusiveness were negatively correlated with leadership.

*Misconduct.* Ackerson (1942), Goodenough (1930), and Webb (1915) obtained correlations ranging from 2.29 to .21 between offensive manifestations and leadership. Ackerson's (1942) findings suggested that misconduct is not necessarily a bar to leadership. Stealing, for example, was correlated .12 and .21 with leadership; stealing and leading others into misconduct were correlated .46 and .16 for boys and girls, respectively.

### ***Popularity and Prestige***

Evidence from 10 diverse studies indicated that leaders tend to be rated higher than average in popularity. Evidence presented by Ackerson (1942), Bellingrath (1930), Carlson and Harrell (1942), Cox (1926), Garrison (1933), Michels (1915), Miller and Dollard (1941), Nutting (1923), Tryon (1939), and Zeleny (1939) all indicated that popularity and prestige were rather closely associated with leadership status. The correlations, ranging from .23 and .80, suggested that the relationship between popularity and leadership was fairly high. However, Nutting (1923) pointed out that popularity cannot be regarded as synonymous with leadership.

### ***Cooperation***

Cooperativeness was related to leadership in 11 studies. Work for the group and corporate responsibility were related to leadership in eight others. The ability to enlist cooperation was related to leadership in seven additional analyses.

Leaders were found by Baldwin (1932), Dunkerley (1940), Fauquier and Gilchrist (1942), Newcomb (1943), and Wetzel (1932) to rate higher than followers in cooperativeness. Drake (1944) and Webb (1915) reported correlations of .44 and .69 between cooperativeness and leadership. The ability to enlist cooperation and to control others in a group enterprise were found by Baldwin (1932), Caldwell (1920), Hanfmann (1935), Merriam and Gosnell (1926), and Nutting (1923) to be characteristics associated with leadership ability. Webb (1915) reported a correlation of .69 between leadership and corporate spirit. Cox (1926) also reported that great leaders rate outstandingly high in a sense of corporate spirit.

### ***Patterns of Leadership Traits Differ with the Situation***

There was a preponderance of evidence from a wide variety of studies (19 in all) that indicated that patterns of leadership traits differed with the situation. Ackerson's (1942) study revealed marked differences in the conduct and personality patterns of children who were regarded as leaders in general and children who were regarded as leaders in misconduct. Boys and girls in these two groups also differed somewhat. Bellingrath (1930) found marked differences in the extent to which leaders in athletics, student government, publications,

and clubs participated in extracurricular activities and were chosen as leaders under various circumstances. The investigation by Caldwell and Wellman (1926) revealed athletic leaders to be tallest among the leaders and to excel in physical achievements, while editors were younger and shorter than average but ranked higher in scholarship than the other groups of leaders who were studied. Cowley's (1928) study demonstrated large differences in the traits of criminal leaders, army leaders, and student leaders. The profiles of the average ratings of the traits of groups of great leaders studied by Cox (1926) differed markedly from one group to another, especially in physical and emotional traits, but much less so in traits that may be classified as intelligence, self-regard, and persistence. Dunkerley's (1940) factor analysis of the intercorrelations of 15 variables representing trait ratings of 167 women college students revealed a factor identified as social leadership and two factors identified as religious leadership.

Hanfmann (1935) observed three types of leaders among preschool children: (1) objective leaders who engage in constructive play and get what they want by saying why they need it; (2) social leaders, whose goal is to play with others rather than play for the sake of play itself; and (3) gangsters, who get their way by force and a complete disregard for others. Schuler (1935) concluded that although teachers may ascertain with increasing reliability the dominant-submissive behavior of older adolescent boys in one situation, such as the school, it becomes less possible to predict those tendencies in another environment, such as the home.

Sward (1933) found that superior socioeconomic status, as well as higher intelligence and scholastic attainment, differentiated 125 campus leaders from 125 followers. However a classification of the leaders into subgroups demonstrated the following distinguishing differences: (1) bright, relatively unmotivated, unsociable, self-confident campus editors; (2) rather insecure, intellectual, and very intelligent debaters; (3) strongly socialized and intellectually mediocre campus politicians; and (4) extroverted women leaders.

Terman (1904) found that children who were leaders in one experimental situation may not have been leaders when matched against different children in other situations. Children who were "automatons," or nonleaders, in most situations might achieve leadership in some situations. Children who were leaders in most situations were said by their teachers to be characterized by intelligence, congeniality, liveliness, and goodness.

In Tryon's (1939) study, the clusters of traits that characterized boys and girls at age 12 differed from those found at age 15. This difference was especially noticeable for girls, who matured somewhat more rapidly than boys in social interests. The leadership cluster for 12-year-old boys was composed of the items: daring, leader, active in games, and friendly. The cluster for 15-year-old boys contained the items: daring, leader, active in games and fights. The leadership cluster for 12-year-old girls contained the items: daring, leader, and humor about jokes. The cluster for 15-year-old girls contained the following items: popular, friendly, enthusiastic, happy, humor about jokes, daring, leader. The total weight of the evidence presented in this group of studies suggests that if there were general traits that characterized leaders, nonetheless the patterns of such traits were likely to vary with the leadership requirements of different situations.

### ***Transferability and Persistence of Leadership***

Six follow-up studies, although yielding somewhat variable results, intimated a certain degree of persistence or transferability of leadership. Levi (1930) studied 230 leaders in elementary and junior high school, 206 of whom were studied again in senior high school. The correlation between leadership in elementary school and leadership in senior high school was .19; the correlation between leadership in junior high school and leadership in senior high school was .52. For athletic leadership there was a low negative correlation between elementary school and high school, but a correlation of .44 between junior high school and senior high school. Kohs and Irle (1920) completed a follow-up study of the military careers of 116 college students. Three faculty members rated these students on various traits. Correlations between the U.S. Army rank attained and

various ratings in college ranged from .11 to .39. The best assessments for predicting military success were found to be the raters' estimates of the assessee's potential value to the service and raters' estimates of the assessee's intelligence. Assessments of leadership in college were correlated .11 with army rank attained, but scholarship was not predictive of army rank. Page (1935), studying cadets at West Point, found first-year leadership rank to be correlated .67 with fourth-year leadership rank. Rank in bearing and appearance was most highly correlated with rank in leadership, while the ranks in athletic activities, tactics, and academic standing were correlated with leadership rank to progressively lesser degrees.

Clem and Dodge (1933) conducted a comparative study of the success of 27 student leaders, 36 high-ranking student scholars, and 38 students selected at random after graduation from high school. High school student leaders ranked highest in subsequent outstanding achievements, number of honors received, and quantity of publications. The random group ranked highest in community leadership and the amount of money accumulated after graduation. In general, the student leaders tended to become more successful than the student scholars and the random group, although the differences were not impressive. Courtenay (1938) studied 100 women leaders and 100 nonleaders from 13 successive high school graduating classes. The two groups were matched in socioeconomic background, ethnic heritage, scholarship, and age at graduation. Courtenay found that 72 student leaders, but only 29 nonleaders, went to college and that twice as many high school leaders as non-leaders were engaged in professional work as adults. The average salary of the adults who had been high school leaders exceeded that of those who had been nonleaders. The high school leaders were more active as adults in community work. Shannon (1929) compared student leaders, scholars (honor-roll members), and a random group from five high school graduating classes. Although the honor graduates were little more successful than the random group, Shannon concluded that "whatever is required to excel in the extracurricular life of the high school seems to be the same thing that contributes most to success later."

These findings strongly suggested that leadership in school activities was somewhat predictive of later success. However, the extent to which leadership persisted and transferred was not clearly determined.

## Conclusions as of 1948

---

1. The following conclusions were supported by uniformly positive evidence from 15 or more of the studies surveyed: (a) The average person who occupies a position of leadership exceeds the average member of his or her group in the following respects: intelligence, scholarship, dependability in exercising responsibility, activity and social participation, and socioeconomic status. (b) The qualities, characteristics, and skills required in a leader are determined, to a large extent, by the demands of the situation, in which he or she is to function as a leader.
2. The following conclusions were supported by uniformly positive evidence from ten or more of the studies surveyed: (a) The average person who occupied a position of leadership exceeded the average member of his or her group, to some degree, in the following respects: sociability, initiative, persistence, knowing how to get things done, self-confidence, alertness to and insight into situations, cooperativeness, popularity, adaptability, and verbal facility.
3. A number of factors were found to be specific to well-defined groups. For example, athletic ability and physical prowess were found to be characteristics of leaders of boys' gangs and play groups. Intellectual fortitude and integrity were found to be associated with eminent leadership in maturity.
4. The traits with the highest overall correlation with leadership were originality, popularity, sociability, judgment, assertiveness, desire to excel, humor, cooperativeness, liveliness, and athletic ability, in approximate order of magnitude of the average correlation.
5. Despite considerable negative evidence, the general trend of the results suggested a low positive

correlation between leadership and such variables as chronological age, height, weight, physique, energy, appearance, dominance, and mood control. The evidence was about evenly divided concerning the relation to leadership of such traits as introversion-extroversion, self-sufficiency, and emotional control.

6. The evidence suggested that leadership exhibited in various school situations may persist into college and later vocational and community life. However, knowledge of the facts related to the transferability of leadership remains meager and obscure.
7. For understanding leadership, the most fruitful studies were those in which the behavior of leaders was described and analyzed on the basis of direct observation or the analysis of biographical and case history data. The factors associated with leadership could all be classified under the following general headings: *Capacity* (intelligence, alertness, verbal facility, originality, and judgment); *Achievement* (scholarship, knowledge, and athletic accomplishments); *Responsibility* (dependability, initiative, persistence, aggressiveness, self-confidence, and the desire to excel); *Participation* (activity, sociability, cooperation, adaptability, and humor); *Status* (socioeconomic position and popularity); and *Situation* (mental level, status, skills, needs and interests of followers, objectives to be achieved, and so on).

It is primarily by participating in group activities and demonstrating a capacity for expediting the work of the group that a person becomes endowed as a leader. A number of investigators were careful to distinguish between the leader and the figurehead and to point out that leadership is always associated with the attainment of group objectives. Leadership implies activity, movement, and getting work done. The leader is a person who occupies a position of responsibility in coordinating the activities of the members of the group in their task of attaining a common goal. This definition leads to a consideration of another significant factor. A person does not become a leader by virtue of some combination of traits; but the pattern of personal characteristics of the leader must bear some relevant relationship to the characteristics, activities, and goals of the followers. Thus leadership must be conceived in terms of the interaction of variables that are in constant flux. The factor of change is especially characteristic of the situation, which may be radically altered by the addition or loss of members, changes in interpersonal relationships and in goals, the competition of external influences, and the like. The personal characteristics of the leader and of the followers are, in comparison, highly stable. The persistence of individual patterns of human behavior in the face of continual situational change appears to be a primary obstacle not only to the practice of leaders but to their selection and placement. It is not especially difficult to find persons who are leaders. It is quite another matter to place these persons in different situations where they will be able to function as leaders. It becomes clear that an adequate analysis of leadership involves a study not only of leaders but also of situations.

The evidence suggests that leadership is a relationship between persons in a social situation and that persons who are leaders in one situation may not necessarily be leaders in other situations. Must it then be assumed that leadership is entirely incidental, haphazard, and unpredictable? Not at all. The very studies that provided the strongest arguments for the situational nature of leadership also supplied the strongest evidence to indicate that leadership patterns as well as nonleadership patterns of behavior were persistent and relatively stable. Jennings (1943, p. 210) observed that "the individual's choice behavior, in contrast to his social expansiveness, appears as an expression of needs which are, so to speak, so 'central' to his personality that he must fulfill them whether or not the possibility of fulfilling them is at hand or not." A somewhat similar observation was made by Newstetter, Feldstein, and Newcomb (1938, p. 92): "Being accepted or rejected is not determined by the cordiality or antagonism of the individual's treatment of his fellows, nor evidently, is the individual's treatment of his fellows much affected by the degree to which he is already being accepted or rejected by them. Their treatment of him is related to their acceptance or rejection of him. Their treatment of him is, of course, a reaction to some or all of his behaviors, but we have been completely unsuccessful in attempting to measure

what these behaviors are.”

The authors concluded that these findings provided “devastating evidence” against the concept of the operation of measurable traits in determining social interactions. Although these findings do not appear to provide direct evidence either for or against a theory of traits, they do indicate that the complex of factors that determines an individual’s status in a group is most difficult to isolate and evaluate.

The findings of Jennings and Newsletter, Feldstein, and Newcomb suggested that *selecting* leaders should be much less difficult than *training* nonleaders to become leaders. The clinician or group worker who has observed the fruitless efforts of socially isolated individuals to gain acceptance or leadership status in a group is aware of the real nature of the phenomena just described. Some individuals are isolated in almost any group in which they find themselves, while others are readily accepted in most of their social contacts. A most pertinent observation on this point was made by Ackerson (1942, p. 45), who noted that “the correlations for ‘leader’ and ‘follower’ are not of opposite sign and similar magnitude as would be expected of traits supposed to be antithetical. These may not be the opposite poles of a single underlying trait.” Ackerson went on: “It may be that the true antithesis of ‘leader’ is not ‘follower,’ but ‘indifference,’ i.e., the incapacity or unwillingness either to lead or to follow. Thus it may be that some individuals who under one situation are leaders may under other conditions take the role of follower, while the true ‘opposite’ is represented by the child who neither leads nor follows.”

The findings suggest that leadership is not a matter of passive status or of the mere possession of some combination of traits. Rather, leadership appears to be a working relationship among members of a group, in which the leader acquires status through active participation and demonstration of his or her capacity to carry cooperative tasks to completion. Significant aspects of this capacity for organizing and expediting cooperative efforts appear to be intelligence, alertness to the needs and motives of others, and insight into situations, further reinforced by such habits as responsibility, initiative, persistence, and self-confidence.

But the studies surveyed offered little information as to the basic nature of these personal qualifications. Cattell’s (1946) analysis suggested that these qualifications could be based, to some degree, on basic intelligence, but Cat-tell and others also implied that these personal qualifications were, to a high degree, socially conditioned. The problems requiring thorough investigation relate to factors that condition social participation, insight into situations, mood control, responsibility, and the transferability of leadership from one situation to another. Solutions to these problems seem basic not only to any adequate understanding of the personal qualifications of leaders, but to any effective training for leadership.

## Traits of Leadership (1948–1970)

---

### ***Improvements in Methods and Measurements***

Many new methods and measurements were introduced into the study of leadership in the decades after 1948. Experiments involving one variable at a time gave way to factorial and multivariate designs in which the effects of various treatments could be analyzed in the same experiment. Theory began to guide much of the data collection. Questionnaire methodologists introduced a variety of techniques to reduce errors such as the halo effect, leniency, and social desirability, and to increase the relevance and reliability of results, although their efforts often met with limited success. The critical-incidents technique, forced-choice checklists, behaviorally-anchored rating scales, and semantic differentials were just a few of the specific new methods used. Factor analysis became the basic tool in the search for and verification of the existence of traits of consequence. Other multivariate regression procedures also became commonplace in efforts to establish the relative importance of

different traits to successful leadership. Varieties of statistical tests increased, to support or reject findings.

The internationalization of efforts also became widespread. Whether the same traits of leadership were relevant to rural agricultural leaders in Chile and Mali or led to promotion to higher management in Norway, Italy, and Japan were among the subjects examined. In the United States, a topic of considerable interest was whether different leadership traits would emerge as important for women and for racial and ethnic-minority leaders. The human-potential movement sparked awareness of the need to deal with leadership at a level of socioemotional feeling that was deeper than surface intellectual perception. More studies focused such traits as self-exposure, empathy, energy level, intuition, and interpersonal competence. The whole field of small-group research expanded, with many investigations in the 1950s. At the same time, much more rigor was introduced into measurements of individual role taking and behavior in small-group interactions. In addition, experimenters became much more aware of the many threats to the validity of their findings.

As the era ended, situational leadership was the dominant theory used for management and leadership training, but some disquieting research that supported the primacy of individual differences in leaders appeared shortly afterward. There was a resurgence of interest in consistent individual differences across situations, braced with meta-analytic demonstrations of the validity and generalizability of a very limited battery of cognitive abilities tests for predicting successful performance in a wide variety of situations (Schmidt & Hunter, 1977). Reexamination of earlier data and meta-analytic theory itself suggested that situational variations frequently could and should be attributed not to substantive effects but to sampling error. Situational effects would have to be shown above and beyond what would be generated by the normal probability distribution of the means generated in the diverse situations. Strong inferences were drawn about personality and early developmental influences that had permanent effects on individuals and their behavior as leaders and followers.

Stogdill (1970) examined another 163 studies of the traits of leadership published between 1948 and 1970 and considered how findings could be meaningfully factor-analyzed and clustered. (These findings were first reported in full in [Chapter 5](#) of the first edition of the *Handbook of Leadership* in 1974.) Stogdill summarized the physical characteristics, social background, intelligence and ability, personality, task-related characteristics, and social characteristics related to leadership. Between 1948 and 1970, the proportion of studies of adults in formal organizations increased and the proportion dealing with children and adolescents in informal groups decreased. In interpreting conclusions caution is urged on the basis of the published survey findings.<sup>3</sup>

### ***Physical Characteristics***

Measures of physical characteristics, such as activity, age, and appearance were of positive consequence to leadership. Appearance can affect first impressions, which in turn have significance for emergent leadership. Fewer than three studies were found for height and weight; nevertheless, height or weight above the average of the peer group is certainly not a disadvantage in achieving leadership status. (Many organizations like to be represented by impressive physical specimens. When faced with taller opponents in television debates, shorter presidential candidates such as Jimmy Carter and Michael Dukakis stood on raised platforms. Frederick the Great required that all his soldiers be tall; however, Napoleon is often cited as an example that a man of small stature can rise to a position of great power. Thus physical stature may complement a leader, or a leader may compensate for lack of physical stature. Yet there is a rational element involved when coercive leadership is needed. Robert Peel, who introduced the “bobbies” to London, made a highly effective police force without firearms by choosing only large men who could dominate scenes of social conflict. Conversely, it has been noted that smaller policemen are more likely to suffer attack and injury.)

*Activity, Energy, Stamina.* The 1970 survey found 25 studies<sup>4</sup> of these factors—many more than were found in the 1948 survey—which suggested that a leader tends to be endowed with an abundant reserve of energy, stamina, and ability to maintain a high rate of physical activity. Even when handicapped by physical disability or poor health, highly successful leaders tended to exhibit high energy.

*Age.* Age appeared in six studies reported between 1948 and 1970.<sup>5</sup> Age continued to be related to leadership in a complicated way, as noted before. A survey by Lehman (1953) on the relation of age to achievement in science, art, politics, and other fields found that great men tended to exhibit signs of outstanding accomplishment at a relatively early age. Many, but not all, had the advantage of specialized education or training because of the early recognition of their talent. However, it usually takes time to rise to the top in a corporate or governmental structure. Standard and Poor's (1967) reported that 74 percent of 66,336 American executives in its 1967 *Register of Corporations, Directors, and Executives* were over age 50. Only 168 executives were under age 30, while 8,085 were in the 71-to-80 age group. The two sets of findings indicate that the creative individual is likely to exhibit evidences of his or her ability at an early age; however, large organizations up to 1970 did not make much use of such creative gifts in administrative capacities. Rather, organizations tended to rely on administrative knowledge and demonstrations of success that come with experience and age.

## ***Social Background***

*Social Status.* Studies of the socioeconomic background of leaders continued to proliferate between 1948 and 1970; 19 studies were found for this period.<sup>6</sup> D. R. Mathews (1954) observed that from 1789 to 1934, 58 percent of the presidents, vice presidents, and cabinet members had fathers in the professional, proprietor, or official occupations; 38 percent had fathers who were farmers, but only 4 percent had fathers who were wage earners. It is apparent that high social status has provided an advantage in rising to high levels of political leadership. But Newcomer (1955) and *Scientific American* (1965) reported that, compared with 1900, more top executives in 1965 were beginning to come from the poorer and middle-income groups, rather than the wealthy strata of society. A. Porter (1965) found that the background of the father of an executive was significantly related to the executive's level in the organization and his authority for making policy. However, the father's background was not related to the size of the organization or to the executive's status in the business world or satisfaction with the progress of his career.

Miller and Dirksen (1965) reported that highly visible community leaders were differentiated from their less visible peers by being business oriented, Republican, members of the chamber of commerce, and named in the mass media. However, the hidden community leaders were characterized as holding administrative or professional jobs; they were not owners of large businesses, nor natives of the city, nor did they come from families in the city that were prominent. R. M. Powell's (1969) large-scale survey of the executive promotion process indicated that religious and ethnic background—usually linked with social status—were also important factors.

Studies of the social background of student leaders by Martin, Gross, and Darley (1952); Weinberg (1965); Krumboltz, Christal, and Ward (1959); and Kumar (1966) revealed few consistent relationships across samples, although Williamson (1948) found that fraternity members occupied a disproportionately large share of leadership positions on the college campus.

*Mobility.* Six studies dealt with the upward mobility of leaders.<sup>7</sup> Jennings's (1967a) study is illustrative of the work in this area; it presented an insightful analysis of the problems, stresses, and adaptations involved in

rapid upward mobility in a large corporation. More specifically, Cussler (1958) found that once women executives reached middle management in an industrial organization, they found it difficult to rise higher. They hit the “glass ceiling.”

*Education.* Fourteen studies showed the importance of education to leadership.<sup>8</sup> Reflecting a national rise in educational levels, senior managers with college degrees increased from 28.3 percent in 1900 to 74.3 percent in 1964 (*Scientific American*, 1965). In contrast, G. F. Lewis’s (1960) review of several studies indicated that small businessmen have less education than top executives in large firms and more often start their careers as unskilled or semiskilled workers. Johnson, Peterson, and Kahler (1968) studied 496 first-line foremen in a company from 1940 to 1961. They found that the average age of these foremen increased from 31.2 years in 1940–1944 to 41.2 years in 1955–1959 and that their years of schooling increased from 10.8 to 11.2 during the same period.

The following conclusions were drawn from these studies of social background and education: (1) High socioeconomic status was an advantage in attaining leadership; (2) Leaders who rose to high positions in industry tended to come from a lower socioeconomic status than their counterparts of a half century earlier; (3) The leaders tended to be better educated than formerly. The rise in the general level of education of the population is common knowledge. Requirements for managerial and administrative positions increasingly demanded a graduate degree, such as an MBA. The trend toward reduced emphasis on social status and more emphasis on education was expected to accelerate as the effects of affirmative action manifest themselves. As firms and agencies aggressively promoted women, blacks, and other minorities, a considerable increase in the upward mobility of these groups was expected. For example, in 1960 hardly any women and blacks were observed in MBA or engineering programs.

### ***Intelligence and Ability***

*Intelligence.* In 1970, 25 reports of a positive relationship between leadership, intelligence, and ability were found to have been published between 1948 and 1970,<sup>9</sup> compared with 17 studies in the 1948 review correlating scores on intelligence tests with leadership status. The average correlation of .28 in the 1948 review was corroborated in the 1970 survey. However, five of the competent studies of 1948 ascertained that a large discrepancy between the intelligence of potential leaders and that of their followers militated against the exercise of leadership. Ghiselli (1963b, p. 898) reported supporting evidence. In a study of three groups of managers, he found that “the relationship between intelligence and managerial success is curvilinear with those individuals earning both low and very high scores being less likely to achieve success in management positions than those with scores at intermediate levels.”

Thus leaders can be too able for those they lead. Persons with greater abilities may suffer from extreme self-preoccupation; their abilities may make it difficult for them to communicate with those they are attempting to lead; and their ideas may be too advanced to be accepted by their potential followers (pioneers are seldom outstanding leaders). The discrepancy in abilities is likely to be paralleled by discrepancies in interests and goals. Also, Korman’s (1968) extensive review on the prediction of managerial performance reported that “intelligence, as measured by verbal ability tests, is a fair predictor of first-line supervisory performance, but not of higher level managerial performance.”<sup>10</sup> But one must also suppose that only those who already possess above-average intelligence are likely to have achieved top management positions in the organization. So there is a restriction in range, which makes it impossible for intelligence tests to discriminate the good from the bad performers at the top of the organization. Nevertheless, it should be clear that a high-level intelligence test that discriminates verbal intelligence among those at the upper end of the population’s intelligence, such as the

Miller Analogies (used for predicting success in graduate and professional schools), is also likely to be a valid predictor of the potential to rise in firms, agencies, and institutions.

*Other Intellectual Abilities.* Uniformly positive findings for studies completed between 1948 and 1970 were found, which indicated that leaders are characterized by superior judgment, decisiveness, or both (e.g., Roadman, 1964), knowledge (e.g., Colyer, 1951), and fluency of speech (e.g., Burnett, 1951b).

## ***Personality***

Up to 31 studies in the 1970 survey dealt with personality and leadership. Several differences were noted between the 1948 and 1970 surveys, which might have been due to changes in personality methods and theories, as well as the change in participants in the studies. Uniformly positive findings found in the 1970 survey were the traits of adjustment (e.g., Terrell & Shreffler, 1958), aggressiveness or assertiveness (e.g., Hobert & Dunnette, 1967), independence (e.g., Hornaday & Bunker, 1970), objectivity (e.g., Argyris, 1953), enthusiasm (e.g., Gibb, 1949), and tolerance of stress (e.g., Lange & Jacobs, 1960). Characteristics that appeared with positive findings in both 1948 and 1970 were alertness (e.g., Porter, 1959), originality (e.g., Randle, 1956), personal integrity (e.g., Stephenson, 1959), self-confidence (e.g., Moment & Zaleznik, 1963), ascendance (e.g., Sanders, 1968), emotional balance (e.g., Harville, 1969), and extroversion (e.g., Harrell, 1966).

*Task-Related Personality Characteristics.* Both the 1948 review and the 1970 review produced uniformly positive results indicating that leaders are characterized by a need for achievement (e.g., Cummings & Scott, 1965) and a sense of responsibility (e.g., Gordon, 1952). Leaders tend to be task-oriented (e.g., Medow & Zander, 1965) and dependable in the pursuit of objectives (e.g., Powell & Nelson, 1969). They display enterprise and initiative (e.g., Helfrich & Schwirian, 1968) and are persistent in overcoming obstacles.

*Social Personality Characteristics.* The positive findings on social characteristics in both 1948 and 1970 suggested that leaders were active participants in various activities. They interacted easily with a wide range of personalities (e.g., Krumboltz, Christal, & Ward, 1959), and this interaction was valued by others. They not only were cooperative with others (e.g., J. S. Guilford, 1952) but were able to enlist cooperation (e.g., Bentz, 1964) and to execute (administer) projects (e.g., Kay, 1959). Interpersonal skills (e.g., D. S. Brown, 1964), including tact (e.g., Tarnapol, 1958), made them attractive to followers (e.g., Price, 1948). Leaders were valued by group members because they had characteristics such as nurturance (e.g., Roff, 1950) and popularity (e.g., Harrell & Lee, 1964) that fostered loyalty and cohesiveness in the group.

## **Factor analyses of the traits of Leadership**

---

Stogdill's (1974) review of factorial studies of leadership published between 1945 and 1970 was based on 52 factorial studies, including surveys of a large number of military and industrial personnel, studies of leadership in military and industrial groups, and reports on experimental groups. It should be emphasized that the factors which emerged depended on the variables originally included in the battery of traits measured or ignored by the investigators. For instance, if an investigator included many measures of social distance, a common factor of social distance could emerge. If no measures of social distance were included, no common factor of social distance could be extracted. Likewise, if only a single reliable measure of social distance was included, it would not appear in a separate common factor of social distance, as such. The most frequently occurring factors were

descriptive of various skills of the leader.

They included social and interpersonal skills, technical skills, administrative skills, intellectual skills, leaders' effectiveness and achievement, social nearness, friendliness, supportiveness of the group task, and task motivation and application. These factors indicated that leaders differed from each other consistently in the effective use they made of interpersonal, administrative, technical, and intellectual skills. Some leaders could be described as highly task-motivated; others were most capable of maintaining close, friendly, personal relationships. The best leaders were able to do both. The next most frequent set of factors was concerned with how leaders relate to their groups. The behaviors included maintaining the cohesiveness of the group, coordination, task motivation, task performance, and high quality of output. A concern for the group's performance was softened by nurturant behavior and the use of informal controls. These factors were as follows: maintaining a cohesive work group, maintaining coordination and teamwork, maintaining standards of performance, maintaining informal control of the group (group freedom), and nurturant behavior. Next in frequency were factors concerned strictly with the personal characteristics of leaders. Leaders could be described in terms of emotional balance, willingness to assume responsibility, ethical conduct, ability to communicate readily, dominance, energy, experience, courage, and maturity.

In sum, successful leadership involves certain skills and capabilities—interpersonal, technical, administrative, and intellectual—that enable leaders to be of value to their group or organization. These skills allow leaders to maintain satisfactory levels of group cohesiveness, drive, and productivity. Leaders are further assisted in the execution of these functions if they possess a high degree of motivation to complete tasks, personal integrity, communicative ability, and the like. The 52 factorial studies as a whole seem to provide a well-balanced picture of the skills, functions, and personal characteristics of leaders in a wide variety of situations. The factors and the number of studies in which they emerged were as follows: ascendancy, dominance, decisiveness (11); willingness to assume responsibility (10); ethical conduct, personal integrity (10); maintaining a cohesive work group (9); maintaining coordination and teamwork (7); ability to communicate, articulateness (6); physical energy (6); maintaining standards of performance (5); creative, independent (5); conforming (5); courageous, daring (4); experience and activity (4); nurturant behavior (4); maintaining informal control of the group (4); mature, cultivated (3); and aloof, distant (3).

## Conclusions by 1970

---

The differences between 1948 and 1970 may be due primarily to the larger percentage of studies in the 1970 survey from the world of work rather than from children's, school, and social groups.<sup>11</sup> The similar results made it reasonable to conclude that many cognitive, social, and emotional traits differentiated leaders from followers, successful from unsuccessful leaders, and high-level from low-level leaders. One practical application of this conclusion was the assessment center for determining leadership potential among candidates for managerial positions (Bray, Campbell, & Grant, 1974; Bray & Grant, 1966). By the 1970s, over 1,000 such assessment centers were in operation. In these centers candidates are observed for two to three days in interviews, leaderless group activities, and other situational tests. They are also tested individually with personality and aptitude tests. The "in-basket," a sampling of managerial action requirements, is also often used. Observers meet to try to pool their results on the basis of inferences from the test results and their observations to yield a picture of the total personality of the candidate and his or her leadership potential in positions familiar to the observers. Much more will be presented about such assessment centers in [Chapter 35](#).

The leader is characterized by a strong drive for responsibility and completion of tasks, vigor and persistence in the pursuit of goals, venturesomeness and originality in problem solving, a drive to exercise initiative in social situations, self-confidence and a sense of personal identity, willingness to accept the consequences of his

or her decisions and actions, readiness to absorb interpersonal stress, willingness to tolerate frustration and delay, ability to influence other people's behavior, and the capacity to structure social interaction systems to the purpose at hand. The clusters of characteristics discussed in this chapter differentiate leaders from followers, effective from ineffective leaders, and higher-echelon from lower-echelon leaders. In other words, different strata of leaders, and followers can be described in terms of the extent to which they exhibit some of the characteristics. Furthermore, research by Bass (1953), Moore and Smith (1953), and Tarnapol (1958) suggested that isolates and, to a lesser extent, followers and nonleaders can be described by the antonyms of trait names attributed to leaders. The characteristics generate personality dynamics that are advantageous to the person seeking the responsibilities of leadership.

The conclusion that traits are a factor in understanding leadership did not represent a return to the pure trait approach. It did represent a sensible modification of the extreme situationalist point of view. At first, the trait approach treated personality variables in an atomistic fashion, suggesting that each trait acts singly to determine the effects of leadership. Increasingly, models were tested describing how combinations of differentially weighted traits contributed to leadership. The wholly situationalist approach, on the other hand, denied the influences of individual differences, attributing all variance among persons to the demands of the environment. Again, it should be emphasized that some of the variance in who emerges as a leader and who is successful and effective is due to traits of consequence in the situation; some is due to situational effects; and some is due to the interaction of traits and situation. For example, suppose that candidates for management positions are tested in three situations: social service agencies, industrial firms, and military organizations. We are likely to find in the aggregate that individual interpersonal competence is predictive of successful performance. But it also may be more predictive in social service agencies and less predictive in military organizations. Considering the importance of competence to perform tasks and interpersonal competence at two stages in the careers of public accountants, engineers, and other technical specialists, one finds that both kinds of competence are important to performance. During a person's early years with a firm, technical competence is most strongly indicative of successful performance; but after two to five years, interpersonal competence becomes more important.

The element of chance would appear to play a part in the rise of individual leaders. A given leader may be able to rise to the top of the hierarchy in competition with one group of peers but may be unable to do so in another group of peers. An individual's upward mobility would seem to depend, to a considerable degree, on being in the right place at the right time. Finally, it should be noted that to some extent our conceptions of characteristics of leadership are culturally determined, as will be elucidated in [Chapter 33](#). Situational contingencies will be examined more fully in chapters 25 through 29. These contingencies may be masked by consistent differences among individuals. This statement implies that there are regularities in individuals' abilities, interests, orientations, values, and personality that endure across time. Other differences of consequence may include age, sex, family background, physique, and so on. Since the beginning of the study of leadership, the question has remained: how much do these individual differences account for the emergence of leadership and its effectiveness, and do the effects transcend situational circumstances? Some individuals will attempt to lead in most situations in which they find themselves, but others will avoid doing so whenever possible. Other individuals will attempt to be leaders only in certain situations, and their personal predispositions can be described. The same may be said about succeeding as a leader.

By 1970, there was plenty of evidence that particular patterns of traits were of consequence to leadership; these included determination, persistence, self-confidence, and ego strength. Additionally, the mass of research findings about the traits of leaders compared with nonleaders and of successful and effective leaders compared with unsuccessful and ineffective leaders included activity level, rate of talk, initiative, assertiveness, aggressiveness, dominance, ascendance, emotional balance, tolerance for stress, self-control, self-efficacy, enthusiasm, and extroversion. This was confirmed with qualification in studies in the years that followed.

<sup>1</sup> The original review *Personal factors associated with leadership: A survey of the literature* appeared in the *Journal of Psychology*, 1948, 25, 35-71. It is excerpted by permission of *The Journal Press*, Provincetown, Massachusetts. This classic marked a turning point in the study of leadership. Prior to this work, the search for universal personal traits of leadership was emphasized. After it, situation-specific analyses took over and dominated the field. Much more emphasis was placed on the situation alone than was done in the publication. Both individual traits and situational assessments are important, as well as the interaction between them. That was Stogdill's main thesis. It was not until the 1980s that the importance of personal factors was restored.

<sup>2</sup> This list of traits of social activities is difficult to classify, since the behavior is clearly defined in few cases. The majority of investigators appeared to emphasize the social aspects of these behaviors, although some emphasized an underlying physical component of energy or vitality. This is merely one example of the difficulty mentioned by a number of investigators, of attempting to analyze human behavior by dividing it into distinct and separate traits.

<sup>3</sup> David Bakan pointed to the existence of a farcical but not necessarily fanciful prospect about positive and negative findings in social science. Suppose, he argued, that the difference between A and B is really zero. Thus in 95% of all studies of A and B, we would expect to reach a negative conclusion—a finding of no statistically significant difference between A and B at the 5% level of confidence. But 5% of all studies will reach a positive but erroneous conclusion—that there is a difference between A and B at the 5% level of confidence. Who publishes? Only those with positive findings! So if we depend on a count of publications of positive and negative findings, we will draw the wrong inference about the true difference between A and B.

Unfortunately, there is some truth in Bakan's burlesque: researchers and journal editors are reluctant to publish negative findings; hence, there is little question that positive findings are more likely to be published than negative ones. Let the reader beware. See for example, Borg and Tupes (1958), M. Coates and Pellegrin (1957), Ghiselli and Barthol (1956) and J. S. Guilford (1952).

<sup>4</sup> The reader who is interested in the complete list of citations of these studies should consult [Chapter 5](#) in the earlier editions of this handbook.

<sup>5</sup> See, for example, A. R. Bass (1964), Johnson Peterson, Kahler (1968), and Newcomer (1955).

<sup>6</sup> See, for example, Ghiselli (1959), Hulin (1962), Lewis (1960), and Matthews (1954).

<sup>7</sup> See, for example, Hicks and Stone (1962, Powell (1969), and Roe (1956).

<sup>8</sup> See, for example, Feil (1950), Kumar (1966), Mandell (1949), and O'Donovan (1962).

<sup>2</sup> See, for example, Ghiselli (1964), Rowland and Scott (1968), Rychalak (1963), and Thornton (1968).

<sup>10</sup> Later chapters show that higher levels of management call for a different kind of intelligence—fluid intelligence—which may be contrasted to the crystallized intelligence of import to lower levels of management.

<sup>11</sup> Stogdill suspected that the absence of some particular positive findings in the 1970 survey were due, in part, to the decisions of his abstracters. We also must be cautious about the volume of results obtained for some traits and not for others. Researchers tend to pursue fads. Also, changes occur over the decades in the names that are used to label the same traits of behavior.

### Traits of Leadership (1970–2006)

A trait is a construct based on consistent individual differences between people. Personality is the organized pattern of distinctive traits of a specific person. Additional meanings may be added, such as the way personality traits are integrated. Simple to complex patterns may be formed. They may form hierarchies. For instance, the trait of agreeableness may consist of correlated sub-traits: trustingness, altruism, compliance, and tender-mindedness.

Traits and their expression may be captured as snapshots, but they are more enduring unlike momentary moods or states of being such as feeling angry or feeling happy. Roberts and DelVecchio (2000) demonstrated that traits were enduring and were not states like a person's mood, which can change in a short time. These investigators completed a meta-analysis of 152 longitudinal studies of 3,217 test-retest correlations of traits occurring during two age periods. The mean correlation between age periods was only .31 in childhood but rose to .54 in later life. Traits are not the same as motives. Thus the trait of extroversion brings about unconflicted social motive expression; the trait of introversion blocks social motive expression and the attainment of social goals (Winter, John, Stewart, et al., 1998).

When traits are requirements for doing something, they are called “competencies.” Traits of leadership are competencies. They are needed if someone is to emerge, succeed, or be effective as a leader. Various kinds of traits are factors in leadership. *Cognitive* traits provide task competence and problem-solving abilities. These include intelligence, judgment, decisiveness, knowledge, fluency of speech, resourcefulness, technical abilities, intellectually stimulating qualities, vision, imagination, articulateness, diagnostic skills, originality, and creativity. *Social competency* traits include social intelligence, assertiveness, cooperativeness and the ability to enlist cooperation, attractiveness, affiliativeness, nurturance, sociability, interpersonal skills, social participation, tact, diplomacy, empathy, social insight, and attributional accuracy. *Emotional competency* traits include emotional intelligence, emotional maturity, self-confidence, self-esteem, self-efficacy, hardiness, and optimism. Those traits with negative impact on leadership include arrogance, narcissism, depression, anxiety, rigidity, neuroticism, lack of self-confidence, lack of self-esteem, and lack of self-efficacy. *Biophysical* traits of consequence to leadership include physical fitness and stature. Traits of *character* include integrity, honesty, moral reasoning, resilience, and discipline. Eye color, walking stride, and uxoriousness are examples of traits which are not ordinarily competencies of consequence to leadership.

### Situationalism

---

The quest for universal leadership traits for all situations was abandoned by most, but not all, researchers in the 1950s and 1960s. Reviews by Bird (1940), Jenkins (1947), and Stogdill (1948) were cited frequently (and incorrectly) after 1948 to support the view that leadership was entirely situational in origin and that particular personal characteristics could not accurately predict leadership. This view overemphasized the situational and underemphasized the significance of the individual leader's traits. For instance, Carter (1953), Gibb (1954), and Shartle (1956) inferred that stable relationships between traits and leadership pertained to specific situations only. The view that many are “born leaders” was rejected. Nevertheless, many scholars before and after 1970 still held that certain personal characteristics improved a leader's chances of success (Van Fleet &

Yukl, 1986). The connection between traits and leadership remained true for a wide variety of situations. Nonetheless, evidence was amassed to indicate that different skills and traits were required for leadership in different situations. Many of the behaviors and traits that enable a mobster to gain and maintain control over a criminal gang are not the same as those that enable a television evangelist to gain and maintain a following. Yet these two leaders may share some important traits, such as persistence, cupidity, and self-monitoring.

### ***The Contrary Evidence***

It was noted in [Chapter 4](#) that, as Stogdill (1948, 1974) concluded, certain general qualities—such as initiative and fortitude—have appeared repeatedly as characteristics of leaders. Stogdill found that particular traits contributed to a person's emergence as a leader in a wide variety of situations. This conclusion was supported in Mann's (1959) survey of research on the relation of personality to performance in small groups. Mann found positive relationships between personal traits (intelligence, adjustment, extroversion, dominance, masculinity, and sensitivity) and leadership in 71% to 80% of the studies he included in his review. As mentioned above, Roberts and Del Vecchio (2000) did a meta-analysis of 152 studies showing the stability of an individual's traits, particularly among adults. They analyzed 3,217 test-retest correlations of personality tests with a controlled interval of 6.7 years between test and retest. Although the mean correlation was only .31 in childhood and .54 during college, it was .64 at age 30 and plateaued at .74 at ages from ages 50 to 70. Individual traits may be consistently important in a wide range of leadership situations.

### ***Rotation Experiments***

Barnlund (1962) rotated 25 participants in groups of six in different combinations but misinterpreted the results. He attributed most of the variance to differences in the composition and task situation of the group. Twenty-one years later, in reexamining Barnlund's data and conclusion, Kenny and Zaccaro (1983) noted that the average correlation in the leadership rank that individuals attained as members of the six composed and recomposed groups was .64. This correlation was substantial evidence of personal consistency in the emergence of leadership across the six situations. Kenny and Zaccaro concluded that Barnlund's results supported the contention that between 49% and 82% of the variance in leadership could be accounted for by a stable personality trait. They inferred that this trait was "the ability to perceive the needs and goals of a constituency and to adjust one's personal approach to group action accordingly" (p. 678). Zaccaro, Foti, and Kenny (1991) rotated their participants through four different group tasks in groups of three so that no two participants worked with the same participant more than once. The emergent leadership of each participant was rated the others after every task. Every task required using a different style of leadership: persuasion, initiating structure, consideration, and emphasis on production. The investigators isolated the variance due to the raters, the ratees, and their interaction. They found that 59% of the variance was due to the participants' traits rather than to the different group task situations.

## **Heritability, Genes, and Biological Bases of Leadership Behavior**

---

Leaders may be born as well as made, as we can see if we examine research of the past 30 years on genes, heritability, and leadership.

Leadership theory and research from 1975 to 2005 have turned us back again to considering the importance of traits. Research in cotwin studies and advances in microbiology and behavioral genetics have been helpful.

Genetic factors have been shown to influence personality traits and their expression in different situations. At the same time, environmental experiences unique to individuals contribute to their development (Fulker & Cardon, 1993). Viken, Rose, et al. (1994) tested approximately 15,000 Finnish twins in extroversion and neuroticism, first at ages 18 to 53, and then six years later. Experience became more important with age, and no additional genetic effects appeared after age 30.

### ***Methods of Genetic Leadership Analysis***

*Cotwin Studies.* In cotwin studies, a strong genetic component has been found in many traits associated with leadership, such as intelligence and assertiveness (Rose, 1995). In a cotwin study, variance in agreement on a specific trait between monozygotic or identical twins (from one egg) is compared with the agreement between a comparable pair of dizygotic or fraternal twins (from two eggs). The higher the ratio of agreement between identical twins compared with the agreement between fraternal twins in a sample, the stronger the genetic effect. Ratios of .3 to .7 have been found for many traits associated with leadership. (A ratio of 1.0 would mean that 100 percent of the variance was genetic. A ratio approaching zero would mean there was no genetic effect.)

*Molecular Biology Studies.* At the level of molecular biology, traits and behaviors have been associated with multiple genes in a particular order in a chromosome (Science, 1995, pp. 4, 77; Cherney, 1998). But genes tend to work in a diffuse way (Hammer & Copeland, 1998). Neither a single gene nor the same genes in a different order may be of consequence. Identical twins share all their genes; fraternal twins share, on average, only half of their genes; nontwin brothers can share much less genetically. Thus, 33 out of 40 homosexual brothers had the same DNA variations in a region of the X chromosome, and half shared the same region of chromosome Xq28 (LeVay & Hamer, 1994). But heterosexual brothers inherited the opposite version of Xq28 (Hu, Patta tucci, et al., 1995).

*Traits of Leadership Likely to Be Influenced by Genetics.* Studies have found genetic effects of consequence to leadership for general intelligence (Bouchard & McGue, 1981), personality traits (Goldsmith, 1983), interests (Keller, 1992), and involvement in a job (Gilbert & Ones, 1998). Berenson (1997) suggested that strong effects based on cotwin studies and molecular biology demonstrate at least 30% heritability in traits related to leadership such as extroversion, shyness, sociability, self-confidence, cognitive abilities, verbal fluency, verbal comprehension, impulsivity, dominance, and aggression. Other traits subject to inheritance mentioned by investigators included achievement motivation, empathy, initiative, persistence, and speed of information processing (Dworkin, 1979; Ghodsian-Carpy & Baker, 1987; Horn, Plomin & Rosenman, 1976; Loehlin, 1992; Johnson, Vernon, & Harris, 2004; Mathews, Batson, et al., 1981; McCartney, Harris, & Bernieri, 1990; O'Connor, Foch, et al., 1980; Rose, 1995; Rushton, Fulker, et al., 1986; Tellegen, Lykken, et al., 1988). Estimates of the heritability of traits associated with leadership vary widely but converge on 30% to 50% of the total variance (Plomin, DeFries, & McClearn, 1990). For example, Loehlin (1992) found that 35% to 40% of the observed individual variation in extroversion attributed to genetics was correlated with leadership.

*Mechanisms.* The biological mechanisms linking genes and personality are beginning to be understood. For instance, "novelty seeking" is linked with variants of the gene for the dopamine molecule receptor in the brain. Dopamine is the brain's reward chemical; it makes one feel good. Parkinson's disease, caused by a degeneration of the dopamine-producing cells in the substantia nigra of the brain, significantly reduces novelty seeking (Hammer, 1997).

## ***Direct Linkage of Genetics and Leadership***

Not only are we able to present numerous studies showing the effects of genes on personality traits found to be predictive of leadership; there are also investigations that have directly connected genetics to leadership. Arvey, Rotundo, Johnson, et al. (2006) obtained data from the Minnesota Twin Registry to compare 238 identical twins (each pair genetically the same) with 188 fraternal twins (each pair with 50% in common in genetic background). They found that 30% of the variance in emergence as leaders was attributable to genetics. As part of a larger project by Vernon, McCarthy, et al. (undated) to study the effects of genetics on multiple dimensions of aggression, Johnson, Vernon, McCarthy, et al. (1998) surveyed 247 pairs of adult twins using mailed questionnaires: 183 pairs were monozygotic (MZ) and 64 pairs were dizygotic (DZ). Forty-three of the pairs were men; 204 were women. The mean ages of the men and women were 42.8 and 44.5 years, respectively. They were recruited from a Canadian registry of twins or from the 3,000 pairs of twins from many countries who gather annually in Twinsburg, Ohio, for the Annual Twinsday Festival. Respondents completed self-report assessments of leadership, Cassel and Stancik's Leadership Ability Evaluation (LAE, 1982); Bass and Avolio's Multifactor Leadership Questionnaire (MLQ, 1991); and Gough and Heilbrun's Adjective Check List (ACL, 1983). Respondents also completed a "zygosity" questionnaire (Nichols & Bilbro, 1966) which had an accuracy of 93% when matched with blood-typing (Kasriel & Eaves, 1976).

For the LAE, the respondents are presented with 50 hypothetical situations and are asked to choose the style of leadership they would use to handle the situation: laissezfaire, democratic-cooperative, autocratic-submissive, or autocratic-aggressive. Additionally, nine transformational and transactional leadership scale scores were obtained from responses to the MLQ. From the ACL, a checklist of 300 adjectives, 49 were identified as descriptive of leader behavior.

Results were corrected for age and sex. All the leadership assessments except the transactional leadership scales showed genetic effects. That is, the correlation between MZ twins was significantly greater than that between DZ twins. For example, the correlation between the MZ twins' transformational leadership scales ranged from .47 to .50; the corresponding correlations for the DZ twins ranged from .13 to .20. However the correlations between MZ twins' transactional scales ranged from .25 to .31 and the corresponding scales for DZ twins ranged from .11 to .33. For ACL, the MZ twins correlated .50 with each other and the DZ twins correlated only .16. Correlations of the four LAE scores ranged from .31 to .45 for the MZ twins and from .09 to .29 for the DZ twins.

## ***Plasticity of Gene Expression and Brain Functioning***

Genes are inherited, but this does not mean their effects are entirely fixed. The expression of genes is often plastic. The brain can be changed through learning. For instance, in one study elderly inactive "couch potatoes" were engaged in a program of physical exercises for an extended period. Compared with a control sample who did not exercise, the experimental sample showed marked improvements in presumably genetically determined brain functions (Davidson, 2001).

Until recently, it was thought that we continue to lose brain cells and synapses (their connections) as we age. Evidence is accumulating from brain scan research that synaptic networks and the numbers of cells may be increased with specialized experiences. "Use it or lose it" implies that cognitive abilities do not decline with aging as much in professionals who continue to carry on their brain work as in unskilled workers who do not engage in as much cognitive activity as they age. The specific areas of the brain impacted by cognitive and physical activities are detected by brain scans.

## *Prenatal Environment*

Monozygotic (MZ) twins may not show 100% concordance even though they share the same genes. This is because their prenatal environment may be different. Some MZ twins, for example, may not share the same placenta and chorion (membrane). Studies of MZ twins developing in the same or different placentas and chorions show that a shared prenatal environment plays a role in identical twins' concordant intelligence, cognition, and personality (Phelps, Davis, & Schwartz, 1997). Use of tobacco, alcohol, or drugs by the mother can have deleterious effects on the fetus, modifying the intelligence and personality after birth that would have been predicted from the genome of the fetus. Mothers' nutrition is thought to be of consequence in fetal development. But Stein, Susser, et al. (1975) found that test scores of 19-year-old Dutch males whose mothers had been exposed to three months of famine in the winter of 1944–1945, just before their sons were born, showed no evidence of depressed intelligence.

## Personality traits Correlated with emergent and effective Leadership

A meta-analysis by Judge, Bono, Ilies, et al. (2006) confirmed that personality variables are consistently correlated with the emergence and effectiveness of leadership. Some personality traits influence leaders' ability to cope with the external environment facing them and their followers. This is their task competence, involving a cluster of cognitive traits (such as intelligence) and abilities. A second cluster involves their socioemotional traits, interpersonal competence, personality, and character. We will follow up [Chapter 4](#) by considering the findings about both clusters as they relate to emergent and effective leadership. [Table 5.1](#) shows the cognitive and socioemotional traits as well as the physical and character traits found to be related to leadership since 1970.

Character traits are increasing in importance in the study of leadership. For instance, in 1999 a survey of 1,354 leaders in New Zealand ranging from supervisors to CEOs found a correlation of .61 between the perceived leaders' integrity and satisfaction with the leadership, .57 with leaders' effectiveness, and .56 with motivation (Parry & Proctor, 2000).

Table 5.1 Traits Found Related to Leadership 1970–2005

<i>Characteristics</i>	<i>Number of Positive Findings</i>		<i>Number of Zero or Negative Findings</i>
	<i>1948 Survey</i>	<i>1970 Survey</i>	<i>1948 Survey Only</i>
<i>Physical Characteristics</i>			
Activity, energy	5	24	
Age	10	6	8
Appearance, grooming	13	4	3
Height	9		4
Weight	7		4
<i>Social Background</i>			
Education	22	14	5
Social status	15	19	2

Mobility	5	6	
<i>Intelligence and Ability</i>			
Intelligence	23	25	10
Judgment, decisiveness	9	6	
Knowledge	11	12	
Fluency of speech	13	15	
<i>Personality</i>			
Adaptability	10		
Adjustment, normality		11	
Aggressiveness, assertiveness		12	
Alertness	6	4	
Ascendance, dominance	11	31	6
Emotional balance, control	11	14	8
Enthusiasm		3	
Extroversion	5	1	6
Independence, nonconformity		13	
Objectivity, tough- mindedness		7	
Originality, creativity	7	13	
Personal integrity, ethical conduct	6	9	
Resourcefulness		7	
Self-confidence	17	28	
Strength of conviction	7		
Tolerance of stress		9	
<i>Task-related Characteristics</i>			
Drive to achieve, desire to excel	7	21	
Drive for responsibility	12	17	
Enterprise, initiative		10	
Persistence against obstacles	12		
Responsibility in the pursuit of objectives	17	6	
Task orientation	6	13	
<i>Social Characteristics</i>			

Ability to enlist cooperation	7	3
Administrative ability		16
Attractiveness		4
Cooperativeness	11	5
Nurturance		4
Popularity, prestige	10	1
Sociability, interpersonal skills	14	35
Social participation	20	9
Tact, diplomacy	8	4

## Task Competence

Competence, the capability that a person brings to a situation, may be a specific aptitude, ability, or knowledge relevant to meeting the requirements for successful performance in a particular setting (Boyatzis, 1982). It may invoke a person's more generalized intelligence, which is of consequence in a broad spectrum of situations. Or it may concern a person's understanding of how to realign an entire organizational culture (Tichy & Ulrich, 1983).

Those who consider themselves competent to deal with the tasks facing a group will be likely to attempt leadership. If the others agree with them about who has task competence, their attempts to lead will be successful. If these emergent leaders are actually task-competent, as they and others believe, their leadership will be effective—that is, the group will attain its objectives (Bass, 1960). But if the would-be leader's opinion of his or her competence is not shared by the prospective followers, the attempt to lead is unwise and will fail—or if the person does emerge as a leader, his or her leadership will be ineffective. Adlai Stevenson in 1952 and 1956, Michael Dukakis, and other also-rans have attempted to win the American presidency. Although they believed they had the competence to be president, the majority of the electorate disagreed with them and failed to support them.

This contribution of the leader's technical competence to the group's effectiveness has been given as one reason for Japan's rapid competitive success globally after World War II, in contrast to U.S. industry. For instance, although most tenth-grade Japanese students can solve and graph simultaneous equations, far fewer U.S. university students are capable of doing so. Also, Japanese executives are more likely to have engineering degrees, whereas U.S. executives are more likely to have degrees in law or accounting (Tsurumi, 1983b). On the other hand, the greater emphasis in U.S. education on initiative and discovery results in greater creativity in general and greater success of efforts to change.

The differences in the task competencies of such leaders as Robert F. Scott and Roald Amundsen go a long way toward explaining why Amundsen's team reached the South Pole first and returned in good order whereas Scott's team, although it managed with great fortitude to reach the pole, failed to survive the return trip. Amundsen knew, from his own experience in polar exploration and the experiences of others, that a small crew of men on skis, using sleds hauled by Greenland dog teams, offered the best chance of success. Scott, who had not profited from his own or Ernest Shackleton's past failures, tried to rely on Siberian ponies, motor sledges, and hauling by hand. Amundsen prepared for as many contingencies as he could; Scott, as on an earlier expedition, assumed the best and left little in reserve for emergencies (Huntford, 1984).

In distinguishing the transactional leader from the transformational leader, Downton (1973) noted that

followers of a transactional leader are most willing to engage in “transacting goods” with the leader on the basis of their assessment that the leader can “grant them their most preferred choices.” The leader’s ability to do so requires task competence. As Downton (1973, p. 95) explained, “The greater a leader’s competence as perceived by the follower, the greater the probability that the follower will transact goods with him. We should expect the leader’s information, skills, and personal temperament to be important factors influencing the formation and maintenance of follower commitments. Competence to cope with the instrumental tasks of the group is an important criterion in selecting leaders, for it is through the leader’s successful performance of his instrumental functions that rewards are accumulated by individual followers.” Hambrick and Mason (1984) observed that when the senior managers of organizations have entrepreneurial experience, the firms will engage in more innovation of products and expansion of markets. Also, when senior managers are more educated, innovation is more likely (Becker, 1970; Kimberly & Evanisko, 1981). Analyses by Child (1974) and by Hart and Mellons (1970) found that the younger a corporation’s managers were, the greater was the corporation’s growth in sales and revenues. Profitability, however, was not affected. In a study of over 1,500 senior managers in 129 large firms in eight countries, Heller and Wilpert (1981) reported that the managers’ competence, as seen in their experience, qualifications, and skills, influenced the extent to which participative and democratic behavior occurred at other levels in their organizations. Nevertheless, such managerial competence tended to be underutilized, according to Heller and Wilpert.

### ***Competence and Leadership***

The quantity of participation forecasts a person’s emergence as a leader because it is correlated with quality. But continued incompetent talk will not be reinforced by others. As will be noted [Chapter 6](#), Sorrentino and Boutillier (1975) and Gintner and Linkskold (1975) found that the “windbag” or compulsive talker who lacks interpersonal or task competence will ultimately fail in attempting to lead. Hollander (1960) found that when a group is given tasks, its leader is usually evaluated with respect to his or her competence. This acknowledged competence builds up the leader’s credit, so the leader can subsequently depart from the group norms and move the group in novel ways, yet still be accepted by the group.

### ***Task Competence versus Interpersonal or Socioemotional Competence***

The most frequently obtained skill factors of leadership tended to involve task or socioemotional performance. Hollander (1978) observed that competent leadership included being a good facilitator, enabling others to make an effective contribution, having skill in handling the inner workings of the group, maintaining activities on a relatively smooth course, giving direction to activity, and acquainting followers with their roles in the main effort. The leader gives competent guidance to other group members concerning their jobs. He or she must be able to evaluate and discriminate between good and bad work.

Limerick (1976) offered a rigorous way to sort leadership in small groups into content or process that influenced performance. Similarly, Dunphy (1963), in a study of adolescent groups, identified two mutually supportive roles—*leader* and *sociocenter*. The leader was influential in group activities whereas the sociocenter relieved group tension. Again, using Bales’s method of observational ratings of the behaviors of actual leaders, Bales and Slater (1955) and Slater (1955) offered two types of leadership behaviors: socioemotional and task-oriented. As one rises in an organization, the task competence that is required changes from technical prowess to cognitive complexity and abstract capabilities. The need for socioemotional and interpersonal competence remains much the same at all levels (Boyatzis, 1982). Baron (2000) concluded that competent entrepreneurs think differently from other people. They are less likely to engage in counter-factual thinking, but they are

more likely to be overconfident in their judgments. At the same time, they are better social perceptiveness and at adapting to new social situations.

### ***Task Competence Emergent and Effective Leadership***

Evidence continues to mount that generalized intelligence or mental ability contributes to emergence as a leader and effectiveness as a manager. But the evidence also indicates variations in the strength of the association for different situations. For example, Mandell (1950a) reported the following correlations between tested mental ability and performance as a civil service administrator: housing agency executives, .30 and .64; Veterans Administration executives, .52; navy executives, .13. Traits that were checked on adjective checklists correlated, respectively, for 95 males and 98 females with their emergence as leaders in initially leaderless group discussions as follows: clear thinking .38 and .43; clever, .49 and .54; wise, .42 and .30 (Gough, 1988).

### ***Intelligence and Leadership***

As was seen in [Chapter 4](#), intelligence generally is a positive indicator of competence. Much more specific information about its effects on leadership can be offered. For instance, its creative component becomes more important for leadership at higher levels of management.

*General Intelligence.* Schmidt and Hunter (1977) introduced theory and method to support the validity of the same particular ability or trait for predicting performance across a wide variety of situations. They argued that much of the variation observed from one situation to another requires correction for restriction in range and unreliability of the measurements. With this in mind, Cornwell (1983) and Lord, De Vader, and Alliger (1986) found from meta-analyses of the relationship that they could reach an even stronger conclusion than Stogdill (1948) or Mann (1959) about the importance of the personal trait—general intelligence—to leadership. Lord, De Vader, and Alliger used the data from 18 studies: those reviewed by Mann in 1959 and others published subsequently through 1977. Both Cornwell (1983) and Lord, De Vader, and Alliger concluded from their meta-analysis, after adjusting the studies for different sample sizes and errors of measurement, that the true mean correlation of general intelligence and being perceived as a leader was .50 across the different situations. These samples included male and female students in high school, college, and graduate school; management trainees and military cadets; and managers and salesmen.

In addition to cross-sectional studies, there is support from longitudinal predictions. Ball (1938) found that intelligence measures yielding an initial .50 correlation with leadership increased to .75 over a 10-year period. After a generation had passed, a follow-up of Terman's (1925) assessment of 1,000 gifted children reported that during their careers, the highly intelligent were far more likely than most to obtain leadership positions and to perform effectively in them, as indexed by such diverse criteria as being admitted to honorary societies and earning military medals. Howard and Bray (1988) noted the importance of initially tested intelligence in the success of managers at AT&T in eight-year and 20-year follow-ups of the assessments of their accomplishments.

Intelligence is a general factor of cognitive abilities such as verbal, spatial, numerical, and reasoning ability. These cognitive abilities are intercorrelated and predict effective performance in a wide variety of assignments including managerial and supervisory jobs. For example, executives, or their speechwriters, have to be able to articulate in appealing and simple language what followers want or should want to do but may not be able to state clearly. Still, specific tests of abilities add little to the prediction of successful leadership beyond what is found with general intelligence, which includes verbal ability (Hunter, 1986). Lord, Foti, and De Vader

(1984) obtained a correlation of .52 between intelligence and emergent leadership. Morrow and Stern (1990) and Hogan, Raskin, and Fazzini (1990), among many others, likewise found significantly positive correlations between intelligence and emergent leadership, as did Smith and Foti (undated). Hater and Bass (1988) found that ratings of inspirational leadership of midlevel managers by management committees correlated .30 with managers' judgment scores and .23 with direct reports of ratings of their managers' intellectual stimulation.

If a group is to be effective, generally there should be a positive correlation between the intelligence of the leader and that of the members. Conflict and failure are likely if the correlation is zero or negative. Ordinarily, we are likely to see greater intelligence among those at higher organizational levels. Requirements are greater and more complex at these levels, as is discretionary opportunity and the need to plan ahead for longer periods of time. A first-level supervisor may have to plan ahead for three days—a CEO, for 10 years (Jaques, 2000).

*Practical Intelligence.* Sternberg (2002) suggested that intelligence as usually measured might be even more predictive of leadership if it were not primarily linked to academic performance. He conceived of practical intelligence relevant to successful adaptation, shaping, and choice in everyday life and based on *tacit knowledge* (Sternberg, Wagner, & Okagaki, 1993). Tacit knowledge is acquired on one's own; it is usually unspoken, implicit, procedural, and not readily articulated. It is directly related to valued practical goals. It is not a matter of knowing formal rules. Tacit knowledge may be about managing oneself, others, and tasks. It may focus on short-term or long-term goals (Wagner & Sternberg, 1986). Generally, tests of tacit knowledge are situational-judgment inventories in which examinees choose among options for dealing with each situation (Wagner & Sternberg, 1991). Alternatively, answers may be obtained through interviews.

Tacit knowledge, like wisdom, increases with learning from experience. It is ordinarily uncorrelated with tests of multiple abilities and styles of personality and cognition. It can predict success on the job better than general intelligence tests do (Grigorenko, Gil, Jarvin, & Sternberg, 2000). Tacit knowledge correlates, .36 and .38 respectively, with the organizational level of managers in a high-tech firm and their compensation (Williams & Sternberg, 1996). Similar results have been obtained for bank managers (Wagner & Sternberg, 1985). The effectiveness of 368 platoon commanders and 163 company commanders as leaders was rated by superiors, peers, and subordinates. Additionally, 31 battalion commanders were rated by superiors and subordinates. Median correlations between practical intelligence scores and effective leadership ratings were highest (.42) for battalion commanders rated by their superiors and lowest (.17) for platoon commanders rated by their superiors (Hedlund, Forsythe, Horvath, et al., 1999).

*Need for Pragmatic Intelligence.* In a study of management students' ability to set appropriate priorities, Gill (1983) concluded that the very bright students spent too much time and put too much emphasis on the exclusive use of logic and rationality in making their decisions. Those who were a bit lower in intelligence were more pragmatic. They could accept the fact that there were costs and limits to the search for alternatives and to their efforts to achieve completely logical solutions. If the brightest students had been more experienced, they might have been more willing to use less reasoning and more intuition in setting priorities. Pondy (1983) and Weick (1983) considered such pragmatic thinking and action basic to the effectiveness of an executive. The ability to think and act incrementally characterizes successful executives, who must unite the intuitive and the rational and respond to behaviors, not intentions or preconceptions. These executives need to be ready to take action, rather than depend on moving ahead solely by thinking about requiring judgments about obvious consequences of matters. In taking action, they need to pay close attention to what is happening and to take corrective steps as needed. They must be able to impose order and logic on situations in the absence of order and logic so as to consistently interpret what is happening.

*Creative Intelligence.* General intelligence has to do with how well one works with words, numbers,

spatial orientation, and abstractions. There is also an independent factor—of creative intelligence—which can be measured by tests requiring judgments about obvious or remote consequences of actions and conditions, and which ask for the generation of unusual uses of objects (Guilford, 1967). Rusmore (1984) found that in comparison with general intelligence, creative intelligence is more predictive of success at higher levels of management than at lower levels (Rusmore, 1984). But although Dubinsky, Yammarino, and Jolson (1995) expected transformational sales managers to be higher in abstract intelligence, they found just the opposite in a study of 140 sales subordinates' ratings of their 34 sales supervisors' abstract orientation—the ability to assess and evaluate critically ideas that seem vague or unformulated. Abstract orientation of the managers correlated between 2.36 and 2.42 with subordinates' ratings of their managers' transformational leadership.

## ***Memory***

Short-term and long-term storage of information are of considerable importance to the leader, especially the political leader. Willner (1968) found that most of the world-class leaders she studied projected “the image of unusual mental attainments.” Gandhi and Lenin were “genuine intellectuals,” but most of the others were primarily action-oriented. The majority displayed an ability to seize on information and ideas from many sources and to use their excellent memory to store information and retrieve it when they needed it. Franklin Delano Roosevelt could soak up facts and ideas and impress coal miners with the details of their situation or businesspeople with the complexity of their firms. He was constantly searching for information and storing it for use when he needed it. Likewise, Mussolini had a prodigious memory with which he could startle and impress others.

Repeatedly, general managers, senior officials, and chief executive officers are praised for practicing walk-around management, in which they can recognize individually a large number of their employees, call them by their first names, and remember small details about them and their families.

## ***Knowledge, Skills, and Abilities***

Knowledge, such as how to evaluate a subordinate's performance; skill, such as how to prepare clear instructions; and ability, such as how to program a computer, all may be involved in what a leader needs to help a group. In field studies with army combat squads performing a variety of field problems, Goodacre (1951); Greer, Galanter, and Nordlie (1954); and Havron and McGrath (1961) found that the characteristics of the squad leaders who were most highly associated with their units' effectiveness included overall ability, knowledge of their jobs, and knowledge of their men.

Knowledge, skills, and abilities that are of consequence to leadership can be more fully detailed, given the multiple functions that may be involved in specific situations, such as serving as a prime minister, a general manager, a school principal, or a naval officer. Specific situations call for specific task competencies in the leader. Leaders with the specific competencies result in more effective groups. For instance, leaders of guidance groups that are made up of members with different kinds of problems must include among their competencies a great deal of flexibility (Hollander, 1978). At the same time, certain specialties provide an impetus to move individuals into positions of leadership. At least half the members of the U.S. Congress are lawyers. In medical schools, leadership tends to be in the hands of physicians who specialize in internal medicine; 42% of deans of medical schools in 1977 were internists (Wilson & McLaughlin, 1984).

To determine what distinguished the competencies of superior and average naval officers, Spencer (undated) and Winter (1978) identified officers' activities according to the motivation and skills that were required to carry them out. This information could then be applied to selection and training. An analysis of approximately

800 incidents of leadership and management performance in a cross section of commissioned and noncommissioned naval officers identified 27 leadership and management competencies. The 27 competencies subsequently were grouped by factor analyses into five factors. Four of the five factors significantly predicted superior leadership and management performance in a new sample. These four factors, which differentiated between superior and average leadership and management performance, were: (1) competence in achieving tasks; (2) skillful use of influence; (3) management control; and (4) competent advising and counseling.<sup>1</sup>

Kaplan (1986) reported results of the content analysis of interviews with 25 general managers and executives who were asked to provide examples of effective and ineffective general managers. The respondents thought that effective general managers did better in strategic long-term thinking than in short-time crisis management and in communicating well. They judged the general managers to have more vision, a greater knowledge of business, and an ability to establish priorities. Similarly, Bryson and Kelley (1978) found that congressional leadership depend on a variety of competencies. Personality, style, and skill, along with political savvy, were deemed crucial in determining who becomes a congressional leader and who stays a leader. Clearly, effective leaders need to be alert and sensitive to circumstances which suggest that a problem exists. Political leaders must be able to read signals of discontent, of the seriousness of natural disasters, and of dangerous international currents. With the aid of their staffs, they must be able to diagnose properly the conditions of a problem so that they can formulate appropriate policy responses (Tucker, 1981). This ability to diagnose the social and technical aspects of problems, to attribute causes accurately, and to identify the elements of consequence in a situation may depend, to a considerable degree, on intuition, which will be discussed below.

### ***Education, Technical Knowledge, and Technical Competence***

The level of management achieved after 20 years by college graduates and non-college men in the AT&T Management Progress Study showed clearly that college education made a difference (Howard & Bray, 1989). Eleven percent of 137 college graduates reached the fifth and sixth levels of management after 20 years of service, but none of 129 non-college graduates reached these two highest levels. Only 23% of college graduates were still at the two lowest levels after 20 years with the company while 68% of non-college graduates remained at the lowest rungs on the managerial ladder. Higher levels of education were expected in those appointed to positions of leadership. Twelve nursing directors, 86 head nurses, and 267 staff nurses in 12 Egyptian hospitals agreed in their expectation that head nurses should have advanced education beyond the baccalaureate degree in clinical nursing and administration (Essa, 1983).

Many surveys document the importance of technical competence in leaders' success and effectiveness. For instance, Penner, Malone, Coughlin, and Herz (1973) found that U.S. Army personnel were more satisfied with their officers and noncoms if they believed them to be technically competent. Farris (1971a) found that among 117 professionals at the National Aeronautics and Space Administration, including 20 supervisors, those who were identified as informal leaders in the informal organization were technically more competent and in more active contact with their colleagues. They were also more motivated by the technical aspects of their work, better rewarded, and more influential in their work.

Bass (1960) proposed that groups will be more effective if the hierarchy of influence in a group matches the members' abilities. Rohde (1954a, 1954b, 1954c) demonstrated this relationship in experimental groups in which members differed in their ability to perform a task. Rohde found that the group performed more effectively if the leader was qualified than if the leader was unqualified, regardless of the members' abilities and ideas. It was more difficult for an unqualified leader than for a qualified leader to retain control of the group, especially when the members were similar in ability.

The link between the technical competence of the leader and the effectiveness of the group was also seen by

T. G. Walker (1976), who examined leadership in state supreme courts. Walker found that when leaders were selected on the basis of their merit instead of seniority, the courts generated less dissent with their rulings. Additional results reported by Jackson (1953b) and by Rock and Hay (1953) suggested that the emergence of leaders was not a matter of chance, unjust discrimination, or keeping good people down. Both leaders and members appeared to recognize the leader's potential for advancing the purpose of their groups. Also, groups were more effective if the leaders and members played the roles for which they were perceived to be best fitted.

Bugental (1964) found that participants who were trained in task-related skills emerged as leaders more often than untrained participants. G. J. Palmer (1962a, 1962b) studied groups in which the members differed in their ability to perform tasks. "Task ability" was related to successful leadership (the successful influencing of the performance of others) and still more strongly to effective leadership (achieving the goals of tasks). Hollander (1966) varied the characteristics of group leaders, including whether they were task-competent or task-incompetent, and found that leaders who were perceived as task competent by members exerted significantly more influence than those who were perceived as task-incompetent. Julian and Hollander (1966) reported that the willingness of group members to accept a leader's attempts to influence them depended on the leader's competence. However, Hollander and Julian (1970) found that a less competent leader would continue to be tolerated if he or she was seen as highly motivated to perform the tasks of the group.

Hollander (1964) assigned an ambiguous task to groups. After a first trial, the groups were required to predict what would occur in the next trial. A confederate planted by the experimenter played the role of deviate from the group norms but was provided with the correct answers. The confederate's influence as a leader was measured by the number of trials in which his suggestion was accepted as the group's choice. Such influence increased as the trials progressed despite the confederate's violation of the group's norms. Thus the members' perceptions of the confederate's ability influenced his emergence as a leader. Similarly, Goldman and Fraas (1965) assembled 32 student groups of four members each to solve discussion problems. The groups worked under four types of leadership: (1) leader appointed because of ability; (2) leader appointed arbitrarily; (3) leader elected by group members; and (4) no leader. The groups worked best in situations in which they perceived the leader to have been correct in previous situations.

In surveys of 176 senior U.S. Army officers, 256 supervisors and managers, 23 educational administrators, and 45 professionals, Bass (1985a) found uniformly that subordinates who described their supervisor as intellectually stimulating also said they exerted extra effort, were more satisfied with their leader, and regarded him or her as more effective. The same findings appeared in data-feedback surveys in a variety of firms, such as IBM, Digital Equipment, General Electric, and Federal Express (Bass & Avolio, 1989). Superiors also thought that such intellectually stimulating supervisors and managers had greater leadership potential (Hater & Bass, 1988).

In a study of 95 employees of a nonprofit organization, Podsakoff, Todor, and Schuler (1983) showed that the expertise attributed to the leader was critical to whether the leader's instrumental and supportive behavior reduced the employees' role ambiguities. That is, ordinarily such structuring of the paths of employees to their goals would have been expected to clarify what employees needed to do to carry out their role arrangements. But when the employees did not perceive the leader as having expertise, their sense of role ambiguity could not be reduced.

Kemp (1983) analyzed 94 questionnaires and 20 interviews of senior industrial and military executives who were concerned with the development of high technology. Kemp found that successful projects were led by project managers who, among other things, fully understood the technology and operational needs and could attract the support of professionally competent and experienced subordinates. Yukl (1998) suggested the same for lower-level supervisors: "Supervisors [of] the work of others need extensive knowledge of the techniques and equipment used by subordinates to perform the work. Technical knowledge of products and processes is necessary to plan and organize work operations, to direct and train subordinates with specialized activities, and

to monitor and evaluate their performance” (Yukl, 1998).

*Technical Competents Who Fail.* Despite their technical competence, many supervisors and middle managers fail to rise in their organizations because of their socioemotional incompetence, according to interview research comparing those who succeed and those who fail. Failure was marked by discharge, transfer, or being “plateaued” until one quit or retired. Success was indicated by promotion to senior management. Failures exhibited neurotic traits: angry outbursts, moodiness, and inconsistency. They were defensive and blamed others for their mistakes or attempted to cover up their mistakes. They were self-aggrandizing and untrustworthy. They were abrasive, intimidating, arrogant, and insensitive. Those who succeeded were more flexible in shifting their focus as they rose in level and were more socially competent (McCall & Lombardo, 1983; Lombardo & McCauley, 1988). Nonetheless, on occasion one may be too competent. A candidate may be rejected as too educated or too intelligent or may be regarded as overqualified for a job.

## ***Intuition***

Intuition is the ability to know directly without reasoning. It is an insight, a hunch, on the experience of seeming to learn in one trial without much awareness of how we have learned something. Since it depends more on induction, intuition allows leaders to deal with complexity and irrationality in the face of uncertainties and contributes to their innovative and creative abilities (Goldberg, 1983).

Barnard (1938) first called attention to the rational and the intuitive components of effective executive decisions. This work was carried forward and qualified by Simon (1947). Simon (1987) explained unconscious intuitive decision making in contrast to conscious rational decision making as being a consequence of the decision maker’s many earlier encounters with similar relevant circumstances. These earlier experiences built up relevant information that the decision maker could bring into play without awareness—leading to an instantaneous flash of insight, intuitive feeling, or assured judgment. In support, Simon called attention to Bhaskar’s (1978) demonstration that although experienced businessmen and novice business students reached the same conclusions about a business policy case, the businessmen did so much more quickly and intuitively. The novices were slower, more conscious, and more deliberate in their analyses.

In addition to explaining intuition in terms of relevant experiences, Simon (1987) noted that some limitations on the rationality of managerial decision making can be explained as a favoring of intuition over reason. Instead of rationally choosing between the lesser of two evils, managers will intuitively choose neither and postpone making a decision. Unlike MBA students, experienced managers are likely to redefine problems on an “in-basket” test rather than accept them as presented (Merron, Fisher, & Torbert, 1987). But the intuitive ability to recognize and quickly diagnose situations calling for remedial action is seen as important to the effective decision making of managers. According to Litzinger and Schaefer (1986), effective managers achieve a balance between analytical reasoning, and their insight and spontaneity. CEOs use strategic planning to lay the foundation for convincing boards of directors and senior management that their intuitively sensed direction for their firms is the right way to go. Justification for the plans is provided by logic and reason.

Agor (1986a, 1986b) surveyed several thousand managers in the public and private sectors. In comparison with lower-level managers, top managers indicated that they were more likely to depend on intuition in making key decisions. But a follow-up of 200 of the most highly intuitive top managers reported that these managers mixed intuition with analytical reasoning in reaching key decisions. Intuition was most often brought into play in making decisions regarding uncertain situations when little precedence existed, when facts and time were limited, when relevant variables were less predictable, and when several plausible possibilities could be entertained.

Burke and Miller (1999) conducted a thematic analysis of interviews with 60 experienced executives holding important positions in a variety of U.S. organizations. The interviewers asked, “What does it mean to make decisions using your intuition?” Five themes emerged: First, consistent with other studies emphasizing the importance of experience, 56% said they made decisions intuitively after looking through their “central processing” unit to base their decision on past experiences. Second, 40% based their decisions on feeling and emotions. “Sometimes, I had a strange feeling that ‘something about the claim isn’t quite right’ and then I dug for more information and found the facts were not absolutely accurate as reported to me” (p. 92). Third, 23% mentioned applying cognitive skills, knowledge, and training in life and business school. Fourth, 11% said that subconscious mental processing led to an intuitively conscious decision to proceed without having available all the necessary information. Fifth, 10% said that the intuitive decision was a matter of ethics—personal or company values—a moral obligation that comes from within, without a book or manual to tell you what to do. Burke and Miller concluded that intuition may not be enigmatic or primarily the working of the subconscious mind.

Clemens and Mayer (1987) suggested that intuition may be the critical variable that separates the successful from the unsuccessful leader: “Those who ‘listen’ to their intuitive inner voice are far less likely than Othello to be manipulated by their Iagos’ ” (p. 120).

Intuition helps people anticipate the future—a trait that is important to successful leadership. In a study of 2,000 managers, top managers rated higher in intuition than managers at lower levels (Agor, 1984). All but one of 12 company presidents whose firms had doubled sales in the past four years scored high in a test of precognition, the intuitive ability to correctly sense what would happen next. Their counterparts with less impressive sales records scored lower in precognition (Rowan, 1986).

Bruce’s (1986) in-depth interviews with chief executive officers (CEOs) of 11 large corporations established that the CEOs intuitively set the tone and direction for their firms. Although they had staffs, senior management, and consultants to provide advice, the CEOs had to be able to make the important final strategic decisions by themselves. These intuitive decisions are difficult to articulate; as Simon (1987) suggested, they are likely to be a consequence of the possession of a great deal of relevant information. The CEOs had a “tremendous reserve of knowledge about their companies” (p. 21). General George Patton replied to the accusation that he made snap decisions by declaring, “I’ve been studying the art of war for forty-odd years. ... A surgeon who decides in the course of an operation to change its objective is not making a snap decision but one based on knowledge, experience and training. ... So am I” (Puryear, 1971, p. 382).

### ***Innovativeness, Imagination, and Vision***

Closely allied to intuition are imagination, vision, and foresight. Imaginative ability has been seen as more important to Abraham Lincoln than intellectual brilliance (Hyman, 1954). Furthermore, imagination is shown, according to Woodrow Wilson, in a president’s capacity to predict the course of events, in the problems to which he calls national attention, in his sense of timing, in his appreciation of the gravity of a problem, and in the urgency he creates when he proposes a solution to it. Imagination is also shown in the way safety nets are built against misfortune and old forms are stretched to cover new functions without arousing excitement about a change. According to the Kirton Adaption-Innovation Inventory (Kirton & DeCiantis, 1986), a leader with an innovative cognitive style thinks tangentially; questions assumptions; and challenges rules, tradition, and consensus. The innovative leader views the need to change as an opportunity. He or she may be abrasive, but produce many ideas, some of which may be unsound and highly risky. Opposite to innovativeness is adaptivity. The adaptive leader is reliable, conforming, methodological, and prudent. He or she favors continuity, seldom challenges rules, and produces safe ideas for prompt implementation (Kirton,

1989).

Miller and Toulouse (1986) surveyed superiors (including the CEOs senior managers), peers, and subordinates of 97 firms in Quebec under 500 employees in size. The effectiveness of leadership was measured by these firms' organizational success. Innovative decentralization in the firms correlated .23 with profitability, .47 with sales growth, and .38 with net income growth. Comparable results were obtained for a large Italian health organization led by a strategic team and an operating team engaged in leading major organizational changes over a five-year period (Previde & Rotondi, 1996). More will be said about imagination and vision in later chapters discussing charismatic and intellectually stimulating leadership.

### ***Optimal Competence***

*Optimal Intelligence.* "A president or would-be president must be bright but not too bright, warm and accessible but not too folksy, down to earth but not pedestrian" (Cronin, 1980, p. 14). There is an optimal level for intelligence and competence. As was noted in [Chapter 4](#), the leader cannot be too superior in intelligence to those to be led. The leader must be more able to solve the problems of the group, but not too much more able. In the same way, the previously cited work of Shaw and Penrod (1962) and M. E. Shaw (1963a) showed that prospective leaders could be given too much information as well as too little information for optimal performance.

A number of factors may militate against the "too superior" member becoming a leader. Communications and understanding may be made difficult by the intellectual disparity of the leader and followers. If a leader is vastly superior in competence the would be leader may no longer appreciate the group's problems or be concerned with helping to solve them. Rather than lead the group, he or she may withdraw from it. The ideas of the overly capable individual may call for too great a change in behavior by the group (Bass, 1960). Although the people who filled cabinet positions and other high governmental positions in the administration of John F. Kennedy were described as the "best and the brightest," Halberstam's (1983) study had to question why so many of their decisions and policies were later proved wrong. A lack of pragmatism in the very bright may be one reason.

*Optimal Knowledge.* Just as leaders may be too intelligent for the group, they can also have too much knowledge. When group members are overloaded with information, they can fail to lead effectively. Shaw and Penrod (1962) varied the amount of information provided to members of different groups. They found that the group's performance improved when moderate amounts of diverse information were given to individual members, but it did not improve when these individuals received large amounts of such information. With large amounts of information, the highly informed members' suggestions became implausible and unacceptable to the less-informed members. M. E. Shaw (1963a) obtained similar results in a comparison of groups in which one member was provided with either two units or six units of information. The specially informed member with two units of information entered the discussion earlier and initiated more task-oriented communication than the rest of the members of the group, but the situation was reversed for the member who received six units. The informed member was named more often as a leader in the two-unit group than in the six-unit group. Evidently, six units of information became an overload that impeded the informed member's ability to lead.

*Wisdom: Combining Intelligence and Knowledge.* Research on wisdom has been increasing but is still sparse, probably because, as Sternberg (1990) noted, wisdom is so elusive. Webster (2001) constructed a reliable and valid self-report questionnaire, the Self-Assessed Wisdom Scale. He found that those with higher scores were more likely to consider many factors when making social judgments, were more concerned about

guiding and mentoring the coming generation, and were not afraid to form intimate relationships.

### ***Moderators of the Effects of Task Competence***

Task competence has its limitations. For example, Justis (1975) found that the competence of a leader had less impact on the performance of members when they were less dependent on the leader. The technical competence of a supervisor may be less important to the group's productivity if the supervisor consults with subordinates about decisions or allows them to share in decision making. Reeder (1981) found that for 78 clerks doing routine work and computer programmers doing nonroutine work for the U.S. Army in Germany, the supervisors' knowledge of the clerks' jobs was less causally related to the clerks' and the programmers' productivity than the supervisors' participative leadership.

*Election or Appointment.* Election increases the demand for competence in a leader (Hollander, 1978). Hollander and Julian (1970) conducted a set of experiments concerned with competence and the election or appointment of a leader. Six hundred college students served as participants in various group discussion tasks. In the first experiment, the members' perceptions of the leaders' competence were more important than how the leaders had gained office. In the second experiment, although only the leaders' competence was highly related to influence, the members tended to admit having been more influenced by elected than by appointed leaders. In the third experiment, the leaders were either elected or appointed to act as spokesmen for their groups. The elected incompetent leaders were rejected regardless of the group's success or failure in the task, whereas the group's success increased the endorsement of the elected competent leaders. The acceptance or rejection of appointed competent leaders was unrelated to the effects of their group's success or failure, but incompetence resulted in rejection of the appointed leaders. Carter, Hay-thorn, Shriver, and Lanzetta (1951) also compared the performance of appointed and emergent leaders. Emergent leaders were more active than appointed leaders and tended to dominate the situation. Presumably, unlike the appointed leaders, they had to struggle for status.

*Relevance of Competencies.* Fundamental to situational analyses of leadership is the realization that the ability to solve the group's problems is a relative matter. An ability relevant to solving problems of a group of farmers in Iowa may be irrelevant to solving the problems of a submarine crew, except to the extent that general intelligence may be important in both situations. As Bass (1960, pp. 174–175) noted, "A mathematician may be vastly superior to stevedores in the arithmetic of space, yet communication difficulties alone are likely to make it impossible for the math expert to supervise effectively the stevedores' loading of the hold of a ship. Similarly, the mathematician may successfully serve as a head of a mathematics department but remain inadequate to solve the problems of a department of agricultural statistics. Ability of a member to help a group must be considered in light of the group's problems. As J. F. Brown (1936) noted, the leader must be superior to other members in one or more characteristics relevant to the problems facing the group. And as Murphy (1941) concluded, the choice of leader is dictated by the needs of the group."

Dubno (1963) observed that groups requiring high-quality decisions did better with leaders who were slow to make decisions, while groups that were under pressure for speedy decisions were more effective with leaders who were fast decision makers. Similarly, Carter, Haythorn, Shriver, and Lanzetta (1951) found that the behavior of leaders differed according to the tasks of their groups. In groups that had a reasoning task, leaders asked for information or facts; in groups with a mechanical-assembly task, leaders asked that things be done; in a discussion task, leaders asked for the expression of feelings or opinions.

Following his review of military leadership, W. O. Jenkins (1947) concluded that military leaders in a given field were superior to other members in skills pertinent to that field. To lead and earn esteem from skilled

followers, it helps to be a master of the craft. Thus in one of the early experiments on the relation of task ability to leadership, Carter and Nixon (1949a, 1949b) found that scores on mechanical tests were related to the emergence of a leader in groups performing mechanical tasks. However, scores on tests of word fluency and clerical aptitude were correlated with the emergence of leaders in groups performing clerical tasks. No test of ability was uniquely related to the emergence of a leader in groups performing intellectual tasks.

Stein and Heller (1978) and Heller and Stein (1978) reviewed studies in which group members' verbal interactions were categorized, through content analysis, according to the relevance of each of their statements to the ongoing group process. Emergent leaders were found to carry out a greater amount and variety of task-related behaviors than nonleaders. Leaders were found to be significantly more active than nonleaders in identifying problems; in proposing solutions to problems; in seeking information, opinions, or structure; in giving information or opinions; and in initiating procedures for the group's interaction or accomplishment of tasks.

## Socioemotional and Interpersonal Competence

---

The traditional view of socioemotional and interpersonal competence emphasized the ability to socialize, to fit with group norms, to comply with authority, to avoid conflict, and to be polite and mannerly. A second view, propounded by the human relations movement, conceived of interpersonal competence as involving empathy, insight, heightened awareness, and the ability to give and receive feedback. Also included was openness to discussions about one's feelings, consensual solutions to conflict, and the development of commitment to actions (Argyris, 1962). Managers with interpersonal competence were considered less willing to depend on power than on trust and shared decision making (Zaleznik, 1965b). It is the second meaning of interpersonal competence that will be accented here. A third meaning, implying the competence to manipulate others, will be looked at more fully in [Chapter 7](#).

### ***Interpersonal Skills***

Everyday experience suggests that people differ in interpersonal competence. Yet beginning in 1920 with E. L. Thorndike (Thorndike & Stein, 1937), the effort to measure and investigate interpersonal competence empirically has been difficult. Earlier researchers found it hard to discriminate between *social intelligence* and general intelligence. Still, Erez (1980) was able to assess the social intelligence of 45 Israeli managers and to show how it related to their tendency to be employee-centered rather than job-oriented leaders.

Empathy has long been recognized as part of interpersonal competence, but as will be shown later in this chapter, efforts to measure empathy have been fraught with difficulty (Hogan, 1969). Virmani and Mathur (1984) conceived of "vivek," the ability to evaluate the implications of the attitudes, needs, desires, and intentions of others and oneself. Vivek, which is associated with effective leadership and management, is a fluid ability in that it can perceive complex relationships in human interactions in new environments.

The quality of one's verbal and nonverbal communication has been seen as contributing to overall interpersonal competence (Rosenthal, 1979b), along with the fear of negative evaluation (Watson & Friend, 1969) and apprehension about communication (McCroskey, 1977). Self-monitoring (Snyder, 1974) also involved basic social skills (Lennox & Wolfe, 1984).

With support from a factor analysis of a lengthy self-report by 339 male and female undergraduates, Riggio (1986) found seven basic socioemotional skills to be of consequence: (1) emotional expressivity ("I have been told that I have 'expressive' eyes"); (2) emotional sensitivity ("It is nearly impossible for people to hide their true feelings from me"); (3) emotional control ("I am very good at maintaining a calm exterior, even when upset");

(4) social expressivity (“I usually take the initiative and introduce myself to strangers”); (5) social sensitivity (“While I was growing up, my parents were always stressing the importance of good manners”); (6) social control (“I find it very easy to play different roles at different times”); and (7) social manipulation (“If I really have to, I can ‘use’ other people to get what I want”).

### ***Interpersonal Competence and Leadership***

Interpersonal competence is manifested in understanding of, caring for, and consideration for others. It is revealed in communicating easily and clearly and in fostering and maintaining good relations with others. It serves to increase harmony, reduce tension, and resolve conflict. Compared with interpersonally incompetent leaders, interpersonally competent leaders are influential but not dictatorial, good at dealing with people and at delegating. They are trustworthy and credible rather than overly political (Kaplan, 1986). They promote group decisions, not to keep their subordinates happy but to take full advantage of their followers’ knowledge. They increase their subordinates’ commitment to decisions (Lombardo, Ruderman, & McCauley, 1987). According to Hogan and Hogan (2002), everyone wants acceptance and status, and leaders are better at obtaining these. Hogan and Hogan see interpersonal competence as including social skills—empathy, communications abilities, and social astuteness—essential to leadership.

Interpersonal competencies discriminated between effective and ineffective managers above and beyond situational effects (Boyatzis, 1982). J. Hogan and Holland (1998) found correlations of a CPI Empathy scale with five criteria of leadership between .45 and .73 for 25 managers at a large retail firm. Also, Baron (1989) ascertained that interpersonally competent members of small groups were more likely than other members to resolve conflicts and emerge as leaders.

Connelly, Gilbert, Zaccaro, et al. (2000) obtained open-ended responses to questions about problem scenarios in order to predict leaders’ effectiveness. Ability measures of complex problem-solving skills, social judgment, and knowledge were obtained from ratings of the responses. These “constructed” responses added to the prediction of career achievement of a sample drawn from 1,807 U.S. Army officers at six grades in rank. This added validity was beyond that accounted for by measures of cognitive ability, motivation, and personality according to a series of hierarchical regression analyses.

Although a multinational sample of faster-climbing managers did not see as much value in being interpersonally competent as did managers whose advancement in their careers was slower, the faster climbers rated themselves higher than the slower climbers in “understanding why I do what I do” (Bass, Burger, et al., 1979). Hall and Donnell (1979) compared 1,884 managers who were either fast, medium, or slow in their career advancement; these researchers found that more rapid promotion was directly related to the self-rated ability to relate effectively with others. Similarly, Wolberg (1977) noted that the potential to be a group leader was directly linked to the ability to relate as a peer in role playing and to avoid immature “acting out” during training.

### ***The Structure of Socioemotional and Interpersonal Traits of Leadership***

Hogan and Hogan (2002) believe there is a general factor of sociopolitical intelligence, which is a generalized ability to take roles (Mead, 1934). It is at the core of social skill and of the ability to build and maintain a team. Hogan and Hogan cited research support from Conway (1999). Conway factor-analyzed 2,000 360-degree *benchmarks*—management appraisals of trainees at the Center for Creative Leadership (CCL)—and found that four of the five factors involved leadership and social skills. The fifth factor involved strategic thinking. By 1946, R. B. Cattell (1946) had applied factor analyses to responses to personality questionnaires.

He generated 16 factors, many of which were found to be related to leadership in subsequent studies. Similarly, Guilford (1952) generated 10 factors—again, many of these were related to leadership. They included general activity, mood swings, ascendancy, sociability, emotional stability, thoughtfulness, and masculinity. Scholars, consultants, and leaders themselves produced many different lists of traits they felt were required for leadership. These were based on experience, published research, or both (Bray & Howard, 1983; Boal & Hooijberg, 2001; Atwater & Yammarino, 1993; Hogan, Curphy, & Hogan, 1994; O’Roark, 2000; Quinn, 1988). Warren Bennis (quoted in Norris, 1992) felt that in choosing managers, large organizations emphasize technical competence, “people skills,” and conceptual skills. But additionally, they ought to focus more on judgment, taste, and character, along with sense of purpose, caring, constancy, competence, optimism, ambition, and integrity. After reviewing the literature on traits of leadership, Kirkpatrick and Locke (1991) listed drive involving achievement, ambition, energy, tenacity, and initiative—the personalized and socialized motivation to lead. Likewise, honesty, integrity, and self-confidence were listed as important. Also included were emotional stability, cognitive ability to marshal and interpret information, and knowledge of “the business” of the organization. Other traits, for which there was less support, included creativity, originality, and flexibility. By 1986, such lists could be replaced by a more rigorous and reliable analysis of accumulated evidence through the use of meta-analysis.

*Meta-Analysis.* This method pools the results of a number of separate research analyses. It provides statistical estimates of the average effects of variables from different research studies. The estimates are based on the much larger size of the pooled results and offer more confidence about the relationship in question—in this case, for instance, showing the likely average correlation between, say, managers’ assessed friendliness and their effectiveness as leaders. The correlations are weighted according to the number of cases contributing to them. They are also corrected for the reliability of the variables and their restrictions in range to obtain the true estimate, which is likely to be somewhat higher than the observed average. Confidence intervals of the true correlations are also provided to determine the probability that a correlation is not zero.

*Meta-analyses of the Socioemotional Traits of Leadership.* Lord, Devader, and Alliger (1986) conducted the first meta-analysis of traits of leadership. Their data were drawn from 18 studies about the emergence of leadership reviewed by Stogdill (1948) and Mann (1959).<sup>2</sup>

Studies through 1977 were added. The traits of consequence included intelligence, dominance, masculinity, extroversion, and better adjustment. A number of other meta-analyses have followed. The most comprehensive, described later, were conducted by Judge, Bono, Ilias, et al. (2002) and Judge, Colbert, and Ilias (2004).

### ***The Big Five Factor Structure of Personality***

Although Tupes and Christal (1961) and Norman (1963) first found evidence for the validity of the “Big Five” factor structure, it did not become a hot research topic until the 1990s, when it was shown to be a reliable and valid model for describing the most important socioemotional aspects of personality. Each of the Big Five factors contains six traits or facets. By the end of the decade, the factor model had been validated for predicting various criteria such as job performance in eight meta-analyses (e.g., Barrick & Mount, 1991). McCrae and Costa (1992) developed the Revised NEO Personality Inventory (NEO-PI-R) as a standard for measuring the Big Five factored trait structure from a lengthy questionnaire. The five factors were: N, neuroticism versus emotional stability; E, extroversion or surgency versus introversion; O, openness to experience (called by others intellect, imagination, or culture); A, agreeableness versus antagonism; and C, conscientiousness or the will to achieve.

*Neuroticism* is the extent to which persons tend to experience distress, emotionality, worry, nervousness, insecurity, and tension. Neurotics view the world, themselves, and others negatively (George, 1996). They are likely to be pessimists (Williams, 1997). Other names for this factor include “lack of emotional stability” and “negative affectivity.” The traits of the intercorrelated subscales or facets of the neuroticism factor that can be scored separately include anxiety, hostility, depression, self-consciousness, impulsiveness, and vulnerability (Costa, 1994).

*Extroversion* is the extent to which persons tend to be assertive, gregarious, and enthusiastic (Barrick & Mount, 1993) and feel themselves to be efficacious. They are optimistic and tend to experience positive moods and emotions. They view others and the world favorably (George, 1996). Other terms for this factor are “social boldness” and “social presence.” The six facets are warmth, gregariousness, assertiveness, activity, excitement-seeking, and positive emotions.

*Openness to experience* involves imagination, artistic sensibility, and intellect. Another name is “intellectance.” Its six facets are fantasy, aesthetics, feelings, actions, ideas, and values (Costa, 1994).

*Agreeableness* is the extent to which a person is sympathetic, trusting, cooperative, warm, loving, affiliative, and good-natured. Its facets are trust, straightforwardness, altruism, compliance, tender-mindedness, and modesty (Costa, 1994). Highly modest self-presenters are favored by audiences if the presenters are female; moderately modest self-presenters are favored if they are male (Wosinska, Dabul, Whetson-Dion, et al., 1996).

*Conscientiousness* is the extent to which a person is dependable, responsible, hardworking, persevering, efficient, needing to achieve, prudent, ambitious, and organized (Barrick & Mount, 1993). Facets include competence, order, dutifulness, striving for achievement, self-discipline, and deliberation (Costa, 1994). (For more about the NEOAC structure, see Digman, 1990; Eysenck, 1970; Goldberg, 1993; Guilford, 1975; Hough, 1992; McCrae & Costa, 1987; Peabody & Goldberg, 1989; and Tellegen, 1985.)

Goldberg (1993) developed a checklist of 100 adjectives, and Saucier (1994) reduced these to the Mini-Marker, a 40-item adjective checklist that when scored provides the same NEOAC factor results but with a little less reliability. Different labels may be attached to the factors. For example, adjustment may be substituted for emotional stability and lack of neuroticism; intellectance may be substituted for openness to experience. Facets are similar (Curphy, 2001).

*Factorial* validity was evidenced because each facet scale correlated much more highly with its appropriate factor than the other four factors. The NEOAC factorial structure displays considerable universality (MacCrae & Costa, 1997). As a demonstration of the construct validity of NEOAC, MacCrae, Zonderman, et al. (1996) compared the varimax-rotated factorial structures extracted from large adult and student samples in seven languages and cultures: American, German, Portuguese, Hebrew, Chinese, Korean, and Japanese. Orthogonal rotation using the normative American factorial structure generated average factor congruence coefficients across the other six cultures for N, E, O, A, and C ranging from .94 to .96. The Big Five factors tend to have low correlation with each other, demonstrating their *discriminant* validity (McCrae & Costa, 1990). The structure may have a biological basis (Eysenck, 1967). For many years, Eysenck advocated a two-factor theory of neuroticism and extroversion with a biological basis. *Convergent* validity was found when each factor scale correlated with relevant scales from other personality tests and inventories. *Discriminant* validity was seen in the expected greater correlation of a facet with its relevant measure on another test or inventory. For instance, the facet of assertiveness was correlated more highly with being forceful, enthusiastic, and confident on the Gough and Heilbrun Adjective Check List, compared with adjectives about other aspects of extroversion.

Supporting *consensual* and *construct* validation, coefficients of congruence of the Big Five factors were between .96 and .98 for a replication of the NEOAC with a sample of 211 people in sales, customer service, and lower, middle, and upper management. Additionally, performance evaluations of their successful interpersonal relations, their task orientation, and the adaptive capacity of their performance evaluated by their

supervisors correlated significantly with their conscientious score. Their successful interpersonal relations and their adaptive capacity increased with conscientiousness and decreased with neuroticism. The facets of competence, striving for achievement, and self-discipline were the highest in correlation with the performance evaluations (Piedmont & Weinstein, 1994). Numerous theoretically expected consistencies were found between the Adjective Check List and NEOAC (Piedmont & Weinstein, 1993).

*The Big Five and Leadership.* Judge, Bono, Ilies, et al. (2002) tested how well the Big Five model provided an adequate structure for the socioemotional traits of leadership, excluding intelligence and other capabilities. The criteria they predicted were emergent leadership, effective leadership, and transformational leadership. These investigators searched the PsychINFO database, 1887 to 1999, for articles on leadership and personality. They also searched for articles on personality, neuroticism, agreeableness, conscientiousness, extroversion, and openness to experience. Results were added from 48 additional traits mentioned in the third edition of this handbook (Bass, 1990), along with traits found in articles in *Leadership Quarterly* from the first to the tenth volume and the studies used by Lord, Devader, and Alliger (1986). A total of 1,200 abstracts were identified. Studies of opinion and fashion leadership were excluded, as were many others that did not provide correlations or sufficient data to calculate them. Extracted for analysis were 275 correlations from 79 studies and 15 doctoral dissertations. A wide variety of data on emergent and successful leadership were included, ranging from teachers' reports and peer ratings of student leadership to election of leaders in informal and formal groups. Studies using indexes of management such as salary level or organizational grade were excluded. Barrick and Mount's (1991) coding procedure was used to categorize traits with many different names into a coherent whole. For instance, as suggested by Hogan, Curphy, and Hogan (1994), the need for power was classified as a measure of extroversion. In addition to obtaining results for the broader Big Five, results were obtained for the more specific facets in the model, such as dominance and sociability. A study was included in the correlational analyses if it compared leaders and nonleaders in emergent, effective, or transformational leadership. Huffcutt, Roth, and McDaniel (1994) presented for each of the Big Five factors the number of correlations, the number of respondents, and the estimated true correlations, corrected for reliability, restriction in range, and the sharply skewed weightings of the 76 correlations based on the total numbers of cases contributing to each of the five factors, ranging from 8,314 to 18,830. The reliability of the Big Five personality factors ranged from .78 to .86.

The corrected average correlations between each of the Big Five personality factors and leadership were as follows: neuroticism, .23; extroversion, .30; openness, .25; agreeableness, .10; conscientiousness, .19. Confidence intervals indicated a high probability that all five correlations were not zero. The multiple correlation was .47 for predicting leadership based on combining the optimally weighted five factors. Specific facets with substantial correlations with criteria of leadership included sociability, .38; dominance, .36; achievement, .36; and dependability, .32.

The criteria and samples of leadership analyzed made some difference. For government and military leaders, agreeableness correlated close to zero with the emergence of leadership, but .23 and .27, respectively, with leadership effectiveness and transformational leadership. Neuroticism correlated .19, .26, and .21, respectively, with emerging, effective, and transformational leadership. Extroversion was most predictive (.34) of emerging leadership and somewhat less predictive of effectiveness (.23) and transformational leadership (.25). In other studies, Caliguri (2000) found that the conscientiousness scores of 94 supervisors of 280 expatriate employees correlated positively with 360-degree ratings of the supervisors' performance. McDaniel (1992) found that openness correlated .37 with the success of 162 change leaders. As rated by others, emotional stability correlated .32 with leaders' self-reports of success.

Martinsen (2000) calculated the stepwise multiple regressions of N, E, O, A, and C and their interactions on 360-degree ratings of entrepreneurial leadership orientation by 94 managers, 80 supervisors, 307 peers, and

426 subordinates. For example, N(2) 1 0 1 A (2), optimally weighted, accounted for 17.7% of the variance in the ratings of entrepreneurial orientation of the leaders. N 1 E 1 A plus the interactions N 3 E and E 3 A, optimally weighted, accounted for 19.3% of the 360-degree ratings of the task orientation of the leaders. N 1 E 1 O 1 A 1 C 1 N 3 A 1 O 3 C, optimally weighted, accounted for 33.4% in the variance of the leaders in dominance behavior.

Makiney, Marchioro, and Hall (1999) found some significant correlations between the 40-item Mini-Marker rendition of NEOAC and the self-reported Multifactor Leadership Questionnaire (MLQ) for 69 undergraduates and other measures of leadership. N (2) emotional stability correlated .23 with transformational leadership. Extroversion correlated .40 with transformational leadership, 2.31 with laissez-faire leadership, and .28 with students' self-schemata of social influence. O, openness to experience, correlated .24 with the same self-schemata and .20 with leadership ranking in the class. A, agreeableness, correlated .32 with leadership ranking and the self-schemata of dedication. A, antagonism, correlated .25 with laissez-faire leadership. C, conscientiousness, correlated .20 with the leadership self-schemata of dedication.

Given the research interest in the Big Five, we will use its structure to present additional single and multiple personality studies since 1970 correlated with leadership. Many have appeared as facets of the Big Five.

### ***Social Intelligence and Leadership***

"Social intelligence" was a term in use before 1950 but then fell out of favor. However, Gardner (1985) defined social intelligence as the ability to distinguish other people's moods, temperaments, motivations, and intentions among others. It is the ability to understand others and act accordingly (Sternberg, 1985). It is also the wisdom to act at the appropriate time and in the appropriate way on the basis of this understanding (Boal & Hooijberg, 2001). For Zaccaro, Gilbert, Thor, et al. (1991), the social intelligence of successful leaders comprises social perceptiveness and behavioral flexibility. I will take the liberty of using social intelligence as the sum total of social competencies, including dominance, sociability, communicating styles, empathy, sensitivity, tact, and other interpersonal skills. Especially strong associations are found with communication styles and skills (Bass, 2002).

*Dominance.* Dominance tended to appear in lists of the traits of leadership drawn up in the 1970s and later (e.g., Hughes, Ginnet, & Curphy, 1993) but was less frequent as a subject of empirical investigations. This may have been due to an increased interest in democratic participation as opposed to autocratic directive leadership. One of the new empirical efforts was that of Stricker and Rock (1998). They developed a set of scales, including a dominance scale, from the biographical information supplied by freshmen at the U.S. Naval Academy. The internally consistent and validated items on dominance included affirmative answers to such questions as these: "Your parents told you that you did not take 'no' for an answer." "You told classmates or friends that they did not stand up for their rights enough." "Classmates or friends told you that you were not interested in other people's ideas and opinions." The dominance scale correlated .57 with a biographical sociability scale and .39 with a similarly constructed emotional ability scale. The dominance scale correlated .82 with peer ratings of leadership. Lord, DeVader, and Alliger (1986) thought that Stogdill (1948) and Mann (1959) had both underestimated the correlation of the personal trait of extroversion and leadership. They conducted a meta-analysis of reports of different types of subjects and situations that related extroversion and leadership. This meta-analysis adjusted the grand mean of results for the sample sizes and various errors attenuating each of the obtained correlations. The researchers estimated that the true mean correlation between extroversion and leadership was .26 across the different samples of subjects and situations. The results for dominance and leadership were less supportive of the importance of the trait of dominance across situations,

however; the estimate of the true mean correlation was .13.

Butt and Fiske (1968) recognized that dominance could be *socialized* or *aggressive*. Different personality scales of dominance emphasized one possibility or the other. Gough's (1957) dominance scale in the California Personality Inventory (CPI) assessed socialized dominance related to leadership in high school. Cattell, Saunders, and Stice's (1957) dominance scale in their Sixteen Personality Factors (16PF) assessed "an aggressive onslaught on the environment by a rather solemn, isolated, and egotistical person" (Butt & Fiske, 1968, p. 513). It would seem that if both scales were used to predict transformational and transactional leadership, the leadership would be true leadership when predicted by the CPI, and pseudo leadership when predicted by the 16PF.

Montagner, Arnaud, et al. (1973) observed differences in children. Socially dominant children were the center of attention, threatened only for short periods of time, and were conciliatory. They were more likely to exert leadership and to be imitated by other children. The aggressively dominant engaged in much physical violence. They were highly self-oriented and spread fear in the other children with their threats. They were less likely to display leadership.

*Socialized and Aggressive Dominance.* Kalma, Visser, and Peters (1993) developed and validated factored scales of socialized and aggressive dominance, averaging results from seven Dutch samples ranging in size from 100 to 550. Statements such as "I have no problems talking in front of a group" loaded highest on socialized dominance (SD), and "I can look everybody in the eye, and lie with a straight face" loaded highest on a second factor, aggressive dominance (AD). In the first sample, students engaged in trios. They said they got their own way with simple statements if they scored high in socialized dominance ( $r = .28$ ) but not aggressive dominance ( $r = .04$ ). Conversely, ADs were more likely than SDs to say that they got their way by being persistent, being persuasive, bargaining, threatening, being deceitful, being evasive, and using hints. The correlations of observers' ratings with AD factor scale scores ranged from .20 to .37. The correlations of observers with SD factor scale scores ranged from .15 to .10. Observers noted that SDs (compared with ADs) looked more at the person to whom they were speaking ( $r = .39$  versus  $r = .216$ ), held a prolonged gaze ( $r = .29$  versus  $r = .10$ ), and gesticulated ( $r = .33$  versus  $r = .24$ ). ADs were more likely than SDs to interrupt others (.23 versus .13), raise their eyebrows (.28 versus .14), and express doubt (.30 versus .11). On self-reports, SDs were more likely than ADs to consider themselves and other people friendly ( $r = .41$ , .40 versus  $r = .219$ , .214). They were less likely than ADs to seek approval from others ( $r = .240$  versus  $r = .230$ ). SDs rated themselves higher than ADs did on task leadership ( $r = .38$  versus  $r = .203$ ); ADs rated themselves lower on socioemotional leadership than did SDs (.23 versus .17). Peers rated ADs higher on task leadership but lower on socioemotional leadership (.24 versus .224).

## ***Socioemotional Competency Traits***

*Emotional Intelligence.* The competency model is a recipe for a good leader, although there is a wide range of opinion on what should be included. Ashkanasy and Tse (2000) theorized that emotional intelligence correlated with transformational leadership and its factorial components. George (2000) agreed that emotional intelligence correlated with effective leadership and its developing collective goals and encouraging flexibility. Cherniss and Goleman (2001) held that successful leaders model emotional intelligence. Caruso, Mayer, and Salovey (2002) qualified the relationship, suggesting that effective leadership could occur in the absence of emotional intelligence or that only some elements of emotional intelligence might be present. Church (1997) that in comparison with average-performing managers, highly effective managers' self-ratings were more in agreement with those of their subordinates. Dasborough, Ashkanasy, and Boyle (2002) theorized that emotionally intelligent followers could discriminate between the intentions of truly transformational leaders

and self-oriented pseudo-transformational leaders who try to mislead their followers (Bass & Steidlmeier, 1999).

Salovey and Meyer (1990) introduced the concept of emotional intelligence as the ability to monitor the feelings and emotions of oneself and others to help guide one's own thinking and actions. Goleman (1995, 1998) popularized "emotional intelligence" as a term encompassing a limited number of socioemotional abilities and traits, including self-awareness; handling one's own feelings and impulses; motivating others; showing empathy; and remaining connected with others through optimism, enthusiasm, and energy. Emotional intelligence implies to think positively, understand relationships, and resolve conflicts.

The scope of the concept of emotional intelligence remains controversial. It may be seen as an *ability* to solve emotional problems as a *competency* mixes observed abilities, traits, and socioemotional behaviors. The ability model points to success in (1) perceiving and identifying emotions in the thoughts of oneself and others; (2) using emotions to think creatively and make decisions; (3) understanding and interpreting meaning in emotions, being open to feelings, avoiding defensiveness, and reflectively monitoring emotions.

The competency model points to: (1) self-awareness: emotional awareness and accurate self-assessment; (2) self-regulation: self-control, trustworthiness, conscientiousness, and innovativeness (Caruso, Mayer, & Salovey, 2002).

The ability model is favored because of its greater psychometric acceptability. The psychometric properties of the competency model are more problematic, since this model is often a collection of various self-ratings (Daus & Ashkanasy, 2003).

*Sociability and Leadership.* Sociability was included in the lists of traits of consequence to leadership drawn up by Kirkpatrick and Locke (1991), Hughes et al. (1993), and O'Roark (2000). It was a facet of extroversion in the NEOAC factor analyses, which figured even more strongly in leadership behavior (see Bass, 1998, on ascendancy). Stricker and Rock (1998) developed biographical information scales of emotional stability, need for achievement, self-confidence, and sociability. Sociability correlated highest with peer ratings of leadership (.28). Avolio and Bass (1994) obtained a correlation of .25 between the Gordon Personal Profile (GPP) sociability score of 188 leaders in a community and their followers' ratings of their charismatic leadership. Elsewhere, in a review of empirical investigations, Bass (1998, p. 125) found that sociability contributed to inspirational motivation, individualized consideration, and contingent rewarding by leaders.

*Competence in Communicating.* Communication competencies are basic to leadership (Barge & Hirokawa, 1989). The leader needs to be able to communicate to followers the framing and interpretation of experiences (Bowman & Deal, 1991). Comrey, High, and Wilson (1955b) found that "high-producing" supervisors in the aircraft industry communicated effectively. Alpander's (1974) survey of 217 corporations to determine which training needs were the highest priorities for currently employed managers found that oral communication abilities were rated highest. Mold (1952) reported that 490 industrial supervisors stated that they needed the most development in "how to sell ideas to my superior." And satisfaction with the effectiveness of officers and noncoms among over 30,000 U.S. Army personnel was strongly associated with their ability to communicate effectively with their subordinates, according to ratings by their superiors and subordinates (Penner, Malone, Coughlin, & Herz, 1973). The quality and style of a leader's communications to followers makes a difference in the success and effectiveness of the leadership.

*Quality of Communications.* Being active as a communicator is not enough. The quality of communicating with others is an important trait and competence of leaders. The quality of communication may be a matter of socioemotional competence as well as task competence, in which it is akin to oral and written fluency. Knowing something is not the same as being able to transfer the information to another

individual or to transfer it to that person's satisfaction. Communicating goes beyond verbal fluency. A listener's acceptance of a message from an anchor on a televised news program is likely to depend considerably on how the anchor looks and how the message is delivered. President Reagan was known as the "great communicator" more for his perceived affability and the sincerity of his delivery than for his accuracy. President George W. Bush was known for mispronunciations and stumbling even when he was reading his speeches, yet he managed to remain popular during his first five years in office.<sup>3</sup>

Talking a lot in initially leaderless situations may result in the emergence of a leader, but the effectiveness of a leader will depend on the quality of the talk. Considerable evidence has been accumulated to demonstrate the connection between competence in *articulation* and effectiveness as a leader and manager. For instance, from 200 interviews with successful corporate leaders, Kanter (1983) found that the leaders had a number of communication skills in common. They were consistently able to expand their thinking by actively soliciting new ideas and feedback from others and were continually reaching out for new information. Also, they knew how to persuade others about the quality of their ideas and had the ability to communicate persuasively to others and to enlist their support by persistently working for it.

In a field setting, Klimoski and Hayes (1980) surveyed 231 editorial subordinates and their 15 assistant managers who abstracted current technical publications. Among the supervisory behaviors noted were *explicitness* in giving instructions and frequency of communication about job-related matters. The managers' explicitness correlated significantly with the subordinates' expectations of success and reward in their jobs, but frequency of communication did not. Explicitness correlated .57 with the subordinates' satisfaction with supervision, but frequency of communicating correlated only .19 with such satisfaction. The managers' explicitness correlated 2.44 and 2.30 with the subordinates' role ambiguity and role conflict. Frequency correlated .04 with each of these measures of problems in doing their jobs. The managers' explicitness contributed to the subordinates' self-rated effort; frequency did not.

Snyder and Morris (1984) were able to link the quality of supervisors' communications in 12 offices of a social service agency with the quality of services rendered by the agency and with lower costs of operations. Colleagues used a reliable four-item questionnaire that was based on previous work by Olmstead and Christensen to rate supervisors on the quality of their communications. The overall quality of the supervisor as a communicator contributed significantly to lower costs of operation, even after adjustments for the different numbers of clients served and the size of the different offices. Ward (1981) collected data from first-line supervisors in two manufacturing plants, three libraries, and two hospital nursing departments. The main concern was the supervisors' *rhetorical* sensitivity—their creative invention of effective discourse in writing and speaking. Ward found that the supervisors' rhetorical sensitivity correlated positively with the satisfaction of their subordinates.

*Ability to Convey Meaning and to Enhance Retention.* Getting across the meaning of a message is crucial and may require innovative approaches by the leader. The feelings as well as the ideas in the message need to be communicated effectively (Bennis & Nanus, 1985); also, the messages have to be remembered. According to survey studies, the messages sent by leaders that become memorable—are influential and are remembered for a long time—are brief oral injunctions such as, "Work smarter, not harder" or "No matter what the other girls are doing, act like a lady" (Knapp, Stohl, & Reardon, 1981). All 65 employees and managers of one firm interviewed by Stohl (1986) could recall such a memorable message. The messages were almost all single sentences and tended to be rules. The employees usually first heard the messages soon after joining the firm, and in a private one-to-one conversation. If an appropriate situation arose, the recipients said they would pass the message on in the same way. A majority of messages in this organizational setting dealt with role behavior and were applicable to various situations. One such message was "If you're not helping, you're hindering." These pithy, memorable messages, usually from a sender of higher status to a recipient of

lower status, provide “sense-making” structures and a guide to what behavior is appropriate in an organization. Memorable messages, content-analyzed, provide information about the norms, values, expectations, rules, requirement, and rationality of an organization’s culture. Clearly, a manager who includes such memorable messages in his or her communications is likely to have a much greater impact on subsequent events in the organization.

*Consistency of Statements.* Inconsistency of contributions may not be as deleterious as one might expect. Contrary to their hypothesis, Goldberg and Iverson (1965) found that the influence wielded by high-status members depended on their status, rather than on the consistency of their statements. They did not lose influence if they changed their opinions several times during a discussion.

*Timing.* The timing of participation makes a difference in the influence of the participation on others. Leana (1985) and M. Smith (1935a) noted the importance of opportunity. Someone who succeeds as a leader may be but one of several in a group who might have been just as successful had they been present to attempt leadership first. Hollander (1978) concluded that to emerge as a leader, one needs to participate early. But M. E. Shaw (1961) found that the members of a group who stated their opinions either early or late were better able to have their opinions accepted than those who stated their opinion in the middle of a discussion. Bass (1967a) experimented with groups of male managers in which the heads of the groups revealed their opinions at the beginning or end of a session, or not at all. The other group members were able to influence each other most when the heads remained silent, but they exhibited greater coalescence around the heads when the heads revealed their opinions. Silent heads were most influenced by the other members and were most dissatisfied with their own final judgments.

Early presentation by a leader of his or her favorite alternatives to decisions followers’ generation of additional alternatives (Maier & Sashkin, 1971). The search for alternatives is narrowed, and the quality of the decision may suffer (Brillhart & Jochem, 1964). When leaders were trained by Maier and McRay (1972) to delay presenting their preferences, their followers were more productive in proposing high-quality alternatives.

*Style.* Managers differ consistently in their style of communicating. Replicating earlier work, McCroskey and Young (1981) found that the communication style of senior managers and the immediate superiors of employees affected different aspects of their employees’ satisfaction. In an information technology firm, a navy civilian agency, and a social service agency, Klauss and Bass (1982) conducted path analyses for the relationships among managers’ communication styles, according to their supervisors, peers, and subordinates. Managers who were described as highly informative and trustworthy contributed considerably to their colleagues’ role clarity, satisfaction with the managers, and evaluations of the effectiveness of the managers. *Trustworthiness* and credibility depended on being a careful listener, on being informal, and on being open in two-way conversations. For the Hanover Insurance Companies (1988), trust was a key to being open, one of their most central values supporting the goals of profitability, of giving customers “good value for their money,” and of creating an environment that would help the individual and others to achieve their full potential. *Informativeness* in the Klauss and Bass path analysis depended on being seen as a careful transmitter of information and using frank, open, two-way communications. Similarly, St. John (1983) observed that the credibility of supervisors was enhanced by personal style, frankness, consistency, accessibility, keeping promises, accepting responsibility, and showing interest in others.

Luthans and Larsen (1986) directly observed the communication behavior of 120 managers from five organizational settings. They also gathered self-reports on how the managers communicated. Two dimensions emerged in analyses of the data. Consistent with the relationship between activity and leadership to be discussed in [Chapter 6](#), the first dimension was the extent to which the manager actively communicated, rather

than remaining a passive isolate who was drawn into communication activities only when these were necessary to manage conflicts. The second dimension involved the extent to which a manager was informal, spontaneous, and oriented toward development, rather than formal and communicative mainly when controlling others with regularly scheduled monitoring.

*Competence with Linguistic Forms.* It may not be what the leader says, but the way he or she says it. Drake and Moberg (1986) suggested that linguistic form may be more important than linguistic substance in affecting whether attempts to lead are accepted or rejected. Some forms can suppress the subordinates' tendency to calculate the costs and benefits of an exchange. For example, subordinate may be *sedated*. He or she may comply without thinking about the cost when told, "We've just got a last-minute rush order that needs to be filled before we leave tonight." The semantically direct "I want you to fill this rush order" might result in the employees' thinking about the cost of compliance and desiring an inducement for complying. Numerous other hints, prompts, teasing, and semantic indirectness can serve to sedate the subordinate. The leader can avoid responsibility for providing inducements for compliance: "You may find it worthwhile to fix the oil gauge." The leader's language can also be *palliative*. For example, a staff manager, with no way of rewarding line employees for information he requires, may get the information by *hedging*: "This won't take long, but would you locate some good estimates of the prices?"

*Quality of Writing.* The advent of electronic mail, through which every employee is in instant contact with every other employee's personal computer terminal, suggests that the quality of writing, although truncated, will regain the status for distance communication that it had before the invention of the telephone. The storage and retrieval of transmitted information will also be greatly improved. Nonetheless, oral communication is likely to remain highly important to leading.

*Competence in Nonverbal Communication.* Non-verbal communication is also important to leadership (Stein, 1975). In investigating the effects of nonverbal and verbal communications among 151 college students on their perceptions of leadership, Gitter, Black, and Fishman (1975) concluded that nonverbal communications could be even more important than verbal communication.

For example, Remland (1984) demonstrated that superiors in videotaped interactions with subordinates would be seen as more considerate (and therefore more satisfying as leaders) if they used nonverbal means to reduce the status differences between themselves and their subordinates. Elsewhere, Remland (1981) pointed out that when nonverbal messages contradicted verbal ones, the listener tended to trust the nonverbal messages more. Thus a manager who talked as if he wanted to share decision making with a subordinate, but looked bored whenever the subordinate spoke, would be regarded as manipulative and insincere. Baird (1977) examined eight categories of nonverbal behavior in 10 discussion groups of five students each. These categories were: (1) head-nodding agreement; (2) head-shaking disagreement; (3) eye contact; (4) facial agreement; (5) facial disagreement; (6) postural shift; (7) gesticulation with the shoulders or arms; and (8) gesticulation with the hands or fingers. A significant relationship was found, in particular, between emergence as a leader and the tendency to gesticulate with the shoulders or arms. Friedman and Riggio (1981) examined the extent to which individuals differed in their nonverbal expressiveness and indicated that those who were more nonverbally expressive were more likely to influence the mood of those who were less nonverbally expressive. Such nonverbal expressiveness was also found to contribute to patients' satisfaction with the interpersonal manners of their physicians (Freedman, DiMatteo, & Taranta, 1980).

*Sense of Humor.* Sense of humor is the ability to perceive, express, and enjoy what is amusing, laughable, or comical. There is more anecdotal evidence but less empirical research showing that leaders who use humor in communicating to their followers are more successful and effective than those who do not (Crawford,

1994). Some leaders have more of a sense of humor than others and make more use of it in their communications. Humorous communicating evokes a response by contrasting incongruent ideas, by engendering a feeling of superiority over others, by releasing tension, or by dealing with ambiguity in the environment (Hudson, 1979). Laughter is provoked by the unexpected punch line. *Clowning* wits are rated low in influence but high in popularity. *Sarcastic* wits are rated higher in influence but lower in popularity (Gruner, 1965). Humor increases the favorableness of an audience toward the speaker, and makes a speech more interesting, persuasive, and memorable. Self-disparagement may be effective if it is witty, indirect, and based on clever wordplay rather than exaggerated personal defects. Put-downs of others need to be avoided if they offend the values of the listeners. (Munn & Gruner, 1981).

*Humor and Effective Leadership.* Southwest Airlines looks for a sense of humor in job applicants (Quick, 1993). Individuals with a greater sense of humor reveal traits associated with successful and effective leadership such as self-esteem, emotional stability, extroversion, and sociability (Kuiper & Martin, 1993). Use of humor by the leaders of work groups helps improve morale (Gruner, 1977), cohesiveness (Duncan, 1982), motivation, (Crawford, 1994), creativity and divergent thinking (Czikszentmihalyi, 1996), and productivity (Clouse & Spurgeon, 1995). Humor has alleviated intimidation and stress and encouraged communication (Vinton, 1989).

Kilinski-Depuis and Kottke (1999) correlated 80 subordinates' ratings of their supervisors. They were all employees of an international marketing firm. Their ratings of the sense of humor of their supervisors correlated .48 with their ratings of the supervisors' consideration. Sense of humor was measured by seven modified items drawn from the Situational Humor Response Questionnaire (Lefcourt & Martin, 1986), which assesses how much a person typically responds with mirth and laughter to a wide variety of life situations. Avolio, Howell, and Sosik (1999) tested, in a large financial insurance company, the impact of 115 leaders' use of humor on the productivity of their 322 subordinates. What was measured was the frequency of occurrence by rated subordinates of instances in which the leader "uses humor to take the edge off during stressful periods," "uses a funny story to turn an argument in his or her favor," "makes us laugh at ourselves when we are too serious," "uses amusing stories to defuse conflicts," and "uses wit to make friends of the opposition." Leadership was measured by the Multifactor Leadership Questionnaire (Bass & Avolio, 1997). The effectiveness of the leader was assessed by consolidated unit performance, the extent to which the leader's organizational unit achieved annual goals. Performance appraisals of the leaders also were available. Transformational leadership correlated .56 with a five-item "use of humor" scale. Contingent reward correlated .45 and laissez-faire leadership correlated 2.50 with the use of humor. A partial least-squares analysis (PLS) showed that transformational leadership combined with the use of humor correlated highly with the leaders' appraised performance and the consolidated performance of the leaders' unit. But combining humor with contingent reward appeared ineffective.

*Consideration.* Consideration can be seen in prosocial behavior, such as helping, sharing, donating, cooperating, and volunteering. Such behavior aims to produce and maintain the well-being and integrity of others. Leaders will manifest it by showing leniency in personnel decisions, practicing a considerate style, sacrificing their own interests, and spending time and energy for the good of the group or organization or the individuals within it (Brief & Motowidlo, 1986). The leader who displays prosocial behavior serves as a role model for a good organizational citizen, who complies with the organization's requirements despite personal inconvenience, suggests improvements without personal benefit, and ignores hardships to carry on voluntarily (Smith, Organ, & Near, 1983). Thus probation officers will have little effect on recidivism if they show empathic, warm regard for parolees but fail to demonstrate prosocial values and socially acceptable ways of achieving goals and do not model, encourage, and reinforce noncriminal alternatives (Ross & Gendreau, 1980).

A sample of 97 first-line supervisors reported spending an average of 2.5 hours a week discussing personal problems with their subordinates, such as difficulties with coworkers; opportunities for advancement; dissatisfaction with their jobs; and financial, physical, family, and emotional problems. Some supervisors also mentioned problems with sex, alcohol, and drugs. The most common strategies of the supervisors were to offer support, to listen, and to ask questions. In these discussions, the subordinates and supervisors generated solutions and shared personal experiences (Kaplan & Cowen, 1981). From structural and factor analyses of the descriptions of helping behavior by 58 first-line supervisors and their 355 subordinates, Konovsky (1986) found one factor in the helping behavior of supervisors that involved offering support and sympathy and a second factor that involved assistance in solving problems. Although better-educated superiors were directly helpful, the supervisors' task competence and experience did not make any difference. Overall, the satisfaction of followers was enhanced when their leaders showed that they cared by demonstrating their consideration for the members of their group. Such consideration emerged early in factorial studies of the behavior of leaders (Fleishman, 1951) and has appeared repeatedly in subsequent analyses.

*Individuation.* Within the immediate group, the interpersonally competent leader can individualize his or her relationships, avoid treating all subordinates alike (Meyer 1980), and discriminate between the more competent and less competent members in the group (Fiedler, 1964). Diffusion of responsibility in group decisions is avoided unless the group decisions serve useful purposes, such as gaining commitment from peripherally involved members. Equity is favored rather than equal-ity—each member may be given equal opportunities, but rewards will be contingent on each individual's contribution to the group's success. Group productivity is enhanced by such individuation (Ziller, 1964). Interpersonally competent leaders are oriented toward the individual development of their subordinates, as well as the development of their team. Morse and Wagner (1978) found that effective managerial behavior provided for the growth and development of both. Assignments are delegated to subordinates to provide such opportunities for development. Competent leaders take on responsibilities as mentors and coaches according to the differential needs of subordinates for guidance and counseling.

Bradford and Cohen (1984) say that the quintessence of “postheroic” transformational managers is their orientation toward developing their subordinates. These managers build teams that share responsibility and visions of the future, as well as support the continuous development of individual skills. In so doing, they enhance the motivation, commitment, and performance of their subordinates. Individualized consideration was one of the transformational leadership factors which emerged from descriptions of leaders by their colleagues and subordinates using the Multifactor Leadership Questionnaire (Bass & Avolio, 1989). Individualized consideration involved showing concern for each subordinate as an individual and attending to the subordinate's development. This factor consistently correlated highly with subjective and objective measures of the leader's effectiveness (Bass, 1985a; Hater & Bass, 1988; Yammarino & Bass, 1989).

*Social Insight, Empathy, and Leadership.* Leadership of a group depends, to some extent, on the leader's ability and motivation to estimate accurately the group's attitudes, motives, and current level of effectiveness. As Bass (1960, pp. 167–168) indicated, “It is not enough for a leader to know how to get what followers want, or to tell them how to get what they want. The leader must be able to know what followers want, when they want it, and what prevents them from getting what they want. Empathic success should increase with increased motivation to attend to clues. It should also increase with information available about others' behavior. Two persons may display the same success in guessing the motives of some other members. One estimator may be more apt; the other estimator may be more interested in the question because of momentary situational demands or acquired motives. An alert teacher ‘senses’ from facial expressions, questions or lack of them, restlessness, and lack of response whether [he or] she is continuing to meet the needs

of the student audience. An effective orator or actor requires similar skills.”

Many others have offered similar propositions. Wittenberg (1951) emphasized the need-estimating aspect of leadership. That is, the leader of a group must know what the individual members need and then apply the group process so that the members will satisfy these needs. Coyle (1948) suggested that to work with young people, group leaders must understand the various motives that draw the group together, to “find the appropriate form to clothe their collective needs.”

For political and organizational leadership, Titus (1950) and J. M. Bums (1978) noted that the leader must be able to choose the group’s objectives wisely and forecast the cost of obtaining the objectives, the likelihood of doing so, and the degree to which goal attainment will be satisfying to the members. Lane (1985) suggested that organizational managers should examine their ability to be followers so that they can better understand the feelings and problems of their subordinates. Managers can do this by examining their own role as followers with different bosses.

Leaders should appreciate whether their subordinates learn from them and whether their subordinates are comfortable sharing problems and confidences with them. They also need to know their subordinates’ strengths and weaknesses. In the same vein, Haislip (1986) saw that a leader needs to be sensitive to those aspects of the work experience that illustrate how the organization values its employees’ personal goals. Such sensitivity will keep the leader focused on helping to maintain the congruence of the goals of the employees and the organization and, thereby, the employees’ commitment. Fielder, Warrington, and Blaisdell (1952) noted the importance of unconscious attitudes in sociometric choice. Deep probes are needed to test whether leaders are better able than nonleaders to diagnose social situations. Empathy is often emotional, intuitive, and unconscious. Projective techniques must be used to study it.

It is expected that leaders will be more insightful. Thus Shartle, Stogdill, and Campbell (1949) found that nominations for “popular leader” were correlated .47 with predictions of “who will be most accurate in estimating group opinion.” In a study of 153 supervisors in seven organizations, E. J. Frank (1973) observed that leaders who perceived their roles as requiring sensitivity to others also perceived themselves as being sensitive. Along with this felt sensitivity, the leaders appeared to feel that they were openly accepted by the group and that the working environment was pleasant. Alertness to changing circumstances and shifts in needs was also considered important to leadership (Hollander, 1978).

In all, from the early studies on, it has been thought that insight and empathy give an individual the competence to gain, hold, and maintain the position of leader. In traditional Japan, the head of a group ostensibly made the group’s decisions; and once the leader made a decision, it was regarded as the “will of the group” and accepted without challenge. But if one looked more carefully, one saw that the leader had the responsibility of sensing the will of the group in order to understand what was wanted, both intellectually and emotionally. He had to *hara de wakaru* or “understand with his belly” (Kerlinger, 1951). It appears that this is still required of the Japanese manager.

Insight, empathy, and accuracy about the other person appear to be particularly important in international negotiations. The ability to diagnose and understand the motives of others and to predict their subsequent actions accurately separates great statesmen from mediocre politicians. Because of the sentiment against war in Britain and France in 1938, the British prime minister Neville Chamberlain and the French premier Édouard Daladier wanted to believe that Adolf Hitler could be conciliated, regarding the local conflict over the Sudetenland, with goodwill and flexibility. In Winston Churchill’s diagnosis, Hitler was using the local situation to destroy Czechoslovakia as a key bastion that was standing in the way of Hitler’s plans to conquer Europe. At Munich, Chamberlain and Daladier completely misread Hitler’s goals, values, and intentions; Churchill understood them accurately (Tucker, 1981). But the leadership and compliance displayed by all parties at Munich were strongly associated with the orientations of all the key figures to personal predilections, power, and politics.

*Insight, Empathy, and Transactional and Transformational Leadership.* Insight and empathic competence should be important if the leader is transactional and engages in an exchange relationship with followers. The leader needs to learn what the followers want so that he or she can make the right offers to them for their compliance. But the transformational leader also can build from a stronger base if he or she understands the current needs and concerns of prospective followers. The individually considerate transformational leader must have a sense of the followers' developmental needs and of how the followers' current wishes differ from one another. The inspirational leader has a sense of which appeals will be heard most readily by followers.

*Problems with Insight and Empathy.* Although insight and empathy have been regarded as important, empirical evidence of the association of these personal traits with leadership is often hard to establish. The data suggest that in comparison with others, leaders do not appear to exhibit a higher degree of generalized insight into the feelings or motivation of followers. Furthermore, various measurement problems complicate the conclusions, and many contingencies force the qualification of results. However, considerable positive evidence has been amassed about the insight of leaders into the feelings of their *immediate* followers and an understanding of the localized situation.

In the most general sense, "empathy" refers to awareness or appreciation, and "insight" refers to an understanding of what others are thinking and feeling about a matter. Empathy is "the ability to walk around in someone else's world" (Kilcourse, 1985, p. 23). President Bill Clinton impressed troubled supporters by saying, "I share your pain." Insight and empathy may be a matter of seeing others in relation to ourselves. But the linkages of empathic ability and social insight to leadership are complicated by the various definitions and ways of measuring empathy and insight.

*Generalized Social Insight and Empathy.* Empathy and insight can refer either to awareness and understanding of social phenomena at a general level (knowledge of cultural norms and social intelligence) or to understanding the most probable tendencies of prototypical others. History is replete with examples of political leaders whose success depended on their accurate sensing of the moods and desires of their constituencies. Many leaders depend on almost daily public opinion polling and focus groups. Others appear to attend to newspaper columnists, editorials, television anchors, and hosts of talk shows.

Various researchers have developed measures of social insight and empathy at this general level. These measures require participants to estimate the percentage of people in a designated population who will endorse the items on a test of personality, attitudes, or job satisfaction. The participants' accuracy is measured by how well their estimates match the actual endorsement by a sample of the population. Chowdhry and Newcomb (1952), Bell and Hall (1954), Nagle (1954), Trapp (1955), and Fleishman and Salter (1963) found that leaders were more accurate than nonleaders in estimating such responses in a general population. Kerr and Spieroff (1951) and Van Zelst (1952) were able to forecast success as a salesman, union leader, and foreman with a brief test that purported to measure individual differences in empathic ability at the general level by the method just described. However, Sprunger (1949); Hites and Campbell (1950); Gage and Exline (1953); Talland (1954); Bugental and Lehner (1958); and Cohn, Fisher, and Brown (1961) did not find leaders to be significantly more accurate than nonleaders in such tested estimations. Along the same lines, Marchetti (1953) found no relation between grocery managers' ability to predict employees' responses on a test of attitudes in general and the managers' efficiency as rated by their superiors. Shartle, Stogdill, and Campbell (1949) reported a slight negative relation between naval officers' popularity as leaders and their tested ability to estimate group opinion in general. Thus decidedly mixed results have been found for the relationship between generalized social insight, generalized empathy, and leadership.

It is even questionable whether generalized empathy exists. Although Cline and Richards (1960, 1961)

found low but significant correlations between a variety of different measures of ability to judge the behavior of other persons, Ausubel and Schiff (1955), Bender and Hastorf (1950), and Crow and Hammond (1957) found no support for the hypothesis that there is an ability to predict interpersonal responses in general. For one thing, education, experience, and general intelligence are likely to affect respondents' performance on measures of generalized empathy and insight.

*Localized Social Insight and Empathy.* Different from generalized insight and empathy are specific perceptual sensitivities at a local level—in a designated group working with specific other members. A considerable array of positive findings supports Stogdill's (1948) conclusion in [Chapter 4](#) that “alertness to the surrounding environment and understanding of ‘social’ situations are intimately associated with leadership ability.” The ability to size up situations differentiated leaders from followers in six pre-1948 studies. Carter, Haythorn, Shriver, and Lanzetta (1951) also found that leaders were able to evaluate situations. Insight into motives, thoughts, feelings, and actions of others was found to characterize leaders in seven pre-1948 studies. Reviews of the literature on localized social insight and empathy generally affirmed the connection between empathy and leadership, although they found that the effects were small and may have been nonexistent or negative in many cases. Thus, for example, after surveying 15 studies that reported 101 results concerning leadership and empathy, R. D. Mann (1959) noted that 74% of the results were positive, but researchers usually were unable to obtain statistically significant positive results in any single investigation.

To illustrate, Williams and Leavitt (1947a, 1947b); G. H. Green (1948); Greer, Galanter, and Nordlie (1954); and Lansing (1957) used sociometric nominations as a basis for studying insight. Group members were asked to nominate other members for leadership and to estimate the ranking that others would ascribe to them. Leaders were found to be more accurate than nonleaders in estimating their own sociometric rank (their esteem or value to the group in the eyes of the other members) or, in some studies, the rank of others. Gallo and McClintock (1962) also found that leaders were more accurate than nonleaders in perceiving their esteem in the group. Furthermore, Fiedler's (1967a) theory of leadership was first formulated around the linkage of empathy to leadership, and one's assumed similarity to others was the main measure of consequence. In studies of basketball teams and surveying teams, Fiedler (1953a, 1953b, 1954a) found that the teams were more effective if their esteemed members, who were likely to be the team leaders, perceived preferred members to differ from rejected members. Fiedler (1954b, 1955, 1959) obtained similar findings for B-29 bomber crews, tank crews, and groups in open-hearth steel shops. The groups were more effective if the crew leaders or supervisors discriminated more distinctly between members with whom they preferred to work and members whom they rejected.

Nagle (1954) reported high correlations between departmental productivity and the ability of departmental supervisors to estimate employees' attitudes. Anderhalter, Wilkins, and Rigby (1952) noted that candidates for the U.S. Marines Officers Candidate School who showed the highest ability to predict other candidates' future effectiveness were likely to make effective company officers themselves. Greer, Galanter, and Nordlie (1954) found leaders of infantry squads to be more accurate than other squad members in their perceptions of the esteem of other members. J. Hogan and Holland (1998) obtained correlations between .45 and .73 with the Hogan Personality Inventory Empathy scale and five criteria of leadership for 25 managers from a large retail firm.

Schrage (1965) reported that accurate perception and interpretation of the environment were more important than the motivation for power or the need for achievement in differentiating successful from unsuccessful entrepreneurs. Jennings (1952a) showed that supervisors who did not understand the behavior of their subordinates felt inadequate and insecure. As their frustration increased, they became less able to obtain cooperation and satisfactory performance from their subordinates. Studies of managers who fail to rise in their organizations find that these managers are unable to understand others' points of view. They are insensitive to

others, unable to build a team, and unable to get work done when the work depends on the efforts of others (J. Hogan & R. Hogan, 2002).

*Negative Results.* On the basis of a survey of managers and their subordinates, Hatch (1962) concluded that the empathic accuracy of the managers had limited practical significance. He found no significant differences between the empathic accuracy of the managers and the superiors' description of the managers as good or poor in maintaining satisfactory relations with their subordinates. Similarly, Jerdee (1964) reported that supervisors' predictions of subordinates' morale were negatively related to the employees' actual morale scores. Andrews and Farris (1967) noted that subordinates' innovation was correlated negatively with their supervisors' effectiveness in planning if the supervisors were sensitive to individual differences, but the correlation was positive if the supervisors were insensitive to differences among people. Williams and Leavitt (1947a) observed that the more successful leaders they studied most underestimated the sociometric status accorded them by other group members. Finally, Shartle, Stogdill, and Campbell (1949) found that nominations for popular leaders were not correlated with errors in estimating group opinion. Likewise, such errors failed to correlate with predictions of who would be most accurate. Although popular leaders were not more accurate than unpopular leaders in estimating group opinion, other group members expected them to be. More often than not, positive or negative results have to be qualified by conditions. Only under particular localized circumstances was one likely to find that a leader was more insightful or empathic than a nonleader. Some of these variations in outcomes, of course, may be due to random error when subjected to a meta-analysis. Nevertheless, successful political leaders can sense what their constituencies want and articulate their needs even without public opinion polls.

*Substance of Judgments.* Foa (1960) found that workers' predictions of their supervisor's responses to a projective (picture) test were more accurate when the supervisor described the action in the ambiguous picture as positive and focused on the job rather than on interpersonal relations. Holmes (1969) compared leaders' estimates of the frequency of interaction and duration of speech of group members with recordings of the groups' performance. Leaders evaluated the duration of behavior by followers more accurately than the frequency of the behavior.

*Specific Relevance.* Chowdhry and Newcomb (1952) found that leaders judged group opinion better than non-leaders or isolates, but the superiority of leaders over non-leaders was restricted mainly to issues that were relevant to their specific groups. When matters concerned groups in which they were not leaders, their superiority tended to disappear. Similarly, Northwood (1953) collected facts and opinions from a sample of residents in a housing project. Officeholders were found to be significantly more accurate than informal leaders and followers as judges of fact and opinion, but they were not superior judges of nonrelevant facts and opinion. Greer, Galanter, and Nordlie (1954) emphasized this type of contingent outcome. Hites and Campbell (1950) failed to obtain positive results, because they did not ask for estimations relevant to the members' goals.

*Cohesiveness.* Since cohesive groups usually involve considerable mutuality of choice among their high-status members, the leadership clique was expected to exhibit higher accuracy about others in the group than the members of lower status. Exline (1960) assigned members to high-or low-congeniality groups to discuss a task and measured the members' accuracy of knowledge of each other's task-relevant and person-relevant opinions. Exline found that only in cohesive groups were the leaders more accurate judges of person-relevant opinions, such as popularity. Lemann and Solomon (1952) also found that the accuracy of interpersonal perception was higher in cohesive than uncohesive groups.

*Familiarity.* Studies of newly formed groups obtained negative results when they correlated a member's first impressions of others with the member's initial success as a leader (C. B. Bell, 1951; H. E. Hall, 1953). Hatch (1962) found that only if managers felt that they were well acquainted with a subordinate were they able to predict the subordinate's attitudes beyond what would be predicted by chance.

The familiarity of members in a specific group related directly to the members' accuracy in judging each other's life goals. Filella (1971) asked 32 Indian college students in groups of eight members to individually rank their own life goals and then to rank the life goals of each of the other group members. The mean correlations between estimations by others and self-rankings systematically declined linearly with decreasing familiarity, from a correlation of .54 for the raters most familiar with the ratees to .12 for the raters least familiar with the ratees.

Lupfer (1965) recorded group members' interactions in a business game. At the end of each session, each subject indicated, on a questionnaire, a prediction of and a prescription for the behavior of every other member. As the sessions progressed, the members' role behavior tended to conform to prescriptive norms, and the prediction of behavior increased in accuracy. In a reversal of these findings, Browne and Shore (1956) noted that although second-level departmental managers were less close to operating employees than first-level supervisors were, the managers were somewhat more accurate than the supervisors in predicting the employees' attitudes.

*Focused Attention.* Lundy (1956) administered a scale of values to 52 students who later met in pairs to discuss a problem. Then each partner predicted the responses of the other, using the value scale, both with attention focused on the self and with attention focused on the partner. Lundy found that focusing attention on the partner increased accuracy in predicting the partner's responses.

*Assumed and Actual Similarity.* Localized social insight and empathy often present a multiple measurement problem. Bass, Burger, et al. (1979) used a model that was first formulated by Cronbach and Glaser (1953). The managers' ability to judge the life goals of specific other managers with whom they had been working in small exercise groups for several days was examined. The procedure was as follows. Participants ranked each of 11 life goals in order of importance to them. Then they ranked the goals in order of importance to each of the other members of their exercise group. Three correlational indexes were calculated. It was assumed that participants generally had an accurate appreciation of their own goals. The indexes were: (1) *Empathy* or accuracy in judging others—the correlation between a participant's judgments about other members' life goals and the other members' self-judgments; (2) *Projection* or assumed similarity to others—the correlation between the ranking participants assigned to themselves and those they assigned to everyone else in the group; (3) *Homogeneity of the group* or *actual similarity to others*—the correlation of a participant's self-ratings with the self-ratings of each of the other members. In addition to the scoring biases pointed out by D. T. Campbell (1955), studies of empathy at the local level are also likely to suffer from the generalized tendency of raters to assume that they are similar to others. Thus, for 1,026 managers in 12 countries, Bass, Burger, et al. found that assumed similarity among the raters averaged .50. But true similarity or homogeneity, evidenced by the average correlation of self-rating among all participants, was only .21. Likewise, Lazar (1953), after a review of eight studies, concluded that in judging the attitudes of groups, people err in the direction of their own beliefs or opinions.

The amount of actual similarity or homogeneity also affected what kinds of outcomes were obtained by Bass, Burger, et al. This finding was consistent with Octet and Silva's (1951) study, which found that the smaller the difference between actual self-descriptions and others' self-descriptions, the smaller the error when pairs of persons predicted each other's responses. Both rationally and empirically we are more accurate about others who happen to be like us because of the general tendency to assume that others are indeed like us. A

leader's accuracy may be accounted for by the bias toward assumed similarity and the homogeneity of the leader and the group. In fact, to be a leader of a group, one must usually share many attitudes, values, and goals with the other members (Cartwright, 1951). By definition, the opinions of group members are more strongly influenced by the leaders of the group than by nonleaders. It follows that the forecasts of group opinion made by leaders will be more accurate than estimates made by nonleaders, since the opinions are close to those held by the leaders. Thus, when leadership was defined in terms of influence on a group decision, Talland (1954) demonstrated that leaders were better estimators of final group opinion because it was closer to their own initial opinion. But leaders are not more accurate in estimating opinion before interaction. These confoundings of measurements need to be kept in mind when one considers the correlations obtained between leadership and localized measures of empathy and insight.

*Accuracy of Perceptions of Status and Importance of Organizational Position.* E. L. Scott (1956) analyzed organizational charts drawn by 696 officers and men aboard 10 submarines in which the status structure was thought to be well defined. He found marked differences in the accuracy of status perceptions of the men on the various ships and among the men in various departments within the same ship. The most frequent type of error was to perceive superiors as peers, peers as subordinates, and persons outside one's department as subordinates in one's department. High-ranking personnel made fewer errors in their perception of superiors and peers, but not in total. The more widely superiors interacted with other persons, the greater was the perceptual error of their subordinates. The greater the disparity between an officer's rank and the level of his position aboard ship, the greater were the perceptual errors of his subordinates. At the same time, the subordinates were able to perceive status relationships more accurately when their superiors retained authority and delegated less. Scott's study pointed to some potent organizational factors that operate to determine the accuracy with which status is perceived in highly structured situations.

## Summary and Conclusions

---

During the third quarter of the twentieth century, situational factors dominated the field. Individual traits and dispositions seemed unimportant. However, after correction, rotation experiments showed that traits were still important in accounting for leaders' behavior. In the last quarter of the century, we had to rethink whether leadership traits and leadership were a consequence of nature or nurture. Rapid advances in genetics, heritability research, and molecular biology suggested that we had to give a lot more attention to nature. Traits of leadership returned to center stage in the study of leadership. Situational effects remained important, but mainly as contingencies. Competence was seen as a matter of task accomplishment and interpersonal relations. Both were fundamental to successful and effective leadership. Task accomplishment involved traits like intelligence and knowledge. Interpersonal competence involved the ability to communicate and to demonstrate, caring, insight, and empathy. Effective leaders needed to sense the needs of their followers and point out ways to fulfill them.

The follow-up of the traits of leadership from before 1970 to after 1970 and into the twenty-first century generally showed renewed continuity and expansion. Competencies to deal with tasks and cognitive abilities were seen in more detail. Task competence results in attempts to lead that are more likely to yield success for the leader and effectiveness for the group. But competence is relative; this suggests that a complete understanding of leader-group relations requires an examination not only of individual differences in competencies, such as intelligence and experience, but of the relevance of the competencies for given situations. Intuition plays an important role in effective management; and leadership, particularly at higher organizational levels, appears to be a consequence of the possession of relevant information based on experience. The true correlation of intelligence with leadership is about .50 across a wide range of situations. Generally, more

intelligent people are likely to be more task-competent and emerge as leaders, regardless of the situation. Other personal characteristics also contribute to task competence and leadership in different situations. On the other hand, since task requirements may vary from one situation to another, situational differences will also affect who emerges as a leader. Finally, other contingencies that moderate the relationship between competence and leadership need to be considered. Task competence is not enough. Many bright, able, and technically proficient individuals fail as leaders because they lack interpersonal competence.

Many socioemotional traits affect leadership. They will be discussed more fully in the next several chapters. Traits of character—conscientiousness, discipline, moral reasoning, integrity, and honesty—will be included in dealing with the ethics of leadership. The negative impact on leadership of neuroticism, arrogance, anxiety, depression, and narcissism, rigidity will also be examined. The biophysical traits of physical fitness, stature, hardiness, and energy level will resurface again, along with self-confidence, self-esteem, self-monitoring, self-regulating, and self-efficacy. We will turn next to when and whether active leadership emerges.

<sup>1</sup> It should be kept in mind that the factors which emerged from the analysis of intercorrelations of items describing leaders depended, to a large degree, on: (1) the kinds of items and variables for which descriptions were obtained; (2) the numbers of items and variables in different descriptive categories; (3) the nature of the population of leaders who were described. Few factorial studies of leadership were comparable when matched against these three criteria. As a result, few studies produced identical factors; however, certain factors with the same or similar names appeared with considerable frequency.

If factors with the same name appeared in two different studies, they did not necessarily contain loadings on identical items or variables. In other words, it could not be assumed that the factors described identical behaviors. A factor was identified or named on the basis of the nature of items or variables with the highest loadings on the factor. If several similar items or variables have high loadings, the element of the similarity of the item or variable is usually given heavy consideration in naming the factor.

The frequency with which a given factor appeared in the reports did not necessarily represent the frequency of its occurrence among leaders in general. An item or variable could not appear in a study unless measures were obtained on characteristics represented by the factor. Researchers, of course, differ in their ideas about what is important in the study of leadership. As a result, they tended to use different sets of items or variables in their efforts to measure leadership. Furthermore, it cannot be assumed that the listed factors constituted a complete catalog of the leader's qualities and abilities. One of the values of factor analysis is that it brings together in the same factor all items that act alike in describing the individuals in the samples. Thus, the resulting factor describes a generalized form of behavior, rather than the minute details of behavior.

It should also be kept in mind that factors can emerge only if leaders behave differently on different orthogonal dimensions. Thus, for initiation and consideration factors to emerge, there must be a low correlation between them. The same leaders who are high in initiation should vary in consideration from high to low. Those who are low in initiation should likewise vary from high to low in consideration. Conceptually, most leaders could be high in both and the factor could fail to appear, although the different behaviors could still be seen.

If the correlation is high between them, generally only a single factor will appear that contains items of both kinds. Nevertheless, the same leaders who are high in consultative behavior are also likely to participate in decision making. Only one factor, consideration, will appear. Consultation, in which the leader decides; and participation, in which decisions are consensual, are conceptually distinct, despite the fact that the same leaders who tend to use one of the approaches will also use the other approach. The distinctions are important both to theory and to practice. It may be particularly important for a leader to consult rather than participate in one circumstance but to share decision making with fully participating subordinates in another situation. Nevertheless, the generalized behaviors described by the 26 factors produce a more meaningful, logical picture of the leader than would be provided by a list of 100 haphazardly selected items or variables that were all correlated with leadership status and effectiveness. The results of the factorial studies indicate that an infinitely large number of variables are not needed to obtain a well-balanced description of a leader. A relatively few of the 26 factors can be the basis for organizing a fairly complete examination of leadership traits and behavior.

<sup>2</sup> Stogdill suspected that the absence of some particular positive findings in the 1970 survey were due, in part, to the decisions of his abstracters. We also must be cautious about the volume of results obtained for some traits and not for others. Researchers tend to pursue fads. Also, changes occur over the decades in the names that are used to label the same traits of behavior.

## CHAPTER 6

---

### Activity Level

Active leaders and managers take the major responsibility for decision making when they are directive and consultative, whereas leaders and managers take little or no responsibility when they are inactive and laissez-faire. Various active leadership styles correlate between 2.30 to 2.60 with inactive, laissez-faire leadership (Bass & Avolio, 1997). The generally positive correlations between factorially and conceptually distinct styles of leadership will be detailed in chapters 17 through 22. That is, leaders who score high in direction, task orientation, change behavior, and initiation of structure also tend to score high in participation, relations orientation, and consideration. Thus for 112 managers, Jones, James, and Bruni (1975) found that the leaders' supportiveness correlated .64 with an emphasis on goals and .74 with facilitation of work. Likewise, facilitation of interaction correlated .58 with the emphasis on goals and .70 with facilitation of work. Schriesheim, House, and Kerr (1976) found a median correlation for 10 studies of .52 between "consideration" and "initiation of structure" on the Leader Behavior Description Questionnaire Form XII. Farrow, Valenzi, and Bass (1980) reported that the frequency of the leaders' *direction*, as described by over 1,200 subordinates, correlated .26 with the leaders' consultation and .13 with the leaders' *participation*.<sup>1</sup> Errors of leniency and halo effects may be involved in these descriptions. Even so, there is a tendency to describe leaders as being more active or less active on several conceptually distinct dimensions concurrently. This tendency may be due to the real behavior of leaders, as well as to subordinates' perceptual biases.

Leadership infused by a motivation to lead and to manage is opposite to that due to a leader's inclination to use the laissez-faire style. Active leadership is seen in much of McClelland's (1975) Leadership Motive Pattern, discussed in [Chapter 7](#); and in Miner's "motivation to manage," detailed later in the present chapter. Miner (1982) theorized that managers actively engage in maintaining good relations with superiors, competing for advancement and recognition, acting as assertive father figures, exercising power over subordinates, being visibly different from subordinates, and accepting responsibility for administrative details.<sup>2</sup>

### Antecedents of active Leadership

---

As will be detailed in [Chapter 7](#), McClelland found active leadership to be undergirded by a need for power and an absence of need for affiliation, coupled with an ability to inhibit the need for power. Miner and Smith (1982) inferred that a desire for control and power lay behind the motivation to manage. For Chan and Drasgow (2001), the motivation to lead involved cognitive abilities, values, personality, and attitudes that are augmented by social considerations such as affective identity and norms. According to Locke, one should lead actively for rational and selfish interests; according to Avolio, one should be motivated to lead actively for altruistic reasons (Avolio & Locke, 2002).

### Effects of Active Leadership on Followers

---

Jongbloed and Frost (1985) attributed the differential budgetary growth and success of two Canadian hospital laboratories to the motivation and activity of their directors. The desire of the director of the more success-ful

laboratory “to achieve international recognition for outstanding research was apparent in the energy he devoted to lobbying hospital administrators and Ministry of Health Canada” (p. 102). The other laboratory director was not similarly motivated and did not engage in lobbying.

More activity by leaders, except when it is coercive, is usually associated with greater satisfaction and effectiveness among their followers. Conversely, more often than not, less activity in any of these active styles is negatively related to the performance and satisfaction of the followers. Thus, for instance, the structuring of expectations contributes positively to the productivity, cohesiveness, and satisfaction of the group. This pattern of behavior is the central factor in leadership when leadership is measured by initiation of structure, detailed in [Chapter 20](#). The leader can accomplish these initiatives through *direction* or *participation*, inspiration or consultation, negotiation or delegation. Whatever the style, as long as it is not coercive and autocratic, it must involve the leader taking action. It is doubtful that leaders in most situations can be of positive value to the group’s performance, satisfaction, and cohesiveness without this kind of active structuring unless all such structure has already been provided by other means such as self-management, culture, or organization.

Being active in direction, consultation, or both was better than being inactive in both. When data collected by Farrow, Valenzi, and Bass (1980) from 1,300 subordinates and their 340 managers describing the pooled frequency of the direction and consultation of the managers were correlated with the effectiveness of the groups, as seen by both the managers and the subordinates, the correlation with effectiveness (.41) was higher than that obtained for direction (.28) or consultation (.37) alone. Even more extreme, the combined direction-consultation index correlated .61 with satisfaction; consultation alone correlated .52. Bass, Valenzi, Farrow, and Solomon (1975) found overall correlations ranging from .30 to .60 between the behavior of leaders, as seen by their subordinates, and the judged effectiveness of the leaders’ work units, regardless of whether the leaders were directive or participative. When *direction*, consultation, *participation*, and delegation were combined, their composite correlated .36 and .61 with effectiveness and satisfaction, respectively. Similarly, to predict increased effectiveness, System 4 participative management was combined with “high performance, no-nonsense goals, orderly systematic goal setting processes, and rigorous assessment of progress in achieving those goals” (R. Likert & J. Likert, 1976). Path analyses reported by R. Likert (1973) demonstrated that managerial leadership, whether task-or relations-oriented, contributed both directly and indirectly to the subordinates’ satisfaction and productive efficiency. For large samples, the direct correlations between total leadership, subordinates’ satisfaction, and total productive efficiency were .49 and .42, respectively. In addition, total managerial leadership correlated .42 with a good organizational climate, .23 with peer leadership, .27 with a good group process, and directly between .25 and .67 with subordinates’ satisfaction and total productive efficiency.

Stogdill (1974) reviewed an array of surveys and experiments, mostly containing concurrent analyses of leader behavior and outcomes, more often than not in temporary, short-term groups and without reference to possible contingent conditions. He concluded that *both* the democratic leadership cluster (participation, relations orientation, and consideration) and the work-related cluster (direction, task orientation, structuring but not autocratic) were more likely to be positively than negatively related to the productivity, satisfaction, and cohesiveness of the group. Participative leadership behavior, as well as leadership behavior that structured followers’ expectations, was consistently related to the group’s cohesiveness.

As will be seen in [Chapter 19](#), Blake and Mouton (1964) argued that the best leadership is achieved with a 9,9 style concerned both with production and with people. Hall and Donnell (1979) confirmed this contention, showing that the 190 out of 1,878 managers who were the fastest in their career advancement were likely to be high in both task orientation and relations orientation, according to their subordinates. And the 445 managers who advanced most slowly were clearly 1,1 and laissez-faire in style—that is, low in both task orientation and relations orientation. In an experiment with 80 undergraduates, Medcof and Evans (1986) demonstrated that plodders are the least desirable leaders in business—a finding that agreed with Blake and

Mouton's argument. Misumi (1985) reported PM leadership, combining above-median performance in both performance and maintenance, was most efficacious in a wide variety of settings compared with below-median PM leadership.

Fleishman and Simmons (1970) concluded that leadership combining the factors of strong consideration and initiation of structure is most likely to optimize a number of criteria of effectiveness for a variety of supervisory jobs. In agreement, Karmel (1978) concluded that the combination of initiation and consideration—the total activity of leaders in contrast to their inactivity—may be the most important dimensions to investigate. A powerful general factor can be produced, if one so decides, by the selection of appropriate factor-analytical routines. It may be that pooling a diversity of decision-making styles for a new measure of generalized leadership activity will be useful.

Caveat: There are some obvious examples in which a group may do better with a less active leader. Leadership activity, as such, does not always guarantee the performance, satisfaction, or cohesion of a group. Highly active but coercive, monopolistic, autocratic leadership will contribute more to a group's dissatisfaction and lack of cohesiveness than to productivity. The qualities of the leadership activity must be taken into account. For the leader, doing something is usually, but not always, better than doing nothing. A calm, steady hand at the tiller may be required rather than an impulsive change of course. Moreover, as will be noted in [Chapter 20](#), activity in two styles may add little more than activity in one style alone.<sup>3</sup>

Not all activity in interpersonal and organizational settings is conducive to successful leadership; nor is successful leadership associated with the generation of any and all activity in oneself and others. For instance, as will be noted in [Chapter 7](#), McClelland's (1985) Leadership Motive Pattern (LMP) includes the tendency of individuals to tell stories about inhibiting activity on the Thematic Apperception Test (TAT). The more relevant question is whether activity will be influential and whether it will necessarily result in the increased performance, satisfaction, and cohesiveness of a group. The answer to this question appears to depend on whether the work-related leadership behavior is autocratic, directive, task oriented, or structuring and whether the person-related leadership behavior is democratic, participative, relations oriented, or considerate. These determinants are in addition to the contingencies that also may have to be taken into account. The activist admonition—"Lead, follow, or get out of the way"—has to be qualified by adding "with fore-thought, responsibility, and care." The pressure for action may need to be inhibited. Many a general has been victorious by waiting patiently to be attacked by a more impulsive enemy.

McClelland's (1975) Leadership Motive Pattern (LMP) is high for individuals who score high on the projective Thematic Apperception Test (TAT) in their need for power but who score low in their need for affiliation and, as was just noted, who exhibit impulse control in their projected inhibition of the expression of power. (They are actually less active than they really are driven to be.) A high LMP index was seen to forecast success in management. Thus McClelland and Burnham (1976) scored the TAT responses of managers' needs for power, achievement, and affiliation. They found that successful managers (managers whose subordinates were higher in morale and productivity) wrote TAT stories with "need for power" scores that were above average and with "need for achievement" scores that were higher than the need for affiliation. The stories contained at least moderate levels of activity inhibition. In a follow-up study of 237 AT&T managers, McClelland and Boyatzis (1982) found that although a high need for achievement predicted the success of lower-level managers, the moderate to high need for power, the low need for affiliation, and high scores in activity inhibition predicted the success of most other managers. Progress over 16 years at AT&T correlated an estimated .33 with LMP (McClelland, 1980).

Cornelius and Lane (1984) collected LMP data for managers in a profit-making professionally oriented service organization. The service organization provided instruction in a second language to full-time students.

The investigators failed to obtain positive correlations of McClelland's LMP profile of a high need for power and a low need for affiliation with measures of the performance of an administrative job or the subordinates' morale. In fact, they obtained a negative correlation of 2.42 of LMP scores against an administrative efficiency index for the lower level of supervisors. Their analyses were weakened by their failure to include an expression for the activity inhibition of power in their measurement of LMR. Also, the service organization was a hierarchically arranged group of professionals. However, Cornelius and Lane did find that LMP scores predicted the assignment of managers to more prestigious work centers.

## The Motivation to Manage

---

According to Miner (1965), people differ in their motivation to carry out the roles required of a manager and their success in doing so in a hierarchical organization. Miner used a projective approach—the Miner Sentence Completion Scale (MSCS), a sentence-completion test—in which examinees, without awareness, project their desires by completing incomplete sentences such as “Giving orders ...”; “Athletic contests ...”; and “My father ...” He originated a theory of managerial role motivation, built on role theory, psychoanalytic theory, and the empirical results of Kahn (1956b) and Fleishman, Harris, and Burt (1955). His theory was directed specifically toward role-taking propensities within the ideal large organization, formalized and rationalized to function bureaucratically. Miner argued that people who “repeatedly associate positive rather than negative emotion” with various managerial role prescriptions are more likely to meet the existing requirements for effectiveness.

### ***Roles and Requisite Motivation***

Six managerial role prescriptions were presented by Miner, along with the required motivation for success as a manager in a hierarchical organization: (1) Managers must behave in ways that do not provoke negative reactions from their superiors. To represent their group upward in the organization and to obtain support for their actions, managers should maintain good relationships with those above them. A generally positive attitude toward those holding positions of authority is required; (2) Since a strong competitive element is built into managerial work, managers must compete for the available rewards, both for themselves and for their groups. If they do not, they may lose ground as functions are relegated to lower their status. Without a willingness to compete, promotion is improbable. To meet this role requirement, managers should be favorably disposed toward engaging in competition; (3) There is a parallel between managerial role requirements and the assertiveness that is traditionally demanded of the masculine role. Both a manager and a father are supposed to take charge, to make decisions, to take such disciplinary action as may be necessary, and to protect others. Even women managers will be expected to follow the essentially masculine pattern of behavior as traditionally defined.<sup>4</sup> A desire to meet the requirements of assertive masculinity will generally lead to success in meeting certain role prescriptions of the managerial job; (4) Managers must exercise power over subordinates and direct their behavior in a manner that is consistent with organizational and personal objectives. Managers must tell others what to do, when necessary, and enforce their words through the appropriate use of positive and negative sanctions. The person who finds such directive behavior difficult and emotionally disturbing will have difficulty meeting this managerial role prescription; (5) Managers must stand out from their groups and assume positions of high visibility. They cannot use the actions of their subordinates as a guide for their own behavior as managers. Rather, they must deviate from their immediate groups and do things that will inevitably invite attention, discussion, and perhaps criticism from those who

report to them. When the idea of standing out from the group, of behaving in a different manner, and of being highly visible elicits unpleasant feelings, then behavior appropriate to the role will occur less often than is needed; (6) Managers must “get the work out” and keep on top of routine demands. Administrative requirements of this kind are found in all managerial work, although specific activities will vary somewhat from one situation to another. To meet these prescriptions, a manager must at least be willing to deal with routines and ideally gain some satisfaction from doing so.

*Contradictions.* As can be seen, Miner did not mince words. He argued that in a typical bureaucratic hierarchy, what is needed for leadership is an authority-accepting, upward-oriented, competitive, assertive, masculine, power-wielding, tough-minded person who will attend to details. In preparing his role prescriptions, he was selective about which facts about leadership he incorporated and which facts he ignored. A positive attitude toward authority may characterize authoritarian-submissive behavior. An organization of submissive managers would not seem to promise innovation and effectiveness. Competitive behavior presents many problems for an organization. Managers who are in competition with their peers hide necessary information from each other. They fail to consider the goals of subordinates. Competition means that managers negotiate with their peers instead of solving problems with them. Decisions are based on power, rather than on merit—again, a consequence that is not calculated to add to organizational effectiveness. It is true that visibility may help one’s own advancement. However, the concern for such visibility may conflict with good team support from subordinates, who may feel exploited. The stern father image and the willingness and need to use sanctions seem to contradict most of the evidence about the costs of coercion and autocratic leadership. If attention to details means the inclusion of sanctions, and if the manager lacks a sense of priorities, this prescription can easily be overdone.

Despite these contradictions, considerable support for Miner’s theory has been amassed for predicting the success of managers in a hierarchical organization. But, as shall be seen, the contradictions are stronger in a professional organization of colleagues in which innovation and creativity are priorities, and where cooperation, open communication, expert power, and helping relationships are paramount. For the professional type of organization, Miner laid out a different set of role prescriptions for leadership, accompanied by a different sentence-completion test (MSCS-Form P) than the one created for assessing managers in a hierarchical bureaucracy (MSCS-Form H).

### ***Measuring the Motivation to Manage in Hierarchical Organizations***

MSCS-Form H was used to measure managerial role motivation in bureaucratic organizations (Miner, 1965). It contains 40 items, 35 of which are scored. As was just mentioned, the scale is a projective measure in which examinees complete a list of incomplete sentences such as “Sitting behind a desk, I ...” A majority of the incomplete sentences refer to situations that either are outside the work environment or are not specifically related to the managerial job. Ordinarily, examinees are unaware of what is being measured, so they are unlikely to distort their responses to present themselves in a good light as managers. Subscales for the motivation to take each of the prescribed managerial roles can be obtained. For instance, completing the incomplete sentence “When playing cards ...” with the response, “I always try to win” would contribute to one’s score on the competitive games scale. The response “I usually become bored” would do the reverse. A multiple-choice version was developed by Steger, Kelley, Chouiniere, and Goldenbaum (1977), whose total score correlated .68, .38, .56, and .68 with the original MSCS-Form H in different samples. However, a considerable inflation of scores occurred when the multiple-choice format was used. Respondents did not choose the socially undesirable negative alternatives of the kind they ordinarily might produce in response to

the open-ended incomplete sentences of the original projective test (Miner, 1977b).

*Concurrent Validities.* Berman and Miner (1985) obtained results indicating that 75 chief executive and operating officers, executive vice presidents, and group vice presidents who had worked their way upward most successfully through a bureaucratic hierarchy earned significantly higher MSCS scores than 65 lower-level managers of nearly the same age who had not risen as high in the hierarchy and 26 others, including the founder-entrepreneur and his relatives. Earlier, Miner (1965) found that the higher the total scores on MSCS-Form H, the higher the hierarchical level, the performance ratings, and the rated potentials of 81 to 100 managers of research and development (R & D) in a petrochemical firm. Furthermore, the total MSCS scores of 70 department store managers related significantly to the managers' grade levels and potential but not to their rated performance. Likewise, Gantz, Erickson, and Stephenson (1977a) reported that the total MSCS scores of 117 scientists and engineers in a government R & D laboratory related significantly to their peers' ratings of their supervisory potential. For 101 personnel and industrial managers, Miner and Miner (1977) established a significant relation between total MSCS scores and a composite measure of their success, compensation, and positional level. Miner (1977) obtained correlations of .20, .57, and .39, respectively, of MSCS with the performance ratings of 81 R & D managers, 61 oil company managers, and 81 administrators in a large school district. Similar correlations of MSCS scores with levels of position were found by Miner (1977a) for 142 personnel and industrial relation managers and for 395 managers from a variety of firms.

With 82 school administrators in a large city, Miner (1967) found that total MSCS scores were related significantly to their compensation, rated performance, and potential, but not to their hierarchical level. However, hierarchical level in the organization was significantly related to the total MSCS scores of 44 women department store managers (Miner, 1977a) and 50 and 37 textile managers, respectively (Southern, 1976). Two additional analyses reported by Miner (1982a) showed that MSCS scores were higher for those who were at a higher organizational level. The mean score for 22 personnel managers who were vice presidents was 5.7, but the mean score was only 2.4 for 79 personnel managers who were below the vice presidential level. The mean was 6.8 for 49 CEOs, presidents, and group vice presidents, but it was 0.9 for 49 matched managers at lower levels. Other concurrent significant differences that were in line with expectations for the scores on MSCS-Form H and the organizational level of managers were reported for hospital officers (Black, 1981). With samples of students, Miner and Crane (1977) obtained positive findings that related MSCS scores to the promotion of 47 MBA students to management, to the selection of a fraternity president from among 40 candidates (Steger, Kelley, Chouiniere, & Goldenbaum, 1977), and to the choice among 190 candidates for student offices. Miner, Rizzo, Harlow, and Hill (1974/1977) also reported positive findings for undergraduate students in a simulated bureaucratic organization. Finally, Miner and Crane (1981) found a correlation of .48 between the MSCS scores of 56 graduate students in management and the students' tendency to describe their present and planned work as more managerial in nature.

*Predictive Validities.* Total MSCS scores forecast the rise in organizational level and subsequent performance ratings of 49 to 81 R & D and marketing managers in a petrochemical firm (Miner, 1965). Lacey (1977) found that total MSCS scores were significantly able to predict the promotion to management of 95 scientists and engineers. Lardent (1977) likewise found that the total MSCS scores of 251 candidates successfully forecast graduation from the U.S. Army Officer Candidate School at Fort Benning. Butler, Lardent, and Miner (1983) were able to do the same for 502 West Point cadets. But Bartol, Anderson, and Schneier (1980) failed to find concurrent differences in motivation to manage among classes of sophomores, juniors, and seniors in business schools; and Bartol and Martin (1982) were unable to find significant changes in the same MBA students in a longitudinal study in which the 232 students were assessed with the multiple-choice form of the MSCS at the beginning of their program and again after graduation. Moreover, unlike the

military findings, no relation was found between the students' completion of the MBA program and their MSCS scores, although Bartol and Martin did report that the MSCS scores of 97 of the graduates were a significant predictor of these persons' salaries after graduation. Support for the construct validity of the MSCS as a motivational measure was also obtained, in that Bartol and Martin found correlations with MSCS scores of .26 and .34 respectively, with the students' desired managerial level and the level the students thought it was possible for them to attain.

*Validity Contingent on Bureaucratic Hierarchy.* Since the role prescriptions were applicable only to traditional bureaucratic hierarchies, Miner (1965) proposed and found that the total scores on MSCS-Form H were unrelated to the success of professionals outside such highly structured organizations. Miner (1977a) failed to find any significant relations between the scores on MSCS-Form H and various criteria of success of 24 to 51 managerial consultants, 49 faculty members at business schools, 36 to 57 school administrators in small and medium-size cities and consolidated districts, and 65 salesmen at an oil dealership (Miner, 1962a, 1962b). More convincing support for this argument was obtained by Miner, Rizzo, Harlow, and Hill (1977), who showed that in simulated low-structure situations, in which 89 students worked on various case projects in small teams of four to seven, scores on MSCS-Form H were unrelated to the students' emergence as leaders. However, in line with Miner's theory, in a high-structure situation in which students chose to work on current problems in assigned positions in a simulated organization with six divisional levels, the total scores on MSCS-Form H of higher-level leaders were highest and the scores of non-leaders and of those who opted to work outside the organization were lowest.

### ***Motivation to Lead in Professional Organizations***

Oliver (1982) created an inventory to discriminate reliably between hierarchical and professional organizations; and Miner (1982a) developed MSCS-Form P, another sentence-completion test, to measure professional motivation to deal with success in a professional, in contrast to a hierarchical, organization. The subscales of Form P concern the motivation to acquire knowledge, to act independently, to accept status, to provide help, and to be professionally committed. Motivation on Form P is more likely to correlate with the level and performance of professional leaders than hierarchical leaders. Miner reported correlations of .51, .55, .42, and .53, respectively, with the professional rank, professional compensation, number of journal articles published, and number of books published of 112 members of the Academy of Management. The correlations of such criteria of professional success with the corresponding scores for the motivation to manage on Form H were, respectively, .02, .08, .01, and .09.

### ***Motivation for Entrepreneurial Leadership***

The motivation to manage on MSCS-Form H failed to relate to the desire of 38 entrepreneurs in Oregon to expand. Consequently, Form T was constructed to assess the motivation for entrepreneurial leadership: the motivation to achieve, to take risks, to seek the results of performance, to innovate, to plan, and to set goals. On Form T, the mean for 23 entrepreneurs with faster-growing firms was 11.9; the mean was 0.5 for 28 entrepreneurs with slow-growth firms and 2.0 for nonentrepreneurs (Smith & Miner, 1984).

*Critique.* A number of difficulties emerge from Miner's work. Even restricting Miner's motivation to manage to traditional hierarchies fails to account for the contrast between his prescriptions for the managerial role and those, say, of most behavioral scientists who favor democratic, participative, relations-oriented,

considerate leadership. Indeed, conspicuously absent from Miner's results are criteria for subordinates' satisfaction, productivity, cohesiveness, and growth. As was noted earlier, the satisfaction of subordinates may be strongly associated with considerate and relations-oriented leadership behavior, but the leaders' superiors may evaluate the leaders more favorably for their emphasis on production and their task orientation. As will be seen in [Chapter 18](#), one leadership style—negotiation or manipulation—was related to the salary levels attained by managers (usually determined by their superiors) adjusted for age, seniority, education, function, and so on. Yet negotiative or manipulative behavior was the one leadership style that was likely to be negatively related to subordinates' satisfaction and subordinates' ratings of the effectiveness of work groups.

Thus individual managers may be most successful in hierarchical organizations if they pursue the role prescriptions set forth by Miner. However, in the absence of evidence, one can only guess, given R. Likert's (1977b) long-range studies (see [Chapter 17](#)), that their organizations are likely to suffer from the consequences of subordinates' grievances, absences, turnover, and dissatisfaction, as well as from vertical and lateral blockages and filtering of communication. Nevertheless, Miner may be performing an extremely important service in pointing out the fundamental conflict, noted by Argyris (1964a) and Culbert and McDonough (1980), among others, between the integration of the long-term objectives of the individual manager and those of the organization.

In the twenty-first century, to survive and prosper, even the largest of hierarchical organizations require flexibility in meeting the challenges of rapidly changing technologies and markets. Professional-like concerns for commitment, loyalty, and involvement have become increasingly important. Entrepreneurial (or intrapreneurial) attitudes and behavior are also important for the organization's members. It would seem that some complex combination of what is being measured by MSCS Forms H, P, and T would become increasingly relevant in the healthiest of organizations.

## Inactive or Laissez-Faire Leadership

---

Bradford and Lippitt (1945) conceived of laissez-faire leadership as descriptive of leaders who avoid attempting to influence their subordinates and who shirk their supervisory duties. Such leaders are inactive and have no confidence in their ability to supervise. They bury themselves in paperwork and stay away from their subordinates. They may condone "license." They leave too much responsibility with subordinates, set no clear goals, and do not help the group to make decisions. They let things drift. Laissez-faire leaders are indifferent to what is happening. They avoid getting involved in making decisions and taking stands on issues. They divert attention from hard choices and abdicate responsibility. They "refuse to take sides in a dispute, are disorganized in dealing with priorities and talk about getting down to work, but never really do" (Bass, 1998). Fortunately, only a minority of elected or appointed leaders consistently abdicate their responsibilities. Although this inactivity is the least frequently observed by colleagues and subordinates (Bass & Avolio, 1989), many leaders still reveal it in varying amounts. Followers may replace such leaders in influence.

To some degree, the perception of leaders' passivity may be due to the motivation of their subordinates. For instance, Niebuhr, Bedeian, and Armenakis (1980) found that among 202 nursing personnel at a Veterans Administration hospital, those subordinates who were motivated toward self-goals of achievement, power, and independence perceived their leaders to be less active. Those with strong other-directed goals, such as a need for affiliation, saw their leaders as more active.

*Presidential Examples.* Ronald Reagan was one of the highest presidents and Lyndon Johnson was one of the lowest presidents in respect to inactivity. Jimmy Carter displayed such leadership only for some issues. Johnson and Carter immersed themselves in the details of what their administrations had to do. Yet although

Carter ordinarily was greatly involved in detail, particularly in the creation of his programs, he was much less active in implementing voluntary wage and price guidelines, a macroeconomic strategy that a president can initiate by himself. Carter's lack of much leadership in this regard contrasted with Johnson's style: Johnson was much more willing to use his presidential powers of persuasion and bargaining with business and labor. Carter was more restricted in his efforts. Johnson would have earned a low rating as a *laissez-faire* leader on this issue, whereas Carter would have earned a higher one. On many matters, Ronald Reagan was much more inactive as president than either Carter or Johnson. Reagan's subordinates usually had free rein to proceed as they thought best. The many scandals that surfaced during and after his administration could be attributed in part to his hands-off style and to poor choices by his subordinates. Still, in some matters he was highly active. He promoted activist interventions in economic policy such as cutting taxes and greatly increasing military spending. He strongly espoused less government intervention in domestic affairs. To take another example, whereas Theodore Roosevelt was a bundle of energetic activity, Calvin Coolidge slept 11 hours a day (Barber, 1985).

### ***Differences from Other Leader Behavior***

Inactive leadership should not be confused with empowering, delegation, management by exception, or granting autonomy to subordinates. Unlike a *laissez-faire* leader, an *empowering* leader sets boundaries within which subordinates are given discretion to act as they think best. The empowering leader follows up with resources, support, and caring. Delegation implies a leader's active direction of a subordinate to take responsibility for some role or task. The active *delegative* leader remains concerned and will follow up to see if the role has been enacted or the task has been successfully completed. The leader who practices *active management by exception* allows the subordinate to continue on paths that the subordinate and the leader have agreed on—until problems arise or standards are not met, at which time the leader intervenes to make corrections. In *passive management by exception*, the leader intervenes only if agreements are not kept or subordinates' performance falls below standards. This is less active leadership but still not *laissez-faire*.<sup>5</sup> More active leaders monitor their subordinates' performance, searching for discrepancies relative to accepted standards; more passive leaders wait for the discrepancies to be called to their attention (Hater & Bass, 1988). When *autonomy* is granted by a leader, subordinates are free to make many of the decisions affecting themselves and their assignments, but they work within constraints set by the leader, the organization, and the environment.

### ***Measuring Laissez-Faire Leadership***

The Multifactor Leadership Questionnaire (MLQ 5X; Bass & Avolio, 1997)—one of several such instruments—contains a 10-item scale that directly assesses *laissez-faire* leadership. Examples of items on the *laissez-faire* scale include “Only tells me what I have to know to do my job”; “Avoids making decisions”; and “If we don't bother him/her, he/she doesn't bother us.” Respondents indicate from 0 5 “never” to 4 5 “frequently, if not always” how often the focal leader displays each behavioral item. The scale total correlates .88 with a higher-order factor of passive leadership and 2.11 with a higher-order factor of active leadership. A factor analysis of the 10 MLQ items disclosed that two factors rather than one factor were needed to account for the 10 items. Six of the items were *laissez-faire*, as expected, such as “Absent when needed.” But the emergent second factor of three items dealt with empowering, e.g., “Avoids telling me how to perform my job.” In a follow-up Italian sample of 1,053 MLQ managers rating their immediate superiors, the second empowering factor could again be extracted (Bass, 1998).

## ***Correlates of Laissez-Faire Leadership***

As expected, laissez-faire scores correlated negatively with various measures of transformational leadership. For 1,006 respondents' descriptions of their leaders on scales of transformational leadership, correlations were as follows: charisma, 2.56; individualized consideration, 2.55; intellectual stimulation, 2.47; and inspirational leadership, 2.49. Correlations are similarly negative with contingent reward and with active (but not passive) management by exception. Van Loan (1994) obtained similar findings from 585 MLQ ratings by the subordinates of 83 supervisors, managers, and executives in a large public telecommunications utility.

## ***Antecedents of Laissez-Faire Leadership***

*Personal Predispositions.* The tendency to be an inactive, absent, or avoidant leader was predictable from several personality traits. Makiney, Marchioro, and Hall (1999) found for 69 undergraduates in 20 groups that MLQ laissez-faire scores were negatively correlated with "Big Five" agreeableness (2.25) and extroversion (2.31) as well as with self-schemata of dedication (2.31) and social influence (2.24). McCroskey (1977) conceived the notion of *communication apprehension* (CA) as a personality trait of fear and anxiety to describe stage fright, shyness, and reticence. CA inhibited verbal communication with others even when such communication was needed in responsible positions of authority. Verbal output was low (McCroskey & Richmond, 1979). A 20-item instrument was provided to assess CA by Scott, McCroskey, and Sheehan (1978). It was expected that some laissez-faire leaders would suffer from CA. In the same vein, Hogan and Hogan (2002) postulated an avoidant personality who fears failure and being criticized. The avoidant personality is cautious, detached, introverted, indecisive, conforming, and irrational. I would expect that an avoidant personality in a leadership role would be an inactive leader.

*Situational Circumstances.* A previously highly active manager can become inactive, avoiding taking any new initiatives, after learning that he or she is going to be transferred to another division or relocated in another country. Such leadership inactivity can be endemic in an organization with rigid boundaries between departments and individuals. Interdepartmental communications may be limited to infrequent e-mail and memos. Contacts may remain superficial and unimportant (Heuerman, 1999). Among 6,359 Roman Catholic priests, sisters, and brothers who responded to an MLQ survey, those in contemplative orders rated themselves highest (2.42) in laissez-faire leadership. Next highest (2.21) were those in mendicant orders. Lowest (2.08) were those in apostolic orders (Nygren & Ukeritus, 1993). Conversely, less inactivity would be expected among American managers compared with nationals from many other countries, because of the American cultural bias for action (Peters & Waterman, 1982). Van Loan (1994) found significant negative correlations in a public telecommunications utility company between MLQ (5X) laissez-faire scores of 83 executives, middle managers, and supervisors and organizational culture. The cultural variables had to do with humanism, achievement, affiliation, and self-actualizing. They were measured by Cooke and Lafferty's Organizational Culture Inventory. Passive management by exception and laissez-faire leadership correlated positively with more dismissals of employees.

## ***Effects of Inaction and Laissez-Faire Leadership***

*Research Beginnings.* Democratic and autocratic leadership<sup>6</sup> were compared with the laissez-faire leadership of adults who were instructed how to lead boys' clubs (Lewin, Lippitt, & White, 1939; Lippitt,

1940a). Laissez-faire leaders gave group members complete freedom of action, provided them with materials, refrained from participating except to answer questions when asked, and did not make evaluative remarks. This behavior was in contrast to that of autocratic leaders, who displayed a much greater frequency of order giving, disrupting commands, praise and approval, and nonconstructive criticism. It also contrasted with the behavior of democratic leaders, who gave suggestions and stimulated the boys to guide each other. The groups were less well organized, less efficient, and less satisfying to the boys under laissez-faire conditions than under democratic conditions. The work was of poorer quality, less work was done, and there was more play, frustration, disorganization, discouragement, and aggression under laissez-faire leadership than under democratic leadership. When groups of boys were required to carry out various projects under highly laissez-faire leadership, they felt a lack of organization to get things done and did not know where they stood. When an autocratic leader was followed by a laissez-faire leader, the group exhibited an initial outburst of aggressive, uncontrolled behavior. This form of behavior subsided during the second and third meetings. Similar outbursts were not observed after the transition from laissez-faire to other forms of leadership. Although it did not stimulate as much aggression as the autocratic condition did, laissez-faire leadership was disliked because it was accompanied by less sense of accomplishment, less clarity about what to do, and less sense of group unity. The investigators (Lippitt & White, 1943; White & Lippitt, 1960) concluded that laissez-faire leadership resulted in less concentration on work and a poorer quality of work than did democratic and autocratic leadership. There was less general satisfaction with laissez-faire leadership than with the democratic style, but somewhat more satisfaction with laissez-faire than with the autocratic style that was employed in this study. Subsequent research suggested that the satisfaction of followers will be lower under laissez-faire leadership than under autocratic leadership if the latter is nonpunitive, is appropriate for the followers' levels of competence, or is in keeping with the requirements of the situation.

*Effects on Productivity, Satisfaction, and Effectiveness.* Laissez-faire leadership has been consistently found to be the least satisfying and least effective management style. The original observations of Lewin, Lippitt, and White have been supported in a variety of survey and experimental investigations of the impact of laissez-faire leadership on subordinates' productivity and attitudes. Pelz (1956) reported that the laissez-faire pattern of leadership was negatively related to productivity in a research organization. In a study of railroad-section groups, Katz, Maccoby, Gurin, and Floor (1951) found that the work groups were unproductive if their super visors avoided exercising the leadership role and re linquished it to members of the work group. These supervisors also did not differentiate their role from the role of worker. Like their subordinates, they engaged in production work rather than spend their time in supervisory functions. Berrien (1961) studied groups that differed in their adaptation to changes in work. Poorly adapted groups felt little pressure from their leaders and appeared to attribute their poor performance to lax discipline.

In an experiment by Murnighan and Leung (1976), undergraduate participants who were led by uninvolved leaders were less productive, in terms of the quality and quantity of the problems they solved, and less satisfied in comparison with participants who were led by involved leaders. Argyris (1954) conducted a case study in a bank in which the management recruited supervisors who were interested in security and predictability, disliked hostility and aggression, and wanted to be left alone. The bank's recruitment policy fostered in employees a norm of low work standards and unexpressed dissatisfaction.

Watson (1993) collected 47 evaluations of 10 radio stations and the MLQ laissez-faire scores of the station managers. The mean laissez-faire scores of the managers was 2.45 at the five poorer stations but 1.88 at the five better stations. The expected negative correlations of laissez-faire leadership with the effectiveness of outcomes and subordinates' satisfaction with the leadership generalized across different kinds of leaders, across different kinds of situations, and for outcomes with both soft and hard data. Thus correlations ranging from 2.29 to 2.60 were reported by their subordinates for 49 division heads, 58 production managers, 75 project leaders, 28

religious ministers, 9 vice presidents, 38 midlevel managers, 186 junior naval officers, and 318 senior naval officers between the laissez-faire leadership of their leaders and the leaders' contribution to the effectiveness of their organizations (Bass & Avolio, 1989). Comparable negative correlations were found between laissez-faire leadership and superiors' appraisals of the performance and promotability of business managers (Hater & Bass, 1988) and naval officers (Yammarino & Bass, 1990), and with financial outcomes of simulated businesses (Avolio, Waldman, & Einstein, 1988). In the same way, Arvonen (1995) established for Swedish workers in two plants that job satisfaction and sense of well-being were lower if their supervisors were rated by the workers as laissez-faire leaders. In the same way, Antonakis (2000) obtained the comparable negative correlations of the MLQ laissez-faire scores of 19 faculty members in 36 classrooms from ratings of 584 students at an international center in Switzerland, as follows: course evaluation, 2.22 faculty member's skills, 2.30, and faculty member's patience and accessibility, 2.31.

*Military Example.* The negative effects of laissez-faire leadership are most pronounced in military commands. The Crimean War has been regarded as the most ill-managed in British history. The commander in chief, Lord Raglan, had no previous experience of command. Five of the seven members of his staff, known as the "nest of noodles," were his blood relatives. Raglan's incompetence was matched by his inactivity as a leader. His staff avoided troubling him with details and made light of possible difficulties. He was aloof and an extreme introvert who avoided direct contact with his men. (He must have had a bad case of oral communication apprehension.) "He could hardly bear to issue an order" (Dixon, 1976, p. 39). His one order before the successful battle of Alma was of little consequence, and the disaster of the charge of the Light Brigade into the Russian cannon batteries at Balaklava was partly due to his ambiguous order. He permitted his commander of cavalry, Lord Cardigan, to live separated from his troops every night on a private yacht and take up valuable Balaklava harbor space. Raglan was so confident that Sebastopol would be captured before the winter of 1854 that he made no plans to house and maintain his troops on high ground above the city. There was no issue of fuel or stores, and 35% of his army strength was lost over the winter due to exposure, malnutrition, and cholera. Raglan took no steps to ease the hardship of his troops, which he could have done if he had been concerned about their welfare and morale. After the first defeat in 1855 in the effort to scale the walls of the fortress at Redan, "Raglan's army had no illusions as to the incompetence of their general and his staff. ... The plans ... turned out to be so execrably bad that failure was inevitable. Others described the battle as mismanaged, botched, bungled and a disgracefully childish failure" (Dixon, 1976, pp. 48–49).

*Other Effects.* Before self-management (with shared leadership) was conceived in the 1970s, Arensberg and McGregor (1942) wrote a case study of an engineering department without supervisors. A management committee approved the department's plans and checked its progress. The management considered this arrangement to be ideal for creative work. The employees, however, felt insecure and constrained in this overly permissive environment. Farris (1972) demonstrated that the less-innovative of 21 scientific groups at the National Aeronautics and Space Administration had less peer and managerial leadership. In addition, the leadership of these less-innovative groups was less task or relations oriented and less consultative or participative. Baumgartel (1957) studied directive, laissez-faire, and participative patterns of leadership behavior. Group members under laissez-faire leadership reported more isolation from the leader and less participation in decision making than those under directive leadership. These results suggested that laissez-faire leadership lessened the cohesiveness of the group members. Makiney, Marchioro, and Hall (1999) noted that in 20 student task groups, less task-facilitation was reported if the leadership was rated laissez-faire. Without "leadership engagement"—that is, if the leader's involvement was limited and the leader lacked commitment—Jaffe and Scott (1998) felt that re-engineering programs were doomed to failure.

Kidd and Christy (1961) studied three patterns of behavior: laissez-faire, active monitoring, and participative leadership. They found that although the speed of processing work was greatest under laissez-faire

leadership, there was much less avoidance of errors, particularly in comparison with active-monitoring leadership. Aspegren (1963) compared laissez-faire, directive, and participative patterns of leadership and found that laissez-faire leadership was associated with lower task motivation and lower satisfaction with superiors. Similarly, W. S. MacDonald's (1967a, 1967b) study of three styles of leadership (laissez-faire, dominant, and democratic) in the Job Corps found that laissez-faire leadership was associated with the highest rates of truancy and delinquency and with the slowest modifications in performance. Wehman, Goldstein, and Williams (1977) reported results from an experiment in which four leadership styles were varied to study their effects on 80 undergraduates' individual risk-taking behavior in group settings and the shift in risk-taking behavior when the responsibility for making decisions moved from the individuals to groups. They found that the shift in such behavior was more likely to occur in "laissez-faire-led" groups and "no-designated-leader" groups than in groups led by a democratic or autocratic leader.

Boss (1978) studied seven top-level administrative staffs from selected public agencies who engaged in a confrontation team-building program for six days. The only group that showed growth, according to subjective pre-post measures, was the group in which the chief executive officer (CEO) was present. The other six groups, in which no CEO was present, either retrogressed or did not change. This finding was consistent with the failures reported in organizational development efforts elsewhere, which were attributable to the lack of support from the CEO (Boss & McConkie, 1976) or the inability of the CEO to understand the objectives and processes of organizational development (Derr, 1972). This was consistent with 360 degree findings by Tsui, Ashford, St. Clair, et al. (1995) that ineffectiveness resulted when 410 managers failed to exert extra effort, failed to explain decisions, and avoided responsibilities.

### ***Effects of Supervisory Lack of Concern for Performance and Maintenance***

Misumi (1985) provided a great deal of indirect evidence that a leader's lack of active concern for subordinates' performance and for the maintenance of relations (combined pm leadership) was consistently worse for organizational outcomes than active PM leadership (that is, (P) (P)erformance-oriented or (M) (M)aintenance-oriented leadership, where p and m signify below median rating and P and M signify above median rating). For example, Misumi reported that the annual accident rate per 100 of Nishitetsu bus drivers for a three year period was 79.1 if the bus drivers were supervised by pm dispatchers; it was 44 to 52 per 100 if the dispatchers were P, M, or PM. Similarly, Misumi found that the job satisfaction of 2,257 employees in 186 Mitsubishi work groups was above average in 28% of the pm-led groups but above average in 37 to 73 percent of the P-, M-, or PM-led groups. A similar pattern emerged for the employees' satisfaction with the company.

Furthermore, the adequacy of communication was 14.7 under pm leadership and 16.0 to 17.5 under P, M, and PM leadership, respectively. The rated performance was high in only three of 92 squads in a bearing manufacturing firm led by pm supervision, but it was high in 10, 11, and 16 of P, M, and PM squads. Similar results with regard to productivity were obtained in surveys in other industrial companies (coal mining, shipbuilding, tire manufacturing, and automobile manufacturing). These surveys also found that regardless of the industry, pm leadership ranked last in relation to the productivity of groups, in comparison with P, M, and PM leadership. Only 6% of 883 pm engineering project managers were found to be successful, in contrast to 25, 16, and 52 percent of P, M, and PM project managers, respectively. Among 967 governmental employees, the measures of morale were uniformly lowest under the pm leadership of section chiefs than under the P, M, and PM leadership of such chiefs. The same pattern held for the leadership of Japanese schoolteachers, according to their pupils, and for children's reports about the consequences of their parents' pm, in contrast to P, M, and PM leadership for the children's understanding, compliance, pride, intimacy, and respect. Misumi (1985, pp. 251–259) also reported the results of a Japanese experiment in which for groups

that were high in motivation to achieve, the highest productivity occurred with PM supervisors. When the motivation to achieve was low, P-type leadership alone generated the most productivity. But regardless of the group's motivation to achieve, productivity was lowest with PM supervisors.

### ***Subordinates' Autonomy and Laissez-Faire Leadership***

Subordinates favor autonomy. Laissez-faire leadership provides autonomy. Laissez-faire leadership is dissatisfying to subordinates. Is this a contradiction? Freedom is a mixed blessing. If it means anarchy—an absence of control of oneself or others; an absence of needed organizational sanctions; the concentration of organizational control at the bottom so that individual goals take precedence over organizational goals; and an unregulated, leaderless, competitive marketplace for resources within the organization in which all the members are trying to maximize their own self-interests—it is likely to generate organizational ineffectiveness (Miner, 1973; Price, 1968; Tannenbaum, 1968).

If freedom implies the lack of systematic processes in problem solving, it will also result in ineffectiveness of outcomes. Thus when Maier and Maier (1957) experimented with discussions under free and more systematic styles of leadership, they found that free discussion produced decisions of lower quality than systematic, controlled, step-by-step discussion. They also noted that freer approaches to problem solving were less effective and less satisfying and yielded less commitment from participants than did systematic problem solving. Thus, when Maier and Solem (1962) compared 50 free-discussion groups with 96 groups of four participants each who used problem solving in systematic steps, the quality of the solutions was likely to be lower in the free-discussion groups than in the systematic groups. Only 12% of the free-discussion groups created integrated solutions that met the criteria of success, whereas almost half the systematic groups did. Maier and Thurber (1969) reported similar results.

Nonetheless, evidence can be mustered to support the contention that employees who feel a great deal of freedom to do their work as they like tend to be more satisfied and productive. When Morse and Reimer (1956) arranged for the authority of operative employees in two departments to be increased to strengthen the employees' autonomy, they found that both satisfaction and productivity increased. O'Connell (1968) changed the responsibilities and behavioral patterns of first-level supervisors in an insurance company. Even though the supervisors became bogged down in paperwork to a greater extent than was expected, sales improved and insurance lapse rates declined to some degree. Meltzer (1956) reported that scientists are most productive when they have freedom to control their research. Pelz and Andrews (1966a, 1966b) studied scientists and engineers in several laboratories. They found that the most effective scientists were self-directed and valued freedom, but that these scientists still welcomed coordination and guidance from other members of the organization. Similar results were reported by Weschler, Kahane, and Tannenbaum (1952) and by Tannenbaum, Weschler, and Massarik (1961) for two divisions of a research laboratory. Indik (1965b) studied 96 organizations of three types and found that workers' freedom to set their own pace of work was associated with productivity and satisfaction with their jobs. Trow (1957) reported that experimental groups with high degrees of autonomy provided greater satisfaction to members than groups in which members were dependent on a centralized structure. March (1955) analyzed patterns of interpersonal control in 15 primitive communities and found that productivity was related to the degree of the groups' autonomy. In A. K. Rice's (1953) study of a weaving shed in India, a type of reorganization that gave workers greater autonomy resulted in increased efficiency and decreased damage.

*Effective Autonomy.* Laissez-faire leadership does not imply effective autonomy for subordinates. Laissez-faire leadership is detrimental to the performance of subordinates, yet the autonomy of subordinates enhances

the subordinates' performance. The reconciliation comes in considering what subordinates need to do their job well. If the subordinates are skilled, professional, or self-starting salespeople, they may need consultation, *participation*, or delegation, with the *directive* boundary conditions specified by the leader, the organization, or even the task itself. Within these boundaries, the leader should permit the already competent and motivated subordinates to complete their work in the manner they think best. This kind of leadership, paradoxically, requires that the leader exercise authority to permit such freedom of action (Bass, 1960). Active follow-up by the leader is also important because it provides evidence that the subordinates' performance is as expected and shows the subordinates that the leader cares about what they are doing. This type of leadership is not related in any way to laissez-faire leadership, in which the leader does nothing unless asked by colleagues and even then may procrastinate or fail to respond. The laissez-faire leader is inactive, rather than reactive or proactive. He or she does not provide clear boundary conditions; may work alongside subordinates; may withdraw into paperwork; and avoids, rather than shares, decision making. Under this type of leadership, subordinates do not feel free to carry out their jobs as they see fit; instead, they feel uncertain about their own authority, responsibilities, and duties. Results reported by Farris (1972) support this distinction between working under laissez-faire leadership and being provided with freedom. In a study of 21 research teams, Farris found that the provision of freedom to subordinates was highly related to innovation when the leaders preceded their decision making consult with their subordinates. But when supervisors made little use of consultation beforehand, their provision of freedom was uncorrelated with innovation by their subordinates.

Further indirect support comes from a review of leaderless groups by Desmond and Seligman (1977). In the 28 studies that were reviewed, groups with more intelligent participants obtained positive results and were likely to be more highly structured by specially prepared audio-tapes, preprinted instruction, and instrumented feedback of group opinion, which substituted for the missing leaders. That is, the freedom of the leaderless group could result in productivity if the participants had the competence and information to deal with the situation and obtained the necessary instructions to clarify the boundary conditions within which they could carry on.

*What About Delegation, Management by Exception, and Participation?* The contrary consequences on the effectiveness of subordinates of the subordinates' freedom and autonomy on the one hand and the ineffectiveness of laissez-faire leadership on the other hand reside to some extent in the confusion of laissez-faire leadership with the practice of delegation, management by exception, and participative leadership. Although delegation and active management by exception are not as satisfying or effective as more active leadership, they nevertheless may contribute to the effectiveness of subordinates in some kinds of organizations, such as the military. This is unlike passive management by exception, which is more like laissez-faire leadership in its effects, and forms a factor of passive leadership with the latter (Bass & Avolio, 1997).

The inactive laissez-faire leader, unlike a leader who delegates, does not delineate the problem that needs to be solved or the requirements that must be met. The inactive laissez-faire leader, unlike a leader who practices management by exception, does not search for deviations from standards or intervene when deviations are found. The inactive laissez-faire leader, unlike a participative leader, does not engage in extended discussions with subordinates to achieve a consensual decision.

The inactivity of laissez-faire leaders—their inability or reluctance to accept responsibility, give directions, and provide support—has been consistently negatively related to productivity, satisfaction, and cohesiveness. Sheer energization, drive, motivation to succeed, and activity are likely to be correlated with successful leadership and influence.

## Summary and Conclusions

---

This chapter began by looking at how some personality traits, such as energy level and assertiveness, contribute to one's attempts to lead, participate, interact, and emerge as a leader. In turn, the emergence of a leader is sustained by its positive consequences. Members of a group who possess information that enables them to contribute more than other members to the solution of the group's task tend to emerge as leaders. However, a would-be leader who is overloaded with information may become handicapped.

Observational studies have identified several patterns of leader behavior that were not anticipated by the trait theorists. Emergent leaders in experimental and in natural groups tend to be valued because their spontaneity is contagious and they stimulate spontaneity in others. They widen the field of participation for others and expand the area of the group's freedom to make decisions and to act. They protect the weak and underchosen, encourage participation by less capable members, are tolerant of those who deviate, and accept a wide range of personalities of members.

Leaders and managers need to empower themselves to shape their work environment. The simple fact that active, energetic, assertive people are more likely than the "silent majority" to influence the course of events around them makes it difficult to accept the notion that leadership is a phantom of our imagination. The data are compelling. Leaders and managers need to be active, not passive. But merely being active is only a small part of the total explanation of who emerges and succeeds as a leader. Managers' successful advancement depends on the motivation to manage, but it needs to be assessed differently in hierarchical and professional organizations. Theory and evidence were presented that contained the seeds of two propositions: (1) to emerge as a leader, one must be active in attempting to lead, and (2) to succeed and remain acceptable to others as a leader, the leader must exhibit competence. This chapter concentrated on the first proposition and indicated how it needs to be qualified.

Uniformly, laissez-faire leaders are downgraded by their subordinates. Productivity, cohesiveness, and satisfaction suffer under such leadership. But laissez-faire leadership should not be confused with delegation, empowerment, or granting autonomy to subordinates. Effective autonomy can enhance subordinates' performance. Freedom of action is usually conducive to innovation by subordinates. In contrast to laissez-faire leadership, active and responsible assertiveness among subordinates may be required. Whether leaders are active or passive may depend on the issues and circumstances, not just their own personal predilections. For example, a sharp increase in laissez-faire leadership may occur when leaders are notified that their positions are being eliminated or that they are to be transferred in the near future. These situational issues, as they affect leadership and management, will be addressed in Chapters 26 through 30. The antecedents and consequences of authoritarianism, Machiavellianism, and power orientation in the personality of the emergent leader will be considered next, in [Chapter 7](#).

<sup>1</sup> As defined in Chapter 18, *direction* refers only to giving orders with or without explanation. Direction (roman) includes ordering, persuading, and manipulating. *Participation* (italics) refers only to sharing in the decision process. Participation (roman) includes consulting, sharing, and delegating.

<sup>2</sup> Bartol, Anderson, and Schneier (1980) found that during the 1970s, there was an acute reversal of the decline in the motivation to manage of students at Syracuse University and the University of Maryland. They observed that the levels of motivation returned almost to those of 1960. However, the differences in trends in Oregon and Syracuse appear to be due to differences in the training of the scorers of the MSCS (Bartol, Schneier, & Anderson, 1985; Miner, Smith, & Ebrahimi, 1985).

<sup>3</sup> See Larson, Hunt, and Osborn (1976); Nystrom (1978); and Schriesheim (1982).

<sup>4</sup> More about this in [Chapter 31](#).

<sup>5</sup> Yammarino and Bass (1989) found that the correlations with laissez-faire leadership are negative when the manager actively searches for exceptions and are positive when the manager gets involved only when exceptions are called to his or her attention. Overall management by exception correlated .44 with passive leadership and .16 with active leadership (Bass, 1985a).

# Authoritarianism, Power Orientation, Machiavellianism, and Leadership

Many seek power and depend on their use of power, rather than on their competence to lead (Jongbloed & Frost, 1985). It would seem reasonable to expect that those who strongly endorse the exercise of power and authority in dealing with subordinates would be motivated to lead. But the authoritarian personality, or syndrome, should not be confused with the overt exercise of authority (Christie & Cook, 1958). Similarly, the personal motivation to gain and hold power is not the same as having power to exercise. Nevertheless, Pinnell (1984) found that compared with leaders in positions that lack power and authority, leaders in positions of power and authority were more likely to perceive power as good. Thus when Pearson and Sanders (1981) conducted a survey of appointed career and political state executives in seven U.S. states using a questionnaire that contained six questions about authoritarianism, submissiveness, conventionality, power, and toughness, they found that the state executives, particularly the less-educated executives with more state service, supported authoritarianism to a greater degree than they opposed it. They also found that public safety executives were more authoritarian in attitude than social service executives.

*Conformity* is the acceptance of influence. *Conventionality* is the acceptance of impersonal standards. *Conservatism* is the acceptance of a social, economic, or political structure. *Ethnocentrism* is the acceptance of one's ethnic group and the rejection of others. *Dogmatism* is the acceptance of one system of thought and the rejection of other systems. *Acquiescence* is the acceptance rather than the rejection of ambiguous or unknown stimuli. *Religiosity* is the acceptance of a particular set of organized beliefs, rituals, and practices having to do with God, morality, the origins of life, and an afterlife. *Authoritarianism* correlates with conformity, conventionality, conservatism, ethnocentrism, dogmatism, acquiescence, and religiosity, but is not the same as any of these. (Citizens of the Former Soviet Union who emigrated to Israel are an exception. Their lack of religiosity was unrelated to their authoritarianism, which was attributed to their socialization under Communism; Rubenstein, 2002).

## The Authoritarian Personality

---

According to Samuelson (1986), Wilhelm Reich was the first to use authoritarianism in Marxist and Freudian terms to explain Hitler's rise to power in Germany in 1933. Erich Fromm (1941) expanded on the idea from an analysis of a survey of German workers. Also influential were the Frankfurt school of Critical Theory in the 1930s and the rise of the Nazis. The concept moved from politics and psychoanalysis into social psychology (Sanford, 1986). In their book *The Authoritarian Personality*, Adorno, Frenkel-Brunswik, Levinson, and Sanford (1950) postulated an authoritarian type of personality, characterized as politically and religiously conservative, emotionally cold, power seeking, hostile toward minority groups, resistant to change, and opposed to humanitarian values. To measure authoritarianism and assess the authoritarian personality, they presented the *F* Scale.

### *The F Scale as a Measure of Authoritarianism*

*Description of the F Scale.* The statements in the *F* scale include such ideological right-wing clichés as: “People can be divided into two distinct classes, the weak and the strong”; “No weakness or difficulty can hold us back if we have enough willpower”; “What a youth needs most is strict discipline, rugged determination, and the will to work and fight for family and country”; and “Most of our social problems would be solved if we could somehow get rid of the immoral, crooked, and feeble-minded people.” The items dealt with conventionality, submissiveness, aggressiveness, superstition, toughness, cynicism, projection, preoccupation with sex, violation of sexual norms, and disapproval of emotionality and intellectuality. Correlations with the *F* Scale suggested that the authoritarian personality was unable to accept blame and favored using status and power over love and friendship (Sanford, 1956). A social and political reactionary was likely to earn a higher authoritarian score than a social and political liberal (Christie, 1954; Shils, 1954).

*Critique.* The *F* Scale was criticized for various reasons, including psychometric weaknesses. Some of its variance was due to the error of response set. For instance, all statements on the *F* Scale were couched in the same power-oriented terms. Endorsement of any statement implied support of an authoritarian ideological point of view. But it appeared applicable only to extreme conservatives. Rokeach (1960) argued that extreme radicals were just as authoritarian in their beliefs as extreme conservatives. He developed the Dogmatic (*D*) Scale which measured closed-mindedness without getting into political ideology and provided a psychometrically better instrument.

Bass (1955a) and Chapman and Campbell (1957b) completed research analyses suggesting that scores on the *F* Scale could be explained mainly by the response set of social acquiescence—the general tendency to agree rather than disagree, to say yes rather than no, to accept rather than reject statements. However, after an error in calculation was corrected, the percentage of variance due to social acquiescence was found to account for only about one-quarter of the variance in the scores on the *F* scale. Some of the responses to the *F* Scale could be attributed to social acquiescence, but for the most part the scores still provided a substantive measure of the authoritarian syndrome (Bass, 1970). Nonetheless, its relationship to social behavior did not appear consistently.

*Factorial Validity.* According to a factor analysis by Altemeyer (1981), some of the expected factors of authoritarianism emerged in the *F* scale; these included conventionality, submissiveness, and aggressiveness. However, in Bass and Valenzi’s (1974) factor analysis, authoritarianism, as measured by the *F* Scale, was one of the four personality factors that appeared independent of assertiveness, sense of fairness, and introversion-extroversion.

*Construct Validity.* Evidence of the construct validity of the *F* Scale was obtained by Campbell and McCormack (1957), who found that the scores of U.S. Air Force cadets were more authoritarian than those of college students. But contrary to expectations, the cadets’ scores on authoritarianism decreased with the time they were in the air force. According to Masling, Greer, and Gilmore (1955), authoritarians among 1,900 military personnel rated other group members less favorably than egalitarians did. In turn—as was consistent with earlier studies by Jones (1954) and Thibault and Riecken (1955a)—Wilkins and DeCharms (1962) reported that, as expected, authoritarians were influenced by external power cues in evaluating others and used fewer behavioral cues in describing others. Authoritarians were also more highly influenced by considerations of status in making evaluations. Many studies revealed that those with high *F* Scale scores were also ethnocentric and prejudiced toward minorities and foreigners (e.g., Linville & Jones, 1980). High *F*’s were conventionally religious and reactionary (Eckhardt, 1988) and scored high on scales of dogmatism and Machiavellianism (Eysenck & Wilson, 1978).

*Low F Scores: Egalitarian Leaders.* In an experiment and its replication, Haythorn, Couch, Haeffner, et al. (1956a,b) formed two groups, one with high ratings on the *F* Scale (authoritarian) and the other with low ratings on the *F* scale (egalitarian). The 32 participants viewed a film and met in their groups to compose dialogue for it. According to pairs of reliable observers, the egalitarian leaders were significantly more sensitive to others, contributed more toward moving the group closer to goals set by the group, showed greater effective intelligence, and were more submissive in their attitudes toward other group members than were the authoritarians.<sup>1</sup>

Since egalitarians are more likely to become leaders in their communities, Courtney, Greer, and Masling (1952) reported that the community leaders they studied were significantly more egalitarian than their followers. Greer (1953) interviewed 29 leaders in Philadelphia and found that the leaders' scores were significantly more egalitarian than those of nonleaders. Tarnapol (1958) obtained similar results. Leaders in highly conservative communities might be different. Egalitarian leaders tended to promote more participation. Thus in experiments by Haythorn, Couch, Haeffner, et al. (1956a, 1956b), followers tended to be able to exert more influence and to express more differences of opinion. Authoritarian leaders were described as being more autocratic, less democratic, and less concerned with the group's approval than the egalitarian leaders.

Rohde (1952) administered the *F* Scale to 176 members of an aircrew who were also rated by their crew commanders on three criteria: authoritarianism (high *F* scores) correlated  $-.33$  with the commander's willingness to take the airmen into combat,  $-.46$  with the commander's perception of the desirability of the airmen as friends, and  $-.11$  with the commander's confidence in the airmen as members of the crew. Ley (1966) found a strong correlation of  $.76$  between the turnover rate of industrial employees and the authoritarian scores of their supervisors. But contrary to hypothesis, a leader's authoritarianism was not related to several measures of the effectiveness and performance of his group. Likewise, Hamblin, Miller, and Wiggins (1961) failed to find a significant correlation between a leader's authoritarianism and measures of his group's morale and success. To obtain such effects from authoritarian leaders, contingent circumstances need to be taken into account.

*Right-Wing Authoritarianism (RWA).* Since both fascists and communists scored high on the *F* Scale, a Right Wing Authoritarianism (RWA) scale was developed and validated by Altemeyer (1981) as a motivational syndrome. It assesses submission to authority, aggressiveness sanctioned by established authorities, and adherence to conventions endorsed by authorities. Those with high RWA scores were more likely to: (1) accept illegal acts by government officials to harass and intimidate their opponents; (2) prefer right-wing political parties; (3) be less convinced that President Richard Nixon was engaged in a Watergate cover-up; (4) favor authoritarian leaders; (5) endorse punishment for disobedience without considering circumstances; (6) award longer prison sentences; (7) give more severe sentences to violent gay demonstrators compared to violent antigay demonstrators; (8) in experiments, administer supposedly stronger electric shocks to participants for failure to learn; and (9) be more ethnocentric.

### ***Relation to Competence***

On the basis of their reviews of the research literature, both Titus and Hollander (1957) and Christie and Cook (1958) concluded that authoritarianism, as measured by high scores on the *F* Scale, was negatively correlated with intelligence. Authoritarians tended to be not as bright as egalitarians and were also less educated. Courtney, Greer, and Masling (1952) administered the *F* Scale to a representative sample of residents of Philadelphia. Those who scored highest on authoritarianism were laborers and those with the least education. The lowest *F* scores were made by managers, officials, clericals, and salespeople. Professionals,

semiprofessionals, and university students scored between these groups.

Newcomb (1961) observed that authoritarians were less able than egalitarians to determine which group members agreed with them, and their sociometric choices were determined accordingly. Authoritarians were also likely to be less popular with their peers. In studying 2,139 naval recruits, Masling (1953) found that authoritarianism was negatively related to popularity.

Authoritarianism appears to decline with experience. Thus Campbell and McCormack (1957) found that authoritarianism decreased with increasing military experience in various samples of military personnel, and Rohde (1952) discovered that authoritarianism was not highly valued by officers who attained the rank of aircrew commanders.

## Authoritarianism and Leadership

---

### *Preferences in Leadership*

Milton's (1952) data indicated that in 1952, authoritarian college students, as measured by their scores on the *F* Scale, supported Douglas MacArthur's nomination for president (MacArthur symbolized and emphasized power and authority in leadership). Students with low *F* scores supported the nomination of Adlai Stevenson, who was portrayed as a more consultative problem solver. Sanford (1950) administered an authoritarian-egalitarian scale to 963 randomly selected adults in Philadelphia. Those who scored high on authoritarianism wanted a stern leader but one who was competent, understanding, and helpful. Those who scored low preferred a leader who was kind, friendly, and guided by the people. The strong leader who tells people what to do was accepted by the authoritarians but rejected by the egalitarians; the egalitarians wanted either to be told nothing by a leader or to be told what to do but not how to do it. The authoritarians tended to choose a leader for his or her personal magnetism and high status, whereas the egalitarians preferred a humanitarian leader who did things for people. Thus authoritarians favored being led by an autocratic, directive, structuring, task-oriented leader; egalitarians favored being led by a democratic, participative, considerate, relations-oriented leader.<sup>2</sup> Medalia (1955), who studied enlisted men in the U.S. Air Force, found that authoritarians expressed greater acceptance of formal leaders than egalitarians. Haythorn, Couch, Haefner, et al. (1956b) also found that authoritarians were more satisfied with appointed leaders and were less critical of their own group's performance.

### *Reactions to Leadership*

Thibaut and Riecken (1955a) studied the effects on authoritarians and egalitarians of attempts to influence them by persons who were of different ranks in an organization. They found that the authoritarians were more sensitive than the egalitarians to the organizational rank of a leader. The results of E. E. Jones (1954) were similar. However, Jones found that compared with authoritarians, egalitarians viewed the *forceful-stimulus* person as more powerful and the *passive* leader as less powerful. The egalitarians were more highly sensitized to differences in personal power and to behavioral cues while the authoritarians tended to differentiate leaders according to the institutional status of the leaders.

Thibaut and Riecken (1955b) also studied group reactions to a leader's attempts to instigate aggressive behavior. They found that authoritarian participants became more submissive when they faced a high-status instigator but tended to reject the efforts of a low-status instigator. In overt communication, the authoritarian

members were less intense in their rejection of the higher-status instigators than of the lower-status instigators. In a similar type of analysis, Lipetz and Ossorio (1967) found authoritarians less hostile toward high-status target persons than toward low-status targets whether or not these persons attempted to instigate aggression. To investigate a similar effect, Roberts and Jessor (1958) used projective tests to study the attitudes of authoritarians toward persons who were frustrating them. Compared with egalitarians, authoritarians tended to exhibit personal hostility toward low-status frustrators and to express hostility toward high-status frustrators only indirectly.

### ***Reactions to Authority***

According to Kelman and Hamilton (1989), persons of higher status and education were more likely to challenge and question authority. By contrast, rule-oriented followers tended to obey authority without question and to carry out orders without accepting personal responsibility. Rule-oriented followers obey out of a sense of powerlessness; role-oriented followers obey out of a sense of obligation to authority; value-oriented followers obey to fulfill a commitment to shared values.

### ***Authoritarianism and the Attitudes and Behavior of Leaders***

*Dominating Behavior.* Kalma, Visser, and Peters (1993) found that highly authoritarian personalities were much more likely to be aggressively dominant than sociably dominant. Aggressively dominant people had poorer interpersonal relationships than sociably dominant people and received lower ratings in task leadership.

*Use of Punishment.* Dustin and Davis (1967) asked participants to indicate whether they would use monetary rewards and penalties or evaluative communications to stimulate maximum performance in hypothetical followers. Compared with egalitarians, authoritarians used monetary penalties and negative evaluations more often. W. P. Smith (1967a) also found that authoritarians used punishment rather than reward as a method of inducing performance in others more than egalitarians. Authoritarian chief petty officers gave recruits more demerits (Masling, 1953). According to a review by Smither (un-dated), authoritarian parents were more likely to punish their children for violations of a code of conduct. However, using a different scale to assess authoritarianism, Baker, DiMarco, and Scott (1975) failed to find that authoritarianism was correlated with the use of penalties.

*Reactions to Unstructured Situations.* Bass, McGehee, Hawkins, et al. (1953) demonstrated that authoritarian personalities, as measured by the *F* Scale, were less likely to attempt or exhibit successful leadership behavior in an initially leaderless discussion—a socially unstructured situation that calls for considerable flexibility if one wishes to emerge as a leader. This finding was consistent with results reported by Bass and Coates (1952), who found significant correlations of .32 and .33 between the tendency of ROTC cadets to display successful leadership in initially leaderless group discussions and their scores on two measures of perceptual flexibility. Similarly, Geier (1963) observed that overly rigid members tended to be eliminated as leaders in the early stages of group discussion. Consistent with these findings, Hollander (1954) obtained nominations for a student commander from 268 naval aviation cadets that correlated 2.23 with the cadets' scores on authoritarianism.

*Authoritarian Parental Leadership.* According to research by Baumrind (1971), authoritarian parents try to teach their children to value obedience, respect for authority, tradition, order, and work. The parents

believe that their children should accept their ideas about what is right and what is wrong without discussion. The children's reactions tend to be distrustful, withdrawn, and discontented. But *authoritarian* parenting is not the same as *authoritative* parenting. Authoritative or directive parents use their status, power, and reason to direct and control their children. Such parents are warm and positively encouraging, and develop children who are self-controlled, explorative, and satisfied.

### ***Contingencies That Modify the Effects of a Leader's Authoritarianism***

The effects of leader's authoritarianism tend to be moderated by their followers' authoritarianism or egalitarianism, as well as by various other personal and situational factors. Researchers have often focused on the impact of the *followers'* authoritarianism on the leadership process, because submissiveness and obedience to a higher authority are firmly entrenched in the authoritarian personality. Thus in a study of Israeli naval officers and crews, Foa (1957) concluded that authoritarian commanders should be in charge of subordinates with authoritarian expectations.

*Match and Mismatch of Leaders and Followers: Effects on the Followers.* Numerous attempts have been made to examine what happens when authoritarian and egalitarian leaders have to work with authoritarian and egalitarian subordinates. Systematic effects have been observed on both the followers and the leaders. Some effects depend on whether followers and leaders are matched or mismatched in personality. Thus Vroom (1959, 1960a) found that subordinates who were authoritarian (according to their scores on the *F* Scale) tended to be less satisfied with and less motivated by working under participative leaders than were egalitarian subordinates. In this study of a package delivery firm, Vroom found that the extent to which employees were satisfied and effective under participative supervision depended on their being egalitarian and highly in need of independence. Campion (1969) confirmed Vroom's findings in an experimental study. But another replication of Vroom's study by Tosi (1970), using the same survey method as Vroom with a different organization and different jobs, failed to corroborate Vroom's results. However, Tosi noted that his respondents were different from Vroom's in terms of values, interests, and gender.

Tosi (1973) tested a supervisory-subordinate congruency hypothesis: that a personality match between the supervisor and subordinate could result in greater satisfaction and morale and in less conflict than a mismatch. Data were collected from 488 managers of consumer loan offices. Four samples were formed, high-*F* and low-*F* samples of authoritarian and egalitarian employees that worked for bosses who rated either high or low in "tolerance for freedom" on the Leadership Behavior Description Questionnaire, Form XII.<sup>3</sup> The congruency hypothesis was partially supported: job satisfaction and degree of participation were highest for the authoritarian subordinates who worked for bosses who lacked tolerance for freedom. But egalitarian subordinates working for bosses who had a high tolerance for freedom had the lowest levels of participation and satisfaction. These results suggest that some degree of structure or direction has to be present, whether in the boss or in the subordinate, to define the situation in which work is done.

Haythorn, Couch, Haefner, et al. (1956a, b) formed combinations of leaders and followers on the basis of high or low scores on the *F* Scale. They found that compared with egalitarian followers, authoritarian followers generally were rated by observers as less democratic and less sensitive to others, were more satisfied with their appointed leaders, and rated their groups higher in productivity and goal motivation. Unexpectedly, the authoritarian followers were not more submissive to the leaders than were the egalitarian followers, and they exercised more influence in their groups than did egalitarians. Observers rated the egalitarian followers lower than the authoritarian followers in productivity and goal orientation and higher in withdrawing from the field of activity.

Frey (1963) studied the disruptive behavior of differently composed groups under authoritarian and egalitarian leaders. The most disruption occurred in groups that were composed of both authoritarian leaders and followers; the least disruption occurred in groups that were composed of both egalitarian leaders and followers. The lowest performance occurred in groups that were composed of egalitarian leaders and authoritarian followers; the highest performance occurred in groups that were composed of both authoritarian leaders and followers.

*Match and Mismatch of Leaders and Followers: Effects on the Leaders.* Bass and Farrow (1977b), using path analysis, showed how the authoritarianism of leaders and followers affected a leader's style of leadership. They administered a short form of the *F* Scale to 77 managers and their 409 subordinates from industry and public agencies, and also asked subordinates to describe their managers' styles of leadership. Bass and Farrow found that authoritarian managers were not perceived to be wholly directive or participative. (Direction covers a variety of leadership styles including telling, ordering, and persuading; participation includes three styles: consulting, sharing decision making, and delegating.) Rather, authoritarian managers were seen as negotiative, manipulative, and opportunistic. Egalitarian managers were seen as more fair minded and more likely to consult with their subordinates. Authoritarian subordinates viewed their managers as more negotiative, particularly if the managers' perspectives were short-term rather than long-term. Managers with authoritarian personalities were short-term maximizers.

*Other Situational Contingencies.* Harrell, Burnham, and Lee (1963) demonstrated that authoritarians were more likely to emerge as leaders in task-oriented groups and egalitarians to emerge as leaders in socioemotional groups. The size and structure of the group were also found to make a difference in the effects of the authoritarianism or egalitarianism of the leader. Authoritarian personalities appeared to do better as leaders when interaction among members was constrained by the large size of the group and by centralization of the organization's communications. In comparing large and small work groups Vroom and Mann (1960) found that supervisors who scored high on the *F* Scale were more readily accepted in large groups than in small groups and that egalitarian supervisors were better accepted in small groups. In large groups, employees described authoritarian supervisors as more participative, exerting less pressure on employees, and creating less tension between themselves and higher management. In small groups, they viewed authoritarian supervisors as less participative and as creating more tension between supervisors and subordinates. Vroom and Mann also examined the relationship between the authoritarianism of the supervisors and the satisfaction of their subordinates. Subordinates whose jobs were characterized by little interaction with their supervisors and little interdependence had more positive attitudes about authoritarian supervisors.

M. E. Shaw (1955) studied the effects of authoritarian and egalitarian leadership in different communication nets. He found that groups under authoritarian leaders were highly productive but had low morale. M. E. Shaw (1959a) further reported that, as expected, groups with leaders who scored high in authoritarianism performed better in centralized networks, whereas groups with egalitarian leaders performed better in less highly centralized networks.

Overall, the evidence suggests that the authoritarian personality syndrome in a leader or a follower systematically affects the performance of both and their satisfaction with each other. Yet by the 1980s, research interest in the leadership performance of the authoritarian personality had dissipated. In its place was a more sharply focused interest in those who most often seek and acquire power, how they use it, and with what effects.

## Power Motivation

Individuals differ in their attitudes toward power; they also differ in their motivation and ability to seek and use it (P. J. Frost, 1986). Those with the motivation and willingness to use power in their dealings with others will use their interactions more consciously to get what they want and to gain control over situations. They will try to influence others directly by giving suggestions and opinions, by trying to change the opinions or actions of others, and by being forceful and argumentative. They may be seen by others as bossy and domineering, although if they have sufficient social skill, they may be perceived as inspirational (Stringer, 2001).

Those with skill in the use of power will embed that power in their communications with others and will use political tactics to influence what happens. Such tactical maneuvering or organizational politics embodies “the exercise of power [seen] ... in the ... tactics [members] use to get their way in the day-to-day, ongoing, present time functioning of [the] organization—it is power in action” (P. J. Frost, 1986, p. 22). According to a review by Dill and Pearson (1984), a model of such organizational politics better accounts for the effectiveness of managers of research and development projects than a rational model. Kotter (1979) adds that such dynamics of power contribute to an organization’s functioning.

Stringer (2002) suggests that those who are power motivated prefer organizations that are highly structured and hierarchical, have formal systems and rules, provide a sense of boundaries, and have control and influence mechanisms. Gordon (2002) laments the insufficient research and development coverage of power, especially when it occurs at a “deep level.”

### ***Measurement of Power Motivation***

Although need for power had been measured directly by questionnaires and personality inventories that assess manifest needs, power motivation and power needs have often been assessed by using respondents’ answers to the Thematic Apperception Test (TAT). Scores on this test are based on how much power the examiners find in stories the respondents invent when shown ambiguous sketches such as one of a man seated at a desk. A “power response” to such an ambiguous sketch in the test would be: “He disapproved because he was determined to get his way.” This response may be contrasted with a response that projects a need for achievement: “He was busy working and didn’t hear the bell.” It also may be contrasted with a response that projects the need for affiliation: “He kept looking at the photos of his family on his desk and wishing he was with them.” The Miner Sentence Completion Scale is another projective technique in which examinees complete sentences beginning with such words as “I feel ...” or “My job ...”, and the like. Power motivation can be estimated from the themes of the completed sentences.<sup>4</sup> Power orientation and motivation have also been measured indirectly but objectively by Harrell and Stahl (1981) by asking for preferences among alternative job assignments. Respondents indicated their relative preference for jobs having characteristics that appealed to different needs, including the need for power.

### ***The Imperial Motive***

Leaders need to have some degree of self-control and the ability to inhibit their own need for power. For instance, Jennings (1943) observed that leaders in girls’ schools controlled their own moods and did not inflict their anxieties and depressed feelings on others. McClelland (1985) concluded that if power motivation is low leadership potential generally will be absent. If power motivation is high *and activity is uninhibited*, the individual behaves like a “conquistador.” The tendency to inhibit activity is measured by obtaining the frequency with which the word “not” appears in stories written by an individual for the TAT. Activity inhibition is thought to reflect the restraint the individual feels about using power impulsively or using it to

manipulate or coerce others. McClelland proposed that some successful leaders are high in power motivation, low in the need for affiliation, and high in the inhibition of activity. This is the imperial motive pattern and signifies highly efficient organizing that may sometimes be channeled into *selfless leadership* that is oriented toward doing good for others. Those who score high in inhibition of activity reveal altruistic images of power. The good managers among McClelland and Burnham's (1976) imperials were motivated to serve their organizations. They generated among their subordinates team spirit, clarity of purpose, and a sense of responsibility for their work. House, Woycke, and Fodor (1986) found that six charismatic U.S. presidents—Jefferson, Jackson, Lincoln, the two Roosevelts, and Kennedy—revealed significantly more power and achievement motivation in their inaugural addresses, compared with the inaugural addresses of six noncharismatics: Presidents Tyler, Pierce, Buchanan, Arthur, Harding, and Coolidge.<sup>5</sup>(In [Part V](#), charismatic imperials are seen as socialized transformational leaders.) Those who score low in inhibition of activity have thoughts of power that center much more on personal dominance and winning at someone else's expense. They are personalized, pseudo-transformational leaders. McClelland found that male imperials joined more organizations than did male conquistadors and argued more frequently. Women imperials were elected to more offices than women conquistadors and accepted more responsibility.

Since activity inhibition, based as it is on the number of “nots” in TAT protocols, has little theoretical support or empirical validation, Winter and Barenbaum (1985) extracted a measure of responsibility from the TAT protocols based on whether moral-legal standards, obligations, self-judgments, concern for others, and concern about consequences were expressed in the protocols.

### ***Acquisition of Power***

Some individuals strive to acquire and to use power. Others obtain it, sometimes reluctantly, by being in a position of authority to deal with uncertainty, to negotiate the allocation of resources, and to maintain collaborative efforts. Power seekers make use of the power they gain if they believe their attempts to lead through power will be successful (Kipnis, 1976). Mowday (1978) agreed. He found that managers who had revealed a high need for power employed it more frequently if they perceived it to be useful to do so. In general, such managers preferred assignments in which they could exert leadership and actively influence and exert control over others. They obtained emotional satisfaction from experiencing the effects of their use of power. Along with satisfaction, they experienced aggressive feelings and physiological reactions like the release of catecholamines, which is associated with emotional experiences.

While power can be wielded for personal aggrandizement, it can be used to benefit others. For instance, entrepreneurs (individuals who behave innovatively in large, complex organizations) are task-oriented personnel who use power whenever they can to ensure that their ideas, inventions, and innovations are accepted in their organizations (Pinchot, 1985). Such entrepreneurs regard power as instrumental for the accomplishment of tasks and as something they share with others, rather than as a basis for personal aggrandizement. Kanter (1983) described such individuals as “quiet entrepreneurs,” who communicate in a collaborative-participative fashion. Although they could use their power to coerce others with threats and cajolery, they tended to be persuasive in their leadership style and to use many of the socially acceptable techniques of interpersonal competence—frequent staff meetings, frequent sharing of information, consulting with others, showing sensitivity to the interests of others, and a willingness to share rewards and recognition.

### ***Power Motivation and Careers***

The need for power was found important for success as a manager in a follow-up of 237 AT&T general

managers in nontechnical areas (McClelland & Boyatzis, 1982). Power orientation, measured using the Miner Sentence Completion Scale, also contributed to predictions of the respondents' plans to work as managers, according to Miner and Crane (1981). Although scientists and engineers were found to prefer jobs that provide opportunities to satisfy their need for achievement, successful executives had a higher need for power (Harrell & Stahl, 1981). A sense of responsibility moderated the effects of power, as predicted. McClelland and Boyatzis (1982) examined the imperial power motive in the 422 managers in the original 1956 AT&T assessment study (Bray, Campbell, & Grant, 1974). Up to 77% of those revealing *responsible power* were at level 3 or higher at AT&T 16 years later. Only 56% with other motive patterns lacking in both power motivation and responsibility reached this level (Winter, undated).

Cummin (1967) and Wainer and Rubin (1969) found that high power motivation coupled with high achievement motivation was associated with the success of managers. Stahl (1983) corroborated these findings in a large nationwide sample of managers in which the rating of the managers' performance and the managers' rate of promotion were connected with a great need for power and for achievement, as measured by an objective test. In a study of elected politicians in two local settings, Browning and Jacob (1964) observed that strongly power-oriented and achievement-oriented men were more likely to occupy political offices with greater potential to achieve and to exercise power. Those with little need for power and for achievement did not hold such offices. Power-motivated individuals also pursue careers other than politics that allow them to exert influence over others, such as teaching, psychology, business, or journalism. Those with little power motivation choose careers with fewer opportunities to influence others.

### ***Power Motivation and Leaders' Attitudes, Abilities, and Behavior***

Power motivation makes for specific differences in leader behavior. For example, Fodor and Farrow (1979) found that leaders in an experiment who had a great need for power were partial toward followers who were ingratiating. Fodor (1984) reported that individuals who were strongly motivated for power became more active when supervising others than did those low in motivation for power. Active attempts to lead were highest when productivity was stressed and rewarded, but such attempts by participants with a high motivation for power to gain control of the situation and to increase productivity were thwarted.

McClelland (1985) noted that men with a high power motive displayed more instability in their interpersonal relations, had more arguments, were more impulsive, and engaged in more competitive sports. Furthermore, both men and women with a strong motivation for power reported holding more offices than those with a weak motivation for power (Winter, 1973). Similarly, Kureshi and Fatima (1984) found that highly power-motivated Indian Muslim students were activists, and showed concern for power in their everyday activities and in student elections.

Consistent with the effects of the personality traits of activity, dominance, and social boldness, those who are more oriented toward power would be expected to attempt to influence others. For instance, Veroff (1957) found that individuals who scored high on projective measures of power motivation also scored high on satisfaction with their status as leaders and were rated high in argumentation and attempts to convince others. However, Frantz (1979) failed to find that power, measured by Stewart's social-maturity scale, predicted emergence as a leader in initially leaderless discussions among male and female students.<sup>6</sup>

*Power, Leadership, and Cognitive Complexity.* Along with personality traits like self-confidence, self-determination, and dominance, the acquisition and use of power to influence others is associated with the individual's cognitive complexity—the ability to differentiate and integrate abstract information. In a four-year study of employees of insurance companies, Sypher and Zorn (1986) found that the cognitive complexity of

individuals contributed strongly to their persuasive ability. Such personnel were promoted more often within the organization than others were. House (1984) observed that cognitively complex individuals are better able to identify power relationships. As is true of leadership in general, communication skills are important in the wielding of power.

*Power, Leadership, and Communication Ability.* Communicative competence is required to articulate arguments, advocate positions, and persuade others—all useful for acquiring and using power (Parks, 1985). With such competence, many other strategies and tactics are available to exert influence by using one's power (Marwell & Schmitt, 1967; Wiseman & Schenek-Hamlin, 1981). These strategies are detailed later.

*Power and Effectiveness of Leadership.* Although individuals who base their leadership on power may create conditions that are unsatisfying to some or all of their subordinates, they may successfully influence the course of events, which results in the fulfillment of tasks and the attainment of goals by their group or organization. Thus Shaw and Harkey (1976) found that groups in which the leaders displayed ascendant tendencies did better than groups in which nonascendant people were the leaders. O'Brien and Harary (1977) reported that those leaders whose power matched their desire for it were more effective as leaders. Batkins (1982) stated that among human service agency directors, those with a great need for power led more efficient agency operations than those with little need for power; the result for the need for affiliation was the opposite. Daily and Johnson (1997) found in a longitudinal study that a firm's successful financial performance enhanced the power of the CEO.

Fodor (1987) found that small, experimental groups of men in the ROTC who attempted to solve a subarctic survival problem did best if their leader had a strong need for power. However, Fodor and Smith (1982) obtained outcomes indicating that individuals with high power motivation tended to inhibit group discussions more than did those with low power motivation. The individuals with high motivation for power brought into the discussions fewer facts and proposals that were available to them exclusively. As a consequence, fewer alternatives were considered and the quality of decisions was lower for groups led by such individuals. Consistent with these findings, House and Singh (1987) concluded that power motivation is predictive of effective leadership only when the assertion of one's social influence is critical and technical expertise is not.

## Machiavellianism

---

Organizational politics are intended and unintended preferences, policies, and practices. They can be constructive or destructive. In the popular mind, Machiavellianism stands for deceit, coercion, and using any means to reach desired ends. There is some truth in this view. Chang and Rosen 2003, in a meta-analysis involving between 2,865 and 11,753 respondents, found that all five criteria of an organization's well-being were adversely affected by the perception that more politics were present in the organization. The average correlations were as follows with the five criteria: job satisfaction,  $-.49$ ; organizational commitment,  $-.47$ ; performance,  $-.11$ ; intention to quit and turnover,  $.36$ ; stress,  $.44$ . But in fact Niccolò Machiavelli (1513/1962) himself did not ignore the possibility of doing some good with power and manipulation.

The pursuit of power and its skillful use were seen as fundamental to successful leadership by Machiavelli and taken further into modern times by Lasswell (1948) and Lane (1961). Machiavelli's treatises *The Prince* (1513/ 1962) and *The Discourses* (1531/1950) are still widely read today by leaders, managers, and executives. Machiavelli served on diplomatic missions to such crafty rulers as Louis XII of France, the Holy Roman Emperor Maximilian, and Pope Julius II. The guile and political tricks Machiavelli observed firsthand were included in his advice to a prince, Cesare Borgia, a local dictator. Borgia was Machiavelli's model prince,

who used all means at his disposal, both good and bad, including deviousness and coercion, to expand his power to achieve and maintain his political position.

Such power motivation and competence in the use of power contrast with the philosophy of the inherent goodness and perfectability of humankind espoused in the writings of Thomas Jefferson, Henry Thoreau, and Ralph Waldo Emerson and by modern socially oriented leadership theorists, such as Lewin (1939), Gibb (1964), Argyris (1962), and Bennis (1964), who reasoned that influence can and should be exerted on others when there is a need for it. For the good of oneself and others, they affirmed, one should be open, frank, and candid in communications; share decision making; and openly commit oneself to positions so that others will know where one stands. Further, they suggested, leaders ought to jointly select and identify mutually satisfying goals to work toward, develop and maintain mutual trust, and encourage group discussions including others above and below themselves in the organizational hierarchy.

### ***Machiavelli's Advice***

"It is impossible to satisfy the nobility by fair dealing ... whereas it is very easy to satisfy the people. ... From hostile nobles [the prince] has to fear not only desertion but their active opposition ... in time to save themselves and with the one whom they expect will conquer. ... The prince is able to make and unmake them at any time, and improve or deprive them of it. ... [The nobles] that are bound to you and not rapacious, must be honored and loved. ... But when they are not bound to you of set purpose, and for ambitious ends ... they think more of themselves than of you. ... From such men the prince must guard himself and look upon them as secret enemies" (Machiavelli, 1513/1962, pp. 71–72). "There is nothing more difficult to carry out, nor more doubtful of success, nor more dangerous to handle, than to initiate a new order of things. For the reformer has enemies in all those who profit by the old order, and only lukewarm defenders who would profit by the new order" (p. 55). Strong, ruthless, and cynical leadership is required of the prince because of his nobles' self serving. As a consequence, they will regularly subvert the state and reduce it to chaos. It is in their best interests for the prince and the people to do whatever he can in whatever way he can to prevent chaos from occurring. Religious and ethical criteria for justifying the leader's actions are irrelevant.

Political calculation is required to control events rather than be victimized by them. For "reasons of state," the ends always justify the means. The ends are the welfare of the state. Whatever the leader does to help strengthen and preserve the state is good; whatever tends to work against the state is bad. The leader must be pragmatic, not idealistic, in facing problems. He must always keep in mind the particular interests of his own state. In a sense, Machiavelli was an *early amoral behaviorist* who argued for studying what we do, rather than what we ought to do. He argued that "he who studies what might be done rather than what is done will learn the way to his downfall rather than to his preservation." Machiavelli was also an early situationalist, for instance, giving different advice to the prince about how to deal with acquired political states, depending on whether the states were culturally and politically similar or different from his own.

According to Machiavelli, the prince must be ready to imitate the behavior of the fox, who can "recognize traps," and the lion, who can "frighten wolves." He cannot place his trust in others. To obtain and maintain power, he needs a calculating attitude without any sense of guilt or shame. He should act in a way that conveys boldness, greatness, and strength. The prince should rely more on being feared than on being loved. If cruelty is required, it should be done all at once, not over an extended period. Although the prince does not need to have a moral character, he must seem to have one; he should appear to be merciful, faithful, humane, sincere, and religious, and avoid being despised. He must maintain an image of personal strength and confidence so that no one will try to mislead him. He must control his emotions. He has to uphold his dignity, "which must never be allowed to fail in anything whatever." He should not pay attention to advice unless he has asked

for it. Machiavelli even had advice for the nobles around the prince. Anyone with cleverness and some power who helped the prince to gain his position must be careful because the prince cannot tolerate any competent, powerful people close to him.

### ***Measuring Machiavellianism: The Mach Scale***

Statements from *The Prince*, as well as from *The Discourses*, were used by Christie and Geis (1970) to form the Mach scale, which measures the extent to which respondents subscribe to Machiavelli's dictums about how the leader should act toward others to be most successful in obtaining and maintaining compliance with his interests. An original list of 71 statements dealt with tactics ("A white lie is a good thing"), views ("It is hard to get ahead without cutting corners"), and morality ("No one has the right to take his own life"). The Mach IV scale, consisting of 20 such items, had a split-half reliability of close to .80. Other versions of the Mach scale were devised to reduce the bias of social desirability that is inherent in the content. Obviously, to admit to being devious is usually not a socially desirable response. A high score on the Mach scale was seen as an indication of a predisposition to maximize self-interest using deceit and manipulation at the expense of others.

*Influence Behavior of Machiavellians (High Machs).* As well as being more authoritarian, Machiavellians are aggressively dominant but less socially dominant individuals, according to Kalma, Visser, and Peeters (1993). These researchers obtained a correlation of .35 between Machiavellianism and their scale of aggressive dominance and a correlation of only .13 with their scale of social dominance. Individuals who score high on the Mach scale (high Machs) resist social influences and are concerned with getting the job done rather than with emotional and moral considerations. They tend to initiate and control interactions with others. In contrast, low Machs—people who score low on the Mach scale—are more susceptible to social influence and are distracted by interpersonal concerns (Epstein, 1969). High Machs frequently practice deception, bluff, and other manipulative tactics in competitive situations and in contexts of uncertainty. They also exhibit a "cool" task-directed syndrome during face-to-face competition that allows for improvisation in both substance and timing of responses to the task or to other people (Shapiro, Lewicki, & Devine, 1995). High Machs are impervious to considerations that can interfere with manipulative behavior and effective bargaining (Christie & Geis, 1970). They are convincing liars (Lewicki, 1983), glib and emotionally detached, superficially charming and duplicitous, bordering on psychopathological (McKoskey, Worzel, & Szarto, 1998).

Drory and Gluskinos (1980) varied the leaders' power as perceived experts with authority and the task so it was more or less structured, to create situations that were more favorable or less favorable to the leaders. They found that as leaders, the high Machs generally gave more orders and reduced tension more than did the low Machs. However, the high Machs became less directive and requested more assistance when they had less power and the task had less structure than when they had more power and the task was highly structured. In respect to their flexibility of response as conditions changed, high Machs were like egalitarians (people with low *F* Scale scores) who had been found to do the same by Bass and Farrow (1977b). Low Machs were similar to high authoritarians in their inflexibility of response to changing situations.

Deluga (2001) agreed with Wilson, Near, and Miller (1996) that although Machiavellianism is generally socially unacceptable, some high Machs may be effective in stressful, competitive, unstructured face-to-face situations where their sense of timing, ability to improvise, persuasive ability, and ability to remain "cool" are assets to bargaining teams, to mock courtroom debates, and in leading temporary small teams (Huber & Neale, 1986). U.S. presidents who are high Machs (according to ratings of their profiles by three undergraduates) are more likely to get Congress to pass the legislation they support (Simonton, 1986). Among 39 presidents from Washington to Reagan, Deluga (2001) found that Machiavellianism was positively

associated with their rated effectiveness according to Spangler and House (1991). Franklin Roosevelt, Martin Van Buren, and Richard Nixon were rated highest on the Mach scale; William McKinley, Rutherford Hayes, and Zachary Taylor were rated lowest. In no way are Machiavellianism and charisma identical, but they share image-building behaviors, self-confidence, and effective emotional regulation.

The impact of a Machiavellian outlook seems to depend on how much a manager interacts with others in the organization. Coates (1984) obtained reports of the frequency of the contacts of 79 managers with their superiors and peers. The rated influence of managers who were high Machs was likely to be higher than that of low Machs if the managers had frequent contact with their superiors and peers.

### ***Other Political Tactics***

The number of politically astute, devious, deceptive, artful, and crafty tactics leaders can employ is much more extensive than Machiavelli described. Many other tactics were mentioned in Greek, Roman, and Chinese classics. However, Machiavellianism is a generic label for all such amoral political manipulateness and deception, although Machiavelli himself mentioned using politics to benefit the people—for instance, to protect them against nobles' efforts to exploit them. Moreover, organizational politics can be seen as functional (Boal & Deal, 1984), and as a constructive management of shared meanings. A political perspective can be applied with a social service rather than a self-serving orientation (Ammeter, Douglas, Gardner, et al., 2002). Lancaster (2002) sees using political tactics as essential for success in management. If you work in a corporation, he advises you to “promote yourself. You must pit your skills and competitiveness against ambitious colleagues, some who play fair and some who don't. You must learn to maneuver through the political thickets and often unjust realities of organizational life.” Political tactics are used extensively by those of lower status to influence others with higher status. They employ self-serving impression management, ingratiation, intimidation, and supplication (Jones & Pittman, 1982). They can create an illusion of control (Alloy & Abramson, 1982).

Martin and Sims (1956), Jameson (1945), and Pfiffner (1951) described political tactics used in modern corporations which could be self-serving or beneficial to others. Politically oriented managers withhold the release of information or time its release for when it will do the most good. They bluff, acting confident even when they are unsure or lack relevant information. They make political alliances with those who have the power to protect their interests. They hide their real feelings about plans that are popular with others by starting to act on them but then retard and delay their implementation so that the plans are in process but never completed. They keep socially distant from subordinates and never become personally involved with them, always remaining the boss when interacting with them. They openly compromise, yet secretly divert or delay plans that involve compromise so that their aims will continue to be pursued despite public statements to the contrary. McCall (1978, p. 227) felt the same way about politically astute creative leaders. They tend to be “crafty, grouchy, dangerous, feisty, contrary, inconsistent, evangelistic, prejudiced, and spineless.”

*Political versus Social Approach.* We advocate and invest less research on the Machiavellian way of establishing and maintaining leadership in contrast to the social approach. The very deviousness of Machiavellianism makes its widespread practice less visible. Overall, the social approach to interpersonal competence is more socially acceptable than the political approach. Bass (1968c, 1970b) found that only a minority of MBA students and middle managers responding to the Organizational Success Questionnaire (OSQ) espoused political tactics and rejected the Gibb-Bennis-Argyris social approach to effective interpersonal relations as the way “to get ahead in most large organizations.” For the majority of the MBA students and managers, least endorsed were the tactics of diverting plans by retarding, delaying, and offering insincere compromises. However, published OSQ results for students in six countries and unpublished OSQ data

gathered from samples of managers in over a dozen countries indicated that different nationalities differ widely in their endorsement of these political and social approaches (Bass & Franke, 1972).

*Influence Tactics.* Kipnis, Schmidt, and Wilkinson (1980) gathered data on what people say they do to influence others who work with them. They found that people used a mixture of both social and political approaches. In these researchers' first investigation, 165 lower-level managers wrote essays describing an incident in which they influenced their bosses, their coworkers, or their subordinates. A content analysis disclosed the use of 370 different influence tactics. The Machiavellian tactics that were identified included the following: lied to the target, acted in a pseudodemocratic manner, puffed up the importance of the job, manipulated information, made the target feel important, cajoled the target, pretended to understand the target's problem, became a nuisance, slowed down on the job, threatened to withdraw help, threatened to leave the job, blocked the target's actions, ignored the target, invoked past favors, waited until the target was in the right mood, was humble, showed dependence, invoked rules, obtained support informally from superiors, threatened to notify an outside agency, and made formal appeals to higher levels.

*Ingratiation and Blocking.* Kipnis and Schmidt extracted 58 tactics from the content analyses and then gave them to 754 graduate students who also worked full time. The students were asked how frequently they had used any of these tactics during the past six months to influence others with whom they worked. When the responses were factor-analyzed, two manipulative factors emerged: *ingratiation* and *blocking*. Ingratiating tactics were used more frequently to influence peers and subordinates than superiors. The primary reason the students gave for using the tactics to influence others was to get help on the job, to obtain benefits from these other persons, or to try to effect change. The ingratiating tactics included (1) making the target feel important ("Only you have the brains and talent to do this"); (2) acting very humble while making a request; (3) making the target feel good about the student before making a request; (4) inflating the importance of what needed to be done; (5) waiting until the target appeared in a receptive mood before asking; and (6) pretending they were letting the target decide to do what the student wanted done (acting in a pseudo-democratic fashion).

Blocking tactics were generally used less frequently than other tactics. These were efforts to get benefits and changes in decisions from the students' bosses. They included: (1) threatening to notify an outside agency if the boss did not give in to the request; (2) threatening to stop working with the boss until the matter was settled; (3) engaging in a slowdown of work until the boss did what the student wanted; (4) ignoring the boss, stopping being friendly, on both; and (5) lying about reasons the boss should do what the student wanted.

Along with ingratiation and blocking, political tactics are used to preserve and enhance one's self-esteem or to be esteemed by others (Kelley & Michela, 1980).<sup>2</sup> These tactics include; (1) engaging in *impression management*—doing or saying what it is should put one in a favorable light; (2) concealing some of the reasons for trying to be influential; (3) forming coalitions with others to exert the combined power of a group, rather than speaking in the lone voice of the individual; and (4) planning one's behavior—imagining or playing through situations to try—to time what one will do and to fit one's appeals to the expected outcomes (Nuttin, 1984).

*Game Playing.* P. J. Frost (1986) conceived tactical maneuvering to gain power and influence in terms of political "games" employees play in organizations:

An organizational "game" involves social actors, payoffs, and a set of interpretive strategies ... [that] specify the rules, data, and successful outcomes in the game. Given the social construction around power that is involved in such games there is a degree of elasticity in the way the game is constructed and played. Invention and adaptation enter into the development and enactment of game rules and meanings, because they come alive in the service of actors' strategic actions in the game (p. 527).

Members of organizations consciously play games to get their way for their own sake, for the sake of others, or for their organization. They use such games to disguise their political intentions, to mobilize support, and to quiet opposition. Power-seeking members play at empire building by following the rules to facilitate their upward mobility in their organizations (Pfeffer, 1981b).

The game of “making it” (moving up the ladder of success) goes along with impression management and esteem building. Mentoring and sponsorship can be seen as games to foster networks of supporters and as empire building (P. J. Frost, 1986). Through such games, players seek justification for and meaning in their actions to allow them to increase their power and hence to participate in other organizational games. Games such as “lording” (Mintzberg, 1983) are played by actors with little power; who “lord it over” those who are subject to their influence. Those who play these games hold on to what little power they have by establishing a context in which they interpret the rules and routines of organizations literally and see that the rules are strictly enforced and the routines are rigidly implemented. They get their way and resist change by invoking the rule book—the bureaucracy—and by threatening to go to a higher authority for decisions (P. J. Frost, 1986). On occasion, they invent rules, expecting no challenge because of the large, complex book of rules that would have to be consulted to refute their argument. In these individual games, players manage impressions (Zerbe & Paulhus, 1985) and join and build networks and coalitions (Porter, Allen, & Angle, 1981).

*Chameleon Behavior.* Like chameleons, *high self-monitors* change in response to changes in situations. They also appear more ready to change careers, employers, or locations. Low self-monitors remain true to themselves and do not change as much; nor do they change careers, employers, or locations as much. Politically tactical moves by 67 high-monitoring MBA graduates followed up for 5 years paid off for them in accelerated promotions across organizations as well as in promotions within their organization if they did not leave. The 72 low self-monitors who did not change careers or organizations did not do as well.

*Heresthetics.* For Riker (1986), leadership as practiced by successful politicians is primarily political manipulation. According to this view, leadership is evident when a politician is able to change an issue in the minds of constituents and legislators so the minority support for the older framing of the issue swells to a majority because of the politician’s new interpretation of the issue. The politician-leader achieves this goal by imparting to his or her description the exact twist to reality that will gain majority approval of the issue. It is a matter not of persuasive rhetoric but of a *heresthetic* argument that shows how the proposal will serve the best interests of the majority. In Riker’s case studies, heresthetic leaders manipulated support by setting and controlling agendas, calculating likely voting patterns, and then manipulating the values of importance. They made appeals to share organizational or societal purposes, but their private motives were paramount.

As Riker (1986, p. 64) noted, “the heresthetic neither creates preferences nor hypnotizes. ... He probes until some new alternative, some new dimension [is found] that strikes a spark in the preferences of others.” He manipulates private incentives even while remaining idealistic. To illustrate: because of isolationist sentiment in the United States in 1940, President Roosevelt could not gain approval from Congress to give 50 old American destroyers to Britain, which was being strangled by German submarines. But he did gain approval for “lend lease,” in which the destroyers were exchanged for bases in Bermuda, the Bahamas, and elsewhere that could be viewed as a first-line offshore defense for the United States. He was able to persuade Congress to pass the Lend-Lease Act of 1941 by emphasizing the age and outmoded condition of the destroyers and the advantages of obtaining the bases.

## Political Psychology and Leadership in Organizations

---

Political perspectives often are the basis for leadership in organizations. Political behavior in organizations is

common and sometimes necessary. Thus impression management can be understood as a political maneuver (Ferris, Russ, & Fandt, 1989). Leadership in organizations can be conceived as a political process.

Harold D. Lasswell (1948) pioneered the study of the psychology of political leadership but did not have continuing impact on either political science or psychological leadership research. His major books and writings appeared between 1923 and 1948. Ascher and Hirschfelder-Ascher (2005) reminded us of his seminal publications, 10 of which have been republished since 1990. The decline in interest in Lasswell's psychodynamic approach to political leadership paralleled a decline in interest in psychoanalytical theory. Nevertheless, Lasswell's framework still provides an unexcelled agenda for the analysis of current policy and political issues (Ascher & Hirschfelder-Ascher, 2005). Lasswell showed: (1) how emotions and beliefs were displaced from one target to another to shift blame; (2) how leaders could use political symbols and propaganda to be understood by appeals to the id, ego, and superego; (3) how democratic processes and civil liberties depend on democratic character, values, and expectations; and (4) how crisis erodes political self-restraint and brings on destructive behavior. Applying Lasswell's framework to the current interest in charismatic and transformational leadership (see [Part V](#)) suggests that such leadership brings risks to democratic accountability.

*Negative Effects.* Playing politics in organizations is often self-aggrandizing and of less benefit to others and to the organization. Politics in organizations is likely to cause job anxiety, stress, dissatisfaction, and withdrawal of followers (Cropanzano, Hawes, Grandby, et al., 1997; Valle & Perrewe, 2000). Politically astute, self-aggrandizing leaders are morally disengaged. Unethical violations committed by their subordinates are justified (Davis & Gardner, 2004). Davis and Gardner (2004) noted that in organizations, a leader who behaved politically resulted in subordinates who were cynical about the organization's sincerity, honesty, and integrity. Such leadership generally had negative effects on subordinates' job satisfaction, performance, morale, and turnover. Beu and Buckley (2004a, b) attributed corporate scandals to politically astute corporate leaders who created an environment where subordinates committed illegalities in obedience to their leaders. The leaders convinced their subordinates that the behavior was morally justified. The subordinates denied that they were the agents of the crime; they were convinced by the power and authority of the leaders and said that they were only obeying orders. (The same plea was made by Nazi war criminals.) According to a qualitative and quantitative study of nurses at a New Zealand hospital by Kan and Parry (2004), politics could offset the usually positive effects of transformational leadership. The leadership of the nurses was repressed, in their efforts to provide patient care, by the political realities of the greater power, status, and importance of the medical staff and the managers.

*Positive Views.* Spencer and Spencer (1993) argued that political skill is even more important for effective management than cognitive competence. Treadway, Hochwarter, Ferris, et al. (2004) proposed that political skill involves the ability to comprehend social cues and build social networks and social capital (personal reputation and support from associates). The components formed two independent factors, which accounted for 16% and 32%, respectively, of work unit performance of an educational administrative staff (Douglas & Ammeter, 2004). Treadway, Hockwarter, Ferris, et al. (in press) modified the work of Ferris, Treadway, Kolodinsky, et al. (2005) to measure the *political skill* of supervisors as potentially positive in the eyes of their subordinates by: (1) trying to show a genuine interest in other people; (2) understanding people well; (3) building relationships with influential people at work; and (4) always instinctively knowing the right things to say to influence others. The investigators showed that politically oriented leaders in organizations could be seen favorably by their subordinates. They found that the supervisors' rated political skill correlated with their subordinates' ratings as follows: trust, .38; job satisfaction, .32; commitment, .41, and cynicism, —.33.

## Summary and Conclusions

---

Leaders may be oriented toward the uses of power and political manipulation, rather than toward social approaches to influencing others. Authoritarianism, power motivation, and Machiavellianism are relevant aspects of their personalities. Measuring the authoritarianism of both leaders and followers has been helpful in understanding the preferences, performance, and satisfaction of these leaders, particularly as a function of the circumstances involved. They tend to be rejected in sociometric choice for leadership. But this tendency does not necessarily prevent authoritarians from performing as leaders in task-oriented, emergent groups, as well as in formal organizations.

The personalities of leaders and followers interact. Authoritarian followers tend to evaluate leaders in terms of status, power, and position, whereas egalitarians evaluate leaders as persons in terms of behavioral and personality cues. With directive leaders, egalitarian followers tend to feel more comfortable in large, structured groups. With directive leaders, egalitarians tend to react more favorably in small, less highly structured groups. Egalitarian followers are somewhat more hostile toward leaders in high-status positions. Thus the degree to which a leader is accepted and the degree of satisfaction that group members feel under authoritarian and egalitarian leaders generally are dependent on a matching of the leader's personality with the follower's personality, along with a congruent group structure.

Power-motivated leaders can be effective if they are task oriented rather than concerned about interpersonal relationships, and if they can inhibit their need for power. These imperialists can use their power for their own advancement or for the good of their organizations. Machiavellians are cool in their performance as leaders and are not distracted by interpersonal considerations or social influences in competitive situations. The use of Machiavellian tactics is probably more widespread than has been acknowledged. Yet the effects of politically astute leaders on their associates can have positive as well as negative effects on the organization, unit performance, and morale.

Many other personal values and beliefs about oneself are associated with the emergence of leadership.

<sup>1</sup> Sensitivity to others is a potential contributor to effective leadership as noted in [chapter 8](#).

<sup>2</sup> These leadership styles will be discussed in [Chapter 17](#) through [20](#).

<sup>3</sup> See [Chapter 20](#).

<sup>4</sup> See [Chapter 6](#).

<sup>5</sup> [Chapter 21](#) will look at length into the power-charisma leadership relationship.

<sup>6</sup> More detail and compelling evidence about the relationship of power to attempted and successful leadership is presented in [Chapter 11](#).

<sup>7</sup> These and still other tactics that those with lower status use to influence others with higher status will be examined in [Chapter 16](#). Self-serving impression management, which uses some of these tactics including ingratiation, intimidation, and supplication—and which may create an illusion of control—will be considered more fully in [Chapter 21](#).

---

# Values, Self-esteem, Well-Being, and Leadership

Leaders are multidimensional, complex personalities. Douglas MacArthur was, according to his biographer William Manchester (1978), “a great thundering paradox of a man, noble and ignoble, inspiring and outrageous, arrogant and shy, the best of men and the worst of men, the most protean, most ridiculous and most sublime.” Manchester used traits, values, actions, orientations, motives, and self-concepts in his word painting of MacArthur’s unique individuality. So far I have detailed how the intricacies of the personal factors of leadership involve a variety of traits including activism and orientation toward authority, power, and manipulateness. This chapter examines how leaders regard themselves; [Chapter 9](#) will discuss how others regard them. Presented are the leaders’ self-ascribed personal values, valued activities, and identification; and how subconscious and conscious motives energize and direct leaders. Their risk taking, self-concept, physical fitness, and mental health are discussed. The attitudes of leaders toward their organization and their satisfaction with their roles as managers are also examined.

## Values

---

A value is “an enduring belief that a specific mode of conduct or end-state of existence is personally or socially preferable to an opposite or converse mode of conduct or end-state” (Rokeach, 1973, p. 5). Objects and actions are valued if they are believed to be right, good, worthwhile, and important. A value may be *instrumental*, that is, a means to some desired end, or *terminal*, an end in itself. Ambition, honesty, and courage are instrumental values. A comfortable life, social recognition, and family security are terminal values. Rokeach (1973) provided 18 examples each of instrumental and terminal values. Values may also be espoused or enacted. *Espoused* values are what people say they value. *Enacted* values are inferred from what people do. Enacted values resulted in greater organizational commitment of 135 assistant managers, according to a study by Furst, Cable, and Edwards (2001).

### **Leaders’ Values**

*Personality* is made up of cognitive and behavioral traits; *character* is made up of values. Piotrowski and Armstrong (1987) concluded that all 30 chief executive officers they interviewed had clear values. Values determine what is considered the right thing to do (Hughes, Ginnett, & Curphy, 1993). The leader who values courage will take unpopular stands on issues; the leader who values self-control will tend to remain aloof from a highly emotional follower. The leader who values being imaginative rather than logical will evaluate others depending whether they appear logical rather than imaginative. The leader who values obedience over independence will not question orders from higher authority. Bad values motivate bad behavior. The manager who scores high in vanity “does not share credit when we do something upper management really likes”; the greedy manager “is not calm when working under pressure” (Hogan, 2003).

Leaders and nonleaders value themselves differently. Peppers and Ryan (1986) found that when 79 individuals in positions of leadership were contrasted with 110 who were not, the leaders differed from the

nonleaders in three general ways in traits and values. First, they saw themselves as more talkative, aggressive, intelligent, committed, and ambitious. Second, they aspired to be more sensitive, democratic, fair, committed, imaginative, confident, and self-assured. Third, there was more congruence between the leaders' aspirations and self-perceptions than the nonleaders'. Trow and Smith (1983) found that people who volunteered to serve on the boards of directors of agencies that planned and advocated social change systematically differed in their values from those in the same community who did not volunteer to serve. Those who volunteered were much more likely to value goodwill and the need to eradicate sin and were much less likely to endorse a hard line in dealing with social problems. Generally, leaders endorse the values of their social and political movements more strongly than do ordinary followers.

*Importance of Values to Leaders.* Baltzell (1980) illustrated how the careers that leaders pursued were influenced by the values they assimilated. He contrasted the values of upper-class Protestant Bostonians and upper-class Protestant Philadelphians. Puritan-influenced Bostonians viewed human beings as inherently sinful, in need of authoritative institutions headed by righteous leaders of superior education. Quaker-influenced Philadelphians viewed human beings as inherently good, individually perfectable, with no need of mediation by state or church, erudition, or professionalism. For Boston's Brahmins but not for Philadelphia's elite, public service became obligatory; Boston's Adamses, Cabots, and Lowells produced a good many eminent political leaders; Philadelphia's Biddles, Cadwaladers, and Whartons did not. Baltzell attributed the difference to the original Puritan and Quaker values inculcated in succeeding generations of family members. The Bostonians, who pursued political leadership, and the Philadelphians, who pursued leadership in business and finance, clearly differed in their attitudes and opinions about what was important to them and what interested them.

In a review of available research, Ghiselli (1968a) noted that managers' personal values correlated .25 to .30 with criteria of their effectiveness. U.S. Army officers and enlisted personnel are expected to live by the army's seven core values: (1) loyalty, (2) duty, (3) respect, (4) selfless service, (5) honor, (6) integrity, and (7) personal courage (Berenson, 1998). Violations could lead to disciplinary action.

*Shared Values.* "Leaders cannot function effectively without some base of shared values in their constituents or followers" (J. W. Gardner, 1988, p. 22). Shared values play an important role in Nel's (1993) value-centered leadership. Unity within diversity in an organization can be developed if its members and teams share a vision and values. Weiss (1978) found that leaders' success and competence were greater when the leaders and their subordinates held values in common. Job satisfaction was also greater (Murray, 1993). Nonetheless, leaders have to choose which values they should articulate (Beckhard, 1995). En gland and Lee (1974) offered six reasons for the influence on a leader's performance of the values that the leader regards as right, good, and important. These values affect: (1) a leader's perception of situations and problems to be faced; (2) a leader's decisions and solutions to problems; (3) the leader's view of other individuals and groups, and thus of interpersonal relationships; (4) the leader's perception of individual and organizational success, as well as how to achieve them; (5) the leader's determination of what is and what is not ethical behavior; and (6) the extent to which the leader accepts or resists organizational pressures and goals. The leader has to choose which values to articulate.

*Values and Transformational Leadership.* According to Burns (1978) and House, Howell, and Shamir (2002), values are central to the neocharismatic and transformational theories of leadership (see Chapters 21 and 22). In these theories, leaders are assumed to move their followers to transcend their own needs for the needs of their group, organization, or society. They foster the sharing of transcendental values with their followers. These values may include altruism, social welfare, supportiveness, service, spirituality,

honesty, fairness, and aesthetics (Engelbrecht & Murray, 1995). Transformational leaders and their visions are also concerned with moral values and end values such as liberty, equality, and justice (Burns, 1976). Such leaders amplify, elevate, or idealize values of consequence to the followers (Conger & Kanungo, 1998). They are strongly convinced of the rightness of these values and imbue followers with the same feelings. Strongly held values underlie the commitments of both the neocharismatic leader and the led (House, 1977). For instance, to achieve a strong customer focus, an organization will need to promote the values of service, honesty, and integrity in its leadership, in its employees, and in itself (Snyder, Dowd, & Houghton, 1994).

For Drucker (1999, p. 73), “to work in an organization whose value system is unacceptable or incompatible with one’s own values condemns a person both to frustration and to nonperformance.” An organization may value a policy of hiring from the outside; a leader may value promoting from within. A leader may value developing subordinates but may be discouraged by the organization from spending time or resources to do so. A leader may value long-term results; organizational policies may emphasize short-term results.

### ***Assessment of Values***

Starting in the 1930s, the Allport-Vernon Study of Values (1931) became a widely used inventory for assessing Spranger’s (1928) six-fold typology of values: (1) theoretical, (2) economic, (3) aesthetic, (4) social, (5) political, and (6) religious. Questionnaires asking respondents to rank Rokeach’s 18 instrumental and 18 terminal values in order of preference became another common approach from the 1970s onward. The Allport-Vernon was criticized as too abstract and Rokeach’s values were said to lack relevance in organizational and management contexts (Hambrick & Brandon, 1988). A more recent addition to the assessment of values, validated with working adults, is Hogan and Hogan’s (1996) Motives, Values, Preferences Inventory (MVPI) with value scales such as aesthetic, affiliation, altruistic, commercial, hedonistic, power, recognition, scientific, and tradition. Each scale is reliable. Validated scale questions address respondents’ valuing of lifestyles, beliefs, occupational preferences, aversions, and preferred associates.

Many methods other than questionnaires have been used to assess values. For instance, Hall (2000) and Benjamin Tonna ascertained that there are about 125 values embedded in written and spoken language that are basic to human behavior. Documents such as a presidential address can be analyzed using a thesaurus of more than 5,000 synonyms of the 125 values, to count their presence in the speech. The values can then be prioritized according to their frequency of appearance in the speech, in English and in translations into French, Spanish, or German. Bass (1975a) developed Exercise Objectives in which the performance of participants was a gauge of their pragmatism or idealism. In Exercise Objectives, five simulated budgeting decisions were required to deal with problems of safety, labor relations, the morale of managers, the quality of products, and environmental pollution. Bass’s (1968c) study of 113 MBA students showed that an unwillingness to spend money to remedy any of the five problems was related to strong economic, rather than humanistic, values. Conversely, willingness to spend money to handle the problems was positively associated with a social orientation to trust others. It was negatively correlated with a political orientation to bluff and to maintain psychosocial distance (Bass, 1968c).

### ***Determinants of Leaders’ Values***

*Education.* Systematic differences in the values of managers are associated with differences in their education. Esser and Strother (1962) found that managers with average amounts of education tended to be rule oriented. Those with the least education were least rule oriented, followed closely by those with the most education. And England (1967a) observed that managers with less education placed more value on

organizational stability. Those with college majors in the humanities, the fine arts, and the social sciences stressed the importance of productivity and efficiency as organizational goals. The Indian civil service, mostly all British under the British raj, had been educated in public schools such as Eton and Harrow and universities such as Oxford and Cambridge. They had been bred and trained to feel and act superior. They despised altruism or sympathy for the Indians. Rather, they had been indoctrinated with ideals like fair and open justice, efficient administration, and the opportunity to make improvements. On this basis, the 1,200 members of the Indian civil service provided rule over hundreds of millions of Indians (Lapping, 1985).

*Cognitive Style.* Values are linked to differences in the way managers sense, think, judge, and feel, according to the Myers-Briggs Type Indicator (Myers, 1962). Mitroff and Kilmann (1976) showed in a content analysis of managers' stories about their ideal organization, that *sensory-thinkers* emphasized factual details, the physical features of work, impersonal organizational control, certainty, and specificity; *intuitive-thinkers* focused on broad, global issues built around theories of organization; and *intuitive-feelers* stressed personal and humanistic values in their ideal organization. Intuitive-feelers were also found to be risk takers (Behling, Gifford, & Tolliver, 1980; Henderson & Nutt, 1980). The sensory-feelers described their ideal organization as one that focuses on facts and processes, with attention to human relationships and qualities.

*Personal Considerations.* A kind of discounting seems to occur on the basis of perceptions of abundance or scarcity. In a study of a hospital, Jensen and Morris (1960) found that supervisors valued leadership and executive ability more highly when these traits were less prevalent among them. And when the supervisors were socially adjusted and personable, they attached even less value to these qualities.

What leaders value as an activity for its own sake obviously depends on their vocation. Distinct patterns of interests demarcate the different professions (E. K. Strong, 1943). Among governmental leaders, one is likely to see leaders with strong political values; in the military, a strong interest in adventure; in business, a strong interest in computational matters; and in science, a strong preference for theoretical activities—understanding the “why” of things. Managers and executives tend to score highest among the professions in economic and political values, in contrast to scientific personnel who tend to value theory and understanding. Artists value creativity more highly; and people in the helping professions have stronger social or religious values.<sup>1</sup>

Student leaders, mostly from the middle class themselves, were more likely than followers or isolates to identify with middle-class values (Martin, Gross, & Darley, 1952). Some strongly valued academic and vocational activities and goals; others strongly valued socializing (Brainard & Dollar, 1971).

*Status.* As one rises on the organizational ladder, one usually finds shifts in values that cannot be attributed to age, education, or seniority. Status differences emerge, and commitment to the organization is generally more highly valued the higher one's level in the organization. Pfiffner and Wilson (1953) surveyed two levels of supervisors. Their results indicated that the higher-level supervisors felt at ease with superiors and were interested in duties involving management functions. The lower-level supervisors identified with their work groups and were less critical of workers than were the higher-level supervisors. Rosen and Weaver (1960) found four levels of management in agreement regarding the importance of factors that affect the effectiveness of jobs (authority, knowledge of plans, consultation) as opposed to the importance of a role in policy making and communication with higher-ups. But first-line supervisors differed from higher levels of management in emphasizing the importance of consideration and fairness. Compared with workers, managers at all levels regarded themselves as upholders of group norms (Fruchter & Skinner, 1966). W. K. Graham (1969) factor-analyzed the intercorrelations among the job-attitude scores of personnel at three levels of organization in life insurance agencies. Higher-level managers differentiated managerial actions from the organizational climate, whereas supervisors and agents did not.

*Meaning of the Job.* Triandis (1960) factor-analyzed the meanings attached to job descriptions by managers and workers. Six factors were isolated, five of which were similar for managers and workers. However, in a study of meanings attached to words describing jobs and people, Triandis (1959a) found that upper-level managers stressed the importance of status, polish, and education; lower-level managers stressed power and position; and workers stressed money and dependability. In comparing the attitudes of Swedish managers, superiors, and workers, Lenneröf (1965b) discovered that workers value good personal relations to a greater extent than do supervisors, and supervisors value it more than do their superiors. Also, the supervisors and their workers felt more strongly than their superiors that the supervisor should strive to attain an independent and influential position. Nonetheless, when Schwartz, Jenusaitis, and Stark (1966) compared the values of U.S. supervisors and workers, they found that the two groups agreed in placing greater value on job security, wages, and working conditions than on interpersonal relations. Similarly, Friedlander (1966a) found few differences between the values of U.S. civil service employees at different levels of status. Top managers often espouse values in their top-down communications that may or may not be practiced. These values include openness, leanness, localizing initiatives, and decisions based on merit.

*Lifestyles.* Bray, Campbell, and Grant (1974) reported on a comprehensive comparison of the assessed values of those who had advanced further in the Bell System with those who had not. Over the eight years of the survey, systematic changes occurred in the lives of 400 Bell System managers who were followed up after evaluations at an assessment center. Two contrasting lifestyles were identified—the *enlarger* and the *enfolder*. The enlarger's lifestyle stressed innovation, change, self-development, and movement away from traditional ways of thinking and doing things. The enfolder's lifestyle was oriented more toward tradition and maintaining the close family and friendship ties that the individual had gained during adolescence and college. Enfolders were less likely to leave their hometown area and were much less likely to engage in any self-improvement activities. More successful managers were enlargers; less successful managers were enfolders. Enlargers gained occupational interests and lost concern for parents and family; enfolders either suffered small losses in such concerns or remained the same. Enlargers sharply reduced their interest in recreational and social activities; enfolders showed only a slight loss in such interests.

Which is cause, and which is effect? As managers rise faster and higher, they may have less time for family ties and recreation. But they do obtain increasingly greater satisfaction from their job as they rise in rank. Less successful managers are likely to derive less satisfaction from their jobs and have more time for family and recreation. However, one cannot ignore the evidence that successful people are more likely to be career-oriented before they actually began to work, which suggests that they bring to their job at least some semblance of a lifestyle that will contribute to their success in the organization.

*Societal Developments.* Early on, the values of unfettered capitalism reflected societal and cultural trends. In developing industrial societies, a belief in social Darwinism (the social survival of the fittest) fit with the doctrine that an "invisible hand" made the unrestricted free market the best economic system. This belief also meshed with the Calvinist doctrine of predestination (of being chosen by God for success) and with the frontier value of individualism. All these beliefs and values combined to justify profit maximization (the bottom line) as the single objective of enterprise. Poverty, drudgery, and exploitative employment of the "unfit" (those not chosen) for the longest possible hours at the lowest possible wages were justified as the best means to achieve the highest profits to enrich the employer-owner and shareholders, who were blessed by God to prosper and were rightfully entitled to profits. Sharing the belief were the employer's agents—the managers. The constraints of governmental regulation and union movements were unnatural, uneconomic, unreligious, and immoral. In reaction to the excesses of unconstrained profit maximization came the voting public's and legislatures' more sophisticated views of the government's regulatory role, the acceptance of unionism, and more socially conscious religion. Equally if not even more important, these came some awareness by

management that profit maximization was a chimera. There was a realization that instead of concentrating on the single objective function of maximizing profits, managers ought to concentrate on maintaining and improving the value of the systems for which they were responsible as stewards. Thus managers needed to integrate the needs and interests of the constituencies of the system—the owners and shareholders; the employees, including the managers themselves; the suppliers; the clients and customers; and the community. Instead of valuing the longest working hours at the lowest possible wages, managers ought to value the highest hourly productivity per employee at equitable and satisfying wages. Integration meant alignment of the employees' and the organization's interests in their mutual growth and development.

More often than not, managers need to view themselves as stewards. For example, in the technologically driven electronics industry, keeping abreast or ahead of competition in new products means maintaining a committed, loyal, and involved management, research and development, engineering, and manufacturing work-force; satisfied investors; cooperative suppliers; and confident consumers.

*Pressures for Short-Term Results.* Mergers, acquisitions, leveraged buyouts, and corporate raiding force managements to keep their eyes on short-term results, current earnings, and the price of their shares in relation to their assets. Nevertheless, attention to longer-term investment and outcomes must still be maintained if the firm is to remain healthy and viable (Freeman, 1984). At the same time, as reviewed by Lavery (1996), managers may still value short-term strategies for a variety of reasons. Intangible investments and qualitative payoffs may be ignored in formal quantitative techniques discounting the future (Hayes & Abernathy, 1980). A short-term strategy may be optimal for the manager who is planning to move out of the organization but suboptimal for the organization (Campbell & Marino, 1994; Rumelt, 1987). Investors and board directors may be impatient and want to see quick results (Jacobs, 1991); information about long-term prospects may be lacking (Thakor, 1990). And as said above, short-term maximizing of stock prices may be necessary when a hostile takeover by another corporation is possible (Drucker, 1986).

Short-term maximizing may be a matter of economic beliefs and ideals. Libertarians share a belief in unfettered free enterprise driven by self-interest. Everyone has a price. Everyone should try to maximize their own self-interests (Rand, 1959). Free-market consultants to Russia in the 1990s underestimated the effects of the human and cultural sides of enterprise. In 10 years, the new competitive economic policies had reduced the Russian economy by 50% and raised the poverty level disastrously (Lawrence, 2002).

*Religious Faith.* Toney and Oster (1998) presented the results of interviews and surveys of approximately 200 CEOs, of whom 65% were Protestant, 23% Catholic, and 12% Jewish. One specific question they were asked was how often they consciously applied the teachings of their religion to the daily decision process. Those who said they always did so were compared with those who said they never did so. The organizations led by CEOs who applied religious teachings earned 8% more net income than the organizations led by those who never did. In relation to their comparison group, these religious CEOs spent more time teaching and coaching and made more judgments on the basis of intuition and experience. They focused less on organizational and personal financial goals, were satisfied with a much smaller personal net worth, were more optimistic, gave twice as much to charity, more enjoyed being of service to others, and reported that their strong faith sustained them and made them more effective in coping with adversity.

*Nationality.* The value references in the annual reports for 1986–1990 of 53 American and 77 Australian organizations were content-analyzed and profiled in terms of nine values. Affiliation and leadership were espoused more frequently by the American organizations and authority and participation were espoused more frequently by the Australian organizations (Kabanoff & Daly, 2000). Presumably, the values espoused reflected the public views of the CEOs and managing directors. The GLOBE project (House, Hanges, Javidan, et al.,

2004) assessed the leadership values of midlevel managers in 62 countries. The values of participative leadership were highest in the managers of the Anglo countries, Nordic Europe, and the Germanic cluster. These values were lowest in Eastern Europe, southern Asia, Confucian Asia (China, Taiwan, Korea), and the Middle East. Valuing team orientation was highest in Latin America and lowest in the Middle East. A humane orientation was most valued by managers in southern Asia, sub-Saharan Africa, and the Anglo countries and least valued in Latin and Nordic Europe. The value of self-protection was most important in the Middle East, southern Asia, Eastern Europe, and Confucian Asia and was least important in the Anglo, Germanic, and Nordic countries (see also [Chapter 33](#)).

## ***Balancing Values***

Some of the balanced, salient values are likely to remain the same in profit-making enterprises as in government, education, health, and social service organizations, although specific values that are consistent with the purposes of the organization obviously need to be substituted. Leaders of organizations providing environmental products and services value the environment more than do leaders of nonenvironmentally-oriented organizations whether or not the organizations are for profit or not for profit (Egri & Herman, 2000). In health organizations, concern for the care of patients is substituted for concern with the quality of products, but the steward in a health organization must keep alert to the employees' as well as the patients' interests. Maslow (1965, pp. 128, 131) captured an ideal set of balanced objectives for the management of any system:

[The leader in the work situation] is the one who ... can help to organize things in such a fashion that the job gets done best. ... [The good leader must also have the] ability to take pleasure in the growth and self-actualization of other people. ... He must be strong, he must enjoy responsibility ... ; he must be able to mete out discipline as necessary, to be stern as well as loving [like] a good father and a husband; ... watching his children grow up well and ... his wife ... grow on toward greater maturity and self-actualization.

*Competing Values.* Quinn (1984) theorized that managers are faced with competing values that need to be kept under consideration. For example, they must make choices either for expansion and adaptation or for consolidation and continuity. They must choose between risk-taking inventiveness and conservative cautiousness, and sometimes between allocation of resources and information gathering and distribution.

Profit-maximizing values and balancing constituents' values may have to compete with a third set of values (Hay & Gray, 1974). For a minority of managers, quality of life, environmental protection, and other social and political values compete with constituent interests of the firm. For socially oriented managers, there can be no balanced compromise about the quality of a product, environmental pollution, or the safety of workers. Likewise, peace-minded investors avoid investing highly in the profitable military weapons industries, and public health advocates refuse to work for tobacco firms.

But it is not enough to say that some executives are profit maximizers, others are systems balancers, and still others have social concerns of consequence. There may be trade-offs between the three objectives that are not mutually exclusive. For instance, Osborn and Jackson (1988) presented data on the safety of 41 nuclear plants that suggested that the past experience of high profitability was associated with fewer major safety violations if the utility's total energy output was not committed to nuclear energy. However, if there was a relatively larger commitment to nuclear than to nonnuclear power, more major safety violations occurred with high profitability. Like riverboat gamblers, executives in the latter utilities appeared to be more willing to increase the risks of losing it all as profits increased. A survey of 6,000 business managers by Posner and Schmidt

(1984) found that of 11 values, the 2 most important were effectiveness and productivity and the least important were value to the community and service to the public. In another study of 803 public officials at the federal GS-15 level, Schmidt and Posner (1986) reported that among the 11 values effectiveness and productivity were first and third in importance, while service to the public and value to the community were seventh and eighth. The general public was tenth in ratings of the importance of constituents' interests; clients, bosses, self, technical personnel, managers, and coworkers were all more important. The evidence suggests that public and private administrators are less concerned about their obligations to society than about their obligations to their organization and its people.

A multiplicity of values involving personal and organizational considerations underlie the objectives of management. For managers to restrict themselves to a single objective function—profit maximization—is a fictional convenience for classical economists and some operational research specialists. For example, when Dent (1959) asked a representative sample of 145 U.S. chief executive officers or their deputies in confidential “off-the-record” interviews, “What are the aims of top management in your company?” only 36 percent mentioned as their first aim “to make money, profits, or a living.” Three-fourths talked about multiple goals including growth, public service, the welfare of employees, and the quality of products. High-quality products and public service were mentioned more often by the executives in larger firms; the welfare of employees was cited more often in smaller nonunion and larger unionized companies. In firms with higher percentages of white-collar, professional, or supervisory employees, fewer executives spoke of profitability and more spoke of growth. In addition, the willingness of managers to pursue noneconomic objectives may be a matter of how much their own income depends on the profitability of the firm. Furthermore, if they have alternative sources of income, they may express a broader range of valued objectives for the company (Hambrick & Mason, 1984).

*Factors in Organizational Values.* Shartle (1956) conducted studies of the elements that executives in several kinds of organizations said they valued to various degrees. A factor analysis of item intercorrelations produced nine factors that described the value dimensions for business firms: (1) organizational magnitude, expansion, and structure; (2) internal consideration for welfare, health, and comfort; (3) the degree of competition, strategy, and shrewdness; (4) the degree of ethical and social responsibility; (5) the quality of the product or service; (6) the degree of change; (7) the degree of organization control over the identifications of members; (8) the degree of external political participation; and (9) the degree of equality and recognition of members.

In a survey of 1,576 first-time supervisors at Japanese National Railways, Furukawa (1981) isolated five valued objectives. Three were task related (to establish order, to increase motivation, and to accomplish goals), and two were interpersonally oriented (to establish and maintain dependable relationships and peaceful work units). To achieve the human relations objectives, the supervisors saw a need to be more considerate and less initiating. To achieve task-oriented objectives, the need was for more initiation of structure and less consideration.

*Individual Differences in Values.* Valuing nonprofitable activities such as social programs, community programs, and employee welfare programs seems rooted more in individual differences than in socialization processes within the organization. This idea was inferred by Sukel (1983), who found that status as a top, middle, or first-level manager in manufacturing, banking, or retailing made no difference to the valuing of such socially relevant activities. At the same time, senior management could be seen as self-serving rather than more broadly interested in the organization and its members. This was seen when the board of directors rejected the bid of its own senior management to buy control of the RJR-Nabisco conglomerate, although the bid matched an outsider's leveraged buyout offer. The board of directors openly said they did not trust the

management to protect the rights of the employees or to maintain the integrity of the firms' operations (Sterngold, 1988).

### ***Priority of Effectiveness and Productivity***

While maintaining some sense of balance, most managers and business leaders, if given the choice, do tend to place a higher priority on organizational effectiveness and productivity, according to Posner and Schmidt (1984). For 803 senior federal officials, results were similar. Organizational effectiveness and productivity were rated first and third; value of service to the public and to the community were seventh and eighth (Schmidt & Posner, 1986). England (1967a, 1967b), who studied managers at nine hierarchical levels, found general agreement that the goals of organizational effectiveness and productivity was more important than social welfare goals. Community leaders of middle-size cities in the Midwest, most of whom were in business or banking, believed that economic development was the paramount goal of university extension services (Moss, 1974). A similar sample did not regard environmental concerns to be of much importance to their communities (Sofranko & Bridgeland, 1975). But community leaders in rural Georgia saw less need for economic exchange than for coordination, in contrast to rural heads of households with whom they were compared (Nix, Singh, & Cheatham, 1974). No doubt, concerns about the environment, climate change, and pollution have risen in importance in the past 30 years, along with concerns about health, education, and public affairs.

Using England's (1967a) Personal Values Questionnaire, England and Weber (1972) contrasted the extent to which U.S. managers regarded various issues as *successful*, as *right*, and as *pleasant*. From these judgments, managers were identified as emphasizing either what is pragmatic, what is moral, or what is pleasurable. England and Lee (1974) then administered the Personal Values Questionnaire to almost 2,000 U.S., Australian, Indian, and Japanese managers. The success of these managers was measured by their income adjusted for their age. In all four countries, successful managers were more likely to hold pragmatic values emphasizing productivity, profitability, and achievement.

*Fast-Track Managers' Priorities.* From 46 to 77% of an international sample of 5,122 managers were willing to spend money for all five budgeting problems on Exercise Objectives described above; but faster-climbing managers tended to exhibit more pragmatism than idealism in that they were less willing to spend money to handle the requests for safety, to settle a strike, to deal with morale, to improve the quality of products, or to eradicate pollution in a stream. Although they did not want to risk wasting money, faster-climbing managers did value generosity and fair-mindedness. The faster-climbing managers wanted productive value for their expenditures (Bass, Burger, Doktor, et al., 1979).

What managers judge to be important and valuable for success as a manager is related to their own success. Managers who stressed the importance of inner-directed values such as imagination and self-confidence were rated more effective in their jobs than those who viewed their roles as demanding other-directed behavior such as co-operativeness and tactfulness (Lawler & Porter, 1967a, 1967b; Mitchell & Porter, 1967; Porter & Lawler, 1968). Bass, Burger, et al. (1979) found that for several thousand middle managers from 12 countries, fast-trackers considered the values of generosity, fair-mindedness, sharp-wittedness, and steadiness as more important for top management, whereas slower-climbing managers considered tolerance and adaptability more important. The values considered most important by fast-trackers for middle managers were generosity, sharp-wittedness, and reliability; for slow-trackers, tolerance, adaptability, and self-control were most important for middle managers. Fast-trackers thought that the most important values for first-line supervisors were generosity and reliability. In contrast, slow-trackers judged fair-mindedness, tolerance, and adaptability most

important for first-line supervisors.

*The Valuing of Pay.* In response to the traditionalists' overemphasis on pay as a motivator, humanist scholars overreacted, attempting to minimize the importance of pay to managers and their subordinates. According to reviews of research on pay and managerial motivation, pay remained a strong motivator for managerial personnel.<sup>2</sup> Senior executives stressed the importance of pay slightly less than did managers at lower levels, but pay was highly significant for all. Pay may satisfy not only lower-order needs such as the need for safety and security, but also higher-order needs such as autonomy and self-actualization. Porter and Lawler (1986) found that managers who perceived that their pay depended to a great degree on their job performance tended to perform better on their jobs when both they and their superiors rated their performance. The relationship between the probability of higher pay and their likely effort was stronger for those who attached a high reward value to pay. Effective performance was related to the extent to which it was seen as instrumental to higher pay.

*The Valuing of Technical Competence.* Studies before 1965 indicated that first-line supervisors valued the technical aspects of their assignments more than their human relations responsibilities.<sup>3</sup> Their higher-level managers tended to agree with them (Rubenowitz, 1962). Increasingly, however, recognition of the importance of other attributes such as interpersonal competence has accompanied the valuing of technical competence in supervision. Such a shift in values (an increased subscription to pragmatism) occurred for managers in Western Australia in a period of 23 years. The change was attributed to changing Australian business conditions during the same period (Spillane, 1980). The valuing of technical competence was enhanced greatly by the information revolution.

*Personal Priorities.* Managers and leaders have their own personal priorities regarding what is important to them. In the aggregate, some personal goals—such as self-actualization, independence, and expertise—are more important than others such as duty, prestige, and wealth. There are wide individual differences among managers and leaders, depending on their organizational level, their nationality, whether they have job security, and so on. Hofstede (1978) found that in the responses of 65,000 supervisors, salesmen, and service personnel to a worldwide survey of IBM employees, these individual differences could be accounted for by two factors: (1) the valuing of personal assertiveness (leadership, independence, and self-realization), and (2) the valuing of personal comfort (pleasure, security, and affection). The Indian civil service, staffed mainly by 1,200 middle- and upper-class Britons educated at British public schools and universities, had contempt for moneymaking and the hustle and corruption accompanying it. They saw themselves as Plato's guardians and the "heaven born" (Lap-ping, 1985).

Bass, Burger, Doktor, et al. (1979) obtained results indicating that 3,082 managers in an international sample valued 11 life goals as follows (with 1.00 5 most important, and 11.00 5 least important): self-realization, 4.09; independence, 4.89; expertness, 5.17; affection, 5.21; leadership, 5.32; security, 5.50; service, 6.01; pleasure, 6.78; duty, 7.08; prestige, 7.65; and wealth to build a large estate, 8.27. But the standard deviations from 2.6 to 3.3 for each goal indicated that some managers rated the same goal first in importance whereas others ranked it eleventh. Wide individual differences, particularly across the 12 countries studied, were the rule.

### ***Belonging, Identification, and Loyalty***

One value of importance that many leaders and managers gain from their membership in an organization is a feeling of belonging to and identification with it (Wald & Doty, 1954). For example, Mullen's (1954) survey

of 140 clubs of supervisors in 32 states found that 88% of the supervisors wanted to feel identified with the company, and 71% reported being treated as if they were a part of management. D. D. Braun (1976) noted that identification with the community of Mankato, Minnesota, was strongly associated with community leadership rather than only with participation in community activities.

### ***Orientation Toward Superiors or Subordinates***

Some leaders tend to feel closer to the attitudes, beliefs, and values of the higher authorities in their organization; others tend to identify with those below themselves. The best leaders are able to do both. Furthermore, their performance will be affected by how much they identify with the organization's values. Their values are a key to understanding the relations between leaders and subordinates (Dienesch & Liden, 1986). D. T. Campbell and associates (1955, 1957, 1958, 1961) developed various methods of measuring orientation toward or identification with one's superiors and subordinates.

With these methods, Campbell and McCormack (1957) compared attitudes of air force and civilian personnel. The leader's location in the organization affected his or her orientation toward those above and those below. The researchers found that colonels were significantly less oriented toward their superiors than were majors or college men, and majors were less so than were air force cadets or their instructors. Air force majors and lieutenant colonels were significantly more subordinate-oriented than were the other groups tested. Orientation toward superiors or toward subordinates appeared to be independent of tested information about leadership (Campbell & Damarin, 1961); nor were self-reported orientation measures consistent with the observed orientation to superiors or subordinates in a role-playing exercise (Burwen & Campbell, 1957a). However, orientation toward superiors did correlate with authoritarianism and with valuing discipline (Chapman & Campbell, 1957a).

*Identification with the Values of Higher-Ups.* The alignment of the individual manager's goals and those of the organization is central to the manager's sense of belonging to and identification with the organization (Culbertson & McDonough, 1980). Vroom (1960b) observed that the goals of a large firm are likely to be more accurately perceived by those executives who have more favorable attitudes toward the firm. Subordinates who resemble their superiors in the personality traits "sociable" and "stable" are better satisfied than those who do not closely resemble their superiors in this respect. Furthermore, subordinates who identify themselves with and express interests similar to their superiors are more satisfied than those who do not (Eran, 1966). Such identification also helps their careers. Top managers generally preferred and rated as more effective those subordinates whose attitudes and values were similar to their own (R. E. Miles, 1964a; V. F. Mitchell, 1968). Identification with management also contributed to the likelihood that an employee would be promoted to a management position (J. C. White, 1964).

Lawler, Porter, and Tannenbaum (1968) found that interactions with superiors were more favorably valued than were those with subordinates. Balma, Maloney, and Lawshe (1958a, 1958b) concluded that supervisors who identified with management were rated as having significantly more productive groups than were those who did not. But the employees' satisfaction with a supervisor was not related to the supervisor's orientation. R. S. Barrett (1963) also discovered that first-line supervisors who perceived that their approach to problems was similar to that of their immediate superiors tended to feel free to do things in their own way. Fleishman and Peters (1962) observed that the effectiveness of lower-level managers was identified with that of their immediate middle-level superiors. Read (1962) found that the successful upward mobility of managers was related to their problem-oriented communication with superiors. This tendency to communicate with superiors was associated with trust in their superiors and a perception of their superiors' influence.

Henry (1949) and others found that rapidly promoted executives tended to identify themselves with their superiors as a primary organization reference group. Campbell, Dunnette, Lawler, and Welck (1970) suggested that fast-trackers tended to identify with fast-trackers higher up in the organization and were less interested in their current group of subordinates. To get promoted, they might even work against the best interests of their immediate subordinates. But the extent to which they enhanced their subordinates' sense of belonging to the organization tended to pay off in their subordinates' better performance. Habbe (1947) demonstrated that insurance agents who thought they were fulfilling their managers' expectations sold more policies and experienced fewer lapses than did those who thought they were not meeting these expectations.

*Identification with the Values of Subordinates.* Some evidence also suggests that for many leaders, satisfaction and success are connected with identification with those who are below them in the organization. According to R. E. Miles (1964a), managers did not regard lower-level supervisors as being highly promotable when they identified only with the company. Similarly, Mann and Dent (1954b) found that supervisors and employees agreed that the promotable supervisor is one who will stand up for employees and their rights, train them for better jobs, and let them know where they stand on matters that concern them. Pelz's (1952) study of industrial work groups indicated that first-line supervisors who were oriented to subordinates tended to be evaluated positively by workers, but only if they were perceived to have sufficient influence with superiors so they could satisfy the workers' expectations.

Supervisors who valued belonging and identification did much to increase their subordinates' sense of "ownership" of activities (Habbe, 1947). Consistent with this finding was Anikeeff's finding (1957) that the greater the satisfaction of managers, the greater the similarity between the attitudes of managers and workers. Satisfied managers prevented a cleavage in attitudes between workers and management.

The favorable attitudes of leaders toward their subordinates are reciprocated. Obrochta (1960) reported that workers' attitudes toward supervisors were favorable only when the supervisors held favorable attitudes toward the workers. Murphy and Corenblum (1966) observed that loyalty to a superior was higher at all levels in an organization if the superior perceived his or her group of subordinates as a primary source of social support.

Leaders can provide a model of behavior and values (Borman & Motowidlo, 1993). They can set examples for their teams that result in the team's productivity (Podsakoff, MacKenzie & Ahearne, 1997). Lock and Thomas (1998) found that such leaders could influence team members in good group citizenship, voluntary behaviors, and suitable responses to the organization's vision that result in desired organizational outcomes. But team leaders who gave a high priority to making money were more likely to lead teams that were less responsive to customers' needs for changes. Also, leaders who valued fun and pleasure were less likely to have teams motivated to find technological solutions for their customers. Sosik (2005) reported that 945 subordinates with higher traditional, collectivistic, and self-enhancement values rated their 218 managers as more charismatic in leadership. In turn, charismatic leadership predicted greater performance, extra effort, and good organizational citizenship behavior.

### ***Values and Political Leadership***

One has to look to journalists, biographers, historians, and philosophers for the best understanding of the values that underlie the performance of political leaders. Rokeach (1973) suggested that two values—freedom and equality—were basic to systems of political philosophy. He analyzed four political leaders: Norman Thomas, Barry Goldwater, Vladimir Lenin, and Adolf Hitler. Each leader, revealed distinctively different patterns of reference to the values of "freedom" and "equality." For Thomas (a Socialist), the values of freedom and equality were both highly salient. Hitler (a Fascist), seldom referred to them. For Lenin (a Communist),

equality was much more important than freedom. For the conservative Republican Goldwater, freedom was prized over equality (Rokeach, 1972).

Paige (1977) offered a number of hypotheses about the importance of values to the behavior of political leaders.

1. Terminal values (the worthwhileness of the end state) can be used by political leaders to justify contrary instrumental values (the worthwhileness of activities). Lenin argued that violence is justifiable to destroy the state and achieve the peaceful communist society. Woodrow Wilson justified the United States' entry into World War I because this was to be the war to end all wars.
2. Values influence the scope of what is relevant. Political leaders who sincerely value "one world" look at the same conflicts between nations differently from the way ardent nationalists look at them and try to act accordingly—for instance, on the subject of nuclear proliferation.
3. Political leaders and followers vary in the intensity of their value commitments. Both loyalty and treachery determine what happens to political movements in crises.
4. To achieve desired ends, political leaders may sacrifice the values of truth and honesty. "A good precinct captain [in Chicago] will always find a way to steal votes" (p. 124).
5. Values become salient to a political leader's behavior in reaction to circumstances and objectives. What a political leaders says to get elected may be the opposite of what he does after he is elected. In his campaign for the presidency in 1932, Franklin Delano Roosevelt argued for the popular economic value of a balanced federal budget. When elected, he moved rapidly into federal deficit spending to stimulate the economy to deal with the Great Depression.

To be politically successful in the United States a leader must emphasize the value of individualism. Since the two major U.S. political parties cross social boundaries to a considerable degree, personalized leadership, rather than social and economic policy issues, dominates elections. But economic values become salient in times of economic downturns, and foreign policy increases in importance in times of real or imagined threats to national security. Leaders differ in how much they value diplomacy over militancy and the support of international institutions to keep the peace. Fascist leaders value militarism and authoritarianism and are against welfare favored by democratic leaders (Eckhardt, 1965).

The U.S. Constitution was designed to check runaway leadership; nevertheless, individual leaders are seen as a panacea. Individual initiative and responsibility are prized in the U.S. culture; the role of leader is similarly valued. During the long-drawn-out electoral process and then after gaining office, the president has to "showcase" and sell his (or her) own qualities as a person to obtain power and remain powerful and influential (Rockman, 1984).

*Values of the Political Revolutionary.* Certain values, including asceticism, appear to stand out among revolutionary leaders such as Oliver Cromwell, Maximilien Robespierre, Vladimir Lenin, and Mao Zedong (Mazlish, 1976). All 32 revolutionary leaders studied by Rejai and Phillips (1979) were driven by a sense of justice and injustice and a corresponding attempt to right wrongs. Nationalism and patriotism were also important. When Rejai and Phillips (1988) contrasted 50 revolutionary leaders who aimed to overthrow their governments and 50 loyalist leaders who aimed to preserve them, according to 96 scholars, values that were more apparent in the revolutionaries than in the loyalists were an optimistic view of their human nature but a fluctuating optimistic view of their countries. Revolutionaries tended to abandon religion and to become atheists.

## Motives

Leaders vary in many motives, drives, desires, and needs that guide and energize them. These include curiosity, the desire for knowledge; order, the desire for structure; acquisition, the desire for saving and collecting; tranquillity, the desire for emotional calm; and eating, drinking, sex, romance, and physical activity (Reiss, 2000). How does a motive differ from a value or trait?

A *value* is a belief that an action or end state is preferable to its opposite. Leadership may be a value. A *trait* is a regular, consistent, and generalized cluster of intercorrelated behaviors. Extroversion is a trait. A *motive* can energize a variety of behaviors that may differ from each other but all create a similar inner affective state of goal satisfaction if consummated. A motive also provides direction or orientation to the energized behaviors. The need or desire to lead is a motive. Traits and motives interact with each other (Winter, John, Stewart, et al., 1998). For instance, in a study of 818 ROTC cadets, Thomas, Dickson and Bliese (2001) found that prediction of the cadets' assessed leadership in summer camp was completely mediated by the need for affiliation, and to a lesser extent by the need for power. Motives and needs may be conscious, implicit, or subconscious strivings toward our goals. If competing motives and obstacles do not interfere, we take action to satisfy our motives (Winter, 2002). The motives may be stable and generalizable propensities that are *far from action*. Or they may be intentions and choices that are *close to action*—momentary and applicable to a specific situation (Locke & Latham, 1990).

### ***The Achievement Motive (Subconscious)***

Believing that we need not be completely aware of our motives to be able to accurately answer direct questions about them, McClelland (1961) and McClelland and Winter (1969) developed the Thematic Apperception Test (TAT). Winter (1969) provided strong initial evidence to support the proposition that the need for achievement is an important value for effective leaders, particularly successful entrepreneurs.<sup>4</sup> Their data were corroborated by numerous studies, both in the United States and abroad, that demonstrated that managerial and entrepreneurial success was predicted by the need for achievement.<sup>5</sup> Likewise, Cummin (1967) found that more successful executives had a higher need for achievement. Wainer and Rubin (1969) observed that the need for achievement of 51 technical entrepreneurs who founded and operated their own firms was related to the growth rate of their companies. The highest-performing companies were those whose owners had a strong need for achievement and a moderate need for power. Furthermore, data from over 1,000 managers gathered by Hall and Donnell (1979) found that the speed of these managers' career advancement was associated with their motivation to achieve. Mussen and Porter (1959) concluded that leaders who were more effective in group discussions scored significantly higher in the need for achievement and affiliation and in feelings of adequacy than those who were ineffective.

However, unlike most other investigators, Harrell and Harrell (1978) failed to find such a measured need for achievement in a forecast at Stanford University of the subsequent success of trainees in small business. And Litwin and Stringer (1968) found that although participants in small-group experiments were more satisfied if their leaders had a high need for achievement, their groups experienced the same satisfaction if their leaders had a high need for affiliation. Nonetheless, the preponderance of many studies of the achievement motive suggest that those high in this motive try to outperform others. They are competitive. Winning makes them feel good. They get satisfaction from succeeding at tasks. They have self-imposed standards of excellence. Easy tasks may not be as interesting to achievers as challenging tasks on which they can succeed. Team success satisfies their high need for achievement only when each individual member's effort can be identified (Springer, 2001).

### ***Power Motivation***

This is concern with emotional impact for reputation, status, and strong actions affecting others. Achievement motivation and power, when each has been assessed alone, have been reasonably accurate in predicting the success of entrepreneurs and increases in their performance (McClelland & Winter, 1969). But each makes only a partial contribution to a full assessment of the motivation to manage. For a full assessment, as was noted in [Chapter 7](#), one needs to return again to the imperial motive—i.e., how need for power combines with high achievement motivation and low need for affiliation to account for their behavior as leaders. (The affiliation motive is concerned with close social and emotional relations with others.) High inhibition also is important. As Browning and Jacob (1964) observed, whether the need for achievement and for power directs individuals toward leadership in the economic or political arena depends on which arena in the community is open and available to them. In the political arena, dynamic, activist, and effective presidents gave inaugural addresses high in both the need for achievement and the need for power. Inactive presidents, less highly regarded by posterity, gave inaugural addresses that were low in both needs (Winter & Stewart, 1977).

Vision statements were analyzed after being obtained from 111 supervisors in a government service organization organization and 269 CEOs heading mainly small manufacturing companies that produced and installed wood products. As hypothesized, the stronger appearance of the achievement motive in the vision statements was more important in manufacturing than in service. The affiliation motive was more important in service (Kirkpatrick, 1999).

### ***Task Orientation (Conscious Motivation)***

*Defining Task Orientation.* The achievement motive, far from action, as measured by projective techniques, reflects a deep-seated, subconscious fantasy about success and accomplishment (Winter, 2002). Task orientation is a self-reported, inventoried, conscious motive scored by the Orientation Inventory (ORI, Bass, 1962b). Although the projected need and the conscious orientation have low correlation with each other (Bass, 1967c), they both appear to contribute positively to the emergence and success of a leader. Successful accomplishment is rated highly as a value and personal goal by managers in diverse organizations and countries (Bass, Burger, et al., 1979; England, 1967a, 1967b). The desire to achieve and to complete tasks successfully is a motive associated with those who emerge and succeed as leaders. Bass (1960a, p. 149) conceived of task orientation as a characteristic of persons who in social settings “will [try] hardest to help obtain the group’s goals, solve its problems, overcome barriers preventing the successful completion of the group’s tasks, and who persist at ... assignments.” Task orientation is distinguished from interaction (relations) orientation (to have fun, work cooperatively, and be helpful) and from self-orientation (to be praised, recognized, respected, and have loyal associates). The ORI assessed orientation toward the task, toward relating to others, and toward the self (Beckhard, 1995).

According to a review of research by Bass (1967b), those who were in higher-status positions in organizations uniformly were more task oriented. Thus top managers scored higher on the ORI than middle managers; middle managers scored higher than supervisors; supervisors scored higher than nonsupervisory workers. In addition, the higher the task orientations revealed by college student leaders in sensitivity training groups, the more they were rated positively by their peers on behaviors that are relevant to leadership. The task-oriented student leaders were seen to help other group members express their ideas, help the groups stay on target, help get to the meat of issues, give good suggestions on proceeding, provide good summaries, encourage high productivity, take the lead, work hard, and offer original ideas (Bass & Duntzman, 1963). Again, observers at an assessment center rated temporary supervisors who were under consideration for promotion as being more promotable if the supervisors were high in task orientation. Task orientation was

higher among second-line supervisors whose superiors rated them “best” rather than “less than best.” Likewise, it was higher among top-and middle-performing first-line supervisors than among those whose performance was low (Dunteman & Bass, 1963). Although tested intelligence correlated only .19 with task orientation, self-sufficiency and resourcefulness correlated .33 with task orientation. Other correlations with task orientation found in various studies were as follows: .31, controlled willpower; .28, need for endurance, .28, sober-serious; and .27, tough-realistic (Bass; 1967b).

*Other Measures of Conscious Task Motivation.* Many self-reporting questionnaire inventories such as the California Personality Inventory contain scales of conscious task motivation. The Saville and Holdsworth Motivation Questionnaire (MQ) generated 18 factored primary scales based on 700 British respondents. Two of the four higher-order factors that emerged were (1) intrinsic motivation, dealing with desire for interesting work that allowed for flexibility and autonomy; and (2) extrinsic motivation, from work which provided material rewards, career progress, and status. Status, in turn, systematically affected the strengths of the different motives. The MQ mean scores from 63 senior, 192 middle, and 231 junior managers revealed that the seniors were motivated most by the need to avoid failure. They would invest further energy in a project to ensure its success. Also, they had greater need for power and autonomy. At the same time, the junior managers were most concerned with their career progress. The middle managers fell in between these differences in motives. All the managers were similar in means on the other primary factor scales (Page & Baron, 1995).

Barbuto and Schell (1998) developed the reliable and valid Motivation Sources Inventory (MSI) to measure intrinsic, instrumental, external, and internal motivation and goal internalization. The instrument was based on a typology by Leonard, Beauvais, and Scholl (1999). Barbuto and Schell administered to 56 middle managers the MSI and Harrell and Stahl's (1981) Job Choice Decision-Making Exercise (JCE), a validated assessment of the needs for achievement, affiliation, and power. They also asked 217 raters to describe the managers' transformational leadership behavior using Bass and Avolio's (1991) Multifactor Leadership Questionnaire (MLQ) assessing the managers' idealized, inspirational, intellectually stimulating, and individually considerate leadership behaviors. Significant correlations were found between the MSI and the MLQ but not between the JCE and MLQ. Idealized influence correlated with internalized goals and instrumental motivation. Inspirational leadership was correlated with the managers' internalized goal motivation. Individualized consideration was correlated with instrumental motivation.

A variety of other indicators of conscious task motivation generally have been positively linked to attitudes and performance in work settings and their effects. For example, Rubenowitz (1962) found that superiors in an industrial situation tended to rate their subordinates higher in effectiveness when the subordinates were production-oriented rather than person-oriented. Tziner and Elizur (1985) created an assessment that was relevant to managers' motivation to achieve. It was unlike previous measures that were derived from projective approaches or self-reporting personality inventories. Their instrument consisted of 18 questions that asked 90 managers from a large Israeli corporation about how much they preferred to undertake difficult, problem-solving, high-responsibility tasks involving calculated risks, and how gratifying it was to do so if they were successful. The motivation to take calculated risks and solve problems correlated modestly with the rated performance of the managers, but no correlation was found between the motivation for responsible or difficult tasks and gratification for success with them.

## ***Risk Taking***

Some people enjoy taking risks, but others do not. Such preferences and behavior affect the leadership that emerges. Older leaders have been found to be generally more conservative and more likely to avoid taking risks

(Alluto & Hrebiniak, 1975). They want more information and higher probabilities of success and may be content with lower payoffs as a consequence. The contrast between older and younger leaders was illustrated by two Roman consuls in 210 B.C.; Fabius who was older, was a delayer, whereas Maximus, who was younger, was eager to fight immediately to try to trap Hannibal's forces. Along with a higher than ordinary need to achieve (McClelland, 1965c) and an internal locus of control (Borland, 1974), entrepreneurs and the founder-leaders of organizations also, as would be expected, have higher risk-taking propensities than do managers, in general (Brockhaus, 1980). They also have a higher tolerance for ambiguity than do managers in general (Schere, 1981). Wallach, Kogan, and Bern (1962) found that high risk takers were more influential in discussions than low risk takers. Marquis (1962) and Collins and Guetzkow (1964) observed that high risk takers were more persuasive than more cautious members of a group.

For a random sample of 26 express-mail managers, Hater and Bass (1988) reported an average correlation of .47 between the extent to which each manager was described by three subordinates as a transformational leader (charismatic, individualizing, and intellectually stimulating) and the extent to which the same managers were judged by their bosses to be high in risk taking. But the correlation was .02 with risk taking judged by the boss if the manager was described by subordinates as transactional in leadership (practicing contingent reward and management by exception). Frost, Fiedler, and Anderson (1983) found that taking physical risks was also related to performance as a leader. In a questionnaire survey of 40 army leaders, they found that effective combat leaders engaged in more personally endangering acts than did ineffective combat leaders. Interviews with 19 fire-battalion chiefs and evaluations of 124 fire-service leaders again suggested that effective leaders exhibit more personal bravery than ineffective leaders. Such personal bravery is expected of combat leaders, as in the Israeli army, where policy dictates that they are expected to go first into danger, to be followed by their men.

*Willingness to Take Risks and Achievement Motivation.* Those high in need for achievement are calculating risk takers (Springer, 2001). Tasks with moderate risks are satisfying to those who have a great need to achieve. A risk-free task will lack challenge, and a highly risky task entails the likelihood of failure (Atkinson, 1964). However, a higher level of risk of failure will be entertained if a task is inherently interesting (Shapira, 1975). Leaders must take calculated risks using the limited information available to them. Thus Cleveland (1985) emphasized that an executive needs to be motivated to achieve and prepared to take risks if he or she is to take the lead in the "perilous, problematic and participatory climate for policy making of today's information-rich world."

*Optimism.* By definition, optimists are more willing to take risks. Leaders need to be optimists rather than pessimists. Successful leaders have revealed a more optimistic view of themselves and the world around them than have nonleaders and those leaders who have tried and failed. Content analyses of archival records by Zullow, Oettingen, Peterson, and Seligman (1988) found that 9 of the 10 losers of presidential elections between 1948 and 1984 tended in their speeches to see the pessimistic side of issues. Other analyses have found that bold leadership was predicted by optimistic styles. President George W. Bush is illustrative. Similarly, those individuals who have learned a sense of helplessness are much less likely to take the initiative in social situations (Abramson, Seligman, & Teasdale, 1978). Cleveland (1985) observed that the generalist executive in an information-rich world of work needs to be optimistic about what can be accomplished. Community leaders have more positive expectations about outcomes than do nonleaders.

### ***Willingness to Trust***

Closely associated with the willingness to take risks is the willingness to trust. Sgro et al. (1980) found that the

leadership behavior of 41 cadet officers, as described by their 149 cadet subordinates, was associated with the officers' scores on a self-inventory of interpersonal trust. Interpersonal trust correlated significantly with their consideration and tolerance of freedom and their subordinates' satisfaction with them. According to Devine (1977), who conducted a survey of opinion leadership in three towns in Minnesota, both opinion leaders and opinion followers showed a willingness to trust others, but opinion isolates were less likely to trust. Rosenberg (1956) suggested that persons with low interpersonal trust would have difficulty establishing close friendships. As leaders, they would be less likely to permit freedom of action in their subordinates. Willingness to trust others increases the likelihood of self-disclosure and the likelihood of obtaining valid feedback from them if the trust is mutual (Rusaw, 2000).

It may be that risk-taking, trusting leaders are able to maintain longer time spans for reaching decisions in contrast to those who press for quick solutions and immediate feedback (Frain & DuBrin, 1981). Clearly, willingness to risk and to trust others are required for meaningful delegation. More delegation should be seen in those leaders who are greater risk takers and are more willing to trust others. Conversely, the Machiavellian authoritarian, who expects others to share the same tendencies toward deception and surprise, is less likely to take chances on others.

Particularly salient in determining the proclivity to take risks is one's self-confidence. Both Clausen (1965) and Burnstein (1969) inferred that high risk takers tended to score high in self-confidence, which, in turn, led them to attempt and to succeed in influencing groups to follow their leadership. But many other aspects of one's self-concept enter into the emergence and success of a leader.

## Concepts of the Self

---

"The leader's orientation toward self and others must be taken into account in order to understand fully the leadership dynamic" (Carey, 1992). How leaders think about themselves and what mental representations they form of their own roles and behaviors as leaders are underre-searched (Murphy, 2002). Apart from what has been said so far, how people think, feel, and act about themselves affects their tendencies to lead. Thus, in contrast to others, *transformational* leaders value their capacity to learn from others and from their environment and believe they can learn more about themselves in doing so (Bennis & Nanus, 1985). Top business leaders, according to Levinson and Rosenthal (1984), have strong self-images and ego ideals. From a meta-analysis of the relationship of self-concepts to job satisfaction and performance, Judge and Bono (2001) concluded that these self-concepts (self-esteem, self-efficacy, and locus of control) were some of the best predictors of job satisfaction and job performance. Estimated true correlations ranged from .22 to .45. Kark and Shamir (2002) noted that transformational leaders may appeal to their followers' *relational self* derived from the interpersonal connections between followers and individual others. Or the transformational leaders may appeal to their followers' *collective self* derived from larger work teams or organizations. The transformational leader's individualized consideration primes the interpersonal connections of the followers' relational self and self-identity. By linking the individual to the group's shared values and key role identities, the leader primes the collective self.

### ***Self-Actualization***

Maslow (1954) conceived of self-actualization—the desire to become what one is capable of becoming—as a higher level of maturity than the need for achievement. Compared with nonleaders, leaders tend to self-actualize more. They are more likely to perform up to their capacities and to develop themselves accordingly. This motivation was at the top of Maslow's (1954) needs hierarchy. Maslow (1965) believed that the

attainment of self-actualization was revealed in characteristics of psychological health and well-being such as perceiving reality efficiently, accepting oneself, tolerating uncertainty, being problem-centered rather than self-centered, and identifying one's defenses with the courage to give them up. For Burns (1978), self-actualizers were potential transformational leaders because of their flexibility and their capacity for growth. Through their drive toward self-actualization, they could continually be one step ahead of their followers and help their followers rise as disciples behind them, as measured by their upward movement on Maslow's hierarchy of needs, from concern for safety and security toward concern for achievement and self-actualization.

*Measurement.* The Personal Orientation Inventory (POI) measures 12 interrelated aspects of self-actualization (Shostrom, 1974). POI assesses such self-concepts and values as self-directedness versus other-directedness, self-regard, self-acceptance, self-actualizing, responsiveness to one's own feelings and needs, capacity for intimate contact, and the extent to which one has a constructive view of humanity. In a survey of 58 executives in a high-technology firm, Gibbons (1986) found many strong correlations between subordinates' descriptions of the transformational leadership behavior (charismatic, individually considerate, intellectually stimulating, and inspirational) of their superiors and the superiors' self-descriptions on the POI. Among these attributes, self-acceptance correlated .41 with being described as a charismatic and inspirational leader. The superiors' self-rated inner direction, self-regard, self-acceptance, and capacity for intimate contact all correlated above .40 with the subordinates' ratings of their superiors' individual consideration as a leader. Inner direction and self-acceptance also correlated above .40 with displaying contingent reward. Gaston (1983), too, found evidence that those managers who were identified in POI interviews and by their colleagues as self-actualized tended to perform well as leaders even in less than optimum organizational systems.

Some of Maslow's elements of self-actualization have to be reconsidered as contributions to the performance of leaders. For example, Gibbons (1986) found that spontaneity generally was closer to zero in correlation with various leadership factors. This finding seems to be consistent with McClelland's argument that the motivation to lead includes a need for inhibiting power; and, as will be discussed later, the emergence and success of a leader calls for a high degree of self-monitoring.

*Ways of Achieving Self-Actualization.* People differ in what they consider self-actualization to be. Politicians may see it as the attainment of power; business executives may see it as the attainment of organizational leadership; technologists, as the attainment of expertise; and entrepreneurs, as the attainment of wealth. Similarly, Maslow's social needs can be satisfied within the family and among friends through affection, on the job through service, and in the organization or community through duty. Wainer and Rubin's (1969) study of entrepreneurs who had started their own companies found that their strong need for achievement and their moderate need for power were associated with their companies' success. Ghiselli's (1986b) analysis of middle managers and hourly workers found that successful managers had less desire for security and financial rewards than did unsuccessful ones. However, Henderson (1977) failed to find support for expectations that self-actualization would influence choice of leadership style. Harrell and Alpert (1979) concluded that to maximize success and satisfaction, the need for autonomy should be strong among business entrepreneurs, moderate among tenured professors, and weak among bureaucrats. Appelbaum (1977) obtained data from 75 suburban supervisors in governments that strongly supported Harrell and Alpert's conclusion about bureaucrats.

## ***Needs Satisfaction***

Although rated as being most important in themselves, self-actualization and autonomy were the least satisfied managerial needs (L. W. Porter, 1961b).<sup>6</sup> Job security was less important and more readily satisfied (Centers,

1948).<sup>7</sup> This pattern changed in the 1980s with the increased concern for security. With the “downsizing” of management in the 1980s, and again during the recession of 2001, job security has become a more potent issue for lower and middle managers (McCormick & Powell, 1988).

Among 3,082 mostly middle managers from 12 countries, as noted before, Bass, Burger, et al. (1979) found that the managers had a clear set of preferences when they were asked to rank their life goals. The most important goals were self-realization (self-actualization) and independence (autonomy). Security was ranked much lower. Goals having to do with assertiveness and accomplishment were emphasized more often by fast-track managers, whereas goals associated with comfort tended to be favored by slow-track managers. Similarly, Hall and Donnell (1979) found that in comparing 190 slow-track, 442 average-track, and 32 fast-track managers, the fast advancers stressed the need for self-actualization, belonging, and esteem in motivating their subordinates. They paid only average attention to the need for safety and security. The slow-track managers emphasized mainly the need for safety and security. This was consistent with Porter and Lawler's (1968) finding that differences in successful managerial performance were more highly related to the need for self-actualization and autonomy than to the need for security, belonging, and esteem.

### ***Self-Awareness***

Self-awareness is assessed by comparing a leader's self-ratings of behavior and the ratings of behavior observed by superiors, peers, subordinates, or others (Atwater & Yammarino, 1992). Often the congruence is lower than expected. To improve their self-awareness, leaders need to be more introspective and to pay more attention to feedback from others (Ulmer, 1996).

Those leaders who underrate themselves receive higher performance appraisals. For instance, Wexley, Alexander, Greenawalt, et al. (1980) studied manager-subordinate dyads and obtained a significant correlation between a subordinate's satisfaction with supervision and the congruence between the manager's self-description and the subordinate's description of the manager.<sup>8</sup> Those who overrate themselves tend to be less effective leaders (Bass & Yammarino, 1991), possibly because they may be highly self-confident and ignore failures and criticism (Atwater & Yammarino, 1997). As Edwards and Parry (1993) and Edwards (2001) have noted, when a correlation is calculated between the criterion of performance (Y) and the difference between the self-rater (S) and the rater (R) score, not only is it the resulting difference between the simple correlation between  $r_{SY}$  and  $r_{RY}$ ; it is dependent also on  $S^2 - 1 - R^2 - 2RS$  and requires a quadratic correlation model. Accordingly, a richer examination of self-awareness was provided by Tekleab, Yun, Tesluk, et al. (2001) using polynomial regression analysis. It showed for 49 leaders and their 222 followers, effectiveness was highest for transformational leaders whose self-reports were congruent with those of their followers; underestimating leaders were next most effective; and overestimators of their transformational leadership were least effective. Leaders who were in agreement with their followers (accurate estimators) were more effective than leaders who were inaccurate estimators. Any change in accuracy from perfect agreement with followers was linked to a reduction in effectiveness. The decline was greater for overestimators than underestimators. Generally similar but not as clear-cut results occurred for the leaders with self-awareness of empowering leadership and its impact on followers' self-leadership. A leader's lack of self-awareness may reveal a lack of listening, a lack of response to followers' demands, and a lack of attention to criticism and failures—a misdiagnosis of the leader's strengths and weaknesses (Tekleab, Yun, Tesluk, et al., 2001). Sosik and Megerian (1999) found that overestimators and underestimators were lower in transformational leadership, performance, and emotional intelligence than those who were more in agreement with their subordinates about their ratings. The results supported earlier findings by Atwater, Ostroff, Yammarino, et al. (1998).

## ***Self-Understanding***

“Know thyself,” a favorite piece of wisdom to classical Greek philosophers, continues to be important advice for leaders today. In most surveys, leaders tend to give themselves an inflated evaluation in contrast to their colleagues’ descriptions of their performance (Bass & Yammarino, 1989). They believe they have more important jobs than their superiors think they have. Modesty is not usually a trait of managers. But self-understanding is essential even for the most successful leaders. As was already noted, the interpersonally competent manager is open to receiving feedback, the approach most likely to promote and maintain a manager’s accurate self-understanding. Supported by the Gallup Organization’s worldwide individual survey feedback and consulting efforts, Clifton (1992) counseled that managers should find out what they do well and do more of it. They should also find out what they do poorly and stop doing it. “Focus on strengths and manage the weaknesses” (p. 18). Nonetheless,

Executives need to be able to handle their own success. They can be derailed when ... success goes to their heads. After being told how good they are for so long, some simply lose their humility and become cold and arrogant. ... People no longer wish to work with them (or continue to provide feedback). (McCall & Lombardo, 1983, p. 11)

Concepts of the self can be at variance with the outside world and affect a leader’s performance. For instance, Ziegenhagen (1964) subjected 15 world political leaders’ autobiographies to content analysis and found that the leaders’ ethnocentric behavior, conformity to in-group norms, and hostility to out-groups correlated highly with inconsistencies in the leaders’ self-conceptions. These inconsistencies were assessed by a lack of agreement between the leaders’ self-concept and the concept that the individual leaders thought others had of them. Interest has grown in helping managers to more accurately differentiate themselves from others, to recognize that they don’t necessarily think like others, and to realize that they should not expect others to react in the same way as they do in situations (Chee, 2002).

Other self-concepts related to leadership that have been of particular interest include self-schemas, self-monitoring, locus of control, field independence, self-efficacy, self-confidence, and self-esteem.

## ***Self-Schemas***

Self-schema (also called self-schemata) are “cognitive generalizations about the self, derived from past experience, that organize and guide the processing of self-related information” (Markus, Smith & Moreland, 1977, p. 64). People with leadership self-schemas are likely to think about becoming leaders and to engage in leadership activities. Thus W. G. Smith, Brown, Lord, et al. (1996) found that high school students with leadership self-schemas were more likely to take leadership positions. They were also more likely to emerge as leaders in groups (Makiney, Marchioro & Hall, 1999).

Grosch, Salter, and Smith (2000) asked 74 managers in a manufacturing division of a multinational firm to complete a modified self-schema questionnaire developed by W. G. Smith, Brown, Lord, et al. (1996). Using five-point Likert scales to measure the self-schemas, the managers rated the self-descriptiveness and importance to their self-evaluation of each of 40 attributes. Twenty-four of the attributes were prototypical leadership traits according to Offerman, Kennedy, and Wirtz (1994). The reliability of the self-schemas was .94. As hypothesized, the leadership self-schemas correlated .50 with the managers’ self-ratings of their own leadership ability. Such self-confidence was expected by Grosch, Salter, and Smith. Using shorter but similar measures of two leadership self-schemas, dedication, and social influence, along with the Multifactor Leadership Questionnaire (Bass & Avolio, 1991), Saucier’s (1994) short version of the NEOAC “Big Five” Personality

Inventory, and peer rankings and impressions, Makiney, Marchioro, and Hall (1999) found with 95 undergraduate students (75% female) that leadership self-schemas of dedication (goal-oriented, determined, organized) and social influence (persuasive, decisive, directing) both correlated .44 with transformational leadership in small groups as judged by peers over six time periods during a semester. The self-schema of dedication correlated .28 with agreeableness; the self-schema of social influence correlated .28 with extroversion and .24 with openness. Stepwise regression analysis showed that the schemas added to the MLQ and NEOAC in accounting for variance in peers' leadership rankings and peers' general impressions of the participants' leadership in the small groups.

### ***Self-Monitoring and Self-Regulation***

*Self-Monitoring and Leadership.* Snyder (1974, 1979) suggested that individuals differ in the extent to which they monitor and control presentations of themselves in social situations. As measured by a revised self-report inventory, self-monitoring involves at least two independent components: sensitivity to others' behavior and the ability to modify one's behavior accordingly (Lennox & Wolfe, 1984). Self-monitors are sensitive to cues about the appropriateness of various types of behavior (Snyder & Mason, 1975) and use these cues to guide their interpersonal behavior. Inhibition of activity is likely to be revealed in self-monitoring. Circumstances and their interpretation will determine whether high self-monitors display more or less leadership behavior than low self-monitors (Cader, Eby, Noble, et al., 1999).

Abilities associated with self-monitoring cut across the factors of sensitivity and control and contribute to a leader's effectiveness. Self-monitoring is concerned with social appropriateness, attention to social-comparison information, the ability to control and modify self-presentation, and the flexible use of this ability in particular situations (Snyder, 1974, p. 529). The elements of self-monitoring correlate with the ability to be a good actor and to give impromptu speeches (Briggs, Cheek, & Buss, 1980). Those who score low in self-monitoring are controlled by their own consistent attitudes and are not molded to the demands of the situation.

Snyder (1979) suggested that high self-monitoring individuals may be more likely to emerge as the leaders of groups because of their ability to regulate the interpersonal relationships in group interactions. Kenny and Zaccaro (1983) further proposed that experienced leaders became sensitive to differences in group situations and patterned their approaches accordingly. These leaders developed acuity in foreseeing the needs of their followers and altered their own behaviors to respond more effectively to those needs. Zaccaro, Foti, and Kenny (1991) demonstrated this in their experiment rotating participants through four tasks. Compared with low self-monitors, high self-monitors perceived the changes in task demands and showed somewhat more flexibility in their styles of leadership, according to their peers. Also contributing to the link between self-monitoring and leadership was the fact that high self-monitors present themselves in a socially desirable manner (Snyder, 1979) and construct an image of the ideal type of person for the situation they face. Using this ideal, the high self-monitors act according to the demands of this role (Snyder & Cantor, 1980).

When high self-monitors attempt to lead in a particular situation, they have several advantages over low self-monitors. Ickes and Barnes (1977) found that high self-monitors tend to speak first in an interaction and to initiate more conversational sequences than do low self-monitors. They also are perceived to be more friendly, outgoing, and extroverted than low self-monitors (Lippa, 1978). They are more successful as boundary spanners, a role that requires greater adaptability to situational requirements (Caldwell & O'Reilly, 1982).

Garland and Beard (1979) tested whether the effects of self-monitoring on emergent leadership would depend on the nature of the task confronting a group: a high self-monitor was expected to emerge as a leader when a task emphasized discussion and when task competence was difficult to assess. Such effects occurred in

all-female groups but not in all-male groups. In an unpublished field study of natural groups, Mendenhall (1983) reported that high self-monitors were more likely to emerge as leaders of initially leaderless groups if they perceived themselves to be leaders rather than being perceived as leaders only by their peers. Nevertheless, peer-rated leadership of male students in semester-long mixed-sex study groups correlated .41 with the Lennox and Wolfe (1984) Revised Self-Monitoring scales, .26 with sensitivity to others' behavior, and .40 with the ability to modify one's behavior accordingly. But the correlations were lower for female participants, in reverse of Garland and Beard's (1979) results for all-male and all-female groups. A generation ago, females in mixed groups seemed more reluctant to assert leadership in the presence of males. This effect is likely to have disappeared since then.

Foti and Cohen (undated) involved three-person same-sex groups of students—one high, one moderate, and one low self-monitor—in a manufacturing exercise. The emergent leader was highly self-monitoring in 41 of the 58 groups, moderate in 11 of the groups, and low in self-monitoring in only 6 of the groups. High self-monitors, as expected, adapted their leadership style to the situation. They exhibited more initiation of structure when instructions emphasized the importance of the task rather than relationships, and more consideration when instructions emphasized developing good interpersonal relationships. Groups led by high self-monitors were somewhat more productive if the task was emphasized.

*Self-Regulation.* Self-regulation functions to enact and revise behavior as well as to change the environment. It involves how we set goals, how we plan or rehearse, and how we monitor progress toward goal attainment (Murphy, 2002). The self-regulatory process begins with *self-awareness* of our thoughts and feelings. Then we estimate our *self-efficacy*—our judged capabilities (see below). Finally, with thoughts, motives, and feelings about what to do, we act accordingly (Bandura, 1986). Self-regulation is important to charismatic leaders (Murphy, 2002). Privately, charismatic leaders, compared with noncharismatic leaders, are more self-conscious, self-monitoring, and more purposeful in their behavior (Sosik & Dworakivsky, 1998). Along with self-schemas, self-esteem, and self-monitoring, they use a dramaturgical perspective to regulate the impressions of their identities they make on others (Gardner & Avolio, 1998).

### ***Locus of Control***

In his popular book *The Lonely Crowd*, Riesman (1950) suggested that the post–World War II generation, compared with its predecessors, was more outer-directed than inner-directed. Members of the postwar generation were controlled more by others and circumstances than by themselves. Locus of control (LOC), internal or external, was widely studied in the mid-1960s as a personal antecedent of consequence to a leader's behavior when the LOC measure of individual differences became available. Rotter (1966) developed and evaluated a self-report assessment instrument of LOC, the I-E Scale, which discriminates between persons who are controlled by internal forces (persons for whom outcomes are contingent on themselves) and persons who are controlled by outside influences (persons for whom outcomes are due to such forces as luck, fate, and powerful others whom they do not and cannot control). Respondents choose between pairs of statements such as “Without the right breaks, one cannot be an effective leader” or “Capable people who fail to become leaders have not taken advantage of their opportunities.”

Carey (1992, p. 217) noted that “the leader's orientation toward self and others must be taken into account to understand fully the leadership dynamic.” Nevertheless, DeBolt, Liska, and Weng (1976) concluded from a review of the literature that internal control, as measured by LOC, failed to relate consistently to the display of leadership in small groups of students. Also, Nystrom (1986) failed to detect much association between LOC and the performance of managers. Anderson and Schneier (1978) disagreed. It was differences in the approach

to leadership that LOC predicted. Thus Durand and Nord (1976) found that the internal LOC of supervisors was linked to which their subordinates thought them to be considerate. In a simulated industrial setting, Goodstadt and Hielle (1973) found that supervisors with an external LOC were more likely to rely on persuasion and those with an internal LOC were more likely to rely on personal power. Mitchell, Smyser, and Weed (1975) obtained similar results. They noted that supervisors with an external LOC were more likely to use coercion and legitimate authority, whereas those with an internal LOC used rewards, respect, and expert power. Pryer and Distefano (1971) confirmed that nursing supervisors with an internal LOC were more considerate than those with an external LOC. In a study of 89 supervisors and their 345 subordinates, Johnson, Luthans, and Hennessey (1984) found that the leaders' LOC affected their influence on their subordinates' productivity and satisfaction with them as leaders. Supervisors who rated themselves as internally controlled were rated by their subordinates as significantly higher in persuasiveness and in their influence on higher authority.

*Confounds.* Some of the relationship between LOC and the performance of managers may be accounted for by the finding that internally controlled managers are more task oriented (Anderson, Hellriegel, & Slocum, 1977). This finding is consistent with those of several other studies, that found that managers with an internal LOC individually put forth more task-centered effort and performed better than did those with an external LOC (Anderson, 1977). There are other confounding elements. Managers with an internal LOC have higher activity levels than those with an external LOC (Brockhaus, 1975; Durand & Shea, 1974), appear more realistic about their aspirations (Phares, 1973), and perceive less stress under the same conditions (Anderson, 1977). The ambiguity of their roles did not seem to bother managers with a stronger internal LOC as much as it disturbed managers with a stronger external LOC (Abdel-Halim, 1980). Those with a higher internal LOC were less dogmatic, more trustful, and less suspicious of others (Joe, 1971). Not unexpectedly, Coates (1984) found a complex statistical interaction between the LOC and Mach scores of 79 managers, the number of contacts they reported with superiors and peers, and superiors' rating of their influence.<sup>2</sup>

### ***Field Independence***

A cognitive trait that is linked to inner directiveness and inner control is field independence. This trait is measured by Witkin's Rod and Frame Test, in which field-independent people judge that the field of a rod and frame is being reoriented, not that they themselves are. Paper-and-pencil correlates of field independence have also been found, for example, in people who can readily see incomplete figures as whole on the Group Embedded Figures Test. Field-independent Israeli managers with engineering backgrounds were more likely to be employee-centered than job-centered in their leadership styles (Erez, 1980). Results elsewhere have indicated that field-independent hospital managers preferred to use participative and delegative, rather than directive, leadership styles, although more managers as a whole were field-dependent than were field-independent on the Group Embedded Figures Test.

### ***Self-Efficacy***

As noted elsewhere, individuals who see themselves as masters of their own fate, rather than at the mercy of luck, fate, or powerful other people, tend to cope better with stress, and generally make more effective and satisfying leaders. Such leaders are also likely to see themselves as more self-efficacious. Bandura (1982, p. 122) defined *self-efficacy* as a judgment of "how well one can execute courses of action required to deal with prospective situations." Self-efficacy is a broad set of expectations associated with beliefs about one's

adaptability, ingenuity, and ability to work under stress, regardless of the ease or the difficulty of the goals (Locke, Motowidlo, & Bobko, 1986). Expectations of efficacy change with new information and experiences of personal attainment, vicarious modeling, verbal persuasion, and emotional arousal (Gist & Mitchell, 1992). Those high in self-efficacy treat the same experiences differently from those low in self-efficacy. Although both see success as due to their abilities, self-efficacious people attribute failure to lack of effort or bad luck rather than to their lack of ability (Silver, Mitchell & Gist, 1991).

Bennis and Nanus (1985) saw the transforming leader as one who has a strong, positive self-regard and who employs the “Wallenda factor” (Wallenda is the name of the family of high-wire walkers)—that is, one who focuses on success with the risky task rather than being preoccupied with the possibility of failure. Self-efficacy “is critical to the leadership process” because it affects the motivation, development, and execution of a leader’s strategies and goals (McCormack, 2001). Thus Savard and Rogers (1992) found that self-efficacy predicted a leader’s persistence in trying to persuade others despite resistance. Wood and Bandura (1989) manipulated the belief in self-efficacy of business graduate students assigned to play roles in a simulated business. Beforehand, one set of students experienced a process that diminished their self-efficacy; the other set had an experience that increased their self-efficacy. The former set became increasingly discouraged as decision makers. Their analytical strategies declined in quality, as did their aspirations and success in attaining organizational performance goals. The self-efficacious set created and met challenging goals for themselves and produced effective analytical strategies that yielded maximum performance. Self-efficacy is closely allied with self-confidence.

### ***Self-Confidence***

Self-confidence was positively associated with leadership in the reviews reported in Chapters 4 and 5. Bass (1985a) and Zaleznik (1977) found that it is particularly strong in transformational leaders. Mowday (1979) found that the leadership of 65 elementary school principals in dealing with four decisions was related to their self-confidence, and that the principals were more likely to be persuasive if they were self-confident. Conversely, Kipnis and Lane (1962) reported that supervisors who lacked confidence in their leadership ability were significantly less willing than self-confident supervisors to hold face-to-face discussions with subordinates. More often, they attempted to solve supervisory and development problems by using administrative rules or by referring the subordinates to a superior for a decision. According to Kaplan (1986), self-confidence weighed heavily in distinguishing between general managers who performed effectively and those who did not. The “effectives” were seen as personally secure, communicating their confidence and decisiveness to others; the “ineffectives” were characterized by incidents displaying their personal insecurity, their lack of “guts,” and their unwillingness to make tough decisions or risk making enemies. The self-confidence of supervisors affected what they did to influence others. Those who felt confident in their ability to influence others were likely to use rewards and promises of rewards; those who lacked self-confidence were more likely to use coercion (Goodstadt & Kipnis, 1970; Kipnis & Lane, 1962).

Nonetheless, self-confidence can also result in an unrealistic, inflated evaluation of oneself. When such a self-evaluation is coupled with extremely low self-esteem, the performance of a leader is likely to be socially counterproductive (Reykowski, 1982). Self-confidence can also give rise to the stubbornness and obstinacy that Willner (1968, p. 65) described in charismatic world leaders “whose ... determination ... would not permit them to lose sight of their goals or swerve from a particular tactic they had decided upon, no matter how remote from achievement the goals may have appeared to others or how unwise the tactic.” Moved by some intuition or an “inner voice,” and undiscouraged by the obstacles that seemed insuperable to those around them, they pursued the course they had set themselves. Handy (1987) agreed that successful leaders have to believe in themselves in order to influence people and events. If they don’t believe in themselves, neither will

the others they seek to influence believe in them. At the same time, leaders must guard against arrogance and unwillingness to hear what others have to say.

## ***Self-Esteem***

Self-esteem differs from self-efficacy in that self-esteem deals with a generalized evaluation of the self and feelings of self-worth across most situations whereas self-efficacy is a belief in one's abilities to cope with specific situations—say, learning a new computer program (Gist & Mitchell, 1992). As was noted in [Chapter 4](#), 17 pre-1948 studies found self-esteem to be higher in leaders than in their followers. Additional support came from subsequent investigations that found a positive relationship between self-esteem and leadership. Market research studies concluded that a majority of opinion leaders in fashion and personal grooming are high in self-esteem. Hemphill and Pepinsky (1955) found attempted leadership to be higher among participants who felt personally accepted or esteemed. Andrews (1984) found that among 64 undergraduates, those with high self-esteem were more likely to emerge as the leaders of their groups and were more likely to be rated as displaying such leadership behaviors as offering problem-relevant information, giving sound opinions, and making procedural suggestions. In Finland, Kalma, Visser, and Peeters (1993) found a correlation of .32 between self-esteem and social dominance.

Burns (1978) noted that the most potent sources of political leadership are unfulfilled needs for esteem and self-esteem. Erikson (1964) believed that great leaders become leaders because they have personally experienced, in a way that is representative of their people, the identity struggle for a particular niche in society compatible with their self-respect and expectations. But Barber (1965) thought that deciding to become a candidate for political office is indicative of either very high or very low self-esteem.

Bass (1960) postulated that those with high self-esteem would be more likely to attempt leadership. Bennis and Nanus (1985) concluded, from 90 interviews with top-level leaders, that such self-esteem was likely to be transferred to their subordinates. The leaders then could operate without having to resort to criticism or negative reinforcement. Higher performance expectations and confidence were generated in subordinates as a consequence. Defensiveness was lower if self-esteem was high. Self-esteem in leaders appears to be related to an ability to accept people as they are rather than as one would like them to be, to focus on the present rather than on the past, to be as courteous to close colleagues as to strangers, to trust others, and to do without constant approval and recognition.

According to Brandon (1998), self-esteem has become increasingly important in the information age because it takes self-esteem for information workers and leaders to initiate, innovate, and be self-reliant, trusting, and accepting of personal responsibility. Leaders need to create an environment that supports knowledge workers' self-esteem. The command and control system of the factory and office must be replaced by a system that promotes trust in the ability to think, to change, and to take on new ideas as new conditions arise. Intellectual capital is prized. Knowledge workers may know more about their work than their leaders do. But the leaders will need high self-esteem to inspire and support the workers. Leaders with low self-esteem will be insecure and likely to generate conflict with their subordinates.

## ***Deployment of the Self***

Bennis and Nanus (1985) suggested that the 90 leaders in their study were effective if they used their strengths as known to them and avoided using their weaknesses. They learned from and reflected on their own experiences. They were experimental, made comparisons with other leaders and organizations, and monitored the effects of environmental change on themselves. They asked their followers to do the same. According to

Kets de Vries (1989), leaders gain influence through the transference and projection of the followers' hopes, desires, and fears onto the leader. The leaders fail if they are unable to live up to the followers' expectations of them. If leaders are narcissistic and have an inflated image of themselves, they become destructive.

## Satisfaction with the Leadership role

---

### *Status, Rank, Level, and Satisfaction*

One of the most consistent findings in behavioral science is the positive correlation between one's status—the worth and importance of one's position in an organizational or social hierarchy—and one's satisfaction with it. Relying on early survey evidence, G. B. Watson (1942) was convinced that managers and supervisors were more satisfied with their work than were rank-and-file employees. Furthermore, top managers were generally more satisfied than managers at lower levels (Bass, 1960). The results of many studies supported the contention that the higher the level of individuals' positions in the organization, the greater was their job satisfaction. For instance, supervisors of municipal employees were much more satisfied with their jobs than were nonsupervisory employees. The supervisors also exhibited much less dissatisfaction (Jurkiewicz & Massey, 1997). And the reasons are not hard to find. Compensation is greater, and the need for self-actualization and autonomy is better satisfied at higher echelons of an organization (L. W. Porter, 1963a). Nevertheless, there are alternative or additional plausible explanations in some organizations in which status is unrelated to power and influence—for instance, organizations in which the top leaders are puppets or figureheads. Thus Ritchie and Miles (1970) studied 330 managers at five organizational levels. They found that satisfaction differed not as a consequence of the level of a position, but according to the amount of participation in decision making.

T. R. Mitchell (1970a, 1970b) studied line and staff officers of different military ranks and in different commands abroad. Not only did satisfaction rise with rank, but line officers of all ranks were better satisfied than were those in staff positions (staff positions are usually accorded less importance than line positions); however, this feeling varied greatly from one situation to another. Porter and Lawler (1965) confirmed these findings in a review of the empirical literature. Line managers were somewhat more satisfied than staff members and perceived more fulfillment of their need for self-actualization (Porter, 1963b). But satisfaction was unrelated to a manager's span of control.

In an experiment, Guetzkow (1954) found that key persons in a communication network saw themselves as most important and were more satisfied than members with less important positions. Bass, Pryor, Gaier, and Flint (1958) found that satisfaction was greater in a member who had been assigned more power, compared with four others with much less power. The attractiveness of a group was significantly lower for the average member when members were assigned control differentially, in contrast to groups in which all members were equal.

*Clarity about Status and Role.* It would seem obvious that a leader's satisfaction is strongly associated with the clarity of the position held and agreement about its importance, its power, and what is required for satisfactory performance. This idea was corroborated by Gross, Mason, and McEachern (1958), who conducted an extensive study of perceptions of role interactions between school board members and superintendents. The results indicated that the greater the consensus among board members, the higher the board members rated the superintendent, the higher he rated the board, and the greater the superintendent's job satisfaction. The board's rating of the superintendent was unrelated to his measured personality traits or to his agreement with the board. Within both samples, the degree of consensus in expectations of a position was

related to the extent to which the role demands of the position had been formally or legally codified.

*Status and Compensation.* One obvious reason why those of higher status in an organization are more satisfied than their subordinates is that they ordinarily earn more pay. But this is not always true. Deans may earn less than professors, and supervisors may earn less than skilled subordinates. However, satisfaction with earnings is relative. One feels relatively deprived, depending on whom one compares oneself with. In a highly inflationary economy, dissatisfaction with pay is seen as being due primarily to inflation, governmental policy, and OPEC, not necessarily to one's employer. In a depression, relatively modest compensation may be highly satisfying. Furthermore, the greater the congruence between managers' feeling about how pay should be determined and their perception of how it is determined, the greater their satisfaction with their pay (Lawler, 1966c, 1967b).

Penzer (1969) found that status-based expectations regarding external opportunities were major determinants of managers' satisfaction with their pay. Those who attended college brought different expectations with them than did those who did not attend college. Those expectations, when compared with external reference groups, partially determined their satisfaction with their compensation. Among the internal factors, commendations, rapid advancement, salary increases, and the like tended to inflate expectations. Thus managers' satisfaction with their pay is obviously related to how much they earn in an absolute sense, as well as to the correspondence between expected pay and actual pay. Managers prefer pay that is based on performance and merit, but they tend to define merit in terms of traits that they perceive themselves to possess.

More effective managers tend to feel more satisfied with their pay (Lawler & Porter, 1966; Porter & Lawler, 1968). Managers who score high in a preference for taking risks but not in achievement motivation prefer pay that is based on performance (Meyer & Walker, 1961). However, the more highly managers rate themselves in comparison with their peers on variables such as education, experience, productivity, effort, and skill, the more importance they attach to these variables as determinants of pay.

Further support was obtained by Klein and Maher (1966) for the relationship between the satisfaction of managers and the extent to which their level of pay corresponds with their status-based expectations for compensation. Middle managers overestimated the pay of subordinates and underestimated the pay of superiors. They believed that the difference between their pay and that of the persons above and below them was too small. The smaller the perceived difference between their pay and that of their subordinates, the less satisfied the managers were with their pay (Lawler, 1965, 1967b).

In a study of 919 low-to middle-level managers, Gorn and Kanungo (1980) isolated a job involvement factor ("For me, mornings at work really fly by; I'll stay overtime to finish a job even if I'm not paid for it"). Ninety-three managers were identified as motivated most by their extrinsic need for adequate salary and security, and 124 as motivated most by their intrinsic need for interesting work, responsibility, and independence. Status was not involved, but involvement was as high among the extrinsically motivated as among the intrinsically motivated, if their respective needs were being met.

### ***Personal Factors Affecting Satisfaction***

J. G. Mauer (1969) found that the job satisfaction of industrial supervisors was unrelated to their age, education, degree of involvement in work, or income, or to the size of their plant; but more often than not, these factors have been found by others to affect the satisfaction of managers.

*Education and Managerial Satisfaction.* Many studies have found that managers' satisfaction with their leadership role depends on their level of education. Higher pay may be expected but not necessarily forthcoming for those with more education. For example, Andrews and Henry (1963) and Klein and Maher

(1966, 1968) reported that managers with more education felt less satisfied with their pay. However, Stogdill (1965b) and Lawler and Porter (1966) reported studies in which no relation was found between the education of managers and their satisfaction with their pay. Better-educated managers may be dissatisfied for other reasons. Stogdill (1965a) studied 442 managers and supervisors in six departments of an aircraft plant. He found that the better-educated managers were less satisfied with the company and with their freedom on the job; however, their level of education was not consistently related to their attitudes about their pay. According to Friedlander (1963), less-well-educated supervisors tended to derive satisfaction from the social and technical rather than the self-actualizing aspects of their work.

*Age and Managerial Satisfaction.* Saleh and Otis (1964) asked 80 managers, aged 60 to 65, to think back over their careers and indicate the age at which they had derived the most satisfaction from their work. These managers said that their satisfaction increased until age 59, then showed a sharp decrease. Another sample, aged 50 to 59, also reported an increase in satisfaction until age 59, but then anticipated a decrease in satisfaction after age 60. The authors interpreted the reduced enjoyment after age 60 as due to a blockage of channels for further development and advancement.

Friedlander (1963) found that older supervisors tended to derive more satisfaction than younger supervisors from the social and technical aspects of their work, and less satisfaction from self-actualization. Results reported by England (1967a) indicated that older managers placed a higher value on social welfare and a lower value on organizational growth and leadership in the industry as goals of their organization. Gruenfeld (1962) found younger industrial supervisors to be more interested than older supervisors in high wages and fringe benefits. Older supervisors were more concerned about regular hours and freedom from stress.

Stogdill (1965a), in his study in an aircraft plant, found that with increasing age, managers tended to be more satisfied with the company but less satisfied with the recognition they received. But J. G. Mauer (1969) failed to find any relation between the age and the satisfaction of industrial supervisors. Some studies failed to find that managerial satisfaction was affected by the manager's age or other factors.

*Tenure and Managerial Satisfaction.* In Stogdill's (1965a) survey, the number of years a manager remained in the same position tended to contribute to all the aspects of dissatisfaction that were measured, but particularly to dissatisfaction with the failure to be promoted. However, Hall, Schneider, and Nygren (1970) reported that in the U.S. Forest Service, tenure, but not position, was related to identification with the organization and the satisfaction of needs.

## ***Performance and Satisfaction***

Consistently, the evidence points to the fact that better-satisfied managers perform better. Lawler and Porter (1967b) found that the degree to which an individual's needs are satisfied is related to his or her job performance, as evaluated by peers and superiors, and that this relationship is stronger for managers than for nonmanagers. Porter and Lawler (1968) reported that managers who were rated high in performance by themselves and their superiors expressed a higher degree of needs satisfaction than those who were rated low in performance. Managers who were rated high in effort also reported that they required a greater fulfillment of all their needs. Finally, Slocum, Miller, and Misshauk (1970) reported that high-producing supervisors were better satisfied than low-producing supervisors.

## **Health, Well-Being, and Leadership**

“A grain of sand in a man’s flesh, and empires totter and fall.” So wrote Émile Zola (1902), referring to Napoleon III’s incapacitation by stones in his bladder. A chronic disorder can have a continuing impact on a leader’s performance, and acute disorders can alter specific situations. Interpersonal relations, concentration on necessary details, energy level, and availability all depend on a leader’s physical stamina and mental health (L’Etang, 1970). However, few controlled studies have been conducted to compare the performance of healthy and ill leaders. Quick, Gavin, Cooper, et al. (2000) defined executive health as including physical, mental, spiritual, and ethical well-being. Discussion of the last two of these aspects will be saved for [Chapter 9](#). The researches attributed a leader’s good or poor health to inherited and acquired conditions such as the loneliness of command, an overload of work, crises, and failures.

## ***Physical Health***

While they were in office, Adolph Hitler suffered from Parkinson’s disease; François Mitterrand, the French premier, from prostate cancer; Lenin from renal disease; Woodrow Wilson from strokes; and the Japanese emperor Hirohito from pancreatic cancer (Accoce & Rentchnick, 1994 & 2003). The acute and chronic ailments of political and organizational leaders are common sources of concern, as are their health, diets, exercise regimens, medications, and lifestyles. Most important, their illnesses are likely to adversely affect their decisions. Prime Minister Neville Chamberlain was taking toxic analgesics for “blinding headaches” that affected his kidneys. Wilson’s stroke of April 1919 brought about a sharp change in his personality and materially reduced his effectiveness in trying to win support for the League of Nations. A stroke on September 3, 1919, resulted in his complete incapacitation; thereafter, his wife, his physician, and Joseph Tumulty ran his office until March of 1920. None of his objectives that required persuading a majority in the Senate could be met. Franklin Delano Roosevelt’s high blood pressure and other debilitating ailments made questionable his suitability for the presidency when he ran for his fourth term in 1944. His physician noted signs of hardening cerebral arteries before Roosevelt went to meet Churchill and Stalin at the fateful Yalta Conference in February 1945. Nikita Khrushchev also had to deal with high blood pressure. Illness dogged Dwight Eisenhower, limiting his activities at important international conferences. His weak heart caused acute problems at meetings in higher altitudes. John F. Kennedy’s chronic back pain was well known to the public, but he was also a victim of Addison’s disease, which was treated with cortisone. This disease and its treatment caused extreme mood swings and emotional instability at a time when Kennedy was dealing with the Bay of Pigs and the Cuban missile crisis. Ronald Reagan suffered from Alzheimer’s disease, which began to show up beginning sometime during his second term. Benito Mussolini’s judgment was impaired by syphilis. By 1938–1939, there was a noticeable deterioration in his intellectual capacity. In the four years before his downfall, he assisted Hitler at Munich, invaded Albania and Greece, and took Italy into a disastrous war with Britain. King George III’s porphyria first appeared during the first year of his 60-year reign. This genetic disorder periodically made him mentally deranged, at a time when the British monarch not only reigned but ruled if he could manage Parliament. Intermittently, George III could do neither, and Britain lost its American colonies.

Park (1988) noted that in leaders, advanced age may be accompanied by a deterioration in judgment and temperament. Paul von Hindenburg, Germany’s president, became decrepit during the last years of the Weimar Republic, making Hitler’s rise to power much easier. During the same years, Ramsay MacDonald, the British prime minister, was a victim of Alzheimer’s disease, which made his continued leadership of the Labour Party an embarrassment of ludicrous speeches and impaired judgment. Likewise, the premature aging of Poland’s post–World War I leader Józef Pilsudski contributed to his delusions about his nation’s military strength and status in its foreign relations with Germany and Russia. In the late 1980s and early 1990s, the political leaders exercising real power in the People’s Republic of China were in their eighties (Fukuyama,

1997). Ronald Reagan's advanced age led to a lot of confusion in his thinking about events in his movie roles and in reality. Park suggested that governments set up independent disability commissions to make judgments and recommendations about removing seriously mentally disabled leaders from office.

Many historical questions remain about how physical health influenced the leadership of generals, politicians, statesmen, and emperors. Was it lead poisoning that resulted in a sudden change for the worse in Caligula (lead was used by the Romans to seal wine bottles and for piping water)? How was John Foster Dulles's last year in office as Secretary of State affected by his carcinoma of the bowel? What was the impact on the course of events of Prime Minister Anthony Eden's acute obstructive colitis, which caused him to have a high fever during the Suez crisis of 1956? Can effective leaders successfully mask or compensate for their debilitating illnesses? How are they affected by the medications they take to treat their conditions? How much of the success or failure of businesses can be traced to the ill health of top executives? Long working hours, lengthy meetings, and long travel time, as well as stressful responsibility for people and their performance, can reach debilitating levels. The impact of the sudden death of a chief executive officer will be discussed in [Chapter 30](#).

### ***Physical Fitness***

Illnesses and early death can sometimes be avoided with suitable exercise and diet. Neck and Cooper (2000) recommended a program of optimum exercise and diet to offset the effects of heavy occupational demands. These authors compiled survey evidence reported by *Fortune*, *The Wall Street Journal*, and other business publications. Two-thirds of executives exercise at least three times a week, and 90% of these do aerobic exercises. Endurance, strength, and flexibility need to be developed and maintained.

Obesity, smoking, and alcohol addiction contribute to a variety of chronic diseases and early death. Neck and Cooper (2000) cite a survey of 3,000 executives who said they were careful about their diet. Only 10% of executives said they smoked, whereas almost a quarter of the U.S. population is still smoking. The need to reduce caloric intake as well as fat and cholesterol to recommended levels of nutritional standards is well-known. Vitamins, minerals, and high-fiber foods are encouraged. Fruits, vegetables, and whole-grain products should form a large portion of the healthy diet. Antioxidants and calcium are also important.

Empirical surveys have supported the argument for maintaining physical fitness and a proper diet. For instance, stockbrokers who took part in an aerobics training program earned greater sales commissions than those who did not participate. A study of 10,000 men and 3,000 women found that in a given period the physically unfit had twice the mortality rate of the fit. Physical fitness also affects mental activities. A study of 56 physically active college professors found that they processed data faster and experienced a slower decline in information-processing speed as they aged. Physical fitness contributed to higher energy levels and feelings of well-being.

### ***The Mentally Healthy Leader***

A healthy self-concept contributes to a leader's effectiveness. What does it mean for leaders to be in good mental health? Effective, mentally healthy leaders retain a balanced view of themselves and how to deal with their work. They are at peace with themselves (Cleveland, 1985). They avoid maladaptive responses to the conflicts arising from their moving up the organizational ladder. They help themselves to understand their own motivations by establishing a firm sense of their identity, by maintaining continuity and predictability in their relations with their colleagues, by being selective in their activities and relationships, and by living appropriately with their own daily rhythms. They can face disappointments realistically and do not hide or

deny their occurrence. They remain the masters of their fate and can tolerate their feelings of loss. They know when to withdraw and when to reexamine their emotional investments in people and activities (Zaleznik, 1963). If they had unsupportive parents and a disadvantaged childhood, they have been resilient. Neurotic and disordered beliefs about oneself, by contrast, are most likely to result in leadership that is fraught with problems for colleagues and for the organization.

### ***The Psychopathology of Leadership***

Forms of mental maladjustment and ill health, including neuroses, psychoses, and personality disorders, are the opposite of emotional stability, self-efficacy, and mental well-being. Eysenck (1985) found neuroticism to be one of two dimensions of central importance in accounting for large amounts of variance in social and leadership behavior. The other was introversion-extroversion. In contrast to the general population, Eysenck noted, managers and administrators were likely to be low in neurotic tendencies and high in extroversion. This is consistent. Nevertheless, although pathological leaders are a minority, numerous links between pathological tendencies and leadership styles have been observed by clinical analysts. For example, Fernberg (1979) described frequently observed pathological character structures in administrators: schizoid, obsessive, narcissistic, and paranoid. Leonid Brezhnev, a leader of the Soviet Union, suffered from senile dementia. Habib Bourgiba, president of Tunisia, suffered from 25 years of depression. Kemal Atatürk, the founding leader of modern Turkey and George III of England, suffered from Korsakoff's psychosis, in which victims fill in gaps in their memory with imaginary events.

*Anxiety.* Heuerman and Olson (1999) postulated that anxiety "engulfs" some people in positions of leadership. They feel "lost, scared, confused, and panicked," in fear of obscure dangers. They repeatedly impose mindless "reorganizations, change programs, and superficial fixes." They are blindsided by their disappointments. "They work futilely to avoid pain, gain control, and find security." Nevertheless, they try to convey an impression of calm and confidence.

*Feelings of Paranoid Persecution.* Leaders may display additional neurotic or psychotic syndromes if their wishes are articulated in fantasies. The fantasies are "scenes in the private theatre of [the leader's] subjective world" (Kets de Vries and Miller, 1984a, p. 8). The syndromes that dominate are the bases for specific styles of leadership. They may, in turn, become shared fantasies that can permeate all levels in a centralized organization, creating a specific organizational culture and determining decision making, strategy, and structure. On the basis of clinical observations of executives in four firms, five pathological leadership constellations were observed to emerge. Kets de Vries and Miller (1984a, 1986) identified them and provided generalizations about their different effects on the organization and on the leaders' colleagues. These five constellations were: (1) feelings of paranoid persecution, (2) feelings of helplessness, (3) narcissism, (4) compulsiveness, and (5) schizoid detachment.

The dominant fantasy of leaders suffering from paranoid persecution is that they cannot really trust anyone and that a menacing superior force is out to "get" them. Thus these leaders are quick to take offense and are always on guard. Along with their mistrust of others, they are suspicious, hypersensitive, and overconcerned with hidden motives and special meanings. They distort reality in an effort to confirm their suspicions. As Kets de Vries and Miller (1986, p. 269) stated:

The boss may feel hostile to those who report to him [or her] and may want to harm or attack others as a defensive reaction to his/her own feelings of persecution and mistrust. ... The leader sees ... subordinates either as malingerers and incompetents, or as people who are deliberately out to raise his/her

ire. As a consequence, he/she is likely to gravitate towards two extremes. He/she might try to exert a tremendous amount of control through intensive personal supervision, formal controls and rules, and harsh punishments. ... The second, less common, reaction of the hostile leader toward ... subordinates may be one of overt aggression. He/she may be reluctant to provide emotional or material rewards, striving always to come out on the winning side of any 'trades.' ... Subordinates hold back their contributions and concentrate mostly on protecting themselves from exploitation.

In organizations that are dominated by paranoid leaders, emphasis is on management controls and continuous vigilance. Power is centralized, and decision making is top-down although information is sought from below. The organization is conservative and reacts to threats rather than being proactive with regard to opportunities. Risk taking is low. There is an increased need for control rather than constant goals, strategic plans, or unifying themes and traditions (Kets de Vries & Miller, 1984a).

*Helplessness and Hopelessness.* According to Kets de Vries and Miller (1986), the dominant fantasy here is that it is hopeless to change the course of events in life; one is just not good enough. This depressive neurosis gives rise to a lack of self-confidence and initiative, feelings of dependence, and low self-esteem (Jacobson, 1971). Feelings of guilt, worthlessness, and inadequacy are exhibited in self-depreciation and feelings of inferiority. Feelings of learned hopelessness develop; the manager believes that the malaise will last forever and that it will affect everything he or she does (Trotter, 1987). Kernberg (1979) noted that such depressive managers avoid responsibility, procrastinate about major decisions, and become passive and laissez-faire in their leadership style. Only routines get done; their groups stagnate, and goals are not clarified.

*Narcissism.* Of 32 revolutionary leaders, 23 were described as egotistical, narcissistic, and searching for personal fame and glory (Rejai, 1980). Narcissists are dominated by the fantasy of getting attention and impressing others dramatically. Some are histrionic, expressing emotions excessively and incessantly drawing attention to themselves. They are likely to be superficial and to exaggerate their evaluations of others (Kets de Vries & Miller, 1984a). Narcissists who reject the object-relations in their fantasy exhibit severe and frequent defensive reactions, are demanding taskmasters, and gather sycophant subordinates around themselves. Narcissists who deceive themselves are overly sensitive to criticism and privately harbor grudges against dissenters. As Kets de Vries and Miller (1985, pp. 16–17) stated:

Such leaders are hyperactive, impulsive, dramatically venturesome, and dangerously uninhibited. They live in a world of hunches and impressions rather than facts as they address a broad array of widely disparate projects, products, and markets in desultory fashion. The leaders' flair for the dramatic leads them to centralize power, allowing them to initiate bold ventures independently. ... Instead of reacting to the environment (when at the top of the organization) the leader, often an entrepreneur, attempts to enact his own environment ... [placing a] sizable proportion of the firm's capital ... at risk. ... Most of these ... moves are made in the service of grandiosity. Unbridled growth is the goal. The organization's strategy is a function of its leader's considerable narcissistic needs—his desire for attention and visibility. ... The top man wants to be at center stage, putting on a show. ... He wants to finally "show the others over there" how great an executive he really is.

Some degree of self-concentration appears to be important for effective leadership. Charismatic leaders develop self-assuring internal images with which they have a dialogue and that form a basis for connections with their followers (Zaleznik, 1984). But concentration on the self may be a mixed blessing. Leaders may have highly inflated evaluations of themselves or severely negative self-images. As was noted earlier, in both instances of such self-concentration, prosocial leadership is unlikely to emerge (Reykowski, 1982).

*Compulsiveness.* This neurosis is fueled by the fantasy "I don't want to be at the mercy of events. I have

to master and control all the things affecting me.” The fantasy is articulated by behaving as a perfectionist. The compulsive person is preoccupied with trivial details and insists that others submit to his or her way of doing things. He or she sees relationships in terms of dominance and submission and is characterized by a lack of spontaneity, inability to relax, meticulousness, dogmatism, obstinacy, and a constant preoccupation with losing control. “Every last detail of operation is planned out in advance and carried on in a routinized and preprogrammed fashion. Thoroughness, completeness, and conformity with standard and established procedures are emphasized. ... Surprises must be avoided” (Kets de Vries & Miller, 1984a, p. 14).

*Schizoid Detachment.* The fantasy here is that “the world of reality does not offer any satisfaction to me. All of my interactions with others will eventually fail and cause harm so it is safer to remain distant” (Kets de Vries & Miller, 1984a, p. 11). The manager with this problem is insecure, withdrawn, and noncommittal. He or she discourages interaction because of a fear of involvement. The world is an unhappy place, filled with frustrating colleagues. Most contacts will end painfully, this manager believes. To compensate for a lack of fulfillment, he or she daydreams. Again, the fantasy is articulated in ineffective, laissez-faire leadership.<sup>10</sup> The manager is detached and feels estranged from others. A cold, unemotional appearance is matched by an indifference to praise or reproof.

*Psychosomatic Syndromes—Type-A Personalities.* The Type-A syndrome may include being hostile, driven, competitive, and time-conscious, Type-As may hurry the speech of others; become unduly irritated when forced to wait; exhibit explosive speech patterns or frequent use of obscenities; make a fetish of always being on time; have difficulty sitting and doing nothing; play nearly every game to win, even when playing with children; become impatient while watching others do things they think they can do better or faster. In addition to hard-driving competitiveness, these Type-A leaders’ sense of urgency, may be accompanied by restlessness, multiple activities against deadlines, and impatience with delays and with others. These leaders may be self-centered and poor in interpersonal relationships.

In general, type-A managers seem to have an overwhelming need to assert control over whatever happens. Nonetheless, when they lose control, they overreact, with signs of helplessness. Their reaction is either “all or nothing.” In the process, they waste energy and strain themselves needlessly. In a survey of 163 South African managers, type-A behavior was found to be correlated with a strong feeling of exhaustion, role conflict, absence of friendliness, and anxiety depression (reflecting joylessness). The behavior of these people as managers and leaders was affected accordingly, concomitant with effects on their hearts (Strumpfer, 1983).

Type-As are prone to heart disease, real and false (Friedman & Rosenman, 1974). False angina (pain in the left arm) and high blood pressure may not be organic in origin but due to frustration. False angina occurs not because Type-As are workaholics but because they are frustrated by feeling of being blocked from full accomplishment. Nevertheless, relationship between Type-A behavior and real heart disease was demonstrated in a large number of studies (Jenkins, 1976, 1978). Men who were in the highest third in Type-A scores on the Jenkins Activity Survey had 1.79 times the incidence of new coronary heart disease as men who were in the bottom third of the distribution. When men who had had a single heart attack were compared with men who had had second heart attacks, Jenkins, Zyzanski, and Rosenman (1976) demonstrated that the Type-A score was the strongest single predictor of recurrent coronary heart disease. However, there are three important qualifications. First, as Strumpfer (1983) noted, the majority of people with Type-A behavior never develop heart disease. Second, it is difficult not to confound Type-A behavior with other risk factors such as smoking and obesity. Third, and most important, if it is a psychosomatic illness, the heart condition is a response to anger and frustration. The happy Type-A workaholic who enjoys his work and the challenges from it is not as likely to be at risk of heart disease. Also more likely to be free of heart disease may be Type-As who are emotionally expressive and genuinely confident in themselves, who laugh a lot, and who can be highly active (Hall, 1986). The entire Type-A syndrome of anger, impatience, aggravation, and irritation may not be the

culprit but rather only one or more elements related to heart disease. For instance a cynical, mistrusting attitude or intense self-involvement may be the particular risk factor of consequence (Fischman, 1987).

## Summary and Conclusions

---

Successful leaders share values with those they lead. What they and their followers regard as right, important, and good shapes their performance. These values depend on occupational and societal influences. But a majority are likely to see themselves as pragmatically balanced in outlook. Leaders differ in their values for many reasons, ranging from education to nationality. They may be selected by an organization because of their values or they may assimilate the organization's values after joining. Their profession and locale also make for obvious differences. Furthermore, their performance depends on their concepts about themselves, their pragmatism, their preference for taking risks, and their valuing of short-term maximization or long-term gain. Motives may be conscious like task orientation and subconscious like a need for achievement. Compensation is a strong motivator, but its effects are relative. Identification with the organization is also a strong motivator, as are commitment to the organization's goals and the managers' location in the organization. Leaders will be affected by whether they identify with superiors, peers, or subordinates. Satisfaction with the role of leader correlates with earnings and status and their accompanying power and control. Role clarity is particularly important. Although exceptions can be found, the higher one's status in an organization, the greater one's job satisfaction. Managers' satisfaction with their role in the organization and with their compensation often depends on their education, age, and tenure and correlates with their effective performance.

Systematic differences in values separate radical from conservative political leaders and revolutionaries from loyalist leaders. Both the projected needs for achievement and task orientation contribute positively to the emergence of leaders. In turn, there is a link between such leadership and risk taking. Among the self-concepts that particularly affect the emergence and performance of leaders are: internal or external locus of control; a sense of self-efficacy, self-confidence, self-esteem; and valuing of self-actualization. Leadership research has been remiss in ignoring the importance of physical and mental health of leaders. Physical health can be essential to a leader's performance, and mental health problems are seen in leaders who feel persecuted, helpless, narcissistic, compulsive, or schizoid. Leaders' and managers' self-concepts, motives, values, and health move them to lead. How much others value them and accord them esteem and status affect the leaders' and managers' efforts to lead.

---

# Ethics and Leadership

Dame Anita Roddick of The Body Shop, James Burke of Johnson & Johnson, Sir Adrian Cadbury of Cadbury-Schweppes, Max De Pree of Herman Miller, and J. Irwin Miller of Cummins were business leaders whose careers exemplified ethical management (Murphy & Enderle, 1995). Anita Roddick (2000), founder of the worldwide retail cosmetics chain The Body Shop, suggested that companies should begin to focus on a new bottom line, making moral decisions. Thus when a new soap factory was needed, instead of being attached more conveniently to headquarters in a prosperous area of England, it was placed in an area of Scotland with 70% unemployment. Jobs were provided for 100 people who had been out of work for nine years, and 25% of the profits were plowed back into the community. An enthusiastic work force was created. Roddick also suggested that along with safe products, companies provide audits of their environmental performance.

Cyanide poison had been inserted into some Tylenol capsules after manufacturing. Although advised by FBI personnel that it would be an overreaction, James Burke, as CEO of Johnson & Johnson, advocating openness and candor, ordered a very costly recall. And when it was determined after a second poisoning incident that even tamperproof packaging could not be guaranteed to make the capsules safe for the consumer, the capsule form was abandoned permanently. For Burke, these actions were the right thing to do and consistent with his moral beliefs. Furthermore, the maintenance and enhancement of trust and goodwill was worth the cost of abandoning the highly profitable product.

Adrian Cadbury was an advocate of openness in dealing with ethical issues. Bribing prospective international purchasers was eliminated by demanding that bribes be shown on the purchase invoice. Openness also applied to gifts. Would a gift be an embarrassment if mentioned in the newspaper? For Cadbury, ethical actions were more important than ethical intentions. In making decisions, one's personal rules of conduct had to be considered, followed by the interests of others who would be affected by the decision.

Max De Pree, as CEO of Herman Miller furniture (after consultation with Peter Drucker), arranged for the CEO's salary to be no more than 20 times the pay of the average factory worker. For De Pree, integrity—a fine sense of one's obligations—was the first requirement of leaders. In his speeches and writings, De Pree called for justice and the fair distribution of results. The leader had to be the steward of limited resources; had to exercise personal restraint; and had to keep in mind the common good of customers, managers, and employees. Also, there needed to be room for God, family, and others in one's life.

J. Irwin Miller of Cummins, Inc., a manufacturer of diesel engines, argued that business had a responsibility to help solve the nation's social problems. Leadership must be provided to help reduce discrimination, poverty, and pollution. Managers needed to set an example of commitment and trust before they could expect either from their employees. Employees learn the values of the organization from the example set by the top executives, not from the executives' sermons and espousals of corporate ethics. Furthermore, Miller advised business schools to add character and selflessness as bases for selecting students. Instructors needed to set an example of ethicality. The content of any course ought to take account of moral issues in decisions reached (Murphy & Enderle, 1995).

And yet, despite the many bright examples of ethical business leaders and honest political leaders, the news has continued to be filled with stories of corrupt and fraudulent executives. Ciulla (1998) could rightfully

begin her book on the ethics of leadership by saying, “We live in a world where leaders are often morally disappointing” (p. 5). Self-aggrandizement among CEOs has increased. In 1965, for Fortune 500 CEOs, the ratio of their average compensation to that of a factory worker was 24 to one. In 2006, in the United States, the ratio was 262 to one (Anonymous, 2006).

According to Scott and Hart (1991), modern management arose with the promise that it would bring material affluence, material growth, and abundance. Its organizations were to be the engines of progress and prosperity. Professional managers who were skilled, competent, rational, and efficient replaced the idealized, wealthy, and powerful entrepreneurs of the nineteenth century. Professional managers were expected to be men with moral integrity. But by 1910, Woodrow Wilson was cautioning against the unrestrained power of some top corporate managers. In 1922, William Riply warned of their unregulated control over corporate assets. Adolph Berle and Gardner Means wrote in 1933 that society was in danger of becoming hostage to the professional managers’ private cupidity. Burnum (1941) noted that the management elite was always able to get more than its fair share by using its power. But Barnard (1937) argued that unless managers had a strong sense of responsibility and were moral, cooperative, enlightened, and fair, they would be “winnowed out” because their organizations would perform poorly. Despite the importance of the ethics of management and leadership, it is only in the past several decades that this has become a major issue for empirical surveys and experimental research.

## Philosophies of ethical Leadership

---

There is much ancient and modern philosophical literature on ethical theories of leadership, and there are hortatory commentaries, but they contain little empirical evidence to confirm or refute derived hypotheses or propositions. The evidence is anecdotal, qualitative, and subjective rather than quantitative and objective. Nevertheless, ethics has been in the domain of philosophy for 2,500 years. Moral philosophies contain the principles and rules that leaders may use to determine right and wrong (Ferrell & Fraedrich, 1994).

*Deontology* treats ethics by considering the values inherent in the rules of human behavior or in the behavior itself. *Teleology* focuses on the consequences of rules or actions. *Virtues* are studied in theories about actions that fulfill good purposes or lead to right outcomes (Elliott & Engebretson, 1995).

[Its study] can be as rigorous [as social science research methods]. The philosophical study of ethics is not just a matter of opinion. Adequate treatment of any area of applied ethics involves sound argumentation, astute articulation of the relevant questions and a strong footing in the realities of the practice that is being analyzed. (Ciulla, 1994, p. 2)

Plato’s republic was an ideal city-state of 5,000 inhabitants, to be led by an ethical philosopher-king. Plato recommended a formal program of education and development for the ruler and his guardians, supported by the working class. The ethical ruler needed to maintain justice and avoid self-interest and abuse of power. For Confucius, ethics was a matter of duty rigidly determined by tradition. The leader sought harmonious living in a well-ordered society. Harmony was derived when all people fulfilled their obligations to one another and to the rules of society. Particularly important were duties to parents and rulers. For Lao-tzu (sixth century B.C.E.), the best rulers behaved so that their people thought they had succeeded by themselves. The best leaders were not noticed. The worst were feared and reviled. Machiavelli (1469–1527) said in *The Prince* (as noted in [Chapter 7](#)) that rulers only needed to appear to be moral but did not actually have to be. A ruler had to be an authority who knew how to use his power to provide justice and order. Thomas Hobbes held that only through authority could an ethical order be established, because people were self-interested, naturally assertive, and power-seeking. Only anarchy could result if they were not ruled by firm authority (Ciulla, 2004).

According to Immanuel Kant, a deontologist, reason demands that moral duty transcends all other duties. Kant's *categorical imperative* was that we ought to believe that what is right for others is also right for us. It was a detailed version of the Golden Rule based on reason, not religion. It was the commanding influence of moral principles (Corsini, 1999). We have a moral duty to satisfy the legitimate needs of others as dictated by logic and reason. We ought to tell the truth because it is the right thing to do. Morality depends on the intention of doing good, not on outcomes. For Kant, morals were self-evident and derived from the natural order. Universal moral duties ought to direct one's conduct consistently and in all circumstances. Leaders must act on their strongly held beliefs even if not in their own self-interests (Ciulla, 1998).

David Hume, however, rejected reason as guide to morals in favor of emotions; and Baruch Spinoza emphasized the importance of the self. Utilitarians such as Jeremy Bentham (1823/1948) and John Stuart Mill argued for the greatest good for the greatest number (Elliot & Engretson, 1995). Friedrich Nietzsche envisioned a superman, a morally superior person who found the greatest power in self-control, art, and philosophy; his will to power made it possible to create the world, not accept it as it was. The superman was in control of his passions and was not motivated by self-interest. His virtues included sympathy, generosity, and honesty. John Dewey (1987) noted that societies change as a consequence of resolving conflict, a process in which leadership is essential. Rediscovered every several years in the psychological literature about the relationship between leaders and followers, and leaders and the situation is William James's (1882) observation of their influence on each other. Kierkegaard (1971) followed in the tradition of Kant but stressed the importance of religion to ethical thinking. Rawls (1985) provided a new philosophical view of justice and fairness. Kohlberg's (1969) six stages of moral development influenced the study of leadership ethics in psychology, education, and business management.

### ***Are Moral Standards Universal or Relative?***

Ethical standards are considerably different for tradition-alists and nontraditionalists. Traditionalists are more Machiavellian: equity is more a matter of entitlement, and questionable ethics are justified in corporate settings if they benefit the organization rather than oneself (Mason & Mudrack, 1997). Militarists and pacifists differ on whether killing in wartime is ever justifiable. Circumstances may make a difference. A leader of a country declares a just war when the country fights to defend itself against an unprovoked attack, and even some pacifists may then change their minds. How much unintended collateral damage is morally acceptable?

Deering, Cavenagh, and Kelly (1994) surveyed individual and group differences in attitudes toward moral questions using Forsyth's Ethical Position Questionnaire (1980). They reported that 83% of the teachers and 66% of the business majors in the survey scored low in relativism and agreed that a universal set of moral principles ought to be followed. Although most ethical theorists, such as Kant and J. S. Mill, are absolutists, many liberal arts undergraduates accept few absolute moral principles as valid and water down their moral reasoning with a relativistic point of view. "An ethical absolutist ... treats ethics like math. ... There are right and wrong answers to moral questions. The answers are the same for all people, in all places and at all times. ... Someone who thinks 5 1 7 5 13 is simply wrong" (Irvine, 2002, p. 43). For relativists, it all depends on who and what is involved. Lying is absolutely wrong, but the absolutist makes exceptions to moral rules for conditional claims. Lying is, therefore, permissible if it will save a life. Also, telling young children about Santa Claus or that they have done a good job or that their handiwork is beautiful is acceptable. Lying to fulfill a promise to keep a secret may be acceptable. A public official may prevaricate early in an emergency to prevent panic, at the expense of losing credibility and circulating false rumors. It is important, though, to get the truth out as soon as feasible. At times, we shade the truth to avoid seeming too harsh and critical. "An ethical relativist ... [adds] relativistic clauses to ... ethical judgments ... [and] is disinclined to label an activity as right

or wrong. ... Rather the activity may be wrong for him (or her) but right for others. ... The activity may be wrong for one culture but right for another culture” (p. 43).

## ***Theories of Moral Leadership***

Burns (1978) maintained that to be transformational, leadership had to have moral ends and had to raise the moral consciousness of followers. Rost (1991) held that to be leadership, the leader-follower process had to provide for ethical means—autonomy and the valuing of the individual leader and follower. Coercion, manipulation, and use of authority could not be leadership or ethical (Potts, 2001). Yet unethical leaders might use ethical means for immoral ends, unethical means for moral ends, or both.

*Dimensions of Ethical Leadership.* Northouse (2001) designed a questionnaire about six briefly stated ethical cases. The scores reflected how much a leader agreed with each of six ethical approaches for dealing with each case. (1) Egoistic: maximizes what is best for the leader (2) Utilitarian: promotes the greatest good for the greatest number; (3) Personally virtuous: the leader is good, worthy, and humane; (4) Distributing justice: each follower is treated fairly; (5) Dutiful: the leader’s ethical duty is fulfilled; and (6) Caring: leaders nurture those with whom they have special relationships.

*Importance of Leadership Ethics.* Barnard (1938) introduced ethical considerations about leadership in his examination of the moral modes of administration. The administrator had to work with people who differed in their moral codes concerning right and wrong. The administrator’s role in dealing with moral dilemmas was to adjudicate among alternative opinions and provide acceptable reasons for moral decisions. But not until the last few decades has the ethics of organizational leadership become a prominent subject of theory and research.

Offerman, Hanges, and Day (2001) noted that founders’ often set the moral climates of their organizations and that a climate may remain long after the founder is gone. Shared perceptions of what is right and wrong behavior often stem from the personal values and motives of the founders and other early leaders of the organization (Dickson, Smith, Grojean, et al., 2001). Blois (1995) discussed the role that ethics, morality, principles, and values should play in leadership. Any works on the subject are likely to be a discourse on robust applied ethics and a superficial examination of leadership, or vice versa. Nonetheless, Kanungo and Mendonca (1996/1997) argued that without a consideration of ethics, understanding of leadership is incomplete: “Ethical values are always involved with leadership, regardless of whether or not leaders are explicitly aware of the fact.” “The best leaders recognize their responsibilities as the chief custodian of the values of their group” (Knapp & Olson, 1996, pp. 84, 85). Leaders balance the fundamental values of the organization with the needs of its stakeholders, such as organizational survival and the bottom line (Grensing-Pophal, 1998). Included among the worst leaders who made *Fortune*’s list of the “greediest executives” (2002) were those who awarded themselves the generous amounts of stock and stock options approved by their boards of directors and who cashed out while their organizations were laying off workers, taking severe losses, and approaching bankruptcy. “The not-so-secret dirty secret of the crash [at the end of the 1990s] as [shareholders] were losing [70% to 100%] of their holdings, top officials of many companies that have crashed the hardest were getting immensely, extraordinarily, obscenely, wealthy” (Fortune, September 2000).

A firm’s ethical reputation has practical importance. A survey by Duke University of 650 graduate business students from 11 top MBA programs found that ethical and political reasons (and possibly the future insecurity of the industries) affected their willingness to accept employment in particular industries. Almost 82% of the students said they would not work for tobacco companies, which had suppressed for 30 years the internal findings about the health risks of cigarette smoking. From 20 to 36% said they would not join firms

with questionable environmental problems, liquor marketers, or defense contractors (Randall, 1994). The large and prestigious accounting firm of 40,000, Arthur Andersen, lost so many clients in 1992 in the wake of the Enron scandal due to the malfeasance of a few managing auditors, that it was forced into bankruptcy and dissolution.

*Role of the Corporate Manager: Agent or Trustee?* Theoretically, if the role of the manager is to act as an agent for the owners (shareholders) of the corporation, then morally the manager agrees to act under their direction on their behalf. The owners consent to accept the agent's actions in substitution for their own. The manager's duties are to do what the agent has proposed to do, to accept reasonable directions from the owners, and not to act contrary to the owner's interests, bearing in mind the interests of the other stakeholders of the organization. An ethical problem may arise when the manager is expert and the owners are not. Ordinarily, the individual shareholders have no institutional way to give routine instructions to the manager. They have to own a sizable percentage of shares to carry much weight. As a consequence, it makes more sense morally to regard the manager as a trustee of the organization. As a trustee, he or she ought to consider the rights of all the other stakeholders in the organization. A trustee has a moral duty to advance the shareholders' interests as well as the interests of the other stakeholders in the organization, such as the employees, customers, and community (McMahon, 1972). As a trustee, a manager and leader helps to lessen the gaps among others created by conflicting values and to adapt—in the face of competing perspectives and creative tension—to new approaches (Heifetz, 1994).

### ***Ethical Principles of Leadership and Influence***

Hodgeson (1994) viewed leadership as a moral activity. Leaders should respect the basic human dignity of followers and their rights and ability to make choices regarding their own affairs. To point to ethical principles of leadership implies that ethics and morality are absolute rather than relative. There are ethical imperatives—e.g., “thou shall not kill.” But the absolute principle is conditional. Thou shall not kill except in self-defense or to save others' lives. To kill in war requires that it be a just war. Other exceptions, such as abortion and euthanasia, remain controversial. For Kant (1959/1985), it is a categorical imperative that humans be treated as ends, not means. Thus employees should be assigned to meaningful jobs and not treated impersonally as a means of production or service (Bowie, 1998). Irvine (2000–2001) argued that cultures tend to be far more similar in morals and ethics than different. It is circumstances that are different. The traditional Inuit left their elderly out in the cold to die, to avoid starvation of the whole family. The world leaders most admired by thousands of respondents—leaders such as Abraham Lincoln, Martin Luther King Jr., Jesus, Mahatma Gandhi, and Eleanor Roosevelt—all had strong beliefs about matters of principle. They were admired for their commitment and willingness to stand up for their beliefs (Kouzes & Posner, 2002).

The ethics of transformational leadership have been questioned. More often than not, these criticisms are about *pseudotransformational leadership* and *inauthenticity* (Bass, 2001)—discussed as vices of leadership later in this chapter. On the basis of his reading in philosophy and literature and his experiences on active duty and as a prisoner of war, Admiral James B. Stockdale (1981) drew up a list of universal ethical principles of leadership. In paraphrase, some of them are

1. If individual freedom is pushed to the limit, equality is lost. If you subordinate every social value to equality, freedom is sacrificed.
2. In a rigid hierarchical organization or a bloated bureaucracy in which people are trying to manipulate others, you need to avoid the temptation of thinking only about yourself. Sooner or later it becomes clear that the greatest good, the key for survival and self-respect, comes from solidarity with the others,

- not from taking credit for their good work or from superficial theatrics.
3. There is no moral economy in this world in which virtue is rewarded and evil is punished. The biblical Job lived a virtuous life and then with no reason or logic suffered the loss of all of his goods and reputation. Life is not fair. People need to be prepared for failure.
  4. A good leader appreciates contrariness. You shouldn't force people to do what you think is good for them.
  5. Goethe wrote that you should not appeal to what persons are but rather to what they might be. According to Aristotle, persuading people to reach their potential was a matter of reason (*logos*), emotion (*pathos*), and—most important—the leader's character.
  6. A leader's moral responsibilities cannot be escaped. You cannot use your position as a shield against responsibility for your actions.

Cialdini (2001) has argued that although it is ethical to use expert advice and authority as a shortcut to deliberation and thoughtfulness in making good decisions, it is unethical to counterfeit or exaggerate consensus, social proof, expert authority, commitment, reciprocity, or scarcity as reasons for taking action. A controlled experiment demonstrated that 120 undergraduate college students could be taught to discriminate between honest authoritative advertisements and manipulative ones.

### ***Ethical Pitfalls of Successful Leaders***

The success of leaders may eventuate in unethical behavior. They may lose strategic focus and develop an inflated belief in their own ability to control outcomes. With privileged access to resources and enhanced status as a consequence of their successful leadership, they may be tempted into unethical acts for their own benefit at the expense of their exploited followers (Ciulla, 1998). The ordinarily ethical leader is corrupted by personal motivation, positional power, and success (Ludwig & Longenecker, 1993). Ethical norms may be violated when the well-meaning leader transforms individuals and their values to attain organizational goals but damages individual members (Stephens, D'Intino, & Victor, 1995). The righteous King David had an ethical lapse when he wanted to marry Bathsheba: he abused his acquired power to arrange the death of Uriah, her husband.

*Ethics in Negotiations.* The transactional leader may be highly successful at negotiating agreements with followers, but at the expense of maintaining ethical standards. The personally moral leader may lower standards in order to achieve settlements (Giampetro-Meyer, Brown, Browne, et al., 1998) or to achieve success by "cutting corners" or pressuring followers to produce (Fleming, 1999). Volkema (2001) presented data showing that among the tactics least offensive to moral sensibility were exaggerating an offer or demand, pretending not to be in a hurry, hiding one's bottom line, and making vacuous promises.

Tenbrunsel and Messick (2001) reviewed the temptations to be unethical in negotiating. Ethical transparency and full disclosure about preferences and alternatives could shift to shading the truth. Negotiators are prone to unethical misrepresentation, false threats, false promises, and falsely demeaning the opponent's best alternative to reaching an agreement. Some of these behaviors appear acceptable—such as making a high opening demand and pretending to be in no hurry to reach an agreement. Unethical behavior tends to escalate as a consequence of expectations about the ethics of the opposition. Differences in power also increase the unethical behavior of the negotiators.

*Trade-Offs.* Winston Churchill was supposed to have said that Lady Astor would not sleep with him for £10, but would for £10,000. Socially conscious investors are willing to accept lesser returns from mutual funds that invest only in firms that meet standards of social acceptability. Consumers may use a firm's services

even though a competitor offers a lower price, because of the firms' ethical stance on the moral role of business in society. Conversely, consumers may boycott the products of a firm because they view the firm as engaged in unethical practices; for instance, Nestlé was accused of selling powdered infant formula in developing countries with unsanitary water supplies. A trade-off may cause an ordinarily moral leader without a strong enough character to ignore or engage in an unethical act because of its unusually beneficial effects for himself or herself or others. Ordinarily ethical leaders may fail to maintain standards so as to protect a family member. Moral actions may be sacrificed for opportunities and expediency (Dunfee, 2001). Ethical constraints are weakened by severe social, political, and economic conditions. Managers in the post-Communist nations of Eastern Europe used their new personal power to act abusively at the expense of their followers. This behavior was a legacy of the former Communist leadership and the socioeconomic conditions they left (Luthans, Peterson, & Ibrayeva, 1998).

*Formal Ethical Education in Professional Schools.* The Association of American Medical Colleges (AAMC) has listed altruism, knowledge, ability, skill, and duty as goals for graduating students. Compassion is given high priority for physicians; nevertheless, patients are likely to prefer a cold but knowledgeable and skilled physician to one who seemed warm but less expert (Gans, 2002). Rest (1988) concluded that deliberate educational interventions in the curricula in schools of law and medicine can effectively raise the moral reasoning of the students, as measured by Defining Issues Test (DIT) scores.

Business schools need to do more to teach business law and proper accounting practices. Many business schools have added ethics courses to their curricula. Taking into account the numerous corporate scandals and the amount of cheating in school, Sowell (2000) inferred that ethics courses in business schools have failed. Of approximately 2,000 MBA students entering one of 13 leading business schools, 68% agreed that maximizing shareholders' interest was the prime responsibility of corporate management. The figure rose to 82% at the end of the first year (Reiter, 2002). One reason may be the domination of many business schools by economists who believe that the sole purpose of business is to maximize shareholders' interests. Sowell's point of view is supported by Ponemon (1993). In a controlled experiment, he found that a semester course in auditing for 73 senior undergraduate and 53 graduate accounting majors did little to raise the students' level of moral reasoning. Etzioni (2002) suggested that part of the problem is what are acceptable lines of moral reasoning in business. Some people see business as a poker game in which bluffing and avoiding disclosure are permissible. Some argue that morality is relative and depends on who benefits from actions. Some suggest that customers may be gained by lying and cheating even though telling the truth may pay off in the long run.

On a more positive note, Williams and Dewett (2005) found empirical evidence to support the value of teaching ethics to enhance business students' moral development, ethical sensitivity to ethical issues, and appreciation and skill in dealing with complex ethical decisions. Penn and Collier (1985) found that business education promoted moral development. Compared with a control group of students in a marketing course, students in a business ethics course became more aware of and more sensitive to ethical issues, according to pre-post testing (Gautschi & Jones, 1990). Skepticism and relativistic attitudes changed to a better understanding of the scope of ethical issues and the complexity of making ethical decisions when students kept logs to reflect on ethical issues during a course in business ethics (MacFarlane, 2001). And students who took a business ethics course showed greater flexibility in reasoning afterward than they had shown before, as well as an increased ability to incorporate the complexities of circumstances. These students were dealing with a complicated case of CEO decision making (Carlson & Burke 1988).

## Ethical Leader Behavior

---

The reputation of organizational leaders depends on their morality as persons and as managers and executives (Trevino, Hartman, & Brown, 2000). They may be moral in beliefs and ethical in behavior; they may be amoral in beliefs and neutral in ethical behavior; or they may be immoral in beliefs and unethical in behavior. Trevino, Brown, and Hartman (in press) conducted one-hour or longer interviews with 20 senior executives from different firms and 20 ethics officers from the same firms. The interviewees were asked to describe anonymously the ethical behavior of another executive. After answering in detail, they then were asked to describe an “ethically neutral” executive.

The ethical executives were more likely than the ethically neutrals to be perceived as people-oriented. The neutrals were more likely to be seen as self-centered and uncaring about others. Compared with the neutrals, ethical leaders were more often seen as role models of ethical conduct who led by example and “walked the talk,” who were more likely to do the right thing and were honest, trustworthy people of integrity. They were perceived as more likely to be good, open communicators and receptive listeners, as well as influential, inspirational, courageous, and strong. In short, they were more likely to be *transformational* leaders. Yet they were more likely to be *transactional* leaders as well (see [Chapter 22](#)). They set standards of conduct, reinforced ethical behavior, used rewards and punishments to hold people accountable for ethical standards, and did not tolerate ethical lapses. Ethical executives cared a great deal about the bottom line but were also concerned about multiple stakeholders, the common good, the community, and society. They were concerned also about the means of achieving business goals, not just the ends. Ethically neutral leaders differed from their ethical counterparts in being more short-term-oriented and financially oriented and being less aware of ethical issues.

### ***Moral Exemplars***

Organizational leaders can serve as moral exemplars:

The moral impact of their leadership presence and behaviors [has] great power to shift the ethics mind-fulness of organizational members ... [They can] establish a social context ... of positive self-regulation that becomes a clear and compelling organizational norm in which people act ethically ... and corporate culture in which principled actions and ethics norms predominated (Thomas, Schermerhorn, & Dienhart, 2004, p. 56).

Excellent basketball coaches were identified as premier role models in interviews with nine of their peers. Not only were the coaches highly successful, competent teachers, committed to personal values and principles, but they also shaped the character of their players (Gerdes, 1994). Twenty-three living Americans were nominated as leading moral exemplary lives, because they: (1) integrated self-concepts and moral goals, did not compartmentalize morality apart from other motivating factors, and engaged in a broad range of commitments; (2) used moral concepts frequently in describing themselves; (3) denied that they had moral courage despite their history of moral courage; (4) behaved morally almost automatically and expressed certainty over doubt in their moral decision making; (5) converted seemingly depressing unfortunate occurrences into positive life-affirming events; and (6) exhibited high levels of religious faith and spirituality.

### ***Measurement of Ethical Leadership Behavior***

The Ethical Leadership Scale (ELS) was constructed, refined, and validated by Brown and Trevino (2002). Forty-eight brief statements were drawn from in-depth interviews with 20 ethics officers, 20 executives, and 20 MBA students. The statements were reduced to 21 items by means of an exploratory principal axis factor

analysis with an oblique rotation of data from 154 MBAs from three large public universities and 127 employees from a large financial services organization. A confirmatory factor analysis followed using 184 employees from the same financial service. The analyses extracted and confirmed a single ethical leadership factor. The final instrument consisted of 10 items rated by subordinates about their supervisor, such as “When making decisions asks what is the right thing to do”; “Disciplines employees who violate ethical standards”; “Has the best interests of the employees in mind”; “Makes fair and balanced decisions”; and “Defines success not just by results but also [by] the way they are achieved.” The ELS demonstrated convergent and discriminant validity for 571 employees from the same organization and 86 MBAs with correlations with MLQ transformational leadership ranging from .82 to .91 and correlations with LBDQ consideration (.72) and cognitive-based trust (.79).

*Relation to Moral Reasoning.* In this chapter, we describe the measurement of *moral reasoning* using the Defining Issues Test (DIT; Rest, 1979). People who reason ethically may not always act ethically. Managerialism was supposed to usher in material affluence and social harmony. According to Barnard (1938), the organizing principle of consensus and material growth was its moral authority. Organization required cooperation; organizations would fail if their leaders were immoral. Management was the steward of modernization, peace, and prosperity. Those in leadership positions must have impeccable moral integrity. In its absence, according to Gardner and Means (1933), the public interest would become hostage to private cupidity. For Drucker (1954), it was management’s responsibility to make whatever is in the public good become the organization’s self-interest. Progress depended on the technical rationality of management. For Simon (1947), management was responsible for the application of logical positivistic science and controlled experimentation for progress (Scott & Hart, 1991). But Scott and Hart (1991), writing about the business scandals of the 1980s, declared that the concept of managerial responsibility was put to shame by management frauds, abuses, and mismanagement. Nonetheless, a fundamental task of leadership may be to persuade people to go beyond a selfish agenda because left to their own devices, they will follow selfish rather than broader agendas (J. Hogan & R. Hogan, 2002).

### ***Unethical Leader Behavior***

We are at the end of a 300-year trend in decoupling the physical world of science, technology, and business from the moral landscape. The moral meltdown that leaves people working in an amoral context produces dissociation from the community. The profane earning of a living is disconnected from our sacred and spiritual cultural heritage (Reeves-Ellington, 1995). In a telephone survey of 1,500 respondents, one-third said they had seen un-ethical activities in their organization in the past year (Ethics Resource Center, 2001). J. Patterson and P. Kim (1991) conducted an anonymous survey of a random sample of 2,000 managers and workers. One-third judged the workers to be more ethical than the managers and only 9% to 13% saw the reverse. A majority judged the managers to be more greedy and willing to take credit for another’s work; workers were judged much less so.

One cause is competitive pressure. Heggarty and Simms (1978) found that demands for performance resulted in unethical management decisions. Burnham (1941) argued that since management was in control of resources, it would use its power for self-interest. Selfless management was unlikely. Management controlled the organization’s resources.

*Management Corruption.* The financial system exacerbates the pressure to concentrate on short-term interests, preventing managers from attending to social responsibilities (Korten, 1996). Supposedly serving the public and the shareholders, certified public accountants (CPAs) who audit the accounts of their clients are

paid by the clients (Ruland, 1993). Bartol and Martin (1990) showed that managers awarded unjustifiably large raises to subordinates who threatened to use their connections with senior executives. According to Baucus and Near (1991), other environmental causes may include rapidly changing market conditions, patterns of wrongdoing in an industry, and lack of legal enforcement. Additionally, uncertainty, opportunities, and crises may be involved. Internal antecedents may include lax controls and a lack of standards. Important also are development, role models, education, work, early life, family experiences, and prior success and failures. Another factor is understanding one's duties and obligations in order to be able to fulfill them (Anonymous, 1997). Trust among members of a group or organization may be seen as an implicit moral duty. Although problematic, an explicit sense of, moral duty to trust one another could be effected and justified (Hosmer, 1995).

It is one thing to know what is right to do; it is another thing to do it (H. C. Smith, 1993). Good business may outweigh good ethics. Unethical behavior may be practiced contrary to one's moral beliefs. Other matters may override one's desire for a moral decision. Leaders may value political success and economic improvement over ethical behavior (Fritzsche & Becker, 1984). Opportunity may take precedence over ethics (Zey-Ferrell & Ferrell, 1982). A low risk of getting caught may tempt people to engage in illegal behavior (Fraedrich & Ferrell, 1992). Striving for goals over lengthy periods of time may generate unethical leadership behavior (Street, 1994). Leaders and managers may know right from wrong but convince themselves that ethically dubious enterprises are not only expedient but all right. We are more willing to harm others if we are pressured by authority (Milgrim 1974), if we are dealing with strangers rather than friends (Yamagishi & Sato, 1986), if we are at a distance from rather than close to those to be harmed, and if our self-efficacy is threatened (Bandura, 1989). But we are less likely to succumb to pressure to harm others, or to acquiesce in unethical commands if we are at Kohlberg's (1969) highest stages of moral reasoning (stage 5 or 6) and consider all people and universal ethical principles, rather than at the lowest stages (1 and 2—the stages of self-interest and personal aspirations). In between (in stages 3 and 4), we are conventional; we obey the rules to avoid being punished, or we conform morally due to social pressure. Whereas 75% of people at the highest stages have refused to obey ethically dubious orders, only 13% at the lowest stages refused (Stewart & Sprinthall, 1994). Noted for his boastfulness about taking a hard line in cutting costs and for his ruthless layoffs that imperiled operations, "Chainsaw Al" Dunlap (1998)—at stage 1—was the epitome of the unethical CEO (Bennis, 1997). Dunlap severely harmed earnings at Sunbeam Corporation before he was fired. He bragged about his efforts to sharply downsize the firm (Dunlap & Andelman, 1996), efforts that subsequently resulted in a serious fall in sales and stock prices. Eventually, Sunbeam went bankrupt. Un-ethical accounting practices that inflated stock prices led to shareholder suits, personally costing Dunlap \$15 million to settle an SEC investigation (Anonymous, 2002).

Daboub, Rasheed, Priem, et al. (1995) suggested that characteristics of a top management team, such as business education, seniority, and functional background, serve to enhance or neutralize illegal activity. The trustworthiness of banking executives was severely questioned and a number went to jail as a consequence of the savings and loan scandals of the 1980s. According to a *New York Times* CBS poll in 1985, 55% of the American public believed that the majority of corporate executives were dishonest and that executive white-collar crime was rampant. Of 671 executives surveyed in 1987, more than half said that they bent the rules in order to get ahead. A Prentice-Hall survey in 1990 revealed that 68% of employees believed that executives' unethical behavior resulted in the decline of business standards, productivity, and success. A majority of the employees justified their own malingering as a consequence of their perception of executives' unethical behavior (Gini, 1996). The Enron scandal of 2001 showed how widespread and devastating corruption could be, as it involved conspiracy and fraudulent behavior by the chief executives Ken Lay and Jeffery Skilling, and 16 chief executives in finance, accounting, and other units, all of whom pleaded guilty. Additionally, two other senior Enron executives in finance and accounting were convicted, as were three Merrill Lynch senior

executives: a vice president and the heads of asset leasing and investment banking. Arrogance, recklessness, greed, buttressed by the size of the incentives, underlay the executives' wrongdoing. The corruption and criminality at Enron were paralleled at other giant firms, such as WorldCom, Adelphia, and HealthSouth (Eichenwald, 2006). The scandal resulted in the bankruptcy of Enron; the near destruction of one of the big-four auditing firms, Arthur Andersen; the loss of employment by thousands of Enron's employees, 4,000 in Houston alone; and the loss of employees' pensions and savings. Thousands of shareholders were left with worthless shares (Barrionuevo, 2006).

In a survey of a representative sampling of 747 human resources professionals, 53% reported they had observed misconduct occasionally (46%) or often (7%) within their organization during the past year; this misconduct violated the law or the organization's standards of ethical business. But 21% failed to report the misconduct, for fear that they would not be seen as team players; and 70% agreed that American business managers would choose profits over doing what is right. Almost all agreed that in the long run, good ethics makes good business sense; but 63% felt that ethical conduct was not rewarded. Only 69% said that their CEO was sufficiently committed to ethical business conduct; 68% felt that this was true of the rest of top management. However, more than four out of five human resources managers rated those closest to them—their direct supervisor and those they directly supervised—as sufficiently committed to ethical business behavior. The larger the organizations in size, the more likely they were to have a written code of ethical standards. Just over half of those with fewer than 100 employees, but 94% of those with over 5,000, had a code. Training in ethical standards of business was provided by 61% of these, and most employees (85%) said they occasionally or frequently used the principles they learned. Included in Martin Marietta's ethical code were: avoiding conflicts of interest; not accepting payments, gifts, or entertainment from suppliers and customers; maintaining complete and accurate books, records, and communications; preserving assets; cost-consciousness; compliance with securities, restrictive trade practices, and antitrust laws and regulations; not biasing or falsifying accounts; and avoiding political contributions, disciplinary actions for violating the code, supervisory failures, and retaliation for reporting violations.

Frauds and swindles such as making secret deals to profit insiders, securing loans with phony assets, selling assets that do not exist, trading of company stocks by insiders, and attempting to "corner" or manipulate a market seem to mount up in boom times and are discovered when the economic bust suddenly occurs. The scandals revealed in the first decade of the twenty-first century involved larger amounts of wealth and more major corporations and their senior executives than in the past, and more questionable business and auditing practices than usual. The wars in Afghanistan and Iraq produced a wave of shady deals and corruption by government contractors. The scandalous bankruptcies at Enron, Tyco International, Global Crossings, Adelphia, WorldCom, and other companies forced financial restructurings that were first brought to light in 2002. They resulted from the looting of these corporations by their top executives and no doubt led to negative feelings among employees and shareholders about corporate leadership. A few top executives, left uncontrolled by friendly, highly paid boards of directors and unchecked by unethical auditors, gave themselves as much as a fifth of a large firm's profits in the form of extraordinary perquisites, salaries, sweetheart deals, stock awards, and pensions, and ignored the corporation's investment needs and the rights of the other stakeholders—the lower-level managers, employees, and shareholders. The boundary between ethical and unethical compensation has become fuzzier. The fact that the CEO's compensation in 2005 averaged 262 times the pay of the average worker in the same firm made it difficult to maintain the rationale that the top executive's compensation was a reasonable practice, legal, and a matter of supply and demand. An ethical decision would be based on a more beneficial and equitable distribution of the firm's returns (Balcom & Brossy, 1997).

*Example: Health Care* As reported in the Minneapolis *Star Tribune* and by the attorney general of

Minnesota, the not-for-profit Allina Health System of 16 hospitals, 47 clinics, and health care insurance units publicly espoused values such as wise use of resources, financial accountability, and earning the community's trust; but lavish expense accounts were provided. The hypocrisy was illustrated by eight Allina executives who attended an ethics seminar and charged Allina for a \$1,500 dinner. A vice president of Medica, its subsidiary health insurance firm, was reimbursed \$8,000 for his late fees at a golf club, to take care of his golf clubs, and to pay for his wife's use of the locker room. In 2001, Allina lost \$71 million and its former subsidiary laid off 20% of its workforce (Heuerman, 2002).

*Example: Labor Union* The founders of labor unions and their successors fought hard to improve their constituents' welfare and working conditions. Nevertheless, corruption and exploitation of the rank and file crept into union movements, sometimes to counter employers' militancy, sometimes to take care of unscrupulous politicians, sometimes to deal with pressure from mobster's, and sometimes for the self-aggrandizement of the union leaders. Bouza (1996) noted that by 1995, 400 officials of the Teamsters Union had been charged with corruption and removed. In addition to the Teamsters, three other national unions were listed by the federal government as being controlled by organized crime.

*Why?* Unethical behavior by executives takes place in spite of ethical codes, laws, regulations, and ethics officers at large firms and agencies. So that "business ethics" does not become an oxymoron, reforms are needed. Marino (2002) noted that corporate officers need to be kept in the loop of information concerning executives' wrong-doing.

Ulmer (1996) suggested that senior executives fail to set an example by their personal behavior. Their misconduct provides a rationalization for everyone else to ignore ethical codes and considerations. They place unreasonable demands on those at lower levels, causing the latter to reveal incompetence and providing them with an excuse to cut corners. Borrowing from Aristotle and Kant, Jeannot (1989) argued that virtuous character is required of leaders. They need practical wisdom, autonomy, and a sense of responsibility. At the same time, business actions and accounting numbers need to be made more transparent. Taking personal responsibility for actions and ensuring a transparent supportive money trail could do the same for political ethics.

Enforceable laws and regulations may also be important. The scandals have resulted in a new federal law tightening accounting rules and toughening penalties for white-collar crime. The Sarbanes-Oxley Act made the CEO liable for the deliberate falsification of earnings in order to raise the price of the firms' shares (Lowenstein, 2002). The New York Stock Exchange began requiring all listed firms to provide a code of ethics. An ethical code is the norm for larger organizations. But scandals occur in firms despite their written codes of ethical conduct. According to an analysis of the codes of 75 Canadian firms and three American studies of corporate codes, their main purpose is to protect the firms against misconduct against them instead of promoting the firms' ethical responsibilities (Lefebvre & Singh, 1996).

Despite the laws, regulations, and codes and the punishments for violation, why do managers and executives engage in unethical and illegal behavior? Fraud in organizations commonly involves cooperation among otherwise ethical, upstanding members of the community. They justify corrupt acts. They have logic-tight compartments—dishonesty in business and loving care for the family at home. Newcomers to the organization are socialized into corruption (Anand, Ashforth, & Joshi, 2004). Bazerman, Bazerman, and Messick (1996) attributed the answer to psychological aspects of decision making. In weighing the desire for gain against possible punitive consequences, all but the one favored aspect of the decision will be ignored. Decision makers are confident that the risk of getting caught is overestimated, or controllable, or can be ignored. Future events are perceived as more likely to be good than bad for the decision makers. They seek information only to confirm what they already believe. Unethical executives are further motivated by the rationalization that their

gains are justified and are fair compensation for what they have contributed (Jenkins, 2002).

What motivates unethical behavior at lower levels in an organization? One's superiors may be an important factor. As a result of pressure from above to reach quarterly goals, sales teams at Global Crossings and Qwest engaged in dubious practices and suspicious deals. Higher-ups were able to overstate actual sales by approving network swaps.

*Changed Norms.* Ethical norms change. Ethical norms are broken. Physicians and lawyers at one time were not permitted to advertise. On the Internet prior to 1994, advertising was informally banned through self-regulation by its mostly educational, scholarly, and scientific early users. The costs were kept low. Management of the Internet was kept at a minimum. Then two lawyers advertised their services in news groups, and refused to quit. The dam was broken. The Internet was flooded with advertising, which led to congestion requiring a greater increase in Internet management. The World Wide Web that followed became even more congested with increased traffic and graphics (Fukuyama, 1995). With commercialization, both became targets of deceptive practices and fraud.

*Bending the Rules.* Of over 100 members of the executive advisory panel of the Academy of Management Executives, 87% said it was a common rationale to "bend the rules" to get the job done, and 77% said this was a common justification if performance standards were unfair and overly restrictive. Similar large majorities agreed that bending the rules was commonly justified in an emergency or if the rules were ambiguous or outdated. Most felt such rule-bending was appropriate behavior. But only between 19% and 27% felt it was appropriate to bend the rules under political or social pressure to do so, to pay back favors, or because "everyone does it." The five most important personal reasons they gave for not bending the rules were: (1) to avoid jeopardizing their jobs, (2) to avoid damage to their reputation, (3) to avoid being held responsible, (4) to avoid creating an unwanted precedent, and (5) their own code of ethics. Also, bending the rules might prove embarrassing and jeopardize the organization and others (Veiga, Golden, & Dechant, 2004).

Van Buren (2002) called for changing the contractual norms for employee-management relations to increase fairness. Employee consensus is usually lacking in the exchange agreements between them. "The goal of any movement for worker justice should be to restore the ability of workers to exercise rights of consent; that is to participate in meaningful ways in corporate governance processes with regard to employment policies and practices" (p. 2).

## Ethics and Effectiveness

---

Ciulla (1998) suggested that leaders who do not look after the interests of their followers and other organizational stakeholders are not only unethical but also ineffective. Lee Iacocca made a moral gesture by cutting his yearly salary to one dollar, showing solidarity with his workforce when Congress bailed Chrysler out of bankruptcy. Ethics and business effectiveness also came together for Alan Weil, whose law firm's offices at the World Trade Center were destroyed by the terrorist attack of 9/11. He first checked to see if all his employees had escaped safely, then rented the necessary space in another building and arranged the same day by telephone for 800 desks and 300 computers to be delivered. The firm was open and ready for business the next day.

*Ethical Imperatives.* The ethical leader ought to be fair and truthful, avoid harm to others, and keep promises. But these absolutes must be conditional, depending on particular circumstances. Often supervisors are faced with dilemmas—two equally capable employees for instance, and room for only one promotion, so that only one or the other can be treated fairly. Should the supervisor tell the truth to a satisfied, valued

employee—that her future in the firm is limited—increasing the likelihood that she will seek employment elsewhere? How much can we harm others by laying them off to save on expenses and at the same time support lavish bonuses for senior managers? It is more ethical as well as more effective to inform job applicants and new recruits about the rules and infractions as well as both the positives and the negatives in their prospective assignments. Recruits selected for employment are less likely to quit when the employment interviewer fairly presents to the job applicant both the positive and the negative aspects of the job rather than the good points alone. The subsequent orientation of newly hired employees with both positive and negative aspects of the job further reduces their propensity to quit. False expectations are avoided.

*Ethical Reputation and Commitment.* Simon Webley and Elisa More reported in a British study that companies with a clear commitment to ethical conduct outperform those with no such commitment. The ethical companies were more effective between 1997 and 2001, as gauged by return on capital and added economic and market value (E. Munson, 2004). Galvin (2000, p. 99) summed up the value of an ethical reputation to e-business, noting that “if four online retailers sell the same book at the same price, most people will purchase the book from the site they trust the most.” According to Panken (undated), in the ideal capitalist marketplace the most efficient organizations should survive and prosper. “The inefficient should sink in a sea of red ink” (p. 40). But ideally, capitalism should not mean minimizing expenses but rather optimizing benefits for all the stake-holders in the organization. Ideal socialism implies “To each according to his needs and from each according to his abilities.” National political economies are now more or less regulated in differing proportions between the capitalistic ethics of efficiency and the socialistic ethics of need controlled by the market, politics, economic and social legislation, and “do-it-yourself” work. In all, ethically, there should be fairness of opportunity to earn a living in an atmosphere of respect.

*Ethical Reputation, Product Quality, and Consumer Satisfaction.* Galvin (2000) cited a number of reports attesting to the payoff to firms from ethical leadership and honesty and fairness in business. According to the Ethics Resources Center, “high standards in the way companies deal with their employees and customers translate into better product quality and assured customers” (p. 99). The ethical intentions of 144 insurance agents depended more on their moral obligation to disclose possibly unfavorable information to clients than to the compensation system. According to a 1999 Walker Report, “companies viewed as highly ethical by their employees were six times [more] likely to keep their staff members. On the other hand, 79% of employees who questioned their bosses’ integrity said they felt trapped at work or were likely to leave their jobs soon” (p. 99). A Harris poll reported in 1988 that 89% of 1,200 workers and managers felt it was important for leaders to be honest, upright, and ethical, but only 41% said met these their current supervisor criteria (Hughes, Ginnett, & Curphy, 1993). The job satisfaction, commitment, and identification of 257 employees were positively correlated with their perceptions of the ethical behavior of management, but their perception of their organization’s ethical climate was of less consequence (Spitzmueller, Gibby, & Stanton, 2003). Having a reputation for the virtues of forgiveness, optimism, compassion, trust, and integrity was found, in 75 interviews in a small hospital and an environmental consulting engineering firm, to contribute to subsequent success after the hospital and the firm downsized. A confirmatory survey of 804 respondents in 18 firms found that those with a reputation for integrity, trustworthiness, reliability, and dependability were more profitable after downsizing. Innovation was associated with optimism, trust, integrity, and forgiveness; customer retention was associated with a reputation for optimism and trust; employee was linked with a firm’s reputation for trust and compassion (Cameron, Caza, & Bright, 2002).

*Corporate Social Responsibility.* Corporate social responsibility ought to be assessed by the extent to which all of the stakeholders’ concerns are considered, including those of the community and the public.

According to Black and Härtel (2002), firms that are *adaptive* in their orientation to social responsibility consider and value stakeholder interests in their operations. Firms *disengaged* in corporate responsibility are the opposite. They place little value on stakeholder' interests or ethical business conduct. The *missionary* type adopts any social cause not limited to its own business operations and sometimes may disturb some of its own stakeholders. The *economic* type acts only on matters it considers of instrumental value to the firm and its stakeholders. Community sponsorships, cause-related marketing, and strategic philanthropy are illustrative. Strategic corporate responsibility is shown when automobile companies invest in engines that use alternative, less polluting fuel. A network of firms oriented to corporate social responsibility would enhance the effort (Johnson & Brennan, 2002).

*Socially Responsible and Irresponsible Accounting Statements.* Pruzan and Thyssen (undated) suggested that accounting statements can be prepared that reflect a consensus among stakeholders' shared values and how the organization has lived up to them. Compared with a traditional accounting statement, such statements involve more values and more stakeholders. Operationalized, concrete verbal expressions in the statement can be applied to creating questionnaires to evaluate the organization's ethical performance. But short-term stock options for CEOs militate against ethically sound corporate governance. Sixty large firms that had to restate their accounts of 1999 or could not certify their 2001–2002 accounts because of corporate accounting irregularities were matched with 60 firms that did not have these problems. Compared with the CEOs of the "clean" firms, the CEOs of firms with irregularities were more likely to have short-term stock options and were judged to be "un-principled" agents of their corporations (O'Connor & Priem, 2003). Fraudulent accounting statements were also found by Troy, Smith, and Gordon (2003) in firms compared with matched firms when their CEOs were younger, did not have an MBA, and had more of their compensation based on stock options. The firms with fraudulent accounting engaged in riskier acquisition strategies, were more distressed financially, and lacked external audit oversight. When superiors turned a blind eye to fraudulent reports, subordinates were more likely to make such reports, especially if the subordinates were more generally accepting of social dominance (Smith-Crowe, Umphress, Brief, et al., 2003).

*Ethical Climate.* Individual character is a source of information about ethical climate (Anonymous, 1997). Over the long run, confidence in the leadership and its institutions depends on the character of the leader. The ethical climate of an organization often is a consequence of the character, motives, and values of its founders and early leaders (Dickson, Smith, Grojean, et al., 2001). It was also assumed that firms with an earned reputation for social responsibility were led by moral executives. In 95 studies, Margolis and Walsh (2001) carefully selected ethically exemplary and ethically notorious firms. For this, they reviewed a number of lists of firms according to the firms' perceived social responsibility. The firms' reputations on nine criteria including social responsibility were obtained by asking executives, outside directors, and corporate analysts. Also obtained were five additional measures of corporate social responsibility toward community, diversity, employee relations, the natural environment, and product safety and quality (pp. 9–10). Control variables were applied to the analysis of the "good" and "bad" firms. In 80 of the 95 studies, the data about corporate social performance preceded successful financial performance. Of these, 53% predicted financial performance. In 19 of the 80 studies, financial performance preceded social responsibility. Here the results were even more positive: 68% supported the argument that financially successful firms could afford to be socially responsible.

Bansal and Roth (2000) conducted interviews in Britain and Japan at 53 firms to ascertain what prompted their sense of ecological responsibility. It was seen as a matter of good business, for instance, to turn a waste product into something of value. This improved the firm's image, reputation, and legitimacy and avoided penalties and fines. It was the right thing to do and made the firm a good citizen, a morally better company, and a company that felt good about itself. However, managers' moral intentions—for example, those of 130

to 138 executives in the metal finishing industry regarding their firm's dealing with wastewater—were moderated by their moral intensity and the magnitude of the consequences. The executives' attitudes, norms, and sense of self-efficacy along with the financial costs and the ethical climate affected their ethical decisions (Flannery & May, 2000).

*Ethical Constraints on Organizational Leaders' Influence.* There are limits on what a superior can ask of subordinates and what the subordinates are permitted or expected to do. Superiors have a positive duty to avoid influence that violates ethical norms of society. They ought to use their influence to promote the common good of the organization and its members (Kelman, 2001). The values and decisions of subordinates should be respected. With justice and fairness, leaders ought to promote the welfare of subordinates and avoid harming them (Beauchamp, Faden, Wallace, et al., 1982). Ethical considerations ought to constrain leaders from being too coercive or directive in group decision processes (Peterson, 2001). Conversely, top managers' perspective on illegal corporate activities can make a difference to what leaders at all levels are tempted to do unethically (Daboub, Rasheed, Prien, et al., 1995). A corporation's code of ethics ought to be consistent with its incentive system, which should avoid shortcuts at the expense of the reputation and long-term survival of the corporation (Darley, 2001). Ethical congruence of the leader and the organization tends to increase the leader's job satisfaction, commitment to the organization, and intention to remain with the organization (Arnaud, Ambrose, & Schminke, 2002). Ethical considerations may cause an amoral leader to avoid giving a direct order to a subordinate to carry out an unethical act, but instead the leader will indirectly hint that the act be carried out. The subordinate can resist the suggestion or claim a misunderstanding if the ethical violation is discovered (Roloff & Paulson, 2001). Perreault (1997) reviewed how subordinates can make a difference in whether an ethical decision emerges in a situation. Often they are unaware of their potential impact. They ought not remain loyal to an unethical leader. Followers are ethical to the extent that they pursue the goals and practices of an ethical leader. Like leaders, they ought to be sensitive to ethical issues and to reason, decide, and act ethically.

*Ethical Failures.* Allinson (1995) attributed several disasters—the first Hubble space telescope, the Challenger space shuttle, the fire at the London Underground King's Cross Station, the ferry flooding at Zeebrugge in Belgium, and the aircraft tragedy at Mount Erebus in Antarctica—to the irresponsibility of management and its failure to be ethically centered. For instance, in the case of the flawed Hubble telescope, management actively discouraged quality control. Top management disowned responsibility for finding out and ensuring that the final product was problem-free and of the highest quality. They did not consider it their duty to inquire if there were any problems. They did not show respect for their employees by paying attention to suggestions and warnings. With regard to the need for independent testing, they ignored consultants. President Bill Clinton's dalliance with Monica Lewinski was a private affair, but once it became public knowledge, this unethical behavior and the attempts to cover it up with lies led to impeachment proceedings and loss of trust in the president.

## Spiritual Leadership

---

Society is undergoing a spiritual revolution (Haasnoot, 2000) and a new awakening that cannot be ignored by organizational leaders (Judge, 1999). This awakening is moving people to a higher level of transcendence and morality, beyond Kohlberg's highest stage (stage 6). Some observers see spirituality as the "hottest new management theory," an opportunity to exploit religious language in service of organizational performance (Wallace, 2001). Southwest Airlines, Ben and Jerry's, and numerous other firms have taken on programs reflecting spiritual issues (Lewis, 2001). More than three-fourths of respondents in a Gallup poll in 1999 said

they felt a need for spiritual growth (Moch & Bartunik, 2002). Mysticism is being introduced into management (Conlin, 1999). Spirituality has been important to the leader-follower relationship in Taoism for over 2,500 years (Johnson, 2000).

*Meaning.* Spirituality is a mind-set that becomes a way of existing at all times and places. It is an approach to life that includes a transcendent being and a sense of oneness with the universe (Bruce & Plocha, 1999). It is a striving to integrate one's life and a desire for wholeness in the midst of fragmentation, for community in the face of isolation and loneliness, for meaning, and for enduring values (Pielstick, 2000). Václav Havel, former president of the Czech Republic and leader of the "velvet revolution," commented, "In my own life, I am reaching for something that goes far beyond me and the horizon of the world that I know. ... In everything I do I touch eternity in a strange way" (Bolman & Deal, 1996, p. 530).

*Concepts and Theory.* Kanungo and Mendonca (1996) found a spiritual quality in the faith that many followers have in their charismatic leaders. Conger (1991) saw a spiritual union between charismatic leaders and their followers. Sanders, Hopkins, and Geroy (2002) maintained that the consciousness, moral character, and faith inherent in spirituality move transformational leadership into a higher *transcendental* leadership, applying consciousness, heart, and soul in the leader's daily accomplishments. According to Matusak (1997), *servant leadership* has deeply spiritual underpinnings. Greenleaf (1977), its originator, assumed that leaders exist primarily to serve their group of followers. The followers grant allegiance to the servant leader in order to achieve common goals. Servant leadership is deeply spiritual but has become a secular approach to promoting service to others, empowerment, shared decision making, participative management, and a holistic approach to work and to personal development (Lee & Zemke, 1993). May and Whittington (2003) describe *affirmative leadership* built on passages in the gospels of the New Testament that they compared with principles of servant and transformational leadership.

*Relation to Religion.* Religious tradition contains support and rules for spiritual seekers. Ethical principles often derive from religion, just as religion depends on spiritual experience. Such spiritual experience in a larger community of faith can lead to moral discourse and ethical behavior (Moch & Bartunik, 2002). Ordinarily, spirituality depends for collective discipline and knowledge on the stewardship of religion. But the relationship between spirituality and religiosity is complex. Conclusions drawn from reviews of evidence about religiosity and ethical behavior, ranging from cheating to criminal activity, are mixed. Religious role expectations, religious identity, and religious motivation may need to be considered as moderators (Weaver & Agle, 2002). Hicks (2002) argued that spirituality cannot be divorced from religious expression. Nevertheless, as noted by Roof (1999), among baby boomers at midlife, only 79% with a religious identity reported that they were spiritual and 54% without a religious identity said they were spiritual.

*Relation to Leadership.* Religious and philosophical teachings on morality and ethical behavior are being recast into research on spirituality and leadership. Bruce (2000) remarks that spiritual leadership pays special attention to the interconnections between God, humanity, and the world of nature; the immanence of the past and future in the present; issues of brotherhood and community; and the rejection of materialism. Emmons (1999) says that spirituality transcends the physical and the material. It provides an ability to experience heightened states of consciousness as well as to sanctify everyday experiences and solve problems. It involves the capacity to be virtuous (Cowan, 2002). Jesus, in his spiritual mission, was both transactional and transformational in his leadership (Ford, 1991). Whittington, Kageler, and Pitts (2002) found 10 principles of leadership in Saint Paul's first letter to the Thessalonians. But Hicks (2005) cautioned that organizational leaders should not promote a single spiritual framework. Rather, they ought to create a structure and organizational culture in which members can respectfully negotiate religious and spiritual diversity. A basic

beginning is *respectful pluralism*, that welcomes fundamental aspects of each member's identity and dignity. Fry (2003) derived a causal theory of spiritual leadership from a model of motivation. Spiritual leadership is seen as creating vision and congruence of values that foster organizational commitment and productivity in individuals and teams. Fry distinguished between spirituality and religiosity but assumed a universal need for spirituality and a humanistic, theistic, or pantheistic higher power. Leaders need to get in touch with the core values of their followers and communicate these values through vision and personal action to create a sense of spiritual survival.

Whereas the spirituality of religious fundamentalists is emotionally justified by a faith in a mythology of the past, the spirituality of religious liberals is more rationally oriented toward a future predicated on continued advances in science, technology, and human betterment (Armstrong, 2000). Both religious fundamentalists and religious liberals engage in leadership that is transformational. But more pseudotransformational leadership and more irrationality are likely to appear among fundamentalist religious leaders and followers.

*Effects.* Milliman and Neck (1994) suggested that spiritual-based values can increase commitment, teamwork, sense of service, and personal growth. Support was provided in a controlled longitudinal experiment by Fry and Malone (2003) using 223 elementary and middle school employees. A sense of spiritual survival, finding meaning in life, and the value of spiritual leadership were fostered that influenced a sense of well-being, commitment, and productivity.

Bolman and Deal (2001) present a parable about a manager who has found organizational life hollow and unfulfilling. His mentor helps the manager to put spirit and emotion into his leadership. The manager is awakened to his own inner world of feelings and soul. The mentor helps the manager to find spirit all around and to recognize the importance of working with others with the gifts of love, power, authorship, and significance. These gifts depend on timing for acceptance and value. The gift of love involves compassion, consideration, and caring. The gift of power is a sharing to bring about autonomy and empowerment. The gift of authorship provides a sense of accomplishment. The gift of significance uses ritual, celebration, and spontaneity to credit shared creativity at the workplace. It remains a challenge for organizational leaders to introduce more spiritual values in the workplace and to evaluate the effects on performance and satisfaction.

## Moral Reasoning

---

Given a moral dilemma, moral reasoning entails why people make the ethical decision they make and what considerations are most important to the decision. But knowing and deciding what is right to do may not result in doing right. Leaders can have an important moral effect on those they lead. The leader may simply ask what is the right thing to do. The leader may direct or request more systematic deliberation on what is the right thing to do, to add confidence in the answer. Thus effective moral reasoning is needed by human resources executives if they are to satisfactorily balance the organization's fundamental values, employees' and other stakeholders' interests, and the firm's profitability (Grensing-Pophal (1998). The leaders' own values affect what they decide is right and wrong. Their moral decisions will depend on the importance they attach to terminal values such as inner harmony, social recognition, and family security, and to instrumental values such as being responsible, courageous, and imaginative (Hughes, Ginnett, & Curphy, 1993). It might be expected that moral reasoning correlates with moral action; that is, the more people are able to reason ethically, the more likely they are to behave ethically (Perreault, 1994), however the relationship is complex (Mudrack, 2002), as will be noted below

*Measurement.* Moral reasoning is most frequently measured by the P score on Rest's (1979, 1986) Defining Issues Test (DIT). The DIT has been used in over 500 studies and over 12,000 cases (Mudrock,

2000). For each dilemma presented, the respondent chooses the right action to be taken, rates the relative importance of 12 reasons in deciding, and ranks the four most important of these. The P score of a respondent is the proportion of reasons cited that respect rights, values, and universal principles (Kohlberg's post-conventional stages 5 and 6). The average P score for adults, in general, is 40.0. P scores increase with age and education. Available averages are those for junior high school students, 21.9; senior high school students, 31.8; college students, 42.3; graduate business students, 42.8; and advanced law students, 52.2. Delinquents have low P scores: 16-year-old delinquent boys, 18.9; prison inmates, 23.5. At the high end are seminarians (59.8) and moral philosophers and theologians (65.2). Professionals score higher than adults in general: physicians, 49.5; staff nurses, 46.4 (Rest, 1993). Blasi (1980) failed to find significant correlations in only 18 of 75 studies of P scores and ethical behavior.

Nonetheless, knowing and choosing the reasons for the right thing to do is not the same as doing the right thing. Rule-bound leaders, those who are consistent in their choice of actions and the reasons they deem most important, earn high utilization (U) scores. The U score indicates whether people would act according to their reasoning. People who explain a decision by giving one important reason that is in conflict with another reason they regard as highly important earn low U scores (Thomas, 1985). Thus U scores are moderators that enhance the correlations of P scores with other expected measures of ethical behavior (Thomas, Rest, & Davison, 1991) and help to explain why moral decisions alone (P scores) failed to correlate with behavior in 18 of 75 studies (Blasi, 1980). Mudrack (2002) demonstrated that the negative correlations of P, U, and Machiavellianism (Christie & Geis, 1970) were high only when high U scores were added to P scores in a regression equation. Similar results were obtained by Mudrack (2002) with the multiple correlation of P added to U scores predicting right-wing authoritarianism (RWA; Altemeyer, 1998).

*Principled Moral Reasoning.* Traditionally, moral reasoning about the best solution to a moral dilemma was *principled moral reasoning*: applying general principles and rules relevant to the case to decide on the most just solution. Following Paine (1991), Reiter (2002) argued for a second approach: *character-based moral reasoning*. Here, the judgment is based on testing available actions against a rational theory that serves as a standard of what is right and good. But there is often a disconnect between the theoretically right thing to do and its actual application—between moral thinking and moral application. Furthermore, moral choice is supposedly impersonal and based on rationality. Broad general decision rules relevant to all similar cases are applied (Kupperman, 1991). However, competing moral claims may engender unresolvable conflicts that do not permit unique solutions. Using principled reasoning to decide on the right thing to do may result in more harm than good to all concerned. King Solomon threatened to give half of an infant to each of two women who were claiming to be its mother. The character of the decision maker supposedly has no effect on the moral decision. The social and historical context is ignored.

Principled participants who also believed strongly in a just world reasoned most ethically on the DIT. Morally principled leaders move their followers to higher ethical levels. Dukerich, Nichols, Elm, et al. (1990) found in a study of 21 four-person groups that if the emergent leaders were more principled in their reasoning, their group's moral reasoning achieved a higher level of ethical reasoning, as measured by the DIT. Similar results were obtained in a follow-up experiment in which members higher in DIT level were assigned as leaders of the groups. Nonetheless, after 118 business students completed the DIT, they engaged in a realistic competitive simulation calling for the sharing and use of common resources. During the competition, in comparison with their DIT scores, their scores on principled moral reasoning declined, as measured repeatedly by a "reasoning list" equivalent to the DIT (Reall, Bailey, & Stoll, 1994).

*Character-Based Moral Reasoning.* In real life, leaders do not use systems of rules to reach moral decisions. Rather, their moral deliberations are personal and contextual. To reason in this way, leaders need to

(1) be ethically sensitive, to identify ethical issues; (2) be able to reason ethically; (3) conduct themselves ethically, with the ability to appreciate and empathize with another's situation; and (4) understand ethical leadership and how organizational factors affect the individual (Paine, 1991). Reiter (2002) suggested that the first two requirements are met by both principled and character-based moral deliberation, but the latter two call for character-based ethical conduct and ethical leadership as described extensively by Johnson (1993) and Senge (1990).

Reiter noted that one's "circle of concern" is a ring of actions and events one cares about. A leader's smaller circle includes the concerns that he or she can do something about proactively, to head off ethical problems early. Leaders should begin moral deliberation with the end in mind. In agreement with Burns (1978), Reiter pointed out that moral leaders should focus on clarifying values and achieving valued ends. They ought to facilitate interaction by converting disputes into win-win situations, seeking first to understand, and using empathic communication. Moral leaders ought to see problems from other points of view and search for alternative solutions. They ought to continue to clarify what is important and continue to see current reality more clearly (Senge, 1990). *Moral imagination* is needed by leaders for character-based moral deliberation in order to explore various courses of action to harmonize conflicting values and conceptions of reason (Johnson, 1993).

*Moral Decision Making.* Covrig (2000) described how 11 school administrators coped with making decisions that forced them to violate one cherished value in order to satisfy another. Sometimes, these decisions were seen as challenges rather than dilemmas, or as dilemmas for which there were routine decisions. Various models of the moral decision-making process were proposed. For instance, Trevino (1986) emphasized the need for the moral dilemma to stimulate moral awareness in the decision maker. Sensitivity to the dilemma should be moderated by reinforcement, by the character of the work, and by the organizational culture. The decision maker's ego strength, locus of control, and field dependence should also be considered. As noted elsewhere, a leader's moral judgment comes after moral awareness and sensitivity indicate that a moral problem exists, a decision to act is made, and action is taken (Rest, 1986). Moderators such as timing, opportunity, and available sanctions occur. Jones (1991) proposed that the impetus to decide depends on the dilemma's social and critical consequences and on its closeness in time and space to the decision maker.

Rest (1984) saw a logical progression in moral reasoning. It begins with interpreting the situation involving possible ethical actions and the welfare of those affected by them, and then making and persevering in a moral choice. According to Langenderfer and Rockness (un-dated), the facts are identified, then the ethical issues and stakeholders. The norms, principles, and values are defined and the best course of action is chosen consistent with them and the consequences of alternatives. There is consultation with trusted others before the decision is made.

*Leadership and Moral Development.* John Gardner (1990) charged leaders with the task of revitalizing the values and beliefs they shared with their constituents—including moral values. Leaders "must conceive and articulate goals in ways that lift people out of their petty preoccupations and unite them toward higher ends" (p. 191). Galaz-Fontes, Hernando Morelos, et al. (1991) held that moving followers up in the stages of moral development depends on their leadership. Hollander (1995) said that ethical concerns of leaders and followers were essential to developing trust and loyalty between them. Hollander suggested that in their need for power and distance, self-serving leaders become detached from their followers' reactions. Poor leadership damages trust, loyalty, and teamwork and raises, in the followers, questions about the ethics of equity, responsibility, and accountability. Paine (1997) suggested that ethical leaders influence the development of morality of their group and organization by: (1) leading by example; (2) developing a framework of aspirations and standards of the behavior they expect of others in the organization; (3) aligning the organization

with the framework of structures that maintain its ethicality; and (4) dealing with external challenges to its morality and integrity. Graham (1995) detailed the relations between leaders and followers' in ethical development according to Kohlberg's (1969) six stages of individual moral development. Leaders at stages 1 and 2 are most likely to foster transactional leadership and dependable task performance by followers. Managers at stages 3 and 4 focus on role and institutional relationships. Managers at stages 5 and 6 most likely are transformational. More managers, and adults in general, reason at stages 3 and 4, but those in larger organizations are more likely to reason at lower levels. Reasoning is also likely to be at a lower stage of morals when it concerns business rather than nonbusiness matters (Weber, 1990).

Williams (1994) suggested that transformational leaders had positive effects on followers' "organizational citizenship behavior" (OCB), but only if the leader was trusted. Turner and Barling (undated) asked 58 supervisors of nonfaculty personnel at a Canadian university to complete Rest's (1990) Defining Issues Test. On that basis supervisors were sorted into three categories of moral reasoning: (1) stages 1 and 2, pre-conventional moral reasoning; (2) stages 3 and 4, conventional moral reasoning; and (3) stages 5 and 6, post-conventional moral reasoning. The supervisors were rated by 173 subordinates using the Multifactor Leadership Questionnaire to assess the supervisors' transformational and transactional leadership scores. The transformational leadership scores increased linearly and significantly from pre-conventional through conventional to post-conventional moral reasoning. Conversely, the trend was reversed for transactional active management by exception. The less morally mature the supervisors, the more they were likely to practice management by exception (N. Turner, 1998).

*Leader Styles, Moral Values, and Ethical Consequences.* The coercive, autocratic leader values authoritarian rules and directions, to be obeyed uncritically. Such leadership is a cause of groupthink, pressure to conform, and biased stereotypes of out-groups (Sims, 1992). Behavior is less ethically developed than it is under democratic leadership. Rule-bound leadership found in bureaucracies and organizational hierarchies constrains moral reasoning and sense of moral responsibility. Mud-rock (2002) found that the DIT P scores of 317 U.S. Coast Guard personnel were significantly lower than adult norms. But P scores rose with rank from seaman to captain, reflecting education and age.

The transactional leader attaches most importance to exchange agreements with instrumental compliance and enforceable contracts. The contract has to have moral legitimacy (Donaldson & Dunfee, 1994) that depends on telling the truth, keeping promises, and fair distribution of rewards and valid incentives. It recognizes the diversity of values and motivations (Rawls, 1971) and virtues in leaders and followers such as honesty, reliability, integrity, sensitivity, and a sense of reciprocity (Burns, 1978). In high-quality exchanges between leaders and members, role obligations are valued and met. (For full details about such exchanges, see Chapters 15 and 16.) The referent value is the personal relationship with the supervisor. For the institutional leader, cultural expectations about the fulfillment of social and organizational duties are deemed important.

Commentaries about ethical charismatic leaders (charismatic leadership is detailed in [Chapter 21](#)) and transformational leaders ([Chapter 22](#)) are consistent with each other. The ethical charismatic leader does what is morally right, goes beyond self-interest for others' benefit, and favors empowerment over control and followers' internalization of the leader's influence (Conger & Kanungo, 1998). Ethical charismatic leaders use their power to serve others rather than for personal gain. They align their vision with followers' needs. To deal with organizational and societal interests, they rely on internalized moral standards instead of convenient external moral standards that satisfy their own self-interest (Howell & Avolio, 1992). Transformational leaders' moral values take into account the costs and benefits to all stakeholders, the application of distributive justice, and universal moral principles (R. S. Peterson, 2001). In the Netherlands, 73 CEOs of small and medium-size profit and voluntary organizations were rated by their 125 direct reports. The MLQ survey and TAT testing examined how much they were charismatic and used their power motivation in a morally

responsibility way. (The voluntary organizations focused on altruistic goals and morally responsible actions such as environmental protection, human rights, or animal welfare.) Overall, a sense of high moral responsibility was near the same mean level in for-profit and voluntary organizations; but in profit-making organizations the CEOs were more likely to be rated as highly charismatic even when they were not seen as morally responsible.

Rest's (1990) Defining Issues Test (DIT) was completed by 132 managers to measure their moral reasoning. Also, the Multifactor leadership Questionnaire (Bass & Avolio, 1995) was completed by their 407 subordinates to assess the managers' transformational and transactional leadership. Moral reasoning correlated significantly ( $r = .26$ ) with transformational but not with transactional leadership. Again, transformational but not transactional leadership increased with successive stages of Kohlberg's moral maturity (Turner, Barling, Epitropaki, et al., 2002). Sixty-one senior executives higher in transformational leadership were lower in the Hall-Tonna (1944) values cycle 2 (Kohlberg's moral development stage of personal aspirations). They scored higher on values cycle 5 matching Kohlberg's higher moral stage of concern for others' rights (Goeglein, 1997). Such leaders provide examples of ethical behavior that should raise the moral standards and values of their followers (Stephens, D'Intino, & Victor, 1995). Brown and Travino (2003) found more trust and liking of their leaders among employees when the leaders were more transformational, but employees' un-ethical conduct was unaffected.

*Accounts.* Moral reasoning is not as strong might be expected among accountants, nor is it related to their success. The Arthur Anderson auditing firm's debacle of 2001 may be explained by the rather less-developed moral reasoning of accountants and auditors when their DIT scores are compared with those of other professionals. Seminarians, judges, and nurses score at the highest levels. At midlevel are CEOs, physicians, dentists, generals, and admirals. Below them are lawyers, college seniors, and staff and senior accountants. Still lower in DIT scores are college freshmen, accountant partners, and junior high school students. A representative U.S. sample of 650 CPAs drawn by mail with a response rate of 31% provided 57 senior CPAs, account managers, and accounting partners. Over a two-year period, those promoted had DIT scores of 36.1; those not promoted had scores of 41.2; those leaving their firm had scores of 48.3. Considerably more results from three studies also indicated that ethical socialization in the accounting firms' leaders resulted in *lower* ethical reasoning (Ponemon, 1992).

*Personal and Moral Development.* Torbert (1991) observed that the stages in personal development have a moral logic consistent with the historical development of moral philosophies from Hobbes in the seventeenth century to Rawls (1971) in the twentieth century. Later-stage leaders are capable of more nuanced ethical judgments (Lichtenstein, Smith, & Torbert, 1995). Torbert found that 24% of 37 first-line supervisors and 9% of 177 junior and middle managers were *diplomats* for whom what is right depends on social norms. Ethics were a matter of consent. Interpersonal conflict was to be avoided. A majority of first-line supervisors (68%), 43.5% to 47% of middle managers, 66 senior managers, and 104 executives were *technicians*. They were assertive, critical, legal-istic, Kantian, and concerned about rights and duties. Only 8% of first-line supervisors were *achievers*, but from 33% to 40% of managers and executives were achievers. The system's success ruled their logic. They were organizers and directors. Like Rawls, they subscribed to a sense of fairness and justice and had internalized moral standards that balanced the ethics of Rousseau and Kant. Only 5% of junior and middle managers and hardly any senior managers were found by Torbert (1991) to be at the lowest stage, opportunism. *Opportunists* were governed by their own interests and giving tit for tat. They were Hobbsian and utilitarian in ethical philosophy and interpersonally manipulative and deceptive. As moral maturity develops from one stage to the next, there is an increase in: (1) ability to accept responsibility for one's actions, (2) empathy for others who hold different or conflicting worldviews, and (3) tolerance of stress and ambiguity (Bartunek, Gordon, & Weathersby, 1983).

General Norman Schwarzkopf declared that managers and leaders are more likely to fail because of lack of character than lack of competence (Mason, 1992). Many CEOs see themselves as needing primarily to watch out warily for their near-term performance. Everything that can be quantified is quantified, and tighter controls are imposed. They avoid risk and long-term investment in research and development (Levinson, 1988). Legal suits, Securities and Exchange Commission regulations, and state and federal legislation emerge as reactions to questionable senior management practices. A 1989 New York State law required that the board of directors consider the costs to the community of accepting a takeover bid, as well as the benefits to the shareholders.

*Morality* is a set of values and social beliefs about right conduct. Moral behaviors are acceptable; immoral behaviors are unacceptable. *Ethicality* is concerned with implied standards such as fairness, justice, kindness, the differences between right and wrong, and morally acceptable conduct. The *character* of a leader involves his or her ethical and moral beliefs, intentions, and behavior. Various questions need to be asked about the character of leaders. Are there just a few bad apples in business leadership? A few rogue politicians in government? A few unethical health administrators? A few immoral religious pastors? A few unethical military and police officers? A few unethical educators? Are leaders using acceptable political means for their self-aggrandizement (Dalton, 1959), or are immorality and lack of ethics endemic among leaders of organizations and societies? Does power corrupt? We will try to examine these and related questions in this chapter.

The robber barons—entrepreneurs who dominated business leadership in the last half of the nineteenth century—brought on the regulatory reforms of the first half of the twentieth century. The latter part of the twentieth century saw history repeating itself. The many business scandals that continued into the twenty-first century reinforced the public's lack of confidence in the ethics of business executives. Fox (2000) noted that confidence in business leadership declined from a high of 70% in the late 1960s to about 15% in the late 1980s. By 1989, the costs of corporate crime—ranging from illegal dumping of waste to price fixing—had greatly exceeded the costs of street crime. Almost every day there were reports in the media about violations of ethical conduct by national and local leaders which Fineman (2006) described as “the fraying of America's moral fabric” (p. 31). A total of 110 senior officials during the eight years of the Reagan administration (1981–1989) were accused of illegal or unethical conduct (Thomas, 1988).

More statesmanship and less politics are needed from our political leaders. Statesmen are magnetized by the truth, unwilling to give up their good name, unable to put their interests ahead of the nation's. They avoid evasion, broken promises and lies for the sake of political victory. They are prepared for self-sacrifice (Halprin, 1998). But an untarnished hero is hard to find. Mother Teresa disclosed that she mistreated subordinates and took money from dictators. President Kennedy plotted to kill Fidel Castro and cavorted with call girls in the White House (Gibbon, 1997).

Ethical issues in communities and organizations increased greatly as a consequence of the increasing complexity and sensitivity of our society and the vast expansion of the mass media. It was difficult for enforceable laws to keep up with the ethical requirements of business and technological advances, property ownership, and political and military developments in the twentieth century. Unfair discrimination against minorities came to be treated as a violation of human and legal rights. Influence peddling became government-regulated lobbying. Many new governmental environmental constraints were imposed. Collective bargaining was legalized, and workers became stakeholders in corporations rather than just a means of production (Steidlmeier, 1989). The military was forced to reexamine its ethical guidelines, prompted by its warfighting emphasis in the last decade on precision engagement and protection of forces. How much collateral damage to civilians could be tolerated? The requirements for protecting forces have resulted in a dys-functional aversion to

casualties and eroded a core value: the possible need for self-sacrifice (Shaping American Military Culture in the Twenty-First Century, 2000). The U.S. military response to terrorism and insurgency in the Middle East has resulted in unethical mistreatment of detainees and killing of innocent civilians.

Questions have always been raised about what is right and good or wrong and bad in work, trade, and political, social, and family life. These issues have accompanied the rise of humankind. Moral codes in primitive cultures accompanied the rise of civilization. The questions have been addressed in writing for more than 2,500 years by philosophers such as Plato in the West and Confucius in the East. However, only in the past several decades have they become a study in the behavioral sciences following commentaries on organizational life and moral concerns formulated much earlier in philosophy, sociology, political science, and social psychology.

### ***Character Education***

Ciulla (1996) suggested that to teach leaders to be ethical, you have to develop their moral imagination, critical thinking skills, and emotional strength to act on what is morally right. Secular and religious schools consider, in their curricula, honesty, democracy, acceptance of others from different races and of different ethnicity, caring for friends and group members, patriotism, moral courage, and the Golden Rule. Religious schools add spirituality, providence, and faith. Character education with a range of virtues has been introduced. Anecdotal reports of positive effects such as reduced conflict, reduced expulsions, and more orderly classrooms have appeared in places as disparate as Tyler, Texas and New York City. Liberals and conservatives seem able to agree about what values to focus on (Sharpe, 1994).

Moral authority ... and the idea of ... ethical leadership emerged as ... important themes in the secular educational leadership literature in the 1990s ... [Included were] moral reasoning ... and how a humanistic, person-centered articulation and embodiment of moral value provides the type of role model that inspires teachers and students. (Bess & Goldman, 2001, p. 432)

### ***Character Traits***

Character is the complex of moral, social, and religious traits. It is what we actually are, in contrast to our personality—what we appear to be (Corsini, 1999). Leadership is an expression of who we are, not just something we do. Therefore much of it must develop from the inside out through both conscious and subconscious beliefs. Leaders guided by their internal character rather than their external personality are more open to opportunities for learning, more meaningful purposes, adaptability, and maintenance of balance (Cashman, 1998). Thompson (2000) agrees that inner spirit is more important than outer strivings in the development of leaders. Posner (2002) has suggested that leaders need to go within to find “what grabs hold of them and won’t let go. ... Just what is it that I really care about?” (p. 3). “Authentic leadership comes from inside out” (p. 6).

Character integrates leaders’ morals and ethical behavior with their personalities. It is grounded in core values, such as integrity, trust, truth, and human dignity, that shape the leaders’ vision, ethics, moral literacy, and excellence. It empowers mentorship (Sankar, 2003). Its moral rectitude strengthens the position of political leaders who depend on public opinion (Mitchell, 1993). In the U.S. Army, doctrine gives primacy to the character of leaders and soldiers and their ethical behavior. Honor, courage, and commitment at the heart of the character expected in members of the U.S. Marine Corps (Lynch, 1995). Gal (1989) stressed the need for Israeli combat leaders to have strong moral commitment and conviction. Commitment to the profession rather than to one’s career should motivate the officer corps. Commitment rather than obedience should

motivate compliance.

*Good and Bad Character Traits.* A leader with good character will have internalized the Platonic virtues of prudence, justice, temperance, and courage, as well as honesty, compassion, keeping promises, and dedication to the common good. A leader of bad character is motivated by vices such as greed, cruelty, indifference, and cowardice. Acts of leadership may be good or bad. *Deontics* relates to the effects of these actions, particularly on the well-being of others. The moral point of view of leaders depends on whether these effects benefit or harm the interests, rights, or duties of the affected parties. *Interests* may be self-interests, group interests, and interest in the greatest good. *Rights* may have to do with fair distribution and basic liberties. *Duties* may include fidelity to relations with others and the community (Goodpaster, No. 7). Ethical executives run firms with applied codes of ethics, have clear channels upward for whistle-blowers, reward integrity, and give the same training in ethics to executives, managers, and employees. All ought to know what to do, for example, if offered a bribe (Stern, 2002). George Washington was transformed from a military hero to the new republic's moral symbol as he refused, repeatedly, the powers and privileges of a king or dictator. His virtues were seen by the public as making him incorruptable (Schwartz, 1983).

*Importance of Culture.* Cultures clearly differ in what are seen as important traits of character. Whereas 79 American CEOs revealed more intuitive personalities, 87 Taiwanese CEOs were more reliant on sensing. The Americans valued honesty, self-esteem, and happiness more than the Taiwanese did; the Taiwanese attached more value to cheerfulness, competence, a comfortable life, a world of peace, and social recognition. The Americans were more spiritual than the Taiwanese. The Americans placed more of a premium on moral values and individualism; the Taiwanese on aesthetic values and collectivism (Judge, 2001). The many parallels in Chinese and Jewish cultural tradition, such as family-centeredness, valuing of education, rootedness in history, and survival despite continued hardships, are also seen in the character of the Chinese and Jewish ideal leaders: the Chinese *junzi* and the Jewish *zaddik*. Both were meritorious, elite, moral men. Their nobility was due to their character, not their birth. Nietzsche (1886) saw ethical concerns as an affliction of the weak character; but to support a moral position or to take an ethical stance in the face of an immoral climate, to be a whistle-blower, requires strength of character (see Singer, 1996). (The impact of culture on character traits will be greatly expanded in [Chapter 32](#).)

### ***Virtuous Traits, States, and Acts of Ethical Leadership***

The Golden Rule is found in all the world's major religions and many of its minor ones. In Buddhism it appears as "Hurt not others in ways that you yourself would find hurtful;" in Brahmanism, "Do naught unto others which would cause you pain if done to you;" in Judaism, "What is hateful to you, do not to your fellowman;" in Christianity, "Whatsoever ye would that men should do to you, do ye even so to them;" in Islam, "A believer desires for his brother that which he desires for himself;" in Zoroastrianism, "Refrain from doing to another whatsoever is not good for (one) self;" in Confucianism, "Do not unto others that you would not have them do unto you;" and in pagan Wicca, "An it harm none, do as ye will" (Morgana's Observatory, 1997).

*Virtues* are positive character traits that are helpful to others in intention, such as fairness and integrity. The virtuous person recognizes and does the right thing. Among Aristotle's four virtues—prudence, justice, fortitude, and temperance—prudence is recognizing and making the right choice in specific contexts; fortitude is the courage to pursue the right path despite its risks; justice is fairness; and temperance is self-discipline and moderation of emotions and indulgences. "A person of good character ... is someone who through repeated good acts achieves an appropriate balance of ... virtues in his life" (Woodward, 1994, p. 39). Virtues cannot be

instrumental. A virtue in search of a reward is not authentic (Cameron & Caza, 2002). Peterson and Seligman (2004) enumerated and described six virtues: (1) *Wisdom*—creativity, curiosity, open-mindedness; (2) *Courage*—bravery, persistence, integrity; (3) *Humanity*—love, kindness, social intelligence; (4) *Justice*—citizenship, fairness, leadership; (5) *Temperance*—forgiveness, humility, prudence; (6) *Transcendence*—gratitude, hope, humor. Socialized traits of leadership tend to be virtues; personalized traits of leadership tend to be vices. *Vices* are negative traits of character, such as lying and abusiveness, that are hurtful to others. (They will be discussed later as the dark side of leadership.) Moral values are virtues; immoral values are vices. The expression may be states, contingent on circumstances, or traits—that is, individual predilections.

O'Toole (1995) found the virtues of trust, integrity, listening, and respect for followers in the four American presidents (Washington, Jefferson, Lincoln, and Theodore Roosevelt) whose faces were carved on Mount Rushmore. Four CEOs—Max De Pree of Herman Miller, James Houghton of Corning Glass, Robert Galvin of Motorola, and Jan Carson of SAS—were identified as “Rushmoreans” with the same virtues as the four presidents. Rushmoreans are able to lead change. They overcome the “ideology of comfort and the tyranny of custom.” Bennett’s *Book of Virtues* (1994) listed self-discipline, compassion, responsibility, friendship, work, courage, perseverance, honesty, loyalty, and faith. According to Bennett, Americans care about character as expressed in ideals of behavior. We need to educate youth in the importance of good character. Yet such a program of nostalgic moralism can turn into political fascism (Morrow, 1994). Integrity and selflessness are usually seen as prime virtues of leaders (Augustine, 1997). Kets de Vries (1995, p. 199) suggested that clinical observation was needed to unravel the knotty questions about the character of top executives. Their observed character traits needed to be understood as consequences of their thoughts and emotions: “Our internal theatre, in which the patterns that underlie our character come into play, influences our behavior throughout our lives and builds an essential role in molding of leaders.” Kets de Vries mentioned Henry Ford’s close relationship with his mother, who loved him unconditionally but died when Ford was 13. This experience was coupled with a difficult relationship with his father, whom Ford perceived as disapproving his career plans. These might be clues to why Ford was unable to retain executives and old friends. It might account for why he famously stuck to the model T for 19 years and “any color paint for the model as long as it was black” despite a big loss of market to competitors who produced more modernized cars in a variety of colors.

## ***Integrity***

The virtue of integrity is at the core of character and ethical leadership. Integrity was mentioned as important to leadership by almost all of 45 British chief executives (Cox & Cooper, 1989). Decrane (1996) declared that integrity of character is overriding for a leader in any field. Integrity is not synonymous with a wide range of virtues such as conscientiousness and honesty, but it is highly correlated with them. It is predicted with a multiple correlation of .20 by the “Big Five” traits: extroversion and agreeableness (Martinsen, 2001). Coherence of values, aims, and behaviors demonstrates a leader’s integrity (Bloskie, 1995). It is the virtue of leaders who do what they say they will do, who keep promises, admit their mistakes, and follow through on their commitments. Such leaders are almost universally esteemed and admired, according to a survey of over 15,000 respondents reported by Kouzes and Posner (1992). Integrity determines the credibility and trustworthiness of the leader. This leader behavior, consistent with the leader’s espoused values, reflects the leader’s integrity (Yukl, 1998). For Ayn Rand objectivists, integrity is loyalty to rational principles. It is practicing what one preaches regardless of emotional or social pressure. Irrational considerations are not allowed to overwhelm rational convictions. The values involved are morally justifiable (Becker, 1998). For Rand, egoism—pursuing one’s own actual best interests—is good in that it is in one’s best interests to be rational, to

be realistic, to aim for being productive, to not sacrifice one's own convictions to the wishes of others, and to never seek what is unearned and undeserved. Along with Edwin A. Locke and Jaana Woiceshyn—disciples of the philosophy of Ayn Rand (1959)—many economists argue that the pursuit of one's self-interest in an open, free market achieves the greatest good for society. Nevertheless, in an experiment in which students were each given tokens that they could exchange personally for money or share with a group to exchange, 40% to 60% chose to share. The exceptions were graduate students in economics. They rejected sharing (Rhoad, 1985).

Leaders with the virtue of integrity are truthful rather than deceptive. They avoid making exaggerated claims. They are loyal and supportive of their deserving followers. They keep confidences about sensitive information. They set an example of what they expect from their followers and take responsibility for their own actions. In negotiations, leaders with a reputation for integrity can be trusted to keep agreements. They are trusted by their followers not to be exploitative or manipulative. They are perceived as dependable (Yukl, 1998). When McCall and Lombardo (1983) compared successful and “de-railed” managers, they found that the successful managers were stronger in integrity. They were more attentive to their tasks and their subordinates. The derailed managers were less dependable and more concerned with impressing superiors or competing with rivals. They were seen as too ambitious and too ready to get ahead at the expense of others. They were more likely to break promises.

*Measurement of Integrity.* Craig and Gustafson (1998) developed the Perceived Leader Integrity Scale (PLIS) that includes several factors of integrity shown by a supervisor's lack of morals and ethics. They winnowed down 100 items originally gathered from undergraduates to 31 based on 299 university employees. Typical items that emerged as indicating a lack of integrity included “Would take credit for my ideas,” “Would steal from the organization,” and “Deliberately fuels conflict among employees.” As a validation of PLIS, Parry and Proctor-Thompson (2002) found that among 6,025 managers throughout New Zealand, PLIS accounted for as much as 35% of the variance of the MLQ transformational leadership factors. The PLIS correlated .49 with satisfaction with leadership and .47 with the motivation of the followers. Brown and Figufe (2001) took a broader approach and included in the assessment both ethical and unethical aspects of leadership, such as various virtues and vices of character, decision making, uses of the reward system, and management symbolism. The survey was administered to 585 supervisors and their direct reports in a division of a large financial services organization. Four factors emerged: (1) Ethical interaction and decision making—“Fair and objective when making decisions”; (2) Ethical symbolic management—“Talks to employees about work-related ethical conduct”; (3) Unethical financial focus—“Is driven above all else by financial considerations”; (4) Unethical lack of integrity—“Acts unethically at work.” Same-source errors were avoided in correlating the factors with leader personality and personnel data. Quite a few statistically significant relationships were obtained. The supervisors' assessed “Big Five” agreeableness predicted their direct reports' appraisals of ethical factors. Lack of agreeableness predicted unethical financial focus. Older supervisors were higher in ethical symbolic management and lower in both unethical factors. Ethical role models contributed to ethical symbolic management, and number of direct reports contributed to unethical lack of integrity.

Den Hartog (1997) found a positive integrity factor in role modeling containing such behavior as meeting obligations, setting a good example, being reliable, and doing what one says. A negative integrity factor included acting without considering others' feelings, holding others responsible for things that were not their fault, and behavior not consistent with expressed values. Den Hartog found that perceived integrity correlated more highly with trust in management than inspirational factors did.

To help manage legal compliance, Trevino, Weaver, Toffler, et al. (1999) created a six-item scale to be completed by employees. This scale assessed integrity indirectly by asking the employees how much their supervisor cared about ethical behavior. Another indirect measurement of integrity was the Self-Reported Inappropriate Negotiation Strategies Scale (SINS). It listed 30 deceptive negotiation tactics, according to MBA students. Three of five factors that emerged were: (1) misrepresentation or lying, (2) deliberate misuse of

information, and (3) false promises. Consistent with the tendency of women to be somewhat more transformational, women were more likely to avoid using these tactics. Self-rated competitive persons were more likely to use them (Robinson, Lewicki, & Donahue, 2000). The problem with direct measures of integrity is that the percentage of false positives is very high (Ronald & Zacharias, 2003). The direct tests are highly susceptible to faking and coaching, according to a research review by Alliger and Dwight (2000).

## ***Authenticity***

Authentic leaders are true to themselves and to others. Leaders may deceive others by not being true to themselves; they ignore Polonius's admonition to Laertes in Shakespeare's *Hamlet*, "This above all: to thine own self be true, and it must follow, as the night the day, thou canst not then be false to any man" (Clemens & Mayer, 1977). Herb Kelleher, the highly rated CEO of Southwest Airlines, declared that he didn't have a leadership style except being himself. Ruth Rothstein, chief of the Cook County Bureau of Health Services in Chicago, described herself as very honest about herself; she never forgot that she had risen from being an organizer for the United Packing house union and a laboratory technician at Jackson Park Hospital in 1940 to head an agency with 12,000 employees and an annual budget of \$650,000. She declared, "I don't delude myself. ... I am willing to face up to [my weaknesses]. ... I put a lot of emphasis on being truthful. If I say it, that is what I mean to do. ... You don't have to love me, but you have to trust me. ... I think you build trust by being authentic" (Heuerman & Olson, 1999).

Authentic leaders are trusted. They do what they say they will do. They look at themselves honestly. They tell the truth. They have core values that are translated into actions congruent with their identity (Heuerman & Olson, 1998). Authentic transformational leaders align their interests with those of others and may sacrifice their own interests for the common good. Their communications can be trusted. They articulate their followers' real needs and envision an attainable future. They sound the alarm when real threats arise. They set examples to uplift the moral values of their followers. They are concerned for their followers' development and well-being.

*Measurement of Authenticity.* Henderson and Hoy (1982) defined *authenticity* as the extent to which a leader was viewed by others as exhibiting a salience of self over role. That is, the authentic leader did not rely on the narrow prescriptions of the role to justify personal actions. The authentic leader did not manipulate followers or treat them as objects. Such a leader accepted responsibility for her or his own personal and organizational actions. This description of authentic leadership was confirmed empirically for 42 elementary school principals, using a 32-item survey instrument (Henderson & Hoy, 1982). That instrument was subsequently refined by Henderson and Brookhart (1996) for more general use as the Organizational Leader Authenticity Scale (OLAS), with a form for a leader's staff (SAS). A typical positively scored item was, "My supervisor accepts and learns from mistakes." A typical negatively scored item was, "My supervisor seems to talk at you and not with you." Data were collected from 63 educational leaders and their 835 staff members for OLAS and SAS along with other measures. According to path analyses, leader authenticity had a sizable impact on staff members authenticity ( $r = .47$ ). The authenticity of both leader and staff contributed to organizational health and a positive organizational climate. Additionally, leader authenticity correlated .83 with the leader's supportive but not directive behavior (.04), initiation (.61), consideration (.81) and influence (.54).

## ***Justice and Fairness***

A virtue of leadership is being just and fair. Some leaders are more just and fair than others; this may be a

consequence of the individual leader's character as well as conditional on circumstances. Being just and fair may be a matter of how the leader distributes reward and punishments, how others are treated and informed, and which procedures are used and when. Sometimes it is a matter of time. What may be ethical and fair in the short run may be unethical and unfair in the long run. Sufficient time is often needed to test whether a pharmaceutical drug is beneficial or harmful. Taking the drug DES reduced morning sickness in pregnant women but caused birth defects (Messick & Bazerman, 1996).

Figure 9.1 A Model of the Effects of Leader and Staff Authenticity on Organizational Health and Organizational Climate

NOTE: All relationships are significant to the .01 level. N = 63.

SOURCE: Henderson and Brookhart, 1996, p. 97.

*Forms of Justice.* *Distributive* justice is the fairness with which rewards and resources are distributed to members of a group or organization, consistent with their contributions, in comparison with others, or both. Even with the best of intentions, according to interviews with senior executives of an online division of a large parent firm, during the first 22 months it was difficult to maintain distributive justice in the new division because of complexity, ambiguities, and required speed (Brown & Gioia, 2002). Rawls (1985) examined the limits to fairness and the impossibility of completely eliminating disadvantageousness. There is inherent unfairness in the differences among us at birth: in our brains, beauty, inherited health and wealth, and the way we are parented. Society needs to provide equal opportunities within these constraints.

Justice comes in several forms of procedures or processes. *Procedural* justice follows along with other forms such as *interactional* justice (fairness of treatment) and *informational* justice (fairness of disseminated information). Procedural justice depends on high-quality information, well-informed opinions, consistency across different groups of employees, suppression of personal bias, and consideration of moral standards (Thibaut & Walker, 1975). Interactional justice involves the informational and interpersonal approaches to implementation that depend on the adequacy and timeliness of information about the procedures, and sensitivity to the quality of interpersonal relations (Konovsky & Folger, 1991). The various forms of justice tend to intercorrelate above .50 and are collectively referred to as *organizational* justice (Bell, 2001). Judgment of the fairness of the distribution of resources depends, in particular, on whether the procedures used to make the distribution are seen as just (Lind & Tyler, 1988). However, Turillo, Folger, Lavelle, and Umphress (2002) suggested that many leaders suffer from a *distributive bias*. They overestimate how much employees care about distributive outcomes and underestimate how much employees are concerned for procedural and interactional justice.

*Distributive Justice.* Although Rawls (1967) agreed that rewards and resources should be distributed for the “greatest good for the greatest number,” he proposed that this required a fair distribution that can meet the expectations of the most privileged to the least privileged—from the wealthy entrepreneur to the poor

unskilled worker. The social system affects their life prospects differently from before birth and according to their different natural attributes. But the system must allow liberty of the person, freedom of thought, and political equality. The differences in distribution are just if the greater expectations of the most advantaged, who play a role in the social system, improve the expectations of the least advantaged (Ciulla, 1998, 2004).

In international joint ventures in developing countries, local employees find it unfair that foreign expatriates are compensated more highly. However, Chen, Choi, and Chi (2002) found that Chinese locals' sense of unfairness was decreased if they were paid more than Chinese locals in other joint ventures, if they accepted the rationale for the discrepancy, and if the expatriates were more interpersonally sensitive toward the locals. As is usually the case, perceived distributive justice increased with satisfaction with compensation and with decreased intentions to quit.

Leventhal (1980) suggested six rules for just and fair processes: (1) Be consistent among people and across time; (2) Suppress the self-interests of authorities; (3) Use accurate information; (4) Maintain opportunities to make corrections; (5) Consider representative concerns; and (6) Maintain compatibility with social and moral values. Leaders can influence whether fair and just outcomes are achieved. They can determine who will be included in decision making. They can set the agenda. They can prioritize deliberations (Hoyt & Garrison, 1997). Leaders may also be able to convince others that they are fair in their procedures and distribution of information, when in fact they may not be (Greenberg, 1990).

Bell (2001) asked MBAs from one business school, in an e-mail survey, if they had ever received a performance evaluation "that was not as positive as they hoped or expected." Of 1,051 respondents, 130 had received such an appraisal. They completed the Colquitt Organizational Justice Scale (2000) to measure their perception of procedural, distributive, interpersonal, and informational justice as members of an organization. Procedural justice correlated highest with distributive justice (.69). Interpersonal justice correlated highest with informational justice (.71). The lowest correlation among the four types of justice was .47. One hundred ten participants also completed a retrospective "shame and guilt" scale adapted from Marschall and Tangney (1994). They answered questions about their loss of self-efficacy, the meaning of the organization to them personally, and their affective commitment to the organization. Regression analyses indicated that a perception of the organization as just and fair in all four types of justice *reduced* the participants' shame, guilt, loss of self-efficacy, and loss of identification with the organization.

These findings were consistent with other research showing that if a recipient considers negative feedback just and fair, the feedback is more likely to be accepted and less likely to have deleterious effects on the recipient (Lind & Tyler, 1988). In considering settling disputes with management, 301 employees of a large firm believed that among arrangements not requiring intervention by a law court, voluntary mediation provided the most justice and fairness, compared with mandatory mediation and binding arbitration (Richey, Garbi, & Bernardin, 2002). In one study, 143 employees who had a strong "exchange ideology" of fairness and justice, according to their supervisor, exhibited less affective commitment when they viewed their work environment as unfair. No such tendency was found in employees who were indifferent to a fair exchange (Witt, Kacmar, & Andrews, 2001).

Equity theory predicts a sense of being treated unfairly when we see others whom we consider similar to ourselves in effort, performance, status, experience, etc., being treated beneficially while we are not treated in the same way (Thibaut & Kelley, 1959; Mowday, 1987). Highly correlated measures of procedural, interactional, and distributive justice were rated by 265 students holding full-time jobs (31%) of part-time jobs (69%). Fairness was seen when leaders were judged to form higher-quality leader-member exchanges (LMXs) with employees who contributed more to their work group, and lower-quality LMXs with employees who seemed to have contributed less to the work group. In controlling for LMX quality satisfaction with supervision was higher if greater justice was perceived. At the same time, those employees higher in performance and organizational citizenship behavior were more negatively affected if they felt that the leaders

were unfair in their differentiation (Erdogan, 2002).

Tyler (1984) found that perceived procedural justice depended on how much control employees had in presenting information to their supervisor on their trust in the supervisor, and on the supervisor's respect for them. When procedural justice was perceived, high-quality LMXs were not as important in contributing to performance, commitment, or citizenship behavior (Sanchez, Bauer, & Trujillo, 2002). Nevertheless, Scandura and Tejada (2003) reported that for 275 supervisor-subordinate dyads, job performance was better when LMX was of high quality and employees perceived that appraisals of their performance were fair. Bazerman, White, and Lowenstein (1995) concluded from a review of research that judgments of distributive justice are "remarkably nuanced, responding to a wide range of ... situational and individual ... factors." At the same time, "there are pervasive biases" in the way that fairness is judged, and "inconsistencies in the importance" placed "on fairness in different contexts" (p. 39).

*Interactional and Informational Justice.* Gratton and Zaleska (2002) analyzed over 300 semistructured interviews with employees to examine the roles played by line managers and human resources (HR) professionals in the enactment of justice. The context was eight large organizations in the United Kingdom, ranging from pharmaceutical and telecommunications firms to a hospital and a postal service. Interaction injustice was most frequently mentioned by interviewees—specifically, a lack of dissemination of information about promotions, rewards, and development:

The greatest outrage [occurred] when employees felt that satisfactory explanations were not provided by the HR (Human Relations) function, and they were not given feedback about procedures, particularly [about] pay and reward decisions. ... They blamed HR if they perceived the ... procedures to be mute and secretive." (p. 11)

HR was expected to design and develop equitable processes. Line managers were expected to tailor policies to meet individual needs and suppress their own biases. When implementing policies, HR was expected to provide opportunities for employees to voice their opinions. Insensitive treatment from a line manager, rather than a sense that procedures were unfair, generated feelings of unfairness. The style of the line manager as well as the HR professional was important in determining whether justice or injustice was perceived. "A skilled HR professional or line manager with clear people-centered values and behaviors could have a positive effect on [employees'] perception of justice" (p. 16).

## ***Altruism***

There are leadership styles, such as servant leadership, that call for extreme altruism. Many other leadership styles also stress the importance of helping others or sacrificing for others (Kanungo & Conger, 1993). Altruism is the virtue of selflessness, reducing personal benefit for the sake of others (Margolis, 1982). But it is not usually associated with the world of business and utilitarian organizations. Supposedly, "the path to profits is not paved with caring concern but with Darwinian cleverness" (p. 37). Nevertheless—just as in our private lives when we devote time, energy, and money to charitable and public causes—altruism has a place in the management of our organizations. Even though a corporation is competing in the marketplace, the complexity of the market calls for more interdependence, attention to cooperation as well as competition, and consideration of all the corporation's stakeholders. Altruism may be utilitarian in the expectation of reciprocity for good deeds; it may be an act of impression management; and/or it may be genuine and morally right. Also, altruism has been found to correlate with self-esteem, perceived competence, internal locus of control, and decreased alienation (Caza, 2002). Altruism is the first factor in one widely used measurement, Organizational Citizenship Behavior (OCB; C. A. Smith, 1983).

In 1993, the Academy of Management Executives surveyed a panel of 40 executives, 24 human resource executives on a conference board council, and peers in their own firms on the question “In the past 20 years, do you think acts of corporate altruism have increased, decreased, or stayed the same?” Of the total, 52.5% said altruistic acts had increased, 31.7% said they had stayed the same, and 15.8% said they had decreased. Three corporate practices were seen by the vast majority (80% to 90%) as *utilitarian* ethics that benefit the company: (1) empowering management practices; (2) company-wide emphasis on cooperation; and (3) attention to work and family needs of employees through family-friendly policies. A majority noted three genuinely ethical practices that were the right thing to do and for which the company expected no payback (Anonymous, 1993, p. 90): (1) a strong commitment to the disadvantaged in the community (64%); (2) recognizing people in the company and demonstrating concern and support for others (60%); and (3) having a well-understood and practiced set of corporate ethics (51%).

Martin-Marietta, now part of Lockheed-Martin, provided telephone and mail addresses of its ethics office, whose director reported directly to the president, the chairman of the five-member ethics committee. Its code of ethics gave examples of conflicts of interest, such as acceptance of gifts from those seeking to do business with the firm, placing business in a firm owned or controlled by an employee or employee’s family, and acting as a consultant for a customer or supplier. Offering, giving, or soliciting bribes or kickbacks were forbidden. Financial statements, books, and records had to reflect accurately all transactions of the corporation. As a major government contractor, the corporation had to be especially sensitive to control of costs and had to follow rigorous procurement standards. It was every employee’s duty to preserve the corporation’s plants and equipment. In compliance with the Securities and Exchange Commission, antitrust regulations, and political campaign finance laws, the following were not permitted: “insider trading” of securities, restriction of trade that is harmful to consumers, and unapproved corporate political contributions. Disciplinary action would be taken against employees who participated in or authorized violations of the code, or who had deliberately failed to report a violation. Action would be taken against the violator’s managerial superiors if the violation reflected their lack of diligence or supervision or if they retaliated against the employee who reported the violation.

*Should Leaders Be Altruistic?* In letters between E. A. Locke and B. J. Avolio, Locke, a disciple of the libertarian philosopher and novelist Ayn Rand (1964), argued that leaders should think and act in a rational way, with self-interest rather than altruism as the basis of action. By accomplishing their own interests, they will display their highest principles and achieve their highest performance. Implicit in the virtue of rationality are honesty that refuses to fake reality, integrity based on loyalty to one’s rational judgments, independence in using one’s own rational judgment to sustain one’s own life, taking responsibility to be productive, judging others by a rational standard, and taking pride in being a self-made soul and seeking moral perfection. Leaders ought to listen to others but make their key decisions themselves. They ought not to pursue careers out of duty or obligation. They ought to seek to hire the best possible people and follow their best judgment as rationality dictates. Because it is the rational thing to do, they ought to treat clients and employees fairly; and they should not feel guilty if they succeed in becoming wealthy. Avolio countered that in many situations, competing interests could not be satisfied. The most effective leaders are those who transcend their own interests for the good of their group, organization, or society. Soldiers are called upon for self-sacrifice. Rationality itself may often be in the eye of the beholder (Avolio & Locke, 2002).

### ***Other Virtues and Character Traits***

The American Association of Medical Colleges called for medical students to be knowledgeable, skillful, and

dutiful as well as altruistic. The order of importance is debatable, since most patients would prefer a “cold but smart doctor [to] a warm, dumb one” (Robinson, 2002). Other virtues of leadership include conscientiousness, wisdom, courage, dutifulness, compassion, and trustworthiness. The virtue of benevolence is also important to leadership. When the leader is benevolent, followers will display good organizational citizen behavior (Skarlicki & Dirks, 2002).

*Conscientiousness.* Conscientiousness tends to predict better job performance and good organizational citizens behavior. It correlates with fewer acts of delinquency such as stealing in work settings (Barrick, Mount, & Strauss, 1991). It also combines with supportive leadership to promote safe behavior at work (Griffin, Neal, & Burley, 2000). Although ability was expected to moderate the effects of conscientiousness on job performance, that was not found in three large samples of managers (Mount, Barrick, & Strauss, 1999). However, conscientiousness may be expected to impede performance when speed is more important than thoroughness, when rapid decisions are required but information is limited, and when rules stifle creativity (Collins, 1998). Sometimes conscientiousness may fail to predict effective management performance (Robertson, Baron, Gibbons, et al., 2000). According to an examination by Moon (2001) of 360 decisions, when conscientiousness was associated with personal striving for achievement, commitment to making effective decisions escalated. But when conscientiousness was associated with an other-centered orientation, commitment de-escalated. Among the middle managers in 131 Fortune large global firms, conscientiousness mapped most distant from “entrepreneurial” as a desired trait—especially in the pharmaceutical industry as compared with the food industry (Chun, 2003). Conscientiousness and moral development begin early in life with bonding, cooperation, affection, and happy interactions. Parental influence and values are embraced (Kochanska, 2002).

*Wisdom.* This virtue allows the leader to activate bodies of factual and strategic knowledge simultaneously to address practical and uncertain aspects of life. It promotes understanding of what is true and right and guides effective rational and moral judgment. Requiring practical wisdom of the moral leader is consistent with Aristotle’s virtuousness and Kant’s moral leader as an autonomous individual (Jeannot, 1989; Baltes, 1999).

*Courage.* Courage is a mix of instant or longer emotional and cognitive states related to taking action in the face of vulnerability, risks, dangers, potential losses, and consequences to oneself. Courage and bravery occur as exceptional events outside the bounds of norms, routines, and expectations about how people should act in a specific context (Worline, 2002). Leaders or followers face uncertainties and dangers for the good of the group or organization in an exceptional event of potential danger to the collectivity. For Gal (1984), moral courage is the essence of leadership. In addition to remaining ethical, U.S. presidents need moral courageousness.

*Compassion.* Compassion is a central virtue in many religions. If authentic, it reflects a genuine empathic concern for others’ pain (Batson, 1991). It is a virtue of benefit to individuals, organizations, and society (Wuthnow, 1991). It may involve an active regard for the other person’s good aimed at alleviating the other’s pain (Blum, 1980). It played a role in the politics of presidents Bill Clinton (“I feel your pain”) and George W. Bush (“compassionate conservatism”). In the workplace, it can increase feelings of well-being and resilience and enhance productivity (Dutton, Frost, Worline, et al., 2000). Compassion and self-sacrifice were shown by Abraham Feuerman, owner of Malden Mills, whose mill burned down. Instead of laying off the workforce while rebuilding the mill, he continued to pay the workers their wages while the mill was being rebuilt. Unfortunately, however, because of overseas competition he was unable to repay the loans needed to continue.

*Dutifulness.* A *sense of duty* is a virtue expected of professionals. They need to avoid being self-serving.

To the best of their ability, they ought to apply the principles of their profession. For instance, certified public accountants (CPAs) are accountable when auditing their clients' financial statements. The statements presented to the public need to be transparent and true (Piaker, 2002). In times of crisis, self-sacrificial leaders are looked at most favorably, according to a controlled experiment by Halverson, Holladay, Kazama, et al. (2004) involving 203 undergraduates. Israeli Colonel Eli Geva was self-sacrificial when he ended his military career in 1982 by refusing an order from his superior to move his troops into Beirut because he had grave reservations about the role of the Israeli military in Lebanon (Avolio, 1999).

*Forgiveness.* This is a virtue that abandons justified resentment, bitterness, and blame in response to harm or damage (Enright, Freedman, & Rique, 1998). The injustices, pain, and suffering inflicted on the nonwhite population of South Africa were met by Nelson Mandela, who spent 27 years in prison, with a plea for forgiveness and reconciliation. Desmond Tutu led the Truth and Reconciliation Commission to provide forgiveness from the testifying victims and amnesty for perpetrators of offenses including rape, torture, and murder during apartheid. To obtain forgiveness, the perpetrators had to confess voluntarily and in public. The wrongdoing had to be acknowledged. The offenses were due to political, government, or police policies. Civil war was averted (Cameron & Caza, 2002). Followers who forgive a leader's threats and punitive behavior are generally more agreeable and emotionally stable in personality. If they are more spiritual and religious, they believe that they are more forgiving. If they are more forgiving, they like and empathize more with the leader and do not ruminate about the leader's actions (McCullough, 2001). Forgivers are physically ill less often and recover faster from illness. They feel more empowerment, hope, and self-esteem (McCullough, 2000).

## Vices of Leadership

---

British treasury officials displayed inhumane vice when they explained as "natural causes" the reason for the starvation of the Irish peasantry during the potato famines of 1845 to 1849. Sir Charles Trevelyan, in charge of organizing relief, promulgated the following principles:

1. Starving men given government handouts would grow to depend on them rather than working for their bread. Therefore, food was to be provided only in county workhouses. (Useless work projects were set up for men too weak to work.)
2. Government intervention to lower the price of wheat and corn would injure traders and merchants.
3. When rent was not paid, the only remaining option for the tenant was emigration or dying. (The tenant's cottage was often burned.)

The population was reduced from 8 million to 3 million. Benjamin Jowett heard a political economist say that he feared the famine of 1848 would not kill more than a million people, and that this would scarcely do enough to do much good. Although not as extreme, such reactions can be found today in leaders and managers who justify unethical managerial behavior. A survey of 3,450 managers in three industries from 28 countries disclosed that managers were more inclined to justify vices in some countries than in others. Counter to some of the hypotheses of the investigators, Parboteah and Cullen (2002), those living in socialist countries—higher in religiosity, higher in social inequality, higher in access to education, but lower in industrialization—were more likely to justify unethical behavior such as buying stolen goods, cheating on taxes, lying in self-interest, and accepting bribes in the course of one's duties. Men were more likely than women, and younger employees were more likely than older employees, to justify unethical behavior.

*Deceiving, Lying, and Cheating.* These are common vices, seen in many of the traits and behaviors mentioned here. An exemplar of the vices of leadership was Sam Goldwyn, a founding father of the

Hollywood movie industry. He was hard, ruthless, and arrogant. He was a chronic liar and compulsively rude. He cheated when he could. He quarreled continually with his partners. He was deceptive. People never knew how they stood with him. He had a dismal view of ethics in business (Berg, 1989). Like Goldwyn, many leaders have states and traits that may bring harm to their associates. They may be corrupt as well as incompetent (Kellerman, 2004). They may use their power and position to be abusive and unjust. They may hoard privileges, betray loyalties, or neglect responsibilities (C. E. Johnson, 2001). They are particularly insidious when they appear beneficial but are actually harmful. They lack authenticity and sincerity. Often they are hypocritical. There are those who may benefit some at the expense of others. Frank Lorenzo boldly persuaded financiers to provide the money for takeovers of businesses, like Eastern Airlines, that were in trouble. "By behaving with startling audacity at the edge of legality or beyond—violating past practice, lying, and employing hitherto unused legal devices, such as bankruptcy, to achieve his goals" (p. 251), he aroused hatred and fear in employees and managers at the companies he threatened, bankrupted, and stripped (Turner, 1993). For many politicians, selfish, personal private aggrandizement has been coupled with aggressive public preaching of altruism and social responsibility. Such has been the case with numerous dictators. Womanizing has been common among powerful reform politicians including Kemel Atatürk, Fidel Castro, John F. Kennedy, and Bill Clinton.

*Moral identity* of a negotiator appears to affect how much lying will occur. Aquino, Ray, and Reed (2003) engaged 224 students in simulated negotiations in a counterbalanced experiment. One student negotiator, who had access to privileged information (while the other negotiator did not), lied about it unless moral identity was important to the negotiator and lying was not rewarded.

Followers may also exhibit behaviors intended to harm their leaders and organizations. For instance, Skarlicki, Barclay, Patent, et al. (2002) showed that when laid off, untrustworthy employees (despite management efforts to explain the reasons) retaliated by such actions as destroying important documents and also considered getting even in other ways.

*Self-Serving.* When they can, self-serving leaders disregard the rights, values, and feelings of others. They reinterpret moral principles for their own benefit. They rely heavily on manipulation. They are unlikely to inhibit their use of power. They detach themselves from how they are perceived by their followers. They act in whatever ways will benefit themselves the most, ignoring the expense to others. Muttayya (1977) found that self-orientation in Indian leaders was associated with less commitment to principled public conduct. Fox (2000) has held that American political culture is dominated by self-serving, expediency, indifference, and opportunism. He questions how much progress we have made toward responsible government. Mitchell and Scott (1990) agreed that corruption, scandals, abuses of public and private trust, and the endemic lack of moral leadership are supported by an ethic of personal advantage and the value of short-run individualism. But a certain amount of this may be necessary. In order to win New Jersey's electoral votes in 1932, Franklin D. Roosevelt befriended Frank Hague, a known corrupt political boss, in order to gain his crucial support (Schoenbrun, 1984).

House and Howell (1992) called attention to the differences between *personalized*, self-serving, exploitative charismatic leaders and *socialized* charismatics. Whereas socialized charismatics were collectively oriented, egalitarian, and nonexploitative, personalized charismatics inhibited their need for power and were Machiavellian, authoritarian, and narcissistic. Roberts and Brindly (1955) saw the risk in training leaders to be charismatic: if these leaders were self-serving, they would practice deception and exploit their followers. Self-serving Machiavellian leaders try to maximize their self-interests. They are more likely to be egotistical and narcissistic. Like Napoleon, the self-aggrandizing "Chainsaw" Al Dunlap (Dunlap & Andelman, 1996) was proud to say how convinced he was of his own greatness (Nocera, 1996). O'Connor, Mumford, Clifton, et al.

(1995) contrasted biographies about the rise to power of 38 personalized and 44 socialized world leaders as judged by five psychologists. The degree of self-serving of the leaders was seen in how much: (1) they felt they would not get what they desired because the world is uncertain; (2) they sought to subdue or convert others; (3) they viewed other people as instruments to achieve their own goals; (4) they were selfish, extremely self-interested, and overly concerned with self-satisfaction; and (5) they felt a strong need to protect themselves and to monitor their thoughts and actions in the presence of others. Personalized leadership—highly related to self-serving—correlated with harm to society, a failure to adhere to morality, and a lack of benefit to individuals. Such leadership was likely to be destructive rather than constructive. Kaiser Wilhelm II was partially responsible for inflicting World War I on humanity as a consequence of his preoccupation with emotional self-interest (Dietrich, 1981). Powerful, self-serving leaders use their power to satisfy their need for more status and esteem. They are rude and sexually exploitative. They collect symbols of prestige: offices, homes, and cars. They keep their subordinates weak and dependent. They centralize authority for making important decisions (McClelland & Burnham, 1976). Saddam Hussein may have seemed irrational, but he represented the extreme of self-serving and calculating craftiness. Anyone who did not support him was his enemy. Anyone within his control who opposed him was subject to severe punishment, including execution. Any movement that would threaten his power was met with force including poison gas. He was unconstrained by conscience. His murderous behavior was consistent with the culture of violence in which he grew up. He had messianic ambitions and dreams of glory as supreme leader of the Arab masses. In invading and looting Kuwait, then trying to destroy its rich oil fields, he defied the military power of the United Nations, led by the United States. He rose like a phoenix after Iraq's disastrous defeat in 1991, once more to challenge the United States and the United Nations for the following 12 years, again at the expense of Iraq's civilian economy and population. At the same time, during his three decades in power he built a modern secular state unlike most in other traditionally religious countries. His violent overthrow was followed by insurrection, civil war, and chaotic conditions bordering on anarchy despite a democratically elected government to replace him.

Most leaders are neither completely self-serving nor completely altruistic. Additionally, self-serving may do some good. Bolino (1999) suggests that leaders may display good organizational citizenship to impress others as a technique of impression management. Or it may be a matter of ingratiation or manipulative politicking. Ferris, Bhawak, Fedor, et al. (1995) noted that good organizational citizenship will be seen as prosocial if it is sincere, but as self-interested politics if it is insincere.

*Greed* is self-serving, seen in the compensation of too many U.S. CEOs and senior executives, relative to their employees. Conger (2005) noted that prior to 1930, professional managers—the agents of owners and shareholders—did not become millionaires like entrepreneurs and owners such as the Rockefellers. In 1929, Eugene Grace of Bethlehem Steel was the first professional chief executive to be awarded a bonus of \$1.2 million. By 2000, Dennis Kozlowski, CEO of Tyco, obtained a compensation package of \$137 million. According to Conger, there are seven reasons for greedy, unjustifiable compensation, a vice widespread in the United States despite monitoring and regulating by the Securities and Exchange Commission.

1. Corporate governance makes the CEO the leading corporation decision maker as the chairman of the board of directors. The directors vote on the compensation of the CEO and expect reciprocity. Many if not most of the directors are CEOs in other corporations and don't raise objections.
2. Outside compensation consultants who provide guidance and benchmark data depend on the CEO to buy other business services they provide.
3. For the media and the public, the CEO is a romantic hero who single-handedly triumphs over daunting challenges.
4. Corporations are conceived of as property of an owner rather than as a social institution accountable to the public.
5. Transparency is lacking in the compensation package.

6. Tax codes provide deductions for options and grants of restricted stock.
7. Too many senior business executives have narcissistic personalities.

*Narcissism.* Nietzsche's (1886) ego-enhancing, inner-directed, self-determined superman had many good qualities but also many elements of the narcissist. He had a sense of duty and responsibility to his unique self. He was free of the expected and was a point of contact with the future. Narcissism, as measured by the Narcissistic Personality Inventory (NPI), includes an inflated sense of self-importance and fantasies of success, superiority, power, beauty, and brilliance. Admiration is sought. Sometimes narcissism is a force for good; more often it is a vice. It is immoral when it leads to exploitation of others, expectations of undeserved special favors without reciprocation, indifference, and lack of empathy for others (Raskin & Hall, 1979). Narcissists "are capable of being extremely charming and manipulative and extremely cruel to others whenever it is in their self interest to do so. ... Narcissists appear to experience little self-doubt ... as a result of their behavior" (House & Howell, 1992, p. 98). Kets de Vries (1994) does not find it surprising that many narcissists, with their need for power and prestige, become leaders. They act out fantasies created by their followers, who become uncritical, submissive, and dependent. Self-loving leaders take advantage of their followers' loyalty by ignoring the followers' needs. Steyrer (2002) used a model to show how the grandiose self of the narcissistic, charismatic leader, when confirmed by attention received, is socially dramatized and results in fascinated, impressed, emotionally stimulated followers who may subsequently engage in destructive acts. Sankowsky (1995) added that such leaders are likely to abuse power. They share their belief system with their followers. Narcissistic leaders only want to hear advice that confirms their opinions; they reject anyone who challenges them. According to Hogan and Hogan (2002), unhealthy narcissistic leaders combine a grandiose sense of certainty with disdain for subordinates. They ingratiate themselves with those above them in the organization and brutalize those below them. Like Walter J. Connelly, Jr., who ruinously expanded the Bank of New England, they are good at self-promotion. Normal rules don't apply to them (Goleman, 1990). Narcissists have also been found by Helland and Blair (2005) to engage in unethical leadership behavior such as insensitivity to others, manipulative communication, and pseudotransformational behavior.

*Hypocrisy.* John Gardner (1990) notes that leaders must combat the hypocrisy that proclaims values and then proceeds to act in violation of them. Hypocritical leaders formulate moral standards that they refuse to apply to themselves. They do not accept the same consequences for ethical violations that they demand of others (Dyson, 2001). Smith and Craig (2002) saw insincerity in many CEOs who called for reforms in business and accounting practices to deal with unethical reporting. These CEOs were dissembling; they called for needed changes but weren't aggressive in carrying them out. Bla-lock (1996) found that the many executives valued self-respect but were ready to commit financial fraud.

*Falseness or Inauthenticity.* "Leaders sometimes behave immorally ... because they are blinded by their own values" (Terry, 2003, p. 67). They may truly believe they are acting altruistically when in fact they are being self-serving. Concern for collective outcomes in the interests of altruism may harm opposing interests of individuals.

Inauthentic pseudotransformational leaders appear to support the common good, but their own self-interests have a higher priority. They ask to be trusted but cannot be. They create artificial and phantom needs in their followers. They manufacture artificial crises. They stretch the truth. They arouse fantasies and delusions in their followers. The example they set for their followers is inconsistent with or even the opposite of what they proclaim is right. At the extreme, they may be psychopaths who mask their antisocial traits, present a prosocial demeanor, and remain successful leaders (Babiak, 1995). They treat opposition as disloyalty. They "pass the buck" and blame others for their own mistakes. False expert authority in dishonest

advertising can be more persuasive than true expert authority although it is possible to immunize students against such ads with brief training (Cialdina, Sagarin, & Rice, 2001).

True, authentic transformational and charismatic leaders respect the rights of others and may appeal for universal brotherhood; inauthentic leaders focus on “us” against “them” and demonize opponents. Authentics are open; inauthentic wear masks. True leaders tell followers what they need to hear; false leaders mislead, prevaricate, and tell followers what they want to hear. Authentics truly empower followers; false leaders appear to empower but actually create dependent followers. Authentics aim to develop their followers into leaders; inauthentic want to develop submissive disciples.

Authentic leaders, in general, are authentic and empathetic; inauthentic leaders shed crocodile tears. Authentic leaders build arguments on truth and evidence; inauthentic build arguments on ignorance, prejudice, and half-truths. Authentic leaders espouse fairness and human rights. Inauthentic leaders are ingratiating, patronizing, and condescending toward others; they talk about concern for the environment, humanity, and society but actually are interested in exploiting them (Bass & Steidlmeier, 1999).

Opinions among historians differ about whether Adolf Hitler actually believed he was doing the right thing. H. R. Trevor-Roper thought that Hitler was convinced of his own rectitude. Alan Bullock called him an actor who sometimes believed his role. Lucy Dawidowicz saw Hitler as a double-talking schemer (Gates, 1998). Hitler was the epitome of the pseudotransformational leader, frequently deceiving others and sometimes even deceiving himself (Evans, 2003).

*Pseudotransformational Leadership.* The behavior of pseudotransformational leaders is inauthentic although they may appear to be like transformational leaders. They are hypocritical politicians who preach the need for morality yet take bribes. They create the impression that they are doing the right thing, but secretly avoid doing so. They ask their followers and others to trust them, but they cannot be trusted. They make exceptions for themselves. Sometimes they may be blinded by their own values (Price, 2003) and come to believe they are doing the right thing by “killing with kindness” or saving a village by destroying it. The pseudotransformational leader’s idealized influence produces a false messiah like Jim Jones who leads all his followers to destruction. The pseudotransformational leader highlights “we-they” differences. (“We have good values. They don’t.”) Such leaders seek power and status at the expense of their followers. They indulge in fantasies of power and success. They believe they know the right answers, which can be sold through impression management; but they may be deceiving themselves. Their visions are grandiose. They engage in self-displays to get attention for themselves. They may lack a sense of responsibility. The pseudotransformational leader’s inspirational motivation appeals to unrealistic fantasies that make it difficult for followers to face reality. These are spiritual leaders who are false prophets, captains who sail under false colors. “They profess strong attachment to their organization and its people but privately are ready to sacrifice them. They downsize their organization [at the same time they] increase their own compensation, and weep crocodile tears for the employees who have lost their jobs” (Bass & Steidlmeier, 1999, p. 187).

Pseudotransformational leaders’ intellectual stimulation uses false assumptions, overweighs authority, and underweighs reason (Sankowsky, 1995). These leaders feed on their followers’ ignorance and willingness to accept ambiguity, which provides opportunities for the leaders’ enhancement. They set and control the agenda to manipulate the values of importance to followers to reach decisions favorable to themselves. They argue that they are doing the right thing but actually do so only when their own interests are not threatened (Howell & Avolio, 1992). They substitute emotional arguments for rational discourse (Bass & Steidlmeier, 1999). Pseudo-transformational leaders’ individualized consideration creates dependent instead of empowered followers. The leaders expect blind obedience and loyalty. They maintain personal distance between their followers and themselves (Bass, 2001). The leaders exploit the feelings of their followers to maintain deference toward themselves (Sankowsky, 1995), and encourage fantasy and magic in visions of shared goals. They seek

to maintain a parent-child relationship with their followers. They are publicly altruistic but privately self-serving. Privately, they are contemptuous of altruism (Howell & Avolio, 1992); privately, they are deceptive, domineering, and egotistical even when their public image is as holy savior. Television and radio preachers caught in ethical scandals are examples.

The esoteric leaders of extremist militias in the United States are pseudotransformationals. They manipulate their followers' fear of change by claiming that they can halt or reverse its impact. They offer simple explanations for complex changes in society. They pursue returning to a fictitious, glorified past. They advocate using violence against those whom they perceive as responsible for extreme changes in society and benefiting from such changes (Katner, 1996). The radio commentator Rush Limbaugh and the outspoken black political leader Louis Farrakhan are examples of popular pseudotransformationals. "Rush Limbaugh and Louis Farrakhan live well off ignorance ... with great charisma. ... [They] look like giants to people of minor intellect. ... They exploit ... frustrated people for personal gain in the name of doing good for the entire nation or race" (Lockman, 1995, p. 9a).

President George W. Bush was pseudotransformational in 2001 when he asked Congress for a resolution to take the country to war against Iraq in response to Al Qaeda's terrorist attacks of 9/11. He may have been misled by faulty intelligence about Iraq's nuclear weapons, but rationally he must have known that Saddam Hussein was a secularist dictator opposed to the Islamists, that at the time there were few terrorists hiding in Iraq, and that Saddam was an enemy of Al Qaeda and its leader, Osama bin Laden. Nevertheless, Bush eventually made a preemptive strike against Iraq to overthrow Saddam. Instead of thwarting terrorism and Iraq's nuclear activity, the effect of going to war in Iraq in 2003 was a great increase in the number of terrorists worldwide, a loss of international popularity for the United States, and the alienation of the Muslim world (Woodward, 2004). Pseudotransformationals dominate, exploit, manipulate, and self-aggrandize rather than seek consensus or foster trust (Connor, Mumford, Clifton, et al., 1995).

Kellerman (2000) ruled out Hitler as a leader because his influence was destructive and evil, even as he probably had a greater impact on the twentieth century than any other man. It seems more reasonable to say that he was a leader but, unfortunately for the world, a pseudotransformational one. In the same way, Potts (2001) conceives of leadership as inherently ethical, since its purpose is to do good (see Burns, 1978) or to use only good means (see Rost, 1991). According to Potts, any other influence in organizations or movements is manipulative management. Does this mean that management without leadership is inherently unethical? It makes more sense to regard leadership with harmful means and ends as false leadership, also keeping in mind that such leadership may be attempted, successful, or unsuccessful, and effective or ineffective whether or not it aims to do good (see [Chapter 6](#)).

*Arrogance and Hubris.* Kroll, Toombs, and Wright (2000) note that narcissism may generate *arrogance* and *hubris* when coupled with ignoring the rules, achieving many successes, and uncritically accepting many accolades. Such a pattern is seen in executives who pursue expansion for its own sake, make unwise and overpriced corporate acquisitions, take uncalculated risks, and knowingly violate moral and legal regulations. Hubris can be outspoken: "Chainsaw" Al Dunlap bragged that he could resurrect almost any dying business. Appointed CEO at Sunbeam in 1996, in 11 months he had eliminated 60% of its management and half its workforce—actions he said were difficult but should have been done by his predecessors (Turner, 1997). Dunlap was fired a year later. The firm subsequently went bankrupt.

Arrogant executives are excluded from the "humor network"—joking on the job (Duncan & Feisel, 1989). Likewise, the arrogance of military leaders has led them to underestimate the enemy, overestimate their own force and position, and ignore the advice of their staffs. Arrogant business and military leaders both rely on simplistic formulas for success and fail to pay attention to changing realities.

By 1812, except for some early, forgotten setbacks, Napoleon had lost very few of the 35 battles of which

he himself had been in command and now had become the master of continental Europe and all its royal rulers. Russia and Tsar Alexander were the exception. They were of little threat to Napoleon's French Empire. But to satisfy his arrogant character, he assembled 150,000 French troops and 350,000 from other nationalities of Europe and set out to march the 800 miles to Moscow, where he expected that the Russians would formally surrender, submit to his authority, and acknowledge his supremacy over the continent. He had plenty of warnings of problems from his staff, which he confidently overlooked. The problems were to be handled by his will to succeed. He lost 50,000 at the Battle of Borodino and all but 20,000 of the remaining 450,000 because of his failure to consider his stretched supply lines, the Russian winter, Russian resilience, and guerrilla warfare. The defeat led to his downfall over the next three years.

*Lack of Social Inhibition.* Lack of social inhibition can be a vice. Socially uninhibited people are less effective as leaders despite their need for power and affiliation. They concentrate on dominating others and on winning at the expense of someone else (McClelland, 1985).

*Abusiveness.* Abusive leaders are arbitrary, condescending, and patronizing. They indulge in emotional outbursts (Ashforth, 1994) and use physical or verbal aggression. A leader's verbal aggression seeks to inflict pain on the self-concept of a subordinate. It is not mere impersonal argumentation (Marrs & Turban, 2002). Physical abuse by supervisors was more common in earlier industry, but nonphysical abuse continues, though it is more constrained by cultural and organizational sanctions. Abusiveness results in employee job dissatisfaction, role conflict, intentions to quit, and reduced organizational commitment (Tepper, 2000). Supervisor bullying, frightening, or threatening employees (Rayner, 1997) may be witnessed by 40% to 60% of employees, although it is likely to be confused with autocratic, directive, "no-nonsense" leadership (Sablinski, 2002). Abuse of power may be subtle when followers regard the leader as a parental figure (Sankowsky, 1995).

*High Self-Monitoring.* High self-monitors have the vice of overconcern about appearing unfavorably in what they say and do. They tend toward amorality. They avoid investing in emotional relationships. They are less committed to their current friends, current colleagues at work, and sexual partners. They are more ready to change employers. They are less constrained about pursuing opportunities wherever they may be found (Kilduff & Day, 1994). In a survey of members of a Canadian human resources professional organization, high self-monitors were more willing to behave unethically in eight scenarios in work and nonwork settings (Wahn, 2003).

*Document Falsification.* Into the early 1990s, as the principal financial institution for a number of Gulf sheikhdoms, arms traffickers, and terrorist organizations, and with branch banks worldwide, the Bank of Credit and Commerce International (BCCI) was ideal for moving funds among the sheikhdoms, arms traffickers, and terrorists because it was flexible in falsifying documents. Illegal and immoral transfers were kept from being transparent. The bank even arranged for princes in Abu Dhabi to pay the families of 16-to 20-year-old virgins and to pay for training them (London *Sunday Times*, 1992). Enron overreported \$9 billion dollars in profits aided by Arthur Andersen auditors. This "cooking the books" cause of bankruptcies in a number of other large firms in 2002. Wessel (2002) listed 18 major corporations, from Adelphia to Xerox as following questionable practices. Adelphia, audited by Deloitte & Touche, failed to properly disclose \$3.1 billion in loans and guarantees to its founder's family. Xerox, audited by KPMG, was fined \$10 million but did not admit or deny that it inflated revenues and profits from 1997 to 2000 by including future payments on existing contracts.

*Malevolence.* This vice of destructive leaders brings harm, pain, and suffering to others (O'Connor,

Mumford, Clifton, et al., 1995). If the vice is intentional and deliberate, the leaders are malevolent in personality. According to Goldberg (1995), they know what they are doing and understand the consequences of their actions. They choose doing evil over doing good in the hope of reducing their own shame and self-contempt, which they project onto others. They feel that they are superior to others and that they live by a higher morality. They become addicted to finding reasons for their cruel and insensitive behavior. They are unable, unwilling, and afraid to examine the dark, unknown side of themselves and believe they already know what needs to be known.

*Masked Intentions.* Dasborough and Ashkanasy (2002) theorized that depending on whether a leader was in a positive or negative mood, members' attributions about the leader's intentions would influence their evaluations and interpretations of his or her leadership and whether the attempted leadership was truly transformational or pseudotransformational. Leaders high in Machiavellianism can conceal their intentions and be evaluated by members as authentically transformational when they actually are pseudotransformational. When the members are in a negative mood, they will be more likely to view the leader as self-serving.

### ***Toxic Leadership***

Leaders with many of the vices listed above have been described as *toxic* by Lipman-Blumen (2005). She noted that such leaders are plentiful in all walks of life and display different vices at different times. Nevertheless, they are tolerated and sometimes admired. They survive despite their faults. Often, they achieve status as celebrities and are supported by the media's myopia about ethical considerations. Among other actions of toxic leaders, she noted that they: (1) do more harm than good to followers; (2) violate the basic human rights of their own supporters; (3) consciously feed illusions to their followers that play on the followers' fears and needs; (4) mislead followers with lies; (5) stifle criticism of themselves; (6) engage in unethical, illegal, and criminal acts; (7) cling to power; (8) scapegoat others; and (9) ignore or promote incompetence, cronyism, and corruption.

## Dealing with Ethical and Unethical Practices

---

### ***Attitudes toward Corruption***

Investigative journalism has, since its inception, put a spotlight on managerial and entrepreneurial corruption. Nonetheless, there has been a marked paucity of empirical research on managers' attitudes toward corruption and the ethics of their behavior. Pitt (1985) gave middle and senior managers in South Africa 15 scenarios involving ethical considerations and asked them to indicate whether they regarded the manager's behavior as wrong, how frequently such behavior had been observed, and what the company should do about it. Over 90% thought it was definitely wrong to accept a large bribe or to tell competitive bidders their rivals' offers for the manager's own material benefit. But 4 out of 10 thought it "understandable" for a firm that had just been awarded a contract by a project engineer to give the engineer a tip. Similar proportions thought it was all right for a geologist to use inside information about new developments to purchase company shares, and for a purchasing manager to accept an invitation from a supplier for a "night on the town" hosted by the supplier's secretary. Over 90% said they had observed colleagues and friends accepting a potential supplier's invitation to lunch and accepting a bottle of whisky as a Christmas gift from a supplier. Half or more said they had seen colleagues or friends accepting free trips and entertainment from suppliers, as well as conducting insider

trading. Only 34% thought the company should take legal action in the case of large bribes, although 62% would fire the bribe taker. Similar reactions were registered for releasing information prematurely to rival bidders, but a plurality would only give such employees a warning for insider trading, accepting free trips, and filing false expense claims.

Although there is much divergence in ethical opinion among managers, a high set of standards can be described and appreciated. Six interviews were held with six leaders who were identified by well-informed observers as models of ethical leadership. These ethical leaders expressed a strong commitment to the mission of their organization, derived great satisfaction from progressing toward the mission, and empowered others to contribute to it. Furthermore, they cared for the various stakeholders in the organization, not only the owners and stockholders, and had a broad sense of community. They also remained informed about what was going on in their complex organizations. In all, they believed that bad means could not be justified to gain good ends (Shapiro, 1985).

### ***Questionable Decisions***

Three sets of questions need to be answered in determining whether one is making the right ethical decision:

1. Is it legal and legitimate? Will this decision violate laws or regulations? Will it violate organizational policies or standards or community norms? Will it violate agreements with unions, outside agencies, or other organizations?
2. Is it just and fair? Is everyone involved being treated equitably? Will some people be helped unfairly at the expense of others?
3. How will you feel after making the decision? How will you feel about yourself? Will you be proud of what you did? Would you be pleased to see the decision published in a newspaper and read by family and friends? (Anonymous, undated).

*Nepotism.* Favoring family members over others for selection, promotion, and organizational support may be embedded in constitutions, cultures, traditions, customs, and norms. Yet it may be unethical when a less qualified relative is chosen over someone more qualified. There are well-known family political dynasties such as the Bushes, Romneys, Longs, and Kennedys. In many countries widows and daughters are elected to replace their husbands and fathers. Brothers and sons are frequent successors to Muslim leaders. Sons may take over authoritarian governments after the death of their fathers. The great majority of American businesses are family-owned. Descendents of Henry Ford, the founder, have been chosen as succeeding CEOs of Ford Motors. Leadership in the crafts and service industries often passes from father to son. Numerous leaders in the movie and television industry owe their positions to their parents' careers in the industry. The father-son tradition continues in trade unions, the military, entertainment, the media, and religious institutions. Family name, connections, and wealth may be exploited; and it may not be regarded as wrong to give a qualified relative an opportunity in competition with an equally qualified stranger (Bellow, 2003). Affirmative action for family members has become an acceptable norm in the United States and in family-built and family-dominated businesses and in collectivistic cultures such as India, Singapore, and Taiwan. But there is a cost. People who are not family members feel that they have less of a future in the business.

### ***Wrongful Behavior***

The unethicity of 15 acts was analyzed by Pitt, Watson, and Nel (1990), who sent 500 questionnaires to purchasing managers in organizations over 500 in size. The managers rated how wrong the actions were and

what punishment was justified, if any. Proposed punishments depended on the harm done to the organization by the wrongful actions. Two actions judged completely wrong were accepting bribes to award a large contract and giving a bidder on a contract information about all the rival bids. Perpetrators ought to be punished by dismissal and possibly legal action. Justifying only a warning but judged as almost equally wrong were siphoning fuel from a manager's company car to his wife's filing false expense claims, and keeping a trunk full of groceries discovered after returning from a supplier. At the other extreme, it was seen as understandable or not wrong to accept Christmas gifts, lunch from a supplier, or an invitation to a sporting event. In another study, using three scenarios of unethical behavior, 337 upperclass undergraduate students said that the perpetrator was morally wrong if they empathized with the victims of the possibly harmful actions (which involved selling autos or real estate). The likelihood that the harm would occur was irrelevant (Carlson, Kacmar, Wadsworth, et al., 2001).

## ***Whistle-Blowing***

In its December 19, 2002, issue, *Time* magazine named three whistle-blowers as "Persons of the Year," an honor ordinarily reserved for world leaders. Coleen Rowley, a middle manager, sent a letter to the director of the FBI about evidence of the 9/11 conspiracy that was ignored, and testified critically to the U.S. Senate that the agency was bogged down in bureaucracy and careerism; Cynthia Cooper, an internal auditor at WorldCom, alerted its board of directors to \$3.8 billion in accounting irregularities; and Sherron Watkins, an Enron vice president, sent memos warning the CEO that improper accounting could cause the firm to collapse.

An ethical conscience, courage to act on one's ethical convictions, concern for others, ego strength, and inner locus of control are character traits of whistle-blowers in reacting to unethical authority (Perrault, 1997). They are willing to report the unethical behavior of higher-ups (Mumford, Gessner, Connelly, et al., 1993). Whistle-blowers also reveal character traits of spirituality and moral absolutism. Compared with pragmatists, idealists who strongly believe in a just world make the most mature ethical decisions about whistle-blowing. In an Australian study, Windsor, Trevino, Ashkanasy (2001) found that given the expectation in an "in-basket scenario" that management condoned unethical behavior by punishing rather than rewarding a whistle-blower, highly principled respondents—those who scored highest on Rest's (1993). Defining Interests Test (DIT)—responded most ethically. In contrast, pragmatic respondents—those scoring lowest on the DIT—were lowest in ethical responses.

*Motivation to Intervene.* For 398 employees in one study, willingness to intervene in the event of witnessing social-sexual behavior at work was affected by recognizing the behavior as a moral issue, by its moral intensity, and by the moral ideology of the witness (Bowes-Sperry & Powell, 1999). In the case of an office romance between an older married senior executive and a younger single employee, taking action was more likely if work was disrupted and the young person was believed to be motivated by job concerns. The desire to intervene was increased by group norms, and by the perceived reactions of the guilty parties (Barnett, Bass, & Brown, undated).

Whistle-blowers can be stimulated by leaders who give immoral orders and suggest actions that are ambiguous so that blame for wrongdoing can be diverted from the leaders (Kelman & Hamilton, 1989). The whistle-blowers may delay or procrastinate until others confirm the seriousness of the unethical behavior. They will act to report the violation of organizational rules if preventive attention is urgent; if the violation is frequent or seriously harmful; if their relations with the violator are not close; if they feel responsible for doing so; if they are less concerned about the violator's reactions to the whistle-blowing; if fewer emotional, financial,

time, and other personal resources may need to be committed by the whistle-blower; if the time and place are appropriate for a confrontation; and if it is likely that the whistle-blowing confrontation will end the violation (Newall & Stutman, 1991).

*Deterrents to Whistle-Blowing.* In the U.S. service academies, reporting on peers' unethical behavior, as called for by the honor system, was in conflict with the institutional norms of mutual support and teamwork. At the Naval Academy, the accepted slogan was, "Never bilge your classmates." Those who blew the whistle and disclosed mass cheating on an electrical engineering examination were expelled, while those who cheated but remained silent were not. For the midshipmen, the honor system was a joke that protected lying and cheating and punished those who blew the whistle (Caplan, 1994).

## Impact of the Internet

---

Galvin (2000) saw 1999 as a banner year for lapses in business ethics, and anticipated the even bigger scandals to come in the years immediately following. The Internet has brought increased opportunities for cheating, lying, and stealing. It has also brought many additional problems, costs, and risks of unethical behavior by corporate leaders and the led, ranging from anonymous sexual harassment to improper contact with competitors by leaders to fix prices and by employees to reveal proprietary information. Stock fraud, bogus business accounting, insurance scams, copyright violations, corporate espionage, and illicit data mining about unsuspecting customers have increased substantially with the increased use of the Internet. Over 60% of employees say they use their office e-mail for personal purposes on company time. Over 50% of firms say they monitor—without permission—their employees' e-mail; but 61% of employees surveyed said it was all right for the firm to do so. When seeking reasons to discharge an employee, firms find the monitored information a good source.

## Summary and Conclusions

---

Many leaders serve as examples of ethical behavior and make moral decisions attributable to their character and professionalism. Others are amoral or immoral. Empirical research on leadership ethics was rare before 1975, although its philosophical underpinnings go back to ancient Greece and China. Spiritual leadership has taken ethical issues to a higher stage. Ethical and moral principles of leadership are well established but remain less well practiced. More attention needs to be paid to organizational and corporate social responsibility. Moral reasoning about what is right, good, and important is principle-based or character-based. Moral reasoning develops from self-interest to seeking the interests of others.

The character of a leader can be delineated in terms of virtues and vices. Among the virtuous traits of leaders are integrity, authenticity, and fairness. Justice may be distributive, interactional, or informational. Other virtues of leaders include altruism, conscientiousness, wisdom, courage, and compassion.

Unethical practices include nepotism, questionable decisions, wrongful behavior, and false accounting statements. The Internet has contributed to many new forms of wrongdoing. Whistle-blowers need a strong set of virtues and the willingness to confront those of much higher status than themselves.

## PART III

---

# Personal attributes of Leadership

---

# Leadership and accorded Status, esteem, and trust

People are valued by others because of the position they occupy in an informal or formal group, an organization, or society—this is their status. They may be valued as persons regardless of their position—this is their esteem. They may be valued as trustworthy by others who have confident, positive expectations about them. Blaise Pascal (1660/1950) described a great nobleman as being valued for the status he had in society that made it possible for him to be “the master of objects that men covet,” and for these objects deference was paid to him. But he was not esteemed by Pascal as a person. In contrast, Pascal mentioned “M. N. [who] is a greater geometrician than I ... [and whom] I esteem for his enlightenment of mind, virtue, health and strength” (Bass, 1960, p. 277). Pascal’s nobleman was of worth to others because of his noble status, the lofty hierarchical position he held in society. The nobleman’s position gave him wealth, control, power, and influence. A poor nobleman position would still be accorded some status and influence. Even without control of wealth to distribute, a nobleman’s position could still be of more importance than a commoner’s. Pascal’s mathematician was esteemed for his technical competence and personal qualities. Many noblemen of high status lacked such personal qualities and were held in low esteem by those who knew them personally or by reputation. Many ordinary folks who lacked status could be esteemed by others for their personal value.

## Status

---

The value that others accord members for their position—informally or in a group, organization, or society—is the members’ *status*. Status contributes to the members’ emergence as leaders. The same is true of the members’ *esteem*, the value accorded them by others for their personal qualities (Bass, 1960). Conflicts abound and ineffectiveness increases in the group, organization, or society when the esteem and status of the members are not correlated. A group will be in conflict and ineffective when its high-status members are low in esteem; it will also be in conflict and ineffective when its highly esteemed members are relegated to positions that accord them low status.

Warner, Meeker, and Eells (1949) observed that all societies and social groups of any size or complexity have status systems. Status structure and differentiation of functions are necessary for the coordination of efforts. Even collectives that are designed to minimize functional specialization and the differential distribution of rewards develop well-defined status structures (E. Rosenfeld, 1951). In traditional societies, age was an important determinant of status. However, the details concerning what was expected of members of different ages—infants, boys, girls, young men, young women, old men, and old women—differed from one society to another (Linton, 1945).

Occupants of various positions are provided with cues to make it easy to identify their status. Status differences in military organizations are clearly visible. In many societies, the adolescent often is easily discriminated by dress from the preadolescent, as is the married woman from the unmarried woman. Until modern times, each profession had its own identifiable costume. And the signs and symbols of differential status in the modern business organization are familiar. The top managers and administrators have extralarge corner offices on the top floor, custom-made desks, large leather desk chairs, carpeting, coffee tables, couches, and special parking spaces for their cars; first-line supervisors have small offices in the basement with wooden

desks and chairs, and park in the lot wherever they can (Barnard, 1952).

Status differences affect how members group with each other. In a mixed social gathering, high-level officials will cluster, as will those who are lower in status. At a cocktail party, men often stay together in one corner of the room and women in another corner. In organizations, members tend to maintain some degree of physical distance between themselves and other members who differ from them in status. Status also determines how people communicate with others who are working at a distance. Thus members of organizations send memos to those above or below them in status but telephone those who are at their same level (Klauss & Bass, 1981). E-mail may substitute for both the telephone and written memos for senders several echelons above, below, or at the same organizational level.

### ***Concomitants of Status***

Some positions provide occupants with direct control over what is rewarding to others; occupants of such positions have greater status in the organization (Barnard, 1951). In turn, such status-derived power makes it possible for the possessors to exert leadership and influence over others. Some roles make it possible for the role players to have access to information and the ability to solve the group's problems.

Sherif, White, and Harvey (1955) found that the higher the importance of a member's position, the greater was his or her competence as judged by other members. This finding fits with the facts of everyday life. Studies of the status hierarchy in social organizations show that positions accord their occupants more status if occupants of those positions either acquire more knowledge once they occupy the position or are selected for the position only if they have the knowledge. The occupations with the highest societal status (that is, value or importance to society), according to college students, are physician, lawyer, banker, engineer, and school administrator—all require a great deal of education and specialized knowledge. Low-status occupations include truck driver, coal miner, janitor, and ditchdigger—all of which necessitate little or no education. The status of occupations is remarkably stable. For 25 occupations, the correlations in status in 1925, 1946, and 1967 were all above .09 (Hakel, Hollman, & Dunnette, 1968) and were likely to be as high in 2000. Furthermore, miners' and laborers' perceptions of occupational status were similar to those of the college students (Cattell, 1942). But a strikingly different occupational hierarchy appeared when researchers asked a random sample of 2,000 Americans to rate the extent to which they valued the honesty and integrity of different occupational groups. The highest 10 occupations were firemen, paramedics, farmers, grade school teachers, college professors, dentists, U.S. military officers, plumbers, college athletes, and advertising executives. The lowest 10 were drug dealers, organized crime bosses, television evangelists, prostitutes, street peddlers, local politicians, congressmen, car salesmen, rock and roll stars, and insurance salesmen (Patterson & Kim, 1991). Evidently, trustworthiness did not coincide with high status.

In primitive societies, the high status of the medicine man and tribal elders was partly due to the knowledge held by anyone occupying such positions. In a world that had to depend on the memory of events and procedures (since no books were available), and in which life expectancy was short, age was highly prized. Because wisdom required age and experience, age, status, and leadership were strongly linked. Conversely, the lower status of women and children in patriarchal societies was often partly due to their ignorance of magic, ritual, and tribal history, which were known by the men only. The reverse was true in matriarchal societies, in which women were accorded much higher status.

*Value and Importance of Positions.* Zaccaro (1996) compared the executive performance requirements found in interviews with generals and lieutenant generals by Harris and Lucas (1991), major generals and brigadier generals by Lucas and Markessini (1993), and colonels by Steinberg and Leaman (1999a). Systematic

differences could be seen in the importance of positional requirements at successively lower organizational ranks. Generals had longer work-time spans than did lieutenant generals and more boundary-spanning responsibilities. Shorter planning-time spans were available for major generals and brigadier generals, who also had less boundary spanning to do. Colonels were more likely than those below them in rank to be involved in goal setting, planning, and policy making.

People are appointed to positions by higher authority, or they may be elected. Their status is established by appointment if it is legitimate. If they are legitimately elected, their esteem is also likely to be higher. Status may also accrue from inherited positions or from volunteering for the position.

A price can be set on one's status in an organization or society. Job evaluation establishes the worth of each position to the organization. One's pay, then, depends on the established value and importance of a position, regardless of who occupies it. To control inflation, in 301 c.e. the Roman emperor Diocletian decreed fixed ceilings on prices and wages with penalties—exile or death—for exceeding the maximum allowed. A brace of chickens was to cost no more than 60 denarii, and first-quality boots no more than 120 denarii. Daily wages with maintenance were to be limited as follows: 20 denarii for shepherds; 25 for farm laborers; 50 for carpenters; 150 for picture painters. Monthly wages were to be no more than 50 denarii per pupil for elementary teachers; 75 for teachers of arithmetic; 200 for teachers of Latin or Greek; and 250 for teachers of rhetoric. For jurists or advocates pleading a case, the maximum allowed was 1,000 denarii (Lewis & Meyer, 1955). Similarly, one's status and value to family, clan, or social organization were clearly fixed in Anglo-Saxon law. The *wergild*, or "man price," varied with a person's status in society. If the person was murdered or killed by accident, it was to be paid by the culprit to the victim's relatives as retribution. The various social strata were valued by their respective prices. The church placed its own members on the wergild scale. It equated a priest with athane. The price of a king was from 6 to 15 times that of athane (Whitelock, 1950). Today, the executive who is incapacitated owing to the fault of another person still sues for a far greater estimated loss of income than does the manual laborer. The estimates are based on the expected future earnings of executives and laborers in the same general circumstances.

*Striving for Increased Status.* The desire for upward mobility is associated with attaining a more important and valued position to increase one's influence. Those with lower status in a group are more likely to be concerned about raising their status than those who already have attained important leadership roles. In three industrial plants, M. Dalton (1950) observed that the lower-status executives tried to get more personnel to supervise and tried to transfer from staff positions (less influential) to line positions (more influential). The line executives, on the other hand, did not seek staff jobs and were more concerned about moving higher on the line and entering the management "eating circle." Similarly, Bentz (un-dated) observed that members of college faculties who accorded themselves lower status tended to report more concern within their department about rank, status, and influence.

*Aspirations for Upward Mobility.* Upward striving for status may be reflected in a desire to identify with those of higher status or to accumulate the signs and symbols of higher status. Beshers (1962) called this striving "one-way status mirrors" when he observed the behavior of poor people of lower-class status aspiring to join the middle class.

Expectations of higher status are conducive to greater satisfaction. Kipnis (1964) reported that those who expect to move up are generally more satisfied with their work. Vroom (1966) studied students working for a master's degree in a business school before and after they accepted positions and found that they rated organizations as attractive when they perceived that these organizations were instrumental to the attainment of their personal goals. H. H. Kelley (1951) found that high-status members with no possibility of promotion were least attracted to a group. Conversely, in another laboratory study, Spector (1953) reported that

participants in an experiment who were placed in a pseudomilitary hierarchy and were promoted were the most satisfied. In the U.S. Air Force, Borgatta (1955b) noted that personnel who saw adequate opportunities for advancement to officer positions were less critical of the rewards and punishments possible. However, those who were actually striving for advancement in status were more critical than those who did not seek promotion.

In addition to seeking higher status, most of us, within limits, enjoy associating with groups of somewhat higher status, since these groups are likely to have more power and influence. J. W. Mann (1961) found that members of a group, especially low-status members, preferred to associate with groups of similar or higher status. Their desire tended to focus on the group that was next highest in status relative to their own group.

This striving for status—usually provided by a position of leadership—often involves the desire to achieve congruence in status among the various positions one holds. Dissatisfaction with one's status in one organization may be due to one's status in another. Benoit-Smullyan (1944) hypothesized that individuals with different status in different groups would attempt to equalize their stature in the various groups. Thus a business leader may endow an art institute to gain status in cultural circles. Fenchel, Monderer, and Hartley (1951) found that subjects' striving for status in five groups to which they belonged was higher in those groups in which their current status was low.

*Rejection of Higher Status.* Although the desire for upward movement in an organization may be the norm, it may nevertheless require changes in residence, associates, and patterns of living. Upward mobility also may require a change in relationships with friends, associates, and former coworkers in the organization. In addition, a higher-status position involves changes in responsibility and accountability for results. It may even mean lower pay for some workers, who, if promoted to supervisor, will no longer be paid for overtime. Not all members of an organization welcome such upward mobility. For example, Springer (1956) found that 13 percent of 10,533 workers who were recommended for promotion to lead-man, assistant foreman, or foreman refused the promotion.

A significant factor in the emotional breakdown of medical officers during World War II was their promotion to a higher-level position of responsibility and status, according to Reider (1944). The young officer who depended on a superior for support not only lost it when he became a status peer of the senior officer but was also expected to provide support for his subordinates.

*Losing Status.* Although Olmsted (1957) found that members of a group can drop from a position of leadership to the status of participant without reducing their activities or losing their liking for their group, most people in important positions will be concerned about losing status. E. L. Thorndike (1940) noted that for many—perhaps most—people, political power is a habit-forming psychological drug. Abdications are rare. It is one's general status that is involved, not the specific position. A president of the Teamsters Union is tenacious about maintaining his union office because it is inconceivable for him to return to driving a truck after a term in such a high-status position. Yet a cabinet secretary or the president of the American Association of University Professors can return to a high-status position in business or in academia after serving a term in office and so usually is not as reluctant to relinquish office (Selznick, 1943).

*Lowered Status, Dissatisfaction, and Performance.* Lowered status is likely to result in dissatisfaction and a decline in performance. H. H. Kelley (1951) studied, experimentally, the written communications of group members in high-status and low-status positions, with and without the possibility of status mobility, and found that low status was associated with relative dislike for the group task. Low-status members communicated their dissatisfaction to other low-status members. Furthermore, the high-status members who could lose their status made fewer positive comments than did those whose status was secure, and the low-

status members with the possibility of upward mobility made fewer negative comments than did those who had no such opportunity.

Burnstein and Zajonc (1965a) observed that the performance of group members tended to suffer when their status was decreased and tended to improve when their status was increased. Loss of status was likely to generate hostility. Lindzey and Kalnins (1958) asked students to compare themselves and other persons with figures in a picture test of projective attitudes. The students tended to identify themselves with heroic figures, but identified other persons more often with nonheroic figures. In the students' projections, changes in status after frustration revealed increased aggression by the hero against others and by others against the hero. Consistent with these findings, Worchel (1961) showed that one's expressions of hostility against others were reduced by restoring one's lost status.

### ***Status and Leadership***

Substantial evidence and everyday experience support a strong connection between status and leadership. Many people confuse and merge the two concepts. The worth or value of a manager's position in the organizational hierarchy increases as he or she moves to higher echelons. Greater responsibility and authority accrue along with higher status. So does the manager's leadership behavior. Thus, according to D. T. Campbell (1956), descriptions of the behavior of leaders and nominations for leadership of submarine officers were highly correlated with the officers' rank and the organizational level of their positions.

A rise in status and status differentiation were reflected in effective leadership. In one Mexican village, economic development resulted in the emergence of a cohesive and wealthier class. These wealthier members led the initiation of projects, the mobilization of community support, and the successful completion of the projects. In a second village, without such economic and class developments, little change was possible. Only the first village could deal effectively with outside influences that sought to control local decision making (Krejci, 1976).

*Increased Requirements.* Systematic differences are observed in the requirements for leadership as one's status increases. Routine production is of concern at the lowest organizational levels; systems and the external environment are of concern at the highest levels. Compared with the position of the lowest-level manager, the position of the top manager requires more innovativeness, vision, persuasiveness, and long-term orientation. It requires less modesty and participativeness.

*Coercive Leadership.* Bass (1960) deduced that the power accruing from members' high status makes it possible for them to become *coercive* leaders—giving orders, demanding, deciding without explanation. This power, coupled with information and the ability to help the group that stem from their high-status positions, also allows them to persuade others or to permit participation by others in decision making. Although coerciveness is still possible, it has been much more constrained in the past century by changes in attitudes against it of both superiors and subordinates, by legislation, and by societal changes in the democratized world. Much of the research of 50 years ago on coercion is less applicable today, although the many current harassment cases in civilian and military life attest to its continuing occurrence.

Schell (1951) suggested that higher-status people may offer security, protection, and opportunity to their subordinates in return for obedience and zeal. Roethlisberger (1945, p. 287) remarked, "Personal dependence upon the judgments and decisions of his superiors, so characteristic of the subordinate-superior relation ... makes the foreman ... feel a constant need to adjust himself to demands of his superior and to seek approval of his superior." Gerard (1957) found in an experiment that participants with high status tended to be *controlling* in their behavior, whether their role relationships was clear or unclear. But low-status participants

required a clearly defined set of role expectations to be effective. Without group goals, high-status participants assumed broader prerogatives, whereas low-status participants seemed bewildered. High-status participants also perceived themselves to have more freedom of action than did low-status participants.

*Attempted and Successful Leadership.* Attempts to lead were more likely to be successful when the members differed in accorded status and when they were highly motivated than under the opposite conditions (Bass, 1963). A correlation of .88 was obtained between the organizational level of 131 supervisors in an oil refinery and their success in initially leaderless group discussions for which no one was appointed leader (Bass & Wurster, 1953b). If the problem concerned company matters, the correlation was even higher (Bass & Wurster, 1953a). A correlation of .51 was found between the rank of 264 ROTC cadets and their tendency to lead discussions among associates. When 180 cadets were retested in a new discussion among their associates a year after an initial discussion, those who had risen in rank from cadet noncommissioned officer to first lieutenant or higher during that year gained significantly more in observed success as leaders on the retest than did those who received a lesser promotion to cadet second lieutenant (Bass, 1964).

### ***Status and Influence***

The power of the higher-status manager to influence his or her lower-status subordinates has been observed in numerous empirical studies. For instance, Jacobson, Charters, and Lieberman (1951) found that subordinate supervisors conformed to what they thought their bosses expected of them. Supervisors who said their bosses expected them to be considerate tended to describe themselves as more considerate leaders and were so described by their subordinates (Fleishman, 1953b). Similarly, F. C. Mann (1951) observed that supervisors who changed more as a consequence of training in leadership received more encouragement from their superiors and felt more secure in their relations with their superiors. Bass (1960) reported finding that the higher a salesman's rank in a sales organization, the more likely was he to be nominated by the others as influential.

J. C. Moore (1968) ascertained that when dyads worked on an ambiguous task, partners of lower status in the same experimental condition tended to defer to the choices made by their partners of higher status. Subsequently, J. C. Moore (1969) found that agreement among partners eroded their expectations of differential performance that were activated by the differences in their status. O. J. Harvey (1953) found that members of a group expected more of their high-status members and overestimated the performance of the high-status members.

The influence of the leader's status may contribute to better performance among subordinates. Thus Doyle (1971) showed how the processes and productivity of schoolteachers were linked systematically to the status attained by their principals. And Tang, Tollison, and White side (1988) reported that among 47 quality circles (QCs), the attendance rate by others was higher over a three-year period when the meetings were attended frequently by senior managers than when these managers seldom attended them. The QCs with a high level of attendance by middle management attempted more projects and had greater cost savings. But the effect of attendance by lower management on QC effectiveness was not significant.

*Reasons for the Status-Influence Relationship.* Influence accrues from high status because more attention is paid to high-status persons and because the behavior of persons with high status is more acceptable. Pedestrians at a traffic signal committed significantly more violations when they witnessed violations committed by a confederate of the experimenter who was dressed to represent a person of high social status, than when the confederate was less well dressed (Lefkowitz, Blake, & Mouton, 1955). Vrugt (undated) found that when a confederate who was introduced as a higher-status graduate student of psychology violated

nonverbal rules in an experiment, it was more acceptable, since the behavior was considered to be intentional. But when a supposedly lower-status undergraduate did the same thing, it was attributed to an inability to behave suitably. In the same way, it has been found that group members address more remarks to high-status than to low-status members (Katz, Goldston, & Benjamin, 1958; H. H. Kelley, 1951). Sabath (1964) presented a confederate as a new member of either high or low status to groups who were performing discussion and construction tasks. During the construction task, the new member exhibited disruptive behavior, followed by actions that enhanced or impeded the group's performance of the task. The high-status disruptive member was seen in a generally favorable manner whereas the low-status disruptive member was viewed favorably only when that person's performance enhanced the group's functioning. Consistent with these results, Pepitone (1958) concluded from a research review that the higher the status of group members, the greater was the attribution of good intentions and justification to their positive and negative acts. Persons accorded high status were more acceptable as authority figures, and their idiosyncratic behavior received greater acceptance (Hollander, 1961a).

*Incorrect Attributions of Status.* Leadership can be incorrectly attributed to high status. The romantic theory of leadership suggests that effective leadership is often attributed to individuals because they have been in high-status positions when the business organization has been effective, when in fact external or internal factors such as market conditions, governmental regulations, or highly qualified employees were responsible for the effectiveness (Meindl, Ehrlich, & Dukerich, 1985).

*Effects of Self-Accorded Status.* When it mirrors status accorded by others, self-accorded status correlates with attempts to lead and to be successful as a leader. Guetzkow (1954) showed that key persons' ratings of their own importance to communication networks correlated with their influential behavior in the networks. If there was a mismatch between self-accorded and accorded status, the attempts were likely to misfire.

A common but not well recognized phenomenon, and a source of potential conflict, is the belief by all people in a hierarchy that they have bigger and more important jobs than their bosses think they have (Haas, Porat, & Vaughan, 1969; Volkerding & Grasha, 1988). Gold (1951–1952) described how interactions between tenants and the janitor in a multiple dwelling changed when the janitor's concept of his status changed as he adopted "professional standards" and began earning a higher salary than some of the tenants. The stage was set for conflict with those tenants who did not appreciate the janitor's changed concept of the importance of his job.

## ***Socioeconomic Status***

*Effects of Socioeconomic Status.* [Chapter 4](#) noted 15 studies through 1947 indicating that leaders were likely to come from a socioeconomic background according them higher status. For instance, C. A. Smith (1937) found that the leaders of an industrial town in Connecticut came from wealthy families with "connections." Many additional works followed in support. Hollingshead (1949) observed that Elmstown's young people displayed leadership behavior as a function of the social class of their family. Baltzell (1958) noted that the descendants of colonial merchants and statesmen, pioneering businessmen, and mining and railroad tycoons of Philadelphia all went to school with one another, lived in fashionable neighborhoods, were Episcopalian, joined the same clubs, intermarried, and eventually entered the elite class. They became the community leaders.

J. A. Davis (1929) found that only 19% of 163 Russian Communist leaders had peasant fathers, and only 29% had working-class fathers.<sup>1</sup> Taussig and Joslyn (1932) observed that 70% of the fathers of 7,371

American business executives were businessmen, although businessmen constituted only 10% of the workforce. Even labor leaders tended to be the sons of professionals and businessmen (Sorokin, 1927b).

Numerous studies of opinion leaders attest to the strong link between socioeconomic status and leadership. Switzer (1975) found that peasant leaders in a progressive industrial-agrarian department of Colombia were better-educated, were more economically secure, and had a clearer land title than peasant leaders in a rural, conservative department. Farmers in Orissa, India, were more effective in motivating other farmers to apply improved agricultural techniques if they were higher in socioeconomic status (Rath & Sahoo, 1974). In addition, Roy, Jaiswal, and Shankar (1974) reported that sociometrically identified leaders in four villages in Bihar, India, tended to be higher in caste and had greater landholdings than their followers. But Chesterfield and Ruddle (1976) warned that extension agents did not pay enough attention to the less-visible opinion leaders in rural Venezuela, such as relatives, symbolic kin, and older community members. The middle class in Muslim countries, not the peasants, supplied the leaders of Al Qaeda.

*Changes in Socioeconomic Status.* Systematic changes have occurred, both in the United States and abroad. In the United States, status increases with money, education, and marriage into a higher class. Starting in 1944, the GI Bill made it possible for many working-class war veterans to attend college. Before this, a college education had been possible mainly for middle-and upper-class students. As a consequence of the GI Bill, a large number of working-class veterans moved up in class by meeting and marrying women who came from the middle and upper classes. The reverse occurred in the communist world. After a decade of socialism, 96% of managers in Poland reported that they came from the working class or lower middle class (McClelland, 1961).

In the United States, the Air Force Command passed in the 1980s to officers whose background was quite different from those who had engaged in World War II. According to Margiotta (1976), because of broader social recruitment in the 1950s and 1960s, U.S. Air Force leaders in the 1980s became more representative of the U.S. population in terms of socioeconomic origin, regional affiliation, size of their hometown, and religion. As with the military, U.S. political, business, and educational leaders in the 1980s, 1990s, and the early twenty-first century have been drawn less often from the mainstream. Affirmative action, a broadening of the right to vote, and a liberalization of attitudes about race, ethnicity, and religion greatly raised the educational level, status, and leadership opportunities of disadvantaged minorities. However, leadership opportunities still remain somewhat less for those not of European ancestry and for ethnic and religious minorities outside the mainstream (Korman, 1988).

*Confounds.* Ability and status are likely to be confounded. For example, early studies (Davis, 1929; Sward, 1933; Taussig & Joslyn, 1932) found that intelligence, skill, and educational level tended to be higher among those who were higher in socioeconomic status. Middleclass adolescents may become school leaders more often because they are somewhat higher in verbal aptitude than working-class students. Regardless of the cause, most psychological studies indicate the existence of class differences in verbal aptitude. For example, among 140 college women, a significant correlation of .21 was obtained between verbal aptitude (as measured by the American Council on Education linguistic score) and socioeconomic status as measured by father's occupation, parents' education, and religious affiliation (Bass, Wurster, Doll, et al., 1953). The relationship between leadership and socioeconomic status is also confounded with the tendency of higher socioeconomic status to be correlated with greater education and opportunity. The collateral interrelations were apparent to Jencks, Bartlett, Corcoran, et al. (1979), who looked at 13 demographic variables having to do with fathers and sons and concluded that a father's occupation, family background, education, and intelligence are the best predictors of a son's occupational success. Although credentials, demonstrated by degrees in engineering, law, or business administration, provide avenues to success in business leadership, it also helps to marry the boss's daughter. Middle-class students can pursue more extracurricular leadership opportunities; working-class students

frequently have to put their time into part-time jobs. Celebrity, wealth, marriage, and education can also move one's status and influence upward. In the information age, education and knowledge have increased considerably in importance relative to the other variables.

The concordance of status and leadership is also confounded by the relationship of both status and leadership to how much time people spend with each other. Stogdill and Koehler (1952) found that the extent to which persons in lower organizational echelons mentioned an individual as one with whom they spent the most time correlated .82 with the mentioned person's level in the organization. However, these mentions of frequency of contact also correlated .31, .33, and .23 with being preferred as a leader. Time spent with persons in other units also correlated highly with the other person's level in the organization ( $r = .69$ ). Similarly, Browne (1949) found that an executive who was mentioned frequently as one with whom others spent time was also an officeholder who described himself as being higher in authority and who was in a higher echelon in the organization. Another confound with status was noted by Jackson and Fuller (1966), who discovered that lower-class pupils liked middle-class teachers better. They seemed to the pupils to be less authoritarian.

### ***Symbolic Value of Status***

Did Pascal overstate the case in suggesting that the nobleman would lose all his influence if he lost the power to control what lesser men wanted? The symbols, signs, and privileges would still make the poor nobleman's position valuable in the eyes of others—a continued source of envy, deference, and respect. The rich commoner might still be willing to exchange places with the poor nobleman or to pay handsomely to have him as a son-in-law. Others' perception of the legitimacy and value of the nobleman's privileged position in the societal hierarchy would still give him some influence apart from his personal qualities. Thus the poor nobleman's position would still provide *referent* power, and the rich commoner might still want to identify with the nobleman, regardless of the nobleman's impoverishment. Nevertheless, Pascal was right to some degree, for the absence of any real power attached to one's position generally results in the reduced ability to lead. Viteles (1953) talked about the first-level foreman as the "forgotten man," since the foreman was left with only some of the symbols of status but little control over his subordinates. In a study of an electric utility company, Pelz (1951) found that supervisors who attempted leadership behavior failed to obtain changes in their subordinates if the supervisors lacked influence with higher-ups, if they had no voice in decisions made by their superiors, if they lacked freedom from superiors' orders, and if their salary was low. Supervisors who were in positions that had more value and importance and had influence with higher authority were more successful when they made the same attempts at leadership. Influential supervisors were seen by their subordinates as being more able to obtain rewards and provide punishments for their subordinates. Supervisors who were unable to grant or deny rewards, despite their title and position, had the signs of status but were unsuccessful in leading their subordinates.

*Status of Celebrities.* Popular icons are famous, or sometimes infamous, personages. They are well-known figures but not necessarily heroes or charismatic leaders. As long as they remain highly visible, celebrities are extremely high in status and highly paid in relation to the general population. Their position as superstars—sports stars, rock music stars, movie stars, playboys, or aristocrats—is of much greater importance and value than their personal qualities because of the public image of their position that publicity agents and media hype create for them. That is, their image, rather than their talent, makes them influential. As long as they remain visible in their celebrated positions, the public will react toward them as if they were truly heroic or charismatic and will want to identify with them (that is, will want to be in their position as media stars). All or segments of the public will be ready to accept the testimonials of celebrities regarding products and politics. With some

exceptions, celebrity status generally tends to be ephemeral, declining with a decline in publicity. Popular television anchors who remain at their posts can maintain their celebrity status over a long career, but movie and sports stars tend to fade if their public careers are short.

## Esteem

---

Esteem is the value of each member of a formal or in-formal collectivity as a person, regardless of his or her position in the collectivity. It is each member's perceived potential to help the group, the organization, or society to attain goals, *independent of the position the member occupies*. Esteem is the person's *reputation* in the eyes of others. Recognition of differences in esteem among members is established during the history of a natural group (Sherif, 1967) and increases in discrimination with the age of the group (Lippitt, Thelen, & Leff, undated). Such evaluations of the adequacy of group members are found among children eight years of age or even younger (Campbell & Radke-Yarrow, 1956). Heroes and heroines are highly esteemed. They serve as examples. They have the ability to persevere and overcome the obstacles that impede others. They may become legends through their sacrifice for the benefit of others. They may be real or fictitious.

While ... [heroic] greatness appears almost magical, it is indeed most human. ... Because of that humanness ... individuals attain heroic stature. They are of us, but are clearly different. ... We look to heroes and heroines for inspiration. Through their achievements, we see humankind more positively. They make us feel good ... and feel proud. They may become definite role models, and our lives follow a different direction. ... By learning about their lives, our lives become enriched. Denenberg, 1997, p. 23

Those with more personal ability, regardless of their position, will be more esteemed, since they can be helpful to others through their ability to solve others' problems. They can help the group, organization, or society to attain its goals. In the same way, those with personal power, regardless of their position, will be more esteemed, since they can directly give or deny love, friendship, security, and other interpersonal rewards. It is possible for them to coerce others by manipulating such rewards, but they are likely to lose esteem if they do. People with esteem that is due primarily to their personal ability will be more successful in persuading others when they attempt to do so (Mowday, 1979). If their esteem depends on both personal ability and personal power, they can emerge as leaders (Bass, 1960). For children, the real heroes of the past such as George Washington have been replaced by cartoon characters such as Mickey Mouse; for adolescents, by the unreal world of 50 Cent; for adults by the hype of Tom Cruise. The picture of George Washington in one classroom was replaced by a cartoon of Snoopy (Dennenberg, 1997).

*Need for Esteem.* Maslow (1954) called attention to the need for esteem. Just as we would like to occupy valued positions, most of us also desire to be valued as persons, particularly by those we value (Wurster, Bass, & Alcock, 1961). Lippitt, Thelen, and Leff (undated) hypothesized that we are more concerned about being criticized personally than about being criticized for the social role we play. This concern with one's value was implicit in Festinger's (1954) theory of social-comparison processes. It results in the practical advice to supervisors that if they need to correct a subordinate's poor performance, they should focus on the performance, not the subordinate's personal motives, attitudes, or value.

We are more satisfied with situations and groups that provide us with esteem. For instance, Van Zelst (1951) indicated that highly esteemed workers were more satisfied with their jobs and with their firm. Heyns (1950) noted that participants who felt they were accepted were more satisfied with the decisions of a conference. But Flint, Bass, and Pryer (1957a) failed to find any relation between esteem of members and their attraction to problem-solving groups.

## Correlates of Esteem

The value, importance, or worth of a person as a person, regardless of the person's status, is in the eye of the beholder. *Pocketbook* voters will esteem a president according to their perception of his effect on their personal economic life; *sociotropic* voters will evaluate a president on what he does for the national economy (Kinder, 1981). Extensive evidence points to the ease with which members share perceptions of each other's esteem. Potential differences in esteem are quickly recognized by other members of a group (Gronlund, 1955a) as well as by trained observers (Stein, 1971).

*Importance of First Impressions.* Gronlund (1955a) observed that group members agree about as well on their relative esteem at the beginning of their interaction as after extended acquaintance. In experiments with dyads, Levinger (1959) found that although later behavior influenced a partner's behavior more than first impressions did, the first impressions tended to determine behavior throughout the experiment. Likewise, Barker (1942) found that after a few moments of getting acquainted, a group of strangers exhibited a high degree of agreement in choosing members for seatmates. Vielhaber and Gott-heil (1965) studied 117 cadets who were rated by four judges after only 20 to 35 seconds of observation. The judges' ratings correlated .45 with the upperclassmen's evaluations after four weeks of observation and correlated .31 with composite evaluations of aptitude for service made 14 weeks later. According to Hall and Lord (1996), these effects of first impressions are due to rapid cognitive processing of likes and dislikes.

Experimentally, it was possible to raise or lower the esteem of a neutral stranger merely by providing some false cues about the stranger. The results depended on others' attitudes toward those cues (Asch, 1946). H. H. Kelley (1950) introduced two persons to an audience, one as "warm," the other as "cold." The audience's perceptions of the personality of the two was altered by the adjective used in introducing them. The "warm" person became more esteemed than the "cold" person.

*Esteem and Self-Esteem.* As with comparisons of self-ratings and ratings received from others, in most situations—unless we are depressed, lack need for control, or are overly modest due to cultural inhibitions or a self-deprecating personality—our self-ratings of esteem tend to be more favorable to us than ratings of esteem accorded us by others. We overestimate our self-esteem. According to Thompson (1999), we have an illusion of control, and therefore of our personal influence if the situation is familiar to us, if we are personally involved, if we have foreknowledge about the desired outcome, and if we are focused on success. Even in circumstances with chance outcomes, we think we personally can influence the outcome. Gilovich and Savitsky (1999) offer a different explanation. When making judgments about ourselves, we anchor them in our own experiences. The *spotlight* effect biases our estimate. We overestimate the attention others pay to our behavior and appearance. We also overestimate the extent to which our unexpressed contributions to the group are discerned by the other members.

Agreement is not high between ratings of our self-esteem and the esteem that others accord us. Gronlund (1955b) correlated each individual's rank according to the others in a group with the individual's ranking of the other group members. The median rank order correlation was only .40 for 104 graduate students. Blake, Mouton, and Fruchter (1954) studied 10 trios in a discussion task. There was limited agreement between the individuals' ratings of themselves and the observers' ratings of them. Generally, 360-degree ratings of merit, leadership, and other personal appraisals highly related to esteem by superiors, peers, and subordinates have only low to zero correlations with self-ratings.

Chapter 8 detailed the importance to leadership of self-confidence and self-esteem. As was noted, Bass (1955b) found a correlation of .38 between self-esteem and emergence as a leader in initially leaderless groups,

but the correlations between self-esteem and objective success as a leader were only .17 and .18 for a total of 95 participants. Moreover, self-esteem may be quite different from the esteem accorded by another person. For instance, one would expect that those with extremely low or extremely high self-esteem would be too preoccupied with their own concerns to be highly esteemed by others (Reykowski, 1982). Nonetheless, one would ordinarily expect some correlation between self-esteem and esteem. Shapiro and Klein (1975) found such a correlation in encounter groups, but only after two days of meetings and only for a composite profile of the leaders as seen by themselves and by the nonleaders. Similarly, Willerman and Swanson (1953) found that members' evaluations of themselves were only modestly related to other members' evaluations of them.

*Accuracy of Leaders.* Leaders tend to be more accurate about their own esteem than are other members. But this tendency is not surprising, since everyone in the group can make more accurate judgments about the leader than about other members. The leader's behavior is more visible, more frequent, and more observable than the behavior of most other members (Bass, 1949). According to H. H. Jennings's (1943) sociometric analyses in a girls' school, a comparison of self-estimates with estimates by others showed that the "overchosen" (the stars) appraised themselves most accurately on having good ideas and making others feel benefited, whereas the "underchosen" (the rejectees and isolates) estimated themselves most accurately in expressing discouragement and being easily hurt.

*Agreement among Others.* Pairs of observers completed final ratings of esteem achieved in initially leaderless group discussions among members of similar status. Correlations between the pairs of observers ranged from .51 to .83. Similar results were obtained for ratings of cadet leaders. A reliability of .68 was obtained as an index of agreement among ratings by 2 to 17 ROTC cadets rating a total of 307 fellow cadets (Bass & Wurster, 1953a, 1953b). Prien and Culler (1964) found, however, that observers agreed better about those who participated a little than about those who participated a lot.

The sociometric ratings among very young children were inconsistent from one period to the next (Lazar, 1953). But according to Newsletter, Feldstein, and Newcomb (1938), as the age of campers increased, the stability of their sociometric ratings increased as well. Northway (1946) reported rate-rater correlations of .8 to .9 when summer campers raterated each other a week after a first rating. Bjerstedt (1956) reported correlations of .82 between ratings and reratings four months apart among 867 Swedish schoolchildren aged nine and older; even after 13 months, the rate-rater correlation was .73. McGuire, Lammon, and White (1953) found a similar consistency among adolescents from one year to the next. Even when half the children in a group, aged 6 to 12, are replaced with new members, the remaining children's ratings of esteem were consistent, to some extent, with earlier ratings (E. Campbell, undated).

*Popularity and Respect.* People desire to be respected, admire those whom they esteem, and want to be esteemed by those they esteem (Wurster, Bass, & Alcock, 1963). The acceptance of a stranger is related to his or her esteem and prestige (Byrne, Griffitt, & Golightly, 1966). Santee and Vanderpol (1976) found a correlation of .83 between being liked and being respected and a correlation of .78 between being liked and being seen to be of value to the organization. In Bass's analysis (1960) of five sociometric ratings of 203 salesmen by their associates, being liked correlated .60 with being seen as of value to the firm and .49 with being seen as capable. Graves and Powell (1988) found that 398 college recruiters rated applicants' subjective qualifications for being hired substantially higher if they personally liked the applicants.

*Perceived Similarity.* We esteem those whom we regard as most similar to us in attitudes, interests, and abilities. We tend to reject those whom we regard as different or unlike us. Thus Graves and Powell (1988) found that recruiters gave more favorable ratings to applicants if the recruiters considered themselves similar to the applicants. Also, we tend to choose as friends those who are similar to us or only slightly higher than us in

socioeconomic status (A. Ellis, 1956).

Many investigators have demonstrated that similarity in attitudes is a significant factor in sociometric choice.<sup>2</sup> Byrne (1965) found that acceptance of a stranger was related to similarity of attitudes. A stranger who was perceived to have attitudes similar to those of the raters was adjudged more intelligent, more moral, and better informed (Byrne, 1961). Furthermore, we particularly like others who are similar to us on socially desirable dimensions (Hendrick & Brown, 1971; Palmer & Byrne, 1970). We prefer those who share our group's norms and values (Stein, 1982b).

In numerous studies,<sup>3</sup> perceived similarity in personality characteristics is also significantly related to interpersonal choices. A review by Berscheid and Walster (1969) suggested that similarity of attitudes and personality was associated with mutual attractiveness and therefore with valuing of each other.

*Mutual Attractiveness.* People tend to like those who like them (Newcomb, 1956). Furthermore, the extent to which people are attracted to each other and the extent to which they actually interact are enhanced by their perceived similarity in attitudes and personality and even more by the degree to which they like each other (Aronson & Worchel, 1966; Byrne & Griffitt, 1966a, 1966b). For instance, the expectation of being liked by a participant in an experimental task was significantly related to interpersonal attraction (Backman & Secord, 1959; Darley & Berscheid, 1967). Similarity in competence also makes a difference in personal attractiveness. Thus Zander and Havelin (1960) found that members of experimental groups tended to be attracted to others whose competence was closest to their own.

*Competence.* M. A. Price (1948) studied esteem among 223 women in a junior college. Women who were esteemed by their schoolmates were mentioned on an 11-item "guess who" test as most similar to the person who has good ideas, expresses joy and satisfaction, keeps the central idea in mind, appeals for group loyalty, and makes others feel that they will benefit by following her suggestions. Women who were rejected were more frequently mentioned as being most similar to the person who expresses fear and worry and embarrasses others.

Bass and Coates (1953) found positive correlations between scores on intelligence tests and peers' ratings of esteem in the ROTC. The "ability" items that were listed on a peer-evaluation scale for assessing esteem among Marine cadets at Officer Candidate School (OCS) included "well trained," "experienced," "performs well before the group," "has sound judgment," "thinks quickly," "exhibits imagination," "is well educated," and "is a fine athlete" (Hoffman & Rohrer, 1954). Likewise, H. H. Jennings (1943) noted that institutionalized girls who were "overchosen" (those who were more desired as associates) exhibited more ingenuity, planning, and organization. The more esteemed members of Whyte's (1943) street-corner society were known for their resourcefulness and the past success of their ideas. In the same way, Zeleny (1946–1947) found that cadets with exceptional ability in flying were more likely to be chosen as flying partners. Similarly, Feinberg (1953) noted that regardless of economic background, esteemed adolescent boys were higher in athletic and scholastic proficiency than were those who were rejected by their peers. But in choosing friends, Riley and Flowerman (1951) suggested, we tend to select those who are "smart, but not too smart; pretty, but not too pretty."

Demonstrated competence increases one's esteem. Gilchrist (1952) found that people who consistently succeeded on assigned tasks became more attractive to others. Lippitt, Polansky, Redl, et al. (1952) reported that at a summer camp, boys with a history of success were most liked. Zander and Havelin (1960) found that those who were highly competent in experimental groups were preferred over those who lacked competence. And Jackson (1953a) noted that when members of a formal organization judged other members of the work group, they valued most those whom they perceived as having contributed to the achievement of the group's goals and having conformed to the group's standards.

An individual's ability to help the group can be increased, of course. R. E. Andrews (1955) suggested that

supervisors should be given as much information about policies and decisions as possible to enhance their standing with their subordinates. Whyte (1943) noted that leaders can increase or maintain their perceived value to their group by making sure the group engages in activities at which the leaders are most proficient.

*“Unearned” Esteem.* Yet it must be clear that one can be esteemed for a variety of reasons that have little or nothing to do with one’s ability to help the group. People may gain esteem merely because of their similarity to stereotypes or popular conceptions of esteemed or popular figures. For instance, youthful looks, gray hair, and a handsome face are strong political assets in television campaigning; immature facial characteristics (associated with infantile helplessness) will reduce a would-be leader’s expected value (Berry & McArthur, 1986). Also, one’s family name may carry great weight. The meteoric rise of George W. Bush to the office of governor of Texas and then the presidency is illustrative.

*Esteem, Conformity, and Deviations.* Before new individuals can be accepted by the other members of an established group and rise in esteem, they usually must demonstrate that they will abide by the rules of the group and share its ways of behaving and its goals (N. Anderson, 1923).<sup>4</sup> Thus Bonney and Powell (1953) found that the highly esteemed children in sociometric analyses were more cooperative. Likewise, Marwell (1966) found that experimental subjects chose those who had been cooperative on a first task assignment as partners for a second task assignment. Christie (1952) found that if a new army recruit increased his acceptance of the prevailing authoritarian attitudes, he was more likely to be esteemed by his peers after six weeks in service. Similarly, Havighurst and Taba (1949) noted that adolescents who conformed best to the middle-class standards of a school were most likely to be esteemed by their middle-class peers. Following a survey of the literature, Northway, Frankel, and Potashin (1947) concluded that esteem was highest in children who were not extremely shy nor so aggressive as to interfere with the group’s activities. However, Stein (1982b) theorized that highly esteemed members of a group only appear to conform to the group’s norms, since they actually exemplify them. They do not have to move from their own points of view to be seen as conforming to the group’s normative values and attitudes.

Numerous exceptions have been reported. Mumford (1959) found more deviation among highly esteemed canteen workers. Blau (1960) reported that when cases were unimportant, caseworkers deviated more from the norms about gossiping. Conformity to the ideals of one’s reference group may be more important than conformity to the opinions of a temporary group or a particular local group (Sherif & Sherif, 1964). What is most important, as Hollander’s (1978) theory and research demonstrated, is that the member with esteem who first conforms to the group builds up *idiosyncrasy* credit that permits him or her to deviate and to emerge as a group leader.

*Meeting Expectations.* We like and value those who behave according to our expectations. Thus Sharpe (1956) reported that the evaluation of principals’ effectiveness by teachers and staff was highly related to the principals’ conformity to the expectations of the teachers and staff. Jackson (1953) found that foremen were evaluated by subordinates according to the match between the foremen’s behavior and the subordinates’ expectations. Baumgartel (1956) reported the same kinds of results for the staff’s evaluations of the directors of a medical research center. Foa (1956) asked Israeli factory workers what they thought was the best way for a foreman to handle difficult situations involving workers, and how their foremen usually dealt with such incidents. Favorable evaluations of their foremen increased as the discrepancies decreased in how the workers thought the foremen should behave and how the foremen usually behaved. Tsui (1982) found that in a sample of 217 middle managers, the managers’ reputation for effectiveness correlated with their bosses’, subordinates’, and peers’ expectations about the managers’ role.

Santee and Vanderpol (1976) correlated the degree to which professors conformed to students’ expectations. One group of students rated their satisfaction with different professorial behaviors; another group of students

indicated which behaviors were typical of their professors and rated the professors' esteem. The professors' conformity to the students' expectations correlated .56 with the students' ratings of respect and .61 with the students' ratings of the professors' value to the university. Fulfilling campaign promises with legislation approved by Congress has been used as an index of public satisfaction with a president's performance. Reelected presidents from Wilson to Nixon fulfilled 75% of their pledges. Jimmy Carter, who fulfilled 60% of his campaign promises, failed to win reelection. The failure was also attributed to the importance of his failed pledge to reduce unemployment and inflation (Krukones, 1985). Because he had been able to fulfill so many of his campaign promises, Bill Clinton was reelected in 1996 and ended his second term in office with high approval ratings despite the scandals that had marred his presidency.

### ***Esteem and Leadership***

Interviews with 11 chief executive officers led Bruce (1986) to conclude that the CEO's status and the power accruing from their top position in the firm were not enough to ensure their success in office. Their first task was to gain acceptance and to get a lot of people in the organization to know and trust them personally. They had to see the company and to be seen. The CEOs took control in such a way that their firms began to take on their personal character.

*Esteem and Successful Influence.* Bird (1940) concluded that leadership reflects the esteem in which the member is held. Similarly, Homans (1950) proposed that those of "higher social rank" in a group initiated the interactions with others. Lazarsfeld, Berelson, and Gaudet (1948) suggested that the influence on opinion of personal contact depended on trust in esteemed persons. Sims and Manz (1981) noted that esteemed leaders attract more attention to themselves and, therefore, could serve as models in organizational life. Rosenthal and Frank (1956) reasoned that the efficacy of psychotherapy depended on the patient's confidence in the therapist.

Brim (1954) discovered that mothers were more willing to adopt recommended child-rearing practices if they esteemed the physician who suggested the new methods. But esteem of the physician was not enough to sustain the new behavior. To sustain the new behavior, approval and support from their husbands was also required. Lanzetta and Haythorn (1954) observed that the more students esteemed their instructors, the more their opinions would coalesce with those of the instructors.

Garrison (1933) obtained a correlation of .82 between the tendency of high school seniors to be admired and their tendency to be chosen as leaders. Page (1984) showed that U.S. presidents from the 1930s to the 1970s could move public opinion on such issues as inflation, energy, foreign policy, and civil rights only if their performance in office was approved by the public. If their performance was disapproved, they either had no effect or actually pushed people farther from their positions.

*Sociometric Evidence.* In sociometric studies, members of a group nominate the person or persons in the group with whom they spend the most time or with whom they prefer to work, to play, and so on. "Stars" receive many nominations; "isolates" receive few or none. As more attractive persons, stars are higher in esteem than isolates. In his seminal sociometric studies, Moreno (1934/1953) observed that the higher the esteem of group members, the more nominations they received and the greater was the volume of words expected and accepted from them by other members. The esteemed member was more frequently permitted to assume the initiative and to terminate activities. In the same way, H. H. Jennings (1947) found that the sociometrically "overchosen" in a girls' institution exhibited four times as much behavior described as "making new events happen" or "enlarging the extent of activities" as the "average chosen." When the girls were free to choose a leader, H. H. Jennings (1943) observed, they tended to select someone who displayed spontaneity and enlarged the field of action for others. C. A. Gibb (1950) and Borgatta (1954) indicated that ratings of the

effectiveness of leaders were highly related to the leaders' ratings as desired work partners but were unrelated to their ratings as persons desired as friends. The member who showed a great deal of initiative and participation attracted a large portion of the positive emotional responses of the other group members. Similarly, Newsletter, Feldstein, and Newcomb (1938) found that an individual's leadership in a group was determined largely by the cordiality received from others rather than by the leader's cordiality toward others.

*Peer and Buddy Nominations.* The highly chosen tend to be successful leaders in future settings. This tendency has resulted in the use of nominations by peers and buddies to forecast the subsequent success of leaders in the military. From World War II onward, peer ratings of esteem by cadets in Officer Candidate School or the military service academies have been found to be one of the best single predictors of subsequent success as a regular U.S. Army officer (Haggerty, Johnson, & King, 1954). Thus, a correlation of .51 was obtained between esteem among peers at West Point and rated success as an infantry officer 18 months later. A correlation of .42 was obtained between esteem among fellow trainees in Officer Candidate School and combat performance as a U.S. Army officer (Baier, 1947). Similar results were reported by the U.S. Air Force (1952) and the U.S. Marine Corps (Wilkins, 1953; Williams & Leavitt, 1947b).

*Evidence from Leaderless Group Discussions (LGDs).* A strong case can be made for the personal factor from studies using an initially leaderless group discussion (LGD) to assess esteem and leadership during the discussion and again in real life as much as two years later. In these small-group discussions, in which no member is appointed leader, high correlations were found between ratings by observers or peers of the value and contribution of members to the group and their influence and emergence as leaders of the group (Bass, 1954a). Moreover, those members who were esteemed most highly by their peers had the most influence on the other members and on the group's decision, according to objective measurements of changes in opinion (Bass, 1955a). Elsewhere, Bass (1961c) reported that attempts to lead were more successful among able and esteemed leaders, especially when the congruence between the leaders' esteem and self-esteem was great. Wurster, Bass, and Alcock (1961) obtained results with 95 LGD participants indicating that they felt more responsive toward the suggestions and opinions of persons whom they esteemed than toward those of people in general. Thus the highly esteemed person had an advantage in opportunities to influence others because the others tended to feel responsive toward his or her behavior. Bass (1954a) reported a median adjusted correlation of .51 for 17 studies of emergence as leader in LGD and subsequent appraisals of meritorious leadership performance from one week to two years later. The criteria included rated merit as a U.S. Army cadet and officer (Weislogel, 1953), nominations for positions of leadership in a sorority or fraternity (Bass & White, 1951), rated potential and general merit as a civil service administrator (Arbous & Maree, 1951), rated adequacy as a foreman (Mandell, 1950a; Wurster & Bass, 1953), and rated suitability for the foreign service of South Africa (Vernon, 1950). Similar findings were reported for British supervisors (Handyside & Duncan, 1954), Finnish foremen (Rainio, 1955), and military trainees (Gleason, 1957).<sup>2</sup>

*Leadership and Perceived Helpfulness.* Leaders will be successful to the degree that they are seen as having the potential to be helpful. In 72 business and governmental conferences, Crockett (1955) noted that emergent leaders were rated as members who were most needed by the group. In another study of industry, N. A. Rosen (1969) obtained ratings of workers' preference for eight foremen. Foremen who were high and low in preference then changed places. The findings suggested that the new foremen were evaluated in terms of their ability to help the group. The greater the consensus among the workers in weeks 1 to 10 that the new foreman "is our leader," the greater was the increase in productivity and cohesiveness in weeks 11 to 16. Also, S. Rosen, Levinger, and Lippitt (1961) found that schoolchildren and college students rated helpfulness and fairness as the most important traits that enable individuals to influence others; and that adults rated fairness

first and helpfulness second in importance. Kelman (1970), Olsen (1968), and Sells (1968) placed particular importance on the confidence and trust that followers had in their leaders. In turn, such confidence and trust in the leader were linked to the competence of the leader. In a report on 72 men in the Antarctic for a year, P. D. Nelson (1964b) concluded that what differentiated leaders from nonleaders in maintaining their esteem was their stronger motivational commitment to the group.

Feelings about the helpfulness of leaders are multidimensional. R. D. Mann, Gibbard, and Hartman (1967) obtained college students' expressions of feeling toward different leaders as well as descriptions of the followers' responses. The data were factor-analyzed. Among the factors that emerged were feelings about the leader as an analyst, as an authority figure, and as committed to the leader-member relationship. The investigators found that the leaders were esteemed for supporting the members' independence, identification, and social closeness. But M. G. Evans (1973) and Lawler and Hall (1970) noted that such perceived esteem in leaders can be induced in subordinates by their own needs and desires for particular behaviors by leaders. The distortion becomes great in the charismatic leader who may be perceived by followers as a savior. Leaders of therapy groups were seen as more helpful if they were evaluated as higher in self-disclosure and as more mentally healthy (May & Thompson, 1973). Bolman (1973) reported on the extent to which therapeutic improvement occurred according to individuals' and peers' ratings of the members of therapy groups. A favorable characterization of the therapist helped, but Bolman failed to replicate previous findings in which liking the therapist as a person contributed to improvement in the members. Though how well one is liked may increase one's emergence as a leader (Schubert et al., 1974), being liked is not necessarily a substitute for esteem in contributing to the leader's performance.

*Visibility, Likeability, Esteem, and Leadership.* Numerous commentators have pointed out that it is important for aspiring managers to make themselves visible to those with higher authority in order to increase their prospects for promotion. Tagiuri and Kogan (1957) found that self-confidence enhanced an individual's visibility in a group. Although visibility made some contribution to a person's emergence as a leader, it did not make as much of a contribution as did the person's perceived value to the group.

Being liked, popular, and chosen as a friend tend to make some contribution to emergent leadership, but not as much as esteem does. Numerous investigators have found nominations received for leader and for friend to be positively correlated.<sup>6</sup> Duncan (1984) observed that managers who were first seen as friends by employees could then be admitted to the employee's "humor network." Perceived friends could become initiators and foci of work-related jokes. However, friendship tended to correlate less with leadership than did other variables, such as nominations for followership and amount of participation (Lana, Vaughan, & McGinnies, 1960).

Bass (1960) found that influence is more strongly associated with one's sociometrically rated value and ability than one's sociometrically determined popularity and visibility. [Table 10.1](#) shows the results of such a sociometric study of 203 salesmen. In each of their sales units, the salesmen nominated seven others as "liked as a coworker" and rejected seven. They repeated these nominations for "value to the company," "ability to solve the company's problems," and "influence." Each salesman's score was the number of his nominations less the number of rejections by others on each criterion. His visibility was the percentage of all salesmen in his division who knew him. Being of value and ability correlated .68 and .74 with influence; being visible correlated only .29 with influence; and being liked or popular correlated .50 with influence. Visibility and popularity were unrelated; but as Riedesel (1974) noted popularity and likeability systematically confound sociometric studies of the esteem-leadership relationship. In all, it would appear that being liked and being visible may still be of some importance to one's influence, but in general, perceived competence and values are of much more importance to leadership. Nevertheless, being visible to higher-ups remains important in moving up the career ladder. Organizations and cultures differ in what is found estimable, so it is expected that in an organizational

culture in which only the “bottom line” is valued and the well-being of its constituents is disregarded, esteem will accrue to the hard-driving, ruthless leader who brings victory over competition. Polls conducted in Russia early in the twenty-first century indicate that despite the killing, imprisonment, and starvation of millions of innocent victims, and despite his authoritarian mismanagement, Stalin is still esteemed by 20% of the Russian public for successfully building the Communist Soviet Union and for defeating Nazi Germany.

## ***Status and Esteem***

It is often difficult to sort out whether members’ value and contribution to the group, organization, or society is due to the information, control, and importance of their position or to their personal qualities. In fact, since more qualified people are ordinarily promoted and occupy higher-status positions in an organization, a positive correlation is expected between members’ status and their esteem. This was found in experimental groups (Flint, Bass, & Pryer, 1957b). Additionally, status is often gained through personal ability and effort. Persons who are likely to be esteemed because of their personal characteristics are also likely to be promoted to positions of greater worth in formal hierarchical organizations. Thus esteem often leads to the achievement of a higher status (Pellegrin, 1952). Promotion to a higher status in industrial and military organizations often depends on superiors’ ratings of one’s worth to the organization, although, of course, upward mobility in status can also be due to chance, tradition, or favoritism—unrelated to one’s esteem.

According to Sherif and Sherif (1953), those in positions of control (high status) are perceived by others to be endowed with superior personal traits. Perlmutter (1954) confirmed that the greater the perceived capacity of individuals to influence the perceiver, the more traits will be assigned to them and the more desirable the traits will be. In the same way, Courtney, Greer, Masling, and Orlans (1953) noted that military recruits who were given positions with the most responsibility and authority were most esteemed. Barnard (1951) agreed that abilities would be imputed to persons of higher status even when the abilities could not be recognized. This, he suggested, was a way that low-status followers maintained their own self-esteem. The followers rationalized that they were being *persuaded* by the most capable members of the organization, rather than *coerced* only because of differences in status.

Table 10.1 Median Intercorrelations among Five Sociometric Ratings of 203 Salesmen by Their Associates

<i>Visibility</i>	<i>Popularity</i>	<i>Value</i>	<i>Ability</i>	<i>Influence</i>
Visibility	-.05	.39	.38	.29
Popularity		.60	.49	.50
Value			.73	.68
Ability				.74

SOURCE: Adapted from Bass (1960, p. 282).

Esteem was found to be higher for individuals with the status of owners and professionals in agricultural communities (Hooker, 1928). Likewise, among three canteen work groups, those living at higher socioeconomic levels were more esteemed (Mumford, 1959). Prestige and popularity were observed to be higher for persons who were heads of organizations in their communities (J. E. White, 1950). D. T. Campbell (1953) noted that among the crews of 7 out of 10 submarines, the commanding officer was most esteemed. He received the most nominations as the person others wanted to see in command. Merit ratings (esteem) of military officers tended to be higher if their military rank was higher (Robins, Willemine, & Brueckel, 1954). A review of efficiency ratings from 1922 to 1945 revealed a positive correlation between the rank of officers and their merit ratings. In Korea, those at higher grades in the service received more favorable ratings of their

performance in combat (U.S. Army, 1952). In a study of 1,900 military personnel, Masling, Greer, and Gilmore (1955) found that the higher individuals ranked in the military organization, the greater the number of favorable sociometric mentions they tended to receive in regard to both military and personal matters.

The fact that status and esteem are correlated may be a valid assessment of the value of both the positions and the personal qualities of the people involved. When status and esteem are truly mismatched, the lack of correlation may reflect the overevaluation of esteem associated with an accurate appraisal of status. Thus almost all high-ranking military officers are usually appraised as excellent or superior in performance. An appraisal may also reflect the overevaluation of a position because of the high esteem earned by the occupant. For example, although paraprofessionals have lower status than registered nurses, the importance of the paraprofessionals' position may be raised significantly in the eyes of patients if the patients think their well-being depends more on the performance of the paraprofessionals than on that of the nurses.

*Maintaining Esteem and Status.* Subordinates value and esteem leaders who are considerate of their needs and who avoid being domineering (D. T. Campbell, 1953). Leaders will lose their esteem if they fail a group or if, as was mentioned earlier, they use their esteem to coerce members into accepting their influence and if they threaten to withdraw support and affection. Conversely, the esteem of leaders will be enhanced if they effectively contribute to their groups' success (Bass, 1960). More important positions and higher status will be assigned to those who are seen to contribute or who have the potential to contribute to the well-being of others or the success of the organization.

## Trust

---

Americans' trust of business, government, organized religion, and one another has been declining rapidly in the past four decades. In 1996, 55% of those polled said they had confidence in big corporations, big government, and organized religion. By the early twenty-first century, such trust was down to 23%. Since 1960, trust in other people had declined from 50% to 30%. The many business scandals and stock and accounting frauds accelerated the mistrust of business corporations. There was a marked decline in trust in companies of 19% between 2002 and 2006. The attacks of 9/11 and the war on terror caused a turnaround in trust of government. Americans' trust in their fellow citizens rose to 65% (compared with 3% in Brazil). Nevertheless, the increasing disparity in the incomes and wealth of the rich and the poor in the United States and the economic segregation of the rich and poor in urban neighborhoods and suburbs increased mistrust among the poor (Purdy, 2004). A similar decline in trust occurred in many other countries. In December 2005, a poll in France found only 1% of voters saying they would support President Chirac's reelection in 2007. Declines in the public's trust in business ranged from 11% to 36% in Germany, Turkey, Canada, and Spain in polls in 2004 and 2005. Trust in business fell from 5% to 9% during those same years in Mexico, China, Indonesia, India, Britain, and Brazil (Kingsbury, 2006).

*Meaning.* Trust in a person has been defined as "reliance on the ... authenticity of a person ... in the absence of absolute knowledge or proof of ... the truth. ... Trust represents our best guess that [the person] is as he or she is purported to be" (Fairholm, 1995, p. 11). Trust in a leader is a follower's belief and willingness to act on the basis of the leader's words, actions, and decisions (McAllister, 1995). In trusting the leader, the follower increases vulnerability to the leader (Deutsch, 1962). Blind trust with no realistic knowledge of the leader, or with no assurance of the truth about the leader, is fraught with risk (Fairholm, 1995).

*Importance to Leadership.* Trust in the leader has become a particularly prominent issue in the study of leadership. Brinkly (1994) argued that the erosion in public confidence in our politicians is due to lack of trust

in their leadership. For Butler and Cantrell (1984), interpersonal trust is a determinant of the amount of cooperation to be expected between subordinate and superior. Podsakoff et al. (1990) found that it was the important intervening variable in a factor-analytic investigation of transformational leadership. Jung and Avolio (2000) conducted a controlled brainstorming experiment with 194 undergraduate business upperclassmen in groups led by two confederates who were trained in either transformational or transactional leadership. The task was to recommend ideas for improving education. Path analyses showed that trust in the leaders and value congruence with them mediated the extent to which the quality of the ideas (long-term orientation and innovativeness) was significantly augmented by transformational but not transactional leadership. There were both direct and indirect effects on the participants' subjective satisfaction with the leadership.

"There is scarcely any form of economic activity, from running a dry-cleaning business to fabricating large-scale integrated circuits, that does not require social collaboration" (Fukuyama, 1997, p. 6). Unless it can be tightly controlled by habit, contract, law, rules, norms, and regulations, such collaboration requires trusting relationships to be effective. *Mutual trust* is an important outgrowth of the exchange between a leader and a member of a group. As leader-member exchanges (LMXs) continue, the leader and the member evaluate each other's ability, benevolence, and integrity. If the evaluations are positive, trust is built between them (Brower, Schoorman, & Tan, 2000).

*Correlates of Trust in the Leader.* Ordinarily, trust in the leader is likely to be correlated with the leader's esteem. It involves confident positive expectations by the follower of the leader's motives regarding the follower in circumstances that are risky for the follower (Boon & Holmes, 1991). The leader's status also makes a difference. Those who were higher in status, as indexed by their position in the organizational hierarchy of a large Australian mining firm, were more trusting of their superiors. They perceived themselves to be more influential than did those supervisors and employees of lower status (Savery & Waters, 1989). Transformational leaders appeared to generate more trust. Den Hartog (1997) found that among 1,289 subordinates in six Dutch organizations, trust in management was greater with charismatic, inspirational, and individualized considerate leadership than with transactional leadership. Jung and Avolio (2000) obtained a correlation of .56 between experimentally created transformational leadership and rated trust in the leader. Blackburn (1992) reported that trust in a leader was increased by participation of subordinates in decision making, and by clear and open communications (Blackburn, 1992). Leaders who explained decisions, delegated, shared control, and showed concern also contributed to trust (Whitener, Brodt, Korsgaard, et al., 1998). But in South Africa, Engelbrecht and Cloete (2000) did not find (as they expected) that how long the supervisor and subordinate had worked together moderated the effects of the supervisor's integrity and benevolence on the trust in the supervisor.

Antecedents to trust in quality LMX relationships have included credibility (Butler, 1991), congruence of values (Sitkin & Roth, 1993), and previous positive outcomes (Gabarro, 1979). Brockner, Siegel, Daly, et al. (1997) conducted telephone interviews with 354 employees. The investigators found that subordinates trusted management if procedures were fair ( $r = .64$ ); the outcomes of their supervisor's decisions were favorable to them ( $r = .63$ ); and they supported their supervisor ( $r = .70$ ).

Unconditional trust was expected to be based on mutual respect and shared values (Jones & George, 1998). Hua (2003) argued that the subordinate's reaction to uncertainty and vulnerability serves as a frame for evaluation of management behavior, generally, which in turn affects trust in the supervisor. Supportive evidence was collected in China and the United States. Kouzes & Posner (1993, p. 108) summed it up: "To be trusted ... we [leaders] have to extend ourselves by being available, by sharing ... personal experiences, and by making connections with the experiences and aspirations of our constituents."

*Personality and Trust in the Leader.* Leaders differ consistently from each other in personal traits associated with how much they can be trusted by their subordinates. Subordinates' trust in their supervisors was linked to the supervisors' integrity and benevolence (Mayer, Davis, & Schoorman, 1995) and to the leader's integrity and ability (Boies & Corbett, 2005). Along with integrity and benevolence, supervisors' competence appears linked—though to a lesser extent—with the tendency to be trusted (Engelbrecht & Cloete, 2000). Other personality traits of consequence to being trusted include loyalty, respect, openness, receptivity, discretion, fairness, honesty, judgment, and consistency. It remains controversial whether or not the traits also apply to supervisors' trust in their subordinates (Schindler & Thomas, 1993). Behaviors and expressed attitudes that increase a leader's trustworthiness in the eyes of followers include caring, helping, moral character, and willingness to serve others.

*Stages in the Trust Relationship.* According to Lewicki, Stevenson, and Bunker (1997), trust between people is dynamic and develops over time. In the leader-follower relationship, early on a follower's trust in the leader is a matter of calculation. The follower learns under which circumstances the leader rewards performance and under which circumstances the leader imposes discipline and penalties. In the second stage of the development of trust, the follower learns about the leader's attitudes and behavior in different contexts and the leader's reactions in different situations. In this second stage of trust development, inconsistencies in the leader's reactions can be forgiven if they are understood by the follower. In the third stage of trust in the leader, the follower identifies with the leader's wants and intentions. The follower appreciates and understands the leader's needs and can effectively act for the leader. The leader can be confident that his or her interests will be protected—for the leader's development of trust in the follower will parallel the three stages of the follower's development. At first, the leader's trust in the follower will not be high and will also be a matter of calculation. The leader will monitor, reward, or take corrective action based on the follower's performance. Trust becomes information-based in the second stage, as the leader learns that the follower can be depended on to do the right things and to do them well. In the third stage—identification—the leader can confidently expect that the follower will be cooperative and can share their common goals. According to Lewicki, Stevenson, and Bunker's (1997) factor analyses of ratings of trust in others by 482 undergraduates, the three stages could be determined by a single general factor. The two ratings of trust with the highest factor loadings were: "This person and I really stand for the same basic things" (.88) and "This person and I share the same basic values" (.87).

*Authenticity and Trust.* Authenticity and trust have been stressed frequently in theory and research on leadership. I have already noted the repeated appearance of trust as an important aspect of interpersonal communications. In one of many such studies, Sgro, Worchel, Pence, and Orban (1980) obtained significant positive correlations between Rotter's Interpersonal Trust Orientation Scale for 41 cadet leaders and how satisfied their subordinates were with the leaders. The trust scores of their subordinates were related to positive evaluations of them on various dimensions of behavior, such as consideration, tolerance for freedom, persuasion, and initiation of structure. A leader caught in insincerity, duplicity, deceit, and double-dealing would be hard to trust. A trustworthy leader would be seen as expressing genuine feelings and thoughts.

Smircich and Chesser (1981) constructed and evaluated a highly reliable standardized questionnaire for subordinates to use in describing the authenticity of their superiors. Convergent validity was demonstrated. The measure of authenticity dealt with existential aspects of the superior-subordinate relationship, for example, "My relationship with my superior is open and direct." It had sociological elements ("My superior shows flexibility in carrying out the role of supervisor"), empathic aspects ("My superior could step into my shoes and know how I feel"), and social-psychological issues ("When we talk, I know my superior really listens to me"). However, authenticity did not necessarily mean mutual understanding between superiors and subordinates.

The authenticity attributed to the superiors was of no consequence for 141 subordinates and 58 superiors whose respective ratings of the subordinates' performance did not agree.

## ***Building Trust***

Hackman and Johnson (1991) suggested five nonverbal ways for the leader to build trust and confidence: (1) Maintain eye contact when talking to others and avoid shifting the eyes, looking away, and downcast eyes. (2) Use spontaneous gestures to emphasize points to convey emotional intensity, and avoid too many pauses or speaking too rapidly. (3) Maintain an open, relaxed posture and avoid keeping hands and arms crossed and close to the body. (4) Maintain a conversational speaking tone with a varied rate, pitch, and volume. (5) Avoid wearing dark glasses, which convey a stereotype of untrustworthiness. Six other suggestions they made are: (1) Be consistent by knowing your own values and clarifying to yourself what you believe; (2) Appreciate the followers and what they believe. (3) Affirm shared values. (4) Help followers to develop. (5) Create a sense of direction. (6) Sustain hope.

Trust in leaders is enhanced by the way they explain their decisions (Whitener, Brodt, Korsgaard, et al., 1998). If subordinates judge the explanation for the decision procedure and the process to be adequate, the decision maker will be rated as more trustworthy than if the explanation and process are judged inadequate (Shapiro, 1991). Adequacy requires more information about the logic and fairness of the decision (Bies, Shapiro, & Cummings, 1988). Lee Kuan Yew was reelected to office by overwhelming majorities for 30 years and was of prime importance in Singapore's rapid economic development, cultural maturity, and political stability as a "guided" democracy. Despite its lack of natural resources, the small former British colony rose in the 30 years to a modern postindustrial state with one of the world's highest per capita incomes. An important factor was the trust placed in Lee by the electorate; this trust was built by his words and deeds. Twenty-six of his annual National Day Rally speeches were content-analyzed by M. D. Barr (2000–2002). His rhetoric appealed to tradition and the desirability of continuity to connect present and future goals to the past. He noted past successes and the need to overcome threats to future successes. He expressed confidence that constituents would meet present and future challenges. He also expressed self-confidence, though indirectly—modesty is a requirement of Chinese culture. Similarities between Lee and his constituents, rather than their differences, were emphasized, as was the collective identity of the three largest ethnic groups: Chinese, Muslims, and Tamils. "We swim or sink together." Lee pointed to adherence to a specific set of values and principles to gain the electorate's trust.

Elsbach and Eloffson (2000) conducted an experiment comparing explanations for decisions that were hard or easy to understand and were or were not legitimated. In contrast to technical explanations, which were hard to understand, trust was much higher when the explanation was in simple language and easy to understand, with cues about the motives and character of the decision maker rather the logic of the decision. Legitimation was of consequence only when the decisions were hard to understand. The authors suggest that the decision maker may not be trusted if decisions are explained only in technical language that is hard to understand or dependent on expert systems. To build long-term trust, leaders need to spend time preparing explanations of their decisions and need to consider the language and labeling of the explanations.

## ***More on Effects of Trust***

To paraphrase Kouzes and Posner (1996, p. 5), the credibility of a leader's message rests on trust in the messenger. Such trust depends on belief in the messenger as honest, forward-looking, inspiring, and competent. One cannot lead successfully without trust. Considerable evidence bolsters the expectation that

effective teamwork hinges on mutual trust between team members and the team leader (Day, 2001). The level of trust between school principals and teachers correlated with the teachers' agreement about teacher certification policy regardless of their principal's position on the issue (Steele & Pinto, 2005).

Martin (1996) examined the effect on 22,000 subordinates' ratings of 4,454 executives when the executives exhibited more trust-directed behaviors, and the effect on subordinates' favorable attitudes. Trust-directed behaviors of the executives were strongly correlated with subordinates' favorable attitudes; this correlation was stronger even than correlations of rated "executive vision" behaviors with subordinates' attitudes. However, trust combined with vision yielded the most favorable attitudes. Martin pointed to the value of executives' establishing an organizational environment in which trust is pervasive and essential to successful leadership.

Dirks (2000) examined trust in the coach among 355 basketball players in a men's college conference. He found that it correlated .57 with future performance and .60 with past performance of the teams. The teams' talent and experience added to the prediction of performance, but trust in the leader was an antecedent as well as a consequence of successful performance by these teams. A meta-analysis of 106 findings based on 847 to 10,631 cases was conducted by Dirks and Ferrin (2002). They examined antecedents and consequences of trust in the leader. Antecedents that were predictive of trust in the leader included transformational leadership (.72), transactional leadership (.59), and participative leadership (.46). Perceived distributive, procedural, and interactional justice, respectively, predicted trust with correlations of .50, .61, and .65, but length of relationship did not predict it ( $r = .01$ ). Unmet expectations correlated 2.40 with trust. In turn, trust predicted outcomes including job satisfaction, .51; job performance, .16; and various organizational citizenship behaviors. Intention to quit correlated 2.40 with trust. In another study, of 1,686 employees, when decisions were made by higher authority with outcomes perceived as unfavorable to the employees, such as relocating work facilities or ordering job layoffs, the establishment of trust in supervision overcame what would have been adverse employee reactions to the decisions (Brockner, Siegel, Daly, et al., 1997).

Trust in management and in the immediate supervisor also goes along with commitment to the leadership and the organization, according to many studies. An ethical trusting relationship between subordinate and superior is established if the subordinate is able to align personal with organizational values, to disclose thoughts and feelings, to seek and learn from constructive feedback, to think and behave independently, to move beyond self-interests, and to work in a warm, friendly, open, and cooperative environment (Rusaw, 2000).

## Summary and Conclusions

---

The value of a person's position in a group or organization is the person's *status*; the value of the person to others—to the group or organization—is the person's *esteem*. Consensus about status and esteem is usually established quickly. More knowledge is usually associated with those in higher-status occupations and positions. Throughout history, differences in the value of positions and differences in the value of occupations have been recognized. In 2002, the average compensation of a CEO was 200 times that of the lowest-paid employee. The rate doubled by 2005. Upward mobility in status is sought and downward mobility is dissatisfying. Individual members of a group or organization can be more coercive if their accorded status depends on their personal control of what is desired by others in the group. Such members will attempt more leadership. However, continued direction, particularly if it is coercive, may lead to resentment and loss of esteem. High-status people can also be more influential because others pay more attention to them and tend to judge their behavior as more acceptable. High-status people can break the rules more easily ("The king can do no wrong"). Conflict arises if accorded status is mismatched with self-accorded status, but the status accorded to figureheads without real power will still give them some influence.

Individuals tend to choose friends whose social status is similar to their own. Group members, however, tend to prefer highly esteemed and high-status persons for positions of leadership. Members interact more frequently with these highly esteemed and high-status persons than they do with low-status members without esteem; they also accept high-status, highly esteemed people more readily as authority figures, justify their actions on behalf of the group more readily, and exhibit more tolerance of their deviant behavior. The highly esteemed members with high status are permitted to suggest innovations in the group, but they are not expected to interrupt or otherwise to behave inconsiderately toward low-status members with less esteem.

Members of a group quickly size up the leadership potential of a new member. Status evaluations that are made on first acquaintance are rather highly correlated with evaluations made several weeks later. Group members tend to choose other members, as well as leaders, whose values, interests, and personalities are similar to their own. They tend to regard leaders as more attractive than members of lower status, and to consider both the positive and the negative actions of high-status members as legitimate.

We tend to evaluate ourselves in terms of the reactions of others. The more attractive the group, the greater its impact on the members' evaluations of themselves. For this reason, a loss of status is damaging to the members' self-respect, particularly if the downward mobility is interpreted as evidence of decreased liking by other group members. A loss of status may be accompanied by a decline in performance, reduced liking for the task and the group, and feelings of hostility. However, ordinary members may reject the opportunity to rise in status if doing so involves radical changes in responsibility and style of living that are in conflict with their self-concept and system of values. Thus those who become leaders appear more willing to accept the responsibilities that accompany the rewards of high status.

The concomitants of esteem include respect, admiration, being liked as a person, and being judged as competent. But esteem may also be earned for irrelevant reasons. Furthermore, esteem may be misjudged as status, and vice versa. Members can be more persuasive if their esteem depends on their being perceived as able to solve the group's problems. To gain esteem, they first need to conform to the rules, but thereafter they can begin to innovate and deviate without losing their esteem. Assumed similarity of beliefs, attitudes, and values contributes to being esteemed and attractive to others. We lose esteem by violating others' expectations of us.

Considerable evidence from sociometric research—use of the LGD, and studies of students, salesmen, managers, school principals, military officers, and therapists—demonstrates the contributions of esteem and perceived helpfulness to success as a leader above and beyond considerations of visibility and likeability. The esteemed leader may achieve charisma in the eyes of others.

Trust of followers in the leader is linked to the leader's esteem. Strongly related to trust in the leader is the follower's perception of the leader's competence, caring, integrity, and willingness to serve others. Also important are the leader's accuracy and consistency in communications that explain decisions in simple, easily understood language. Perceived authenticity is likely to make a difference as well.

<sup>1</sup> After generations of communism, leaders were likely to emerge from the new privileged classes of party members, intellectuals, military officers, and managers.

<sup>2</sup> See, for example, Byrne and Clore (1966); Davitz (1955); Fensterheim and Tresselt (1953); Fielder, Warrington, and Blaisdell (1952); and A. J. Smith (1957).

<sup>3</sup> Hoffman (1958); Izard (1960); Lindzey and Urdan (1954); Lundy, Katkovsky, Cromwell, and Shoemaker (1955); Secord and Backman (1964); and Steiner and Dodge (1957).

<sup>4</sup> See also Merei (1949), Pellegrin (1953), Thrasher (1927), and Whyte (1943).

<sup>5</sup> As will be noted in [Chapter 35](#), the LGD is now a routine part of management assessment centers.

# Power and Leadership

Power as an engine of influence and leadership has been of concern to priests, philosophers, and kings since the beginnings of civilization and to chiefs and medicine men before that. Who can influence whom clearly depends on who is more powerful and who is less so. Only with God on his side could Moses persuade the pharaoh to let his people go. Shakespeare's plays are filled with concern about power and innocence, failing power, and personality and power (Hill, 1985). "To say a leader is preoccupied with power is like saying that a tennis player is preoccupied with making shots his opponent cannot return" (Gardner, 1986a, p. 5). This chapter explores the meaning of social power, the bases of power, and how power contributes to leadership in societies, communities, formal organizations, and small groups.<sup>1</sup>

## Definitions of Social Power

---

Power is the force that can be applied to work. It is the rate at which energy can be absorbed. Social power is the ability to take actions and to initiate interactions. It is a force underlying social exchanges in which the dependent person in the exchange relationship has less power and the person with more power is able to obtain compliance with his or her wishes. Compliance implies acceptance of the more powerful person's influence. It can be assent given enthusiastically or reluctantly. The compliant person depends on the more powerful person for desired outcomes that cannot be obtained from other sources (Emerson, 1964).

### *Power as Force*

Power has been defined as the production of intended effects (Russell, 1938); the ability to apply force (Bierstedt, 1950); the right to prescribe behavioral patterns for others (Janda, 1960); and the intended, successful control of others (Wrong, 1968). But, as Gardner (1986a, p. 5) observed, "power does not need to be exercised to have its effect—as any hold-up man can tell you." Most behavioral theorists maintain that power can be exerted without intention. Cartwright (1965) conceived of power in terms of controlling information and personal affection. Bierstedt (1950) focused on prestige.

Simon (1957) saw power as a manifestation of an asymmetry in the relationship between A and B. For J. R. P. French (1956), as well as Cartwright (1959a, 1959b), the power of A over B equals the maximum force that A can induce on B minus the maximum resisting force that B can mobilize in the opposing direction. For Dahl (1957), "A has power over B to the extent that A can get B to do something that B would not otherwise do." For Pfeffer (1981a), power is A's ability to change the course of action of B from what B would otherwise have done. A can overcome B's resistance or reluctance to act. For Pres thus (1960), power was a matter of A's and B's rapport with each other. Emerson (1964) emphasized the dependency relationship between A and B. If B is more dependent on A than vice versa, B has less power than A. B's dependence on A can be due to A's control of resources that B cannot obtain elsewhere. It can be due to A's ability to reduce uncertainties for B, or to A's ability to cope with critical contingencies in the attainment of organizational goals based on the organization's strategy, environment, or technology (Daft, 1983). A can obtain B's compliance

with A's wishes. Thus Bagozzi and Phillips (1982) calculated that 64% of the power that suppliers have over wholesale distributors can be accounted for by the inability of the distributors to find other suppliers, the critical value of the resources controlled by the suppliers, the countervailing power of the distributors, and how much business is involved. According to Bennis and Nanus (1985, p. 17), power is "the basic energy needed to initiate and sustain action ... the capacity to translate intention into reality and sustain it." For Burns (1978), power can be wielded nakedly, as when people are treated as things; or it can be relational, collective, and purposeful.

### ***Power as Social Exchange***

Thibaut and Kelley (1959) regarded power as an exchange relationship in which one member has control over another's behavior or fate. As Gardner (1986a, p. 5) said,

It is possible to think of the exercise of power as a kind of exchange. You want something from me and you have the power to produce in return certain outcomes that I want—or want to avoid. You can give me an A or flunk me. You can promote me to supervisor or reduce me to clerk. You can raise my salary or lower it. You can give or withhold love.

Individuals tend to maintain a balance in the exchange of social values (Homans, 1958). The differentiation of social roles that results in organizations is based initially on such exchange relations (Gouldner, 1960).

Blau (1964) and Adams and Romney (1959) saw power as negative in A's use of deprivation, aversive stimulation, and sanctions to control B's behavior. Harsanyi (1962a, 1962b) took a broader view and weighed social benefits against social costs in defining power relations. Bass (1960) defined the power of A and B as A's control of what B needs and values. If B is satiated or uninterested in what A controls, A loses power over B. Burns (1978) agreed. Cartwright (1965) emphasized the importance of ecological control: power can be exercised by controlling resources or necessities, by occupying space, or by avoiding or boycotting a location. Thus a leader's power is reflected in the ability to impose standards, limits, and boundaries on a group and to indicate what is expected of members to obtain rewards or avoid harm. It also hinges on the ability to enforce such rules. The boundaries are likely to be areas of increasing threat and impenetrability. This situation requires judgment by those who are being controlled about how far they can deviate without punishment (Timasheff, 1938). One way lack of power manifests itself is in hesitant speech: hedges like "I guess;" tag questions such as "Isn't it?" at the end of an affirmative sentence; and disclaimers such as "Don't get me wrong but ...". Powerlessness also shows itself in excuses and justifications for doing the wrong thing (Hackman & Johnson, 1991, p. 99)

The social exchange can be seen in the exchange relationship between the Roman patron and his freedmen clients and between the ward boss and his neighborhood constituents. The clients' and constituents' votes and obedience provided the bases of power for the patron and the ward boss, in return for which the followers received protection, security, and material support. Lobbyists can exert power over state and federal legislators through financial support of their political campaigns. The political leader in the United States disperses tangible divisible rewards, favors, contracts and services to his or her constituents. For example, Borowiec's (1975) study of 83 Polish-American leaders in Buffalo indicated that they provided constituents with special information and personal assistance in dealing with public agencies. Privatization of government agency functions has meant billions of dollars in no-bid contracts for private firms in exchange for political support.

The exchange calculus may be complex; leaders of more powerful constituents are likely to be more powerful than leaders of less powerful followers. The leaders can mobilize the power of their followers and can be granted or deprived of power by their constituents. In combination with their constituents, they can

collectively acquire more power (Burns, 1978). This mutuality in the power relation is seen when constituents must complete their assignments if they and the leader are to be rewarded. The slowdown, inattention, or corruption of constituents can result in a loss of benefits for the leader.

### ***Power Is Not Synonymous with Influence***

House (1984) operationalized the measurement of power by its effects. Power was equated with “the capacity to produce effects on others. These effects are achieved by the exercise of authority, expertise, political influence and charisma ... each having a different base or source and each having different effects” (p. 26). But it is useful to maintain the distinction between power and influence, although the boundaries between power and influence remain unclear (Faucheux, 1984). Unfortunately, “power” is often used synonymously with “influence.” Tautologies have been endemic. We observe that A influences B; therefore, we conclude that A has more power than B. Inferences about power and its effects must begin with measures of power that are completely independent of observed relations between A and B. The observed relations are a product of the power differences between A and B, not the behavior observed. Leadership can be conceived of as the exercise of power (Berlew & Heller, 1983). Thus Milewicz (1983) concluded, after interviews with purchasing agents about their relations with their many suppliers, that the tendency of the agents to exert leadership in dealing with suppliers was a consequence of the agents’ self-perceived power. The agents had such power because they could, for example, control the length of the order cycle. Whether they fully used this power to exert leadership depended on their personal desire to be influential.

Leadership and influence obviously are a function of power. Power is the potential to influence. It is the probable rate and amount of influence of a person or the occupant of a position. Thus, for instance, Barber (1966) inferred that the power relations among members of a legislative committee could be accounted for by such factors as the rate of success in getting suggestions accepted and the rate of agreement received. Although Lord (1977) found that for 144 undergraduates, perceived leadership and social power were related, the unexplained variance required maintaining separate conceptual distinctions between them. Follert (1983) constructed a 20-item scale to measure the power of a manager. The scores obtained were related to the structuring leadership of the manager and to subordinates’ compliance with requests, but were clearly distinguishable from the scale of power.

We need to separate the holding of power because of: (1) one’s person, (2) one’s office, (3) the willingness to exercise it, and (4) the tendency actually to do so. Studies tend to confuse all four causes and sometimes even fail to distinguish between power and influence.

### ***Moderators of the Effects of Power***

Status, gender, personality, and subordinates’ power moderate the effects of a leader’s power.

*Status.* How leaders use power will depend on their status. A leader higher in the organizational hierarchy uses more aspects of power to influence (Koslowsky & Schwarzwald, 1993). Vecchio and Sussman (1989) argued that the leader’s status altered the effect of his or her power on subordinate compliance. According to Fitness (2000), the status of a leader markedly altered reactions to a situation that provoked anger. Structured interviews were conducted with 175 participants about a work-related incident with a superior, peer, or subordinate that made the respondent angry. Angry superiors were more likely to vent their anger and consider the incident closed; angry subordinates were more likely to suppress their anger and consider the incident unresolved.

*Gender.* When men's satisfaction with a heterosexual relationship decreases, they tend to become more coercive and unfeeling toward their partner; when women's satisfaction with the relationship declines, they tend to fall back on their *referent* power based on being liked or identified with in the relationship (Schwartzwald, 1993).

*Personality.* Thomas, Dickson, and Bliese (2001) found that ROTC cadets' extroversion partially mediated the relationship between the power of the cadets and their effectiveness as leaders. For 818 cadets, the *direct*-path correlation between their power and their leadership was only an insignificant .07. The *indirect*-path correlation from power to extroversion was .35; from extroversion to effective leadership it was .11.

*Power of Subordinates.* Power is not an absolute amount. As was already noted, it depends on the power of those to be influenced, both positively and negatively. The power of those who are influenced adds to the total power available in the situation and can be increased by the synergistic action of the leader and the followers. The leader's power may be diminished to the extent that it can be offset by the power of individual followers or of the group led. Self-managing teams clearly reduce the power of a leader (Manz & Simms, 1980).

Bass and Valenzi (1973) developed one set of five-point scales to assess a boss's power and another set of five-point scales to assess a subordinate's power. The subordinate and boss each described how frequently the boss could override or veto any decisions made by the subordinate, grant or deny promotion or salary increases to the subordinate, reverse the subordinate's priorities, control the size of the subordinate's budget, and get support from a higher authority for what he or she wanted to do. In turn, the superior and subordinate each described how frequently the subordinate could bring outside pressure to support what he or she wanted; do the opposite of what the boss wanted him or her to do; maintain final control over his or her plans, assignments, and targets, regardless of what the boss thought about them; ignore the boss and submit requests to a higher authority; and nominate or vote for who would be the boss. The differences in the power of superiors and subordinates then became the metric of importance in predicting the superiors' styles of leading the subordinates through, direction, consultation, negotiation, or the delegation of decision making (Chitayat & Venezia, 1984; Shapira, 1976).

Gardner (1986a, p. 16) pointed to the reversals that can occur between hierarchical rank in an organization and the power accompanying it: "Every experienced observer knows of cases in which such second and third level leadership is formidable—capable, for example, of paralyzing a newly appointed top executive." Gardner concluded that the efforts to reform high school curricula in the 1960s failed because of the power of rank-and-file teachers whose support was not enlisted in the attempted improvements. The power of subordinates over their superiors is widespread when the skills and knowledge of the subordinates are hard to replace. On the one hand, superiors need to guard against becoming overly dependent on subordinates with power; on the other hand, the superiors need to maintain good interpersonal relations, trust, and openness of communications with them (Kotter, 1985a).

Numerous other factors reduce subordinates' willingness to comply with the attempted influence of the power figure. For example, 240 Israeli subordinates of 40 police captains said they were less likely to comply with their captains if the captains coupled their power with acts of transactional instead of transformational leadership (Schwarzwald & Koslowsky, 1998).

## Personal versus Positional Power

---

### *Personal Power*

As noted before, power can derive from one's person or one's position. Although it may seem otherwise, the evidence to date suggests that prospective followers tend to consider the personal power of a highly esteemed expert more important than the legitimacy and power to reward and punish that may derive from appointment to a position of leadership. Those with personal power can grant affection, consideration, sympathy, and recognition, and can secure relationships and attachments to others (Bass, 1960). For example, Rosen, Levinger, and Lippitt (1961) asked teachers and emotionally disturbed boys to rank in order of importance six items related to power. The two groups basically agreed on the relative importance of physical strength, sociability, expertness, fairness, fearlessness, and helpfulness as sources of power. But those with personal power were seen also as able to punish others by becoming more distant, formal, cold, and businesslike.

Bass, Wurster, and Alcock (1961) demonstrated that we want to be valued and esteemed mainly by those we value and esteem. We endow these people with personal power. Hurwitz, Zander, and Hymovitch (1953) showed that we seek the affection and support of those we hold to be personally powerful. Professional personnel were continually reshuffled to form 32 sextets. The power to influence and the extent to which each member was liked after the first half hour of interaction were assessed. Those with low esteem wanted most to be liked by those with high esteem. According to Yukl and Falbe (1991), personal power is based on expertise, referent power, esteem, persuasiveness, and charisma. Transformational leaders have more personal power and accordingly generate more compliance from subordinates than do leaders lacking in personal power (Atwater & Yammarino, 1996).

*Identification and Personal Power.* As will be described in [Chapter 21](#), the charismatic leader can serve as the focus of positive emotional feelings, as the ideal object for psychoanalytic transference and identification (Kelman, 1958). The transference of coping with problems to parental figures provides followers with an escape from responsibility and making decisions—let the leader do it (Fromm, 1941). Followers identify with their successful superiors. Business executives see successful superiors as symbols of achievement (Henry 1949). Leaders of gangs of delinquents become the superego of the members. By submitting to the leader, members are relieved of all personal responsibility for their antisocial activities (Deutschberger, 1947).

The charismatic leader is the ultimate in personal power. Such a leader is personally endowed by followers with infallibility, wisdom, omniscience, virtue, and supernatural powers. Personal power is manifested in the emotional bonding between the leader and followers and in the followers' dependence on the parental figure. They may have deep-seated affection for the leader. Charismatics such as the Reverend Jim Jones and Osama bin Laden have had the power to induce extremes of behavior—suicide and martyrdom—in their followers. Understanding such personal power requires an examination of strong emotional fixations that go beyond the ordinary considerations of social exchange, cognitions, rewards, and punishments.

### ***Positional Power***

The status associated with one's position gives one power to influence those who are lower in status. Custom, tradition, rules, and regulations assign power to incumbents of positions. Some superiors can be the "purveyors of rewards and punishments" to their subordinates (Krech & Crutchfield, 1948). Leaders with positional power can recommend punishments and rewards, instruct group members on what to do, and correct each member's job performance (Fiedler & Chemers, 1974). Such power can be wielded crudely or with subtlety. It may be obtrusive or unobtrusive and overt or covert (Ford, 1980). Overtly, a superior may have the power to recommend or deny pay increases to subordinates. Less obviously, a first-line supervisor, for example, may have power because of his or her influence with more powerful leaders who are higher up in the organization

(Pelz, 1951). This power, in turn, may be due to the higher-ups' attitudes about the role of supervisors who are lower in the organization, as well as to the personal attributes and merit of specific supervisors. Pelz found that only those supervisors who had influence with higher-ups exhibited behavior that made a difference in their subordinates' satisfaction. Supervisors without influence "upstairs"—although they tried—were much less likely to have effects on their subordinates. Supervisors who had influence with higher-ups were much more likely to be able to obtain rewards for their employees. Their power was greater and, therefore, what they did in their own group made more of a difference to their subordinates.

Supervisors' position in a hierarchy provides them with various sources of power. Supervisors command resources that are not ordinarily available to subordinates. They have discretion in assigning dirty and boring or interesting and challenging tasks. They can open or close doors to opportunities for the subordinates' growth and advancement. They have power to reduce uncertainty or to prolong anxiety in subordinates by providing or withholding hard information. They can act as a buffer to keep their subordinates from becoming too vulnerable to an unstable external environment and thus sustain their subordinates' optimism and hope (Hollander, 1978). According to Fiedler and Chemers (1974), leaders' positional power combines with their esteem and orientation—task or relationship—to determine whether they will be effective in designated situations. According to Yukl and Falbe (1991), the power derived from one's position is based on legitimacy, the power to reward or coerce, and access to and control of information. The use of positional power is more frequent among transactional than transformational leaders (Atwater & Yammarino, 1996).

Executives' power over decisions depends on their functionally specialized roles. Accounting executives have more power over budgeting decisions; marketing executives have more power over decisions about advertising and distributing products. Extra power also accrues to those executives involved in activities critical to the firms' strategic success, that is, to those who scan critical information and the environment for threats and opportunities (Hambrick, 1981). Similarly, although clinical interdisciplinary teams of health professionals are supposed to meet as equals, physicians dominate decisions about treatment, according to a survey of 137 team members' descriptions of 19 meetings (Fiorelli, 1988).

One's position in an organization can provide power because occupancy of the position gives control of important organizational resources and information. Control over resources such as the size of the staff, budgetary expenditures, and evaluation procedures may be involved (Gomez-Mejia, Page, & Tornow, 1982). A manager who controls such resources may be able to maintain a good working relationship with subordinates even if they have little trust in him or her (Novak & Graen, 1985). Power also accrues to positions that control critical contingencies originating in the environment or technology of the organization. This hinges on the extent to which the position makes it possible to cope with critical demands that the organization is facing (House, 1988b). The importance of positional power was illustrated when Geissler (1984) compared 131 women heads of university nursing programs with 108 women heads of other university departments. The heads of nursing felt significantly more powerful in their preferred roles than did the women who led other university departments. Position upgrades in a department were more likely to be recommended in job evaluations for those with more positional power (Welbourne & Trevor, 2000).

*Socialization Processes.* Members of organizations need to know how to use increases in their positional power (Taylor, 1986). Gouldner (1960) maintained that power is based on socializing norms, role differentiation, and organization that binds people together in the same social system. Gilman (1962) agreed that a power relationship is authoritative anywhere within the boundaries of a social system that gives it consensual support.

In many cultures, business transactions are conducted without written contracts because norms of obligation are regarded as binding (Macaulay, 1963). Similarly, politicians wield considerable power based on IOUs through which they can expect that favors they granted to other politicians in the past will be reciprocated when they call in their unwritten "chits" for services rendered.

*Power Begets Power.* House (1984) pointed out that individuals who are in positions of power not only can assert it successfully, but also can maintain and increase their level of power. Thus power-oriented individuals who gain positions of power will strive to retain and increase their power, since they are in a favored position to ensure that their power continues. Unless there are limits, incumbents of political offices tend to be reelected. (Over 99% of the members of the U.S. House of Representatives are reelected every two years.) On the basis of interview data from a study of the administrations of California governors Ronald Reagan and Jerry Brown, Biggart and Hamilton (1987) added the corollary that for people to sustain their power in an organizational setting, they must self-consciously exercise their power to signal those working for them to be aware of obligations to carry out assignments as expected.

## Varied Uses of Power

---

Leaders may exercise both *competitive* and *collective* power. In a survey of 350 business and university managers, Roberts (1986) observed the widespread use of power to compete with bosses, peers, and subordinates, as well as the use of collective power to collaborate with others. McClelland (1975) saw the competitive exercise of power in the exertion of personal dominance or the search for victory over adversaries. This use of power was in contrast in cooperative settings with joining with others to form shared goals to instill in the collective a sense of power to pursue such goals. Undergraduates acting as managers in a simulated organization used their control of useful information to influence those acting as subordinates only if they saw themselves as being in a cooperative situation with their “subordinates” rather than as being in a competitive or individualistic situation (Tjosvold, 1985a).

The power of supervisors could be used in four ways, according to Jones (1983). (1) Power could be *obtrusive* or *unobtrusive*; (2) it could be *situation-based* or *personal*; (3) it could be *professional* or *paternalistic*; and (4) it could be exercised over *process* or *output*. Ford (1980) agreed on the utility of looking at covert power and showed experimentally that dependent participants in peripheral positions in a network will suppress decisions, particularly if they are uncertain about the preferences of the person in the central location in the network<sup>2</sup> who has covert positional power.

## Power and emergence as a Leader

---

Power over others depends on one's control of resources to give or deny and control of rewards and punishments to distribute. Power manifests itself in influence over others (Bass, 1960). The labeling of positions may induce a sense of control of leaders over subordinates. Power may be sought for its own sake or for social reasons. The *personalized* leader is motivated to use power to dominate others; the *socialized* leader is motivated to use power to achieve mutually desired goals with others (McClelland, 1975).

### ***Control and Power***

Bass, Gaier, and Flint (1956) studied experimental male ROTC groups in which members varied in the amount of control they could exercise over each other's avoidance of punishment—extra marching—because of demerits. Each member drew a card that specified whether he could exercise one, two, three, or four units of control to reduce the required marching. Members with four units of control attempted twice as much leadership as those with one unit of control under high motivation, but there was no difference in unmotivated groups with no demerits requiring the extra marching. Attempted leadership increased with the

amount of control a member obtained in the lottery. But the amount of control ceased to have import when what was being controlled was unimportant to the member. Thus members attempted more leadership acts when they had a lot of control and when what was controlled was desired. Members had power to influence when they had control over what was desired (Bass, Pryor, Gaier, & Flint, 1958). Members' attempts to lead increased with increases in their control and power, even if the control and power accrued from a lottery.

## ***Power and Influence***

Influence is correlated with power but is not the same. Power is the ability to exert some amount of control over others. It correlates with authority and may be coercive in its effects. Influence is more likely to depend on persuasion, with followers having more latitude to accept or reject the leader. Since "the unfettered use of power can be highly dysfunctional in creating numerous points of resistance and lingering negative feelings" (Hollander, 1985, p. 489), leaders tend to prefer persuasion rather than coercion. Nonetheless, some members of a group tend to be more influential than others if they perceive themselves as having more power. Moreover, they tend to be more satisfied than members who have little power. They are also better liked, and their attempts to influence are better accepted. Lippitt, Polansky, Redl, and Rosen (1952) found that children at a summer camp who had more power attributed to them by other children were better liked, made more attempts to influence others, and scored higher in the initiation of behavioral contagion (imitation by others without intent or awareness). The camper's perceptions of their own power were highly correlated with the power that others attributed to them. Consistent with these results, Levinger (1959) demonstrated that members of experimental groups, informed that they had more power than other members, tended to perceive themselves as actually having more power, became more assertive, and made more attempts to influence others.

Yukl (1998) noted that power has a variety of effects on influence. Power makes it possible for a leader to choose which influence tactics to use. For instance, the leader needs power to be able to make an exchange of benefits with a follower. A leader's power may enhance or diminish the effectiveness of an influence tactic. For example, a leader with considerable power will influence decisions about relevant operations more than a leader without such power. Wolman (1956) found a strong relationship between a leader's power and the leader's acceptability to members as seen by observers and in peer ratings. Ziller (1955) showed that group opinion was influenced more strongly by a high-power figure than by a low-power figure. Similarly, Levinger (1959) found that the perceived relative power of a group member correlated .55 with number of attempts to influence others, .51 with range of assertiveness, and .48 with degree of assertiveness. A change in attempts to influence tended to change along with a change in perceived power as the group continued with the problem. Dahl, March, and Nastair (1957) observed the power of some U.S. senators whose announced roll-call votes influenced other senators in making their final decisions. According to Krupp (1986), the power of school principals provided them with the influence "to develop staff to high levels of productivity and enthusiasm" (p. 100).

Michener and Burt (1975a) examined determinants of leaders' success in inducing compliance. They found that compliance was greater when leaders had reward power (i.e., justified their demands as being good for the group), had coercive power (i.e., could punish those who did not do as they had asked), and had a legitimate right to make demands on subordinates. However, neither the success nor failure of the groups, nor the approval of the leaders by their subordinates affected the leader's ability to be influential. Consistent with this, Gainson (1968) suggested that leaders would shift toward coercion of subordinates if they felt they lacked the subordinates' approval but had legitimate authority to ask for compliance, although such coercive power is often counterproductive.

Power can be counterproductive, undermining one's efforts to be a leader, because it can be threatening, particularly in unstructured situations. A. R. Cohen (1953, 1959) found that in the face of powerful leaders, followers felt more threatened in unstructured than in structured groups. Followers whose self-esteem was low also tended to feel more threatened in the presence of power, and this feeling was intensified in unstructured situations.

### ***Motivation for Power***

McNeese-Smith (1999) conducted a study of 19 nurse managers, 221 staff nurses, and 299 patients. The managers' motivation for power was negatively correlated with their leadership behaviors, as was the staff nurses' job satisfaction. Nevertheless, the nurse managers' power motivation contributed positively to patients' satisfaction. According to a study by Kirchmeyer (1990) of 225 managers of both sexes, women, but not men, who were higher in need for power were more active in office politics. Men who played office politics were high self-monitors who felt that they worked in a difficult world. Matusak (1997) suggested that in many organizations, people strive to possess and guard their power, which they see as a valuable personal possession limited to a few. But in a trusting workplace, sharing power is seen positively and is unlimited, as will be discussed in [Chapter 12](#) when empowering others is considered.

## **The Bases of Power**

---

Etzioni (1961) conceived of power as physical, material, or symbolic. He defined these three forms of power as follows, giving the bases of each:

*Coercive* power rests on the application or ... threat of ... physical sanctions ... ; generation of frustration, ... or controlling through force the satisfaction of needs. ... *Remunerative* power is based on control over material resources and rewards. ... *Normative* power rests on the allocation and manipulation of symbolic rewards and deprivations.

Parsons (1951) held that normative power could be based on esteem, prestige, and ritualistic symbols or on acceptance. Etzioni also pointed out that it would be wasteful for a leader to emphasize remunerative power if the followers were already committed to the leader's choice of action, since only normative symbolic rewards would be appropriate for such followers. Highly alienated followers would be inclined to disobey, despite material sanctions. Followers would be more likely to consider normative power legitimate and least likely to accept coercive power as legitimate.

### ***French and Raven Model***

French and Raven (1959) identified five kinds of power that quickly became popular among investigators as a way to type variations among the bases of power. Their five bases were as follows:

1. *Expert* power is based on B's perception of A's competence.
2. *Referent* power is based on B's liking or identification with A.
3. *Reward* power depends on A's ability to provide rewards for B.
4. *Coercive* power is based on B's perception that A can impose penalties for noncompliance.
5. *Legitimate* power is based on the internalization of common norms or values.

*Measurement.* Several earlier survey questionnaires (e.g., Hinkin & Schriesheim, 1989) preceded the

Interpersonal Power Inventory (Raven, Schwarzwald, & Koslowsky, 1998). Rahim (1988) developed a “leader power” questionnaire from the answers of 1,256 respondents. The final inventory contained five factorially independent scales to measure each of the bases of power. Subsequent validations were completed with a national random sample of 476 executives and a sample of 297 employed college students.

*Problems with the Five-Base Model.* The French and Raven model had a number of problems. First, the five bases are not conceptually distinct. For example, expertise is valued highly, so that sources of personal power in bases of expert power and referent power are likely to be correlated empirically, that is, lodged in the same people. In the same way, the position holder with the power to reward is also likely to have the power to punish. The position will give some degree of legitimacy as well. By definition, formal hierarchies are structures of legitimate, reward, and coercive power relationships.

Further conceptual difficulties were noted by Patchen (1974), who suggested that French and Raven’s classification was inadequate because the various bases of power were not conceptually parallel. Thus reward power and coercive power were defined in terms of resources that the influencer could apply. Referent and legitimate power were defined in terms of the characteristics and motives of the target person. Expert power depended on the characteristics of the influencers and on the information resources they personally possessed.

It was not surprising, therefore, to find that the five bases of power are empirically correlated. Rahim (1986) obtained, in a national random sample of 477 executives, a correlation of .58 between the expert and referent power the executives attributed to their superiors. The superiors’ control of rewards and coercive punishments correlated similarly with their legitimate power according to their subordinates. For 280 employees in 45 organizations rating the power of their 118 supervisors, Atwater and Yammarino (1996) reported correlations ranging from .33 to .55 among referent, expert, legitimate, and reward power. Coercive power correlated .51 with legitimate power and .41 with reward power.

Student (1968) regarded referent power and expert power as *individually derived* but thought that reward power, legitimate power, and coercive power were *organizationally derived*. He found that supervisors’ scores on incremental influence, referent power, and expert power were positively and significantly related to the quality of the group’s performance and to a reduction in costs. But average earnings declined with the reward power of the supervisor, and the maintenance costs of the group rose with coercion.

Podsakoff and Schriesheim’s (1985) review found expert and referent power positively correlated with each other as well as with employee performance, attendance, retention, and satisfaction with supervision. Legitimate, reward, and coercive power were intercorrelated and less effective. The empirical correlations between the bases of power make sense because power begets power. Power from one base can generate power in another. For example, individuals whose power is based on the legitimacy of their positions can acquire additional power by controlling the rewards that accompany the legitimacy of the positions. In the same way, people tend to defer to those they perceive to be experts. Perceived expertness, in turn, tends to legitimate the leadership role (Goodstadt & Kipnis, 1970). Although we may be able to sort out conceptually the different bases of power, in nature they are likely to be intertwined.

### ***Added Sources and Bases of Power***

Filley and Grimes (1967) emerged with a finer set of distinctions. They studied 44 full-time professional employees in a nonprofit organization who reported to a director and to an associate director. The employees were interviewed about hypothetical incidents that might require them to seek a decision from the director or the associate director. The respondents were asked to whom they should go for a decision, to whom they would like to go, and to whom they would in fact go, and why. Answers to the “why” questions were

classified according to the bases of power to which the organizational members appear to have responded. Twelve different bases were discerned. For example, instead of one category for legitimate power, several emerged. Legitimate power could be based on formal authority, on responsibility, on control of resources, on bureaucratic rules, or on traditional rules. Raven (1993) added equity, reciprocity, and dependence as bases for power. If A could control the equitable distribution of rewards to B, then A had power above and beyond reward power. If A could exchange one good for another with B, then A had the power of reciprocation. And if B depended on A, then A had power over B. An old adage is “Knowledge is power,” and in the information age it is not surprising to suggest that if A has knowledge personally or from his or her position that is desirable or useful to B, then A has informational power over B. Ordinarily, A is a leader and B is a follower, but the roles can be reversed.

Yukl and Falbe (1991) looked at the differences between *lateral* and *downward* power. In interviews with the peers of 49 middle and lower managers, *persuasiveness* was an important additional power. Persuasiveness, legitimate power, and expert power were the most important reasons mentioned by employees for their compliance with supervisor and peer requests. Rahim (1989) showed that expert and referent power were associated with compliance and satisfaction, while legitimate power was positively correlated with compliance but negatively correlated with satisfaction.

Hinken and Schriesheim (1989) made sharper distinctions in the French and Raven model:

*Expert power* is the ability to administer to another person information, knowledge, or expertise.

*Referent power* is the ability to administer to another person feelings of personal acceptance or approval.

*Reward power* is the ability to administer to another person things he or she desires or to remove or decrease things he or she does not desire.

*Coercive power* is the ability to administer to another person things he or she does not desire or to remove or decrease things he or she does desire.

*Legitimate power* is the ability to administer to another person feelings of obligation or responsibility.

[Table 11.1](#) is a list of statements that emerged in factor analyses of the extent to which respondents agreed that the statements described their supervisors. The three samples of over 500 respondents were part-time employees enrolled in undergraduate business courses, full-time employees at psychiatric hospitals, and full-time employees taking MBA courses.

Table 11.1 Final Scale Items Responding to the Statement “My Supervisor Can ...”

1. *Expert Power*

Give me good technical suggestions.

Share with me his/her considerable experience and/or training.

Provide me with sound job-related advice.

Provide me with needed technical knowledge.

2. *Referent Power*

Make me feel valued.

Make me feel like he/she approves of me.

Make me feel personally accepted.

Make me feel important.

3. *Reward Power*

Increase my pay level.

Influence my getting a pay raise.

Provide me with special benefits.  
Influence my getting a promotion.

#### *4. Coercive Power*

Give me undersirable job assignments.  
Make my work difficult for me.  
Make things unpleasant here.  
Make being at work distasteful.

#### *5. Legitimate Power*

Make me feel that I have commitments to meet.  
Make me feel like I should satisfy my job requirements.  
Give me the feeling I have responsibilities to fulfill.  
Make me recognize that I have tasks to accomplish.

## Antecedents and Consequences of the Bases of Power

---

### ***Expert Power***

In 1597, Sir Francis Bacon declared that “knowledge is power.” Expert power, perhaps unseen, can lie behind effective leadership. Gardner (1986a, p. 12) quoted Lyndon Johnson as saying, “When the press talks about my successes as Senate majority leader they always emphasize my capacity to persuade, to wheel and deal. Hardly anyone ever mentions that I usually had more and better information than my colleagues.”

Expert power may be manifest in information, knowledge, and wisdom; in good decisions; in sound judgment; and in accurate perceptions of reality (Watts, 1986). An item that is highly loaded (.78) on a factor of expert power is, “Has considerable professional experience to draw from in helping me do my work” (Rahim, 1986). In comparison with other bases, expert power appears to be most acceptable to and most effective with followers. It most readily gains their compliance and is least likely to provoke their resistance (Podsakoff & Schriesheim, 1985a).

The power of revolutionary or reform leaders often begins with their perceived power as experts, which they use to define prevailing problems and to develop innovative solutions. Followers are persuaded that the leaders have the right answers to their problems and are organized to provide support (Gjestland, 1982).

In the physician-patient relationship, the physician wields expert power and the patient plays a distinctly subordinate role, particularly if the patient is also lower in socioeconomic status (Fisher, 1982). But whether the patient complies with the physician’s expert advice will depend on what that advice entails as well as the physician’s referent power. Members of a group who have relevant information about a task will attempt to lead the group (Hemphill, Pepinsky, Shevitz, et al., 1954). Such attempts are likely to be successful if the members are perceived to be expert, and effective if they really have the expertise. Groups tend to defer to the actual and the perceived expert. They are likely to be persuaded by the perceived expert, to accept the expert’s opinion both publicly and privately (Bass, 1960).

H. T. Moore (1921) obtained experimental support for the idea that we readily accept the influence of those whom we accept as experts. Moore observed that students shifted their judgments (about linguistic, ethical, and musical matters) toward what the experimenter led them to believe was the opinion of experts. When Mausner (1953) introduced one student as an art student and another as an art expert, the group’s

opinion was more strongly influenced by the art expert than by the art student. Knight and Weiss (1980) arranged for leaders of task groups to be seen as “expert” or “nonexpert” on the basis of how they were chosen. Those who were chosen as experts were better able to influence the group than were those who were chosen as nonexperts. The selection of leaders from inside or from outside the group made no difference.

In another experiment, Mausner (1954b) demonstrated that subjects tended to agree more often with a partner whom they observed to succeed than with one whom they observed to fail. Luchins and Luchins (1961) demonstrated that an expert’s opinion was more influential than the majority opinion of the group in determining the group’s response to a judgmental task. Torrance (1952) and M. A. Levi (1954) both obtained greater improvement on survival problems when groups were fed back expert information after an initial training period.

Evan and Zelditch (1961) studied experimental groups with supervisors who differed in their knowledge of the task. Differences in the supervisors’ knowledge did not affect the group’s productivity; however, group members exhibited more covert disobedience and resistance to the least informed supervisor than to the moderately or well-informed supervisor. This effect was attributed to changes in the followers’ attitudes toward the right of the poorly informed supervisor to occupy a position of leadership. Similar results were reported by G. M. Mahoney (1953), who found that workers were much more satisfied with a wage-incentive system when they thought the supervisor did a good job of explaining the reasons for changes in the system. A survey of more than 200 graduate students found that faculty members with a large amount of expert power were more likely to be acceptable to the students as thesis advisers, coinvestigators in research, and coauthors of conference papers. This was in contrast to potential faculty advisers who were perceived as coercive (Aguinis, Nesler, Quigley, et al., 1996).

*Caveats.* The impact of expert power has its limits, as was noted in [Chapter 4](#): would-be leaders must be able, but not too much more able than their followers. Many examples can be cited of experiments in which experts failed to be influential. C. B. Smith (1984) observed that apparent technical and administrative expertise in a contrived short-term employment situation did not increase the experimental subjects’ output as coders or their compliance with directives. Collaros and Anderson (1969) studied groups with one expert, all experts, and no experts. Groups in which all members were told that they were experts were more inhibited in their performance.

Although individuals can become more influential by acquiring more knowledge and expertise, the technological revolution in the spread of knowledge, and the ease with which information can be transmitted, can quickly alter who is expert about the available information and thus alter the resulting patterns of influence. Under some circumstances, then, a clerk with access to a computer program may become more expert and influential than a PhD without access to the program. Cleveland (1985) noted that information is expandable, compressible, substitutable, transportable, diffusable, and shareable. It is not necessarily a scarce resource. Expert power is more fluid than fixed in a position or a person. It can be found in a computerized database, a computer software program, or in a search engine such as Google. Custom-made expert programs can substitute for human expertise. Increasingly, research focuses on information power, which may differ from expert power as such.

Some further qualifications are in order. The stronger status-leadership relationship can override expert power. Torrance (1955a) concluded that the high status of a team member contributed more to influencing other members to accept the correct answer to a problem than did knowing the correct answer. Paradoxically, two supposed experts may generate less confidence than one alone. Torrance and Aliotti (1965) studied groups involved in information seeking with one or two randomly selected students in the role of expert. They found that groups with two “experts” obtained more accurate information than did those with one “expert,” but the groups with two “experts” were less certain of their judgment.

## ***Referent Power***

Liked, respected, and esteemed leaders have referent power. Followers want to identify with leaders who have referent power and be accepted by them. The evidence is primarily indirect about the extent to which referent power contributes to influence and leadership. Like expert power, referent power is correlated with the tendency to use rational tactics (Hinkin & Schriesheim, 1990). Referent power has become more important with the downward shift of power to lower organizational levels and the increasing importance of personal values and convictions in the influence process (Behr, 1998). Being esteemed and valued by followers is highly related to leaders' referent power. Yukl, Kim, and Falbe (1996) asked 195 full-time-employed MBA night students to describe three critical incidents in their organizations. In these incidents, leaders who had more referent power were also likely to generate more commitment. They were less likely to use pressure tactics. Hinkin and Schriesheim (1990) reported similar findings, as well as a substantial direct relationship between referent (and expert) power and the use of rationality as an influence tactic.

We need to consider indirect evidence of referent power due to ingratiation and the desire for acceptance by followers. For much of this indirect evidence, referent power is assumed from friendship or popularity. Thus Rahim (1986) found factor loadings for referent power of .81 and .85 for such items as, "I like the personal qualities of my superior" and "My superior is the type of person I enjoy working with." Studies of referent power need to capture its essence in the desire of the less powerful to identify with those who have referent power (Podsakoff & Schriesheim, 1985a). For example, referent power is clearly seen when a charismatic relationship exists between the leader and the follower, since what binds the follower to the leader is the desire to identify with the leader.

Esteemed individuals are more likely to emerge as leaders. In 17 studies of executives in various organizations, esteem—as estimated by merit ratings received from superiors—was highly related to "real-life" success as a leader (Bass, 1960). The same has been found in controlled experimental settings, but with qualifications based on selected experimental manipulations of referent power. French and Snyder (1959) found that more highly accepted leaders in experimental groups attempted to exercise more influence, and had more effective groups, than did those who were less well accepted. Followers also attempted to use more influence when they were accepted by their leader. In a review, Podsakoff and Schriesheim (1985a) found that the use of referent power by leaders usually contributed to better performance, greater satisfaction, greater role clarity, and fewer excused absences among their subordinates.

*Acceptance, Popularity, and Power.* Zander (1953) and Zander and Cohen (1955) introduced two strangers to groups. The one introduced as high in prestige felt better accepted and more at ease than the one introduced as in a low-prestige role. Hurwitz, Zander, and Hymovitch (1953) combined and recombined members of six-person discussion groups. Each individual rated the others on the degree of liking and perceived power and participation. Members with a high degree of power were better liked and participated more often than those with a low degree of power.

*Ingratiation.* As mentioned earlier, Bass, Wurster, and Alcock (1961) demonstrated that we want to be esteemed by those we esteem. We are more concerned with being liked and accepted by those we respect and accept—those with referent power. This concern, in turn, may lead to ingratiation—the striving by followers to be valued and rewarded by those they esteem or see as more powerful. A line of investigation by Jones and Jones (1964) indicated that followers who want to be liked by high-power figures employ subtle ingratiation tactics, such as flattery, in an effort to gain acceptance. Jones, Gergen, Gumpert, et al. (1965) showed that participants in an experiment who faced the prospect of poor task performance attempted to ingratiate

themselves with the experimental supervisor by presenting themselves as strong and competent, but only if the supervisor was open to influence. L. Wheeler (1964) demonstrated that low-power subjects remembered more autobiographical statements made by the high-power figure. Wheeler did not find that participants who were highly dependent on their task leader sought information as a means of ingratiation or to increase their own power. But A. R. Cohen (1958) demonstrated that low-status members who could increase their status in the group tended to communicate in friendly, ingratiating ways. These tactics were designed to protect and enhance their relations with those who controlled the upward-mobility process. But those members with little perceived opportunity to increase their status made relatively few such attempts. There may be a rational payoff in ingratiating behavior by followers. Thus Kipnis and Vanderveer (1971) observed that leaders tend to reward their ingratiating followers.

Referent power can become coercive. Moreno (1934/ 1953) postulated that if A highly valued B, B could injure A. And Bass (1960, p. 289) described how referent power could be subverted:

[If] you can give me affection, self-esteem through association with you and vicarious satisfaction by identification ... although I may not privately accept what you say, I will publicly agree with you so that you will grant me what I want from you ... (And such referent power may be lost as a consequence) ... because if I must continue to inhibit my own opinions ... I will begin to value you less, to dislike you and eventually reject you.

### ***Reward Power***

Reward power implies an ability to facilitate the attainment of desired outcomes by others. An item highly loaded on a factor of reward power is, "Can recommend a promotion for me if my performance is consistently above average" (Rahim, 1986). Marak (1964) studied some groups who were rewarded for a correct decision and others who were not. The results indicated that the ability to provide rewards was related to leadership, as measured by sociometric, interaction, and influence scores. The more valuable reward a member could provide, the more closely this ability was related to leadership. Evidence for the emergence of a leadership structure was suggested by the finding that attempted leadership, actual influence, and rewards for initiating leadership increased as the sessions progressed. Similarly, Herold (1977) showed that the behavior of subordinates in 32 trios depended on the manipulation of monetary rewards by the trio leaders. In a leader-subordinate experimental simulation, Dustin and Davis (1967) observed that when given a choice, leaders used monetary rewards twice as much as they used praise. Kipnis (1972) also found that economic incentives were favored over other ways of improving subordinates' performance. As before, Hinton and Barrow (1975) found that when subordinates performed at high levels, supervisors tended to make more use of economic reinforcements than of praise. However, when subordinates performed poorly, leaders tended to make more use of reproof.

Many of the critical behaviors that separate successful from unsuccessful noncommissioned officers in situational tests were found by Flanagan, Levy, et al. (1952) to be due to the differential reinforcements provided by these officers. Successful officers more often encouraged their men to follow rules and regulations, gave pep talks when the men were tired, and constantly checked the behavior of their men. However, S. Kerr (1975) noted that in their desire to achieve one kind of behavior, leaders as well as organizations sometimes unintentionally reward another kind.

Greene (1976a, 1976b) conducted the first longitudinal study of the effects of rewarding behavior by leaders and concluded that it could result in improved performance by the subordinates. Sims (1977), Sims and Szilagyi (1978), and Szilagyi (1980b) also found a causal relationship between such reward behavior and

follower performance in a series of longitudinal studies.

Justis (1975) examined effective leadership as a function of the extent to which followers' rewards depended on the leader's competence and performance. The leader's effectiveness and influence were greater the more the leader was seen to be competent and the more the followers' rewards depended on the leader's performance. Expert power interacted with reward power.<sup>3</sup>

*Interdependence Effects.* Berkowitz (1957b) experimented with pairs of participants, one or both of whom could earn a reward. The perception of interdependence increased the members' motivation when both were eligible for valued rewards. Participants were also motivated to work toward a partner's reward even when they were not eligible. Berkowitz and Daniels (1963) demonstrated that participants worked harder for a "supervisor" whose success was dependent on their performance than when no such interdependence existed. Berkowitz and Connor (1966) varied both success and dependence for pairs who could win rewards. Participants who experienced failure expressed stronger dislike for their partner the greater their feeling of responsibility toward the partner. Successful participants, however, worked harder for their dependent partner than did the control participants.

The leader may also have to share the power to reward with other authorities, especially in matrix organizations where a subordinate reports to a functional leader and a project leader. In such a case, Hinton and Barrow (1975) found that leaders were more likely to use their reward power if they had to share its use than if they operated alone.

*Distributing Rewards.* A norm that is often common to students and workers in the same small-group settings is "Share and share alike." Thus Morgan and Sawyer (1967) found that pairs of boys, when permitted to earn equal or unequal rewards, preferred equal rewards whether their partners were friends or strangers. But their perception of the other's expectation played an important part in determining their preference. Even ingratiating subordinates who disparaged the competence of their student supervisors failed to modify the allocation of rewards by the supervisor (Fodor, 1974). And when Shriver (1952) gave leaders of discussion groups checks of various amounts with which they were required to reward the contributions of other members, some leaders solved the problem by drawing lots; others, after delay and emotional upset, passed out the checks quickly and departed. Shriver interpreted these results as indicating that there are limits to the reward power that an emergent leader can exercise with comfort. Nevertheless, W. P. Smith (1967b) found that participants with a highly valued outcome liked their partners less than those with less highly valued outcomes. Those with little power valued their outcome more highly and used their power more positively than did those with much power.

Yet considerations of equity and loyalty do have an impact on the situation. Thibaut and Faucheux (1965) varied equity and loyalty to one's group in bargaining for individual gain. Partners who were told that they had greater power tended to use it; other partners tended to acquiesce. Lower-power members appealed for "a fair share" when the high-power members could manipulate rewards, but they appealed to "loyalty" when rewards were manipulated by an outsider. Thibaut and Cruder (1969) found that participants tended to form contractual agreements when they discovered that an agreement restricted the power of each to prevent their joint attainment of maximum outcomes. P. Murdoch (1967) observed that members tended to develop contractual norms when the divider of rewards was presented as being likely to withdraw from the relationship. Butler and Miller (1965) and McMartin (1970) determined that participants tended to distribute rewards in proportion to the difference in the average rewards received from others. Swingle (1970a) demonstrated that cooperative participants were exploited more when they were powerful than when they were weak, even when exploitation resulted in reduced rewards for the exploiter.

Power affects promises to cooperate for mutual benefit. Tedeschi, Lindskold, Horai, et al. (1969) studied

reactions to participants who repeatedly promised to cooperate but who varied in credibility (their degree of cooperation following their promises). Powerful teammates ignored the promises and failed to cooperate. Participants equal in power were most cooperative with the willing member. Participants weak in power became more exploitative as the credibility of promises increased. L. Solomon (1960) demonstrated that unconditional offers of cooperation by one member equal in power to a partner was exploited by the partner who became less liked. However, if the offers to cooperate were conditional, more cooperation and more liking of the partner were elicited. If the partners were unequal in power, the results were reversed.

*Antecedents to Usage and Effects.* Hinton and Barrow (1976) showed that reward behavior was most frequently used by responsible, confident, and enthusiastic leaders. Barrow (1976) and Herold (1977) found that leaders rewarded good performers and were more punitive toward poor performers. Hunt and Schuler (1976), Oldham (1976), and Sims (1980) obtained similar results. But Greenberg and Leventhal (1976) reported that leaders offered financial bonuses to poor performers to motivate them when that was the only motivator available.

Bennis, Berkowitz, Affinito, and Malone (1958) studied reward power in hospitals. They found that supervisors at hospitals where the rewards that were given were congruent with those hoped for by the subordinates exercised more influence than did supervisors at hospitals where the rewards were not congruent with the subordinates' hopes. Furthermore, the hospitals that gave congruent rewards were more effective. But supervisors exhibited little awareness of the subordinates' preferences for rewards. A participative style of leadership (see [Chapter 18](#)) was reported by Singh-Gupta (1997) among Indian managers correlated with their use of expert and reward power.

To appreciate fully the effects of reward power, one must consider how it is used. On the one hand, many studies have demonstrated the utility of rewarding by supervisors in exchange for compliance by subordinates. Supervisors' recommendations for rewards that are contingent on the subordinates' performance have been widely found to contribute to productivity and to effective operations. However, such rewards may be resented by subordinates and may actually be coercive. In such cases, compliance will be public only, not private, especially when subordinates see the supervisors' use of rewards as capricious, arbitrary, and unfair, rather than reasonable, predictable, and fair.

## ***Coercive Power***

Epictetus declared:

... no one is afraid of Caesar himself, but he is afraid of death, loss of property, prison, and disenfranchisement. Nor does anyone love Caesar himself unless in some way Caesar is a person of great merit; but we love wealth, a tribuneship, a praetorship, a consulship. When we love and hate and fear these things, it needs must be that those who control them are masters over us. ... That is how at a meeting of the Senate a man does not say what he thinks, while within his breast his judgment shouts loudly. Starr, 1954, p. 144

The leader who uses coercive power controls the granting or denying of valued rewards or feared penalties; subordinates' private opinions and feelings remain hidden, but there is pressure on them to express publicly what they really feel. In hierarchical settings, coercion is manifest when the subordinate "holds in abeyance his own critical faculties for choosing between alternatives and uses the formal criterion of the receipt of a command or signal as his basis for choice" (Simon, 1947, p. 126). Extremes in coercive power were seen in Shaka, the Zulu king, who was known to have summarily executed his courtiers for a breach of etiquette, a smile at the wrong time, disagreeing with him over a minor point, or one of many other slight causes of his

displeasure (Morris, 1966). As Matusak (1997) noted, "Power without caring, commitment, and empathy can become a selfish tyranny."

Tannenbaum (1950) listed ways in which executives may use their power to restrict or inhibit subordinates' behavior. The executives may arbitrarily identify the organization's goals, set up criteria for evaluating alternative paths to the goals, rule out alternatives, limit the general activities in which subordinates are permitted to engage, identify the positions with control and power, give or withhold information, and set deadlines to be met to avoid punishment or earn rewards.

Among Indian managers (as well as elsewhere), authoritarian leadership is associated with the use of coercive power (Singh-Gupta, 1997). Coercive power implies the ability to impose penalties for noncompliance. Rahim (1986) found that endorsement of the statement "My superior can fire me if I neglect my duties" correlated .82 with a factor of coercive power. French and Raven (1959) reported that conformity by followers (public acceptance but private rejection) was a direct function of earlier threats of punishment for noncompliance. Although coercion most commonly involves punishment or its threat, more subtle uses of power to coerce may involve promising rewards for compliance. One will comply publicly but perhaps not privately as a consequence of such promises and one's concern about failing to obtain promised rewards in the absence of compliance. Thus A has power over B if A can control whether B is rewarded or punished and B seeks rewards and wants to avoid punishment. A is coercive if B behaves publicly according to A's demands, although B privately rejects A (Bass, 1960). A clear demonstration of coercion that results from power was reported by French, Morrison, and Levinger (1960). In laboratory assignments, participants serving as subordinates exhibited a much greater discrepancy between their public and private reactions when supervisors could assess monetary fines than when no fines were established.

Militant leaders of social and political movements apply coercive pressure on officials who are vulnerable to their attacks, such as "high-minded" university presidents, elected politicians, or executives whose business may suffer. These militant leaders gain visibility and mobilize their supporters to support their coercive efforts, which are directed at changing the actions of their targets before changing the targets' attitudes. Such leaders harass, threaten, cajole, disrupt, provoke, and intimidate in speeches, dress, manners, gestures, slogans, rituals, and violent confrontations (Simons, 1970).

*Usage.* The use of coercive power is less popular with leaders and subordinates alike. Leaders tend to use this form of power to deal with unacceptable performance by a subordinate when they do not have the power to reward the subordinate for acceptable performance (Kipnis, 1976) or do not have other bases of power. But even in this instance, there is reluctance to use coercive power. McFillen and New (1979) demonstrated that leaders were less willing to exercise monetary sanctions for poor performance when they had only the power to punish. They were more willing to use monetary rewards for good performance when they had only the power to reward their subordinates. Leaders were more inclined to use their coercive power when they were under pressure to maintain high-productivity schedules and had lost their power to reward good performance (Greene & Podsakoff, 1981). Nonetheless, Simon (1947) argued that the use of coercive power is hard to avoid in any formal hierarchy, for five reasons: (1) subordinates develop expectations for obedience to symbols of higher status; (2) the superior can satisfy the subordinates' personal need for security from a substitute father or mother; (3) the subordinates may share the same goals as the superior and perceive that blind obedience provides a means to obtain the goals; (4) the subordinates are freed from the responsibility for making difficult decisions, and the superior bears the burden of these decisions for them; and (5) most simply, the superior may be able to reward or punish the subordinates materially.

Subordinates in a business organization are coerced by others besides their immediate superiors. They may have to accept publicly, yet reject privately, the dictates of buyers of the organization's products; contractual agreements with labor unions or industrial cartels; and the demands of government, custom, and tradition

(Bass, 1960). More often than not, coercion in a hierarchical setting is subtle. Subordinates may not even be aware that they are being coerced (Timasheff, 1938) and may repress any private feelings that are at odds with their public statements. For example, an executive may be reminded by the CEO of the costs in lost stock options if the executive quits. Or a young executive with new ideas may be coerced by a superior who keeps emphasizing the possibility of failure (Kets de Vries, 1980).

Although it may not be very subtle, pure political influence can be coercive when it displaces the rational and legitimate use of power with Machiavellian deception, divisiveness, defensiveness, or emotional appeals. Even an offer of rewards for political favors can be seen as coercive and may require a strong countervailing conscience to resist. Power can be wielded by political manipulations, such as covertly denying, delaying, or distorting information that is sent to another member of the organization so that the latter's choices are restricted (House, 1984).

*Indirect Coercion.* Observing vicariously how penalties are tied to the performance of one's colleagues may be more effective than direct threats in maintaining performance in the short term. Schnake (1986) studied the effects of punishment on the attitudes and behavior of coworkers who observed a peer receiving punishment. Students hired for temporary clerical employment observed a coworker receiving a reduction in pay, a coworker receiving a threat of a reduction in pay, or a coworker who was not penalized. Those who observed the coworker receiving a reduction in pay produced significantly more output than those who observed the coworker being threatened with a reduction in pay or not being penalized. Job satisfaction was not affected, and the effects held for at least a week.

*"It's Not What You Say, But the Way You Say It."* Compliance can actually be due to coercion even if the person who complies does not feel coerced, as a consequence of the language used in the attempt at influence. Drake and Moberg (1986) detailed how both public and private compliance can result from the language used by A to obtain B's compliance when ordinarily B would see A's request as exploitative and coercive. For instance, A can use sedating language, which suppresses B's tendency to analyze whether B will gain or lose by complying. Or A can be indirect ("Something needs to be done about the trash"), rather than direct ("Take out the trash"); in this case, A becomes the observer, not the leader. Also, A's observation of the existence of a problem and related hints, prompts, and teases can substitute for a direct order. A can first determine B's availability and willingness to comply before assigning new responsibilities to B. (But if A behaves this way routinely, B may interpret A's effort as a characteristically annoying ploy and hence may lose trust in A.)

Giving orders or making requests without explanation is likely to produce less compliance and more sense of being coerced than giving logical reasons. However, more compliance will occur and less coerciveness will be felt even if the reasons do not really make any sense. Such reasons can be substituted because cognitive processing is limited when decisions are made to follow orders in many seemingly legitimate situations. For example, Langer, Blank, and Chanowitz (1978) showed that personnel who were using a copying machine would allow a usurper to take over the machine for an irrelevant reason ("I have to make copies") but they would comply less often if no reason was given.

Power is legitimated in the language used. Hence, A increases power over B by using rich, rather than redundant, vocabulary and by expressing less uncertainty in appeals (Berger & Braduc, 1982).

Another approach to offset the potential coerciveness of a direct order is to precede it with *disclaimers*. As quoted by Drake and Moberg (1986, p. 578), Hewitt and Stokes (1975) outlined five forms of disclaimers:

*Hedging* (I'm not really committed): "I haven't given this much thought but ..."

*Credentialing* (I'm not prejudiced): "Some of my best friends are ..."

*Sin licensing* (I'm not a rule breaker): "I know this is against the rules but ..."

*Cognitive disclaimers* (I'm not confused): "This may seem strange but ..."

*Appeals to suspend judgment* (Don't get offended): "Don't get me wrong but ..."

Excuses and justifications may also be used to palliate feelings of exploitation and to increase compliance. Compliance can be increased by avoiding messages of powerlessness. O'Barr (1982) reported that more convincing witnesses in court trials avoided using power-less language—intensifiers (e.g., "very") and hedges (e.g., "sort of").

*Conditions That Increase the Use of Coercive Power.* Coercive power dominated supervisory-subordinate relations in a factory where workers were marginal, handicapped, without skills, and unable to get jobs elsewhere (Goode & Fowler, 1949). Kipnis and Cosentino (1969) compared corrective actions used by military and industrial executives. Industrial supervisors tended to reprimand and to transfer offending employees, whereas military supervisors more often used instruction, reassignment, extra work, and reduced privileges as corrective measures.

Boise (1965) studied attitudes of supervisors in a city's police, street, and water departments toward correcting subordinates' performance. All but authoritarian supervisors (those with high *F* scores) and police supervisors agreed with the concept of a uniform penalty for unacceptable performance. Coercive power is most likely to be used to deal with noncompliance. Katz, Maccoby, Gurin, and Floor (1951) found that the foremen of low-producing railroad section gangs were more punitive. A longitudinal study by Greene (1976b) concluded that supervisors are punitive in reaction to their subordinates' poor performance. Szilagyi (1980b) established that higher levels of punishment tended to follow higher levels of absenteeism by employees. Bankart and Lanzetta (1970), Barrow (1976), and Hinton and Barrow (1975) also reported the tendency of supervisors to become coercive as a consequence of subordinates' inadequate performance. Situational variables, such as difficulty of the task and prospects for failure, increase a leader's tendency to employ coercion (Michener, Fleishman, Elliot, et al., 1976). That is, leaders who face failure will tend to become more coercive (Kipnis, 1976). T. R. Mitchell (1979) further showed that more coercion was practiced if the supervisor attributed poor performance to a lack of motivation rather than to a lack of ability, or to policy changes or bad luck.

Goodstadt and Kipnis (1970) studied student work groups under different types of supervisory power. Student supervisors tended to use coercive power to solve disciplinary problems, but they used expert power to solve problems arising from ineptness. Sims (1980) concluded from a review of both longitudinal field studies and laboratory studies that punishment tends to be more a result than a cause of employees' behavior. More specifically, managers tend to increase punishment in response to the poor performance of employees. Illustrating the use of punishment in reaction to other events, including the loss of other bases of power, Greene and Podsakoff (1979) found that after a contingent (positive reinforcement) pay plan at two paper plants had been abandoned, supervisors began to use rewards less and punishment more. Fodor (1976) found that leaders were more authoritarian and coercive with disparaging and disruptive subordinates. The leaders rated such subordinates lower and gave them less pay than they gave to other subordinates. In the same study, Fodor noted that supervisors who were subjected to group stress also tended to become more coercive and less rewarding.<sup>4</sup>

*Support for Coercive Power.* Legitimacy coupled with coercion will increase public and private acceptance of coercive demands. In a study of experimental groups, Levinger, Morrison, and French (1957) found that the threat of punishment induced conforming behavior in group members before punishment but not after punishment. Most to the point was the fact that the group members' perceptions of the legitimacy of

the punishment reduced their resistance to conform. Particularly important is the support of the status structure. When Iverson (1964) presented taped speeches by people who were identified as high or low in status, those who listened to speakers who made punitive remarks formed more favorable impressions of the personalities of the high-status speakers than they did of the low-status speakers. The coercive demands of an attractive esteemed leader are more likely to be accepted, although continued use of coercive power will reduce such attractiveness and esteem. Another support for ready obedience to coercive power is the immaturity of participants. Kipnis and Wagner (1967) found that immature participants performed better than did mature participants under a leader whose decisions to administer punishment were backed up by superior authority. Brass and Oldham (1976) examined the reactions of first-line supervisors to an "in-basket" simulation.<sup>5</sup> Overall, the supervisors punished more often than they rewarded their subordinates. The more active supervisors, those who used both more reward and more coercive powers, were rated as more effective.

Leaders use coercion more easily when they rationalize that they are only following orders from higher authority without questioning the legitimacy of those orders. They are more coercive if they attribute the coercion to their position, rather than to themselves as persons, and if they can maintain sociopsychological distance by thinking of those they are coercing as enemies, inferiors, and troublemakers. Adolf Hitler made coercion acceptable to the Germans by consolidating the attention of the German people as the "master race" against a single adversary and then lumping different opponents together in the single category of those who were antithetical to the master race (Paige, 1977).

*Resistance to Coercive Power.* When Milgram (1965b) instructed students to activate a device that supposedly administered electric shock to subjects who made errors in a learning experiment, the students were willing to administer "dangerous" degrees of shock on command. The students had a strong tendency to obey authority and to accept being coerced by it. But when students who were administering the electric shock were permitted to observe two other individuals who refused to do so, the number of refusals was significantly increased. Stotland (1959) found that when participants were required to work with a domineering supervisor, they tended to identify with the supervisor. However, when they were able to interact with a peer from another group, they would exert more independence from the power figure, show more hostility toward him, and exhibit greater motivation to reach the goal despite the supervisor's hindrance. French, Morrison, and Levinger (1960) observed that the greater the threat of punishment, the less the resistance to compliance, but the resistance increased after the threat disappeared.

A form of "group compensation" may arise, according to Stotland (1959), in resistance to attempts to be coerced if the opportunity to do so is made available. In Stotland's study, individuals used models to design a city and were subject to the veto power of a "supervisor," who interrupted their work twice. Some of the participants were given the opportunity to meet privately in the absence of the "supervisor;" others were not. Those who met privately became much more aggressive and hostile toward the supervisor, whereas those who did not continued to accept the supervisor publicly. Private assembly permitted the formation of an informal organization to present a unified front against the "supervisor's" continued attempts to coerce the participants. In sum, group members were better able to resist coercive power when they had an opportunity to interact with peers in the absence of the supervisor or to observe other members who disobeyed orders. Resistance would be higher if the orders were judged to be illegitimate and the leader was personally unattractive.

Resisting attempts by superiors to exercise their coercive power may be productive. In an experiment by Horwitz, Goldman, and Lee (1955), students were frustrated by the arbitrary refusal of their teacher to repeat instructions. However, they shifted to more favorable attitudes toward the teacher, were less annoyed, and regarded the teacher as less coercive when the teacher read their opinions and agreed to repeat the instructions. These more favorable attitudes occurred less often when the teacher was informed by a "higher authority" that the instructions should be repeated. The students solved problems and learned best when they could take direct

action to “reform” the coercive teacher; problem solving and learning were somewhat less efficient when the students could only state their grievances, and were poorest when the students were led to believe that all the other students accepted the coercive teacher’s refusal to repeat the instructions.

*Unintended Consequences of Coercion.* Those with coercive power will readily fall back on it when necessary. They are tempted to exploit their power by demanding a greater share of available resources and rewards. The process is reinforced by colleagues’ development of mistrust of the coercive power holder and by the power holder’s counterreaction of suspiciousness about the colleagues’ intentions, which results in his or her greater reliance on coerciveness (Kipnis, 1976). Coercive power can turn a mutually benevolent relationship into one of mutual hostility (Deutsch & Krauss, 1960). The costs of depending on coercive power in formal organizations are well known. For instance, satisfaction with supervision is almost uniformly lower. Thus whereas the satisfaction of life insurance agents was related positively to their manager’s use of referent and expert power, it was related negatively to their perceptions of the degree of reward, coercive, and legitimate power that the manager exercised (Bachman, Smith, & Slesinger, 1966). Weshler, Kahane, and Tannenbaum (1952) observed that a research laboratory headed by a coercive leader was more productive but less satisfying to its members than a laboratory that was under less coercive leadership. Zander and Curtis (1962) indicated that participants in a coercive situation found each other less attractive, less well accepted, and less motivated than they were in a referent situation. Weiss and Fine (undated) found that participants who had experienced insult and failure were receptive to arguments to be hostile and punitive, whereas comparable participants who had satisfying experiences were more ready to accept communications asking them to be lenient. Hostility toward power figures who can coerce other members was also found by Stotland (1959). Participants may withdraw from the problems at hand to avoid being coerced. Riecken (1952) attributed such withdrawal to the frustrations of coercion. Oldham (1976) related punishment by leaders to evaluations of their subordinates’ effectiveness. Generally, punishment was correlated not with subordinates’ performance, but with their lack of “motivational effectiveness.” Punitive leadership was found by Sims and Szilagyi (1975) and Sims (1977) to be uncorrelated with the subordinate performance of professionals and technical personnel, but it had a significant inverse correlation with the satisfactory performance of administrative and service personnel as subordinates.

A line of investigation beginning with Janis and Fesh-bach (1953) generally supported the contention that strong threats are less productive than moderate or mild threats. In the prototype experiment by Janis and Fesh-bach, conditions of strong, mild, and minimal fear were included in propaganda about dental hygiene, and resistance to counterpropaganda was measured. The arousal of minimal fear seemed to provide the most persistent influence, whereas the arousal of strong fear resulted in the ignoring or avoiding of attempts to influence (a form of withdrawal) or the development of conflicting tendencies to minimize the importance of the threatening propaganda. On the basis of similar findings, Kelman (1953) argued that when coercion is too great, interfering responses and hostility toward the coercer made participants less prone to accept the coercer’s attempts to influence them. Yet the crushing of the prodemocracy movement at Tiananmen Square in 1989 in China illustrates that credible strong threats followed by application of overpowering force and punishment can be a powerful deterrent. Nevertheless, subjugation to continued coercion is likely to contribute to dysfunctional outcomes such as learned helplessness, feelings of powerlessness, alienation, and depression. When possible, it can generate verbal and interpersonal aggression and provoke sabotage in those who are being coerced (Spector, 1975). In a study of 216 nurses and nurses’ aides, Sheridan and Vredenburg (1978a) found that the use of coercive power contributed to heightened tension.

*Caveat.* Most of the research on coercive power was completed before 1980. Since then, the use of coercion has probably declined or become more subtle, owing to societal enlightenment, threats of lawsuits,

liberalization of education, and public condemnation of glaring examples of abusiveness. Coercion is still more acceptable in authoritarian societies than in western democracies. But terrorism and military force remain strong as efforts to use coercive power to influence.

## ***Legitimate Power***

Legitimate power is based on norms and expectations regarding behaviors that are appropriate in a given role or position. The legitimization of a role is derived from such norms and expectations. Members are more likely to accept the position of the leader and his or her influence as legitimate when the leader holds attitudes that conform to the norms of the group or organization. Read (1974) argues that the legitimacy of leaders involves a complex set of attitudes toward them and their source of authority; the leaders' actual behavior contributes to their continuing legitimacy. Bleda, Gitter, and d'Agostino (1977) observed that the satisfaction of enlisted personnel with army life was related more to the leadership of those they saw as the originators, rather than as the relayers, of their daily orders.

French and Raven (1959) suggested three sources of legitimate power: (1) cultural values that endow some persons with the right to exercise power; (2) occupancy of a position organized to confer authority; and (3) appointment or designation by a legitimizing agent. An item that Rahim (1986) found to be highly correlated (.74) with a factor of legitimate power was, "My superior has the right to expect me to carry out her (his) instructions."

According to Hollander (1993), "influence and power flow from legitimacy" (p. 29). By legitimizing leadership, followers affect their leaders' influence and behavior and the performance of the group. The legitimacy of leaders depends fundamentally on their standing with their followers.

In goal-setting experiments, students and workers usually try to do what they are asked (Latham & Lee, 1986); they generally regard the requests from experimenters in laboratories and supervisors in work settings to be legitimate. The experiment is a "demand situation." In the workplace, employees think it is legitimate for their supervisor to tell them what to do—that this is inherent in the employment contract (Locke, Latham, & Erez, 1987). The legitimacy of supervisors' orders was significantly related to the subordinates' intention to work hard for an assigned goal in Oldham's experiment (1975).

A survey of 1,155 soldiers who had completed basic training to prepare them for action in the Korean War showed that the soldiers had a stronger "fighter spirit" to the degree that they perceived their leader had legitimacy (R. B. Smith, 1983). According to Michener and Burt (1975a, 1975b), studies of college students indicated that recognition of the authority of the leader's office was more important to their compliance than was endorsement of the leader's personal right to exercise power.

House (1984) provided a rationale for the fact that although people accept leadership based on legitimate power, they do not do so with any special enthusiasm or as readily as they accept leadership based on expert power. When influenced by legitimate direction, followers are being responsive to the source, not the content, of the attempted leadership (Wrong, 1980). They tend to attribute the consequences of their compliance to external factors, not to themselves (Litman-Adizes, Raven, & Fontaine, 1978). They are less personally involved and can take less credit for and less satisfaction from success due to their compliance. They do what is expected of them but not more than may occur in response to leadership based on referent or expert power.

*Legitimacy Through Appointment, Election, or Emergence.* How the legitimacy of a position is established makes a difference. Appointment or election to a position tends to legitimate the leadership role to a greater extent than does emergence in the role through interaction or capture of the role by force. Thus in an experiment with 82 groups of three to five male undergraduates, Burke (1971) found that the basis on which

leadership was legitimated by election, emergence, or counterelection was more important to the role differentiation that occurred within the groups than whether the goal was or was not established by consensus and whether pay was distributed equally or differentially. Huertas and Powell (1986) found an increase of ingratiation and conforming statements among members if a leader was not appointed but was allowed to emerge.

Legitimacy was manipulated in an experiment by Goldman and Fraas (1965). Leaders of groups playing “twenty questions” were either elected, appointed by reason of their competence, or randomly appointed. Control groups had no formal leader. The groups’ performance, as measured by the time required and the number of questions needed to reach the solution, was poorer if the leaders were randomly appointed or if no leader was put in place than if leaders were legitimated by election or appointment because of their competence.

Hollander and Julian (1969) and Firestone, Lichtman, and Colamosea (1975) demonstrated that leaders are in the best possible position to get things done if they first emerged informally as leaders in the group and then were elected by the members. Ben-Yoav, Hollander, and Carnevale (1983) similarly observed that elected leaders were more likely than are appointed leaders to contribute to the group’s discussion and to receive greater responsiveness and support subsequently from other members. Group members regard elected leaders as more competent, more responsive to the members’ needs, and more interested in the group’s task. Election gives followers a greater sense of responsibility for leadership and heightens their expectations for the leader’s performance (Hollander, 1978).

Legitimacy will allow leaders more latitude when representing their group in negotiations with higher authority or with other groups. In turn, legitimate leaders will expect to receive more support from the group they are representing (Boyd, 1972). If elected leaders are also self-confident, they are likely to use their legitimate power and persuasion instead of punishment to correct their subordinates’ poor performance (Goodstadt & Kipnis, 1970). Hollander, Fallon, and Edwards (1977) found that elected leaders had greater influence than appointed leaders on small experimental groups that were perceived by their members to be failing, although the greater influence of a newly elected leader in a group that continued to fail was soon lost.

Winning the election establishes a much higher degree of legitimate acceptance of the U.S. president as the embodiment of the nation and as the head of state, head of government, head of political party, and commander in chief of the military than would be expected from the president’s initial support from the voters. Usually, only about half of the eligible U.S. electorate votes in presidential elections. Often, the difference between the votes for the winner and the votes for the loser is so close that the president, with his enormous powers, is legitimated by only about 25% of the eligible voters. In 2000, the Republican candidate, George W. Bush, received 500,000 fewer popular votes than his Democratic opponent, Al Gore; but the Republican-appointed majority of justices of the U.S. Supreme Court decided 5–4 to award the contested 25 electoral votes of Florida to Bush to give him a majority of the electoral vote and thus legitimacy as president. Although for a while many Democrats continued to question Bush’s legitimacy, it was helped by Gore’s quickly announced concession of defeat.

Other experiments have shown that legitimacy is enhanced when an office is permanent rather than temporary and when it is filled by appointment by a higher authority rather than by election. As mentioned earlier, leaders’ negotiations with higher authorities will have more legitimacy in the eyes of group members if the leaders are elected by the groups rather than fortuitously appointed (Julian, Hollander, & Regula, 1969), but arbitrarily appointed leaders can increase their legitimacy by consulting with the members (Lamm, 1973).

Appointed leaders in a hierarchical setting also are likely to have legitimate power. The amount of power they have is a direct reflection of the power and status of the legitimating authority. For example, the commissions of U.S. Army officers confer powerful legitimacy; the appointment of a university chancellor by a board of trustees does likewise. However, when the legitimator is seen as incompetent and lacking in

authority, the appointee's power and ability will be questioned (Knight & Weiss, 1980). In Torrance's (1954) study of decision making in established and newly formed groups, the members' influence on decision making depended on their position in the power structure of the group and was stronger in permanent than in transitory groups. Furthermore, although Raven and French's (1958a) examination of groups with elected and emergent leaders concluded that "the very occupation of a key position in a structure lends legitimacy to the occupant," the authors also noted that elected leaders were better liked than emergent leaders and their influence was better accepted. Anderson, Karuza, and Blanchard (1977) observed that individuals who were elected to an undesirable leadership position had greater social power than those elected to a desirable position, but that appointment to either position made no difference. Julian, Hollander, and Regula (1969) found that the appointed leaders in experimental groups had a source of authority that was perceived to give them stability in their position. But election made the leaders more vulnerable to censure if they later proved inadequate. Members were most willing for the leaders to continue in their positions when the leaders were competent at the task, interested in the group members, and involved in the group's activities.

*Inner Circle versus Outer Circle.* Vecchio (1979) showed that the leader's legitimate power was particularly important to the performance of those subordinates who were not part of the leader's "inner circle" of confidants and trusted assistants. At the same time, the subordinates in the inner circle did best when their superior did not possess power that was due to his or her formal position. The inner circle was most optimistic about its leader when the outer circle treated their leader in a friendly manner (Koulack, 1977).

*Enhancement of Legitimate Power.* Leaders can increase their legitimate power by becoming the accepted "makers of meaning," definers of reality and the situation (Conger, 1991). In a formal organization, legitimate power becomes equivalent to the authority vested in a position. Illustrating the importance of such legitimate power, Klimoski, Friedman, and Weldon (1980) set up a laboratory simulation of an assessment center<sup>6</sup> that required the assessors in a group meeting to integrate their assessments. The chairpersons of these integrative panel discussions either were or were not granted formal voting rights. If they were granted such rights, they were able to exert more influence on the panel and in the final evaluations of the candidates that emerged.

Subordinates' trust of legitimate authority makes a difference in the authority's power. Earley (1986b) reported that British tire workers who were assigned goals accepted them more when the reasoning for the goals was explained by their union steward, in whom they presumably felt more trust, than when the explanation was offered by their supervisors, whom they viewed as members of management—the untrustworthy opposition. The loss of such trust and confidence is particularly damaging to legitimate power.

*Reduction in Legitimate Power.* In [Chapter 10](#), we noted the sharp fall in public trust in our business, government, and other institutions between 1945 and 2005 (Kingsbury, 2006). Mitchell and Scott (1987) examined the dramatic decline in the American public's confidence in the legitimate leaders of various institutions. In the late 1970s, President Jimmy Carter saw it as a "crisis of confidence." According to public opinion polls, trust in government declined from about 80% in the 1950s to 33% in 1976 (just after the Watergate scandal). From the late 1960s to the late 1970s, the American public's confidence in business leaders fell equally dramatically. It was the leaders of government and business who were seen as particularly untrustworthy, not necessarily the institutions. In the 1980s, over 100 political appointees of the Reagan administration were forced to resign in a cloud of scandals and indictments. The "sleaze factor" in the Reagan administration did not help to restore confidence in governmental leaders; nor did the Wall Street scandals, the Iran-Contra affair, the many plant closings, or the stock market crash of 1987. Confidence in Ronald Reagan appeared to have been maintained during his administration because he conveyed the impression of a

personable, likeable, strong, and decisive leader.

New and different scandals emerged during the presidencies of Bill Clinton and George W. Bush. Business leadership again suffered a crisis of confidence in the 1990s and the early twenty-first century from scandals, bankruptcies, the collapse of the boom in technology stocks, the huge expansion of the federal deficit, the continuing overseas migration of jobs, the decline in real income of the working class, the increasing gap between the rich and the poor, the lack of one-seventh of the population of health insurance, and the unpopular war in Iraq. Lipset (1985) found that a “great deal of confidence in the people running the various institutions” was expressed in 1966, but by 1984 it had declined, as follows: physicians, from 72% to 43%; educators, 61% to 40%; military leaders, 62% to 45%; religious leaders, 41% to 24%; members of the Supreme Court, 50% to 35%; CEOs of major companies, 55% to 19%; leaders of labor unions, 22% to 12%; members of Congress, 42% to 28%; and journalists, 29% to 18%. These figures continued to fall into the twenty-first century (Kingsbury, 2006).

The legitimacy of these institutional leaders is founded on the public’s belief in their special expertise, in their serving as stewards with legal and moral responsibility for the management of their institutions in the best interests of their constituencies, and in their ability to innovate and to inspire progress. Mitchell and Scott (1987) suggested that the decline in confidence was due to the loss of belief that institutional leaders had the expertise and motives that were once attributed to them. Rather than serving as stewards, the leaders had become self-serving. With the decline in confidence has come the loss of legitimacy. The competence of the leaders in government is increasingly questioned, particularly because of continued mishandling of terrorism and natural disasters. Progressive taxation has been bent out of shape, with the heaviest relative burden falling on the poor and working classes and increasingly favored treatment of the wealthiest. Leaders appear to be more self-aggrandizing. Their prospective innovations are increasingly constrained by the felt need to protect others from them. The decline in their legitimacy results in a public that feels much less “obligation or responsibility to believe in what their leaders tell them or to do what their leaders ask of them” (Mitchell & Scott, 1987, p. 449).

Countervailing power can also reduce legitimacy. Caplow (1968) observed that a majority coalition formed in opposition to leaders may not only undermine the legitimacy of their position but may take over the leadership. For instance, Worthy, Wright, and Shaw (1964) created groups in which a confederate accused a naïve teammate of losing a game. When the accusation was legitimate, other members of the team were less willing to interact with the accused member. When the accusation was not legitimate, they were less willing to interact with either the accused or the accuser.

Those with legitimate power may also be ready to give it up or to avoid exercising it. This tendency is more common in young low-level managers. In a survey of 569 managers, Veiga (1986) identified various causes for giving up control:

1. The manager, especially the young low-level manager, may think the group lacks direction, commitment, or a belief that it can do well.
2. The manager personally feels no commitment to or responsibility for the outcome and has nothing to gain from it.
3. The manager feels unwilling or unable to make a meaningful contribution to the decision.
4. The group’s task may seem ill-defined or too difficult.
5. The manager may believe that someone else in the group has more conviction, experience, ability, and willingness to take responsibility.
6. Someone else’s idea may be seen as similar to the manager’s.
7. The manager may feel intimidated by an attack or by higher authority.
8. The manager may wish to avoid damaging a relationship.

*When Legitimacy Is Counterproductive.* Kaplan, Drath, and Kofodimos (1985) noted that legitimate power may be counterproductive if the superior's demeanor, isolation, and autonomy impede the flow of criticism from the subordinates to the superior. The subordinates' performance may suffer if the leader's legitimacy results in an aura of power, in a tendency to monopolize discussions, or in an abrasive style. The use of power in this way may increase social distance between the superior and the subordinates, further restricting communication. If subordinates perceive that the superior's power is an embodiment of the organization, they may interpret criticism of the superior as disloyalty to the organization.

Legitimacy will be counterproductive if powerful superiors appoint only subordinates who agree with them or if the subordinates exempt themselves from the formal appraisals that others who are less powerful must undergo. But knowingly or unknowingly, supervisors may give up some of their legitimate power to their subordinates as a way of increasing overall satisfaction and responsibility. Blake and Mouton (1961a) asked a supervisor and a subordinate to rank lists of items in order of importance. The level of satisfaction and responsibility of both supervisors and subordinates combined was higher when they alternated in exercising power.<sup>7</sup>

### ***Additional Aspects of the Bases of Power***

Yukl and Falbe (1991) added to or replaced the five bases of power with charisma, persuasiveness, and information. Information is a particularly important base of power for political leaders. It gives political, congressional, and parliamentary leaders important knowledge about the rules of their legislatures, the predilections of key members, and their constituents' needs and attitudes. Yasir Arafat's continued presidency of the Palestinian Authority was based partly on his encyclopedic knowledge of the tribes and factions from the many towns, cities, and refugee camps whose diverse interests he had to reconcile if he was to maintain internal harmony (*Dallas Morning News*, 1997). For business leaders, accurate information about the informal networks in an organization of friends, potential advisors, and central figures can also be an important base of power (Krackhart, 1990).

### ***Comparisons of the Bases of Power***

*Relative Importance.* In 13 studies reviewed by Podsakoff and Schriesheim (1985a), large samples of respondents ranked French and Raven's five bases of power according to their importance in the superior-subordinate relationship. Agreement was high among the respondents, regardless of whether they were salespeople, members of a liberal arts faculty, insurance agents, or factory workers. For each sample as a whole, expert and legitimate power always ranked first or second in importance. Mean ranks were tied at 1.6. The other bases were seen as far less important. Means were: referent, 3.3; reward, 4.1; coercive, 4.6. However, Podsakoff and Schriesheim urged caution in interpreting these findings on their face value.

*Relative Willingness to Use Power.* Effective principals establish higher standards for their school by using their power to enlist the support of the teachers to improve standards. They use their power to support the teachers' career development during early adulthood to midlife and to help teachers find fulfillment in their work (Krupp, 1986). Leaders differ in their willingness to use power that derives from one base rather than another. Lord (1977) identified 12 functions that are typically performed by a leader, such as developing plans, proposing solutions, and providing resources. He watched to see how often each leader in a sample displayed the 12 functions. He also determined which of French and Raven's (1959) five bases of power the leaders used

in attempts to exert their power. Lord then correlated the occurrence of each leadership function with the basis of power the leader used. He found that task-relevant behavior to complete the work of the group correlated with the type of power used, but the leaders' efforts to establish socioemotional relations did not. For example, the extent to which leaders relied on themselves as task experts correlated with the extent to which they proposed solutions. However, the extent to which the leaders tried to use referent power in their socioemotional efforts did not increase their being liked.

Coercion is more likely to be used by leaders who lack self-confidence and who have coercive power. In a laboratory experiment, Instone, Major, and Bunker (1983) found that, compared with those whose self-confidence was high, those who lacked self-confidence tended to use coercion rather than expert power. House (1984) listed other personal attributes that contribute to a leader's tendency to use coercive power, including the leader's power orientation, Machiavellianism, and dogmatism. In another laboratory study, Goodstadt and Hjelle (1973) reported that individuals who perceived themselves to be externally controlled by their environment used punishment to maintain their influence much more frequently than those who saw themselves as internally self-controlling. "Self-controlling internals" attempted to lead through their expert power rather than coercively.

Raven and Kruglanski (1970) suggested that those with power anticipate the consequences of using the various kinds of power they may have and avoid using powers that are believed to be least effective. Thus coercive power will be avoided unless the power holders expect resistance—in which case they will be tempted to employ more coercive power if they are capable of doing so (Kipnis, 1976). Support for this contention was found for managers in state agencies, industry, and the military (Kipnis & Cosentino, 1969), as well as in laboratory experiments (Goodstadt & Kipnis, 1970). In the Kipnis studies, supervisors were asked to describe an incident in which they had to correct the behavior of a subordinate. Which type of power was brought to bear in this situation depended on the supervisors' diagnosis of the subordinate's problem, the subsequent and most likely reactions of the subordinate, and what was likely to be best for the continuing relationship with the subordinate.

Culture, tradition, hierarchical relations, and organizational norms will also determine what type of power may be applied in a given situation. For instance, tradition may give those with seniority and age power that can be used and accepted by those who are younger and have less seniority. Age itself may make a difference. When I asked Japanese managers meeting with each other for the first time at a workshop to form informal groups with group leaders, the groups selected their leaders by asking members who was oldest. More authoritarian, coercive uses of power will come into greater use and acceptability during times of stress. Managers can use more reward and legitimate power with subordinates than with peers (Yukl, Kim, & Falbe, 1996).

Legitimacy will be stressed by those who believe in "rules of law rather than rules of men." House (1984) suggested that legitimate power will be favored over arbitrariness and political influence because legitimate power provides more orderliness and predictability. Legitimacy has more clear-cut limitations; unbounded arbitrary power generates excess costs and inefficiencies. Legitimate power can be exerted impersonally without a buildup of allegations of political exchanges. Legitimate power is ordinarily more acceptable to the subordinate and more supported by the larger group than power based on the personal arbitrary predilections of the superior. House (1984) obtained considerable support for the greater acceptability of legitimacy in studies in which employees were asked why they complied with manager's requests, suggestions, or directions.

Willingness to use one type of power rather than another was observed by Rosenberg and Pearlin (1962) in a study of the attitudes of 1,138 hospital nurses toward power. The percentages of nurses who stated that they would use each form of power were as follows: persuasion, 54%; benevolent manipulation, 38%; legitimate authority, 5%; coercive power, 2%; contractual power, 1%. Kappelman (1981) reported that male school principals were more likely than their female counterparts to use reward and coercive power, although women

principals were likely to be described as more active leaders.

Since the bases of power are interrelated, changes in one will have effects on the others. For example, Greene and Podsakoff (1981) found that when the reward power of 37 supervisors in a paper mill was lowered by abandoning an incentive pay plan in which the supervisors' evaluation of the performance of 392 subordinates had figured strongly, not only did the supervisors' reward power decline, but their referent, legitimate, and organizationally sanctioned power declined as well, while the subordinates' perceptions of the supervisors' coerciveness increased significantly. No such changes in the bases of supervisory power were found in a second comparable paper mill that did not change its pay policy. Consistent with this, Garrison (1968) concluded that when leaders' efforts to succeed through legitimacy failed, they resorted to coercive power.

### ***Effects of Different Bases of Power***

The compliance caused by different bases of power is perceived differently. Rodrigues and Lloyd (1998) concluded from five studies using a total of 570 participants that compliance induced by reward, informational, and referent power was more internalized and controllable than compliance induced by expert, legitimate, and coercive power. Rubin, Lewicki, and Dunn (1973) found that cooperativeness, benevolence, friendliness, and generosity were attributed to those in power who used rewards rather than penalties. The reverse attributions were made about those who used authority or political persuasion.

[Table 11.2](#) shows correlations between the perceived power base of first-line supervisors and their *initiating* behavior and *consideration* as leaders.<sup>8</sup> Martin and Hunt (1980) found these results for 289 professional personnel in a construction bureau and 118 in a design bureau of a midwestern state highway department who responded to a mailed survey. As can be seen, of all the bases of power, expert power made the most important contribution to leadership. The effect was not always beneficial; design professionals who complied with their supervisor because of the latter's expert power signaled a greater intention to quit.

Ivancevich (1970) reported that the satisfaction of life insurance agents correlated .35 with the agency manager's use of referent power, expert power, and reward power, but satisfaction correlated 2.28 with the use of coercive power and .14 with the use of legitimate power. Bachman (1968) found that faculty members at colleges were better satisfied under powerful deans with control over college affairs whose influence was based on expert and referent power than under deans who relied on reward, legitimate, or coercive power. However, in a study of salesmen's perceptions of branch managers' power, Ivancevich and Donnelly (1970a) found that coercive and legitimate powers were not related to productivity. Only the expert and referent powers of the branch managers were positively related to the salesmen's performance.

*Caveat.* Podsakoff and Schriesheim's (1985a) review of these and other field studies of the relationship of the five sources of power of supervisors and the outcomes for subordinates concluded that unlike studies of the *actual* reward behavior of supervisors that usually generates positive outcomes, the supervisors' *power to reward* was unrelated or even negatively related to such outcomes. But Podsakoff and Schriesheim attributed the difference in findings to the way these field studies measured power. Often the measure consisted only of respondents' rank ordering of the bases of power as defined. The power to reward was confounded with a sense of illegitimacy used in exchange for reluctant compliance rather than for performance. Coerciveness was seen to be confounded with the potentially illegitimate use of punishment. The actual narrow content of the scales of legitimate power failed to match French and Raven's broader conceptualization, and the desired identification of the subordinate with the superior was not included in measures of referent power, which often seemed no more than assessments of friendship.

Table 11.2 Correlations between the Perceived Basis of Power and Ratings of the Initiation of Structure

## and Consideration by First-Line Supervisors

<i>Basis of Power</i>	<i>Initiation of Structure*</i>		<i>Consideration*</i>	
	<i>Construction Bureau</i>	<i>Design Bureau</i>	<i>Construction Bureau</i>	<i>Design Bureau</i>
Expert	.44	.41	.50	.48
Referent	.23	.16	.15	.10
Reward	.24	.06	.11	.02
Coercive	.10	.01	-.10	.01
Legitimate	.04	.11	-.03	.00

\* See [Chapter 20](#) for detailed definitions of initiation and consideration.

SOURCE: Adapted from Martin and Hunt (1980).

Hinkin and Schriesheim's (1989) surveys of three samples of students who described their part-time or full-time supervisors found that although coercive power correlated with legitimate power to some extent, it was likely to be independent of the other bases of power. The other bases—expert, referent, and reward—correlated with legitimate power as a base as well as with each other as bases.

Despite these shortcomings, seven of the field studies<sup>2</sup> in Podsakoff and Schriesheim's (1985a) review emerged consistently with positive associations between supervisors' expert and referent power and subordinates' satisfaction and performance. The results were uniformly negative or reversed for coercive power and mixed for legitimate and reward power. Negative correlations were found between the supervisors' expert and referent power and the excused absences of production workers (Student, 1968), but no power measure was related to unexcused absences or turnover. However, Busch (1980) found that the expert power of supervisors contributed to the subordinates' intentions to remain in the three companies studied. Less consistent findings emerged for referent and legitimate power. A similar pattern was noted by Gemmill and Thamhain (1974) in the outcomes of support by supervisors and the commitment of subordinates to the work associated with supervisory powers. Only expert power was consistently positively correlated with such outcomes and with the clarity of the subordinates' role. Also, such role clarity appeared to be enhanced if the superiors had referent power.

Yukl and Taber (1983) agreed with Podsakoff and Schriesheim (1985a) that the use of expert and referent power is most efficacious. Nevertheless, the skill of application and appropriateness of power must be considered. Leaders need to exercise authority with courtesy and clarity and to verify compliance. Reward power should be used to reinforce desirable behaviors after they occur. Coercive power should be used only when absolutely necessary, for example, to deter behavior that is detrimental to the individual, group, or organization. Leaders accumulate and foster expert and referent power over time by showing that they are confident, decisive, considerate, and protective of subordinates' interests. In the same vein, Watts (1986, p. 286) suggested that "using too much power can express the need to control, the flip side of which is the fear of being out of control. Using too little power can express a tremendous need to be liked, to avoid conflict." Furthermore, leaders need to avoid promising more (on the basis of their reward power) than they can deliver, and they need to avoid being corrupted by their power.

## ***Power and Corruption***

In the 1840s, Count Cavour, a future cofounding statesman of modern Italy, wrote that "absolute power inevitably corrupts," a remark which Lord Acton later made famous as "Power tends to corrupt; absolute power corrupts absolutely" (D. M. Smith, 1985, p. 26). The process was elucidated by Kipnis (1976). First,

the desire for power becomes an end in itself. Next, access to power tempts the officeholder to use institutional resources for illegitimate self-aggrandizement. Self-aggrandizement is followed by false feedback from others, which elevates the leader's self-esteem, devalues the worth of others, and distances the leader from them.

Gardner (1986a) listed four ways to help mitigate the corruption of power in government. First, the rule of law and the accountability of leaders to abide within explicit and universally applicable constraints must be accepted. Second, power needs to be dispersed, as in the U.S. system of checks and balances of executive, legislative, and judicial powers. Third, a strong private sector must be maintained. Fourth, an alert citizenry is essential.

So far, analyses of power and corruption have been left to investigative journalists and the legal profession. Controlled surveys and experiments are needed to increase our understanding of the interrelation of power-corruption relationship, its antecedents and its consequences for business, governmental, and other institutions. How do various factors—the fear of being caught; public humiliation; regulatory control; a sense of duty, obligation, patriotism, and loyalty; and internalized ethical and professional standards—inhibit the corruptive influence of holding power over others? [Chapter 9](#), on the ethics of leadership, has already dealt with some aspects of the corrupt use of power.

### ***Importance of Content***

Organizational formalization, rules, and norms can substitute for the expert power of leaders and their influence. On the other hand, if the *expert* power of leaders is seen to improve the functioning of their subordinates or to be applied usefully, their perceived influence will be enhanced (Podsakoff & Schriesheim, 1985). A leader's *referent* power was found by Yukl and Falbe (1991) to be most important to compliance by followers; a leader's *legitimate* and *coercive* power were most important for employee compliance in routine operations. If the holder of power is working on a task in an experiment with another person requiring cooperation, power will be used for their joint benefit. If they are in competition, power will be used to benefit its holder at the expense of the other. The amount of power used will not differ. The perceived competence of the power holder will affect the use of power in the cooperative context, but not in the competitive context (van Kippenberg, van Kippenberg, & Wilke, 2001).

## **Summary and Conclusions**

---

Power is a force giving one person the potential to influence others. Power can be personal (expert and referent) and positional (reward, coercive, and legitimate). It contributes to leadership and influence but is not synonymous with them. Information is among many other sources of power. It makes power expandable. Status and esteem provide power, influence, and leadership. Followers react differently to leaders whose power derives from different sources. The followers seek to be liked by those with referent and reward power. Although the threat of punishment tends to induce compliance, followers find leaders who use coercive power less attractive than those who use other forms of power. Furthermore, followers respond to reward power either by developing contractual agreements or by forming coalitions that tend to equalize the bargaining positions of participants in the power structure. Appointment or election to a position tends to legitimate it to a greater degree than does acquisition of a position by force or by the emergence of a leader in interactions.

Leaders draw consciously or unconsciously on multiple sources of power. Reward and coercive power are controlled most easily. Leaders have less control over referent power—the extent to which group members like them and are attracted to them. Self-confidence, self-esteem, and knowledge of the task enable subordinates to resist the effects of power. Interacting with peers and gaining support from reference groups strengthen the

followers' resistance to coercion. The influence of a leader can be weakened if the followers form coalitions with counter-vailing power. Followers can reduce their subjection to influence by asking and receiving a clear definition of the situation. The power of a leader is weakened by the presence of members whose values and goals are in opposition to those of the leader and the organization and who challenge the legitimacy of the leadership role. Ingratiation may also be a means of private resistance. Power can corrupt both leaders and their followers. It can be shared and distributed for personal or organizational reasons.

<sup>1</sup> Power and its effects on leadership were the subject of comprehensive reviews by Cartwright (1959a, 1959b, 1965), House (1984, 1988), Podsakoff and Schriesheim (1985a), and Yukl (1981), among others.

<sup>2</sup> More will be said in [Chapter 29](#) about the power and importance of central and peripheral positions in a network.

<sup>3</sup> [Chapter 15](#) will review the use of rewards and punishment by leaders in much more detail.

<sup>4</sup> [Chapter 15](#) will detail further conditions under which leadership will be punitive. [Chapter 28](#) will examine the effects of stress on leadership.

<sup>5</sup> A standard sample of memos, notes, letters, and bulletins requiring actions and decisions likely to be found in a supervisor's in-basket. The adequacy with which the problems in the correspondence are handled can be scored. [Chapter 35](#) will provide more details.

<sup>6</sup> See [Chapter 14](#).

<sup>7</sup> Voluntary power sharing will be discussed in Chapters 18, 25, and 26.

<sup>8</sup> See [Chapter 20](#) for detailed definitions of initiation and consideration.

# Leadership and the Distribution of Power

The distribution of power and the leadership associated with it have been a main theme in both political history and the history of management-worker relations. Autocracies and oligarchies have represented concentrations of power; democracies have represented a wider distribution of power. In the former, the individual autocrat with a patronizing staff of subordinates dictated to a relatively powerless membership. In the latter, power was dispersed voluntarily or as legally mandated. The past century has witnessed in the developed world a substantial reduction in the range between the powerful and the powerless. The differences in power between women and men, parents and children, teachers and students, and supervisors and supervisees have all been reduced. Apart from some Asian, African, and Latin American countries, autocracies, dictatorships, feudalistic, and tribal societies have been replaced by more democratic forms of government, business, and other institutions. Nevertheless, in many organizations, communities, and countries, large differences in political, economic, and social power are the rule rather than the exception. In informal groups, power differences are likely to evolve. In initially leaderless groups, power accrues to the active and more knowledgeable members.

## Importance of Differences in Power

---

Mulder (1976) focused attention on such differences in power in organizations and the tendency of those who are striving for more power to reduce them. Hofstede (1980, 1997) unearthed a “power distance” factor in a large-scale survey of employees’ attitudes in 50 countries. A large power distance was indicated, for example, in countries in which employees expressed fear of disagreeing with their supervisors.

*Power and Leadership Style.* Hofstede suggested that with a large power distance between leaders and followers, or supervisors and employees, the followers and employees became either dependent or counterdependent. When differences in power are great, more autocratic leadership and more coercion are likely. Large differences within a group, organization, or society—particularly in coercive power, and to a lesser extent in personal, reward, and legitimate power—may guarantee public success and acceptance of the leadership. But resistance, at least private resistance, will bring about unintended consequences, such as resentment and apathy. On the other hand, the maintenance by leaders and supervisors of a small power distance between themselves and their followers and employees encourages consultation and participation. Many behavioral science theorists<sup>1</sup> have observed that the sharing, leveling, and equalization of power among members of a group increases the members’ participation and results in their full commitment and their acceptance, both public and private, of the leader.

*Elitism versus Populism.* Even within a society’s democratic order, there are wide differences in power. Populism competes with elitism. Populists believe that all citizens share equally in the opportunity to exert influence through political activity. Elitists believe that power should be delegated to those who are committed to the rules of decision making and are highly knowledgeable and skilled in analysis, negotiation, persuasion, and manipulation. Populism calls for a high degree of citizen participation; elitism calls for a relatively passive,

un-involved citizenry, who, from time to time, “in a single elemental choice,” elect active officials who will be responsible for the stability, efficiency, and authority of the state (Summers, 1987). Populism within the work organization translates into shop-floor democracy, in which all employees share consultation and decision making with their immediate superiors. Elitism within the organization translates into the election of experienced and knowledgeable union officials and council representatives, or heavy dependence on informal leaders from within the workforce.

### ***Distribution of Power in the Small Group or Team***

Populism within the small group or team translates into shared decision making by the group members; elitism translates into elected heads whose power to decide is unchallenged by the members, who remain passive following the election. In elitist groups, most of the power resides in the leader; in populist groups, it is widely shared and equalized among the members and the leader. With such equalization of power, the members become as influential as the leader, and their effects on each other become important to the process of interpersonal influence. Thelen (1954) noted the power and control of the group over its members. Group agreements “have teeth in them.” The determination of what is possible and at what cost or with what reward is under the control of the group. Leadership occurs in changing the agreements and working out new ones to fit the continual diagnosis of realities in the group problem situation.

According to Tannenbaum and Massarik (1950), shared decision making increases the likelihood that workers will accept the goals desired by the management. This results in their greater satisfaction and increased efforts to move toward the selected goals. Likewise, McGregor (1944) argued that the effectiveness of workers will be increased when they are given opportunities to participate in finding solutions to problems, to discuss actions that affect them, and to assume responsibilities when they are ready to do so. If members of a group participate in setting goals, they will be more motivated to achieve the goals. If they have the capabilities, they can be delegated more responsibility or freedom to act without a review by a higher authority (Learned, Ulrich, & Booz, 1951).

When all members are equal in status and power, more communication of feelings will occur (Bovard, 1952). Differences in status and power in a group result in the inhibition of the ventilation of feelings by members who are lower in the status and power hierarchy. Such inhibition can be detrimental to the group's functioning. Thibaut and Coules (1952) found that the communication of hostility toward instigators will reduce the residual hostility toward them. Again, power differences can offset the influencing effects of participation. Bass, Flint, and Pryer (1957b) and Bass (1963) ascertained that for individuals to influence a group's decisions, they had to participate and to attempt to lead. Nonetheless, such active participation did not necessarily influence the group's decision when the members of a small group varied widely in power.

*Caveats.* This does not mean that all communications are easier and all outcomes are better when members are equal in status and power. Although some believe that power sharing and participation are a universal panacea for promoting change, productivity, and satisfaction, experimental researchers such as Locke, Latham, and Erez (1987) have pointed out that considerable qualification is needed. For instance, if the leader is clear and supportive, the members' acceptance of hard group goals can be obtained without the power sharing implied in group discussions and decision making. More competition from members and persistence by the leader in the face of rejection are likely to be required of the would-be leader of a group in which all members are equal in status and power. Thus Bovard (1951a) observed that in groups where there is little status differentiation among members and all have similar power to influence each other, verbal interaction is higher and more influencing is attempted than when a single person of higher status directs the activities. It may be

that although communication seems easier when members are equal in power, it really is more difficult. Shepherd and Weschler (1955) studied work groups that differed in internal status stratification. The members of these groups felt they had fewer communication difficulties, but they actually experienced more such difficulties.

*Formation of Coalitions.* The distribution of power in a small group is dynamic. Two or more members can combine their power to increase their joint power and influence the course of events. Lawler (1975) found that expectations of support from others were an important cognitive determinant of the formation of a coalition against inequitable and threatening leaders. How reward power is distributed in the triad has been the focus of experiments regarding the bargaining process. Mills (1953) assembled triads in which one member was given high reward power; one, medium reward power; and one, low reward power. A strong tendency was found for two of the members to form a coalition that acted in opposition to the third member. Vinacke and Arkoff (1957) confirmed hypotheses advanced by Caplow (1956) that: (1) when all members of a triad are equal in power, all possible combinations will be formed; (2) when two equal members who are stronger than the third member combine, they will form a coalition in opposition to the third member; (3) when one member is weaker than the two equal members, he or she will form a coalition with one of them; and (4) when one member is stronger than the other two combined, no coalition will ensue. Turk and Turk (1962) confirmed the fourth of these hypotheses. But Kelley and Arrowood (1960) found that the results reported by Vinacke and Arkoff depended on the clarity of the game and on whether a player was assured of a certain return whether or not he or she joined a coalition.<sup>2</sup>

Coalitions are also organized as a tactic to increase one's upward influence. Kipnis and Schmidt reported that respondents exerted more upward influence on their boss by obtaining the support of their coworkers and subordinates to back up their request, or they arranged a formal meeting with the boss at which they made their request. Such coalitions were used at about the same frequency to influence coworkers, subordinates, and the boss.

### ***Stability in Small Groups***

The stability of the distribution of power begins early. In an observational study of kindergarten children, Hanf-mann (1935) noted a stable power structure that was similar to a pecking order. The same child would continue to give orders to the same second child, who did the same to the same third child. Gellert's (1961) observations of pairs of preschool children during three play periods found that in a significant proportion of these dyads, the same child maintained the same position of dominance or submission during the three periods. This again suggests that a pecking order was at work.

### ***Structuralism versus Human Relations***

There are two opposing arguments about how power should be distributed in organizations. In the *structuralist* view, organizations are mechanistic rather than organic (T. Burns & Stalker, 1961). It is inherent in the nature of organizations with systems of command and control that power is distributed unevenly. As organizations develop, power accrues in varying amounts among the units and supervisors. Some units (and, therefore, their supervisors) obtain more power than others in influencing the allocation of the organization's scarce resources (Pfeffer & Salancik, 1978). The units and supervisors with more power have control over strategic contingencies and the activities of other departments that are critical to their functioning; this makes it less likely that there will be any way of substituting for the more powerful units' and supervisors' activities.

Also, information is provided to the less powerful units and supervisors to decrease uncertainties. Thus more powerful units and supervisors are in the center rather than at the periphery of information and work flow (Hickson, Hinings, et al., 1971). Support for these propositions was found in 20 subunits of five breweries by Hinings, Hickson, Pennings, et al. (1974). Similar results were obtained for 62 vice presidents, deans, and directors of six universities (Saunders & Scamell, 1982).

Power holders want to retain their power, so the power distribution in mechanistic organizations remains stable over time unless there are shifts in technological and environmental demands or the power holders are replaced (House, 1991). But temporary downward shifts in power become necessary as leaders' positions enlarge. Increasingly, leaders need to rely on subordinate staff as intermediaries, deputies, and surrogates. Kings had to share their power in distant colonies with viceroys. Whyte (1953) and Simon (1957) argued for structure, power differences, and status differentiation. They contended that hierarchical organization is the natural, biological, and sociological solution for ensuring a group's survival. R. B. Cattell (1953) hypothesized that status differentiation and the accompanying power differences promote speed in decision making and the faster attainment of goals.

*Human Relations Perspective.* The opposing *human relations* perspective sets forth that increasing the equalization of power in organizations was essential to the organization's health. Reducing power differences was a basic tenet of modern organizational development theory and practice (Bennis, 1965) and the human potential movement (Maslow, 1965). The organic organization was favored. It had its roots in those aspects of democratic and egalitarian values that stress the importance of informal trusting relationships rather than a formal structure in which relationships depend on the authority of position and role requirements. Practical applications include unstructured leadership, job enlargement, leadership sharing, participative management, consultative supervision, joint consultation, workers' councils, and other forms of industrial democracy. Patchen (1970) administered questionnaires to 90 employees in plants operated by the Tennessee Valley Authority and found that the degree of control workers had over their jobs was significantly correlated with their general interest in their jobs, concern with innovations in their work, and pride in their work. These findings were supported by communication studies (McCurdy & Eber, 1953).

Argyris (1957) and McGregor (1960) were convinced that individuals, motivated by their basic desire for autonomy and self-actualization, were frustrated by organizational structure, specialization of work, and philosophies of management that assumed that workers would remain complacent and unproductive unless they were subjected to controls hampering unwanted initiatives from them. When workers were less encumbered by controls, their first-line supervisors also benefited. Atwater (1996) found that in organic organizations, more power was bestowed on first-line supervisors relative to the power at higher levels of management, as reported by 280 employees from 45 traditional or organic organizations.

*Stability in Organizations.* House (1984) deduced that the distribution of power in organizations would tend to become stable over time and would change only if there were major shifts in environmental or technological demands on the organization. But even here, changes in the power distribution would come slowly because those in power are reluctant to part with any of it. In fact, given the tendency of the powerful to gain more power, demands for change in the organization may bring about a greater concentration of power rather than equalization.

*Implications for Organizational Design.* The two views have been the basis of opposing prescriptions for how organizations should be designed. *Structuralism* emphasizes designing organizations with power differences; *humanism* emphasizes designing organizations with more power equalization. Legitimate differences in power are manifested in an organization in how much the positions of members are structured—

that is, prescribed and bound by rules and regulations or the dictates and policies of a higher authority. An infantry squad is highly structured; an initially leaderless discussion group is not. In the infantry squad, there is a clear legitimate hierarchy of power from the squad leader down to the new private; there is no such legitimate hierarchy in the leaderless discussion group. Equalization of power is fostered by humanism in its support for informality, trust, learning, and the sharing of information.

Structuralism as enunciated by such classical management theorists as Taylor (1911), Fayol (1916), Follett (1918), and Davis (1942) depends on external constraints to gain the compliance and commitment of followers. The human relations viewpoint, through the equalization of power, expected to gain even more commitment as well as compliance through the individual's awareness of and insight into effective interpersonal relations and trust.

Structuralism called for someone to be responsible for supervising all essential activities. The hierarchical pyramid of supervisor-subordinate relationships was mandated. Power sharing proposed that any team member could take on leadership responsibilities when he or she saw the need to do so. The autonomous team with no formally appointed leader was the extreme example.

Structuralism avoids the duplication or overlapping of responsibilities. However, overlapping, cross-training, rotation, and other forms of sharing responsibilities to increase the reliability of the system are encouraged by human relationists when informal relationships are developed among workers who are committed to see that their group prospers. The simplification of jobs is fundamental to a structuralist approach. According to this perspective, no individual should be responsible for a wide assortment of unrelated acts. In contrast, human relations theorists call for the enlargement and enrichment of jobs; they believe that subordinates who receive bigger jobs with greater responsibilities become closer in power to superiors.

The structuralist position calls for subordinates to receive clear, written job specifications and role assignments. The human relations position calls for making goals clear and allowing subordinates, commensurate with their training and experience, to decide how to reach the goals. Both structuralists and human relation-ists agree that authority should be delegated so that decisions take place as close as possible to the action. For structuralists, the decision maker is the superior in the situation; for human relationists, the decision is shared or delegated to the subordinates as much as possible.

Structuralists emphasize the chain of command. Human relationists argue that organizations require much communicating, reporting, proposing, influencing, complying, and deciding in complex vertical, diagonal, and horizontal paths that are not shown on the formal organizational charts. Again, participants need some sense of the equalization of power for this flow to occur effectively.

Neither the structuralists nor the human relationists have a monopoly on the most effective design (Bass & Ryterband, 1979). Situational elements and personal preferences affect which approach pays off. Young professional workers, compared with older unskilled employees, are likely to call for less structure and more equalization of power. Small-business managers, secure in their personal relations with their parents and attachment to their spouses, will be more comfortable in decentralized organizations with less structure; less secure counterparts who prefer distance in their personal relationships will want centralization of power (Johnston, 2000). Some pupils thrive in schools with a great deal of freedom to choose what and how to learn, but others do best in a highly structured environment. Juvenile delinquents who adjust most readily to institutionalization may have more difficulty avoiding antisocial, criminal behavior once they are back on the streets. The optimum differentiation of power is likely to lie between the extreme structuralist and extreme human relations positions, depending on the situation. In a pluralistic society, the only thing one can safely say is that wide differences in performance, attitudes, and response to hierarchy are likely to depend on task, time, place, immediate needs, and such.

## Distribution of Power in Communities and Organizations

---

The distribution of power provides the potential for leadership and influence over events and people. It shows itself and its effects in how it is distributed in communities, in formal organizations, and in smaller groups. In small communities, citizens may have the power to directly participate in decisions, such as at town meetings. In cities, they may have the power to participate indirectly through attendance at civic meetings, consultation with officials, and keeping themselves informed. They may reveal their power in elections, formal petitions, protests, initiatives, and referenda. Or they may be powerless and manipulable (Couto, 1992). Central to civic improvement in many U.S. metropolitan areas has been citizens' power to directly participate in decisions regarding innovation and change. In Portland, Oregon, citizen participation became expected as mayors, governors, and legislators introduced land laws, new parklands, light rail, and a revived active downtown to provide a high quality of life. In San Antonio, civic organizations pushed their elected officials into major changes, such as on the riverfront. In many cities such as Denver, business and government leaders shared power and responsibilities in turning the economy around. Catholics were mobilized by a bishop in Cleveland to deal with urban sprawl and its effects on the poor of the inner city. Neighborhood associations, commonplace in cities and suburban communities, deal with local as well as communitywide issues (Pierce & Johnson, 1997).

### ***Community Power Structures***

The earliest research on power was concerned with identifying individuals who had the power to influence their local communities. Lynd and Lynd (1929) pointed the way in their study *Middletown*. F. Hunter (1953) used interviews in a large city to obtain a list of 175 persons who were mentioned as wielding influence in the community, with reasons for the belief that they had such power to influence. A panel of experts reduced the list to 40 persons who were regarded as constituting a monolithic power structure in the city. However, Dahl (1961) maintained that the nominating technique hid important details that could be uncovered by a study of community issues. He concentrated on identifying those individuals who had played key roles in promoting or blocking issues. His analysis of the data suggested that there was a pluralist power structure in the city. Using both Hunter's and Dahl's methods, Freeman, Fararo, Bloomberg, and Sunshine (1963) and Presthus (1964) found that the two methods identified a common core of power figures and that Dahl's method revealed additional subgroups of individuals who could influence different issues.

The status and power structures of many communities were studied.<sup>3</sup> Consistently, people who were identified as having power also tended to rate high in social and economic status. Educational level, as such, was less important (Alford & Scoble, 1968). However, the acceleration of the importance of new technology in everyday life has given professionals increased power in their communities. That is, as problems of health, economics, safety, and so on come to the fore, the expert power of professionals takes on increasing importance in the community.

When Hunter and Fritz (1985) studied the power structures in four Chicago suburbs, they found that the smaller communities contained less complex structures. This finding fit with V. Williams's (1965) conclusion that smaller communities may be able to function effectively without the differentiation of roles and individuals in specialization, power, and authority. Similarly, Nix, Dressel, and Bates (1977) described the dispersion of power in small rural communities, drawing on 189 interviews and the reconstructed history of a country in the southeastern United States since 1900. They noted that the initial bossism was replaced by informal cliques, organized pluralism, bifactionalism, multifactionalism, and amorphous leadership. In the Chicago suburbs studied by Hunter and Fritz, the informal status structures were less complex in the richer suburbs than in the poorer ones.

Equal status and equal power are more commonly found when familiarity, homogeneity, and the potential to interact are high. Caplow and Forman (1950) observed that when neighborhoods contained families who were homogeneous in duration of their residence, their interests, and their type of dwelling, no status differentiation occurred. Form (1945) reported similar findings for Greenbelt, Maryland, when it was a newly established community for federal white-collar employees of similar occupations, age, nativity, and housing. Similarly, Munch (1945) found that the homogeneous inhabitants of isolated Tristan da Cunha in the South Atlantic maintained their community without status differentiation or institutionalized government.

*Interlocking Office Holding.* Perrucci and Pilisak (1970) compiled a list of 434 organizations in a community with a population of 50,000. Of 1,677 executives in these organizations, 1,368 held a position in only one organization. Twenty-six executives who occupied positions in four or more organizations were compared with 26 executives who occupied a position in only one organization. The multiorganizational leaders were regarded by both groups as being more powerful and as having more influence on actual and theoretical issues. These leaders were named more often as social and business friends and were found to constitute a powerful network of influence relationships. The concentration of power was seen in the city boss, studied in detail by Banfield and Wilson (1963), Moos and Koslin (1951), and Zink (1930). Mayor Richard Daley of Chicago epitomized the use of social exchange relationships with other bloc leaders and centers of community power to build the powerful political machine that claimed to “make Chicago work.” His son, as mayor, continued the tradition of relationships.

## ***Power Systems***

Power reveals itself in formal organizations in the extent to which it is associated with status and authority—the formal authority system—and in the beliefs shared by the members in the organization’s system of ideology. An organization’s *system of authority* involves the way legitimate power is distributed and enacted in goals, rewards, sanctions, and the division of labor. It is based on the legitimate power of the different roles and positions, and the status and authority of the position holders. The organization’s *system of expertise* is the way information and knowledge are distributed among its positions and position holders. It is more informally applied to solving the complex problems of the organization (Mintzberg, 1983). The interlocking of systems was illustrated by Majchrzak (1987), who found that rates of unauthorized absences in units in 20 Marine Corps companies were significantly reduced, in contrast to 20 control companies, if policies were clarified and communicated effectively to all levels involved and there was a hierarchical consistency in agreement and understanding of the policies and requirements at the different levels.

The systems offset each other. Although the authority system would dictate otherwise, the system of expertise may result in managers being less influential than their subordinate staff experts. B. Walter (1966) traced the transmission of influence in two municipal organizations. Superiors generally were found no more influential than their staff subordinates in making decisions; in fact, the subordinates were more influential when making novel decisions.

The *political system* operates outside the system of formal authority to benefit some constituents at the expense of others or at the expense of the organization (Mintzberg, 1983). Although the political system is likely to conflict with the other systems, it can also serve to mobilize power when needed for the acceptance and implementation of new strategies. The interacting systems of power can be observed in community settings as well.

*Status and Power.* One of the most consistent findings in social science is the general tendency for those higher in status in an organization to wield more power to influence those who are lower in status. Thus, at

Walt Disney World leaders are expected to encourage their staffs of “cast members” to connect with visitors emotionally by “owning” their roles and monitoring their performances and the visitors’ reactions. Among many studies of the relationship, Blankenship and Miles (1968) found hierarchical position to be a more important determinant of managers’ decision-making behavior than the size of a company or the number of subordinates that the manager supervised. Bass (1960) argued that by creating greater differences in power and status between the leader and followers, one can increase the proportion of success in acts of leadership. This outcome was observed by Hemphill, Seigel, and Westie (1951) in a study of 100 groups that varied in status differentiation. Such leadership was also likely to be more dominating, directive, and coercive and more likely to define and structure the work for the membership. Again, as was expected, a related study of 212 aircrews by Rush (undated) found that commanders were much less considerate of their subordinates when the crews were highly stratified in status.

House (1988a) concluded that when social stratification (status differentiation) exists and the holders of authority feel strongly about their status, they will have fewer inhibitions against being coercive. The greater the social stratification, the more likely they are to be coercive in order to obtain compliance from those at lower levels. Nevertheless, high-status powerful persons may fail to be successful leaders over the powerless. They may become distrusted (Tenbrunsel & Messick, 2001), particularly if they usurp power or are coercive.

*Effects of the Total Amount of an Organization’s Power and Control.* A. S. Tannenbaum (1956a, 1956b, 1968) proposed that the total power and control in an organization varies rather than remaining fixed. Power and control can be expanded by increasing authority—legitimate power—at one or two levels or at all levels of the organization. An organization tends to gain most in the total amount of its control of its members when authority is expanded all the way down the line particularly to the lowest levels. In studies of two industrial plants (1956a) and four labor unions (1956b), Tannenbaum found that organizations of the same type could differ in the amount of authority exercised by executives at different levels and in the total amount of organizational control.

Smith and Tannenbaum (1963) studied 200 units of large firms. They found that the total amount of organizational control was positively and significantly related to the members’ loyalty, morale, and judged effectiveness but not to objective measures of effectiveness. Nevertheless, leader-member agreement on the ideal amount of control and the actual total amount of control over members was related to rates of effectiveness. On the other hand, when Smith and Tannenbaum (1965) examined the effects of the total amount of control by the members of women’s organizations, the total amount of control failed to increase the coordination of leadership, although such leadership contributed to the group’s effectiveness.

In a study of insurance agencies, Bowers (1964b) reported that total organizational control was related to the members’ satisfaction and performance but not to the volume of business, the growth of business, or the turnover of personnel. Furthermore, the amount of power at different levels of an organization was not associated with effectiveness. Smith and Ari (1964) observed that a consensus among members of work groups and among superiors and subordinates was related to the total amount of organizational control but not to the amount of control of individuals at the work level.

Ivancevich (1970) studied the effects of the total amount of organizational control and members’ satisfaction in insurance agencies. The agents’ satisfaction with status, autonomy, and growth was correlated about .30 with the manager’s control over the agency, the agents’ control over the agency, and the total amount of organizational control. Ivancevich found that agents were equally satisfied whether they or the manager exercised control. In another study of insurance agencies, Bachman, Smith, and Slesinger (1966) found that the agents’ satisfaction was highly related to the total amount of control, control by the manager, and control by the agents.

In addition to the effect of differences in the total amount of control exercised by members, the total

amount of control is higher when exercised by members in all echelons of the hierarchy rather than at just one or two levels. The total amount of control, but not control in the various echelons, is related to productivity and to members' satisfaction. Furthermore, in some organizations members tend to feel more satisfied when the top-level leader is charismatic and exercises strong control over organizational activities (House, 1988).

Although this point has not been examined, the reason why high total control increases satisfaction and productivity may be that goals and expectations are much clearer for members and conflict is much lower than when organizational anarchy exists. Nonetheless, many of the older studies of satisfaction with control need replication, because organizations have become flatter and workers and managers expect more from participation and democratic leadership.

### ***Measurement of the Distribution of Power***

The distribution of power is ordinarily inferred from observing variance among members of a group or organization in the success of their efforts to influence each other. This inference leads to a tautology. Observed differences in influence indicate the distribution of power; differential power begets differential influence. The equalization of power is seen in shared leadership. Power differences are also inferred from differences in status and esteem. The general has more legitimate power than the colonel. The admired parent will have more referent power in the family than an estranged one.

Measuring the responsibility, authority, and delegation associated with a position is a more direct way to understand an incumbent's power.<sup>4</sup> To obtain a direct measure of power differentiation independent of observed influence and status, Bass and Valenzi (1974) asked subordinates and managers to describe the power that managers had over manager-subordinate relations and the power the subordinates had over these relations. Questionnaire items dealing with the managers' power included the extent to which the managers had the power to override or veto any decisions the subordinates made; grant or deny promotion or salary increases to subordinates; reverse the priorities of subordinates; control the size of subordinates' budgets; and get the support of a higher authority for what the managers wanted to do. The subordinates' power included bringing outside pressure to support what they want; doing the opposite of what the manager wants done; maintaining final control over their own plans, assignments, and targets; ignoring the manager and submitting their own requests to a higher authority; and nominating or electing the manager. Bass and Valenzi obtained alpha coefficients of .60 for the reliability of both management's and subordinates' power. They found that on scores ranging from one to nine, superiors' power was typically above six whereas the subordinates' score was below four.

*Dependency.* Kotter (1978) took a different route to study power differences in organizations. His interviews focused on whom the incumbent in a particular management position felt dependent. Kotter also assessed the incumbent's efforts to obtain cooperation, compliance, and deference from others in the system. Integrating these concerns about power and dependence with a concern for the organization's goals was seen as the key to effective performance and was consistent, as was noted in [Chapter 7](#), with McClelland and Burnham's (1976) demonstration that effective managers have a strong need for power but are oriented toward organizational goals rather than self-aggrandizement.

*Power of Departments.* For their study of the distribution of power among departments at universities, Saunders and Scamell (1982) modeled their assessments after Hinings, Hickson, Pennings, and Schneck (1974). They were able to obtain valid measures of three determinants of how departments differed in power. From data obtained in interviews and questionnaires, they indexed the department's centrality in the flow of work and information, the difficulty of substituting an alternative department for the department's activities,

and how much ability the department had to cope with uncertainties. Using small-space analysis, Shapira (1976) showed that the differences between the power of managers and subordinates, when combined with the information that each had, could predict, as theoretically expected, which style of leadership would be most often displayed by the managers. Managers with more power and information than their subordinates were most *directive*; managers with more power but less information were most *consultative*; managers with more information but less power were most *negotiative*; managers with less power and information were most *delegative*.

*Autonomy.* The distribution of power can be measured indirectly by how much is delegated to the less powerful and by how much autonomy and freedom they have to choose how to operate in the work setting. Objective characteristics of the situation may constrain autonomy. It also is a subjective experience, such as being one's own boss. Sinha and Viswesvaran (1998) conducted a meta-analysis of 99 samples of autonomy from 56 published studies. The variety of scales and measurements registered a mean reliability of .69 for the managers' perceived autonomy and .73 for nonmanagers. Meanings of autonomy included being allowed to try and fail without fear of reprisals; freedom from constant evaluation; freedom from close supervision; sense of ownership of the work; discretion in scheduling the work; determination of what needed to be done; freedom to make decisions without checking with a supervisor; taking part in decisions affecting the work situation; exercising personal judgment; having an opportunity to express ideas, and being treated as an equal by the supervisor.

## The Power of the Group

---

Power sharing with all members of a group does not necessarily mean increased initiative and freedom for members. On the contrary, powerful groups can constrain and influence their members more strongly than any individual leader with power can. Mere membership in a group makes a difference. Deutsch and Gerard (1954) found that individuals in a group were more influenced by observed standards than were those who were not in a group. Katz and Lazarsfeld (1955) concluded that people are more likely to change their opinions if their relatives or friends are undergoing a similar change. The changes are also more likely to persist if supported by such group affiliations. In the same way, individuals are more influenced by the mass media when they are listening in groups than when they are alone.

Socialization processes in organizations are a familiar phenomenon. For example, after liberal students enter the world of work, they tend to adopt more conservative attitudes involving the norms of the firms they join. S. Lieberman (1954) found that workers who were promoted to foremen tended to shift their attitudes in favor of the management as they became members of management. Workers with the same attitudes as those who became foremen but who subsequently were elected as union shop stewards, shifted their attitudes in the union's direction after 12 months as stewards.

### ***The Tendency to Conform***

Many early investigators demonstrated the tendency of members of a group to shift toward the attitudes and behavior of the group.<sup>5</sup> Subsequently, Bass (1957b), Hare (1953), and McKeachie (1954) found in various experiments that group discussions were more effective than reading or listening to arguments in increasing group members' agreement with one another, both publicly and privately. Generally, such group discussion leads to improvement in the members' understanding, commitment, and decision making. But the reverse is also true. Janis (1972) saw groupthink as the reason why highly competent members made extremely poor

collective decisions, such as in the Bay of Pigs fiasco shortly after Fidel Castro seized power in Cuba. Highly cohesive, highly intelligent top officials of the Kennedy administration assumed a unanimous view when it did not exist. Conformity occurred out of a sense of loyalty to the group.

The signs of conformity in workers' performance as a consequence of the work group's power over its members were well known when pay-for-performance was commonly established by the number of pieces a worker produced in an hour or day. The fear of "rate busting" and that management would lower the price per piece paid to workers resulted in distributions of outputs of workers that peaked at an arbitrary limit set by the group. The variance in output was not a normal probability distribution; the distribution was truncated at the upper end.<sup>6</sup>

*Subtle Influences.* In a series of well-known experiments, Asch (1952) showed that conformity to the opinion of a simulated group can be induced even when the group decision defies the senses. A fair proportion of duped participants will agree that the clearly shorter of two lines is longer if they see all the other persons (all confederates) in the same situation stating that the shorter line is the longer one. Subtler influences of group power were measured by A. L. Hoffman (1956) and Horwitz (1954). Hoffman confronted participants with group norms that alternately agreed and disagreed with the participants' responses. The psychogalvanic skin responses of participants suggested that tension was reduced when they believed they had conformed to the group instead of being in disagreement with others. Horwitz (1954) found that individual members were under the greatest tension according to their greater recall of interrupted tasks (Zeigarnik effect), when they voted not to continue a task that the group had voted to continue.

The effects of conformity persist even after the group disbands. When partners are separated after experiencing a judging situation together, they continue to influence each other's judgments when asked to judge alone (E. Cohen, 1956). Bovard (1948) found that the tendency to be affected in this way persisted for at least 28 days.

### ***Power Sharing to Promote Change***

Speaking to government employees, Robert Reich, the secretary of labor, declared:

To provide quality service is through fundamentally changing the relationship between management and labor, by pushing responsibility downward and giving people on the front line the power they need to do their jobs.... It's not giving up authority. It's joining in partnership to give everybody more authority (including me). Reich & Copening, 1994, pp. 35, 36.

*Group Discussion.* The use of discussion in groups is an approach to increasing power sharing in the decision-making process and to increasing the influence of the group decision on individual members. K. Lewin (1943) conducted a seminal experiment to demonstrate how group discussion influenced housewives' choice of meats for their families' meals. Group discussion will produce more change in members than will the arguments of individuals; it has been found superior to lecture techniques in reducing biases in the merit-rating tendencies of supervisors, prejudice, hostile attitudes, alcoholism, and emotional disturbances in children. Group discussion has also proved superior to lectures in reaching solutions to community problems and modifying food habits (Lichtenberg & Deutsch, 1954). In addition, Radke and Klisurich (1947) observed that new mothers who engaged in discussions under the leadership of a dietitian much more readily adopted desired behavioral patterns that coincided with the usual recommended procedures than did a control group who received individual instruction. Similarly, Levine and Butler (1952) significantly reduced the halo effect in merit ratings by foremen by permitting them to discuss and make decisions regarding more realistic

evaluations. Torrance and staff (1955) found that B-29 aircrews were more likely to reach a state of efficiency that enabled them to go into combat if they had been observed to participate in decision making earlier in survival school.

Coch and French (1948), J. R. P. French (1950), and French and Zander (1949) reported the results of an experiment in a clothing manufacturing plant. The factory had experienced a considerable turnover of labor after each change in operating methods. The experimenters studied four groups of employees. For the control group, a change was merely announced. For the three experimental groups, the workers were given an opportunity to discuss the change, to offer suggestions, and to agree on the necessity for the change. Productivity increased and turnover of personnel decreased in the experimental groups but not in the control group.

The same plant studied by Coch and French and a second plant were studied in 1962, 1964, and 1969 by Seashore and Bowers (1963, 1970) and by Marrow, Bowers, and Seashore (1968). Managers and workers were given group training in joint problem solving. Although the employees' satisfaction did not change to a marked degree, their commitment to the task improved, productivity norms were raised, and productivity increased. Ronken and Lawrence (1952) studied a firm that was experiencing difficulties in communication. When small groups and committees were formed to discuss and analyze the problem and to suggest solutions, communications became freer and operations were conducted more smoothly.

### ***Additional Evidence of Group Power***

Lawrence and Smith (1955) compared groups of workers who set their own production goals with other groups who merely discussed production problems. Groups who set their own goals showed significantly greater increases in productivity. Lawler and Hackman (1969) reported experimental results using group power to develop a pay-incentive plan for maintenance crews. Three groups developed their own pay-incentive plans to reward good attendance on the job. The plans were then imposed on two other groups. One type of control group was given a lecture about job attendance and the other received no experimental treatment. Only those in the groups who developed their own plans increased their attendance.

Sharma (1955) surveyed 568 teachers in 20 school systems and found that their satisfaction was related to the extent to which they reported that they were involved in decision making as individuals or as groups.

Zander and Gyr (1955) examined employees' attitudes toward a merit rating system. They found that a significant change in attitudes required monthly feedback, and that consultation and discussion were somewhat more effective than mere explanations of the system. In addition, under both conditions, changes in attitudes occurred only when subordinates described the supervisor as sincere, when the supervisor knew the plan and the issues, when the supervisor's and the subordinates' opinions were in agreement, and when the supervisor was skilled as a chairperson.<sup>2</sup>

### ***Increasing Group Power and Its Effects***

The more power the work group has over its members, the fewer differences will be seen in the members' output. Thus Seashore (1954) found less variance in productivity among different members of the more cohesive of 228 factory groups. The more members expect to be rewarded and to avoid punishment through membership in the group, the more they value the group and—as in Asch's experiments described above—the more the group will have the power to produce conformity (Deutsch & Gerard, 1954). Gerard (1954) noted that the greater the attraction of the members to a group, the more their opinions coalesced. Gorden (1952) observed more conformity in members who were identified most with the group. Similarly, Newcomb

(1943) observed that the extent to which Bennington College students wanted to “belong” on campus determined the extent to which they shifted their social attitudes in the direction of the liberal attitudes prevailing on campus. Rasmussen and Zander (1954) found that teachers’ levels of aspiration conformed more to the ideal of their group the more they were attracted to the group—that is, the more they saw the group as potentially rewarding.

*Visibility and Salience of the Group.* Groups will exert more power over their members when the members’ behavior is visible than when it is unobservable (Deutsch & Gerard, 1954). The effects of conformity can be increased by giving the group more power and by making it more important to its members. For example, Dickinson (1937) observed that the effectiveness of a group’s wage incentives depended on mutual policing. Members who work for group rewards are more likely to keep up with each other in groups that are sufficiently small to permit effective mutual observation. Grossack (1954b) found that members of such groups, rewarded as groups, demanded more uniformity from each other than did individuals who were competing with others for rewards.

A significant factor in a group’s power over its members is whether the members are clear about the modal or majority opinion of the other members. The clearer the members are about what they must conform to, the more likely they are to conform. In judging intelligence from photographs, participants tended to shift their judgments toward the group decision if they obtained knowledge of it (S. C. Goldberg, 1954). Gorden (1952) observed that when expressing their public opinion, members of a cooperative living project tended to be influenced by what they perceived to be the group’s opinion. Bennett (1955) found more compliance with a request for volunteers among those who perceived most others complying. Pennington, Haravey, and Bass (1958) obtained the greatest objective increase in agreement among members in groups in which members made their initial opinions public in discussions or when a group decision was announced rather than kept secret; agreement was less when either group decision or group discussion was absent, and it was least when both were absent. Similarly, in studies of autokinetic judgment, N. Walter (undated) found that agreement among participants decreased when they were no longer given information that was ostensibly based on the judgments of typical students at a prestigious school.

## *Power, Leadership, and Structure*

---

As was noted earlier, differences in power are established in formal organizational structures. Some positions and roles are assigned more power than others, and power increases as people move from the bottom to the top of the organization. Management-worker hierarchies and political bureaucracies replace traditional power structures based on family, class, tribe, wealth, strength, and age. Even in a country with long-standing democratic traditions, preferences for formal power structures vary. Some citizens prefer highly structured settings, and others prefer highly unstructured ones.

### *Preferences for More Structure or Less Structure*

In some situations, everyone wants total structuring. Automobile drivers on through streets want assurance that drivers coming from side streets will halt at stop signs and red lights, and that oncoming drivers will stay on their side of the white dividing lines. Conversely, the hostess at a social gathering may be faulted for trying to structure interactions. In work and educational settings, there is much divergence of opinion about structure. Thus Heron (1942) observed that if employees do not have access to information about rules and procedures and must learn by trial and error, they are dissatisfied and afraid to take the initiative because of possible

infractions and penalties. Seeman (1950) found that a majority of schoolteachers preferred a group-oriented style of leadership yet also exhibited a substantial preference for a type of leadership that called for the differentiation of power.

Bradshaw (1970) obtained ratings of the ideal as well as the actual behavior of leaders in a professional organization. The rank order of the means for both observed and desired behavior was as follows: (1) structuring of expectations, (2) tolerance of freedom, (3) consideration, and (4) emphasis on production. The observed tolerance of freedom was close to ideal, but more structure was desired than was provided by supervisors. More autonomy and self-actualization were desired than realized. Bradshaw concluded that deficiencies in structure were associated with failure to satisfy higher-order needs.

Wispe and Lloyd (1955) found that low producers preferred a more structured group whereas high producers favored a less structured group. The high producers perceived their superiors as less threatening than did low producers. Lowin and Craig (1968) studied supervisors in experimental groups and found that supervisors advocated more structure and closer supervision of subordinates who were incompetent. This was consistent with what has been noted earlier about the effect of subordinates' incompetence on their supervisor's punitiveness.

### ***Structure and Effectiveness***

If any sizable group is to reach a common objective, some degree of structure in its internal role relations is required. Individuals need to be able to predict each other's behavior. Unless informal means are possible, the reliability of individual performances will be obtained only by distributing authority, power, and responsibility to holders of the various positions in the group through some structure. Otherwise, the group is likely to remain highly ineffective. Lucas (1965), who studied the effects of feedback on problem solving in groups, found that a group's effectiveness was related to the degree of its structure. Gerard (1957) observed that leaders tend to perform more effectively when they have a wider scope of freedom but that followers are more effective in a somewhat more highly structured situation. Gross, Martin, and Darley (1953) found that groups with strong formal leaders were more productive and more cohesive than groups with weak informal leaders. Sexton (1967) studied 170 line workers in jobs whose structure varied widely, according to both the supervisors and the workers, and reported that the degree of job structure was positively and significantly related to the employees' satisfaction of needs. Hickson, Pugh, and Pheysey (1969) studied a variety of organizations in England and found that the structuring of activities, role specialization, and functional specialization were positively and significantly related to the size and productivity of the groups. Similarly, in a study of manufacturing firms, Pheysey, Payne, and Pugh (1971) noted that formality and an orientation toward rules were related to the employees' satisfaction with their promotions and with fellow workers, and to greater involvement by the managers with the group. Bass and Valenzi (1974) also obtained a positive association between the perceived effectiveness of work groups and the extent to which relations between managers and subordinates in such groups were structured.

Hobhouse, Wheeler, and Ginsberg (1930) rated the level and complexity of development of some 200 societies. They found that efficient government, which resulted from a strong and stable leadership position or council of leaders, was positively correlated with high cultural achievement. Two opposing factors were found to reduce the power of the leader. In less well-developed societies, the frequent lack of a permanent government deprived the leaders of any effective structure for exercising power except in sporadic undertakings. In more highly developed societies, the presence of a stable governing council limited the powers of the primary leader.

Fox, Lorge, et al. (1953) compared the effectiveness of six-to-eight-man discussions by U.S. Air Force

officers with groups of 12 or 13. Although smaller groups ordinarily would be more effective, here the larger groups yielded higher-quality decisions. The larger groups overcame their disadvantage by organizing themselves to solve the problem so as to make maximum use of the larger number of participants. F. L. Bates (1953) observed that the performance of four medium-size bomber wings was better when there was a greater use of authority and a greater frequency of production plans, orders, and instructions sanctioned by authority. Again, if additional members are not redundant in contributing to a group's decision and if efficient computerization can be arranged to process, establish priorities, distribute, and pool their individual contributions, groups of 35 with computers may be able to become as effective in utilizing the informational resources of their individual members as can groups of six lacking computerization and information-processing technology (see [Chapter 29](#)).

*Bureaucracy and the Distribution of Power.* The theory of bureaucracy is concerned with problems involved in the structure of power relations in formal organizations. Weber (1924/1947) observed that bureaucracy is characterized by the continuous organization of official functions bound by rules, specified spheres of competence, the hierarchical ordering of authority relations, and impersonality. Responsibility and authority reside in the office, rather than in the person. Bureaucratic structure does not necessarily limit all autonomy for the organization's managers, although as expected, Engel (1970) found that managers' autonomy was greater in organizations with moderate bureaucratic structures than in those with extreme ones. Numerous case studies<sup>8</sup> have suggested that when organizations become overly concerned with rules and formalities, they tend to lose touch with the external demands made on them and to become insensitive to the internal problems that they generate. (These defects are not confined only to bureaucracies.) Dissatisfaction and ineffectiveness are unintended effects. Although it is the rational purpose of a bureaucracy to use specialized talent effectively, bureaucratic organizations and institutions often emphasize formalisms and legalisms to such a degree that the perpetuation of the system takes precedence over whatever function it was intended to perform. In agreement, Burns (1978, pp. 295–296) declared:

Bureaucracy is the world of explicitly formulated goals, rules, procedures, ... specialization, and expertise, with the roles of individuals minutely specified and differentiated ... organized by purpose, process, clientele, or place. [It] prizes consistency, predictability, stability, and efficiency ... more than creativity and principle. Roles and duties are prescribed less by superiors ... than by tradition, formal examinations, and technical qualifications. Careers and job security are protected by tenure, pensions, union rules, professional standards, and appeal procedures. The structure ... approaches the ... elimination of personalized relationships and ... reciprocity, response to wants, needs, and values. ...

Through its methodical allotment of tasks, its mediating and harmonizing and “adjustment” procedures, its stress on organizational ethos, goals, and authority, bureaucracy assumes consensus, discounts and discredits clash and controversy, which are seen as threats to organizational stability. Bureaucracy discourages the kind of power that is generated by the tapping of motivational bases among employees and the marshaling of personal—as opposed to organizational—resources. Bureaucracy pursues goals that may as easily become separated from a hierarchy of original purposes and values as from human needs. And bureaucracy, far from directing social change or serving as a factor in historical causation, consciously or not helps buttress the status quo.

Thus the status and power differentiation of a bureaucracy, initially organized to meet objectives expeditiously and efficiently, often experiences hardening of the arteries when it fails to adapt to changes in outside conditions and its own personnel.

But a complete lack of power differentiation generates problems that are equally damaging to the group's and organization's performance. To illustrate, Kingsley (1967) described a group of therapists that fell apart

and disbanded after the collapse of its structured power relations when the discussion leader left. Members were unable to maintain interactive relationships in the absence of the power structure provided by the leader. Similarly, over a period of one year, L. M. Smith (1967) observed an experimental elementary school whose administration, scheduling, curriculum, teaching, and discipline were highly unstructured and in which authority resided in the pupils. The teachers engaged in a ceaseless struggle for power, and there were continuous confusion, delay, noise, and frustration. All but two of the teachers decided to leave at the end of the year. J. W. Gardner (1998, p. 13) summed up the utility to organizations of sharing power to maintain their vitality. There needs to be

the willingness of many people scattered throughout the organization to take the initiative [in] identifying problems and solving them. Without that, the organization becomes another of those sodden, inert, non-adaptive bureaucracies that are the bane of corporate and governmental life—rigid, unimaginative, and totally unequipped to deal with a swiftly changing environment.

## Empowerment

---

The past century saw the rise and acceleration of a movement to change the distribution of power by delegating decision making to lower levels of organizational managers and employees closer to the need for action (Kanter, 1977, 1993). Power sharing took on a life of its own as empowerment at all organizational levels became a popular strategy in the 1980s (Block, 1986; Burke, 1986). Empowerment gave organizational members the responsibility and authority to carry out their jobs so that psychologically they felt they “owned” their jobs. It aligned their personal mission to the organization as a whole (Potter, 1994). It was adopted by service industry firms such as American Airlines, Marriot, American Express, and Federal Express. It meant encouraging front-line employees to exercise initiative and imagination. It also implied giving overall direction with considerable autonomy to employees, and latitude to carry out their assignments. It could be limited to deciding on the best way to complete an assigned task. It could involve identifying and solving problems and dealing with larger organizational issues (Ford & Fottler, 1995). It also came to mean empowering individuals at all levels in the organization, although in a study of hospital personnel perceived empowerment was higher among those higher in rank and tenure (Koberg, Boss, Senjem, et al., 1999). “Organizations must move away from policies that encourage employees to ‘leave their brains at the door’ to those that nurture, develop, and more directly reward employees’ intellectual capital” (Avolio, 1997, p. 2). But Wall, Cordery, and Clegg (2002) opined that empowerment was not a universal panacea—its effectiveness was contingent on the extent of operational uncertainty. In discussing new product development projects, Forrester (2002) agreed that management should yield power to the development team when uncertainty is highest, as when a radical innovation is being sought. When there is less uncertainty about the product—as when a change is to be just an incremental improvement—empowering the team is less important. Also, Shamir and Howell (1999) suggested that followers can empower leaders by cooperating and showing respect and admiration. They can also provide the leader with resources.

Empowerment is similar to but not the same as delegation. It is a more exacting kind of involvement. It implies “the freedom and ability to make decisions and commitments, not just to suggest them or [only] be a part of making them” (Forrester, 2000, p. 67). Organizational structures are changed. In many cases, middle managers are eliminated. Their decisions are now made by the empowered first-line supervisor and shared with the workers or work team. For Lawler (1986), this was an important aspect of *high-involvement* management. Team members were granted more autonomy, more self-direction, and more control over how they accomplished their tasks. As a consequence, they had more positive attitudes about their responsibilities

and more positive feelings about their work. For instance, at Ericsson General Electric, suggestions from gainsharing programs were reviewed by employee teams, not managers. These teams could accept suggestions, put them into action, and authorize limited expenditures (Filipczak, 1993). Conger and Kanungo (1988) linked a sense of empowerment to a sense of self-efficacy. When leaders were supportive and empowered by higher authority, Parker and Price (1994) found that subordinates were more likely to perceive that they had control over decisions affecting themselves. Keller and Dansereau (1995) reported that for 92 superior-subordinate dyads, empowerment gave subordinates more control and a perception of more fairness in their superiors. Among 194 employees in a human service organization, self-efficacy and intrinsic motivation were enhanced by fostering their autonomy (Seltzer & Miller, 1990).

Empowerment can be structural or psychological. *Structural empowerment* accrues from occupying a position that is visible and central to the organization's goals and allows the occupant flexibility (Kanter, 1993). An employee or manager is also empowered by structures that give access to information, support, access to resources, and opportunities to learn and develop. *Psychological empowerment* is intrinsically task-motivating by providing meaning to one's role in the organization, a sense of competence, a sense of self-determination, and awareness of the impact of what one is doing (Thomas & Velthouse, 1990). Spreitzer (1995) extracted and validated as dimensions of psychological empowerment: *meaning* (for example, "The work I do is very important to me"); *competence* ("I am confident about my ability to do my job"); *self-determination* ("I have significant autonomy in determining how I do my job"); and *impact* ("I have a great deal of control over what happens in my department"). Shea and Howell (1992) combined structural and psychological empowerment in their model, understanding of the relationship between actions and desired outcomes. However, although structural empowerment enhanced job satisfaction for 185 staff nurses, psychological empowerment had no effect on job satisfaction after structural empowerment was taken into account (Laschinger, Finegan, Shamian, et al., 2002).

Herrenkohl, Judson, Thomas, et al. (1999) validated three additional dimensions that discriminated between those with more and less empowerment, fairness in the recognition system, fairness in decision processes, and clarity of company goals for 28 work groups. Felt empowerment was higher among middle managers if there was little role ambiguity in their work unit and if the unit had access to information, strong support, and a participative climate. Leaders learned empowerment roles from models provided by higher-ups in their organization. Compared with 561 male counterparts, 351 women leaders in 25 organizations were likely to be more empowering, according to their 912 direct reports (Howard & Wellins, 1994). Empowered managers worked for a superior with a wide span of control. Empowering management recognizes that reducing organizational controls can increase the individual's shift toward personal control and outcomes. Management arranges conditions to facilitate the shift. The empowered individuals are induced to engage not only in "role behaviors" but also in discretionary behaviors that go beyond their roles and beyond minimum job requirements. Empowered persons expect to have favorable effects on outcomes if they take action (Spreitzer, 1996).

### ***Benefits of Empowerment***

Empowerment is seen to be of benefit to the empowering leaders, their followers, and their organization. The leaders are relieved of routine work and are more committed to their organization, according to a survey by Howard and Wellins (1994) of 32 senior managers, 29 middle managers, and 323 supervisors from 25 organizations. The 948 nonleadership employees reporting to these leaders felt more positive about the work and the organization and experienced less work-related stress. The organization also benefited from an improved customer focus and improved quality. Pfeffer (1995) suggested that the organization also benefits by

gaining a comparative advantage over traditionally organized rivals, and in the greater commitment, satisfaction, and involvement of its employees and managers.

Moreover, the organization benefits from making it possible for every member to be a source of ideas, initiatives, and influence. Benefits increase over time. Empowered people feel that they have a greater impact on their work and are more satisfied with it (Thomas & Tyman, 1994). They feel that they have a greater impact on the organization (Brossoit, 2001). This also contributes to greater satisfaction with their work (Ashforth, 1989). For instance, among 612 technically skilled professionals and managerial hospital employees those who felt more empowered reported greater job satisfaction, work productivity, and intent to stay (Koberg, Boss, Senjem, et al., 1999).

Democratic organizational flexibility replaces hierarchical rigidity. The controlling manager becomes the enabling leader (Cook, 1994). Nonetheless, the expected effects of empowerment on effectiveness, work satisfaction, and job-related strain vary with how much each of the components of psychological empowerment—meaning, competence, self-determination, and impact—is involved (Spreitzer, Kizilos, & Nason, 1997).

*Contingent Effects.* In some studies, empowerment was found to only indirectly affect beneficial outcomes. Niehoff, Moorman, Blakely, et al. (2001) observed that empowerment indirectly increased the loyalty of 203 employees as a consequence of enriching their jobs. In 128 leader-employee exchange dyads, managerial trust contributed to empowerment, but only when the exchange relationship was good for both the management and the employees (Gomez & Rosen, 2001).

*Effects of Operator Control of Machinery.* In manufacturing operations, empowerment meant giving operators the power to control loading, unloading, and monitoring their machinery. They also took responsibility for maintaining their equipment and for programming changes and corrections that formerly had been the province of staff specialists. Operators developed into their own staff specialists. A survey of 584 machining manufacturing plants in 1987 showed that plants where the machine operators routinely wrote and edited their own programs were 30% more efficient than plants where the operators were not so empowered (Ralls, 1994).

Operator empowerment in a British electronics manufacturer resulted in a saving of 10 hours of production time per week in the operations of seven numerically controlled insertion machines. The operators reported increased intrinsic satisfaction with their work and less job pressure. The former staff specialists were freed to work on other projects (Jackson & Wall, 1991). Over time, machine reliability was increased as the operators developed more skill in preventing problems. Downtime was reduced by 20% and eventually by over 70% (Wall, Corbett, Clegg, et al., 1990).

Empowering industrial employees by involving them in management decisions—according to a survey of human resources managers at 30 U.S. mini steel mills—reduced scrap rates, reduced employee turnover, and reduced the number of labor hours to make one ton of steel (Arthur, 1994).

### ***Problems with Empowerment***

A British laundry and work wear business, in dealing with small problems, generally found improvements from empowerment; yet some workers did not want to be empowered—nor did some managers want to change their practices to accommodate empowering their workers (Seath & Clark, 1993). Forrester (2000) enumerated several reasons why empowerment might cause problems and might fail to improve performance and satisfaction:

1. Empowerment may be introduced precipitately without adequate preparation of the people who are to

be empowered. At the lowest levels, work has been enriched—i.e., increased—by administrative duties, decision making, and coordination requirements, but the workers have been given no additional time and no training to carry out functions that were previously done full-time by better-paid persons. The hasty changes take away power from supervisors and managers, who now suddenly must supervise differently, also without adequate time to train and prepare.

2. While increasing intrinsic task motivation matters, other motivations need to be considered, such as individual differences in preferences regarding autonomy, structure, money, competitiveness, desire to help others, and being accountable for results.
3. Accountability and responsibility for results may be confused and distorted.
4. Managers and supervisors may not be willing or ready to accept their loss of control, their reduced sense of achievement, and their reduced recognition.

Managers may have a problem with being accountable without control. They may feel that their job security is threatened—as indeed it may be, with the flattening of the organization (Stewart & Manz, 1995).

Additionally, managers of technology may have been negatively indoctrinated about empowerment by their engineering education. Fewer than half of 100 engineering textbooks and equipment design books made any mention of the operators' or workers' roles in production. Where people were mentioned, they were always subordinate to technology (Ralls, 1994).

A survey of 282 MBA students revealed another possible reason for resistance to empowering subordinates. These students felt that the quality of work would be better if workers were supervised than if they were unsupervised. They thought the supervisor would be more personally involved than subordinates in the quality of the product (Pfeffer, Cialdini, Hanna, et al., 1998).

### ***Successful Empowerment***

For successful empowerment of others, Burdett (1991) suggested that leaders need to manage the context, not the individuals. A common vision is required. Organization values have to be enunciated, and leaders have to facilitate opportunities for action. According to Payne, Cangemi, Fuqua, et al. (1997), an environment of support and decentralized decision making must be created, and certain values must be communicated: high quality, good service, and excellence. For Randolph (1995), the most important factors in successful empowerment were sharing information about the organization, promoting understanding about it, building trust through the sharing of sensitive information, and replacing hierarchy with teams. Paradoxically, forceful leadership must be used, and power must be used effectively to give it to others, with limits—letting go of controls but remaining ready to help when necessary (PriceWaterhouse Change Integration Team, 1996). Forrester (2000) suggested that empowerment needs to proceed top-down, cascading from higher to lower levels in the organization as each level becomes knowledgeable, familiar, comfortable, and successful with it. Those with power must have enough control to share it. There is a need to develop members at each lower level in knowledge, skills, and information as well as to provide more access to important people. At each level, initially, low-risk decisions should be delegated. Censoring mistakes should be avoided. Rather, mistakes should be corrected and treated as learning experiences. Roberts and Thorsheim (1987) suggested that in interaction with employees, leaders need to express their own doubts, concerns, and uncertainties; ask and listen; reflect feelings; identify common experiences; paraphrase and summarize; and acknowledge and use others' ideas. Howard and Wellins (1994) noted in their large-scale multiechelon survey that the empowerment strategies used most frequently were reengineering, training, pushing down decision making to lower levels, reducing layers of management, and using high-quality problem-solving teams. Support was provided by satisfying, high-involvement leadership but with no special financial rewards.

Feelings of empowerment among 531 individuals in 53 organizations were positively related to the rated transformational behavior of their leaders (Masi, 1994). Among a randomized sample of 327 managers in Fortune 100 firms, Brossoit (2001) found that transformational leaders provided their empowered employees with a sense of meaning in their jobs, a perception of choice, a sense of progress toward goals, and the belief that they were influencing the system. However, while transformational leadership resulted in a sense of empowerment at 76 Israeli banks, according to their 932 employees, as expected, it also increased the sense of dependence on the managers (Kark, 2000). A converse effect has also been reported. If managers feel they are empowered, they are more likely to be transformational but not transactional, according to a survey of 314 diverse middle managers of Fortune 50 firms rated by themselves and their subordinates (Spreitzer & Janasz, 1994).

### ***Unsuccessful Empowerment***

Cook (1994) suggested that empowerment suffers if senior management endorses it but does not set a positive example; fails to communicate the reasons for empowerment and how it will help the organization; fails to explain the leader's role as more than getting rid of work; and fails to provide training and a support network. According to Howard and Wellins's (1994) survey of 948 employees, 323 supervisors, and 61 higher-ups in 39 business units of 25 organizations, some leaders might discourage empowering their subordinates by failing to get higher management to act on subordinates' suggestions or by failing to praise success publicly. Leaders often failed to match empowering their direct reports with the readiness of the direct reports to handle more responsibility. The leaders couldn't let go. Faulty implementation of empowerment could be also due to other reasons, such as failure to provide sufficient direction and training to accompany the empowerment. Chakravarthy and Gargiulo (1998) noted that in the restructuring of a hierarchy, trust and the legitimacy of leadership may be lost. Dover (1999) mentioned two other reasons for failure: being impatient, and expecting that giving power would provide self-reliance, competence, and commitment. Empowerment might be the objective, but its opposite might appear, as learned helplessness (Campbell & Martinko, 1998) or as *bogus empowerment* (Ciulla, 1998), in which subordinates feel they are free to make decisions as long as the decisions are ones their boss wants; or when subordinates are given responsibility they did not expect nor want nor request (Stayer, 1990).

### ***Other Perspectives***

Burns (1996) argued that empowerment comes about from collective leadership, which occurs in a "web of relationships" in which different people take on roles of influence as needed. Some initiate action; some join with others to take action. Different reactions occur: some follow the initiator; some oppose or ignore the initiative. Mutual empowerment is seen when team members influence one another both positively and negatively. An opponent may consider alternatives to an initiative.

Political scientists view empowerment of minority voters as evidenced by increased political participation and success in elections (Bobo & Gilliam, 1990). For educational administration, empowerment is pushing decision making from the district office to the local school, and from the board and superintendent to the principals, teachers, parents, and students (Glickman, 1990).

One of the best examples of empowerment—long before the term came into vogue—is what happened during the Normandy landings on D-Day, June 6, 1944. The U.S. Army suffered more casualties on that one day than in any 12 months in Vietnam. Omaha Beach turned into a killing zone.

But what happened in the face of this was truly a decentralized empowered event. ... For the most part, the beach assault was an unorganized mass of intermixed units with little or no functioning chain of command. ... Individuals moved forward, took initiative, took risks, and displayed awesome courage. *Ad hoc* teams formed on the beaches and ... inland where paratroopers had been scattered over the landscape miles away from their planned drop zones. Ulmer, 1994, p. 8.

## ***Self-Empowerment***

Since the settling of America, groups, movements, and organizations have arisen—and continue to arise—who are self-empowered or empowered by local, state, and federal governments in communities to organize action to meet needs and satisfy common purposes not adequately addressed by other formal institutions (Bachrach & Botwinnick, 1992). Critics viewed them as bureaucratic self-defense, co-optation of government agencies, and surrogates for public policy (Couto, 1992). But much citizen action now depends on the empowerment of such voluntary assemblages, ranging from neighborhood to environmental organizations.

## ***Measurement of Empowerment***

Two of the more prominent questionnaires about empowerment serve different purposes. The Leader Empowering Behavior Questionnaire (LEBQ), developed by Konczak, Stelly, and Trusty (1996), contains 22 statements to be rated from 1 (strongly disagree) to 7 (strongly agree), which assess leader behaviors that empower followers. The Empowering Instrument (EI), developed by Chiles and Zorn (1995), assesses the extent to which followers feel empowered. Its six statements are rated using the same seven-point scale of agreement as the LEBQ.

## ***Leader Empowering Behavior***

In the Howard and Wellins (1994) survey, modeling trust and facilitation were, on average, the most important leadership empowering behaviors (6.2 on a 7-point scale of importance). Many other behaviors were cited as of considerable importance (5.8); these included supporting, coaching, partnering, envisioning, inspiring, team building, and championing. Ensuring compliance (5.4) was the only transactional behavior seen as important. Other transactional behaviors—such as controlling the way work is done (3.9) and pointing out failures (3.1)—were seen as not important to empowerment. Heslin (1999), along with many others, called attention to the need for empowering leaders to raise the self-efficacy of subordinates through mentoring, coaching, stimulating, demonstrating, and providing satisfying outcomes. Empowering leaders, willing to relinquish control and authority, did so on the basis of reasoned planning and actions, according to a study of 502 external team leaders from 64 Australian organizations (Wu, Cordery, & Morrison, 2001). Stewart and Manz (1995) ascertained that supervisors with positive attitudes about empowerment, according to their subordinates, helped subordinates' empowerment. Arad, Arnold, Rhoades, et al. (1995) obtained the best-fitting model of the behaviors of the empowered team leaders of 95 customer service representatives and 110 building products supplier employees. The five correlated factors were: (1) leading by example, (2) coaching, (3) practicing participative leadership, (4) informing, and (5) interacting frequently. A similar analysis by Konczak, Stelly, and Trusty (1996) based on 424 managers and their 1,309 direct reports yielded a best-fitting model of empowering with six factors: (1) delegation of authority, (2) accountability, (3) encouragement of self-directed decisions, (4) information sharing, (5) skill development, and (6) coaching for innovative

performance. Ford and Fottier (1995) agreed that empowerment involved shared responsibility and sharing of information. For Manz and Sims (1990), empowering members of self-managed groups involved encouraging self-set goals, positive thinking, personal initiative, and self-directed problem solving. Leaders lead the members to be self-leaders.

*Discrepancy between Leader and Follower Perceptions.* Larmore and Ayman (1998) administered the LEBQ, the EI, and the 20 transformational leadership items from the Multifactor Leadership Questionnaire (MLQ) to 52 CEOs and their 217 direct reports. The CEOs rated their own empowering and leadership behaviors. The direct reports rated the empowering and transformational leadership behaviors of their own CEO. The direct reports also rated their own feelings of empowerment. Correlational and variant analyses indicated that although the CEOs as a whole did not overrate the extent to which they empowered their direct reports, results suggested considerable disagreement between particular CEOs and their teams of direct reports. When some CEOs thought they were empowering their direct reports, the direct reports felt otherwise. Nonetheless, a correlation of .56 was obtained between the individual direct reports' ratings of their own CEO's empowering behaviors (LEBQ) and ratings of their own felt empowerment (EI). Direct reports' sense of empowerment correlated .49 with their ratings of their CEOs' transformational leadership. The transformational leadership was found to have mediated the relationship, among the teams of direct reports, between their feeling of empowerment and their perceptions of the empowering behaviors of their CEOs. These findings were more a matter of team differences than individual differences. Keiser and Shen (2000) found that leaders believed they were empowering subordinates more than the subordinates felt they had been empowered. When 9,098 school principals and their 47,105 teachers were queried, the principals reported that they gave teachers more power than the teachers felt they had to evaluate teachers, hire new teachers, decide on expenditures, establish curricula, determine the content of in-service programs, and set disciplinary policy. Howard and Wellins (1994) reported similar discrepancies between leaders at various organizational levels and their direct reports.

*Differences in Empowering, Laissez-Faire, and Delegating Leadership.* Empowering, laissez-faire, and delegating leadership behaviors are similar but not the same. When the 10 laissez-faire items of the Multifactor Leadership Questionnaire (Bass & Avolio, 1991) were factored by themselves for diverse samples of leaders rated by their followers, two distinct factors emerged. Six of the items were, as intended, measures of laissez-faire leadership (e.g., "Likely to be absent when needed," "Avoids making decisions," and "Fails to follow up requests for assistance"). Two items on a second factor were closer in meaning to empowering leadership: "Avoids telling me how to do my job," and "Resists expressing views on important issues" (Bass, 1994). *Delegation* is assignment by the leader to a subordinate of activities and responsibilities. Leaders pass on to others tasks or specific aspects of their own jobs. They delegate to free their time to do other things, to develop the subordinates, or for other reasons. The leaders need to provide necessary direction and power for subordinates to effectively carry out the assignments (Shackleton, 1990). Adequate and inadequate delegation discriminated between innovative and uninnovative groups of Dutch teachers in 10 schools, according to keyword analyses of interview statements about the groups (Geijssel, Slegers, & van den Berg, 1999). The innovative capacities of the primary schools (Geijssel, van den Berg, & Slegers, 1999) and secondary schools (van den Berg & Slegers, 1996) were also calculated. For leaders in their schools to effectively delegate and to sort out "the failures that are the price of delegation," clear statements of purpose and secure, strong leaders and followers were needed. Babbitt (1987) suggested that these are also needed in bureaucracies.

## Industrial Democracy

---

Power may be formally redistributed by assigning worker-representatives to management boards and committees. The redistribution may be voluntary on the part of management, as in the United States, or mandated by legislation, as in Germany. Although some attempts had been made earlier in the United States, and elsewhere, representative industrial democracy appears to have been initiated in Sweden about 1938. It arose from the deliberations of national representations of employees and workers in response to labor unrest that was more common to Sweden in the 1920s and 1930s than in most other countries. The occupying military authorities in Germany after World War II, interested in ensuring that resurgent German industry could not again be exploited for military purposes or for the subversion of democratic government, passed a law prescribing *Mitbestimmung*—the representation of workers on a firm's supervisory board. The *Betriebsverfassungsgesetz* (Works Constitution Act) was also formally prescribed by law somewhat later, to provide for the participation of employees in a wide range of matters. To signal Yugoslavia's break with Soviet state centralism in 1950, Marshal Tito introduced self-management, another early method to use legislation to guarantee employees representative participation in the management of production and administration (Stymne, 1986). In the United States, along with a century of trade unionism came efforts, especially in the 1920s, to establish representative democracy in industry. However, it has been within the past 30 years that legislated tax advantages have contributed to the growth of employee stock ownership plans (ESOPs), through which employees begin to share in the company's ownership. By 1986, 7,000 U.S. firms had ESOPs (Meek, 1987). Also, representatives of employees and consumers have been elected to serve on the boards of directors of corporations. Finally, groups of employees, such as those of United Airlines, began to purchase control of their own firms, and employees began to elect the directors who are responsible for the firm's management and policies. Thus, quite a few businesses became partly or fully employee-owned. But attempts to share profits or gains in productivity such as Scanlon Plans, ESOPs, suggestion schemes, and productivity bonuses may founder on conflicts of interest and power differences between management and labor (Collins, 1995).

### ***Difficulties with Industrial Democracy and Worker Representation***

Efforts to create power-sharing institutions may be only a semblance of worker participation that may not yield the same degree of commitment, motivation, or productivity. Workers may have sat on boards of directors in the former Yugoslavia, but in fact party members, financial experts, and technocrats held most of the power, initiative, and influence (Obradovic, 1975). In some countries, unionism has declined. In the United States, for example, it declined to 11% of employees in 2005 since its peak in the 1930s and appears to remain strong only in the public sector. In Europe, it has remained stronger and better aligned with government, often controlling major political parties.

Representative democracy at the workplace is different from empowerment of employees. In workplace empowerment, workers participate directly with their immediate supervisor in decisions that are of consequence to their own work and working situation. Industrial cooperatives, such as Mondragon in Spain, became community-and-employee-owned holding companies for subsidiary plants. In the United States, ESOPs gave employees voting privileges and sometimes control over management. In reaction to threatened plant closings, on occasion, employees purchased the ownership of their plants. Trade unions, such as Histadrut in Israel, became holding companies for large conglomerates of business and industrial establishments. But none of these formal developments necessarily means that a participative climate in superior-subordinate relations will develop as a consequence; nor do such developments necessarily produce a real equalization of power. For example, who owns the company may not be as important to a new employee entering the firm at a low level as to an older employee with an important position in the company.

Nonetheless, empowerment of employees can result in increased democratization of union-management

relations. In the 1960s, Ed Dulworth, an engineer working for General Foods, discovered how much he could enhance a Gaines Pet Food plant by designing into it all the elements that subsequently became known as employee empowerment. Output rose 50% in four years, but the successful redistribution of power became a threat to General Foods' top management and to managers in other plants, and Dulworth had to move on. After arriving in Scranton, Pennsylvania, he organized a labor-management council to spread the word about what he had learned. By 1983, 15 in-plant labor-management committees had been established in the area (Osborne, 1988).

One purpose of equalizing power is to increase the commitment of those who initially have little power, despite their desire for more. However, Styskal (1980) failed to find the expected increased commitment in three federally sponsored temporary educational organizations in New York City when subunits were given more decision-making authority over the curriculum, program, employees, budgets, and work assignments. Many other problems can be cited. Discussing efforts by U.S. corporations to introduce voluntary and obligatory participation, Kanter (1982b) noted such problems as the paternalistic imposition of democracy; the need that results of participation be visible; concern by both management and the union about losing power; the time required; the lack of relevant knowledge by many employees; the limiting of participation to more abstract decisions that are remote from the employees' concerns at the workplace; tension between innovation and democracy; the constraints of previous decisions; the need for leadership; the resistance to change of various interest groups; tension between social, emotional, and business needs; and excessive expectations about gains that may accrue from participation. Management may resist sharing power, not only from a fear of losing its prerogatives but also because of a disinclination to learn new leadership styles involved in consensus building. Unions may not only fear a loss of power but may remain suspicious of the management's motives. And employees may be satisfied with their current inefficiencies in getting the work done (Alexander, 1984).

Dixon (1984) proposed that some interrelated elements are necessary for any participatory program to succeed. First, an information system is required to provide feedback on the organization's performance. Ownership of the information must reside with the group, feedback must be timely, and results must be visible to all employees. Second, employees at all levels need to be represented. Representation calls for groups of competent employees to identify and solve problems, to have the power to act on their decisions, and to agree on a common vision. Finally, the organization's leadership needs to believe in the creativity and responsibility of the employees.

### ***Early Examples of Voluntary Programs***

Selekman (1924) reported the results of a management sharing plan in a chemical firm. For management to gain a better understanding of the workers' point of view, two boards were created. The board of operatives was composed of elected workers, and was responsible for working conditions, grievances, recreation, training, company housing, and the like. The board of management, which was composed of a representation of executives and stockholders, was responsible for production, wages, farm equipment, hours, and financial policies. Although the board of operatives was slow to accept responsibilities, it gradually participated in planning and decision making. Effects attributed to the experiment included a reduction in the turnover of personnel and greater cooperation to improve production. Given (1949), a company president, experimented with a "bottom-up management" plan, in which he delegated authority down the line to employees and encouraged the employees to use their initiative and to assume responsibility. Results were good. Another company president worked directly with employees to stimulate their responsibility and initiative at the workplace. His activities placed foremen under great conflict and stress, but he worked with them until they

accepted his philosophy of participation. He concluded that his organization became more informal and his workers more responsible and involved (Richard, 1959). W. M. Blumenthal (1956) described the management of steel plants in Germany. Each plant was managed by a board of three men, one a union representative. The general trend was for the two management representatives to assume responsibility for production while the union representative assumed responsibility for personnel, wages, and grievances.

*Joint Consultation.* Wyndham and White (1952) found that workers in an Australian refinery tended to regard the elected representative to worker-management committees as an alternative to their foremen. The foremen then regarded their positions as threatened, even though they were members of the joint consultation committees. H. Campbell (1953) concluded that for joint consultation to be effective, the foreman had to be involved in the process as an active participant.

A study by W. H. Scott (1952) of joint consultation in three British industrial firms also indicated that the procedure was subject to strains in different segments and levels of the organization. Although workers' representatives were generally well accepted in their discussions with management, both the workers and their representatives reported that little was accomplished because only trivial issues were discussed. The workers felt that they were neither consulted nor kept informed by the representatives. The foremen reported that they were bypassed in communications between management and workers' representatives. The workers and their representatives complained that the foremen failed to take action on many matters that could have been handled more effectively on the spot rather than being referred to joint consultation. Although the majority of workers' representatives were also union stewards, the union members complained that they were not adequately represented. Scott concluded that joint consultation resulted in few advantages that could not be produced as well as by responsible leadership.

Jaques (1952) completed an intensive case study of a single British factory that formed works councils and work committees to participate in management. The workers tended to feel dissatisfied with the performance of their elected representatives. The representatives were under heavy stress because of their different, conflicting demands; because they had little authority for making decisions; and because of their increasing separation from the workers. Other, similar problems were also revealed, but the study threw greater light on details of the consultative procedure. Jaques's findings suggested that the difficulties encountered resulted not so much from the unwillingness of either management or employees to make the system work, as from their confusion about their respective responsibilities. Management tended to feel that it should not trespass on the responsibilities of workers' representatives on the works council, particularly in matters involving social relationships; hence, the managers tended to take passive roles. The workers' representatives tended to regard operative problems and policies as the responsibility of management and adopted passive attitudes toward those matters. When the general manager of the factory accepted the idea that he was responsible for all aspects of organizational life and activity, and that giving orders is not necessarily autocratic or un-ethical, he was able to "assume more fully his leadership mantle." In turn, his subordinates accepted theirs. With their responsibilities more clearly focused, they were able to initiate building a works council more broadly representative of the factory. Jaques's study suggested that members cannot act effectively in their own interests or in behalf of the group unless the leader exercises the functions of his or her role and takes the initiative in clarifying the definitions of roles throughout the system.

*Power Sharing Cost-Reduction Plans.* The Scanlon Plan is a means for sharing reductions in unit costs that are under the control of labor. Such reductions are determined first by establishing a normal labor cost for a factory. This labor cost may be arrived at by a joint worker-management agreement. Whenever labor costs fall below the norm, the workers receive from 50% to 100% of the amount. A second element of the Scanlon Plan is a suggestion system in which benefits that accrue from the reduction in labor costs are shared

with all workers in the plant. Reports indicate that as many as 80% of the suggestions submitted in a Scanlon Plan plant are accepted, whereas plants with individual suggestion plans commonly accept only 25%. Furthermore, with the Scanlon Plan there is no reason for the workers to withhold suggestions that will increase productivity; the result is lower labor costs and consequently a bonus for everyone (Lesieur, 1958).

To determine the effects of the Scanlon Plan, Puckett (1958) surveyed 9 firms with 11 plants that made many different products, and whose workers' skills ranged from manual labor to highly technical. In the 11 plants that were followed over a two-year period, the gain in productivity varied from 17% to 49%, with a mean gain of 23%. Bonuses averaged 17% of gross pay and were based on splitting the savings in labor costs, with 75% going to the workers and 25% to the company. Besides the direct benefits from increased production and higher profits, there were also better service to the customers, higher-quality products, an improved competitive position, and no decline in employment.

Many other power sharing cost-reduction practices now in evidence can be mentioned, some of which, such as suggestion systems, were first introduced by the Yale Manufacturing Company in 1892. The upward communication provided by quality circles and survey feedback systems are other examples.

### ***Employee Stock Ownership Plans (ESOPs)***

Rosen, Klein, and Young (1986) completed a survey of 2,804 employee stock owners at 37 firms with ESOPs. A majority of the respondents reported that stock ownership increased their interest in their company's financial performance, their personal identification with the company, and their desire to stay with the firm. However, the ESOP arrangement was seen as having less of an effect on their job satisfaction and their influence at the work-place or over company policy. Nor did it result in managers treating them more like equals.

French and Rosenstein (1984) conducted a survey in a prosperous plumbing installation and services firm that began an employee stock ownership plan in 1958. Its managerial employees held 76% of the shares, which have substantially increased in value. For 461 respondents, the amount of their equity in the firm correlated with their desire to be of influence in it. However, the extent to which they identified with the firm depended more on their status and perceived influence in the firm than on the amount of stock they held. Also the amount of their equity was unrelated to their job satisfaction, which correlated only with their perceived influence. But their interest in financial information about the firm did depend on their equity position and their white-collar status.

### ***Mandated Programs***

Legislation in the United States has been directed toward establishing fairness in collective bargaining of employees and management and in employment practices. Elsewhere, power sharing through the representation of employees on supervisory and directors' boards was legislatively mandated. Countries have tended to concentrate on one or two types of power-sharing legislation (Walker, 1975). [Figures 12.1](#) and [12.2](#) show the degree of legal support for individual workers and representative bodies in 12 European countries. For each country, the figures show the average right to participate in 16 specified decisions, ranging from such daily routine decisions as the assignment of tasks to workers, to such long-range decisions as major capital investments. Each of the decisions was rated from "no right" to "final say," based on assessment of laws and collective bargaining agreements and on interviews with labor and legal experts, and employers about company policies. Then they were averaged (Industrial Democracy in Europe, International Research Group, 1981).

Figure 12.2 Legal Rights of Representative Bodies of Workers in 1976

SOURCE: From "Industrial Democracy in Europe (IDE)," International Research Group, *Industrial Democracy in Europe*. Oxford: Clarendon Press, 1981.

*Effectiveness and Acceptance.* Evaluations of the operations and effectiveness of workers' councils have been reported for the former West Germany (Hartmann, 1970; Wilpert, 1975), Norway (Thorsrud & Emery, 1970), Great Britain (K. Walker, 1974), the former Yugoslavia (Obradovic, 1970, 1975; Rus, 1970), Sweden (Link, 1971), and socialist countries (Sturmthal, 1961, 1964). Derber (1970) suggested that although effective power sharing implied in industrial democracy was considerable, it tends to be moderated by a number of factors. First, as managers become more professional, their professionalism imposes a barrier to involving employees in decision making. Second, the majority of employees are not strongly motivated to assume managerial responsibilities as long as their financial and other personal needs are satisfied. Third, when union officials and employee representatives become involved in management decision making, they stir up political and factional conflicts that weaken their influence with workers. Last, joint decision making involves too much of management's time for operations to run efficiently.

A number of other studies pointed to differences among managers in their acceptance of industrial democracy and power sharing. In agreement with Derber, Norrgren (1981a) found that Swedish managers who were young, had little seniority but much formal education, and were high in the hierarchy had positive beliefs and intentions about participation. Managers who were involved in white-collar union activities had positive beliefs and intentions and evaluated participative activities highly. Managers from several Canadian companies expressed more willingness to share power with employees if the managers felt they had more job security and influence and if they regarded their employees as competent (Long, 1982). Bass and Shackleton (1979) called attention to the exclusion of the lower-and middle-management levels from the participatory process when representatives of workers meet with top management. These lower-level managers, often

ignored and eliminated from the mechanisms of industrial democracy, disassociate themselves from the participatory process and undermine its potential effectiveness.

After a carefully planned observational study of worker-management council meetings in the former Yugoslavia, Obradovic (1975) concluded that initiatives came mainly from the engineers, financial experts, and members of the Communist Party, not from the rank-and-file employees serving as council representatives. The few attempts of ordinary workers to lead were unlikely to be successful. Consistent with this finding, Rubenowitz and Norrgren (1980) used survey questionnaires and interviews to study the effects of different forms of participation in 10 Swedish plants that varied in size from 40 to 830 employees. The actual participation of employees was of much more perceived consequence when formal agreements for power sharing included acceptance of a policy to promote decision making by employees in their daily work. Much less participation was perceived if it involved only formal participation by representatives of the employees. Rosenstein (1977) observed that just because a powerful trade union with a strong social mission is the entrepreneur and owner of industries, as is the case with the Israeli Histadrut, this does not necessarily mean that participation by employees will be encouraged. Actually, the various power centers of the Histadrut—the managers, the trade union officials, the ideologists, and the politicians—have had to be persuaded and educated about the nature of the joint management program that is in effect. As of 1977, Histadrut had established such joint management in 30 of its plants. Success depends on the continuing support of both top management and employees. Nevertheless, a 12-country longitudinal survey revealed extensive behavioral changes in organizational relationships that were derived from mandatory programs of industrial democracy (Industrial Democracy in Europe, International Research Group, 1979).

*Selective Power Sharing.* Bass and Rosenstein (1977) and Bass and Shackleton (1979) proposed that industrial democracy is most likely to work well for some issues, such as dealing with pay and benefits, career development, working conditions, and job security, but not for others, such as financial planning or marketing strategies. The 12-country consortium study (Industrial Democracy in Europe, International Research Group, 1981) revealed in detail the extent to which these arguments were valid. In the same way, a total of 103 top Scottish managers and shop stewards who were interviewed by Dickson (1980) tended to favor the direct participation of employees on safety committees and briefing groups, and in dealing with the job enrichment of groups. The managers were less enthusiastic about the employees' participation through representatives on company boards, works councils, and plantwide committees. However, shop stewards felt a bit more positive than the managers about the value of such representative participation. The managers saw the direct involvement of employees as a way to enhance communication and the acceptance of decisions. The shop stewards thought that both direct and representative participation were a moral right and that both contributed to the employees' morale if they were acknowledged by management.

A random sample of 7,832 employees from a total of 134 European firms in metal engineering, banking, and insurance were asked how much they were involved in the 16 decisions for which they had legal rights (refer back to Figures 12.1 and 12.2). Their legally mandated involvement was more important in determining power sharing about long-term decisions. For workers in the 134 firms, the laws and regulations accounted for 24% of the variance in their involvement in short-term decisions; 50%, in medium-range decisions; and 58% in long-term decisions. The legal right of unions and other representative bodies to participate collectively short-term in such decisions had a negative effect on the actual involvement of individual workers. For the involvement of workers in medium-and long-term decisions, the right of both workers and their representatives to participate had a positive effect. The degree of power sharing that could be explained by legal norms was much higher than what could be explained by the firm's technology, its organizational structure, or market conditions. It was concluded that the actual participation of employees depends on "an intricate interrelation of internal management practices and externally promoted support systems based on formal laws

or collective bargaining agreements” (Industrial Democracy in Europe, International Research Group, 1981, p. 292).

The success of introducing industrial democracy in different countries was mixed. Straus & Rosenstein (1970) found that most plans in India had died. Israel’s plant council and Norway’s work council did not survive. In England, shop floor bargaining between union stewards and workers replaced joint consultative committees. In France, important welfare and shop floor bargaining functions survived, although joint consultative activities were hampered by interunion rivalries and union-management conflicts. Industrial democracy was most successful in the former Yugoslavia, in Sweden, in the German iron and steel industry, and in some American Scanlon Plan companies. Industrial democracy gave labor a sense of having won something. It broadened the scope of bargaining and strengthened management to the extent that the leaders of unions and workers were co-opted to advocate common goals. It provided channels of communication and opportunities for training prospective new managers. In 2006, a central issue in the United States was how to share rising employee health insurance costs, which, unlike in many other industrial nations where health insurance is covered by single-payer government programs, are becoming such a burden that 16% of the population are uninsured.

## Power Sharing in Planning Change

---

Roethlisberger (1941) observed that any technological change by management may affect not only the physical but also the social location of an individual in the organization. The possibility of social dislocation within the organization constitutes a severe threat to many members. Individuals in leadership positions tend to feel more tolerant of change and stress than do those in follower positions. In addition to being more receptive, members in leadership positions usually have access to information that enables them to predict some consequences of change. The member in a follower position has less access to such information unless it is provided by the management. Rumor, imagination, and speculation often lead to grossly inaccurate evaluations of the effects of an announced change. Participation in planning change provides at least a minimum base of information on which a member may evaluate some possible effects of a given change on his or her work, status, and relationship to the organization. Workers will feel more receptive to change if they are involved in planning it. Reducing the power differences between superior and subordinate at the shop floor level in the work group is a main theme of behavioral theorists and practitioners’ interventions. “Every employee a manager” sums up M. S. Myers’s (1968) changeover of supervisor relations. Formerly, the powerful supervisor fully planned for and controlled the performance of the powerless operator, whose only responsibility was to carry out orders. Now, as much as possible, the operator becomes self-planning, self-directing, and self-controlling.

Legally mandated democracy is not a substitute for participation in decisions. The correlation between legally mandated democracy and participation in decisions that affect daily work was only .10 in the 12-country survey mentioned above (Industrial Democracy in Europe, International Research Group, 1981). The workers’ satisfaction with the firm was also unrelated to legally mandated democracy, which suggests that mandated democracy is not a substitute for participative management and democratic leadership. The Swedish Codetermination Act gave legal rights for employees to be consulted by their supervisors at the workplace. White- and blue-collar workers reported an increase in their own influence five years after the Swedish Codetermination Act was passed, but managers did not report increased power sharing with their bosses as a consequence of the act (Stymne, 1986).

*Sharing the Power to Plan Change.* Shifting the distribution of power results in a sharing of planning and control that has positive effects on the commitment, understanding, satisfaction, and productivity of

workers. Structure still remains, but it is based not on differences in power but on a structural design to which the workers have contributed. The utility of such self-planning was reaffirmed in a series of experiments by Bass (1970a, 1977) and Bass and Leavitt (1963).

In a first simulation, Bass and Leavitt (1963) demonstrated the importance of self-planning, both to productivity and to satisfaction. Several simple exercises were devised. In each, trios of managers in training developed a plan for themselves and then exchanged plans with another trio. A counterbalanced order was used so that half the teams executed their own plan first and half executed the other team's plan first. Then they executed both plans. The result was that managers were more productive and more satisfied with operating their own plan.

In a similar simulation, 1,416 managers in training settings completed Exercise Organization (Bass, 1975h). As expected, the objective output and efficiency were significantly greater when they executed their own plans. Moreover, self-planning resulted in greater felt responsibility, job satisfaction, and satisfaction with the plan. However, the payoff was much greater when participants with practice, experience, and knowledge made their own plans than when those without the advantage of practice did so.

The importance of maintaining some special elements that the supervisor can bring to the planning process, such as support, experience, and knowledge, was illustrated by Schlacter (1969), who studied six highway maintenance crews over 25 weeks. In two crews, the fore-men assisted their supervisor in planning and reported results back to their crews. Two other crews assisted their superiors in planning. The third pair of crews assumed full responsibility for planning. The first two crews maintained stable job satisfaction scores and production records throughout the 25 weeks. The third pair of crews gained significantly in job satisfaction, but lost significantly in productivity. Similarly, Latham and Saari (1979) showed experimentally that supportive leadership resulted in higher goals being set by student participants than did nonsupportive leadership.

*Rationale.* Reasons given by participants for the utility of reducing differences in power for the purposes of planning included: (1) it increases the sense of accomplishment when carrying out the plan; (2) it generates more efforts to confirm the validity of the plan by executing it successfully and generates more confidence to see that it can be done; (3) it may increase commitment to see that the plan works well; (4) it may increase flexibility, room for modification, and initiative to make improvements; (5) it is likely to generate a greater understanding of the plan; (6) it may allow for better use of human resources; (7) it may reduce communication problems and the consequent errors and distortions in following instructions; and (8) it may avoid competitive feelings among planners and those who must execute the plans (Bass, 1970a).

*Utility of Self-Managed Teams.* Increasingly, project teams are being formed with informal leadership in which no one member is appointed as leader. Rather, power is fully shared in planning, operations, and control. Manz and Sims's (1980, 1984, 1986) research investigated the utility of such self-managed teams (Cohen, Chang, & Ledford, 1997). More will be said about these teams in [Chapter 26](#).

## ***The Redistribution of Power***

Copeland and McLaughlin (2000) called for redistributing power and authority in schools from the principals to staff and teachers, to meet shared responsibilities and shared purposes. "The capacity for leadership lies in the larger school community ... originating from many peoples' personal resources, and flowing through networks of roles" (p. 2). The authors reported on the success of the redistribution over a five-year period in 86 schools in the San Francisco Bay Area. The principals found increases in teacher leadership (90%), teacher voice in school decisions (69%), staff discussion of teaching and learning (95%), and parent voice in school decisions

(70%). A survey of the teachers in 27 of the same schools disclosed some agreement that there had been increases in shared leadership and the development of leadership capacities.

In countries with large power differences, power is redistributed usually by a peaceful or violent coup d'état in which those in power are replaced. Where differences in power are smaller, redistribution is a matter of election (Hofstede, 1997). Redistribution of power in a country may also be due to changes in the rules and in political control. The power of women in Afghanistan increased with the fall of the Taliban and with women's suffrage. In Kuwait, women were given the right to vote in 2005, and in the 2006 election for legislators, about 78% did so. Expectations were that corruption would be reduced and economic development and women's rights would improve as a consequence (*New York Times*, June 30, 2006).

House (1988) suggested that increased power sharing may come about through major shifts in environmental or technological demands that require the lodging of greater power with lower-status but expert employees. Power sharing may also come about through the replacement of managers and employees; by a deliberate redesign of the organization's structures and systems, so that critical information is broadly disseminated throughout the organization; by creating multiple centers of control; and by decoupling parts of the organization with different interests and unconnected requirements. However, the voluntary redistribution of power is likely to come about slowly and only after prolonged debate and conflict. Thus Dalton, Barnes, and Zaleznik (1968) intervened to shift power downward from managers to scientists in departments of a research and development organization. The scientists at the different levels gained in functional power and favored acceleration in the downward shift. But at the same time, the managers at various levels experienced a reduction of their hierarchical power and consequently favored slowing the downward distribution of power. The privileged, dominant coalitions in an organization will be reluctant to surrender power. They may shift technologies or move the organization into different environments to maintain their own competence-enhancing power.

By the 1990s, the downward shift in power had become commonplace to meet the organizational needs for flexibility and innovation. Structural changes in hierarchical relations had shifted to more collaborative relations across divisions and organizations. More channels had developed for influencing and taking actions. Peer networks were becoming more important than chains of command. Higher-ups increasingly had to face redistributed power that required them to use new ways of motivating their subordinates (Kanter, 1989).

## Summary and Conclusions

---

How power is distributed in groups, organizations, and societies determines relations between leaders and followers. Power distribution depends on the structure of role relations. The human relations point of view about the distribution of power calls for its equalization among members. Structuralists favor strengthening it. Personal and situational contingencies need to be taken into account in determining whether differences in power and structure need to be reduced or increased to promote effective operations and relationships. Different distributions of power are likely to exist side by side, and deal with the legitimacy, politics, expertise, and identification processes. The total power of a group, which can be increased or decreased, strongly affects the conformity of members, their persistence, and their changes in attitudes and behavior. Research about the power of the group to induce conformity among its members peaked between 1950 and 1970. Structure is necessary under conditions of stress, threat, and the pressure of tasks. Group and organizational members are more satisfied under moderate degrees of structure than under overly structured or totally unstructured conditions. Sharing power under normal conditions has many benefits. Opportunities to consider a proposed change facilitate the acceptance of the change by members who will be affected by it. Participation in planning and decision making regarding the change induces a still higher degree of acceptance. As a consequence, power-

sharing programs and restructuring, both voluntary and legally mandated, have become common. Their acceptance depends on the nature of the problems and decisions to be reached, as well as on whether the power sharing is voluntary or legally mandated, direct or through representatives. The practice of industrial democracy has been increasingly institutionalized by legislation in western Europe since World War II. Industrial democracy in the United States has been more likely to take the form of voluntary power sharing and collective bargaining. Increases in legislation to promote the fairness of collective bargaining and to equalize the power of employers and employees came in the 1930s. But how power is distributed can be a major source of conflict.

---

# Resolution of Conflict

Dealing with conflict has been recognized as of particular importance in leadership. In organizational life, the typical manager may spend 25% of his time dealing with conflicts (Thomas & Schmidt, 1976). A common conflict occurs between the manager's boss, whose paramount concern is for productivity, and the manager's subordinates, whose paramount concern is for consideration.

The leader's personality affects his or her rational and emotional feelings about conflict and what to do about it. One president, Lyndon Johnson, wanted every American to love him; another president, Harry Truman, concluded that, "If you can't stand the heat, stay out of the kitchen." National leaders must settle for less than universal affection. They must be willing to be unloved and they must deal with conflict (J. M. Burns, 1978). And so must most other leaders, for conflict often attends the leadership role. No leaders can be successful if they are not prepared to be rejected (T. O. Jacobs, 1970). Nonetheless, Levinson (1984, p. 133) pointed out that executives go to great lengths to avoid conflict because of their discomfort with feelings of anger. He observed that "much of the irrational in management practices arises because of people's efforts to cope with their own anger and to avoid the anger of others. ... But the very fact that they have angry feelings, when they often feel it is wrong to be angry, leaves them feeling guilty." To contend with these feelings of anger and guilt, they make irrational decisions to deny their anger and to appease their conscience. Or they may avoid making or announcing the decision to avoid the conflict implied. Many leaders are like President Nixon, who had to rely on subordinates to relay the bad news to someone whom he wanted to fire or whose actions had been displeasing to him.

## Sources of Conflict

---

Appointed leaders with appropriate competencies and styles may still find their attempts to lead stymied because of numerous possible conflicts with their subordinates. The appointed leader may be resented as a representative of higher authority (Seaman, 1981), or subordinates may favor the appointment of someone else. The leader and the subordinates may have different opinions about the means and ends of their efforts, as well as other ideas. For example, college presidents and vice presidents may disagree about their institutions' goals, although they generally are more likely to agree about means (Birnbaum, 1987a). A superior's and a subordinate's differences of opinion about the difficulty of achieving competence in the superior's job may be another source of conflict. In an eight-country sample of 1,600 managers, the average time that senior executives thought it would take their subordinates to learn the senior executive's job was 18 months; their subordinates estimated it would take them less than six months (Heller & Wilpert, 1981).

### *Cognitive versus Emotional Conflict*

A conflict is mainly cognitive in nature when, say, executives disagree about the legality of an action and then call on the legal department to inform them about the law or regulation involved. A conflict is mainly emotional if, say, executives disagree on whether or not they have been disparaged and ignored by the CEO

and should or should not tell him so. According to an analysis of conflict among 72 supervisor-subordinate dyads, cognitive and emotional conflict form a two-factor structure. One factor is purely emotional; the second factor is a combination of emotional and task conflict (Xin & Pelled, 2003). Generally, if a conflict is mainly cognitive, the outcome could lead to better understanding, affective acceptance, and a higher-quality decision, but more often does not. Making conflict constructive will be discussed later in the chapter. If a conflict is mainly emotional, the outcome will be less well understood and will result in a less emotionally acceptable decision. The resulting decision will be poorer (Amason, 1996). Xin and Pelled's (2003) data revealed that both emotional, and a mix of emotional and task conflicts, were negatively related to supervisory leadership behavior—more strongly in the case of emotional conflict. In agreement, Carsten and Weingart (2002) conducted a meta-analysis, which showed that in studies of task conflicts the average correlation was  $-.27$  with individual satisfaction (12 studies) and  $-.26$  with team performance (25 studies). The corresponding correlations in studies of socioemotional conflicts were  $-.48$  (14 studies) and  $-.22$  (24 studies). From 1,048 to 1,808 individuals were involved.

### ***Role Conflict***

Sources of role conflict for leaders include the ambiguity of a role, personal inadequacy to meet the demands of a role, incompatibility among several roles, conflicting demands, mixed costs and benefits associated with playing a role, and discrepancies between actual and self-accorded status. Role ambiguity occurs when leaders' roles are not clearly defined and the leaders cannot determine what they are expected to do (Kahn, Wolfe, Quinn, et al., 1964). Also, leaders may not be able to meet the demands of a task or the interpersonal demands of their role (D. J. Levinson, 1959). An incongruence occurs when, for instance, old, experienced workers are assigned to young, inexperienced supervisors. The workers are likely to perceive a discrepancy between their seniority and their rank in the status hierarchy (S. Adams, 1953). *Interrole incompatibility* occurs when an individual plays two or more roles in a group and the demands of these roles may be incompatible. For example, the role of group representative may be incompatible with the role of enforcer of discipline (Stouffer, 1949). Or there may be *within-role conflict*. That is, when different followers make conflicting demands on a given leadership role, the occupant of the role will find it difficult to take any course of action that will satisfy the various sets of expectations (Merton, 1940).

Conflict can occur if one would lose power, esteem, autonomy, or self-determination by joining or forming another group. For example, group members may reject an opportunity to join suggested coalitions with others in three-way bargaining situations even if that would be otherwise rewarding, because joining would cause loss of esteem in relation to the other members (Hoffman, Festinger, & Lawrence, 1954). Holt (1952a, 1952b) inferred from analyses of French cabinets and college interfraternity councils that otherwise mutually rewarding coalitions were rejected because a loss of autonomy or self-determination was involved.

Conflicts and disagreements may arise in the legitimatization process—in the right to function as a leader. Thus, when kingdoms were reconstituted in the nineteenth century in such countries as Belgium, Bulgaria, Greece, and Sweden, outsiders from Germany and France were legitimated as kings to avoid internal dissent. Selection of a presumably impartial outsider as constitutional monarch is consistent with the tendency for a leader of an organization to be acknowledged as the one organizational member with the legitimate power to play the role of final arbitrator, the superordinate whose judgment can settle disputes among political factions. This function was often believed to be critical for the avoidance of anarchy. The maintenance and security of the state depended on the existence of a legitimate position at the top whose occupant could arbitrate conflicts among all followers. Daum (1975) looked at the impact of internal promotion versus bringing in an outsider to lead the group. The results were as expected. The selection of a leader from within the group tended to

cause the remaining members to express lower overall satisfaction and to reduce their voluntary participation following the change.

If members can agree on the leadership structure, they are more likely to be satisfied with the group, according to results obtained by Shelley (1960b). Similarly, Bass and Flint (1958a) found that early agreement about who shall lead increases a group's effectiveness. Heslin and Dunphy (1964) noted that the satisfaction of members was high when the degree of consensus about one another's status was also high.

### ***Location in the Organizational Hierarchy***

*Role Ambiguity.* One's location in an organizational hierarchy will make a difference in how much role ambiguity one experiences. Culbert and McDonough (1985) suggested that much of the conflict observed in organizations starts at the top with excessive competition among senior executives with special interests vying for power. Without their awareness, a domino effect is created; the competitive conflicts at the top set off conflicts at each echelon below. Culbert and McDonough (1985) attributed much of the conflict in industry to the failure of those who are in conflict to recognize that they actually have compatible interests. Sometimes they did not acknowledge one individual's contributions to another or to the organization, and sometimes they did not achieve "a common frame of reference so that each could see that the other's efforts made organizational sense."

More role ambiguity occurs among lower-level managers. The responsibilities and authority of first-line supervisors and middle managers are less clearly defined than those of top management. Uncertain about what they are allowed and expected to do, they experience more tension than the top managers and feel less satisfied with their jobs. Thus D. C. Miller and Schull (1962) reported that middle managers registered more role stress than top managers and more frequently stated that they were unclear about the scope of their responsibilities and what their colleagues expected of them. Likewise, Brinker (1955) reported that first-line supervisors in industry worked under constant frustration because they were not given enough authority to believe they were part of management or to solve the problems presented by their subordinates. Supervisors of 140 management clubs wanted to be more closely identified with higher management because most of them felt that they did not know the company policy on many important matters and, as a result, they had to work in the dark (Mullen, 1954). Moore and Smith (1953) found that in the military, non-commissioned officers rather than higher-ups felt constant pressure because of their inadequate authority, a lack of distinction between supervisors and technicians, and conflicts among the leadership philosophies of different levels of organization. Consistent with all these findings, Wispe and Thayer (1957) found less consensus about the functions of the assistant manager than about those of the manager. The assistant manager's role was ambiguous in that neither the manager nor the assistant manager knew whether certain functions were obligatory or optional. Strain and tension were higher for the assistant manager in the more ambiguous role.

*Different Assignments.* Conflict arises between managers and professionals; between people in *boundary-spanning* activities that link activities outside and inside an organization, such as marketing, and people in internal operations such as manufacturing. Interviews have established that boundary spanners had interpersonal and cooperative orientations, whereas line managers emphasized authority, power, and rationality (Anonymous, undated). Conflict arises between staff and line workers and between individuals, in general, who work in different parts of the same organization. For example, there is continual tension between university administrators and faculty members and between hospital administrators and community physicians. Much of this tension is due to their differences in perception (Browne & Golembiewski, 1974), attribution (Sonnenfeld, 1981), and cognitive orientation (Kochan, Cummings, & Huber, 1976). Nystrom (1986) found systematic significant differences in the work-related beliefs of middle managers who were

responsible for the supervision of line personnel and those in the same manufacturing organization who were responsible for designing the work processes and specifying outputs and controls. Middle-line managers believed more strongly in the desirability of structuring people's work activities than the technical design managers, who had a stronger belief in internal rather than external loci of control. The middle managers also were more motivated to manage than the technical design managers.

*Different Perspectives.* A mail survey of 155 organizations indicated that divided or unclear support by senior management for employees' involvement resulted in resistance by middle management to such involvement. The expected benefits to the firms of employees' involvement failed to appear when management was in conflict about the practice (Fenton-O'Creevey, 1998). Those at the bottom and top of their union hierarchy may have unflattering opinions about each other. S. M. Peck (1966) found that union stewards saw corruption in their top union officials but justified the unethical activities of the top officials on the grounds that strong methods were required to cope with existing conditions and that corruption was endemic. Miles and Ritchie (1968) reported that high-ranking union officials "agreed" that shop stewards and rank-and-file members should be encouraged to participate more in decision making and that such participation would result in improved morale, better decisions, and willingness to accept the goals of bargaining. Nonetheless, they were uncertain whether stewards and rank-and-file members would set reasonable goals for themselves if given the opportunity.

### ***Control of Resources***

Another source of continuing conflict is the limited control that managers have over the resources they need to get their work done (Pfeffer, 1981a). In a study of laboratory directors at hospitals, Jongbloed and Frost (1985) found that the laboratory directors were constrained by numerous individuals and groups outside the laboratories, including the physicians who were responsible for ordering the laboratory's tests; by the hospital's higher administration; and by the head of the department of pathology, as well as accreditation councils, labor unions, and professional societies. One laboratory director coped satisfactorily with this conflict; another did not. The successful laboratory director devoted a lot of energy to lobbying for increased resources and gained more needed funding. The unsuccessful director concentrated on the technical aspects of the laboratory operations and was forced to continue with a less adequate budget.

Pfeffer and Salancik (1978) examined the amount of discretion mayors had in determining items for their cities' budgets. They found that mayors who dealt with powerful organized interest groups, such as businesses, professional societies, and labor unions, had less discretion over the budgets than mayors whose cities had a higher proportion of nonwhites, governmental employees, and construction workers, and a lower median income.

### ***Conflict Between Family and Work***

Conflicts between work and family—particularly conflicts over child care and home care—have become major issues since the movement of large numbers of women into the workforce (Lerner, 1994). Imbalance between work and life has become a major source of stress at the workplace and in the family (Kozek 1998). Fisher-McAuley, Stanton, Jolton, et al. (2003) calculated the path analysis for 603 physical fitness professionals (89% female, mean age close to 41). Their opportunity to balance their work and life revealed a path coefficient of .50 with their job satisfaction, which in turn correlated  $-.61$  with their intention to quit.

### ***Relation of Conflict to Leaders' Performance and Satisfaction***

To some extent, role conflict and its effects are in the eye of the beholder. Maier and Hoffman's (1965) study of role-playing groups found that some discussion leaders perceived interpersonal conflict as a source of lower-quality decisions. Other leaders saw disagreement as a source of innovation and new ideas. But more often, role ambiguity and role conflict tend to be deleterious to leaders' performance and satisfaction. Uncertainty about whether one's performance is adequate is a symptom of role ambiguity and a source of ineffectiveness, according to Pepinsky, Pepinsky, Minor, et al. (1959), who studied experimental groups working on a construction problem. The leaders of half the groups were required to work with a superior officer whose approval or disapproval of transactions could be predicted. The leaders of the other groups were required to deal with a superior whose behavior could not be predicted. The researchers found that the productivity of the team was higher under conditions of high predictability than under conditions of low predictability.

Rizzo, House, and Lirtzman (1970) found that with more perceived role ambiguity and conflict, less overall leadership behavior and less job satisfaction were reported in two industrial firms. Tosi (1971) also obtained results indicating that role conflict was negatively related to job satisfaction but not necessarily to the effectiveness of the group. Supervisors seemed able to tolerate role conflict better if they did not have to interact much with their own immediate bosses. In a study of seven companies, supplemented by a national survey, R. L. Kahn, Wolfe, Quinn, et al. (1964) found that role conflict increased as the ambiguity of the situation increased and the rate of communication with one's superiors was high. Job satisfaction decreased under these same conditions. They inferred that the source of most role conflicts is in interactions with one's immediate superiors. Subsequent studies corroborated this, reporting that as much as 88% of all role conflict was with one's boss.

In all, anyone in an organizational hierarchy needs to act both cooperatively and competitively. Roberts (1986) surveyed 350 managers from three levels of management in two business firms and two universities. In all four organizations, managers reported using both cooperative and competitive styles in their relations with their bosses, peers, and subordinates. This is likely to be one reason why successful performance in an initially leaderless group discussion is a valid predictor of success in management positions (Bass, 1954a): both situations call for cooperating and competing with others.

### ***Incongruities in Status, Esteem, and Roles, and Other Mismatches***

Conflicts within and between individuals arise when there are incongruities or mismatches among their levels of status and esteem, their rules, roles, influence, competence, personality, and expectations.

*Status-Status Incongruence.* Ordinarily, people have multiple roles and positions and are accorded status for each. Each status may be matched in value with the other statuses, or it may be incongruent. In organizations that are a mix of bureaucracies and collegial entities, conflict arises because the same individuals must play roles with various degrees of status and importance, depending on the decisions involved. For example, in a university hospital, the university president, the vice president for health sciences, and the medical school faculty will have more influence than the hospital's governing board over the selection of the dean of medicine, the hospital director, and the chief of the medical staff; but the reverse will be true of issues related to the financial integrity of the hospital. Among 26 such decision-making issues, Wilson and McLaughlin (1984) found that with regard to influence there was little correlation between the medical school department head, the dean, and the hospital director. The influence of the incumbent of a particular position in the hospital depended mainly on the issue.

Conflict results if there is an incongruity between one's status in one situation and in another. For example, military enlisted personnel who had high-status civilian positions were more dissatisfied with their officers than

were enlisted personnel who came from civilian jobs of lower status. Former engineers were more critical of their officers than former truck drivers were (Stouffer, Suchman, De Vinney, et al., 1949). Conflict is less and performance more effective when there is congruence between two sources of a leader's status. Knapp and Knapp (1966) studied elected officers and nonofficers who served as group leaders in a verbal conditioning experiment. Groups led by officers exhibited a higher rate of response and conditioned more readily than groups led by non-officers. The official status of the leaders facilitated the groups' learning.

*Search for Congruence.* People tend to try to increase status-status congruence. In class-conscious Britain, 156 first-line supervisors varied in the social class to which they felt they belonged. Those who perceived themselves as higher in social class more readily identified with their senior managers. And the more they thought that their role as supervisor was lower in status than the status of their social class, the more they identified with the senior managers (Child, Pearce, & King, 1980). Jaques (1952) observed much anxiety and confusion when a British worker (low status) was assigned to chair (high status) a conference with management. Relief and satisfaction came only after the managing director took the chair. Trow and Herschdorfer (1965) found that groups with *incongruent* status structures that were free to change did so, whereas those with equal freedom but with *congruent* structures did not change. Furthermore, groups with high degrees of status incongruency were rated low in the performance of tasks and in the satisfaction of their members. Similarly, in a study of 50 workers in one department of a firm, Zaleznik, Christensen, and Roethlisberger (1958) found that members with high status congruence were most likely to meet the productivity standards of management. Likewise, S. Adams (1953) demonstrated that group members were better satisfied when leadership and other high-level positions were occupied by persons who ranked high in age, education, experience, and prestige. The group's productivity tended to suffer when the high-status positions were occupied by persons who ranked low in other aspects of status (age, education, experience, and social position). Yet Singer (1966) found that although status incongruence in groups was associated with tension, disorganization, and hostile communications, it did not result in lower productivity by the group or in the dissatisfaction of the group members.

*Two Leaders.* Two consuls were appointed each year to lead the Roman republic to avoid the possibility of dictatorship by one. Groups with two appointed, elected, or emergent leaders are inherently likely to generate conflict. Osborn, Hunt, and Skaret (1977) looked at potential conflicts between two leaders whose duties overlapped—the fraternity chapter adviser and the elected president—in each of 33 local chapters of a national business fraternity. The authors concluded that organizational effectiveness would be enhanced if only one leader played an active role in influencing subordinates and exchanges with other units. Similar conclusions about the inherent conflict in the overlapping roles of two leaders were reached by Whyte (1943), who examined two-leader configurations in mental institutions.<sup>1</sup> When coleaders are appointed as joint heads of social work training groups, conflicts between the leaders will block the groups' development. But if the two leaders can work together and resolve their potential disagreements, advantages will accrue in the greater opportunities to vary their roles, the wider perspectives for solving problems, and better management of and support and reinforcement for the group (Galinsky & Schopler, 1980). Such duality is built into German firms, which are led by a technical director and a commercial director and—unlike U.S. firms—have no single president. Again, although conflicting loyalties may be created, the benefits of this organizational design include equal attention to the quality of the products and to commercial success. Co-directors and co-presidents of organizations can conflict, and this will block an organization from successfully functioning.

*Formal-Informal Incongruence.* Mismatched formal and informal structures in any organization may be a threat to the organization (Selznick, 1948). Moreno (1934/1953) noted that the formal groupings which a higher authority superimposes on informal, spontaneous groupings are a chronic source of conflict. Roethlisberger and Dickson (1947) associated workers' dissatisfaction with discrepancies between the formal and informal organizations in an industrial plant.

Cause and effect may be reversed. Inadequacy of and dissatisfaction with the formal organization may give rise to an unrelated informal organization that is at variance with the formal one. The informal organization emerges as a means to resist the coercive demands of high-status members of the formal organization (Shartle, 1949b). Such an informal organization may arise if the formal organization cannot provide the members with rewards like recognition or opportunity (Pfiffner, 1951), and may bypass incompetent, high-status members in order to achieve the goals of the formal organization (Lichtenberg & Deutsch, 1954). When the formal and informal structures are remerged, however, conflict is lower and the group's performance is better. Stouffer, Suchman, DeVinney, et al. (1949) observed that discussions were more satisfying to the participants when the informal leaders were given higher status by being placed in the position of discussion leaders. Haythorn (1954a) reported that the performance and cohesiveness of bomber crews were highly related to the extent to which the aircraft commander (the formal leader) performed the informal leadership roles usually expected of the formal group leader.

*Role-Role Incongruence.* Playing a variety of roles is not necessarily stressful. The average individual learns to play the role of child, sibling, parent, subordinate, peer, and superior without apparent effort. However, some individuals play only dependent roles well, and others are content only when they play the role of superior. Professionals tend to assume the role of authoritative, independent agents. Professional actors seem to enjoy enacting a great variety of roles but can experience personal conflict in separating their real selves from the parts they play: that is, in separating their private life from their public image. Although we may not be accomplished actors, we can play a variety of roles without apparent stress if the different roles are compatible. Nevertheless, we may find different roles incompatible with each other and, therefore, a source of conflict for us. Thus Getzels (1963) found that schoolteachers were expected to maintain a socioeconomic role that was higher than their salaries could sustain. On the one hand, in their role as citizens, they were often expected to be more active in church affairs and less active in political affairs than the average citizen; on the other hand, in their professional roles, they were expected to be certified as experts in various fields of knowledge, but they could be challenged by any parent or taxpayer. Thus teachers were subject to several sources of conflict in each of several incompatible roles. Getzels and Guba (1954) also studied individuals with two or more roles that were subject to contradictory or mutually exclusive expectations. They found that such role conflict tended to increase when one of the individual's roles was perceived as illegitimate. Moonlighting workers would be an example if their daytime bosses frowned on their workers taking a second job or if taking a second job was illegal.

*Status-Authority Incongruence.* Evan and Simmons (1969) studied students who were hired to work as proofreaders. In the first experiment, their pay (supposedly an indicator of the worth and importance of their position) was inconsistent with their acknowledged level of competence. In the second experiment, their pay was inconsistent with their level of authority. Incongruity, particularly the underpayment of students in relation to their authority, resulted in a reduction in the quality of work and in conformity to the organization's rules.

*Status-Esteem Incongruence.* Conflict ensues and a group's performance is adversely affected when the group members who are in positions of importance (high status) are not esteemed (Bass, 1960). J. G. Jenkins's (1948) study of two naval air squadrons—one with high morale and one with low morale—found that in the high-morale group, the squadron commander and executive officer were most often nominated as individuals with whom others would want to fly (that is, they were esteemed as well as high in status); but in the low-morale squadron, the commander or executive officer was not the most esteemed member. Palmer and Myers (1955) found a correlation of .38 between the effectiveness with which 40 antiaircraft radar crews maintained their equipment and the extent to which they esteemed their key noncommissioned officers. Similarly, Bass, Flint, and Pryer (1957b) obtained a correlation of .25 between the extent to which status was correlated with esteem in an experimental group and the subsequent effectiveness of the group. Gottheil and Vielhaber (1966)

also observed that groups performed more effectively when their leaders were esteemed. Using interview studies, Shils and Janowitz (1948) concluded that German enlisted soldiers' high morale and motivation to resist surrender during World War II seemed primarily due to their esteem for their officers. It continues to be true that German workers esteem their supervisors (Fukuyama, 1997). Among those Israeli soldiers in Lebanon in 1982 who believed the incursion to be immoral, morale remained high only if they highly esteemed their officers (Gal, 1987).

Firestone, Lichtman, and Colamosca (1975) had college students elect their own group leader after participating in an initially leaderless group discussion. The groups that were subsequently most effective in an emergency were those led by the elected member with the highest ratings for performance in the leaderless group discussion. Those that were worst in the emergency were led by the person they believed had the lowest ratings for performance in the preceding leaderless group discussion.

*Status-Influence Incongruence.* Ordinarily, those who are higher in status more frequently emerge and succeed as leaders. It becomes a source of conflict if a person of low status attempts to lead. Watson (1982) coded the taped interactions of 16 leader-subordinate dyads in a goal-setting discussion to discern their specific effects on each other. The dyads were made up of an elected leader of a student team and one randomly chosen subordinate team member. When the elected leaders attempted to dominate by abruptly changing the topic, by challenging a previous comment, or by making an ideational or personal challenge, the subordinates were most likely to respond with deference and a willingness to relinquish some but not all behavioral options. When the subordinates tried to dominate, however, the leaders resisted and competed for control of the situation. Thus when persons of higher status, the elected leaders, acted in congruence with their status, the subordinates complemented and completed the interaction with deference and simple agreement; but when the subordinates with lower status tried to dominate, the leaders resisted.

Inversions can occur in which those who are lower in status are able to be more influential than those who are higher in status. Such inversions can be a source of continuing resentment and hidden conflict when the high-status figures grudgingly acquiesce to those who are lower in status. Obviously, subordinates can be more influential over leaders who abdicate their role. Pettigrew (1973) gave examples of situations in which subordinates or those who are otherwise lower in status have influence over those who are higher in status. Generally, in these situations, higher-status superiors became dependent on their subordinates (Mechanic, 1962). Physicians can become so dependent on attendants in hospital wards that the attendants can block reforms. Prison guards can become dependent on the inmates for the inmates' good behavior. Although guards can report prisoners for disobedience, too many such reports from the same guards create the impression among their superiors that they are ineffective. As a consequence, guards agree to let certain violations by prisoners go unreported in exchange for the prisoners' cooperation in other matters. Experts can keep their superiors dependent on them for information, particularly about risky innovations, and thereby maintain power over their superiors (Crozier, 1984). Subordinates in the Soviet Union held their superiors hostage with their knowledge of illegal acts the superiors committed in order for the group to meet its production quotas (Granick, 1962).

*Status-Competence Incongruence.* If those with high status are incompetent for their role assignments, the group will be less productive, less successful, and less satisfied; and more conflict will be generated within the group. But strong positive associations between competence and effective leadership have been found in surveys and experiments. Woods (1913) related the judged ability (strong, mediocre, or weak) of 386 European sovereigns to their states' performance from the eleventh century to 1789. A correlation of .60 was found between judged ability of a sovereign and ratings of the political, material, and economic progress of the state the sovereign headed. Similarly, Rohde (1954c) reported correlations up to .63 between the success of groups learning to go through a maze and the adequacy of the pretest performance of the person in charge of each of the groups. Furthermore, in a comparison of nine orientation discussion groups, Stouffer, Suchman,

DeVinney, et al. (1949) observed that members were much more likely to say they “got a lot out of the discussion” when the member of the group who was chosen to lead the discussion was better educated. Bass (1961c) found that successful leadership was more highly related to ability in effective groups than in ineffective groups.

The choice of a competent leader is a major determinant of the effectiveness of a team and stimulates effective mutual influence among team members (Borg, 1956). Thus after analyzing a large number of small-group studies, Heslin and Dunphy (1964) concluded that group members are most likely to achieve consensus on the status structure of the group when: (1) the leader is perceived to be highly competent; (2) a leader emerges who is high in both group-task and group-maintenance functions; or (3) two mutually supportive leaders emerge, one specializing in task functions and the other in group-maintenance functions. (But two leaders of a single group may present problems, as was noted earlier.)

The mismatching of status and competence in a group is likely to result in the downgrading of the group leader. Thus Ghiselli and Lodahl (1958a) found that a supervisor was likely to be poorly regarded by higher management if he led a group containing a worker whose supervisory ability was superior to his. Goldman and Fraas (1965) noted the importance of matching competence and status in their comparison of groups whose leaders were elected, appointed for competence, or appointed randomly. They found that groups with leaders who were appointed for competence did best; groups with elected leaders did next best; and groups without leaders or whose leaders had been appointed randomly did the worst.

*Effects of Loyalty.* Ordinarily, we would expect that competent groups would produce higher-quality decisions. But Dooley and Fryxell (1999), in a study of 86 strategic decision teams in hospitals, found that the quality of these teams’ decisions was higher—according to independent judges—only when the members were seen as more loyal (they did not try to take advantage of each other) and expressed many differing opinions. The quality of decisions suffered when the team members expressed many different opinions but were low in loyalty (tried to mislead each other). For high-quality decisions and commitment, both competence and willingness to disagree were necessary.

*Incongruence of Competence and Power.* Exline and Ziller (1959) assembled groups in which members held positions that were incongruent in competence and power, and other groups in which competence and power were congruent. The participants rated the congruent groups as significantly more congenial, as exhibiting stronger agreement between members, and as involving less overlap of activities.

*Incongruence of Personality Traits and Roles.* As might be expected, effectiveness is reduced by incongruities between the organization or group members’ personality traits and the roles required of them. Smelser (1961) selected students who scored either high or low on a personality test of dominance. The least productive dyads were composed of pairs in which the partner assessed as submissive was assigned to a role that required dominance and the partner assessed as dominant was given a role that required submissiveness. The most productive dyads were those in which role assignments were consistent with personality assessments.

Requisite personality may be a matter of expectations. Violated expectations generate conflict. Lipham (1960) tested the hypothesis that personality traits compatible with expectations about a leadership role will be related to the leader’s effectiveness. In a study of school principals, Lipham found that those who scored high on expected characteristics, such as drive, emotional control, and sociability, were rated more effective than those who scored high on unexpected characteristics such as submissiveness and abasement. In a study of insurance agencies, Wispe (1955, 1957) found that successful agents were characterized by a strong drive for success. But the same attitude toward success, when exhibited by the agency manager, was at variance with the agents’ expectation of a more humane, considerate orientation toward their problems. Thus the characteristic that was perceived to contribute to successful selling was not necessarily expected to contribute to effective supervision.

Overt conflict was avoided (at a price) when those of lower status hid their abilities from those of higher

status. Before the social revolution of the 1960s, college women often used to “play dumb” on dates, just as black subordinates did in dealing with white superiors. Ordinarily, a better way for an organization to avoid conflict and to enhance satisfaction and performance is to develop suitable promotional policies that match the competence of employees with their status (Bass, 1960).

### ***Within-Role Conflicts***

The failure of individuals to align their own needs for personal meaning, identity, and success with what they believe the organization needs to receive from those in their roles is at the heart of individual members' conflicts within an organization (Culbert & McDonough, 1980). Organizational and personal needs must be fused to allow both the individual and the organization to reach high levels of achievement and satisfaction (Lester, 1981).

*Within-Role Expectations.* The negative effect of within-role expectations in groups, organizations, and society is largely attributable to discrepancies between what the members expect they should do and what others expect them to do. They experience conflicts when others make contradictory demands on their roles in the group, organization, or society that cannot be satisfied by any compatible course of action (Brandon, 1965). The man or woman in the middle is a well-known example.

*The Man or Woman in the Middle.* This is a common dilemma. Like everyone else at each successive level in an organizational hierarchy, the supervisor is a man or woman in the middle. Such persons face conflicting role demands from at least two sources: their superiors and their subordinates. Although the person in the middle is likely to be subjected to competing demands from numerous other sources—peers, higher authority, rules, suppliers, and customers—most attention has been paid to the conflicting demands on supervisors from superiors and subordinates (Gardner & Whyte, 1945; Smith, 1948). Superiors expect results, initiative, planning, firmness, and structure. Subordinates expect recognition, opportunity, consideration, approachability, encouragement, and representation (Brooks, 1955). Thus Pfeffer and Salancik (1975) demonstrated that superiors expected more task behavior from first-line supervisors whereas subordinates expected more socializing from them. Likewise, Snoek (1966) found that supervisors “in the middle” experienced more conflict than operatives “at the bottom.” Supervisors had a wider diversity of interactions than the operating personnel, and the conflicting demands placed on them led them to experience more role strain.

In military organizations, officers above and enlisted personnel below disagree on what characterizes the good noncommissioned officer in between them (U.S. Air Force, 1952). Factor-analytic studies by J. V. Moore (1953) showed, for example, that subordinates wanted noncoms to be less strict whereas superiors emphasized noncoms' military bearing and ability. Halpin (1957b) found that commanders of aircrews who highly emphasized consideration were most highly rated by their subordinates, whereas those who most often initiated structure were more likely to be rated effective leaders by their superiors. Similarly, Zenter (1951) noted that 87% of the officers studied thought that a good noncommissioned officer follows orders while only 44% of the enlisted men accepted this idea. At the same time, 49% of enlisted men believed that a good noncommissioned officer has to gain popularity, but only 7% of officers agreed. One discordant note in these findings was that Graen, Dansereau, and Minami (1972b) failed to find the expected discrepancy between subordinates' and superiors' role expectations of executives in the middle.

Nonetheless, Lawler, Porter, and Tannenbaum (1968) found that interactions with superiors were more valued than those with subordinates. In addition, the managers reacted more favorably to interactions that their superiors initiated than to those initiated by others. Porter and Kaufman (1959) devised a scale for determining the extent to which supervisors described themselves as similar to top managers. Self-perceptions that were

similar to those of top managers were associated with patterns of interaction that peers perceived to be similar to those of managers in high-level positions.

Subordinates whose attitudes and role perceptions were similar to those of their superiors were preferred by their superiors (Miles, 1964a) and rated by them as more effective (V. F. Mitchell, 1968). In turn, subordinates who resembled their superiors in the personality traits “sociable” and “stable” were better satisfied than those who resembled their superiors less closely. Henry (1949) and others found that rapidly promoted executives particularly tended to identify themselves with their superiors. On the other hand, Pelz (1952) found that first-line supervisors who were subordinate oriented tended to be evaluated positively by their workers, but only if they were perceived to have sufficient influence with superiors to satisfy the workers’ expectations.

Balma, Maloney, and Lawshe (1958a, 1958b) studied more than 1,000 foremen in 19 plants. They found that foremen who identified themselves with management were rated as having significantly more productive groups than those who did not identify with their superiors. However, the employees’ satisfaction with a foreman was not related to the foreman’s orientation. R. S. Barrett (1963) discovered that foremen who perceived that their approach to problems was similar to the approach of their immediate superiors tended to feel free to do things their own way. Fleishman and Peters (1962) observed that top-level managers tended to connect the effectiveness of lower-level managers with that of these managers’ immediate middle-level superiors.

*Customers and Management.* Employees who are in contact with customers face competing expectations from customers and management. Management expects these employees to follow the rules while providing high-quality service. The customers may have requests that require bending the rules. Customers may exacerbate the situation by rewarding the contact employees with tips. Such employees need to balance the competing expectations of customers and managers (Eddleston, Kidder, & Litzky, 2002).

*Conflicts between Organizational Levels.* Neuberger (1983) viewed the supervisor as the focus of multilateral expectations that could be ambiguous, conflicting, and contradictory. Rules, regulations, and structure do not necessarily provide solutions to such conflicts, which can result in political behavior and unstable leadership behavior. Conflict may arise because there are decided differences in what members at different levels of the organization expect is appropriate behavior for them. L. W. Porter (1959) reported that first-level supervisors viewed themselves as careful and controlled in their approach to the job and to other people. Their second-level managers, in contrast, described themselves as enterprising, original, and bold. First-level supervisors differed from line workers as much as they differed from higher-level managers; they perceived themselves to be significantly more careful and controlled than the workers saw themselves. The first-level supervisory role imposed demands for behavioral patterns that differed from those of superiors and subordinates. A form of conflict that has long been recognized (Coser, 1956) is superior-subordinate conflict involving viewpoints, opinions, and ideas about the task being performed and, on the other hand, tension, animosity, and annoyances—socioemotional, interpersonal incompatibilities (Jehn, 1995). D. E. Frost (1983) reported that for 121 first-level supervisors, perceived conflict in their own role correlated .27 with their boss’s emphasis on production and .35 with conflict with their boss. Consistent with the multiple-screen model of Fiedler, Potter, Zais, et al. (1979), *experienced* first-level supervisors’ performance was greater if conflict was high with their bosses and declined when conflict was low. The reverse was true of the relationship between the first-level supervisors’ *intelligence* and their performance.

The conflicts of middle management were reflected in an opinion research poll of 1982, which found that over half the respondents had “lost confidence in their superiors”; 69% saw too many decisions being made (and made poorly) at the top by persons who were unfamiliar with the particular problems (Fowler, 1982). Adding to the middle managers’ malaise was job insecurity, brought on by drastic reductions in middle-management positions in the 1980s (Clutterbuck, 1982a)—a development predicted 30 years earlier by Leavitt

and Whisler (1958), who foresaw that dramatic improvements in information processing would substitute for this level of management. The trend continued into the early twenty-first century, when many plants and offices closed because of foreign competition and the movement of companies offshore.

*Conflicts with the Boss.* Kahn, Wolfe, Quinn, et al. (1964) found that 88% of all organizational role conflict involves pressure from above. D. E. Frost (1983) discovered that the boss's behavior created most of the role conflict and ambiguity for first- and second-level leaders in an urban fire department. Managers were the overriding reason for the role ambiguity and conflict experienced by 123 salaried employees of a metal fabricating firm who were surveyed by Deluga (1986). Jambor (1954) found that when supervisors' perception of their role differed from their superiors' perception of it, the supervisors experienced more anxiety than when their role perception differed from their subordinates' perception of it. Fiedler (1984) amassed considerable evidence to show that when *experienced* leaders are in conflict with their boss, they tend to be able to maintain productive groups. But *intelligent* leaders without such experience are handicapped by conflicts with their boss. Experience, not intelligence, helps leaders deal with the stress engendered by conflicts with their own superiors.

*Conflicts with Subordinates.* Using clinical observation and psychoanalytical theory, Zaleznik (1965a) conceived of four types of malfunctioning subordinates, each representing a type of personality that is in conflict with the demands of a higher authority:

- (1) *Impulsive* subordinates rebel and strive to overthrow authority and its symbols; unconscious motives may be to displace parental authority or to deal with painful loneliness;
- (2) *Compulsive* subordinates also want to dominate the struggle with authority, but they do so passively. Their behavior is rigid, and they avoid making decisions. Underneath, there are doubts, rapid shifts in feelings about interpersonal encounters, hidden aggression, and denial of responsibility, coupled with a power conscience and strong guilt feelings;
- (3) Immature early development results in *masochists*, illustrated by accident-prone employees who evoke sympathy when hurt. Their performance is inadequate and invites criticism and shame. Their identity is with the oppressed, helpless, and weak;
- (4) *Withdrawn* subordinates turn their interests inward and passively submit to a perceived malevolent world and untrustworthy superiors. Although they may handle routine tasks well, they make little effort to be innovative.

Zaleznik's advice for supervising these four types of subordinates is to avoid being trapped into their dynamics—for example, by reinforcing the doubts of compulsive subordinates or losing control to the impulsive, rebellious subordinates. Conflict with such subordinates needs to be objectified, and conflicting issues need to be broken into their components. Realities need to be recognized.

*Discordant Expectations.* Discrepancies between people's expectations about assignments, jobs, or positions and the expectations of their subordinates, peers, superiors, and clients about these assignments, jobs, or positions have been studied extensively as fundamental sources of conflict. Similarly, conflicts arise as a consequence of discrepancies between what is done by people and what ought to be done. Thus Colmen, Fiedler, and Boulger (1954) reported little agreement among 45 leaders in the U.S. Air Force in evaluating their own duties. Further confusion resulted from a discrepancy between what potential leaders thought they ought to do and what they actually did. Halpin (1957b) found little relationship between how aircraft commanders and school superintendents said they might behave and how their subordinates said they actually behaved.

Stogdill, Scott, and Jaynes (1956) asked officers at various levels of a large naval organization to describe what they did and what they ought to do. In addition, their direct reports described what the immediate superiors did and ought to do. The subordinates' self-expectations were much more highly related to their expectations for their superiors than were their self-descriptions to their descriptions of their superiors.

Subordinates entertained similar expectations for themselves and for their superiors, but their descriptions of their own and their superiors' behavior were not as similar. Except for handling paperwork and other forms of individual effort, they did not perceive that their own behavior resembled that of their superiors. Discrepancies between superiors' self-descriptions and self-expectations were highly related to their level of responsibility.<sup>2</sup> Superiors who obtained high scores from their subordinates on level of responsibility perceived themselves as having too much responsibility and as acting as representatives of their followers more extensively than they should. They also reported spending too little time inspecting the organization and too much time on paperwork and engaging in all forms of leadership behavior. Discrepancies between subordinates' self-descriptions and self-expectations were greater at higher organizational levels where their superiors were recipients of frequent interactions. Under these conditions, the subordinates perceived themselves to be doing more than they should in attending conferences, interviewing personnel, handling paperwork, and representing their own subordinates. When a superior delegated a great deal, the subordinates thought that they had been given too much responsibility, and spent less time than they should on coordination and professional activities.

Along similar lines, Triandis (1959a) found that the smaller the discrepancy between workers' ideal supervisor behavior and actual descriptions of their supervisors' behavior, the better the supervisor was liked by the workers. Results obtained by Holden (1954) indicated that the more a leader's behavior conformed to the group members' expectations, the more productive the group was. Havron and McGrath (1961) suggested that the leaders of highly effective groups either behave as expected or are successful in inducing group members to form ideals that are similar to the leaders' actual behavior. Thus Foa (1956), who studied supervisors and workers in Israeli factories, found that these supervisors and workers agreed on the ideal behavior for a supervisor, but that they did not agree on what the supervisor actually did. The more agreement there was between the ideal and perceived behavior of the supervisor, the better satisfied the workers were with their supervisor. Workers who identified with their supervisor tended to attribute to the supervisor the ideals that they held. Ambivalent workers attempted to conform to the ideal attributed to their supervisor but were aware of the supervisor's deviation from it. Indifferent workers felt less inclined to accept the ideal of the supervisor in their own behavior and were also less likely to notice discrepancies between the supervisor's ideal and real behavior. However, F. J. Davis (1954) failed to corroborate these effects among U.S. Air Force officers: in his study the successful adjustment of the followers did not depend on their agreement with the leader about the leader's role.

*Other Sources of Within-Role Conflict.* Differences in perceived needs, values, interests, and goals are structural sources of conflict among managers at different hierarchical levels as well as between leaders and followers in the community. For example, Fiedler, Fiedler, and Camp (1971) found that whereas community leaders thought poor government, neighborhood disunity, and the failure of public services were the concerns of consequence, householders believed that crime, immorality, traffic, and unemployment were the issues that needed attention. Managers and union leaders both generally overemphasize the importance of pay as a source of dissatisfaction of employees and underemphasize the importance of such concerns as security, job satisfaction, and opportunity (Bass & Ryterband, 1979).

Contradictory demands may stem from discrepancies between one's immediate work group and one's reference group. At some colleges, professors may be caught between the demands of their cosmopolitan, professional, research-oriented reference groups and the role demands of their local campus for high-quality teaching and good relations with students. Industrial scientists may be caught between their professional reference groups' demand that they get their work published and their business firms' demand for secrecy. These conflicts are a source of dissatisfaction, as was illustrated in an industrial study by Browne and Neitzel (1952), who found that workers' satisfaction declined as the disagreement between what their leaders demanded of them and what was wanted by their reference groups increased. Jacobson (1951) and Jacobson, Charters, and Lieberman (1951) studied foremen, union stewards, and workers. The fore-men expected the

stewards to play a passive role in the organization, whereas the stewards and the workers expected the stewards to play an active role on behalf of employees and the union. Foremen and stewards whose expectations deviated from the norm of their reference group got along more easily with each other.

Supervisors in training are often caught in a conflict when their managers are opposed to what the supervisors are being taught by their trainers. Furthermore, trainers are more likely to succeed in modifying the supervisors' behavior if their bosses show interest in the training program, participate in its development, and take the training course first (W. Mahler, 1952). Politicians must continually cope with conflict between what they must do and what they would prefer to do. They must choose between what they find expedient and what they know is right. Personal integrity has to be sacrificed to unholy alliances. Henry IV of France, a Protestant Huguenot, converted to Catholicism because "Paris is well worth a mass." For Adolf Hitler and Joseph Stalin, making a deal with each other in 1939 bought them time. For President Dwight D. Eisenhower, keeping silent in the face of Senator Joseph McCarthy's virulent attacks on George Marshall, Eisenhower's close friend, was justified as a means of maintaining the Republican coalition. Presidents Ronald Reagan and George H. W. Bush both embraced the agenda of the far right while campaigning for election but tended to give a lower priority to many of the right wing's demands once they were elected.

### ***Habitual Sources of Conflict***

*Punctuality.* Some celebrities, such as Madonna and Elizabeth Taylor, have been noted for being chronically late for appointments. Politicians such as Bill Clinton and Jesse Jackson were likewise known for showing up late for meetings. According to Janine Braier, "Being late is a statement; if you are chronically late ... it's a way of saying 'you need me but I don't need you.' ... I never want to have the experience of needing someone. I always want them to want me." People who are habitually late usually are overloaded with tasks and somehow schedule impossibilities into their workdays. They deny the reality that by being late they are delaying others. They feel omnipotent and in complete control. Being late may be a way of deliberately manipulating time to emphasize one's own importance and others' dependence (Jennings, 1999, p. 18).

*Identification.* Racial, ethnic, and national identification is well known as a source of conflict. Conflict may then be exacerbated by divergent beliefs based on historical memories, "we-they" polarization, religious intolerance, and economic, social, and political privileges (Rouhana & Bar-Tel, 1998). But Kelman (1999), in discussing the continuing Israeli-Palestinian confrontation and each side's negative identification with the other, is realistic, also noting positive interdependence (Palestinians are a source of labor for Israel; Israelis are a source of jobs for Palestine). The leaders of both sides must work to change the beliefs of their own people that they are the victims and the other side are the aggressors.

Identification with superiors or subordinates appears to be a key to understanding the man or woman in the middle. Potential conflicts with supervisors and subordinates depend on with whom identification and similarity are sought. Thus Pfeffer and Salancik (1978) observed that when leaders were more responsive to their subordinates' demands, the leaders' characteristics and activities were more like those of their subordinates. The leaders were more responsive to their bosses' pressure to produce when the leaders' activities were more like those of their own superiors. A second study found that supervisors who were required to engage in a great deal of peer-oriented interdepartmental coordination were less likely to be responsive to their subordinates.

D. T. Campbell and his associates developed various methods of measuring identification with superiors and subordinates. Of the variety of independent sub-scales that emerged (Campbell, Burwen, & Chapman, 1955), the most promising were identification with discipline, superior-subordinate orientation, and eagerness for responsibility and advancement. Identification with superiors rather than subordinates correlated .21 with

authoritarianism, .25 with identification with discipline, and  $-.20$  with cooperation (Chapman & Campbell, 1957a). Paradoxically, those of higher rank appear to be less concerned about their superiors and more concerned about their subordinates. Campbell and McCormack (1957) found that colonels in the U.S. Air Force were significantly less oriented toward superiors than were Air Force majors or college men, and majors were less so than Air Force cadets or their instructors. Furthermore, Air Force majors and lieutenant colonels were significantly more subordinate-oriented than the other groups tested.

*Generational Conflict.* A generational conflict resulting in a lack of identification with senior leadership was suggested as a cause of an expected 13% attrition of U.S. Army captains in just one year, 2001. The captains were members of the cohort called Generation X, who were born between 1960 and 1980. Above them in rank from major to general was the baby-boomer generation, whose members were born between 1943 and 1960. The Generation Xers tended to have more divorced, two-career parents, more disruptive families, and less idyllic childhoods than the baby boomers, whose families were more stable, with parents in more traditional roles. Compared with Generation Xers, baby boomers value work and promotion as more important. Baby boomers are more likely to be workaholics. In contrast, Generation Xers value having more free time, more friendships, and a better family life (Wong, 2000).

## Conditions that Resolve or Reduce Conflicts

---

Both the leader and the led determine whether conflicts can be readily reduced or resolved. Among the six factors that identified the effective manager, Morse and Wagner (1978) found one that involved the ability to deal with conflict among colleagues and associates and to avoid continuing conflicts that got in the way of completing assignments. Walton (1972) noted that effectiveness as a leader was associated with the ability to convert conflicts of interests among subordinates and colleagues into accommodation, conciliation, compromise, and, better yet, consensual agreement. Effective leaders did not run away from conflict or try to deal with it arbitrarily.

In contrast with transactional leaders, transformational leaders seem to have more ability to deal with conflict. They are less readily disturbed by it, possibly because they are “more at peace with themselves.” Gibbons (1986) reached this conclusion on the basis of in-depth interviews with 16 senior executives in a high-technology firm identified as transformational or transactional by peer nominations and by subordinates’ descriptions of them on the Multifactor Leadership Questionnaire (Bass & Avolio, 1989).

In organizational mergers, a source of considerable conflict, the acquired employees are more satisfied with the merger when their leaders are transformational (Covin, Kolenko, Sightler, et al., 1997). Followers also make a difference. Lien, Kottke, and Agars (2003) found that emotional conflicts among 84 employees of public organizations in southern California were lessened by collectivistic rather than individualistic attitudes and by tolerance for multicultural diversity.

### ***Dual Loyalties***

Conflicts may be resolved or lessened if the leaders and the led have *dual loyalties*. They may be loyal both to the management and to the union in conflict. They may have interests in both the organization and its members. They may want to remain concerned about the feelings of both their superiors and associates who may be in conflict.

Conflicting interests may be overridden by multiple identifications and allegiances. Potential conflicts may be reduced, avoided, and even resolved because people who are members of two groups or organizations with conflicting interests may consider themselves loyal to both. For example, Stagner (1954) obtained a correlation

of .33 between the favorableness of workers' attitudes toward their company and toward the union. Purcell (1954) found that although more workers identified with the company than with the union, 73% of the men and women surveyed expressed loyalty to both. Supervisors and stewards each identified with the organization that they represented officially, but both supervisors (57%) and stewards (88%) generally felt favorable toward the others' organization. In a case study of 18 supervisors at a British shoe factory, Armstrong (1983) was chagrined (because of his Marxist orientation) to find that despite the supervisors' resentment about their deteriorating income and status relative to the workforce, they remained loyal to the senior management. For Armstrong, this continuing loyalty to senior management meant that the supervisors failed to recognize their interests as members of the working class who were exploited by the capitalist senior management.

Obrochta (1960) obtained results indicating that supervisors and workers were most similar regarding their attitudes toward the company and least similar regarding their attitudes toward union leaders. The supervisors' attitudes toward both the union leaders and the company were more favorable than those of the hourly workers, and the attitudes of the hourly workers toward the union were more favorable than the supervisors'. Obrochta also found that the workers' attitudes toward their foreman were somewhat more favorable than the supervisor's attitude toward them. Further evidence on reciprocity or the lack of it was gathered by Derber, Chalmers, Edelman, et al. (1965) in a study of 37 industrial plants. The results indicated that managers' attitudes toward the union and union leaders' attitudes toward the management were positively and significantly correlated; each group was moderately favorable in its attitude toward the other. Obviously, there are variations and exceptions. For instance, Stagner, Chalmers, and Derber (1958), using separate scales for measuring attitudes toward the company and the union, found no relation between the management's attitudes toward the union and the union's attitudes toward the management. Yet in many firms, managers and union officials regard each other in generally favorable terms, despite the conflict between them about substantive issues, particularly issues involving their respective powers. Investigating managers in a southern city, Alsikafi, Jokinen, Spray, et al. (1968) suggested that unfavorable managerial attitudes toward the union tended to be connected with the inclusion in labor contracts of union security clauses that the managers perceived as challenging their authority to manage. Spillane (1980) noted that in contrast to a survey done in 1959, a survey done in 1978 found that the gap between the attitudes of Australian union leaders and Australian business executives had narrowed substantially. Both groups in the later survey strongly supported arbitration as a way of resolving industrial disputes. On the other hand, Edwards and Heery (1985) noted that when the interests of shop floor democracy in 35 British collieries came into conflict with the interests of union officials or national interests the local leaders upheld the concern for shop floor democracy.

In a plant of 3,400 employees, in which top management and union leaders espoused cooperation and mutual confidence, one-fourth of the shop stewards did not share information with the shop supervisors, and half of the supervisors held back from sharing information with the stewards. Yet in a survey of 263 U.S. firms, information exchange was reported as the most frequent form of union-management cooperation.

As elected officers appealing to their constituents, union leaders need to publicly enunciate more extreme points of view than their counterparts in management (Bass, 1965). To study perceptual distortions between 76 union officers in a central labor council and 108 human resources executives, Haire (1948) showed photographs of two middle-aged men to half of a sample: one photo was identified as secretary-treasurer of a union, the other as the local manager of a small plant. The identifications were switched for the other half of the sample. The union officials used a checklist to describe the photo identified as a union secretary-treasurer as that of a man who was conscientious, honest, trustworthy, responsible, considerate, cooperative, fair, and impartial. The human resources executives were even more complimentary in describing the same photo as that of a plant manager.

Differences in communication behavior show up when union stewards are compared with counterparts who are plant supervisors. Nonetheless, dual allegiance to the union and the company is the rule rather than the

exception. This was seen in interviews with 202 employees in the garment, construction, trucking, grain processing, and metalworking industries. If the employees had favorable attitudes to either the union or the company, they had favorable attitudes toward the other as well. Dual allegiance was found in 73% of packinghouse employees, 88% of union stewards, and 57% of company supervisors (Purcell, 1953).

### ***Multiple Orientations***

Three of every four first-line supervisors who were rated as promotable by their superiors were described by their subordinates as pulling for both the employees and the company. Only 40% of those seen as less worthy of promotion were so described (Mann & Dent, 1954b). Simultaneous upward and downward orientation and sensitivity are required of the effective supervisor, as a person in the middle. Sarbin and Jones (1955) reported that a successful supervisor not only is competent in the eyes of superiors but fulfills the expectations of subordinates. According to Wray (1949), this is not an easy task, since superiors and subordinates present conflicting expectations that are difficult to reconcile. Nonetheless, in his study of an industrial plant, H. Rosen (1961a, 1961b) found that managers could have an upward orientation toward the demands of their superiors while remaining sensitive to the demands of their subordinates. The experience of supervisors in their subordinates' jobs has been found to be of consequence. Maier, Hoffman, and Read (1963) compared managers who had previously held the jobs of their subordinates with peers who had not held these jobs. Subordinates trusted mutual agreements about their current problems only when the agreements were made with managers who had previously been in the subordinates' jobs, although a manager's previous assignment to a subordinate's job did not facilitate effective communication.

### ***Perspective-Taking***

Conflict has a tendency to escalate and to be exacerbated by *mirror imaging*—attributing opposite qualities to the opposition in a conflict. Thus, “we” are honest, just, rational, and benevolent; “they” are dishonest, unjust, emotional, and malevolent. Leaders of groups, organizations, and nations tend to exploit and exaggerate these opposing attributions, as was seen among Americans who exhibited mirror imaging of Iranians soon after the American hostages were seized in Tehran in 1979 (Conover, Mingst, & Sigelman, 1980). However, McPherson-Frantz and Janoff-Bulman (2000) found in an experiment with college students about parent-adolescent conflict that partisanship could be ameliorated to the extent that partisans liked the opposing party. Instructions to be fair and unbiased resulted in reducing attention to arguments from both sides but also bolstered original partisan perspectives.

### ***Union-Management Relations***

The marked decline in union membership in the United States in the past half century has been paralleled by a decline in studies of union-management relations. Furthermore, there has been a shift in unionization from industrial business to governmental agencies. Despite mirror imaging, K. F. Walker (1962) found that managers and union leaders were accurate in predicting each other's attitudes, but both perceived more conflict than actually existed. Supervisors and shop stewards who wanted the company and union to coexist amicably experienced more stress than normal and tended to hold favorable attitudes toward each other (Purcell, 1954). However, the underlying bases for evaluating the management and the union differed. Stagner, Derber, and Chalmers (1959) surveyed the attitudes of two labor leaders and two managers in each of 41 establishments.

When they computed a composite score for each establishment for each of 35 attitude and satisfaction variables, they found that the management's evaluation of the union emerged as a single general factor but that the union's evaluations were denoted by two factors, one involving union-management relations and the other concerned with the union's achievements (1949). Miller and Remmers (1950) examined the attitudes of managers and labor leaders toward human relations-oriented supervision. Managers tended to overestimate labor leaders' scores, whereas labor leaders underestimated managers' scores. In a comparative study of managers and union officials, Weaver (1958) found, as expected, that union officials exhibited strong pro-labor attitudes. But not as obviously, managers were neutral about grievances, arbitration, the labor movement, and working during a strike.

Schwartz and Levine (1965) compared the interests of managers and union officials in the same companies. The managers scored higher on interest in supervisory initiative and production, and the union officials scored higher on interest in seeking power and in propaganda, bargaining, arbitration, and disputation. Similarly, Bogard (1960) compared the values of management trainees and labor leader trainees and found that management trainees scored higher in aggressiveness and lower in altruistic values than the union trainees.

## Managing Conflict

---

The management of conflict is an important component of most leadership roles. Thomas and Schmidt (1976) reported that middle managers spent more than 25% of their time dealing with conflict with their colleagues. The figure was even higher for first-line supervisors. Often, managing a conflict may involve gaining the acceptance of a resolution by persuading the conflicting employees, groups, or organizations that the proposed settlement will bring more benefits and less cost to both parties than continuing the dispute.

Leaders can manage conflict with supportive, friendly, obliging, compromising, and integrative efforts to move the parties from a competitive to a cooperative stance (Musser & Martin, 1988). The conflict between the felt security of employees in the old ways of doing things and changes required by new demands can be managed by a leader who instills pride in the past coupled with a need to meet the challenges of the future (Tichy & Devanna, 1986). According to Oscar Arias, a former president of Costa Rica, reelected in 2006, who has frequently been involved in international negotiation of conflicts, the negotiator needs patience but not passivity, perseverance but not inflexibility, commitment and respect for others' viewpoints, skills in building trust, and the ability to compromise in good faith.

### ***Diagnosis and Remediation***

Diagnosis of the causes of a conflict is a rational way to begin to manage it. For example, if a conflict is due to a failure to match status and esteem, it can be reduced by incorporating the results of subordinates' evaluations of esteem into promotional policies or building up the esteem of those with high status. If conflict is anticipated because of a rise in status of one member at the expense of the others, it can be avoided by bringing in an outsider to lead the group (Bass, 1960). Kabanoff (1985a) proposed a typology of conflict situations. Each type suggested a relevant rationale for its management. For instance, if a diagnosis showed that the team members' esteem was lower than their actual ability and expertise, public praise could be used to increase their esteem. In addition, counseling could help peers increase their acceptance of expert but unesteemed members.

### ***Conflict-Management Tactics and Strategies***

Kabanoff (1985a, 1985b) provided a list of diagnosed *intrapersonal* conflicts, such as conflict between one's status and esteem, with implied or self-explanatory strategies for handling them. In addition, tactics were suggested for dealing with conflicts of status and esteem, when conflicts arose between low esteem and high-needed ability, low commitment and high centrality, low popularity and high status, incompatibility and required collaboration, low ability and required-high ability, low ability and high status, and low ability and a highly critical task.

Kindler (1996) focused on resolving *interpersonal* conflicts by suggesting ways a person such as a leader could deal with a conflict, depending on the diagnosis of the circumstances. The ways of dealing with such conflicts included direction, resistance, adapting, accommodating, and yielding. They also depended on a diagnosis of the intention to be firm or flexible, and on how involved a party in the conflict wanted to be in the resolution. According to Kindler, *domination* pressures the opposition to comply. This is a costly, inflexible alternative because of its potentially negative effects, but it may be necessary when speed is vital, when confidentiality prevents disclosing all the relevant facts, or when a stalemate cannot be ended. *Smoothing* is another inflexible tactic; it accentuates the information that supports the benefits of one's position and steers the conversation away from alternatives that would intensify the opposition. *Maintenance* is a firm but interim tactic to deal with conflict when time is needed to collect information, calm emotions, enlist allies, take care of higher priorities, or allow nature to take its course—as when an obstinate opponent is expected to retire soon. *Bargaining* works when each side wants something that the other controls. Offers and counteroffers lead to a compromise agreement if both parties can gain from it. *Coexisting* is an agreement for the parties to follow separate paths until after additional testing, when an agreement on a single path can be made. *Deciding by rule*—such as by seniority, arbitration, or coin-flipping—may be appropriate when any alternative solution is better than none and decisive action is needed. *Collaboration* requires time, trust, and interpersonal competence with attentive listening and the probing of underlying assumptions in the search for creative solutions. Each side must be flexible and open about what it wants to see in the solution. *Releasing* allows the decision to be made by the other party, as when a flexible supervisor delegates the matter to the subordinate to handle after limitations on what is possible have been set. *Yielding* occurs when a flexible supervisor expresses a difference of opinion with a subordinate but agrees to go along with what the subordinate wants to do. It is useful in dealing with an issue that may be more important to the subordinate than to the supervisor.

Another approach to diagnosis of the conflict situation, leading to the use of political skills, was offered by Block (1987). *Allies* are those with whom you share a high level of trust; *opponents* can be trusted but are in disagreement with you over issues; *bedfellows* are in agreement but can't be trusted; *fence sitters* can be trusted, but you don't know their positions; and *adversaries* are those with whom trust and agreement are low. Like Kabanoff's and Kindler's models, solutions depending on the diagnosis are implied and need empirical testing.

*Influence Tactics.* The extent to which threats or promises were used for dealing with interpersonal, intergroup, and international conflicts was studied by Betz and Fry (1995). Promises were seen as more likely to be used in interpersonal conflicts, and threats as more likely to be used in intergroup and international conflicts. It was more important to use strength and force to resolve international conflicts. Filella (1971) queried 27 Spanish managers who formed the top three levels of their banking organization about how they dealt with disagreements with each other. In terms of the influence tactics described by Kipnis, Schmidt, and Wilkinson (1980), the bankers used reasoning most often, followed, in order, by the formation of coalitions, friendliness, assertiveness, bargaining, and appeals to a higher authority. Subordinates used all these tactics—except reasoning—more often than their superiors in trying to resolve disagreements with them. Rational justification appears to be particularly useful to superiors in heading off potential conflict and dissatisfaction when managers are faced with maintaining the status quo or with trying to promote change. Bies and Shapiro

(1986) asked 137 evening MBA students who had full-time jobs during the day to recount an incident in which their current manager had rejected their proposal or request. The managers could reject the proposal or request without losing their subordinates' respect, trust, and esteem if the subordinates judged that the managers provided good and sufficient justifications for their decision. Such justification was either that the issue was not in the manager's control or that the request did not fit with goals and priorities. Managers who are facing the need to make changes likewise must be prepared to give their subordinates good and sufficient justification. According to Deluga (1986), the ambiguity of the employees' role was unrelated to the influence tactics they used in dealing with their bosses. However, those who experienced more role conflict were more likely to use reason and assertiveness with their bosses than try to bargain with them. If a manager continued to resist their efforts to influence, the subordinates who felt more role conflict then tried ingratiation, impression management, flattery, the creation of goodwill, and gaining the support of the higher authority and their coworkers.

Although resistance to change is a problem in all social settings, it is both endemic and fraught with increasing penalties in productive and service enterprises that must deal with rapidly changing markets and technologies. Tichy and Devanna (1986) suggested that senior managers can assuage middle managers' tension about the need for stability and change by creating organizations that "embrace paradox." Such organizations can provide a balance between the need for adaptation and the need for stability and between the denial and acceptance of reality. (For example, "We're not number one yet, but we will be.") The old forms can be abandoned, and the new can be better.

Tichy and Devanna noted that senior managers must deal with *technical* reasons for resistance to change, such as habit, inertia, fear of the unknown, loss of organizational predictability, and sunk costs (the organization's investment of resources in the old ways). Senior managers must also deal with *political* reasons for resistance to change, including the threat to currently powerful coalitions of vested interests, win-lose decision making about scarce resources, and fault found with their own previous decisions. They must likewise deal with *cultural* reasons for resistance to change, such as the extent to which the organizational culture has highlighted old values and methods that now must be abandoned. Or, they must handle the felt security in regressing to the "good old days." The organization may lack a climate for change. There may be demands for conformity to the old ways, and a lack of receptivity to new ideas.

In managing the *rational* and *socioemotional* conflicts associated with resistance to change in industrial firms, senior managers must summarize the past and eulogize its value, emphasize the continuities of the past with the future, and justify the changes. To counter the political and socioemotional reasons, they must mobilize coalitions of support for the changes (Tichy & Devanna, 1986). Thus Kanter (1983) mentioned 200 *change-masters*—executives who could successfully bring about new developments in their organizations. They knew how to build coalitions to get the funds, staff, and authorization to move ahead to carry out their innovations.<sup>3</sup>

*Palliation.* Student participants in an experiment, whose anger and aggression had been aroused, could be induced to collaborate with an accomplice by palliating their anger and aggression. Baron (1984) arranged for undergraduate subjects to play the role of executives who discussed important issues with an accomplice of the experimenter. The accomplice disagreed strongly with the students in an arrogant and condescending manner that angered them. But subsequently, the accomplice palliated the situation by offering a token gift of candy (a Life Saver), by generating sympathy with justification for his earlier aggressive behavior, or by asking for help with a humorous task. These palliative efforts increased the like-ability of the accomplice. In contrast to the subjects in a control condition, in which such palliative efforts were not made, the subjects in the experimental condition indicated that they would be more likely to collaborate with the accomplice and be less likely to avoid him if conflict with him arose in the future.

*Force and Avoidance.* Dutch studies of a test for handling conflict found satisfactory agreement among

self-reports, opponents' reports, and observers' ratings of *forcing* and *yielding*, but not *avoiding* (De Dreu, Evers, Beersma, et al., 2001) The use of force by superiors and avoidance by subordinates to manage the conflicts between them appears to be a matter of individual differences, for conflict is in the eye of the beholder. In some circumstances, some people see conflict with others but the others see none. To illustrate, in a study of one supervisor and one subordinate each from 113 agencies for parks and recreation, Howat and London (1980) found that the supervisors and subordinates who perceived more frequent conflicts were likely to be rated unfavorably and tended to see each other as more likely to use force as a way of dealing with conflict. Supervisors who perceived more conflicts were also viewed by their subordinates as likely to withdraw from conflict; subordinates who perceived more conflicts were viewed by their supervisors as likely to avoid confrontation and compromise. Sometimes avoiding the use of force turns a conflict into a tragedy. In 1995, a Dutch peacekeeping force stood by when Serbs took prisoner 8,000 Muslim men and boys in Srebrenica, Bosnia, and subsequently massacred them.

*Identification.* Halpin and Winer (1957) listed four ways for an airplane commander to manage conflicts with his superiors and subordinates: (1) he could identify completely with the higher authority and disparage the need to be considerate of the welfare of his subordinates; (2) he could reduce intimacy with his subordinates to minimize any guilty feelings he might have about having been inconsiderate of them; (3) he could be inconsiderate to his subordinates on the job but "pal around with them" off the job; (4) he could focus completely on satisfying the needs of his subordinates. Evidence in support of these findings accrued from a factor analysis by Hites (1953) of the results of a survey of aircrews. Hites noted that leaders varied in their loyalty and deference to superiors and also varied in their loyalty to their subordinates. That is, some commanders were loyal to their superiors, some were loyal to their subordinates, some were loyal to both, and some were loyal to neither. Halpin's (1953) followup study of 89 commanders of B-29 aircraft found that the commanders were likely to be highly rated by their superiors and their subordinates if they exhibited consideration, friendliness, and warmth toward their subordinates and initiated clear patterns of organization and ways of accomplishing missions.

Pelz (1952) and Likert (1961a, 1961b) observed that managers in the middle can perceive themselves as members of overlapping subgroups. Effective leaders can see themselves as members of two groups: one composed of their superior and their peers, the other composed of their subordinates and themselves. They have sufficient influence with their superior (as members of their peer and superior group) to represent their subordinates' interests effectively; they are well enough identified with their subordinates to be supported by them (as members, themselves, of their subordinates' group). Thus, they are both good followers and good leaders, able to satisfy the expectations of both their subordinates and their superior.

Summarizing the results of organizational surveys, Kahn and Katz (1953, 1960) inferred that effective leaders differ from ineffective leaders in making it clear that their role differs from that of their subordinates. They do so by avoiding performing the subordinates' functions; by spending time on supervision but not closely supervising subordinates; and by concerning themselves with their subordinates' needs, rather than with rules. A chain effect was observed by Bowers (1963, 1964a), who studied management-supervisor-worker relations in an industrial firm. The more supportively the supervisor's superior behaved toward him, the higher was the supervisor's self-esteem. The higher the supervisor's self-esteem, the less often he discussed his problems with subordinates and the better he perceived their attitudes toward him. The better the attitudes that the supervisor perceived his boss and subordinates sharing about him, the more he felt friendly toward his subordinates. The more friendly he felt, the more supportively he behaved toward his subordinates. Bowers concluded that the supervisor's self-esteem converted the behavior of his boss into a mandate for the supervisor's actions. A study of nursing supervisors by Kamano, Powell, and Martin (1966) provided corroborative evidence. These authors reported that supervisors who were evaluated more favorably by higher-level administrators likewise tended to rate their own subordinates more favorably.

*Organizational Politics.* The competing self-interests of people in an organization give rise to organizational politics. In this situation, the members vie for control in a struggle to obtain cooperation. Their different beliefs about desired actions and outcomes are complicated by their uncertainties over the link between means and ends. The win-lose possibilities of political activity are threatening to the members' self-interests and are likely to arouse resistance if the politicking is open rather than concealed (Frost & Hayes, 1979).

Organizational politics may be seen in the performance of *intrapreneurs*, who break the organization's rules to pursue new products and ideas in which they are personally interested (Pinchot, 1985). According to P. J. Frost (1986), politicking can be seen in the intentional building of frameworks of the rules and meanings of communication for systems of influence. Although the exertion of influence on the surface activities of the organization is primarily a matter of the appropriate open use of ability, power, and control of resources, organizational politics may be required, particularly if the deeper organizational structure calls for *reshaping*. Reshaping is necessary when the organization can no longer function with the old arrangements for balancing members' self-interests. New alignments are needed to accomplish objectives in the face of likely resistance. Such legitimate politics can be seen in whistle-blowing (dissent based on principles) and bargaining. Conflicts can be reshaped by enlistment of critics, as when a legislative majority vote can come about only with the help of members of the opposition. Channels of communication need to remain open. The CEO must avoid letting the "palace guard" block the view from below or from organizational outsiders (Block, 1987).

Politicking is overtly rational, but much of the time it covertly caters to the self-interests of the political actor. It aims to confront others and gain their compliance by manipulative actions. At deeper organizational levels, it becomes an effort to shape conscious and unconscious organizational values, beliefs, and practices. Resistance from others is reduced by concealment of the true self-interests of the political actor. Machiavellian tactics are applied.

*Machiavellian Tactics.* Although it would seem that people in the middle use open compromise to manage the contradictory demands placed on them, they may employ more subtle or sometimes devious ways of momentarily reducing but not resolving conflict. First, all the conflicting parties may be told what they want to hear. For example, when he addressed liberal audiences, President Lyndon B. Johnson would emphasize how much he admired Franklin Delano Roosevelt's liberal policies. When he met with his conservative financial backers, however, he would say how much he was against the liberal policies (Caro, 1982). Chairman Yasir Arafat of the Palestinian Authority talked about peace when addressing international and Israeli audiences in English. But when addressing Arab audiences in Arabic, he talked about driving Israel into the sea.

Persons in the middle may withhold information from superiors or subordinates and mask their feelings. Thus W. H. Read (1962) found that managers who communicated to their superiors with less than complete accuracy were more upwardly mobile. The relationship was conditioned by the extent to which managers trusted their superiors and perceived them to have influence with higher management. Walker, Guest, and Turner (1956) studied the problems of supervisors on an assembly line where the workers were under constant pressure because of their inability to control the speed of their work. The most effective supervisors were found to absorb the pressures and criticisms from higher management without communicating their frustrations and tensions to the workers.

In her survey of 350 managers, Roberts (1986) noted that managers in the middle said they were more inclined to try to impress their boss, somewhat less likely to try to impress their peers, and least likely to try to impress their subordinates. A negotiated solution was more often sought with the boss or peers than with the subordinates. Jambor (1954) suggested that persons in the middle of conflicts, between those above and those below them in the hierarchy, often yielded to their more powerful superiors and rationalized their position with their less powerful subordinates. Jablin (1981) observed the same pattern but thought that such political

behavior might result in a loss of support from the subordinates. Subordinates who perceived their supervisors as highly political were less open in their communications with these supervisors and less satisfied with them than they were with other supervisors whom they saw as less political. This same effect was also noted by Roff (1950). Political behavior by combat officers led their immediate subordinates to rate them as less sincere, less impartial, and more concerned with personal advantage. Wickert (1947) found that an officer had to appear sincere and consistent to be rated as a successful leader of a combat crew. Elected officials are caught in a cauldron of conflicting demands from their various constituencies. Followers have difficulty checking on the authenticity of their leaders, who often can maintain office indefinitely without much need for sincerity and consistency. One person's hypocrisy is another's tactfulness. According to Titus (1950), hypocrisy may be necessary in dealing with followers, but minimal use should be made of it. Jameson (1945) noted that leaders need to "wear masks" to disguise their own feelings and to live up to expectations, despite conflicting demands made on them. Political leaders contrive both conflict and its resolution. For instance, the Nazis set fire to the Reichstag in 1933 and pinned the guilt on the communists, setting them up as criminal plotters against the government. In 1934, Joseph Stalin secretly arranged for the assassination of a party leader in Leningrad, then dramatized it as a plot against the state, providing a rationale for the terroristic purge that followed. In 1964, the Johnson administration contrived to magnify the Gulf of Tonkin incident into a major assault on the U.S. Navy so as to gain congressional support for escalation of the U.S. response in Vietnam. In 2003, George W. Bush took the United States to war in Iraq on the basis of intelligence that Iraq had weapons of mass destruction, but this intelligence had been discredited a year earlier.

"Divide and conquer" is a classic strategy that Machiavellians use to gain and maintain their power over subordinates. Dissension within the opposition weakens it and keeps it from mobilizing effectively against those in control. Lawler (1983) examined how this strategy by an imaginary leader affected two female subordinates in a triad who were working under inequitable rates of pay. Conflicts of interest were increased between the subordinates, but co-optation—a promise of advancement—was more effective than threats in preventing their rebellion. The subordinate who was promised advancement was less susceptible to pressure from the other two subordinates to rebel against the imaginary leader. (For more on Machiavellian tactics, see [Chapter 7](#).)

*Ignoring Dissonance.* Political leaders may also avoid immediate conflict by ignoring the facts about the circumstances and relying on their own strongly held beliefs, needs, and wishes. When Hitler broke the Treaty of Versailles of 1919, he promised to keep the Treaty of Locarno of 1925. He broke the Treaty of Locarno, but he promised no further territorial aggression when his troops marched into the Saar in 1936. When he entered Austria by force in 1938, his government promised no interference in Czechoslovakia. Later in the year, at the time of the Munich crisis in 1938, when the British prime minister Neville Chamberlain and the French premier Édouard Daladier were confronted with such interference and more territorial demands, they ignored all of Hitler's previous broken promises. For the sake of peace at any price, and because of their image of Hitler as a "bulwark against Bolshevism," Chamberlain and Daladier engaged in wishful thinking. They appeased Hitler and relied again on his good faith. His troops occupied Czechoslovakia and attacked Poland in 1939.

*Reserving Judgment.* Barnard (1938) described the "fine art of executive decision" and noted that superiors' demands for conflict-laden decisions by the executive must be met, but responsibility for them can be delegated. Subordinates' demands for such decisions need be met only when the decisions are important, and they cannot be delegated. The tactful executive can avoid conflict-laden decisions on questions that are not pertinent, as well as premature decisions, impossible solutions, and decisions that others should make.

*Effective Leadership.* Shartle (1956) noted that efficacious organizational leaders are able to switch from one goal to another. This can be done if the leaders have a balanced, flexible set of identifications with various organizational projects and plans. If they find themselves blocked in one line of activity, they can shift to

another, thus avoiding a sense of frustration and failure. J. M. Burns (1978, p. 39) saw conflict as an opportunity to display leadership. Leaders (in contrast to status quo administrators) convert the demands, values, and goals of conflicting constituencies into workable programs: "Leaders, whatever their professions of harmony, do not shun conflict; they confront it, exploit it, ultimately embody it. Standing at the points of contact among latent conflict groups, they can take various roles, sometimes acting directly for their followers, sometimes bargaining with others, sometimes overriding certain motives of followers and summoning others into play."

Feyerheim (1994) observed influence patterns for a year in two groups that were formulating governmental regulations regarding pollution. Diverse interests were represented in these groups, but shared frameworks had to be developed so as to create solutions. Several individuals took the lead. The leadership that was most successful in shifting the frameworks highlighted assumptions, created new possibilities, and initiated collective actions.

Eisenstat (1954) found leadership to be ineffective when followers were apathetic toward an issue that required integrative action, when the leaders' broader orientation did not correspond with the practical issues faced by the followers, when the leaders had no authority to deal with broader issues, and when the leaders were in conflict with other leaders.

*Conflict Management Styles.* Lehen, Ayman, and Korabik (1995) used the Rahim Organizational Inventory (ROCI—Form B) to obtain descriptions of conflict management styles according to the subordinates of 120 Canadian vice principals of schools and managers from an accounting firm, a bank, and a manufacturer. Five styles are assessed by the ROCI: (1) integrating, (2) obliging, (3) compromising, (4) dominating, and (5) avoiding. Consistent with earlier investigations by Rahim and Buntzman (1989) and Witteman (1991), Lehen, Ayman, and Korabik found that the *integrative* style (solving problems and listening considerably to subordinates) was most positively related to subordinates' satisfaction with supervision. The *avoiding* style was most negatively related to subordinates' satisfaction. What is required here is a belief that discussions of conflict can be constructive and that conflicting parties can be trusted to work toward effective outcomes if communications between them are open. According to Culbert and McDonough (1980), awareness of every member's self-interests and the need to deal with them is essential to organizational and individual effectiveness. Subordinates need to confront their superiors about their needs. Out of this confrontation can come an alignment of the subordinates' needs and the organization's needs. The conflict between downward and upward demands can be best resolved through such open confrontation and discussion.

But evidence is mixed in support of this contention. On the one hand, according to a survey of 350 managers by Roberts (1986), a search for consensus was the most popular way for the managers to deal with their superiors, peers, and subordinates. Likewise, Friedlander and Margulies (1969) found that the task motivation and involvement of research personnel were maximized by their trust in management. Wilcox and Burke (1969) concluded that openness between workers and supervisors resulted in greater job satisfaction for both. Similarly, Klauss and Bass (1982) reported that colleagues were more satisfied with focal persons perceived as more open in their communications. In 147 established managerial work groups, Crouch (1986) found that managers were more willing to encourage the open expression of conflicting views and that they, as well as their subordinates, had little need to dominate. Strong dominant personalities were likely to suppress such conflict. Crouch also found that the work groups' performance was enhanced to the extent the managers legitimized such open expression of conflicts in points of view.

However, Rubin and Goldman (1968) found no difference in the openness of communication of effective and ineffective managers. Crouch and Yetton (1987) suggested that the benefits of open group discussions depend on the leader's skills in managing conflict. Willits (1967), who studied 20 small manufacturing firms, found that although the measures of their success were positively related to the president's openness in

communicating his *ideas*, as was expected, the ideas were negatively related to the open communication of his *feelings*. Furthermore, open communication by the other executives did not coincide with a company's success.

*Conflict Management by Political Appointees and Career Civil Servants.* Even if they have strong political or professional credentials, new political appointees to senior management positions in public bureaucracies move into a situation that is inherently full of conflict. They must confront long-established rules and regulations, entrenched cliques, and deception from career civil servants who become defensive, passively obstruct new policies, and withhold or delay providing information to and from the appointees (House & Covello, 1984). For their part, the career governmental executives often must keep an agency operating while they await a new political appointee as its new head. Potential conflicts between incoming, newly appointed agency heads and permanent civil servants are likely to be minimized by a mutual understanding that is established before the appointee takes office, or is developed later. "Civil servants have some ideas of the thinking and requirements of their [newly appointed heads], and [the agency heads] acquire knowledge of the dispositions of their civil servants. A civil servant who gives advice is likely to frame it on the basis of his understanding of the needs of [the agency head], and [the head] is likely to modify his policy preferences on the basis of his knowledge of what is ... feasible" (Page, 1987, p. 133).

To reduce potential conflicts with the incoming political head of the agency, Schmidt (1985) suggested that while awaiting the new head, the career executive should continue to make normal decisions about filling vacancies and about policies to be implemented or postponed, emphasize greater cooperation among antagonistic organizations, hold informational meetings, avoid the usurpation of power by bureaucratic processes, and try to keep rivalries about turf to a minimum. Newly appointed incompetent political heads and replacements of many experienced civil servants can quickly change an efficient agency of competent civil servants into an incompetent organization—as was seen in the disastrous handling by the Federal Emergency Management Agency of hurricane Katrina in 2005.

*Converting Conflict to Problem Solving.* Walton and McKersie (1965, 1966) and Likert and Likert (1978) thought that conflict can be managed best when it is converted from win-lose negotiations to a problem-solving situation from which both parties can emerge as winners. Furthermore, Likert and Likert noted that it is particularly important for conflicting parties to avoid becoming adversaries who debate solutions to a conflict before they have reached agreement on what outcomes they deem essential and desirable. This position is consistent with Bass's (1966b) finding that negotiators who began with committed solutions were much more likely to reach a deadlock than those who entered negotiations without firm solutions in mind. It also fitted with Maier's (1967, 1970b) results, which indicated that an early focus on ready-made solutions causes groups to avoid trying to find more creative ways to deal with their problems. Adversarial groups cling to their favorite solutions as they proceed with negotiations. Brams (1990) demonstrated how it was possible to use mathematical game theory to reach an overall greater gain for each side if both sides were disputing the weighted importance of the various divisive issues.

*Changing Win-Lose to Win-Win.* Conflict between union and management over costs and benefits may be resolved by working out arrangements to increase the returns both to management and to employees. Management can invite joint decision making and profit sharing and support the importance of seniority, security, and pension benefits. The union can support the redesign of jobs, the introduction of cost-reduction techniques, and the retraining of employees. The management and the unions can collaborate on safety programs. Win-lose bargaining is converted into win-win problem solving. At the level of the individual union and management representative, Rosen, Greenhalgh, and Anderson (undated) pointed out that studies have found that union stewards may spend an average of 11 hours per week on socioemotional leadership functions, as do their counterparts in management in dealing with the absenteeism, insecurities, and grievances of employees.

Druckman (1994) conducted a meta-analysis of 82 experimental studies of negotiating to reach compromises and the time required in 28 of them to reach a compromise. Compromises were more difficult to negotiate when: (1) the negotiators were representing constituents and did not expect to have any further interaction with the opponents in the future; (2) the negotiators prepared strategies in cohesive groups beforehand; (3) bureaucratic superiors introduced competitive orientations and new strategies; (4) negotiations took place with an audience and under face-saving pressures; (5) long-held social attitudes and contrasting ideologies were involved; (6) a tough exploitative opponent was faced.

*Institutionalizing Collaboration.* A mature, collaborative approach substitutes a mutually acceptable culture and a common philosophy for minutely detailed agreements that cover all possible contingencies. Fixed periodic negotiations are replaced by joint study groups and more open discussions. A reward system is determined, but the levels of reward are not (Lawler & Mohrman, 1987). According to Long's (1988) survey of two Canadian firms, managers were most likely to favor such a collaborative approach if they were dissatisfied with the behavioral and attitudinal conditions in the firm and if they thought that increasing the workers' influence on policy decisions would improve these conditions. In 1987, General Motors and the United Auto Workers agreed to establish continuous joint methods for addressing specific issues at each plant. The objective was to design solutions that would improve the efficiency of each plant and the quality of its products. Johnson (1988) thought that such continuous joint processes worked well if the local manager was adept at mobilizing the skills and energies of the workers and providing them with sound direction. Continuous joint process emphasizes mutual listening and the sharing of information and ideas. But managers need to have more than just labor's interests in mind; they are also custodians of the interests of the shareholders and various other constituencies of the corporation, and they are concerned with its need to remain competitive in the international marketplace.

*Promoting Congruence of the Formal and Informal Organization.* A leader can avoid or reduce conflict by fostering congruence of status, esteem, and competence within the group and its activities, and congruence between the informal and the formal organization. For example, formal-informal incongruencies were seen within technical units of the U.S. Air Force. On the one hand, the formal and informal organizations agreed that cooperation and pride in the formal organization were desirable and that the most competent personnel were most valuable. On the other hand, the formal and informal organizations had conflicting attitudes about punishment for laxity and the need for high standards of performance (Anonymous, 1945–1946). Leadership increased the congruence in attitudes. According to Whyte and Gardner (1945), leaders of the formal organization foster such congruence by becoming aware of the informal organization, discovering the informal leader, and obtaining his or her cooperation and agreement to work toward common goals. Formal leaders use the informal organization constructively to convey attitudes, to locate grievances, and to maintain social stability (K. Davis, 1951). They identify the differences and values that buttress the informal organization relative to the formal organization.

## Legitimatization and Conflict

---

“Legitimatization” of a role refers to others’ perception of an individual’s right to function in a given position. An individual’s appointment to a given position legitimates his or her status and performance of the role, at least for those who do the appointing. Likewise, in democracies, election to an office legitimates the role of the office-holders in the eyes of those who voted for them as well as in the eyes of most others. In traditional societies, legitimacy can be provided by inherited status and rank as well as election or appointment. For instance, Vengroff (1974) noted that it made no difference in community participation in the development of 31 villages in Botswana whether the leaders were elected councilors or were traditional tribal chiefs. But

conflict would arise when what was regarded as legitimate for one member in one situation was viewed as illegitimate for others in the same situation or different situations. Although legitimacy might be lost if an individual fails to perform as expected, the legitimacy of an appointment has to be sharply separated from competence or perceived competence to perform the role. C. B. Smith's (1984) experiment showed that the presence or absence of competence in appointed supervisors did not affect the legitimacy of their authority or the conformity of subordinates to organizational directives.

### ***The Meaning Attached to Legitimacy***

Legitimacy is affected by the culture in which an appointment is embedded. It is not just a matter of agreeing on a list of uniformly interpretable regulations about appropriate behavior in the organization. Indeed, it is a fundamental source of conflict in that what is legitimate depends on both written and unwritten rules whose creation and interpretation are a developing process of shared meanings. In analyzing the relationship between the CEO and vice presidents of a Bell Telephone operating company, Feldman (1986) noted that the meaning attached to the positions held by the executives was often overlooked. The meaning is provided by the cultural system of the bureaucracy. In turn, it restricts the courses of action that are open to position holders. Neilsen and Rao (1987) agreed that the meaning of legitimacy that emerges about a position is a dynamic process, which develops as new ideas and understandings are accepted within the organization. The meaning is enhanced when it is given more credence from demonstrations of trustworthiness as hidden agendas surface. Additionally, the language that reinforces the legitimacy of a leader's actions is multilayered. At the institutional level, shared meanings evolve from history and habit. For instance, many business leaders may be legitimately consumer-oriented rather than technology-oriented because their business has been driven by customers' loyalty and interests. At another level, such meanings may be supported by stories and myths. A customer-oriented engineer may convince a new client about the product with a humorous demonstration. At a third level, theories are articulated that legitimately guide action. Changing market conditions add more response to clients' needs. Finally, "symbolic universes of meaning" buttress legitimacy. Modern professional management is more market-oriented than traditional management was.

### ***Legitimatization and Conflict in Different Settings***

As was already noted, discrepancies between what others expect and one's own expectations will be a source of role conflict. A group's failure to achieve consensus in its expectations about requirements likewise causes conflict. Conversely, agreement about role requirements and conformity to normative expectations about what is legitimate action for the role generally contribute to effectiveness in organizational life.

Many research analysts point to similarities and differences in opinions about what constitutes departures from legitimacy and the effects of such departures in political, educational, military, and industrial settings. For example, Schein and Ott (1962) studied the attitudes of managers, union leaders, and college students toward the legitimacy of influencing various kinds of behavior. The three groups and a sample of U.S. Air Force personnel (F. J. Davis, 1954) agreed about the legitimacy of influencing job-related behaviors. The groups considered it legitimate for a supervisor to try to influence the job performance and work environment of employees. However, they differed about the legitimacy of a supervisor's trying to influence behavior that was not job-related.

*Public and Community Settings.* Substantive conflicts over the legitimatization of the leader's rights can best be cataloged in the context of their social settings. Numerous examples have been reported of a loss or lack of legitimacy due to incongruities, discordant expectations, and within-role and between-role conflict.

These incongruities resulted in dissatisfaction and ineffectiveness. Homemakers are faced with the same pressures to deal with new technologies and ambiguous standards of quality as professionals and managers are. However, because homemakers are not accorded the social legitimacy that professionals and managers receive, they experience an unusual conflict (Chafetz & Dworkin, 1984). For instance, homemakers are likely to see themselves as lacking the power and resources to confront a manufacturer of a shoddy product. Conflict may be sharper in public bureaucracies because of their legal obligations to respond to clients who can exert pressure on them. Conflict within public bureaucracies is exacerbated when the external political climate restricts objective goal setting and evenhanded decision making (J. M. Burns, 1978). Those who are at the outer boundaries of a bureaucracy are much more likely to face such politically based conflict than those who are deep inside the organization (Katz & Kahn, 1966).

Each of several resettlement communities in Israel that Eisenstadt (1954) studied had developed specific norms. At the same time, the communities had also incorporated the norms of the surrounding culture. The norms prescribed proper behavior for given roles and role situations. To some extent, reference group norms served as general standards by which various patterns of behavior were evaluated. Because of their wider range of reference groups, the leaders served as a medium for consolidating the subgroups and integrating them into an effective larger group.

*Business and Industry.* In a study of managers' attitudes, Schein and Lippitt (1966) found that managers whose roles involved close supervision and centralization of responsibility regarded it as legitimate to influence subordinates in more areas than did other managers. Contrary to the hypothesis, managers whose subordinates had more visible roles and interacted more frequently with outsiders did not exercise more influence than those whose subordinates had less visible roles.

Both superiors and subordinates expected communication, development, delegation, understanding, know-how, and teamwork from supervisors (Brooks, 1955). But for the supervisors, their own autonomy was more critical to them than their legitimacy. In a study of first-line supervisors, Klein and Maher (1970) found that the supervisors' lack of autonomy was related to role conflict, but neither the perceived legitimacy of autonomy nor the discrepancy between legitimate and actual autonomy was related to it. However, Ulrich, Booz, and Lawrence (1950) observed that superiors made legitimate but conflicting demands on managers.

Conflict was latent in Freeman and Taylor's (1950) survey of 100 top executives. These executives said they looked for aggressive, energetic applicants for management positions in the company, even though they personally wanted "tactful subordinates." The executives attributed their own success to "brains and character," but they preferred "emotionally controlled and balanced" rather than overly bright or highly ethical subordinates. Conflict was illustrated most clearly when the executives' self-perceptions were compared with those of 170 middle managers. Whereas the executives emphasized their self-determination, enterprise, and dignity, the middle managers emphasized their discreetness, modesty, practicality, patience, deliberateness, and planfulness. Whereas the top executives disavowed stinginess, shyness, and a lack of ambition, the middle managers avoided describing themselves as reckless, disorderly, aggressive, and outspoken (Porter & Ghiselli, 1957). However, Bass, Waldman, Avolio, et al. (1987) generally found positive correlations between what subordinates in New Zealand said they required in the leadership of their supervisors and what the supervisors, in turn, required of their bosses. This domino effect suggested that, in reality, there tend to be more positive than negative associations in what is legitimated for supervisory roles at each successive level in the organization, although some strong bosses may prefer to keep their subordinates weak in power and autonomy.

Wernimont (1971) found that workers tended to make contradictory demands on their supervisors. On the one hand, they expressed a desire for clear instructions and goals. On the other hand, they wanted considerable freedom to work in their own way. Similarly, Foa (1956) compared ideal and actual descriptions of the behavior of first-level supervisors and workers in Israeli factories. He found that the workers complained most

frequently about their supervisors' ineffective social relations but were more critical of their own conduct than of their supervisors' conduct. But the supervisors complained little about work behavior. The smaller the discrepancy between the workers' ideal for the supervisors and their descriptions of a supervisors' actual behavior, the better satisfied the workers were with the supervisor. When the workers identified with their supervisors, they attributed their own ideals to the supervisor.

There seems to be a fundamental difference in the ideals of managers' roles and how managers are actually required to enact the roles. Hortatory admonitions, managerial ideals, popular literature, and normative expectations all counsel the need for system and deliberation at every level. As McCall (1977) noted, the assumption is that managers are likely to be engaged in just a few events and will have enough time to ponder over how they should behave in response to these events. In reality, however, the demands on a typical manager make such deliberation impossible. For example, Guest (1956) found that supervisors were involved in 200 to 583 activities in a single day. S. Carlson (1951) reported that Swedish top executives were undisturbed for only an average of 23 minutes during a day. Mintzberg (1973) found that half the activities of the five top executives he observed lasted nine minutes or less and concluded that the executives' activities were fragmented, brief, and varied and that the executives had little control over them. Also, 93% of the executives' contacts were arranged ad hoc, and the executives initiated only 32% of them.<sup>4</sup>

*Educational Settings.* Generally, students are prepared to accept direction from instructors who are behaving legitimately. Torrance (1959) studied groups that were under different degrees of pressure from instructors to accept a new food. He found that group members expected instructors to exercise influence and that they did not perceive such influence as pressure. In Lee, Horwitz, and Goldman's (1954) experiment, each of three instructors of classes of ROTC cadets was given more authority or less authority to decide whether certain instructions should be repeated. Most students voted to repeat the instructions, but in each class, the instructor arbitrarily decided not to repeat the assignment. The instructor met the greatest resentment and hostility when the students believed he had little authority to make a decision. The rejection was even greater when the instructor acted as if he had a great deal of authority but did not have it. If the students believed the instructor had the authority, he could act in this manner and was less resented by the students for doing so.

M. V. Campbell (1958) reported that when teachers' needs and role behavior were close to the principal's expectations for them, the teachers tended to feel better satisfied, were more confident in the principal's leadership, and were rated by the principal as more effective. Seeman (1953, 1960) found among principals and teachers in 26 communities that although the teachers expected their principal to attend to matters within the school, the principal's success in improving the school situation depended on devoting time to public relations outside the school. When principal and teachers disagreed about the principal's role, the principal reported less indecision than the teachers, because the principal was required to take action more often than the teachers were.

Gross, Mason, and McEachern (1958) and Gross, McEachern, and Mason (1966) studied role conflict in school superintendents. They found that the superintendents differed in their perceptions of the legitimacy of the various expectations that others held for them. In particular, the superintendents differed about the severity of sanctions that might be applied if they did not comply with what they thought was expected of them. Those superintendents with a moralistic orientation tended to conform to what they regarded as legitimate expectations but rejected expectations they regarded as illegitimate, regardless of the sanctions that might be involved. Those with an expedient orientation tended to conform to the expectations that were attended by the strongest sanctions for noncompliance, or to compromise between what they actually would do and what they expected to do to minimize possible sanctions. A third type of superintendent gave equal weight to legitimacy and possible sanctions.

Gross, Mason, and McEachern (1958) also studied reference group identifications and consensus among superintendents and members of school boards. The superintendents were more strongly identified than the

school board members with external professional reference groups. In the division of responsibilities, both the superintendents and the members of the school boards assigned more tasks to themselves and expressed great approval for bypassing each other. Superintendents rated the school boards more highly and were better satisfied with them when there was consensus among the board members. In turn, the greater the consensus on the board, the higher was its rating of the superintendent.

*Military Settings.* Numerous military studies have examined the effects of role sanctions, legitimacy, and conflict. For instance, Greer (1954) reported finding that in six hours of simulated combat, only among the more effective of 26 infantry rifle squads did appointed leaders act more closely to what was desired and expected of them by the rest of the squad. Failure to live up to subordinates' expectations resulted in conflict and the squads' ineffectiveness.

Stouffer, Suchman, DeVinney, et al. (1949) found that U.S. officers and enlisted personnel disagreed markedly during World War II on whether officers should maintain social distance from enlisted personnel. Although 82% of the enlisted personnel agreed that "an officer will have the respect of his men if he pals around with them off duty," only 27% of the captains, 39% of the first lieutenants, and 54% of the second lieutenants agreed. Similarly, E. L. Scott (1956) found that enlisted personnel on small ships perceived the organization's status structure more accurately when superiors interacted less extensively throughout the organization, retained authority, and delegated less freely. Merton and Kitt (1950) discovered that enlisted personnel who expressed attitudes in conformity with the norms of the U.S. Army were promoted more rapidly. If the enlisted personnel accepted the status structure of the army as legitimate, they were more readily identified with others at their own level or those of the next highest status level.

The effects of more legitimacy or less legitimacy were examined by Levy (1954), who contrasted aircrews led in periodic discussions by their own commanders with air-crews whose discussions were led by clinical psychologists. Members of the groups led by their commanders had more favorable attitudes toward their groups and a greater sense of well-being than members of groups led by the clinical psychologists.

In the military, the most extreme conflicts between subordinates and higher authority are likely to arise when acts of collective insubordination occur, despite fears of reprisal. In the Israeli defense forces, these acts seem to be due to unresolved grievances about impersonal conditions, such as slow demobilization, poor food, unacceptable discipline, or unfair discrimination, rather than individual resentment (Gal, 1985). Personal conflict over goals and commitments (Rose, 1982), such as occurred among American servicemen in Vietnam and Israeli soldiers in Lebanon in 1982, produced withdrawal or protest rather than group revolt. Gal (1985) saw a need for legitimacy in military decision making to deal with such personal conflicts. Decisions must serve proper goals, must be made through appropriate processes, and must be in accord with a common value system with which the individual soldier identifies.

### ***Conditions Affecting Legitimacy and Conflict***

Various conditions can be enumerated that enhance or reduce legitimacy and, therefore, affect the amount of conflict and inefficiency that occurs. For instance, legitimacy depends on clear, accepted group norms. B. R. Clark (1956) found that high-status members of a group could not be fully legitimate if the group norms were not clearly defined and were not well accepted by the members. Legitimate power can enhance the positive impact of a leader's effectiveness. Knapp and Knapp (1966) studied elected officers and nonofficers who served as group leaders in a verbal conditioning experiment. Groups led by officers had a higher rate of response and conditioned more readily than groups led by nonofficers. Official status of the leaders facilitated the groups' learning. The importance of legitimate power was illustrated in a Dutch experiment by Mulder, Van Dijk, Stirwagen, et al. (1966). The power distance between leaders and followers was varied by permitting leaders to

distribute rewards of different amounts. The legitimate leader was elected by the group. The illegitimate leader (a confederate of the experimenter) forced his way into the experimental control booth and took over the leadership function. Under conditions of great power distance, the followers resisted the illegitimate leader more than they did the legitimate leader. P. B. Read (1974) demonstrated how conflict arose among jurors in mock trials if their differences of opinion were legitimate. Paradoxically, organizations with excessive levels of hierarchy and excessive dependence on the differentiation of power are hotbeds of politics and conflict (Culbert & McDonough, 1985). For communications to move through the excessive layers requires an illegitimate bypassing of channels. For timely decisions to be made, illegitimate actions may be needed. For work to get done, the pursuit of creative ad hoc alternatives may be required, rather than conformity to the rules.

*Election versus Appointment.* Experimentation offers an opportunity to compare the legitimization of the leadership role by election and by appointment. When N. A. Rosen (1969), in an industrial field experiment, used the preference of work group employees to reassign those who became their supervisors, all seven groups showed initial increases in productivity. Similarly, Ben-Yoav, Hollander, and Carnevale (1983) gave a decision-making task to 21 groups of four college students each and compared leaders who were appointed or elected. Elected leaders were considered more responsive to the followers' needs, more interested in the group task, and more competent than those who were appointed. Dellva, McElroy, and Schrader (1987) compared 64 formally appointed leaders with leaders who emerged in student groups at the U.S. Army Command and General Staff College. Over time, the formally appointed leaders tended to lose influence, whereas the emergent leaders gained influence. Raven and French (1957) instructed experimental groups to elect one of their members as supervisor and subsequently replaced the supervisors of half the groups with appointed leaders. These researchers found that in contrast to the appointed leaders, the elected leaders became more personally attractive to the other members and their suggestions were more likely to be accepted by the groups. In the same vein, Hollander and Julian (1970) found that members of problem-solving groups were more willing to accept a selfish action by an elected leader than the same action by an appointed leader. In another experiment by Hollander and Julian (1970), team members ranked the relative importance of several items, and the leaders could accept each ranking or reverse it. Elected leaders deviated from their groups more than appointed leaders. Both types of leaders deviated more if they had strong rather than weak support from group members. The authors concluded that more is expected of elected than appointed leaders. Elected leaders are given greater latitude to deviate and act on behalf of the group's goals; but to profit from this advantage, they must be aware of it.

When spokespersons for a group were elected rather than appointed, their legitimacy was greater, but they were more likely than appointed spokespersons to be rejected if they were seen as incompetent or as unable to produce results. Nonetheless, the appointed spokespersons also had to be competent or successful in order to satisfy the group members (Julian, Hollander, & Regula, 1969). According to Hollander (1978), election created greater demands by group members for their spokesperson's performance. The elected spokespersons showed greater firmness than the appointed spokespersons, who were as firm only if they could consult their members (Hollander, Fallon, & Edwards, 1977). Elected spokespersons also felt freer to yield (Boyd, 1972) and to accept or reject the decisions of the group they were representing (Hollander & Julian, 1970). This is consistent with the finding that elected leaders evaluated their followers more highly than appointed leaders did (Elgie, Hollander, & Rice, 1988). But appointed leaders, when representing their own groups, could achieve agreement with each other about the solutions to problems more easily and with less conflict than elected leaders in the same circumstances (Manheim, 1960).

*The Struggle for Status and Legitimacy.* When all members of a community, a work unit, or an experimental setting are initially equal in status (the value of their initial positions in their groups), a struggle for status will result. In an informal discussion, no one initially has the "right to lead." Gaining the right to lead and obtaining the status of leader will depend on individual initiative, assertiveness, competence, and

esteem. To the degree that individuals strive for status, a struggle for status is likely to occur unless a leader has been elected or appointed in advance. Many factors will affect this struggle, including each contestant's self-esteem and credibility. Furthermore, leaders seem more concerned than followers about maintaining their status. Gallo and McClintock (1962) studied leaders and nonleaders in sessions where three accomplices were present. The accomplices supported the participants in the first session but withdrew their support in the second session. The researchers found that leaders initiated more task-oriented behaviors than followers, especially when their positions were threatened during the second session. The leaders also exhibited more hostility and antagonism when their status was threatened. Gartner and Iverson (1967) informed experimental groups that one member would be selected for a superior position in another group. This chance for upward mobility in status interfered with the task performance in well-established groups but reduced the members' morale rather than their productivity in newly formed groups.

The struggle for status is most likely among a group of strangers. But if the abilities and past performance records of members are made clear to all, and if their esteem is made more visible, the conflict about who will lead is reduced. Bradford and French (1948) emphasized that the productivity of group thinking depended on the ability of group members to clearly perceive each other's roles. Drucker (1946) observed that despite the informality of relations among executives in the different divisions of General Motors, the executives worked together with relatively little conflict. The absence of conflict was attributed to objective measures of the performance of the divisions that made the effectiveness of the executives visible to each other.

*Overestimated Self-Accorded Status.* The struggle for status is augmented by a general tendency of members of organizations and groups to overestimate their own status and power (Bass, 1960; Bass & Flint, 1958a). They believe that their positions are more important than others do. In this situation, role conflict is inevitable. People at a designated organizational level think that all those below them have "smaller" jobs than the job holders themselves think they have; and all those above the person at the designated level perceive that the occupants' jobs are "smaller" than the occupants perceive these jobs to be (Haas, Porat, & Vaughan, 1969). This bias is quite general. J. D. Campbell (1952) found that 250 residents of Boston tended to rate the value of their own jobs higher than they rated jobs similar to their own. Conflict results when people who interact or work together overestimate the importance of their own positions and underestimate the importance of others with whom they interact. For example, a janitor of an apartment house may adopt "professional standards" and accord himself more status than his tenants grant that he has (Gold, 1951–1952). When supervisors accord themselves more status and authority than their unionized subordinates grant them, their attempts to lead their subordinates will be rebuffed (Wray, 1949).

Bass and Flint (1958a) showed with 51 groups of ROTC cadets that although members with greater power attempted more leadership and were seen by others as having exhibited more success, they actually were no more successful. Moreover, high-control<sup>5</sup> members significantly overestimated their esteem compared with low-control members. The control and power differences that were arbitrarily assigned to some of these participants were likely to have aroused hostility and resentment among those without control. Although low-control members perceived themselves as submitting to the powerful members, a greater proportion of them actually rejected the attempts to lead by the arbitrarily more powerful members.

*Self-Authorization.* Morrison and Phelps (1999) surveyed 275 white-collar employees to ascertain what made some of them authorize themselves to take charge despite a lack of status that made their efforts questionable. Factor and regression analyses established that three factors contributed most to such self-authorizing behavior: (1) felt responsibility, (2) self-efficacy, and (3) top management's openness. These factors explained 27% of the variance in self-authorization.

*Credibility.* Legitimation involves gaining credibility for being trustworthy and informative. Klauss and Bass (1982) found strong positive correlations in social service agencies, military organizations, and industrial firms between subordinates' ratings of managers' credibility and the managers' success as leaders. One

establishes one's trustworthiness by gaining "membership character," by being seen as loyal to the group, by conforming to the prevailing norms, and by establishing that one is motivated to belong to and identify with the group (Hollander, 1958).

*Stability of Legitimacy and Leadership.* The stability of legitimate power and the tendency of leaders to hold on to their offices are fostered by at least five factors: (1) the validators, (2) continuing redefinitions, (3) acquisition of relevant information, (4) controlling the resources that are needed for change and thwarting the restructuring of the situation, (5) maintaining favorable conditions. In regard to the first factor, *validation*, Hollander (1978) pointed out that leaders have validators of their positions who can support the leader's legitimacy or withdraw support. The validators uphold the leader's right to office even when a leader's performance may be inadequate. Unable to admit their errors, because they have an investment in and a sense of responsibility for the leader, they continue to support a failing leader (Hollander, Fallon, & Edwards, 1977). The second factor, *redefinition*, was demonstrated by A. R. Cohen (1958). Cohen found that leaders who are threatened with losing their status can redefine their groups' boundaries to isolate themselves from the very members whose support they need. High-status members, faced with the loss of status, communicated less with low-status members than did high-status members who were not facing a loss of status. The third factor, *acquisition of knowledge*, is illustrated by an incumbent political leader who amasses knowledge of rules and regulations; develops the required organizational constituents, contacts, and contracts; acquires the trappings of power; and is more visible than rival candidates for the office. The fourth factor, *control of change*, involves high-status members blocking the restructuring of a situation if a new structure would cause them to lose their status (Burnstein & Zajonc, 1965b). Those with high status control the machinery for change. In authoritarian states, dictators coerce the opposition; in democratic states, elected officials use their legitimate power to reject electoral reforms in financing, redistricting, limited terms of office, and so on that would threaten their reelection. Party officials in the former Soviet Union were most reluctant to relinquish their power, privileges, and perquisites. Over 99% of members in the U.S. House of Representatives sought reelection and were reelected to office in 1988 (Rosenbaum, 1988). *Maintaining conditions* favorable to the leader is the fifth factor. Katz, Blau, Brown, and Strodbeck (1957) studied four-member groups who first engaged in a discussion about possible tasks. The members then chose a task for the next session, in which half of all the groups performed the chosen task and the other half were required to complete tasks imposed on them. The chance that a member would remain a leader from the first discussion to the completion of the chosen or imposed task depended on whether the task was chosen by the group or imposed by the experimenter. If the group's choice of task was guided by the leader, the imposition of a different task threatened his leadership. However, his position was strengthened if he did not enforce the imposed task that the group rejected. In addition, the more the leader stirred up controversy about the choice of tasks during the first discussion, the less likely he was to remain a leader during the task-completion phase. If the leader experienced little initial opposition to his choice of task and his choice was supported by the group, he was more likely to retain his leadership than if a different task was arbitrarily imposed on the group by the experimenter.

*Changes in the Behavior of Leaders.* Only after the struggle for status has ended and a stable hierarchy has been organized can those who achieved the high status reduce their level of activity (Heinicke & Bales, 1953; Whyte, 1953). Once a person is fully recognized by the other members as the leader and has won the struggle for status, he or she needs to attempt less leadership in order to exhibit the same amount of successful leadership. Thus, Bass, Gaier, and Flint (1956) found that when all members of a group of ROTC cadets had equal control over each other, any member had to attempt more than the average amount of leadership to exhibit more than the average amount of observable leadership. But when the members of a group differed initially in their control over each other, the successful leader did not require as many attempts to lead.

*Usurpation.* When the legitimate leader continues to be inadequate in meeting the needs of the group, the

role may be usurped. However, the usurper may not do as well in the leadership role as the legitimate leader. According to Crockett (1955), who studied conference leadership, emergent leaders tended to take control when the designated chairperson failed to set enough goals, seek enough information, and propose enough problems and solutions. Usurpation also occurred when cliques with divergent goals were present. Similarly, Lowin and Craig (1968) found that members initiated more structure in work groups when their superiors were incompetent. Katz, Maccoby, Gurin, et al. (1951) found the same usurpation of leadership in groups of men who were engaged in railroad maintenance work. Heyns (1948) observed that if the appointed leader of a group fails to perform his or her duties satisfactorily, the attempts by other group members to assume leadership are more readily accepted than they would be if the leader were adequate. P. J. Burke (1966a, 1966b) noted that disruptive behavior in experimental groups was significantly related to the leader's failure to establish an authority structure. Stogdill (1965a) found that in metal shops in which the work was precise and a piece could be ruined by interference and horseplay, the workers applied pressure on deviant group members when the supervisor failed to provide structure. In textile mills, women operators of high-speed sewing machines who were paid on an output basis applied pressure on deviant members if their supervisors were inexperienced or failed to keep order. Many other investigators have concluded that members initiate needed actions in a group if the leader fails to do so.<sup>6</sup>

*Replacement of Leaders.* In addition to the democratically required replacement of term-limited heads of state, governmental, ministerial, and agency leaders are deposed as a consequence of their failure to serve their constituencies, or they are replaced when their validators or higher authorities lose confidence in their competence (Hollander, 1978). Also, they may fall out of favor politically. In business and industry, for the years 1988 to 1992, Ward, Bishop, and Sonnenfeld (1999) compared voluntary exits by the CEOs of 1,000 corporations with exits forced by the boards of directors because of poor performance, personal mismanagement, illegal improper behavior, strategic disagreement, personality clashes, takeovers, and single issues such as the failure of a pet project. The replacement process was costly to the initiators of the replacement and to those deposed. The boards that forced out a CEO underwent much more involuntary change themselves afterward than after a CEO voluntarily retired or exited amicably.

*Personality Differences in Reactions to Conflict.* People vary in their willingness to subject themselves to conflict and to serve in marginal roles. Those who are higher in task orientation and lower in interpersonal orientation, as measured by the Orientation Inventory (Bass, 1963), have shown that they are more ready to engage in conflict in small-group discussions (Bass, 1967c) and are more likely to accept marginal roles. Marginal roles exist between groups with conflicting norms, values, and goals (Stonequist, 1937). Individuals who prefer such marginal roles have lower social needs (Ziller, 1973), are less extroverted (Wonder & Cotton, 1980), and reveal a higher task orientation and a lower interpersonal orientation (Cotton & Cotton, 1982).

Other personality differences make some leaders more prone than others to generate conflict with their subordinates, with consequential losses in effectiveness. Tjosvold, Andrews, and Jones (1983) asked 310 medical technicians to describe the cooperative, competitive, and individualistic orientations of their immediate superiors. The technicians' satisfaction, desire to perform well, and willingness to remain in their jobs were reduced substantially if they reported that their leaders were competitive and individualistic rather than cooperative. Kohn (1986) came to similar conclusions after a review of other survey and experimental investigations. Even among business leaders, there seems to be more interpersonal payoff from a cooperative than from a competitive outlook.

These personality differences in competitiveness and cooperativeness manifest themselves in feelings about conflict and reactions to it. They can be understood through a model created by Blake and Mouton (1964) and Thomas (1976). As [Figure 13.1](#) shows, individuals differ in their concern for themselves and for others as well as in their assertiveness. Self-concern and assertiveness give rise to competitiveness; self-concern and a lack

of assertiveness produce avoidance and withdrawal; assertiveness and a concern for others yield collaboration; and a lack of assertiveness and a concern for others generate accommodation. Compromise is literally an in-between result. According to Blake and Mouton (1964), ideal leaders are both assertive and concerned about others. They deal with conflict by integrating conflicting ideas through collaborative problem solving.

Kabanoff (1985a) validated Blake and Mouton's model of conflict by asking 104 MBA students to describe their feelings, reactions, and preferred ways of dealing with various overt or covert conflicts described in scenarios. Four of the five ways of coping emerged as expected. The exception was a finding that accommodation was equally acceptable to the unassertive respondent whether he or she was self-concerned or concerned about others. A factor analysis by Rahim (1983) of the self-descriptions of a national sample of 1,219 executives on how they deal with conflict substantiated the a priori conceptualization of the five independent styles of coping with conflict. A factor analysis by Kipnis, Castell, Gergen, et al. (1976) resulted in a modified version of Blake and Mouton's model for how husbands and wives resolve their disagreements. Using the model, Rim (1981) found that the spouses' values affected how they resolved conflicts with each other. For example, they were more likely to be accommodating if both valued broadmindedness, independence, loving, and true friendship but not self-control. An empirical personality assessment by Kilmann and Thomas (1975) provided further indirect support for Blake and Mouton's model. For example, introverts avoided conflict, and extroverts collaborated. Terhune (1970) and Jones and Melcher (1982) found that those who had a high need for affiliation were more likely to accommodate than to compete. Chanin and Schneer (1984) reported more of a tendency to compromise or accommodate than to compete or collaborate among undergraduate seniors who were higher in feeling than in sensing, according to their scores on the Myers-Briggs Type Indicator.

## Constructive Conflict

Conflict and disagreement can be constructive, and when they are, they should be encouraged. Paraphrasing Caudron (1998, p. 48), "Instead of pulling out the weeds of conflict, leaders should nurture them. From the roots of conflict come the fruits of innovation." Heifitz (1994) suggested that leaders need to confront followers with quandaries needing examination, clarification, and solution. The movement toward team efforts has generated the possibility of constructive disagreement with old ways of doing things instead of conformity to whatever was thought to be wanted by management. Out of the conflict have come new and better ways of doing things (Burke, 1970). Constructive leadership can attempt to find the reasons for a conflict, clarify the differences in a team, and indicate how much they are valued. It can convert a win-lose conflict to a win-win solution, encourage positive changes in attitudes to improve communications among team members, and focus attention on mutual goals.

## Summary and Conclusions

---

Leaders face many conflicts. There are many sources of conflict that need the leaders' attention. Role ambiguity and lack of a clear definition of a task are conducive to less job satisfaction and to reluctance to initiate action. Location in an organization predisposes leaders to engage in some conflicts more than others. Incongruities, discrepancies, and imbalances between roles, status, esteem, and competencies give rise to many of these conflicts. Emotional conflicts are harder to resolve than rational conflicts. The leadership role is subject to a variety of conflicting expectations, which may result in an inability to fulfill these expectations and may diminish the effects of the leader's authority and responsibility in the formal organization. Conflicts arise within discordant roles, norms, and expectations. Within their roles, managers are faced with contradictory demands from superiors, peers, subordinates, and others. Multiple identifications by the managers are a way of coping with the resulting conflicts. Conflicts are also reduced or resolved by rational cause-effect analyses, by open discussion of the conflicts to convert negotiations into problem solving, or by more devious means.

Middle managers and first-line supervisors experience more role ambiguity than top managers. Workers are better satisfied and more productive when their supervisors are able to predict the reactions of their superiors. The failure of a superior to support supervisors decreases the supervisors' self-esteem and also reduces their subordinates' esteem of them. Disagreement between supervisors and their superiors about the roles of the supervisors results in greater anxiety and disagreement between the supervisors and their subordinates. Conflict can be constructive, but an important function of leaders is to reduce or resolve destructive conflict.

Conflict has been observed in business, industry, education, the military, and the public sector when a leader's legitimacy is questioned. Legitimacy may be an outcome of a struggle for status or a matter of election or appointment. The basis of legitimacy will affect its acceptance by followers. Effective management and resolution of conflict can be brought about when authority, responsibility, and accountability are aligned.

# Authority, Responsibility, Accountability, and Leadership

In ancient Egypt, the *Instruction of Ptahhotep* (c. 2300 B.C.) declared, “To resist him that is put in authority is evil” (Lichtheim, 1973). Pericles, in Athens during the fifth century b.c., said that a spirit of reverence and respect for authority and the laws constrained public acts and inhibited wrongdoing (Thucydides, 404 b.c./1910). In the sixth century, Saint Benedict’s rule for the authority and responsibilities of the abbots, priors, deacons, and monks were essential to the survival of the monasteries he founded (Chittister, 1992). John Locke (1960), writing at the end of the seventeenth century, held that authority was needed to make a liberal society work and survive. He noted that for the creation, maintenance, and progress of a liberal society, authority that would be more than leadership had to be established (Weaver, 1991). Edmund Burke (1790/1967) believed that those appointed to exercise authority were assigned a holy function. Recognized authority gives rise to power, and power brings responsibility. Thus Friedrich Nietzsche (1888/ 1935) declared that responsibility increases toward the summit. Abraham Lincoln, in his second annual message to Congress, observed that those who have the power to save the Union also bore the responsibility to do so.

The legitimate power of individuals in groups, organizations, and societies derives from their authority and responsibility. Whether they are viziers, company presidents, military officers, school principals, or first-line supervisors, their responsibility should be commensurate with their authority so as to minimize their role conflict. Often, it is not. Variations in and mismatches of authority and responsibility have been reported for people who hold the same kinds of positions. Surveys by Bass and Valenzi (1974) discovered many managers who thought that they were delegated responsibility without the necessary authority to go along with it. Interviews with 32 college presidents by Birnbaum (1988a) disclosed that responsibility without authority made the presidents’ leadership role most difficult. The presidents coped by accepting the ambiguities of their situation, by incrementally pursuing limited objectives, and by practicing management by exception.

A study by Munson (1981) of social work supervisors and their subordinates revealed differences between preferred and actual authority and in the structure of relations that were relevant to supervisory practices and control. Aiken and Bacharach (1985) studied 44 local governmental administrative agencies in Belgium and found considerable discrepancy between subordinates’ self-reported authority to make decisions and the authority their superiors said these subordinates had. The discrepancy was increased if the local government was controlled by a coalition, the organization was open to outside influences, and the structure of control was fragmented.

The allocation of responsibility and authority to managers should reflect what is required to meet organizational objectives. However, responsibility and authority may, in fact, be allocated as rewards or punishments, as political symbols, or as political gestures to imply that improvements are occurring in the organization (Benze, 1985). The managers’ accountability implies their acceptance of the responsibilities of their leadership position, the expectation that they will be linked publicly to their words and actions, and the expectation that they may be called on to explain them (Wood & Winston, 2005).

## Authority

---

## ***Meaning of Authority***

Formally, authority is the legitimate right to exercise power. According to Freud (1939), the need for authority figures develops during childhood from the yearning for a father. Zander, Cohen, and Stotland (1957) observed that the felt possession and exercise of authority and the exercise of authority are highly correlated. Traditionally, legitimacy comes from norms dealing with society, organizations, and membership within them (House, 1991). It includes the right to command and to induce compliance as well as the ability to control subordinates and to make decisions by oneself (Katzenbach & Smith, 1992). Authority is a central feature of the structure of formal organizations. It prescribes “expectations that certain individuals should exert control and direction over others within defined areas of competence.” Authority is derived from implicit or explicit contracts concerning the individual’s position or knowledge. The potential conflicts arising from incongruities between authority and responsibilities and between authority and knowledge are the same as those for imbalances in status and competence. Loss of authority because of a restructuring of the organization will be reflected in feelings of deprivation (C. S. George, 1972).

Both traditional and behavioral definitions are phrased in terms of value judgments in support of two conflicting moralities or ideologies (Wells, 1963). Peabody (1962) found that executives in a city welfare agency emphasized legitimacy and position as the basis of authority, whereas policemen in the same city stressed knowledge and competence as the basis. In a later study, Peabody (1964) observed that supervisors in a police department, a welfare agency, and a public school thought of authority in terms of internal (superior-subordinate) relations, whereas the people supervised thought of it in terms of external (worker-client) relations. Supervisors in the police department unquestioningly accepted authoritative instructions that produced conflict more frequently than did those in the welfare agency or the school. The unacceptable use of authority was more common in the welfare agency than in the police department or the school.

## ***Scope of Authority***

Influenced by Barnard (1938), behaviorists maintained that leaders have authority only to the extent that followers are willing to accept their commands. Authority was defined operationally in terms of the areas in which members of an organization are to carry out their responsibilities (Petersen, Plowman, & Trickett, 1962). Authority in an organization specifies a member’s perceived area of freedom of action and interaction, along with the formally delegated or informally recognized right to initiate action. Members act in accordance with their perception of: (1) the degree of freedom that is allowed to them, and (2) the initiative that they feel they can safely exercise. Their perception may or may not coincide with the expectations of their supervisors, peers, or subordinates. Authority is also connected with the affirmation of certain values, as illustrated by the inaugural oath of the president of the United States to preserve, protect, and defend the Constitution (Paige, 1977).

In general, group leaders perceive themselves as having a higher degree of authority than do the leaders of subgroups; and leaders of subgroups, in turn, perceive their authority to be higher than the perceived authority of individual members of the subgroups who are responsible for performing individual tasks. Authority gives legitimate power, which depends on the norms and expectations held by a group that are appropriate to a given role—the accorded rights, duties, and privileges that go along with appointment or election to a position.

## ***Authority as Dependent on Superiors and Subordinates***

Authority depends on the relationship between leaders and followers. Leaders can restrict the authority of subordinates by withholding their rights to act and decide. They can increase their subordinates' authority by delegating to them the right to act. Followers can reduce the leader's authority by failing or refusing to accept the leader's decisions. They can increase their leader's authority by referring matters to the leader for decision. The authority of leaders and followers also depends on other sources of power. The authority of professionals, for instance, stems from a wide variety of sources, such as their exclusive information, their control of resources, and their assigned responsibilities (Filley & Grimes, 1967).

Conflict results if colleagues think that leaders have misperceived or exceeded the limits of their authority (Pondy, 1967). For example, U.S. workers would find it unacceptable if their supervisors gave them orders about where they should live. According to Haas, Porat, and Vaughan (1969), an almost universal source of conflict is the tendency of individuals at any designated level to see themselves as having more authority and responsibility than their superiors believe they have. Lennerlöf (1965a) also noted a tendency for supervisors to rate themselves as having more authority than their superiors reported delegating to them. George W. Bush has argued that as president during wartime he has the authority to ignore congressional statutes and the Constitution, as did Abraham Lincoln during the Civil War.

Legitimacy for actions may be accorded by higher officials, but it still depends on an acceptance by subordinates. Followers give a form of consent to legitimacy, which they can grant or withhold, sometimes at considerable cost (Hollander, 1978). According to Barnard (1938), this means that authority is delegated upward and is granted by one's subordinates. Furthermore, the perception that a superior has the right to give orders must be widely held and shared by other subordinates. Nor does one gain such support of one's authority from subordinates passively. Bendix (1974) thought that the compliance of subordinates with authority depends on the leader's active cultivation of the legitimacy of authority. Whitson (1980) suggested that there is a tense equilibrium between authority and the confidence followers have in the authority structure. Ironically, as confidence wanes, more formal authority and more coercion are applied, escalating the loss of confidence. Presumably, renewed confidence, accompanied by less coercion, is required before authority can be restored.

*Zones of Indifference and Acceptance.* Barnard expanded his argument about the extent to which authority derives from subordinates' acceptance of orders by noting conditions that increase or decrease such compliance. Orders will be complied with to the extent that they are understood, are consistent with the purpose of the organization, and are compatible with the personal interests of the subordinate. Also, orders will be followed to the extent that the subordinate is physically and mentally able to comply with them. Each subordinate has a "zone of indifference" within which orders are acceptable with no conscious questioning of authority. These zones of indifference are maintained by the interests of the group. In bureaucracies, they give the higher authority some latitude and autonomy in its dealings with organizational members (Downs, 1967).

A leader's authority, legitimated by his or her position, can bring about a wide or narrow zone of acceptance in subordinates by instilling in them the belief that the benefits of compliance will exceed the costs involved in remaining members in good standing in the organization. Using the Professional Zone of Acceptance Inventory (Hoy, Tarter, & Forsyth, 1978), Johnston (undated, b) surveyed 490 teachers in 55 elementary and secondary schools. In the 26 secondary schools, the teachers' zones of acceptance correlated .71 with their loyalty to the principals. However, the more authoritarian the principal, the lower was the teacher's zone of acceptance. The more the principal enforced the rules rationally and legitimately in the eyes of the teacher, the larger was the teacher's zone of acceptance. This finding was consistent with Gouldner's (1954) observation that according to the factory workers he interviewed, rational discipline was necessary for efficient functioning of the work process. Rational discipline maintained workers' loyalty to their supervisor. Workers thought that it required being lenient and "not too strict" (p. 46): "[When] there's work to be done they expect you to do it. ... Otherwise they leave you alone" (p. 47). However, with professionals, Johnston found that the zone of

acceptance was increased more by the extent to which the principals granted the teachers professional autonomy than by rational discipline and rule enforcement.

### ***Authority and Power***

Authority is not power. “No amount of legal authority over the grizzly bears of British Columbia would enable you to get yourself obeyed by them out in the woods” (National Research Council, 1943). In supervisor-subordinate relationships, coercive and reward power, as well as legitimate power, are expected in the supervisor’s position in addition to authority, but subordinates have learned to associate reward and punishment with the supervisory position and its symbols of status and authority. An analysis of authority and power requires an examination of attitudes and expectations about authority figures and symbols, as well as of the rules and regulations that describe what should be expected of holders of positions of authority (Bass, 1960).

Authority is power that is legitimized by tradition, law, agreements, religion, and the rights of succession; it is distinguished from force and coercion (J. M. Burns, 1978). In bureaucracies, superiors in the hierarchy have authority over subordinates. This provides formal organizational coordination of members’ behavior based on officially defined structure. In traditional societies, authority is the legitimate support for the father, the priest, and the noble. It comes from God, the will of heaven, or nature. In modern societies, formal authority derives from man-made constitutions, compacts, charters, legislation, judges’ rulings, and due process. The state has the authority to charter the board. The board has the authority to appoint the organization’s president. The president has the authority to hire a staff, and so on. Decisions can be reversed in the same way. Those who appoint the leaders to a given position usually have the authority to revoke functions previously assigned, to remove units of the organization from the leaders’ jurisdiction, and to dismiss leaders from office. Even when supported by their superiors, appointed leaders may find themselves frustrated and powerless if subordinates (like grizzly bears) refuse to obey their commands. In volunteer organizations, nongovernmental organizations (NGOs), and political protest groups, formerly powerful elected or appointed leaders may find that they no longer have influence after their followers and subordinates withdraw support or give it to opponents. Thus the concept of role legitimization calls attention to the fact that the power and influence of leaders are dependent on the acknowledgment of their authority by followers and, in some circumstances, by superiors or peers. Needless to say, the acceptance and exercise of authority will also depend on the interpretation by the individuals in authority of their rights, duties, obligations, privileges, and powers. Thus, for instance, “President Eisenhower simply did not believe that he should be leading crusades of a moral, humanitarian, or civil rights nature. He believed that his job was to operate exclusively within the governmental powers of his office” (Larson, 1968, p. 21).

### ***Centralized or Distributed Authority***

Some people argue that authority and the concomitant differentiation of power are essential for cooperative efforts in organizations; others advocate equalization, leveling, and power sharing. At one extreme, Carney (1982) saw authority as the organization’s universal panacea for keeping power in the hands of a few. The absence of such authority made improbable the spontaneous and comprehensive cooperation of the organization’s members to work together toward common goals. Authority provided managers with the right to control rewards and punishments; to maintain discipline, order, and security; and to avoid confusion and frustration. However, at the other extreme, Baker (1982) noted that when members of an organization are committed to equality in the distribution of power, as was seen in a radical feminist community, the

maintenance of an encrusted bureaucracy was prevented, and a shifting cadre of leaders could emerge, both informally and formally, to generate policy and cooperation. Authority could be shared.

School principals were seen as administering rules in three ways. In 31 secondary and 39 elementary schools, Johnston (undated) observed that when some principals enforced the rules with explanations and understanding, compliance by the staff was high. When some other principals enforced rules with discipline and punishment, the staff complied grudgingly. When still other principals did not enforce the rules, the teachers did not obey the rules. The principal's influence and the felt loyalty of the teachers to their principal correlated .39 and .51, respectively, when the principal used explanation and understanding to enforce the rules. The correlations when punishment was used to maintain the rules were .01 and  $-.03$ . The correlations with influence and loyalty were negative ( $-.31$  and  $-.20$ ) when the rules were neither enforced by the principal nor obeyed by the teachers. Venable (1983) corroborated the finding that the principals' exercise of nonpunitive legitimate authority (use of "rule-administration behavior") correlated with the teachers' loyalty to the principals.

### ***Strength and Ubiquity of Authority***

Authority is pervasive in its effects, often accounting for unquestioned influence. Thus in Milgram's (1965b) famous experiment, participants accepted without much consideration an experimenter's authority and delivered supposedly dangerous shocks to other student participants. Scheffler and Winslow (1950) found that people in low-status positions did not reject authority any more than did those in high-status positions. W. E. Scott's (1965) study of the attitudes of workers in a professional organization that allowed little autonomy on the job found that workers tended to accept the system of restrictive supervision. However, those who were professionally (externally) oriented were more critical of the authority structure than were those who identified themselves as internally oriented. Self-confidence about one's interpersonal relationships also appeared to make a difference in one's responsiveness to authority. Thus Berkowitz and Lundy (1957) observed that individuals strong in interpersonal confidence tended to be influenced more readily by authority figures than by peers, whereas the reverse was true for persons weak in interpersonal confidence.

Authority is not confined to the leadership structure. All members of an organization possess or believe they possess some degree of authority to perform their respective jobs. In a study of more than 1,700 individuals in formal organizations, Stogdill (1957a) found that only about 1 in 500 checked the statement, "I have no authority whatsoever." Unskilled mechanical workers rated themselves as having more than zero responsibility and authority.

*Motivational Effects on Acceptance of Authority.* Control over what others want establishes power over them (Bass, 1960). For leaders, such power, rather than empty formal authority, depends on the extent to which they can activate the needs and motives of their subordinates (J. M. Burns, 1978). The stronger the motivational base the leader can tap, the more authority, power, and control he or she can exercise. Thus Hollander and Bair (1954) reported that compared with members whose motivation was low, highly motivated members of a group identified more strongly with authority figures. According to the German field marshal Erwin Rommel, "The commander must try, above all, to establish personal and comradely contact with his men, but without giving away an inch of his authority" (as quoted in Mack & Konetzni, 1982, p. 3). Taylor (1983) suggested that leader-subordinate relationships in the U.S. Army were systematically undermined during the 1960s and the 1970s by the decrease in personal contact because of the introduction of information technology. More detached, self-centered subordinates and institutional policies also contributed. Lower-level commanders were given more responsibility but less authority. An effort to restore personal contact and authority at each level was initiated in 1979. In the same vein, H. I. Bowman (1964) revealed that

school principals who described their superiors as high in consideration on the Leader Behavior Description Questionnaire tended to rate themselves as high in responsibility and authority. In Shakespeare's plays *Richard III*, *Macbeth*, and *Coriolanus*, fear was used to maintain authority, and ultimately loyalty to the leaders was lost (Corrigan, 1999).

*Effects of the Scope of Authority.* Scope of authority depends on the influence needed to accomplish legitimate and recognized role requirements and organizational objectives (Barnard, 1952). Even though the scope may be expressed in writing, the boundaries may be blurred, and conflicts in understanding and actions may result (Reitz, 1977). Bachand (1981) contrasted Canadian crown corporations headed by government-appointed boards of directors with Canadian private-sector corporations headed by boards of directors who were elected by stockholders. The boards differed in their scope of authority, which affected their actions and those of the executives who reported to them. The members of the crown boards of directors, compared with those of the boards of directors of private corporations, believed they had the authority to do more than just give advice and counsel. The members of the crown boards faced more potential for direct conflict between political and economic objectives and had to be more active than members of the private-sector boards. As appointees of the government, the members of the crown boards of directors believed themselves to be more independent than did the members of the private-sector boards. In turn, the chief executives of the crown corporations sought their support for specific policies and decisions more often than the chief executives of private-sector corporations sought the support of their boards.

D. E. Tannenbaum (1959) observed that boards of directors in five agencies enlarged or restricted the chief executives' role by their willingness or refusal to delegate authority to the executives to act and decide. S. Epstein (1956) studied the effects of this enlargement or restriction on supervisors in experimental groups who were given different degrees of freedom of action. Severe restriction induced the supervisors to restrict the behavior of their subordinates, to supervise them more closely, and to supervise in a management-oriented manner. The absence of such restrictions induced the supervisors to give their subordinates more freedom and to supervise them less closely.

Dalton, Barnes, and Zaleznik (1968) studied the effects of changes in the authority structure of some departments of a research organization when other departments were left unchanged. In those departments where authority was transferred from department heads to scientists and engineers, the scientists and engineers favored the change, but the department heads did not. In the unchanged departments, expectations were heightened by the shifts in authority in the changed departments. Subordinates in the unchanged departments became dissatisfied with their superiors, and there was a greater tendency of those whose authority remained unchanged to seek positions elsewhere.

*Parallel Authority Structures.* Throughout the former Soviet Union, the scope of authority of the formal organizational leadership was limited by a parallel Communist Party structure. The dualism was seen in the parallel state and party organizational structures, factory management and party representatives, military commanders and political commissars. The recognition of the costliness of this dualism resulted in its elimination in the military (Mack & Konetzni, 1982) and industry (Gorbachev, 1988). Heifetz (1994) clarified the role of authority relative to leadership by considering the physician-patient relationship. In a type 1 situation, when faced with a purely definable technical problem with a clear solution about which the physician is expert and the patient lacks any knowledge, the physician should use his or her authority to recommend the appropriate course of action. In a type 2 situation, the problem is definable but the solution is not clear. Here, adaptive work is needed. The physician and patient need to pursue the solution together. In a type 3 situation, the problem is not clearly definable and there are no recognizable technical solutions. Again, adaptive work must be done in which leadership is required to promote learning to understand the problem and create solutions.

## ***Discretionary and Nondiscretionary Leadership***

Traditionally, leadership was fully determined by authority (Barker, 1994). But Hunt, Osborn, and Schuler (1978) conceptualized leadership as consisting of a discretionary and a nondiscretionary component. According to this concept, discretionary leadership is under the control of the leader, and nondiscretionary leadership is invoked by the organizational setting in which the leader operates. With civilian control and with concern about avoiding incidents that might provoke war, U.S. military officers, in particular, are limited in their discretionary activities. Although they are fully accountable and responsible for the actions of their subordinates, they are held on a tight leash by the higher command (Mack & Konetzni, 1982). Interviews with 32 college presidents revealed that their discretionary opportunities to lead are increasingly being constrained by governmental intervention, demographic trends, fiscal constraints, unrealistic public expectations, divergent interest groups on campus, and confusing patterns of authority. Beyond the presidents' nondiscretionary responsibility to balance their budgets, they still have discretion in how much they try to locate new sources of support (Birnbaum, 1988b).

One way of measuring discretionary and nondiscretionary leadership is to use subordinates' responses to the Leader Behavior Description Questionnaire (LBDQ), asking them on selected items if their supervisor "can and does," "could but doesn't," "can't and doesn't," or "can't but tries anyway" (Martin & Hunt, 1981). Van de Ven and Ferry (1980) asked supervisors and employees to judge the amount of authority they had in making decisions in four areas of their jobs: (1) determining what tasks the employee will do; (2) setting quotas; (3) establishing rules and procedures; (4) determining how exceptions to the usual work were to be handled. In a large engineering division of a public utility, Hunt, Osborn, and Schuler (1978) derived a leader's nondiscretionary score from the results of a leadership survey. Nondiscretionary leadership was that portion of the original score predicted by organizational practices. The discretionary score was equal to the difference between predicted and original scores. [Table 14.1](#) shows the relative extent to which each of four original behaviors by leaders toward subordinates (approval, consideration, disapproval, and ego deflation) were accounted for as discretionary and nondiscretionary. It can be seen that in the public utility, the rewarding leadership behavior of managers had more of a nondiscretionary component than did disapproval or ego deflation.

Table 14.1 Percentage of Variance That Accounts for the Discretionary and Nondiscretionary Leadership Components of a Manager's Behavior

	<i>Manager's Leader Behavior</i>			
	<i>Approval</i>	<i>Consideration</i>	<i>Disapproval</i>	<i>Ego Deflation</i>
Discretionary	77	77	90	81
Nondiscretionary	20	22	9	1
Error	3	1	1	18

SOURCE: Adapted from Hunt, Osborn, and Schuler (1978).

Effective leaders in order to clarify what is required of their subordinates use discretionary leadership (Gast, 1984), but the subordinates may also display discretionary leadership behavior. Goodacre (1953) studied the performance of good and poor combat units on simulated problems. There was a greater tendency in good units than in poorly performing units for the men without authority to take the initiative in giving orders during the problem and to be better satisfied with their leaders' management of the problem. Hambrick and Abrahamson (1995) obtained academics' and security analysts' ratings of managerial discretion in selected industries. Discretion was rated highest in R & D-intensive industries such as computers, motion picture production, and scientific instruments; discretion was rated lowest in steel mills, petroleum and natural gas

production, and gold and silver mining.

## ***Changing Patterns of Authority***

Heller (1985, p. 488) summed up the decline in authority in Britain and elsewhere during the past several decades, at the macro level and the microlevel, as the basis of relationships between the subordinate and the superior: "The loss of authority is ... evidenced by a decline in public confidence in institutions and institutional leaders, a loss of loyalty and commitment of organizational members, and a trend toward identification with multiple organizations. ... The loss is [also] evidenced in a decline in willingness to be bossed as well as a loss of desire to be the boss, and in a trend toward rating oneself as 'better than' the boss on desirable traits." However, Heller noted that the loss of authority, brings on a challenge for new bases for inducing compliance. One possibility is a return to strong, personal, charismatic leaders. Other alternatives include industrial democracy, power sharing, participative management, and the development of commitment to common goals. The social network may be another substitute for authority. Personal initiative may also substitute for authority. One night, when the outpost of guards responsible for patrolling for North Korean submarine infiltrators refused to take action because an incident was outside their area, a Korean taxi driver took it on himself to arouse a sleeping South Korean army garrison and lead the soldiers to a group of suspicious men he had noticed. They turned out to be North Korean infiltrators from an offshore submarine (Kristoff, 1996).

In addition to cultural changes that have diminished authority as a basis for successful leadership, Zaleznik (1980) presented a number of cases of executives whose neuroses got in the way of their obtaining compliance from subordinates. Sometimes, for example, the superior isolated himself, became tyrannical, and caused a palace revolution against his authority. In other cases, executives could not exert their authority because of their obsessive fear of hurting their subordinates. Generally, managers are becoming less dependent on their authority for their leadership and influence. Peter Drucker sees a marked change from the command and control structure where rank provides authority. This was copied from the Prussian army in the 1870s by the emerging big businesses system. "We are now evolving toward structures in which rank means responsibility but not authority ... and in which your job is not to command but to persuade" (Cohen, 1996, p. 16). Boccialetti (1996) argued that a more reciprocal approach to authority is needed, particularly in times of change in internal and external organizational conditions. Those lower in the organizational hierarchy need to become more proactive in their relations with higher-ups, stay better informed about big issues, and accept more responsibility.

## **Responsibility**

---

### ***Meaning of Responsibility***

Organizational leaders are given *responsibility* to carry out an assignment and are held *accountable* for it. They are expected to carry out their responsibilities in conformance with the norms and rules of the organization. The leaders should have the *authority* (legitimate power, right, or permission) to do so. Authority in organizations is meant to be used to fulfill assigned responsibilities (Hollander, 1978). The responsibilities are the members' perceptions of expectations by the organization that they will perform on its behalf. Generally, leaders perceive their responsibilities to be broader and more far-reaching than other group

members perceive their own responsibilities. Leaders consider it their responsibility to make policies and to initiate action for themselves and for those members for whom they are responsible. The other members perceive themselves to be responsible for initiating action in specific subgroups or for executing individual assignments. In any event, neither leaders nor followers can learn to assume responsibilities until they are given them (Deci, 1972). Supervisors in naval organizations who are more conscious of their active leadership are perceived to be more responsible naval officers by their subordinates (Stogdill, Scott, & Jaynes, 1956). In Senge's (1990) learning organization, mind-sets are shifted so that members assume responsibility for actions connected to outcomes. Negative outcomes may result in rejection of responsibility. Thus failure of group decisions may result in a diffusion of individuals' sense of responsibility (Whyte, 1991). Sense of responsibility may be a matter of: (1) moral and legal standards of right and wrong, or legal and illegal; (2) obligation or sense of duty; and (3) concern for the consequences (Winter, 1991). Alternatively, having a sense of responsibility may be a matter of how one evaluates one's own character.

### ***Interdependence***

Like authority, responsibility also depends on leader-follower relations. The leader can reduce the responsibility of other group members by failing or refusing to relinquish duties that others could perform, by overly close supervision, and by requiring consultation before others can perform. Other group members can reduce the leader's responsibility by performing tasks that the leader would be expected to perform. They can increase the leader's responsibility by failing to carry out assigned and expected duties. Even when responsibilities are closely defined, the actions of their leaders tend to condition the perceived responsibilities of the subordinates, and the performance of the subordinates tends to condition the responsibilities of the leader. To be effective, anyone desiring influence in an organization needs to accept responsibility for knowing about values, strengths, performance, and communications with other members (Drucker, 1999).

### ***Relation of Responsibility to Effective Leadership***

H. H. Meyer (1959) found that supervisors and their bosses did not differ significantly on 77 items in their evaluations of the amount of the supervisors' responsibilities. However, more effective supervisors rated themselves significantly higher in responsibility than ineffective supervisors did. In a later study in 21 plants, Meyer (1970b) found that the most effective supervisors assumed that they had full responsibility when there was any ambiguity about who was in charge. Ziller (1959) studied group leaders' decision making regarding a difficult problem that risked the safety of their group. The leaders could base their actions on a throw of dice or by making a rational decision. Leaders who accepted responsibility for their group's action tended to be nonconformists. They possessed personal resources that enabled them to take risks without undue stress and strain.

## **Accountability**

---

### ***Meaning of Accountability***

Accountability of an organizational leader may be defined as: (1) acceptance of responsibility for one's own and associates' behavior and effects; (2) answerability—providing explanation and justification of actions,

commitments, decisions, and opinions; and (3) liability for them (Dubnick, 2003). In the governance of public and private institutions, accountability is a formal means of feedback and control common in bureaucracies (Gruber, 1987). Wood and Winston (2005) expanded the definition so that accountability implied: (4) willingness to accept the responsibility to serve the well-being of the organization; (5) the expectation that position holders would be linked to their actions or words; and (6) the expectation that they would be called on to explain their beliefs, decisions, commitments, and actions to their constituents.

Along with a leader's authority and responsibility must come accountability. The leader is held answerable for using authority legally and meeting responsibilities (Brooks, 1995). Leaders are more likely than others to be held accountable. A leader cannot evade the consequences of having more influence over others; more control over events; greater visibility and recognition; and greater responsibility for failures, misplaced efforts, or inaction in the face of an evident threat to the group's well-being (Hollander, 1978). Mack and Konetzni (1982, p. 5) noted: "In navies in general, and in the United States Navy in particular, strict accountability is an integral part of command. Not even the profession of medicine embraces the absolute relationship found at sea. A doctor may lose a patient under trying circumstances and continue to practice; but a naval officer seldom has the opportunity to hazard a second ship." More safeguards are imposed as a leader's reputation for trustworthiness declines (Hall, Blass, Ferris, et al., 2004).

In democracies, leaders need power to get things done. But accountability must go along with that power. Many others, such as bureaucrats, elected officials, educators, military leaders, land developers, marketers, and bankers, are granted powers that have important consequences to the public and need to be held accountable for their actions (Gardner, 2003). Formal accountability mechanisms are placed on leaders in the public and private sectors as safeguards against violations of the public trust. Fry, Scott, and Mitchell (1987) obtained survey results about accountability of deans, chairpersons, and faculty members at 369 business schools. Sources of information were the president, the dean, and two department heads. Faculty members were much more likely than deans to be evaluated formally and more frequently by multiple raters from below. Deans and department heads were more likely to be evaluated informally from above, and less frequently.

### ***Purposes of Accountability***

Accountability builds and sustains a climate of trust and credibility in leadership. The accountability of leaders to their group has important effects when they represent their group in negotiations (Lamm, 1973). Studies have found that being held accountable increases resolution of ethical issues (Brief, Dukerich, & Doran, 1991) and leads to more thoughtful decision processes (McAllister, Mitchell, & Beach, 1979). Also, making corporate boards, executives, and managers more accountable for their decisions and actions reduces illegal behavior, reduces lawsuits (T. M. Jones, 1986), and reduces the use of unapproved influence tactics (Baucus & Near, 1991). In a study of 210 respondents from a variety of occupations, Hall, Hochwarter, Ferris, et al. (2003) reported, as expected, that increases in accountability were correlated with increased "organizational citizenship." But an unexpected finding was that for respondents high in job efficacy (their ability to perform their jobs), political behavior increased with accountability, whereas for those low in job efficacy the ability decreased.

Demands for accountability have increased with increased reports about violated trust and scandals in the clergy, business, politics, and government. Accountability reminds leaders of their need to comply with prevailing norms (Wood & Winston, 2005). However, leaders may try to avoid accountability or displace blame by resorting to collective responsibility vested in a committee, a board, or shared authority.

### ***Sensed Accountability***

A leader's feelings of accountability depend on perceptions of the applicability and enforcement of external laws, rules, and regulations to which organizations add their own norms, standards, and constraints on actions and outcomes for which managers should feel accountable. Accountability will also be a matter of what we think others expect of us and how they will treat us for our actions (Tetlock, 1985). In the Fry, Scott, Mitchell study, accountability appeared to be greater with the use of multiple evaluators, frequency and formality of evaluation, and accessibility of results. We may feel accountable as individuals. Also, we may be socialized into feeling accountable if we and others in a group are interdependent (Roberts, 2001). Accenture and Williams (2000) surveyed 104 respondents from a midwestern marketing firm and found that they felt personally accountable for their own development to the degree that that: they could do their work well ( $r = .47$ ); they were high in need for achievement ( $r = .34$ ); they were in a supportive work situation ( $r = .25$ ); they had a supportive supervisor ( $r = .55$ ); they intended to engage and actually engaged in developmental behavior ( $r = .80$ ). Their time and resources for development mediated how much they participated.

*Time Span.* As a measure of responsibility, Jaques (1956) introduced the time span of responsibility—the length of time during which a manager or employee can be held accountable for decisions. Time span was found to correlate between .86 and .92 with the compensation that the job occupant judged to be fair (Richardson, 1971). It also was a good index of the location of a position in an organizational hierarchy. Thus a supervisor may have a time span of one month; a department head, one year; a general manager, three years; and a chief executive officer of a corporation, 20 years. Similarly, in an army, the company commander may have a time span of three months; the battalion commander, one year; the brigade commander, two years; and a full general, up to 20 years.

*Ethical Accountability.* Berman and Van Wart (1999) suggested holding managers, particularly public service administrators, ethically accountable to the public. Cost efficiency and profitability are relatively less important to evaluate than effectiveness of services. Public service managers may be held accountable for providing services working with partners in the private sector that are timely, responsive, reliable, accurate, error-free, customer-friendly, and convenient.

## ***Ensuring Accountability***

Formally, in a hierarchy in the private sector, accountability is ensured when a leader's mandated actions and decisions are evaluated by his or her higher authority, with consequential reward or punishment (Kearns, 1996). For administrators in the public sector, authority is vested in the elected president and his appointees, the legislature, and the judiciary. Elected officials are held accountable through the election process, rules, regulations, and traditions. But leaders create arrangements to protect their positions and avoid openness, transparency, and accountability. As evidenced by numerous financial scandals, the CEO is often not held accountable by the corporate board of directors—a signal flaw in corporate governance in the private sector and NGOs. Monitoring systems are required. In the private sector, these include effective legal regulation and uncorrupted accountants, dedicated lawyers, investigative media, and protected whistle-blowers. In the public sector, they include a free press, citizen advocacy groups, open political parties, rule of law, minimum secrecy in agencies, and an uncorrupted electoral process and judiciary (Gardner, 1988). Unfortunately, T. R. Mitchell (1993) found no assured accountability in either the public or the private sector. Neither government administrators nor business managers can be recalled by democratic voting procedures. More often than not, administrators and managers are protected by a concentration of economic and governmental power and by immunity from criminal and civil liability. Unconstrained power affects accountability by biasing appraisals of one's own and others' performance (Kipnis, 1987). Nevertheless, "The requirement that one be answerable for

one's decisions and actions is an implicit, if not explicit, assumption of organizational systems. Accountability is an integral part ... of understanding ... organizational theory" (T. R. Mitchell, 1993, pp. 116–117).

## Delegation

---

Delegation implies that one has been empowered by one's superior to take responsibility for certain activities. The degree of delegation is associated with the trust the superior has for the subordinate to whom responsibilities have been delegated.<sup>1</sup> When a group is the repository of authority and power, it likewise may delegate responsibilities to its individual members.

The delegation of responsibilities should not be confused with laissez-faire leadership<sup>2</sup> or abdication. A leader who delegates is still responsible for following up whether the delegation has been accepted and the requisite activities have been carried out. The leader remains accountable (Anonymous, 1989).

The delegation of decision making implies that the decision is lowered to a hierarchical level that is closer to where it will be implemented. Such delegation is consistent with the encouragement of self-planning, self-direction, and self-control.

### *Why Delegate?*

Yukl (1998) suggests several reasons why leaders delegate: (1) the task can be done better by a subordinate; (2) the task is low-priority and not urgent; (3) the task is a career development experience; (4) the task is not central to the leader's role. Furthermore, the leader can use the time for other necessary activities. The leader's capabilities and influence can be multiplied. Better use can be made of the subordinate's time and abilities. The leader can demonstrate trust in the subordinate. Delegation can develop a greater sense of challenge, initiative, responsibility, authority, and autonomy in the subordinate (Avolio & Bass, 1991).<sup>3</sup>

Kuhnert (1994) offered several reasons why leaders may avoid delegating. A transactional leader cannot suspend an agenda or coordinate an agenda with others. A transformational leader may place too much weight on current role expectations and may be unable to make difficult decisions that might entail possible loss of respect.

### *Responsibility, Authority, Delegation—Approximating Accountability*

Stogdill and Shartle (1948, 1955, 1975) developed the RAD scales to measure organizational responsibility (R), authority (A), and delegation (D). Responsibility and authority, when combined, were said to approximate accountability. The self-rated responses by individuals describing their own jobs formed scales that had high reliability. Correlational results were obtained in 10 organizations engaged in the production of chemicals, the manufacturing of metal products, and governmental work. As expected, the responsibility and authority of job occupants were correlated positively, ranging from .13 to .63 with a mean of .45. But the relationship of delegation to authority and responsibility was not as high. Delegation averaged .17 in correlation with responsibility in the 10 organizations, with a range from  $-.27$  to  $.38$ . Delegation averaged only .23 with authority, with a range from organization to organization from  $-.42$  to  $.49$ . (These surveys are over half a century old and would be worth replicating in the twenty-first century.)

A complaint of managers is that they are often delegated a great deal of responsibility by their superiors without the associated authority. This is a commonplace occurrence where leaders are delegated to lead teams of professionals (McKenna & Maister, 2002). The leaders need to depend on their personal expertise, esteem,

and persuasiveness. Yet satisfaction and productivity are greater when delegation, responsibility, and authority are matched. In one of the 10 organizations that Stogdill and Shartle studied, there was a correlation of .42 between the managers' self-rated delegation and their actual authority. Dissatisfaction and ineffectiveness were rampant. In the eight organizations in which delegation correlated highly, authority, satisfaction, and effectiveness were much higher than in the two organizations in which delegation and authority were mismatched. Similar inferences could be suggested about the wide range of correlations, from .13 to .63 obtained between responsibility and authority. In the organization in which responsibility and authority correlated .63, operations went much more smoothly than in the organization in which the correlation was only .13.

*Age, Rank, and R, A, and D.* Some other patterns of interest emerged in Stogdill and Shartle data that were a useful way to describe likely differences among organizations in leadership and management. For instance, age and seniority varied from one organization to another in their relation to responsibility, authority, and delegation. In one organization, authority was invested in older members, but in another organization it was invested in younger ones. The correlation between age and authority within the organizations ranged from  $-.26$  to  $.45$ . It does not take much imagination to contrast the organization in which self-estimated authority correlated  $.45$  with age and the one in which the correlation was  $-.26$ . The organization with the negative correlation was a rapidly expanding technology firm; the organization with the high positive correlation was a stable agency where age and promotion were in lockstep. More often than not, the educational level of an organization's managers correlated positively with their responsibilities and authority. The managers' own perceived responsibility and authority were unrelated to their subordinates' job satisfaction, but a mean correlation of  $.19$  for the 10 organizations was found between the managers' perceived authority and the extent to which their superiors were seen as considerate in leadership behavior. Evidently, the higher members rise in authority in an organization, the more they are treated with consideration by their superiors. H. J. Bowman (1964) found, similarly, that school principals who rated themselves higher in responsibility, authority, and delegation described their superiors as being more considerate of them.

*Rank, Salary, and R, A, and D.* Kenan (1948) used the RAD scales to study large governmental organizations and found, as expected, that executives in higher-level positions described themselves as being higher in responsibility and authority than did those in lower-level positions. Correspondingly, Browne (1949) noted that executives' salaries related positively to self-estimates of responsibility and authority. D. T. Campbell (1956) reported that authority and delegation but not responsibility were positively and significantly related to one's level in various organizations, military rank, time in the position, and recognition for being in a position of leadership. Strong positive correlations should be expected between Jaques's (1956) time span of accountability and authority and responsibility as measured by the RAD scales.

*Hierarchical Effects.* In four large naval organizations, Stogdill and Scott (1957) found that the higher the responsibility and authority of their superiors, the less the subordinates tended to delegate. Yet, as might be expected, those superiors who delegated the most had subordinates who rated themselves highest in responsibility, authority, and delegation.

When superiors rated themselves as having a high level of responsibility, their subordinates rated themselves as having high levels of responsibility and authority, but these subordinates' self-ratings were unrelated to the authority of their superiors.

Stogdill and Scott (1957) analyzed the responsibility, authority, and delegation scores of commanding officers and executive officers and the average RAD scores of their junior officers on submarines and on landing ships. The executive officers tended to delegate more freely to those below them on both types of ships when the commanding officers exercised a wider scope of responsibility and authority and delegated more freely. But the relationship between commanding officers and executive officers on the submarines and landing ships differed substantially. Executive officers reported more responsibility and authority when their commanding

officers were high in responsibility, authority, and delegation on the submarines, but the reverse was true on the landing ships.

The RAD scores of the junior officers were systematically related to the RAD scores of their executive officers and to those of their commanding officers. As the authority of their executive officer increased, junior officers' RAD scores tended to decrease. When their commanding officer delegated more freely, the junior officers reported an increase in responsibility on landing ships but a decrease in responsibility on submarines. Stogdill and Scott concluded that the commanding officers could increase or decrease the workloads and freedom of action of their executive officers. In the same way, junior officers tended to tighten their controls as superiors increased their own sense of responsibility and freedom of action. However, responsibility and authority did not flow without interruption down the chain of command. The responsibility, authority, and delegation of subordinates were more highly influenced by the subordinates' immediate supervisors than by their higher-level commanding officers and executive officers.

According to Stogdill, Scott, and Jaynes (1956), when U.S. Navy supervisors were perceived as delegating freely, their subordinates not only rated themselves higher in responsibility and authority but thought that they should have a high degree of responsibility and authority. However, the subordinates believed that they themselves spent too much time on inspections, preparing procedures, training, and consulting peers and not enough time on coordination and interpretation.

The responsibility of subordinates appeared to be more highly related than their authority to the responsibility and authority of their superiors. An increase in the responsibility of superiors had the effect of increasing the responsibility of their subordinates, but it did not necessarily increase the subordinates' authority. This was a latent cause of dissatisfaction. An increase in the superiors' responsibility, authority, and delegation also appeared to require that the subordinates increase their coordination activities.

## Summary and Conclusions

---

Authority, responsibility, delegation, and accountability have been subjects of commentary and research in leadership and management since early in the twentieth century. Authority is the legitimate right to exercise power, but it depends on the willingness of others to accept it. It is less often the main source of leadership than it used to be. Authority is both allocated from above and acknowledged from below before it converts into power and leadership and becomes strong in its effects on leadership and wide in scope. Leaders are assigned responsibility and held accountable for using it commensurately with their authority. This situation can provide a check on leaders. Discretionary leadership is needed beyond that required by authority and responsibility, particularly as a consequence of changing patterns of authority. Authority and responsibility are correlated, and both contribute to accountability. Leaders' responsibilities are broader than those of their subordinates but are dependent on their subordinates. Responsibilities but not accountability can be delegated. Delegation should be to levels in the organization closest to the decisions that need to be made.

Supervisors with more responsibility generate more responsibility among their subordinates, but the same is not true for the downward flow of authority. The responsibilities of superiors tend to influence the performance of subordinates, but their authority has a stronger impact on the subordinates' expectations. When superiors have a great deal of responsibility and authority, their subordinates believe that the demands made on them for coordination increase. However, when superiors delegate a great deal to their subordinates, the subordinates report that they are overburdened with responsibilities and need more authority than they possess. Subordinates do not view delegation as an unmixed blessing when they have critical or burdensome duties to perform.

Organizational effectiveness depends on the congruence of responsibility, authority, and delegation and their

interrelationships at different levels of the organization. Their combination provides a gauge of their accountability. The link between the authority and responsibility of superiors and subordinates is embedded in the larger framework of superior-subordinate interdependence and mutual reinforcements.

<sup>1</sup> The relationship between a leader's trust in subordinates and the tendency to delegate will be discussed more fully in [Chapter 18](#).

<sup>2</sup> See [Chapter 6](#).

<sup>3</sup> Delegation will be discussed as an aspect of managerial style in [Chapter 18](#).

# Reinforcement and Instrumental Leadership

Contingent reinforcement occurs when leaders arrange for followers to be praised, commended, or rewarded materially for successfully carrying out agreed-upon assignments—or to be reprimanded, or disciplined for failure to do so. Responsiveness by followers to a leader is heightened by their expectation that satisfactory performance will be rewarded and unsatisfactory performance will be punished materially, socially, or symbolically. According to Sims and Lorenzi (1992), effective leadership reinforces desired followers' behavior and eliminates undesired follower behavior through providing or denying social, symbolic, and material rewards and punishments. According to Sims (1977), a leader is a manager of reinforcement contingencies. Connelly, Gaddis, and Helton-Fauth (2002) have suggested that leaders arouse positive emotions in followers by consistently applying contingent reinforcements and generating mutual liking. Negative emotions are aroused when leaders display a negative demeanor during punitive incidents.

The *Iliad* is filled with stories of contingent reinforcement. The heroes of the *Iliad* often engaged in contingent reward or punishment with men and the gods to gain compliance with their wishes. Achilles refused to fight further and went off to sulk over the arbitrary confiscation of Briseis, a girl captured from Achilles by the king, Agamemnon. Briseis was taken from Achilles to compensate Agamemnon for the loss of his own prize, Chryseis. To assuage the wrath of Apollo, public pressure was brought on Agamemnon to return Chryseis to her father, a priest of Apollo. Without Achilles, the Achaeans faced defeat. Agamemnon sent Odysseus and Ajax to lure Achilles back to take charge of the Achaean forces with promises by Agamemnon that Achilles would receive booty, land, and women if he achieved victory over the Trojans (*Iliad*, 1720/1943, Book IX).

For effective leadership, leaders need to let followers know what rewards are available and what behavior will be rewarded. They need to make clear what behavior will be rewarded—for example, quality rather than speed; lasting solutions not quick fixes; and creativity, not conformity. Reprimands should be directed against specific behaviors, not the person. They are given privately. They should be low-key, prompt, and unemotional. The leader should take responsibility for the reprimand. It should be accompanied by information about what behavior would be desirable (Howell & Costley, 2001, 2006).

## Leadership as a Social exchange

---

Transformational leadership may transcend the satisfaction of self-interests; nevertheless, the dynamics of leadership-followership have most often been explained as a social exchange. The exchange is established and maintained if the benefits to both the leader and the followers outweigh the costs (Homans, 1958, 1961). This exchange is fair if “the leader gives things of value to followers such as a sense of direction, values, and recognition, and receives other things in return such as esteem and responsiveness” (Hollander, 1987, p. 16). Followers expect that the leader will enable them to achieve a favorable outcome, and they believe the exchange to be fair if the rewards are distributed equitably. However, they perceive the leader's failure in this regard as unjust, particularly if the leader has not made an effort or is self-serving. “Fundamentally, there is a *psychological contract* between the leader and followers, which depends upon a variety of expectations and actions on both sides” (Hollander, 1987, p. 16).

The exchange or transaction cycle contains the following phases. The leader and the followers perceive each other as being potentially instrumental to the fulfillment of each other's needs, say, for the completion of a task. If necessary, the leader clarifies what the followers must do (usually, they must successfully complete the task) to fulfill the transaction to obtain the material or psychic reward, or to satisfy their needs.<sup>1</sup> The followers' failure to comply may move the leader to take corrective action. The followers' receipt of a reward or avoidance of punishment is contingent on their successful compliance with and completion of the task. Satisfaction of the leader's need accrues from the followers' success. Wilson, O'Hare, and Shipper (1989) expanded the description of the task cycle for the tasks performed by service and sales personnel ([Table 15.1](#)).

Table 15.1 The Task-Cycle Model

A Generic Task	Executives	Leaders	Managers	Personnel	
				Service	Sales
<i>The Goal</i> What do I do?	<i>The Goal</i> Clarify and direct mission achievement	<i>The Goal</i> Envision and initiate change for future	<i>The Goal</i> Clarify and communicate today's goals	<i>The Goal</i> Give service, keep one's own goals clearly in mind	<i>The Goal</i> Meet the client's needs, earn revenues
<i>The Plan</i> How do I do it?	<i>The Plan</i> Develop and communicate strategies	<i>The Plan</i> Solve novel problems resourcefully	<i>The Plan</i> Plan and solve problems that are encountered	<i>The Plan</i> Solve the client's problems as an adviser	<i>The Plan</i> Give service, be professional, analyze needs
<i>Resources</i> How do I carry out the plan?	<i>Resources</i> Develop a supportive culture	<i>Resources</i> Modeling, mentoring, and challenging	<i>Resources</i> Facilitate by coaching and training	<i>Resources</i> Professional/technical skills	<i>Resources</i> Knowledge of the product, empathy, probing skills
<i>Feedback</i> How do I know I am performing?	<i>Feedback</i> Track and share information	<i>Feedback</i> Develop an awareness of the impact of the task	<i>Feedback</i> Obtain and give feedback on the subordinate's performance	<i>Feedback</i> Inquire about and follow up on the impact	<i>Feedback</i> Ask and identify questions and resistances
<i>Adjustments</i> How do I fix my mistakes?	<i>Adjustments</i> Direct/oversee other managers	<i>Adjustments</i> Use persuasion to gain and maintain commitment	<i>Adjustments</i> Correct the time and details to meet the goal	<i>Adjustments</i> Self-control to meet commitments to service	<i>Adjustments</i> Answer objections, ask for order
<i>Reinforcement</i> Satisfaction from achievement of the task	<i>Reinforcement</i> Share rewards for the organization's success	<i>Reinforcement</i> Share rewards for supporting the change	<i>Reinforcement</i> Recognize and reinforce the subordinate's performance	<i>Reinforcement</i> Recognize and reinforce cooperation	<i>Reinforcement</i> Express appreciation to clients
<i>Result</i> Task achieved	<i>Result</i> Mission accomplished	<i>Result</i> Change for the better	<i>Result</i> Today's goals achieved	<i>Result</i> Service rendered	<i>Result</i> A sale

Blanchard and Johnson (1982) set out the following rules for contingent reinforcement in the "one-minute manager's game plan": First, obtain the subordinate's agreement with the goal, including the appropriate behavior for achieving it. Check the subordinate's behavior to see whether it matches the agreed-on goal. Second, if the goal is achieved, provide praise (contingent reward) as soon as possible that is specific to what the subordinate did right. Indicate how the subordinate's action helps others and the organization. Third, if the subordinate's performance fails to match expectations, deliver a reprimand (contingent punishment) as soon as possible after the failure. Despite the reprimand, it must be added, you should continue to think well of the subordinate, though not of this specific performance. Fourth, the subordinate's success may call for setting a new goal; the subordinate's failure may require a review and clarification of the old goal.

## Reinforcement (Instrumental) Leadership and Followership

It takes at least two people for leadership to occur. Someone has to act, and someone else has to react. Whether the actions and reactions take place will depend on who the "someones" are and what their needs, competencies, and goals are. If one is perceived as instrumental to the other's attainment of the goal, because of

greater competence or power, the stage is set for an interaction and leadership to occur. *Reinforcement* leadership is often referred to as *instrumental* leadership.

In this transactional process, leaders are agents of reinforcement for the followers. At the same time, the followers' compliance or noncompliance makes them agents for reinforcement of the leaders. "Leader and subordinate accept interconnected roles and responsibilities to reach designated goals. Directly or indirectly, leaders can provide rewards for progress toward such goals or for reaching them. Or, they can impose penalties for failure ranging from negative feedback to dismissal. ... Contingent-positive reinforcement, reward if agreed-upon performance is achieved, reinforces the effort to maintain the desired ... employee performance. Contingent-aversive reinforcement ... signals the need to halt the decline in speed or accuracy of the employee's performance, to modify or change the employee's behavior. It signals the need for a reclarification of what needs to be done and how" (Bass, 1985a, pp. 121–122).

Adams, Instone, Prince, and Rice (1981) collected West Point cadets' narratives about incidents of good or bad leadership that occurred during summer training. High on the list of good incidents was contingent-rewarding behavior. High on the list of bad incidents was punishing subordinates with or without provocation.

### ***Utility of Reinforcement Leadership***

Rewarding by leaders, whether contingent on followers' performance or noncontingent, was seen by 84 college students as exemplifying the good leader. Noncontingent punishment, but not contingent punishment, biased the students in the opposite direction (Korukonda & Hunt, 1989). Atwater, Dionne, Avolio, and Camobreco (1996) obtained 1,109 critical incidents along with leadership ratings for 286 cadet leaders at Virginia Military Institute (VMI), each rated by five subordinates. Of the four transactional reinforcers, only contingent reward was related to the effectiveness of leadership. Noncontingent reward was irrelevant. At VMI, noncontingent punishment such as reprimands, extra physical exercise, and assignment of extra duties was counterproductive (Arvey, Davis, & Nelson, 1984). Similar findings were obtained about the effects of noncontingent punishment on cohesiveness at the U.S. Naval Academy (Roush, 1991) and the U.S. Coast Guard Academy (Blake & Rotter, et al, 1993).

According to Peters and Waterman (1982, p. 123), the managers of the excellent companies they examined exerted a good deal of effort to provide positive reinforcement for the successful completion of tasks. They made a conscious effort to reinforce any action that was valuable to the organization. Subordinates' satisfaction was increased the most, according to a field study by Reitz (1971), when their supervisors praised and rewarded them for acceptable performance (but reprimanded them for unacceptable work). For 231 subordinates surveyed by Klimoski and Hayes (1980), particularly strong associations were found between their satisfaction with their supervisors and the supervisors' explicitness in giving instructions on what was required, support for efforts to perform effectively, and consistency toward the subordinates. The supervisors' explicitness and consistency also had moderate effects on reducing role ambiguity and role conflict. The supervisors' consistency contributed to some extent to the subordinates' performance and knowledge of the job, although these appeared to be enhanced by the subordinates' involvement in determining standards. The leaders' behavior in the contingent-reward path-goal processes contributed to the subordinates' efforts and performance by clarifying the subordinates' expectations that a payoff would accrue to them as a consequence of their efforts. To a lesser extent, some of the contingent rewarding behaviors also contributed directly to the subordinates' improved performance and satisfaction with supervision by reducing role ambiguities and role conflicts.

*Effects on Satisfaction.* Podsakoff and Schriesheim (1985) completed a comprehensive review of field

studies of the effects on subordinates of supervisors' contingent and noncontingent reinforcement.<sup>2</sup> Among the general conclusions they reached was that subordinates were more satisfied with their situation if their leaders provided them with rewards (positive feedback) contingent on their performance.

Such satisfaction was not present if rewards were not contingent on their performance. "I feel well treated by my supervisor no matter what I do. In other words, it makes no difference how I perform; my supervisor will always arrange for me to be rewarded." This noncontingent reward by the supervisor was not as satisfying as earning rewards for the subordinates' good performance. Particularly dissatisfying to subordinates was noncontingent negative feedback—that is, not really being able to link reprimands with the behaviors that elicited them. This condition is likely to promote learned helplessness.

Field studies involved 17 large samples, with a median size of 275 cases, of financial managers, paramedics, engineers, white-collar employees of public utilities, registered nurses and nurses' aides, administrators of nonprofit organizations, city and state government employees, hospital pharmacists, and mental health employees. For the 17 samples, a mean positive concurrent correlation close to .50 was found between the subordinates' satisfaction with supervision and the extent to which the supervisors practiced contingent reward. The corresponding mean correlation was near zero between satisfaction with supervision and the practice of contingent punishment. Noncontingent reward had little relation to satisfaction with supervision. At the same time, noncontingent punishment was negatively correlated with satisfaction with supervision in these samples. The mean correlation here was  $-.32$  for 11 of the samples in which the measures were available. Even after the same single source of variance was removed by removing the general factor of each individual's responses to all questions (the subordinate raters described the leaders' as well as their own satisfaction and performance), Podsakoff and Todor (1985) still found a positive association between contingent reinforcement leadership and a group's cohesiveness, drive, and productivity. But Brown and Moshavi (2002) did not find that contingent rewarding of 440 faculty members by chairpersons in 70 academic departments enhanced the faculty members' job satisfaction, expenditure of extra effort, or organizational effectiveness.

*Effects on Performance.* Considerable evidence from laboratory experiments and field studies has indicated that reinforcement leadership contributes to the effectiveness of subordinates and collegial groups. Spector and Suttell (1957) contrasted reinforcement leadership with authoritarian and democratic leadership of teams in producing correct plans in a controlled, laboratory setting. The reinforcing leader was encouraging and expressed approval of good solutions to problems every time the teams reached them. When incorrect planning occurred, the reinforcement leader suggested how it could be improved. The authoritarian leader made the groups' decisions and did their planning. Under the democratic leader, the leader and the teams shared the responsibility for planning and decision making. The teams that received reinforcement leadership were the most productive, and members with little ability appeared to profit most from it. According to a survey of 526 subordinates and 543 peers describing the downward influence tactics of their 128 managers, least effective leadership involved using demands, threats, and persistent reminders; seeking the aid of others to persuade teams; and claiming the authority to legitimate requests. Moderate results were achieved with getting teams to think favorably of the leader before making a request, or making promises of later reward or reciprocating the favor later on. Most effective were rational persuasion and inspirational appeals to values, ideals, and aspirations.

For 11 of the samples in the Podsakoff and Schriesheim (1985) review, the mean concurrent correlation was .32 between contingent rewarding supervision and the effectiveness of the performance of subordinates and work groups. For 10 samples, the mean correlation was close to zero between contingent punishment by the leader and subordinates' performance. Luthans and Kreitner (1975) did find that contingent penalization for unacceptable actions improved performance, but only when it was coupled with contingent reward for acceptable performance. The mean correlation was also close to zero between performance and noncontingent reward for eight samples and  $-.12$  between noncontingent punishment and performance.

*Material versus Nonmaterial Rewards.* Pay for performance still remains a popular contingent reward in the United States, Britain, and elsewhere, with schedules set by the human resources staff. Supervisors may recommend pay raises in their performance reports of subordinates, but nonmaterial rewarding may be more important in motivating and maintaining performance. Although pay motivates people to seek and accept employment for better wages and salaries, leaders are likely to have even more discretionary effects on their subordinates in their use of nonmaterial positive feedback of praise and recognition for work well done (Kohn, 1993).

### ***Contingent Reward and Other Leadership Behavior***

Generally, contingent rewarding correlated almost as highly as transformational leadership with outcomes in effectiveness and satisfaction. Among 19 female managers rated in transformational leadership by 38 subordinates, transformational leadership did not further account for performance of the subordinates rated by the managers beyond what was accounted for by contingent reward (Dionne, Yammarino, Comer, et al., 1996). *Behavioral management*, which included providing rewards contingent on performance, proved more effective at increasing productivity than did *participative management*, according to an experiment in a Russian textile factory by Welsh, Luthans, and Sommer (1993). According to a survey of 125 managers by Howell, Neufeld, and Avolio (2005), contingent rewarding was correlated with better communication—frankness (.41), two-way communications (.45), and careful transmitting (.22). Generally, creative performance and divergent thinking were increased by promises of reward contingent on performance (Eisenberger, Armeli, & Pretz, 1998). On the basis of his own experience in the Israeli Army, and after reviewing the literature, Berson (undated) noted that rewarding soldiers for the adequacy of their performance was especially relevant for their motivation.

In cross-lagged causal analyses of 206 employees, Greene (1976a) demonstrated that contingent rewarding by supervisors resulted in the improved *subsequent* performance and satisfaction of subordinates. The correlation was .48. The effect had some permanency. In a six-month longitudinal field study of 61 working MBA students, Sims (1977) corroborated Greene's conclusion about how much contingent rewarding by supervisors contributed to the respondents' subsequent performance. The correlation was .50. Szilagyi (1980b), in a three-month longitudinal study of 128 employees in a controller's department, obtained a comparable coefficient of .48.

### ***Contingent Punishment***

Szilagi's (1980b) results were reversed or nil (−.23, −.12, −.07) for the effects of earlier contingent punishment by supervisors on the future performance of subordinates in Greene's, Sims's, and Szilagyi's studies. Future punitive supervision appeared to be more a consequence of past poor performance of subordinates: the correlations for the three studies were −.40, −.04, and −.59. But future contingent reward was not consistently a consequence of subordinates' earlier good performance: the correlations for the three studies were .26, .09, −.17.

Laboratory and field studies have indicated that although contingent reward leads to improved performance by subordinates, contingent punishment has less consistent effects. The performance of subordinates may be improved by a supervisor's correction and by other forms of negative feedback (Arvey & Ivancevich, 1980). Sims and Szilagyi (1975) suggested that negative sanctions may improve performance by reducing role ambiguity. According to Podsakoff (1982), high-performing leaders use both contingent-positive and contingent-aversive reinforcement. O'Reilly and Weitz (1980) found that managers of high-performing units

used negative reinforcers more quickly. Franke and Kaul (1978) reinterpreted the statistical inferences that could be drawn from the Hawthorne experiments (Roethlisberger, 1941) and concluded that managers' tightening of discipline was an important reason for the increased productivity of workers—a change that was ignored by the original investigators. O'Reilly and Puffer (1983) asked 142 sales representatives to describe critical incidents of good and poor performance with and without supervisory reinforcement. They found that effort, satisfaction, and a sense of equity were enhanced as well by formal or informal reprimands for poor performance as by favorable recognition for good performance.

*Reasons for Disciplinary Action.* Contingent punishment is more likely to occur if the manager's authority is challenged, or if the manager is inconvenienced by a trained and experienced subordinate's failure to live up to expectations. For example, a subordinate might deviate from the norms, production might fall below agreed-on standards, or the quality of the product might become unacceptable (Rollinson, Hook, Foot, et al., 1996). The leader may call attention to the deviation. Being told of one's failure to meet standards may be sufficient to provide aversive reinforcement for what was done wrong. Being told why can be particularly helpful to an inexperienced subordinate, especially if the message includes further clarification of the desired performance. The leader may administer penalties, such as fines or suspensions without pay. The leader may withdraw support, or the employee may be discharged.

*Effects of Disciplinary Actions.* Following initial interviews with a random sample of 100 hourly refinery employees, Arvey, Davis, and Nelson (1984) surveyed 526 hourly employees. The employees were asked to describe their perceptions of their immediate supervisors' disciplinary behavior, as well as the factors that supervisors take into account when applying discipline. Of the employees, 20% reported that they had experienced disciplinary actions. The employees' evaluation of the supervisors differed strongly, depending on how much and in what ways the supervisors used punishment. The more the supervisors used formal punishment ("Write you up for an infraction") or informal punishment ("Yell at you"), the less satisfied their subordinates were with them. The employees' satisfaction with their supervisors correlated  $-.46$  with overly harsh discipline and  $-.50$  with discipline lacking a clear explanation. On the other hand, satisfaction with the supervisors correlated  $.31$  with the supervisors' tendency to discipline people immediately after an infraction of the rules occurred,  $.60$  with the tendency to maintain close and friendly relations with employees they had disciplined, and  $.32$  with consistency in disciplining employees from person to person and situation to situation.

*Justifications for Punishment.* Future-oriented punishment aims to reduce or eliminate undesirable behaviors such as unsafe behavior. By itself, it does not reinforce the correct way to act, but it can avoid costly errors. Past-oriented punishment, by contrast, is retribution for past misdeeds, and it may only assuage the administering leader and increase the emotional reactions of the follower. According to qualitative interviews with 77 managers from diverse organizations by Butterfield, Trevino, and Ball (1996), the interviewed managers generally were uncomfortable with punishing subordinates for poor performance and sought to avoid it. Many managers felt pressure against it from the subordinates as well as from the organization and work groups. These managers were aware that the emotional effects could spread much beyond what was intended. Nonetheless, the investigators concluded that punishment could be instrumental in improving subordinates' behavior, attitudes, respect, and vicarious organizational learning. Many of the managers engaged in impression management when punishing, using justifications and excuses in acknowledgment of past mistakes. They considered the subordinates' expectations, reactions, and acceptance, and their own past relations with the subordinates. To many of the managers, fairness and timeliness were less important than consistency, privacy, and the poor performance of the subordinates. Judging from the reactions of 421 graduate business students to scenarios, Fukami and Hopkins (1990) concluded that the severity of punishment meted out depended on the subordinates' past performance and the amount of property damage and personal injury, not on whether the offending employee was a man or a woman.

Incorrect behavior may be only temporarily suppressed by disciplinary punishment alone, but when disciplinary punishment is coupled with advice on correct behavior, it is more likely to suppress the undesired behavior permanently (Arvey & Ivancevich, 1980). In a simulation experiment in which 182 undergraduates played roles as managers and poorly performing workers, the “managers” advice added to corrective action increased the “workers” sense of interactional justice.

Content analyses by Atwater, Waldman, Carey, et al. (2001) of interviews with 123 disciplined persons and 46 observers disclosed some positive effects of the discipline. But respect for the discipliner was lost and negative attitudes developed toward the organization. The discipline was seen as unfair, particularly when it was applied for violations of informal rather than formal rules. Ball and Trevino (1990) asked 65 managers from different organizations and different kinds of positions to indicate whether they had been pleased or discouraged by a disciplinary event they had reported and whether justice had been served. As expected, the perception of justice depended on the appropriateness of the severity of the punishment ( $r = .31$ ), the closeness of the punishment to the violation ( $r = .22$ ) and the constructiveness of the punishment ( $r = .54$ ). Managers were less discouraged when the punishment was perceived as just ( $r = -.21$ ), when it was given in private ( $r = -.26$ ), and when the manager perceived the relationship with the disciplined employee as remaining good ( $r = -.29$ ).

*Management by Exception.* When leaders take corrective actions and intervene only when subordinates’ failures and deviations occur, they are practicing management by exception (MBE). In practicing MBE, some managers *actively* search for deviations and shortfalls. They set up standards and regularly monitor subordinates’ performance to see if the standards are being met. Other managers are more *passive*, asking no more than what is essential to get the work done (Hater & Bass, 1988). Leaders who practice MBE intervene only when something goes wrong. If a subordinate’s performance falls below some threshold, the leader feeds back information to the subordinate, at the emotionally mildest level, that the threshold has been crossed. The negative feedback may be accompanied by a contingent reward from the leader, in the form of reclarification and encouragement. At the other extreme, it may be accompanied by disapproval, a reprimand, a formal citation, suspension, or discharge. MBE is consistent with the cybernetics of negative feedback—feedback that signals the system to move back toward its steady-state base. The manager is alert for deviations and provides the negative feedback as needed.

A simulation of management control strategies used 182 students acting as managers and poorly performing employees. Punitive corrective actions and verbal reprimands were used repeatedly; but over time, the “managers” experimented in the search for effective management control (Gavin, Green, & Fairhurst, 1995) and the “employees” sense of justice was affected. In most surveys of descriptions of industrial leaders by their colleagues and subordinates, MBE—especially if it is passive—does not contribute to positive appraisals of the leaders’ effectiveness or to satisfaction with the leaders (Bass, 1985a). However, it correlated .23 and .25 with the rated effectiveness of officers in the U.S. Army and U.S. Air Force and .29 and .31 with subordinates’ satisfaction with the officers’ leadership (Colby & Zak, 1988).

Particularly important to the effectiveness of leadership is whether MBE is active or passive. A leader who arranges to monitor errors and deviance that need to be corrected is said to be *actively* engaged in management by exception. A leader who waits to be informed about errors and deviance before taking action is said to be practicing *passive* management by exception. The correlations for 186 junior naval officers described by their subordinates as actively managing by exception were .50 and .54 with the subordinates’ evaluation of the effectiveness of the officers and satisfaction with them, and .28 and .22 with fitness reports and recommendations for early promotions from their superiors. The same correlations with passively managing by exception were, respectively, .11, .19,  $-.04$ , and  $-.05$  (Yammarino & Bass, 1988).

*Personal and Situational Modifiers.* In interviews with 474 managers about their use of discipline, Beyer (1981) found that both personal and situational factors could account for the extent to which

supervisors took disciplinary actions with problem employees. For example, managers who personally endorsed humane pragmatism—concern for both the employees' welfare and the company's productivity—were more likely to be constructive and confrontational with problem drinkers and less likely to take disciplinary action against these employees. At the same time, the judged seriousness of the drinking problem was the strongest determinant of whether disciplinary action, including issuing warnings in writing or ordering a suspension or discharge, would be taken. Union and management policies had systematic effects, as did the managers' expectations that their constructive or disciplinary efforts would or would not please their higher authority. Unfortunately, the results were often different when the managers dealt with problem employees other than those who had drinking problems. Commentaries suggest that less serious disciplinary cases are handled personally by supervisors with a prescriptive autocratic style. More serious threats to the organization result in stronger disciplinary action. Additionally, whether the supervisor takes any disciplinary action depends on the subordinate's length of service and on how much the subordinate's violation inconveniences the supervisor, is a threat to the organization, and challenges authority. Also important are the supervisor's training and the subordinate's length of service (Hook, Rollinson, Foot, et al., 1996; Rollinson, Hook, Foot, et al., 1996). Observing coworkers who are being threatened or punished by supervisors can also provide vicarious reinforcement that promotes the productivity of the onlookers. Schnake (1986) hired students at \$5 an hour ostensibly to perform clerical work, along with a confederate of the experimenter who made sure to perform more poorly than the student subjects. Threats to reduce the confederate's wage to \$3.50 and actually cutting the confederate's pay resulted in significant increases in the output of the student subjects.

## Applying Contingent Reinforcement

---

According to Zaleznik (1967), contingent reinforcement with an emphasis on the exchange should be practiced by managers who are interested in efficient processes rather than substantive ideas. It will be facilitated by the managers' flexibility in using their powers to reward or punish to maintain or improve processes and organizational arrangements. Blanchard and Johnson (1982) advised that inexperienced subordinates may need to be told by their superior what they did right and how their superior feels about their work, and encouraged to continue. Experienced subordinates may need to be told what they did wrong without diminishing their self-esteem. Furthermore, a reprimand will work if it is timely and specific to the behavior involved, not to the person. It should focus on what was done wrong, how the supervisor feels about it, and the expectation that the subordinate's performance is going to improve. The subordinate's failure to appreciate what is expected calls for a clarification of requirements, rather than punitive actions. Failure that is due to a lack of knowledge calls for information, training, or transfer. Failure that is a result of insufficient challenge calls for enlarging the task, transfer, increased extrinsic incentives, or acceptance of reality by the subordinate. A lack of commitment requires that the employee's involvement in the planning or control process be increased. An overload of goals necessitates the establishment of priorities.

### ***Operant Reinforcement***

According to Scott and Podsakoff (1982), if leadership and followership can be conceived of as behaviors, then the principles of operant reinforcement can be used to modify these behaviors. Leaders need to learn what reinforcers work with what kinds of followers. They also must be able to identify and specify the types of behavior by subordinates that will maximize the group's performance. If this is not possible, they need to identify and specify the desired results and to keep up with changes that are required. Over time, a shift of control by the leader to self-control by the followers is salutary.

If extrinsic reinforcers are used, leaders must be able to link the reinforcement to the subordinates' performance. Leaders need to be consistent in their administration of reinforcements. Punishment must be delivered quickly, and with reasons, in order to stamp out undesirable responses. Environmental events that sustain the dysfunctional behavior need to be eliminated. McElroy (1985) also argued that reinforcement is not received mindlessly. Rather, when reinforced, a subordinate will develop a reason for the reinforcement that may be the same as or different from the reason given by the leader. It is likely that the subordinate will attribute rewards for successful performance to his or her personal efforts but attribute penalties for failure to external causes. It is presumed that because of this attribution, penalties will have less effect on the subordinate's subsequent behavior. Schedules of reinforcement will systematically affect causal attributes. For example, if one is rewarded only some of the time for good performance, one will tend to attribute the reward to effort or luck, rather than to ability.

*Caveats.* Caution is required in applying reinforcement theory that is based on animal research to human leader-subordinate relations. If animals are faced with choices X and Y and are reinforced 90% of the time for choosing X and 10% of the time for choosing Y, they will choose X 90% of the time. However, humans will make a cognitive leap, deducing that they will maximize their reward by choosing X 100% of the time. Animals will earn rewards only 81% of the time; humans will earn rewards 90% of the time (Mawhinney, 1982).

Using contingent reward or punishment is a tricky business. A 100% schedule of praise for every success will probably satiate the subordinates, lead them to discount the supervisor, and cause them to perceive the superior's behavior as ingratiating. Continued praise in front of associates may create considerable feelings of discomfort and defensive feelings. Too infrequent a schedule of contingent praise may raise questions about the superior's motivation. The subordinate's expectation of an extrinsic reward that is contingent on his or her performance may reduce the intrinsic motivation to continue that performance (Deci, 1972). Thus in a field study of 48 health care technicians caring for handicapped and mentally retarded children, Jordan (1986) found that the intrinsic motivation of those whose rewards were contingent on performance decreased 21 or 22 months after the extrinsic incentive program started. The technicians' intrinsic motivation increased if the rewards of the incentive program were not contingent on performance. Their satisfaction with the extrinsic reward of pay was not affected, however.

Mild punishment in private, in the form of suggested corrections by the superior of the subordinate's behavior, may be salutary. Severe punishment, in the form of a suspension, may provoke hostility, resentment, and anxiety. Frequent contingent punishment may increase anxiety to the point where it interferes with the subordinate's performance. Contingent punishment that is too infrequent may allow incorrect habits to become so entrenched that they are difficult to eliminate.

In a nationwide survey of 5,000 employees, almost half the respondents said that the managers at their firm were too lenient with poor performers (Anonymous, 1988a). Nonetheless, according to Veiga (1988), a majority of executives are in favor of candor in dealing with problem subordinates. Unwanted behaviors and outcomes need to be clarified. Both the leader and the subordinate need to acknowledge their responsibilities for the situation. Clear-cut expectations about what will be changed need to be established, and positive support for making a small new change needs to be given.

On the basis of theory and research, Arvey and Ivan-covich (1980) offered a set of propositions that outline the conditions under which punishment is likely to be effective in organizational settings. They stated that punishment should be delivered as close as possible to the time of the subordinate's undesired behavior, should be given by an otherwise close and friendly supervisor, and should be moderate in intensity. Furthermore, punishment should be accompanied by explanation. Alternatives to the undesired behavior should be available.

Contingent motivation remains a reality at the macro level. It was possible to eliminate the draft and change to an all-volunteer military. Opportunities for education, training, and advancement became important

inducements to influence volunteers to enlist in the U.S. Armed Forces, Reserve, and National Guard. But at the time of this writing, as the insurrection in Iraq had heated up and threats to safety and security had increased, enlistment rates had fallen.

### ***A Model for Contingent Reinforcement***

Bass (1985a, pp. 147, 149) presented a model of the most important linkages between contingent-positive and-aversive reinforcement by leaders and the resultant effort of their followers to comply and carry out the transaction:

Leaders ... reward followers to encourage the followers' acceptance of their work roles. Followers comply with the leaders' directions ... to gain the rewards promised by the leaders for such compliance. If the followers succeed, they earn material rewards, ... satisfaction and enhanced self-esteem. ... [In maintaining their] role behavior and ... [in] renewing their efforts ... [to] comply with what is expected of them ... the leaders also clarify such expectations. Such clarification promotes followers' understanding of their roles and builds followers' confidence, further contributing to their compliance.

If the followers fail to comply and the failure is attributed by the leaders [to a lack of] follower clarity and understanding, then the leaders will renew their clarification of what they expect. If the leaders attribute the failure of their followers to lack of motivation [and they wish to be positively reinforcing] the leaders will renew their promises of reward and confidence in the followers. ... [Or if the leaders wish to use] aversive reinforcement such as reprimand, they [run the risk] of followers' anxiety and withdrawal.

Leaders practicing contingent aversive reinforcement ... will foster followers' efforts to comply with the clarified standards to avoid negative consequences for failure. If followers succeed in complying, they avoid being aversively reinforced and may increase in self-esteem and self-reinforcement. If they fail and leaders attribute the failure to lack of clarity, ability, and understanding, the leaders will renew clarification and attempt to improve followers' ability through training, thus increasing the likelihood of ultimate successful performance by followers. On the other hand, if aversively reinforcing leaders attribute followers' failure to comply to [a] lack of follower motivation, they are likely to reprimand or threaten, possibly generating the unintended effects on followers of hostility, apathy, anxiety, and loss of self-esteem. In turn, there will be a reduction in self-reinforced effort and interference with the efforts of followers to comply.

### ***Specific Behaviors and Measures of Contingent Reward and Punishment***

*Contingent Reward Behaviors.* Klimoski and Hayes (1980) found four of six behaviors of supervisors that 231 surveyed subordinates thought were ways their supervisors provided contingent reward: (1) being explicit when giving instructions, (2) allowing the subordinates to be involved in determining standards of performance, (3) giving support for efforts to perform effectively, and (4) being consistent toward subordinates. When a supervisor behaved in these four ways, subordinates expected that their effort would lead to successful performance and that their successful performance would generate commensurate rewards. Two other seemingly relevant behaviors of supervisors—frequency of communications and frequency of reviews—were irrelevant to these subordinates' expectations.

Yukl (1981) used content analysis to derive a category of "structuring reward contingencies"—the extent to which a leader rewards a subordinate's effective performance with tangible benefits, such as a pay increase, promotion, more desirable assignments, a better work schedule, or more time off. Examples of contingent

reward structuring included: "My supervisor established a new policy that any subordinate who brought in a new client would earn 10 percent of the contracted fee" and "My supervisor recommended a promotion for a subordinate with the best performance record in the group" (p. 122).

Leaders who give contingent rewards establish "contracts" with subordinates to set goals for each important aspect of a subordinate's job, measure the subordinate's progress toward reaching the goals, and provide concrete feedback. Yukl (1981, p. 123) cited these examples: "The supervisor held a meeting to discuss the sales quota for next month" and "My supervisor met with me for two hours to establish performance goals for the coming year and to develop action plans"

Using factor analyses of survey results, Sims (1977) found that contingent reward took two main forms: (1) praise for work well done; and (2) recommendations for pay increases, bonuses, and promotions. Also, there may be commendations for meritorious effort and honors for outstanding service. The first positive-reward behavior factor explained 37% of the variance among the supervisors. Items most highly correlated with this first factor included: "Your supervisor would show a great deal of interest if you suggested a new and better way of doing things." "Your supervisor would give you special recognition if your work performance was especially good." "Your supervisor would personally pay you a compliment if you did outstanding work" (p. 126). The second factor, which accounted for 18% of the variance, dealt with recommendations for promotion and advancement. Items highly correlated with the second factor included: "Your supervisor would see that you will eventually go as far as you would like to go in this organization, if your work is consistently above average." "Your supervisor would recommend that you be promoted if your work was better than others who were otherwise equally qualified." "Your supervisor would help you get a transfer if you asked for one" (p. 126). Bass and Avolio (1989) validated a scale of 10 items within the Multifactor Leadership Questionnaire (MLQ) to measure contingent reward in an exchange context that contained items such as: "Tells me what to do if I want to be rewarded for my efforts" and "There is close agreement between what I am expected to put into the group effort and what I can get out of it."

*Management by Exception and Contingent Punishment.* Yukl and Van Fleet (1982) found numerous critical incidents of management by exception and contingent punitiveness among officers in Korea, such as: "Checks to see that tasks are accomplished satisfactorily." "Shows concern about the appearance of cadets." "Expresses disappointment that the unit did not perform better." "Explains to a person why he is being disciplined." Sims (1977) uncovered a factor of supervisory behavior that dealt with contingent punishment. The items include: "Your supervisor would get on you if your work was not as good as the work of others in your department" and "Your supervisor would give you a reprimand [written or verbal] if your work was consistently below acceptable standards." As was noted earlier, a contingent-aversive or -punitive factor is involved in the practice of management by exception. Hater and Bass (1988) and Yammarino and Bass (1988) created factored scales of active and passive management by exception within the MLQ. The active practice of management by exception (MBEA) dealt with monitoring and searching for subordinates' deviations from standards and making suitable corrections ("Checks to see if things are going along all right"). The passive practice of management by exception (MBEP) involved reacting only when deviations were brought to the manager's attention ("Endorses the adage, 'If it ain't broke, don't fix it'"). Compared with other ways of measuring leadership performance, these behavioral scales of contingent reinforcement by leaders tend to be relatively free of the usual biases of respondents to rate according to the social desirability of the behaviors (Podsakoff, Todor, Grover, & Huber, 1984) or the raters' implicit theories of leadership (Bass & Avolio, 1988). MBEA tends to correlate with contingent rewarding whereas MBEP tends to correlate with laissez-faire leadership (Bass, Avolio, & Jung, 1999).

*Scales of Contingent Reinforcement.* The Contingency Questionnaire (Johnson, 1970; Reitz, 1971) assessed the extent to which subordinates perceive contingencies between their performance and how the organization responds to it. Three factors emerged: (1) supportive instrumentality—the contingency between

the subordinate's behaviors and a supportive or rewarding organizational response; (2) punitive instrumentality—the contingency between the subordinate's undesirable behaviors and the administration of punitive events by the organization or the withdrawal of rewards; and (3) advancement instrumentality—the contingency between the subordinate's behavior and the subordinate's advancement in the organization. The three factors accounted for approximately 50% of the common variance in the scale of 20 items. House and Dessler (1974) developed four-item scales to measure leader-contingent approval behavior and leader-contingent disapproval behavior. Scales to assess noncontingent reward and noncontingent sanctioning were also added. Hunt and Schuler (1976); Fulk and Wendler (1982); and Podsakoff, Todor, and Skov (1982) likewise developed and evaluated the Leader Reward and Punishment Questionnaire, which had a total of 23 items to measure both contingent and noncontingent reinforcement by the leader. In typical items from the most recent report, supervisors were described in paraphrase as follows: *Contingent reward*—personally compliments me when I do outstanding work; *Noncontingent reward*—Praises me when I do poorly as when I do well; *Contingent punishment*—would reprimand me if my work was below standard; *Noncontingent punishment*—holds me accountable for things over which I have no control. Schriesheim, Hinken, and Tetrault (1988) corroborated the factorial validity of the four dimensions of contingent reward, noncontingent reward, contingent punishment, and noncontingent punishment with the responses of 176 aircraft controllers and 375 employees of a psychiatric hospital to a questionnaire in which they were asked to describe their supervisors.

## Reinforcement and the Emergence of Leaders

---

In addition to the use by leaders of contingent reinforcement to develop and maintain effective follower compliance, contingent reinforcement processes also can explain who emerges as a leader. A variety of experiments have been conducted to show how reinforcement can increase individual members' attempts to lead and their processes in leadership.

Who attempts and continues to lead and who attempts and continues to follow in newly formed groups without appointed leaders can be explained by the differential reinforcement experiences of the various members of the groups. To be successful in influencing others, one must attempt to lead. Such attempts to lead are increased by the positive reinforcement of success as a leader and are decreased by failure and aversive reinforcement. If one member's attempts at leadership are inhibited by failure, the leadership attempts of others may increase. The positive reinforcement of one member can result in "crowding out" the other members. Contrived reward has been applied in experiments to test its efficacy in reinforcing attempts to lead the interaction process, as well as its efficacy in reinforcing the probability of successfully leading others.

### ***Reinforcing Attempts to Lead***

Bavelas, Hastorf, Gross, and Kite (1965) assessed the amount of activity of each participant in initial discussions without an appointed leader. In a second session, only one particular member of each discussion group was reinforced for participation, by the flashing of a green light. Additionally, in some of these groups the participation of the remaining members was inhibited by the flashing of a red light. When other members were not inhibited by a red flashing light, those who were positively reinforced with the green flashing light significantly increased their talking (which is highly correlated with attempts to lead in initially leaderless discussions). But it was necessary to use positive reinforcement (the green flashing light) with the initially least active talker and to inhibit (with the red flashing light) the initially most active talker in order to increase the amount of talking by the originally least active talker. The least active talker's gain was mostly at the expense of the originally most active talker.

Jaffee (1968) and Jaffee and Skaja (1968) reinforced the leadership acts of one member of pairs of experimental partners. The number of leadership attempts by the members who were reinforced by the appearance of a light significantly exceeded attempts by the nonreinforced and control participants. The effects lasted over a test period of one week and were found to generalize to a different experimental situation. Zdep and Oakes (1967) likewise demonstrated that reinforcement of a group member's leadership acts resulted in an increase in talking and leadership. In the same way, Binder, Wolin, and Terebinski (1965, 1966) and Wolin and Terebinski (1965) controlled the proportion of decisions as a leader for which each member of a group was reinforced. The resulting emergence as a leader fit a Markov mathematical model. Increases in leadership behavior were found to be responsive to changes in such rates of reinforcement.

Aiken (1965a) rewarded a group member in a second session who had talked the least in a preceding session. The other three members were punished for speaking in the second session. The rewarded member's verbal output significantly increased in comparison with the output of unrewarded control group members, but punishment did not significantly decrease output. After the second session, the three unrewarded members of the experimental group rated the rewarded member higher than members of the control group rated each other in leadership, participation, and self-confidence.

### ***Reinforcing Successful Leadership***

In these experiments, mainly with school pupils and college students, group members whose leadership was reinforced with success rather than failure were more likely to increase their influence over the other members. Mausner (1954a) gave participants either positive, negative, or no reinforcement when they were working alone on a judgmental task. When combined in pairs, the non-reinforced partners had a significant tendency to shift their judgments to comply with those of their reinforced partners, whereas the reinforced participants did not change. The participants who had received positive reinforcement were significantly less influenced by their partners than were those who had received negative reinforcement. Thus Mausner demonstrated that the participants' perception of the success of their partners gave them prestige and reinforced their expectation of future success. The participants who worked with previously successful partners were significantly more influenced by them than were those who worked with previously unsuccessful partners in a judgmental task. Banta and Nelson (1964) showed that for positively reinforced participants, the probability of having their suggestions adopted increased over 60 trials, whereas for negatively reinforced participants, the probability decreased. Kanareff and Lanzetta (1960) also found that the tendency to be imitated by others was related to the rate at which the imitated participant was positively reinforced. McClintock (1966) used paid accomplices who either supported, shifted their support of, or did not support the leaders of discussion groups. It was found that leaders evidenced more release of tension, more positive affect, and more task-oriented responses when they were supported than when they were not supported.

Cohen and Lindsley (1964) gave pairs of subjects a monetary reward for social responses or punished them, by blacking out the room, for individual (nonsocial) responses. They rewarded acts of leadership by opening a panel that permitted subjects to see each other briefly. Differential leadership responses were established by the differential reinforcement procedures. James and Lott (1964) rewarded some members of an experimental task group with six nickels, rewarded others with three nickels, and did not reward still others. Those who were rewarded with six nickels chose each other significantly more often than did those who were rewarded with three nickels or those who were not rewarded. G. Gardner (1956) studied groups of boys who were assigned fictitious scores for success in operating switches that activated various combinations of lights. The scores correlated .93 with their nomination as team captain. Observations of success appeared to reinforce the group's perception of a member's suitability for the leadership role. Katz, Blau, Brown, and Strodtbeck (1957) found

that the greater the extent to which the leader's suggestions were reinforced by the follower's acceptance and support in the first session of a discussion task, the more the leadership was retained in later sessions. Likewise, York (1969) and Hastorf (1965) demonstrated that reinforcement of member's behavior in a group significantly increased their leadership.

Hamblin, Miller, and Wiggins (1961) studied the effects on a group's morale of the leader's competence, reinforcement of the leader, and conflicting suggestions by group members. Reinforcement rate, perceptions of the leader's competence, manipulation of the leader's success, and the group's morale were all highly and significantly intercorrelated. The members' opposition to the leaders' suggestions was reduced by reinforcement of the leader, the leader's success and competence, and the group's morale. Mausner and Bloch (1957) found that reinforcement of a partner and the partner's prestige interacted in a judgmental task. That is, both the partner's prestige and earlier reinforcement contributed to the partner's influence in a condition of success but not when failure was contrived. Reinforcement did not overcome the effect of a partner's failure to make correct judgments in a previous situation.

*Caveats.* Some qualifying considerations are in order. Reinforcements may have unintended and unwanted effects on attempted and successful leadership. Zdep (1969) assembled groups of four members in which one member scored either high or low in self-reported leadership (the Leadership Scale of the California Psychological Inventory). Under the experimenter's reinforcement, the participation rate increased for high scorers but not for low scorers. As the high scorers' rate of participation rose, the subsequent leadership ratings by the other members increased. But the experimenter's reinforcement of one member built up expectations about that member among the others. Low scorers who failed to respond when given the reinforcement were rated as poorer leaders than low scorers who were not so reinforced. Aiken (1965b) also found that the use of reinforcement for operant conditioning of specific behaviors, such as giving suggestions and asking for contributions, resulted in marked changes in leadership style but produced a tense, anxious leader. This finding suggested that simple reinforcement technology, by itself, may be inadequate for leadership training. The shaping of one member's responses must take into consideration the larger context of the interaction with other active participants.<sup>3</sup>

## The Dynamics of the Exchange Relationship

---

The superior-subordinate relationship has been conceived of as a social exchange or negotiated transaction. This conception led to a fully developed theory to explain the effects of leadership on the compliance of subordinates. Leader-member exchange implied an informally developed role—one that was negotiated between each individual group member and the leader (Graen, 1976).<sup>4</sup> Coworkers may get involved in the role definition, but the leader, in particular, has a vested interest in the member's role. The definition of a member's role indicates what the member and the leader will expect the member to do. This was found with 62 new nonacademic employees on a college campus by Graen, Dansereau, Minami, and Cashman (1973). Given the leader's control of reinforcements, the interpersonal exchange relationship of the member and leader is particularly important in shaping the member's performance.

The leader-follower transactional exchange is the essence of the dynamics of leadership, according to Hollander (1958, 1978). Hollander concluded that the leader and the follower enter into an exchange that begins with negotiation to establish what is being exchanged and whether it is satisfactory. The exchange results in the follower's compliance for the leader's assistance in pointing the way toward the attainment of mutual goals.

### *Idiosyncrasy Credit*

In real life, there is no experimenter to reinforce the attempts of one member rather than another to lead. On a playing field with similar personalities and a common situation, what, then, makes one member a leader and another a follower? According to Hollander, it is a matter of how much *idiosyncrasy credit* each member has previously earned. The interplay that determines who will lead and who will follow builds up idiosyncrasy credit for the emerging leader relative to the follower. Competence in the group's task and conformity to the group's norms earn idiosyncrasy credit for a member and, as a consequence, emergence as leader or success as an appointed leader. A buildup of such credit makes subsequent initiatives even more likely to be accepted and strengthens the member's status as a leader. With idiosyncrasy credit, the emerging leader can deviate from the group's norms in a way that is not permitted to those without such credit. Newcomers, for instance, are unlikely to have the necessary credit, although some may bring derivative credit with them from another group as a consequence of their reputation in that group. There is a complex interplay between the requisite competence and the requisite conformity in maintaining idiosyncrasy credit. Alvarez (1968) observed that a leader's greater deviance from the norms was tolerated when it was accompanied by the group's success. In a study of a simulated organization, Alvarez found that the leader lost credit at a slower rate than did the followers, but only in successful organizations. In unsuccessful organizations, the leader lost credit at a faster rate than the followers.

Consistent with the concept of idiosyncrasy credit, Zierden (1980) suggested that leading through the followers' points of view is the way to achieve success and effectiveness as a leader. Litzinger and Schaefer (1982, p. 139) saw the fundamental conformity of leaders to their followers' norms and values as being manifested in the way the Pope John Paul II called himself "The Servant of the Servants of God" and in Hegel's conception of leadership: "Leadership is possible ... not only on the condition that followership has been learned, but on the more radical condition that the leader has known ... the travail of the follower; he must here and now incorporate within himself all that the follower is. The school for leadership is indeed followership, a followership that is fully preserved within leadership, but transformed for having moved beyond itself." Litzinger and Schaefer also saw the idea that good followership precedes good leadership in the West Point faculty doctrine that leadership is developed by cadets first learning how to be good followers. Prior to gaining powerful office, many world leaders, such as Otto von Bismarck and George H. W. Bush, were seen as "faithful takers of orders." To be elected, the first President Bush strongly espoused the norms of the majority of the electorate about law enforcement, the flag, taxes, education, and the environment. Once he was elected, his actions could deviate to some extent from these espousals without alienating too much of his majority constituency. President Bill Clinton consulted public opinion polls daily. President George W. Bush spoke of the political capital he earned by winning reelection in 2004, which would make it possible for him to launch new programs. But he failed to recognize that he could rapidly lose his credit with increasingly unpopular policies such as "staying the course" in Iraq. By February 2006, according to a Zogby-LeMoyne (2006) poll, only 23% of 944 American soldiers serving in Iraq supported staying as long as necessary. They agreed with polls of previous civilian majorities that the policy was wrong. But President George W. Bush said that to be successful, all he had to do was continue to ignore his critics and please the majority of voters who had elected him. By 2008, it was clear that a majority of citizens had no desire for an open-ended war in Iraq and wished for an exit strategy to be developed.

*Limitations on Idiosyncrasy Credit.* With idiosyncrasy credit, the leader can step out from the rest of the pack and suggest innovations that will bring about changes in the group. Nevertheless, although the leader is able to deviate from the group's norm, he or she must continue to pay attention to the group's norms, values, and standards in order to remain successful in influencing others. Holders of idiosyncrasy credit have other limitations on the deviance that they are permitted. For example, they have less latitude to deviate from particular role obligations (Hollander, 1961a, 1961b), although they may deviate from norms with less cost

than other members. In effect, the leader's freedom to deviate from general norms is exchanged for conforming more closely to the expectation others have about the requirements of the leader's role.

A leader will lose much of his or her idiosyncrasy credit by an outrageous violation of the members' expectations. In 2006 President George W. Bush got into trouble with his supporters as well as his critics and lost a lot of credit when, after five years of creating a climate of fear by maintaining that terrorism was the greatest continuing threat to national security and well-being, he gave immediate and strong support for a firm owned by an Arab country to take over the management of six U.S. seaports (Krugman, 2006). Ironically, the port deal was innocuous. Still, his policy of "staying the course" in Iraq became increasingly unpopular and resulted, in June 2006, in his accepting a plan for a phased withdrawal of American troops.

There is experimental evidence about possible limits of deviation from norms. Hollander (1961a) conducted an experiment in which the participants were given brief descriptions of persons who were to be ranked from high to low in accorded status. The participants were then given lists of behaviors that might be exhibited by the persons whom they had ranked. As the perceived status of those who were ranked increased, the participants expressed progressively less disapproval for "suggesting changes from group plans" and "discussing group concerns with outsiders." However, "interrupting others to make comments" was increasingly disapproved for persons with increasing status. High-status members were permitted to innovate group changes but were not expected to interrupt low-status members.

Looking at the same issue, Michener and Lawler (1975) found that group members were more likely to endorse the continuance of leaders in their positions when the groups were positively reinforced by success in their efforts, when the members got more rewards than the leader, or when the leaders were not permanently fixed in the office. But the members were less enthusiastic about endorsing the continuance of leaders in office if the leaders were inconsistent in their competence or fairness. Polansky, Lippitt, and Redl (1950a) and Grosser, Polansky, and Lippitt (1951) showed that those group members who attempted to be more influential and those who were more successful in this attempt were more susceptible to contagious influence from other members. Compared with members who tried but failed to exert influence on the group, they were more likely to act in reference to the demands of the group situation than in terms of their own needs. Although they were able to react spontaneously to others and to initiate spontaneity in others, they also felt secure enough to resist direct attempts by others to influence them. They could maintain conformity to the steady state as well as enlarge the other members' freedom to act.

### ***Negotiation of Equity***

In the social exchange, followers may exert influence and make demands on the leader. Negotiation may be required about what will be done and by whom. The negotiation may consider the distribution of effort and rewards between the leader and the followers, including need, justice, merit, equity, and fairness. Dyer, Lambert, and Tracy (1953) observed that in the more effective of two bomber wings (the wing in which the most successful leadership was likely), there were more favorable attitudes toward the method of allocating rewards and punishments. A satisfactory interchange between the leader and followers has been found to be enhanced by mutual trust (Deutsch, 1973), a sense of fairness and equity, mutual support, involvement, and wider latitudes of acceptance (Dansereau & Dumas, 1977; Graen, 1976). But the interdependence of the followers affected how important equity was the satisfactory exchange. According to Miller and Hamblin (1963), differential rewarding for relative achievement decreased a group's productivity when the members were highly interdependent but not when they were less interdependent.

True equity would require that rewards be commensurate with contributions. But equity is relative. Members judge the equity of their costs and benefits in comparison with the costs and benefits of others

whom they regard as similar to them (J. S. Adams, 1963). Negotiations may be between the leader and the group or between the leader and each individual member. Graen and Cashman (1975) suggested that such individualized exchanges will be closer to the parties involved than an exchange between the leader and the group would be. Such closeness will increase acceptance of more responsible tasks by the individual members and also increase the leader's assistance of the members. There will also be more support, sensitivity, and trust in the closer relationship.

## Limits to Contingent reinforcement

---

How much can a leader depend on using contingent reinforcement? What limits it? What moderates its use and its impact on subordinates? Like most other concepts and practices in social science, contingent reinforcement is neither a universal panacea nor of trivial importance. Rather, the limitations to its use and effectiveness need to be detailed. For instance, subordinates may take shortcuts to complete the exchange of reward for compliance. Quality may be sacrificed to obtain rewards for quantity of output. Complicated piece-rate, reward, and bonus systems generate ambiguity and are likely to induce game playing and a fear of rate busting. Subordinates may react defensively. Reaction formation, withdrawal, or hostility may ensue. Also, the schedule of reinforcements—their timeliness, variability, and consistency—will have considerable effect on the inducements (Bass, 1985a).

Perceptions of injustice may outweigh cost-benefit considerations. Tyler, Rasinski, and McGraw (1985) found that the changes in the governmental benefits that 584 undergraduates and 300 Chicago residents personally received were less important to them than more abstract judgments of injustice when they endorsed their leaders. In the same way, federal managers regarded merit-based pay as inequitable and as undermining their agencies' effectiveness. However, they believed that performance appraisal and performance standards contributed to supervisor-subordinate communications and to the planning of work, particularly if the appraisals and standards focused on the subordinates' development (Gaertner & Gaertner, 1985). Silverman (1983) argued that the merit-pay contingent reward system in the federal government failed for numerous political, economic, and psychological reasons, including open-ended regulations, drifting implementation policies, overcomplication, inconsistent treatment of employees, the compression of managers' pay, and simultaneous budget reductions. To this list could be added administrative blunders and unintended statutory provisions. Pearce, Stevenson, and Perry (1985) collected data two years before and two years after the introduction of a merit-pay program in the Social Security Administration and found no improvement in organizational performance.

### ***Pay and Performance***

As was already noted, contingent rewards for compliance may entail recommended increases in pay or advancement. If it is possible to make pay fully contingent on performance, such as by placing employees on a straight piece-rate or straight commission basis, productivity may rise as much as 30%, according to some studies. But in practice, for most work, there is likely to be little linkage between pay and performance, despite revealed wisdom to the contrary. Often when workers are placed on a piece-rate or straight commission basis, the work group exerts strong pressure to restrict all its members to conform to the same standard output so that all earn the same pay (Rothe, 1960, 1961). At the executive level, Barkema and Gomez-Mejia (1998) have argued for linking pay to performance, but within a larger framework of a long-term orientation and relative to a designated level of compensation. They recognize that in addition to performance, compensation should reflect market conditions, peer compensation, personal and positional factors, and the size of operations.

Miscellaneous other factors need to be considered, such as the tax system, industry regulation, and the ownership structure.

In Japan, a familiar practice is to link pay and promotion primarily to age and seniority, not meritorious performance. In the United States, according to an interview study of a representative sample of 845 U.S. workers by Yankelovich and Immerwahr (1983), only 22% said there was a direct relationship between how hard they worked and how much they were paid. A similar representative national survey of 5,000 U.S. employees found that only 28% saw a correlation between the salaries and performance of workers (Anonymous, 1988b). In the first survey, 61 percent said they preferred a closer link between performance and pay.<sup>5</sup> In the second survey, almost half the respondents said that managers at their firms were too lenient with underperformers and continued to reward them despite their continuing poor performance. Even when rewards have been found to be distributed according to merit, the link is modest. Lawler (1966c) surveyed 600 middle-and lower-level managers in several organizations and discovered only a small correlation between their pay and their performance ratings. In examining salary ranges at a single corporation, Patten (1968b) found no statistically significant evidence that employees whose performance was rated more highly were also paid better. Heneman (1973) reported one instance of a high correlation between performance and reward: .65 for a sample of 51 managers. In line with these contradictory findings, Kopelman and Reinharth (1982) found much variation in the correlation between performance and reward among 10 branches of a large financial organization.

### ***Contingent Recommendations***

In contracts, the compensation of chief executive officers (CEOs) is usually related to industry norms and comparable firms and depends not only on a CEO's performance but also on the size and scope of the organization (Deckop, 1987). Firms going into bankruptcy may award the CEO a multimillion-dollar compensation because of contractual obligations, not the CEO's performance. However, Gomez-Mejia, Tosi, and Hinkin (1987) found that the compensation of CEOs was linked to their performance if the firms were owner-controlled.

In simulations, recommended pay increases by 4,255 managers in an international survey correlated with meritorious performance, although they were modified extensively outside North America for other reasons, such as family considerations and personal circumstances (Bass, Burger, et al., 1979). Nonetheless, awarding more pay or less pay to subordinates seems to be a matter of the recommenders' values. Bass (1968a) reported that students' value orientations were related to their generosity in recommending pay increases for fictitious engineers. Students who were lower in intelligence and ability and those who scored high in social and service values, as opposed to theoretical and economic values, were more generous in recommending salary increases. In the international survey, Bass, Burger, et al. (1979) found that more successful managers recommended significantly greater salary increases for a fictitious average meritorious engineer, but they were no different from their slower-climbing counterparts in their salary recommendations for engineers on other grounds. In another simulation, Martin (1987) showed that recommendations increased for both meritorious performance and specialized expertise needed in particular circumstances.

### ***Moderating Conditions***

Time and events can modify the influence of the same behavior by leaders that was effective earlier, and subordinates' reactions to it. Similar behavior by the leader can be ineffective (Sleeth & Showalter, 2000). This is a case of negative transfer of an old response to a new stimulus. A breakdown can occur. A leader can lose

control of a situation by ignoring the changes caused by an event. For example, suppose that a leader is accustomed to loosely monitoring an operation, but a new employee who needs close supervision enters the scene. The same leadership is now inadequate. A breakdown can occur in the operation.

In managerial in-basket experiments by Martin and Harder (1988), students' use of simulated financial-related rewards, such as profit sharing, office space, and company cars, was contingent on satisfactory performance; but simulated interpersonal rewards, such as help or friendliness, were distributed according to subordinates' needs.

Managers may lack the necessary reward power required to deliver recommendations for pay increases. Those who can fulfill the self-interested expectations of their subordinates gain and maintain the reputation of being able to deliver pay, promotions, and recognition. Those who fail to deliver lose that reputation in the eyes of their subordinates and, therefore, no longer can be seriously seen as effective contingent reward leaders (Tsui, 1982). Worse yet, they may be seen as having become more punitive, and their legitimacy and influence will be reduced (Greene & Podsakoff, 1979, 1981). Subordinates' resistance will increase according to Tepper, Schriesheim, et al. (1998), who asked a sample of 389 respondents to recall an instance within the last month in which they resisted and avoided doing something their supervisor asked them to do. Thirty-two scale items were extracted from the responses. These items formed two factors: (1) passive resistance ("I procrastinate, hoping that my supervisor will forget about it"; "I say OK but don't get to it"; "I don't do it in a timely manner") and (2) active resistance ("I explain that the request will not yield the expected results"; "I explain that it should be done differently"; "I present logical reasons for doing the task differently or at a different time"). In multiple regression analyses for 133 subordinates of 50 managers in a mental health rehabilitation organization, scores for passive resistance were higher if they worked for abusive supervisors and were less conscientious on the NEOAC Personality Inventory. Active resistance was higher if they worked for higher-status managers and were more open and less agreeable on the personality inventory.

Yukl (1981) enumerated the conditions that made it possible for managers to engage profitably in the contingent rewarding of their employees. As was already indicated, the managers needed substantial authority and discretion to administer tangible rewards to their subordinates. Their subordinates had to be dependent on them for access to the valued rewards. It was necessary for performance outcomes to be determined primarily by the subordinates' efforts and skills, rather than by events beyond the subordinates' control. It was also necessary to be able to measure the subordinates' performance accurately. Finally, contingent reward was likely to have more impact if the work was "repetitive, boring, and tedious, rather than varied, interesting, and meaningful" (p. 141).

### ***Positive versus Negative Reinforcement***

In the Soviet Union, workers were fined for failing to meet production quotas. Workers everywhere face suspensions for infractions of rules. A sufficient cause for dismissal may be simply displeasing a domineering boss. Feedback can be negative as well as positive. As indicated in earlier chapters, such contingent penalization, in general, is less effective than contingent reward. After observing 126 incidents of feedback, Balcazar, Hopkins, and Suarez (1985–1986) noted that feedback does not uniformly improve performance. In a survey by Ilgen, Fisher, and Taylor (1979), the role ambiguity of 527 Australian employees was reduced much more by positive rather than negative feedback about their performance. Although the effect of positive feedback is to reinforce behavior already displayed and hence to generate more of the same, for negative feedback to be effective, changes are required in performance as a consequence of changes in perception, motivation, or learning. Also, negative feedback may fail to work because of its unfavorable motivational impact on the subordinate's self-image.<sup>6</sup>

Disciplinary actions may cause emotional reactions and a deterioration of supervisory-subordinate relations instead of their intended correctional effects, according to a survey of 177 firefighters in eight cities (Greer & Labig, 1987). The unintended results will occur if the administration of the actions is unpleasant, if poor relations already exist, and if the supervisor is judged to be inaccurate in his diagnosis and fails to represent adequate reasons for the disciplinary action.

Despite its potential to contribute to conflict and its relatively lower contributions to the improvement of subordinates, negative reinforcement is often used. There are many reasons for “accenting the negative,” despite the greater utility of emphasizing the positive and despite the decreased contribution of such leadership to the performance of subordinates. For instance, a supervisor may have a large span of control; as a consequence, the supervisor’s time may be fully occupied with monitoring deviations from the standard. Failure to pay attention to the deviations may invite disaster. A preoccupation with prospective failures will inhibit attention to the positive, particularly in the absence of clear goals, clear policies, and long-term objectives. Managers may lack the power to provide or recommend rewards. Faced with continuing demands for productivity, they will increase their tendency to use punishment, especially since managers report less difficulty identifying poor performance than good performance (Podsakoff, 1982).

Performance of subordinates that is below standard is more salient for a supervisor than performance that exceeds the standard (Larson, 1980). Thus subjects who were acting as supervisors were found, in a laboratory experiment by Fisher (1979), to require a smaller sample of work to evaluate a subordinate who was performing below average than to evaluate one who was performing above average. Larson (1980, p. 199) offered the following reasons for the greater sensitivity of supervisors to the failure rather than to the success of subordinates: “The criteria for minimally acceptable ... performance are frequently more clearly defined than are the criteria for superior performance; poor performance often has a more significant impact upon the work group’s functioning than does superior performance.” Supervisors are likely to be more sensitive to their subordinates’ failure if how well the supervisors do their job depends on how well the subordinates have completed assignments and if, as was noted earlier, the supervisors’ pay, recognition, or promotion depends on the subordinates’ performance (Larson, 1980).

### ***Other Problems***

Contingent reinforcement may fail because there is no clear differentiation of reinforcements for functionally adequate and functionally inadequate performance. Praise alone, without other accompanying rewards, may not work. Feedback may lack impact because goals have not been clearly set. In addition, to understand the effects of reinforcement leadership, according to Fedor, Buckley, and Eder (1990), the impact on a subordinate’s behavior of a supervisor’s attempts at differential reinforcement of the subordinate will depend on the subordinate’s perception of the supervisor’s intentions: “Does the supervisor want to dominate me, to focus my attention on unit standards, to support me, or to urge me to increase my productivity?” Many of the 220 subordinates in this study believed it was most likely that their supervisor wanted to dominate them rather than to support or assist them in achieving higher performance levels. This belief may be due, in part, to the tendency of subordinates to attribute their poor performance to situational causes like bad luck or difficulties with the problem, equipment, or supplies. As the observers of the subordinates’ behavior, the supervisors, especially if they are unfamiliar with the specific tasks involved, are more likely to attribute the poor performance to the subordinates’ lack of ability or a lack of effort. Mitchell and Kalb (1982) showed that if the supervisor had no experience with the subordinate’s job, he or she was less likely to accept situational reasons for the subordinate’s performance. Whether a supervisor likes or dislikes a subordinate also makes a difference. According to an experiment and field study by Dobbins and Russell (1986), although leaders may

attribute the same reason for the poor performance of subordinates they like and subordinates they dislike, they will tend to act more punitively toward the subordinates they dislike and will be less inclined to punish the subordinates they like.

*A Jackass Theory?* Many scholars, consultants, and practitioners find contingent reinforcement a full and sufficient driving force for predicting, controlling, and understanding leader-follower relations. Many others are considerably less confident. Still others find that faults and failures override its successful applications. Levinson (1980) termed contingent reinforcement the “jackass theory” of leadership: When you, as a subordinate, are between a carrot and a stick, tempted by the carrot or threatened with the stick, it makes you feel like a jackass. Your self-esteem as a mature, conscientious, worthy individual is diminished. Furthermore, when you are between a carrot and a stick, you may see yourself in a contest that requires agility to reach the carrot or to avoid the stick. Or you may be immobilized by uncertainty, not knowing whether the benefits of the carrot are outweighed by the costs of being beaten by the stick. Feelings of being manipulated may outweigh responsiveness to the contingent rewards. Drawing from Dostoyevsky, Vice Admiral J. B. Stockdale (1981, p. 15) argued that people do not like to feel they are being programmed: “You cannot persuade [people] to act in their own self-interest all of the time. A good leader appreciates contrariness. . . . Some men all of the time and all men some of the time knowingly will do what is clearly to their disadvantage if only because they do not like to be suffocated by carrot-and-stick coercion. I will not be a piano key; I will not bow to the tyranny of reason.”

As Maccoby (1988) noted, with increasing technology and its servicing, employees are expected to work and think as mature persons. They are expected to make judgments; to solve problems; to develop good working relationships with colleagues, clients, and customers; and to be committed to and understand what they are doing. These expectations require a broader view of what motivates people to work. About half the sample studied by Maccoby regarded themselves as experts who got much of their reward from doing the work itself. Being helpful to others and maintaining good relationships are important to many employees. Although about a fifth of the sample were interested in material rewards, their self-development of a full career and personal life was more important to them.

Simple carrot-and-stick supervisory reinforcement clearly has considerable limitations. It will not work well in the absence of a trusting relationship between superiors and subordinates. Subordinates need to trust that their leaders can fulfill their promises. Leaders must be able to trust that their subordinates will comply as expected rather than take shortcuts or superficial actions to achieve promised rewards (Dwivedi, 1983). Many other forces constrain the superiors’ intentions when they use reinforcement to deal with their subordinates’ performance. These forces include information requirements, conflicting interests, biased perceptions, differential use of reward and punishment, and individual differences in reaction to contingent rewards.

*Conflicts.* Contingent reinforcement may fail to achieve the compliance of subordinates because intra-personal or interpersonal conflicts may be involved. For instance, the leader may establish dyadic contingent reinforcement with each member of a group, although the members need to reach decisions in a highly coordinated fashion. The members may suffer from *pluralistic ignorance*, each subordinate not knowing every other member’s views (Schanck, 1932). Or the members may find the costs greater than the promised benefits and, wishing to avoid confrontation with the leader, they may withdraw into anomie, apathy, or alienation. Followers may also rationalize, concluding that the leader’s demands on them are excessive or that the leader is incompetent. Ansbacher (1948) interviewed German prisoners of war during World War II, providing extensive evidence that although many continued to esteem Adolf Hitler and maintain confidence in him, they personally disagreed with him on many significant issues and interpreted his directions to suit their own needs. For example, Hitler demanded that Germany should never capitulate. But a majority of those who had confidence in him decided that he did not really want unnecessary bloodshed; therefore, they thought he would consider it his duty to end a lost war. And so, despite the fact that Hitler issued explicit orders that

soldiers were to fight to the end, his supporters rationalized that it was all right to surrender.

*Ephemeral or Negative Effects.* Contingent reinforcement may succeed only in the short run, or sometimes not at all. In some circumstances, feedback about one's job performance actually may be counterproductive and yield negative results, as Kiggundu (1983) reported for 138 employees at a head office. Greene's (1979a) longitudinal study of new employees during their first nine months of work found that the subordinates' performance, compliance, and satisfaction improved because of contingent rewards by the leader. Satisfaction accompanied the leader's rewarding of subordinates for their good performance, and dissatisfaction emerged from the leader's punishment of the subordinates for their poor performance. But the effects mainly occurred earlier in the subordinates' employment. Contingent reinforcement may generate conflicting deleterious side effects that contribute to long-term failure. For example, subordinates may continue to accept the top managers' direction but displace their aggression onto less powerful targets. Purcell (1953) found that packinghouse employees were more ready to blame their lower-status supervisors than their top managers for difficulties entailed in trying to comply with directions.

*Biased Perceptions.* Despite Peterson's (1985b) conclusion that, in general, rewards for good performance tend to be effective, many errors are likely to be made in the application of contingent reward. Leaders' performance evaluations are likely to be biased. Subordinates are likely to overestimate their own performance and that of their peers. Also, biased judgments may work both ways. Subordinates may inflate the attractiveness of an order to justify their compliance with it (Campbell, Dunnette, Lawler, & Weick, 1970). Furthermore, subordinates' attributions of the reasons for the leader's behavior will affect their satisfaction with it. And a leader whom subordinates judge to be willing but incompetent may be more forgivable than a leader who is judged to be competent but unwilling (Bass, 1982). The same leadership behavior—say, initiation of structure—has been seen more favorably by managers than by graduate students, although a more punitive emphasis on pushing for production was seen more unfavorably by both managers and students (Butterfield & Bartol, 1977).

*Contingent Reinforcement May Be Avoided or Ignored.* The use of contingent reinforcement is not essential for effective leadership or for a productive organization. Jacoby, Mazursky, Troutman, and Kuss (1984) found considerable avoidance of opportunities for obtaining feedback or ignoring it if it was given. In their simulation, they had 17 security analysts decide which common stocks represent a good purchase. During a sequence of four periods, the analysts were able to request feedback about their performance. The feedback provided results that could have predictive or explanatory value for the analysts. Some analysts did not request or consider any feedback, and other analysts were not consistent about doing so. The researchers found that the better-performing analysts were more likely than the poorer-performing analysts to ignore feedback that had no predictive or explanatory value.

*Communes.* When selected individuals and groups have a strong feeling of community, they have been able to maintain the high productivity that is associated with a strong work ethic without using reinforcement as the basis of their motivation to work. Communes depend even more strongly on trusting relationships than organizations where motivation to work is based on contingent reinforcement. In the Israeli kibbutz, "The underlying philosophy of the kibbutz insists that there must be no linkage between what a particular individual is able to contribute through his efforts and ... what rewards he is entitled to. ... In the kibbutz, everyone is entitled—as a human being and as a member of the community—to the comprehensive satisfaction of his needs ... subject to limitations due to the economic capacity of the particular kibbutz. ... This right is no way infringed if, because of health or for any other reason, he is unable to contribute to the kibbutz anything at all. In this respect the kibbutz constitutes a full-scale insurance system for every member. ... [Although there may be some slackers] the large majority of kibbutz members generally perform at their best, and the prevailing differences in efficiency are the result of individual differences in ability, rhythm, [and] energy, ... rather than of deficient motivation" (Tsur, 1983, pp. 24, 26). The young people who leave the kibbutz to work elsewhere

tend to be highly praised by their employers because of the strong self-reinforcing work ethic of the kibbutz they continue to maintain.

*Group Rather Than Individual Reward.* There may be much more of this group effect in the U.S. industrial sector than one ordinarily supposes, which again points to the lesser importance of contingent reinforcement to the individual employee. For example, for the 71 managers and professionals of a manufacturing facility, Markham (1988) reported a correlation of  $-.03$  between their rated performance and their merit raises within their own units, but  $.45$  between the performance ratings of all the members of a unit and the merit raises they received. In this facility, group, not individual, performance was being rewarded.

*The Augmentation Effect.* Bass (1985a) theorized that contingent reward can be catalyzed by transformational leadership. Empirical support came from Waldman, Bass, and Einstein (1987) and Waldman, Bass, and Yammarino (1988) and indirectly from Schriesheim, Castro, Zhou, et al. (2006). The leadership of Ernest Shackleton, whose men overcame formidable obstacles in the Antarctic—or the leadership of Joan of Arc, Martin Luther King, Jr., Mahatma Gandhi, or Winston Churchill—can be perceived as leadership that added to any cost-benefit exchange a transformation of the followers' needs from those at lower levels to higher-level concerns for achievement, glory, humanity, fortune, country, faith, or family, demanding excessive costs relative to tangible benefits. Self-interest was transcended; cost-benefit calculations were abandoned. It is difficult to conceive of the emotional response to the Ayatollah Khomeini in the rush to martyrdom during the Iranian-Iraqi war by the Iranian masses or the terrorist suicide bombers since then, merely as a social cost-benefit exchange between a leader and followers. On the positive side of reinforcement, appeals to self-interests alone will not result ultimately in leadership that is able to reward followers as much as they want. Continued attention to followers' self-interests alone will not permit a group, organization, or society to operate optimally. A culture of cooperation is needed, as is trust in the benefit of optimal organizational outcomes. A prosocial charismatic leader who appeals to interests that transcend the individual member will be more likely to create such a culture than a leader who is limited to contingent reinforcement and the use of individual incentives (Miller, 1987). In the public sector, political leadership must appeal to both self-interests and shared values (Meier, 1988). In the early twenty-first century moral issues have become as important as bread-and-butter issues to American voters. The shared environment has become as powerful a political issue as self-interested economic gains. A 50-cent increase in the federal gasoline tax (from 18 cents) was supported by 70% of the American public as a response to automobile pollution and global warming.

*Individual Differences.* Contingent reinforcement may also be irrelevant if the subordinate attaches no importance or value to the reinforcement—if the subordinate is not interested in the rewards, promises of reward, or avoidance of punishment (Ilgen, Fisher, & Taylor, 1979). Subordinates' indifference may be due to low expectations that satisfactory levels can be attained to merit the rewards or that the promises of reward will be kept (Larson, 1984).

Beyond the specialized circumstance of communal living or group reinforcement, one finds that individuals differ in their preference for external or self-reinforcement. In a survey of 339 utility company managers, Parsons, Herold, and Turlington (1981) found that the managers varied in their preference for external feedback—that is, in their agreement with the statement, “Even though I may think I have done a good job, I feel a lot more confident of it after someone else tells me so.” They also differed in their ability and tendency to reinforce themselves—that is, in agreeing that “If I have done something well, I know it without other people telling me so” and “As long as I think that I have done something well, I am not too concerned about how other people think I have done.” Bass (1967c) concluded that task-oriented subordinates and experienced subordinates are more likely to be self-reinforcing, whereas relations-oriented and self-oriented subordinates are more likely to be sensitive to both positive and negative reinforcement from others.

One is likely to see personally counterdependent followers working in opposition to what the leader intended with contingent rewards. Much of this reverse twist may also be seen in personally independent and

even dependent followers. Among five styles of leadership—(1) directive, (2) manipulative, (3) consultative, (4) participative, and (5) delegative—displayed by large samples of managers, Bass, Valenzi, Farrow, and Solomon (1975) found manipulative leadership least satisfying to subordinates and least effective with them. But the managers' superiors may not find fault with the manipulative potential of the managers in practicing contingent reinforcement. In fact, manipulative managers are more successful with higher-ups in that they earn salaries, after adjustment for their seniority, function, education, sex, and organization, that are higher than average (Farrow, Valenzi, & Bass, 1981).

## Constraints on the Use and Impact of Feedback

---

Feedback is not always effective (Fedor, Buckley, & Eder, 1990). In fact, according to a meta-analysis by DiNisi & Kluger (2000), among 131 studies of feedback, 38% were ineffective in outcomes. Overall, the improvement in performance from feedback was less than half a standard deviation. Numerous factors constrain the use and impact of downward feedback, in which supervisory contingent reward is delivered. These factors include problems with the performance appraisal interviews, coping with unintentional consequences, and a reluctance to give feedback. For instance, among 508 air force personnel, lack of feedback was one of the highest concerns of leadership and management (Kunich & Lester, 1996). Even when given, it is not very helpful if it is insufficiently frequent, if it comes too late, if it is not based on evidence, if it is a one-way discourse instead of a dialogue, or if it is unclear or inaccurate. Rather, feedback should be timely, flexible, direct, specific, and descriptive (Hughes, Ginnet, & Curphy, 1993); and it should be about the subordinate's performance, not the subordinate as a person: "Your report came in too late to be used," not "You're too slow" (Kluger & DiNisi, 1996). DiNisi and Kluger's meta-analysis indicated that for improvement in performance, feedback must focus on the recipients' performance, not on their self-concept. Furthermore, the recipient's ego must not be threatened. Information on how to improve should be included; the performance of specific others should be excluded.

### ***Reluctance to Give Positive Feedback***

Contingent reinforcement may be constrained by the reluctance of some supervisors to give positive feedback. Komaki (1981) offered numerous reasons for this reluctance: time pressure, poor appraisal methods, doubts about the efficacy of positive reinforcement, lack of skill, and discomfort to the leader and the subordinate. Feldman (1986, p. 39) offered a number of reasons why some supervisors may avoid giving positive feedback: "Who among us has not found, much to our chagrin, that our praise, rewards, and favors often go unnoticed and un-thanked? ... Consider the colleague who responds to subordinates' efforts above and beyond the call of duty with no comment, as if those efforts were simply his due. Consider the supervisor who compliments a subordinate for a job well done, and receives in return a comment like 'No thanks to you.'"

Subordinates may interpret feedback as a signal that the superior expects them to continue to perform at a high level. In such a case, the subordinates will regard the positive reinforcement as pressure to keep performing at the top of their capacity. Particularly when positive reinforcement is rare, subordinates may be ambivalent about receiving it for fear of becoming emotionally dependent on the good opinion of the supervisor, a good opinion that may easily be lost. Subordinates with low self-esteem will be jarred by the contrasting praise given to them and will evaluate it as only a momentary departure from their generally poor performance. Furthermore, the positive feedback that is given is often actually trivial and meaningless, or it may be interpreted as such. The supervisor who gives it frequently may be seen as politically motivated, manipulative, ingratiating, and insincere. Feldman (1986) agreed that positive feedback will be less favorably received when it

is given frequently and for trivialities than when it is given only for unusually good performance.

Subordinates who are in conflict with their supervisors may react defensively to positive feedback and even interpret it as negative feedback or a precursor of negative feedback. “When receiving praise, some people may be waiting, like Pavlov’s dog, for the anticipated punishment to follow” (Feldman, 1986, p. 40).

### ***Feedback May Not Work***

Even if positive feedback is given, it may not provide the expected reinforcement. Subordinates may not believe that positive feedback from a supervisor is a consequence of their performance. Rather, they may perceive that the supervisor praises when he or she feels like doing so, not when the performance is good. Subordinates may also believe that positive reinforcement is too small or inequitable, which makes the subordinate angry because the subordinate believes that more of a reward should have been given for the performance. Finally, subordinates may feel a need to reciprocate and give unjustified, unwarranted positive feedback to the supervisor, and they will resent feeling pressured to do so.

Gaddis, Connelly, and Mumford (2004) set up an experiment to study the effects of a leader’s feedback that a subordinate had failed. Negative affect of the leader accompanying the feedback (as compared with positive affect) reduced the leader’s perceived effectiveness and lowered the quality of performance.

### ***Reluctance to Give Negative Feedback***

Supervisory negative feedback may be delayed, distorted, or avoided following poor subordinate performance whether or not the poor performance is attributed to lack of effort or failure of mastery of what needs to be done (Moss & Martinko, 1998).

*Attitudes about Discipline, Reprimands, and Punishment.* Although some supervisors and subordinates may find even positive feedback discomforting, many more are reluctant to give and receive negative feedback (Larson, 1986; Sims & Manz, 1984). An experiment by C. D. Fisher (1979) with 168 college students indicated that “supervisors” gave feedback sooner when the “subordinates” performance was poor than when it was good; but Fisher believed that the results would be reversed in any long-term field study, since supervisors in real life are more likely to be reluctant to give negative feedback. It is one thing to say something negative to a stranger in a transient experience than to say it to someone with whom one will remain in close contact. Managers often are reluctant to discipline an employee because it is an unpleasant task for most of them. Discipline and friendship are difficult to maintain side by side (Harrison, 1982). Nevertheless, numerous factors contribute to supervisors’ willingness to use punishment. These factors include positive attitudes about punishment (O’Reilly & Weitz, 1980), supervisors’ independence of their subordinates’ performance (Ilgen, Mitchell, & Fredrickson, 1981), subordinates’ poor performance relative to coworkers’ (Ivancevich, 1983), and supervisors’ lack of reward power (Greene & Podsakoff, 1979/1981).

*Salience of Poor Performance.* It may take a considerable worsening of a subordinate’s performance for a supervisor to overcome his or her reluctance to give negative feedback (Larson, 1986) although, as was mentioned earlier, subordinates’ poor performance is more salient to supervisors than their subordinates’ good performance. The salience of the poor performance must outweigh how much the supervisor personally admires a subordinate. A supervisor may avoid giving negative feedback for poor performance to avoid risking a deterioration in personal relationships with subordinates. The supervisor may also be less likely to attribute poor performance to subordinates if relations with the subordinates are good (Bass, 1985a).

*Use of Distortion.* When supervisors are faced with poor performance that they attribute to the subordinates’ lack of ability, they tend to pull their punches. They distort their feedback and make it more

positive than it should be (Fisher, 1979; Ilgen & Knowlton, 1980). Programmatic efforts to change the supervisor's feedback behavior were not successful (Frank & Hackman, 1975; French, Kay, & Meyer, 1966). Some of this distortion may be due to the effort of the supervisor to act prosocially, to be more concerned with the subordinate's feelings than with the supervisor's or the organization's best interests. To avoid causing distress to the subordinate, the supervisor may remain lenient and avoid giving needed negative feedback.

The reluctance to give negative feedback is abetted by supervisors' tendency to search for excuses and justifications for the poor performance of subordinates. Gioia and Sims (1986) arranged for 24 experienced managers to handle a simulated performance appraisal interview. During the interviews, the managers tended to probe for excuses to justify the subordinates' performance. After the interviews, the managers reduced their blame of the poorly performing subordinates.

*Other Reasons.* Various other reasons may also make the supervisor reluctant to use negative feedback. The supervisor may be highly dependent on the subordinate to attain their mutual objectives (Tjosvold, 1985) or may have limited authority to bring about a punishment (Beyer & Trice, 1984). Since negative reinforcement may cause the employee to quit (Parsons, Herold, & Leatherwood, 1985), the supervisor's reluctance may be based on that concern. Political considerations may deter a supervisor from giving negative feedback for fear of the employee's retaliation. An admonished employee may file a grievance for unfair discrimination or may complain to powerful friends in the organization. The supervisor's ability and motivation to correct a problem employee are also decreased if the performance of most of the work-force is poor (Crawford, Thomas, & Fink, 1980).

Nevertheless, despite their reluctance, managers will become punitive with continuing poor performers and problem employees after asking questions and trying to solve the problems they believe are causing the poor performance (Fairhurst, Green, & Snively, 1984). In the case of problem drinkers, for example, discipline by supervisors is widespread when the work context supports its use (Beyer & Trice, 1984). O'Reilly and Weitz (1980) found that supervisors who used informal warnings, formal warnings, and discharges led groups that performed better; but Kipnis (1976) concluded, from research evidence, that supervisors were most likely to use such sanctions when they did not expect to be successful in using their influence to improve their subordinates' performance.

*Improving the Positive Effects of Negative Feedback.* Salespeople said they worked harder if they had a performance orientation but said they worked harder and smarter if they had a learning orientation (Sujan, Weitz, & Kumar, 1994). A review by Ilgen and Davis (2000) concluded that feedback was more likely to be effective if the recipients believed they had control and influence regarding the performance in question, if they were oriented toward a learning rather than a performance goal, and if they were self-efficacious. If they had a learning goal, failure was legitimate. If they had a performance goal, negative feedback, if not too harsh, could generate specific alternative ways of doing the task more effectively. "Mastery goals facilitate positive ... strategies in the face of performance decrements" (Ilgen & Davis, 2000, p. 560).

### ***Subordinates as Moderators of Supervisors' Feedback Efforts***

Fedor, Buckley, and Eder (1990) found that subordinates perceived four possible intentions for supervisors to give them feedback: (1) to build relationships, (2) to provide self-evaluation, (3) to facilitate productivity, and (4) to serve the interests of the supervisor. The subordinates' perceptions of a supervisor's intentions may have an effect on their interpretation and acceptance of feedback. By expressing dissatisfaction with the process, subordinates, the intended receivers of feedback, may also add to the reluctance of supervisors to give it (Greller, 1978). They may discourage the supervisor from efforts to provide it by frequent rejections of the supervisor, displays of hostility, and displacement of the blame onto others. Many subordinates are likely to

take personal responsibility for their successes but to attribute failures to external or situational causes, such as the difficulty of a task, bad luck, or a lack of cooperation and assistance from others (Greenwald, 1980; Sims & Gioia, 1984).

*Interpretation and Acceptance.* The contingency between performance and outcome may be more apparent to the subordinates when they are successful. Subordinates may expect success and tend to validate their expectations by reinterpreting as an actual success a failure that their supervisor sees. They may base their judgments of their performance on the desirability of the outcome to them personally, rather than on the explicit link between performance and outcome (Miller & Ross, 1975).

Negative feedback may be interpreted as helpful and therefore may be regarded as a contingent reward, rather than as a contingent punishment. It all depends on how the feedback is presented, how much it is embedded in sedating and palliating language, and how open the subordinates are to it. The subordinates may fail to “hear” negative feedback because they convert it into what they want to hear. Subordinates accept positive feedback more readily and recall negative feedback less accurately (Ilgen, Peterson, Martin, & Boeschen, 1981). Considerable discrepancy is found between the extent to which supervisors say they give feedback to their subordinates and the extent to which the subordinates say they receive such feedback. For example, in a survey of 178 managers and their subordinates by Mann and Dent (1954b), 82% of the managers said they gave “pats on the back” to their subordinates often, but only 13% of their subordinates agreed with them. Eighty percent of the managers said they gave subordinates sincere and thorough praise often, but only 14 percent of their subordinates agreed with them.

*Context.* Subordinates may ignore supervisors’ feedback because it is not backed up with evidence, because it is not consistent with feedback they have received from coworkers, because they judge it to be unimportant, or because they regard self-reinforcement as more relevant. Different working situations and levels of experience of the recipients of the feedback will determine which source of feedback the subordinates think is most useful and important (DeNisi, Randolph, & Blencoe, 1983). Greller and Herold (1975) obtained results indicating that a heterogeneous sample of working people attached more importance to feedback from a higher authority than from their peers; but Pavett (1983) noted that in a hospital, feedback from patients and coworkers had a greater impact than feedback from supervisors on nurses’ perceptions of the connection between delivering high-quality care and valued outcomes. In a different work setting, Ivancevich and McMahon (1982) reported that self-generated feedback about the attainment of goals did more than feedback from supervisors to improve the subordinates’ performance, intrinsic job satisfaction, and commitment to the organization. And according to Greller (1980), who surveyed 26 supervisors and 63 of their subordinates in the maintenance department of a metropolitan transit agency, the subordinates attached more importance than the supervisors to the feedback from the task itself, to their own comparisons with the work of others, and to coworkers’ comments about their work.

Insurance salespeople have fewer contacts with each other than do metropolitan transit employees, for whom feedback from coworkers is important. Brief and Hollenbeck (1985) found that among the 62 insurance salespeople they interviewed, the greatest amount of feedback on performance came from the supervisor and themselves, not from coworkers. Despite the general observation that we attribute our successes to ourselves and our failures to others and to external conditions, most of the contingent self-reinforcement of the insurance employees was negative, in the form of self-criticism; and it had detrimental effects on their performance.

*Views about the Supervisor.* Subordinates may rationalize feedback as being due to a supervisor’s need to complain, the supervisor’s failure to understand the situation, or the supervisor’s boss’s malevolence. According to Coy (1982), who conducted a laboratory experiment with undergraduates, “subordinates” were readier to accept feedback from a leader they perceived as competent rather than incompetent, particularly if the leader had a strong need for achievement. If they perceived the leader as incompetent, they would seek

alternative sources of task-relevant information.

*Self-Esteem.* Subordinates' self-esteem will moderate their request for feedback and their acceptance of it. Those with high self-esteem set higher goals, perform at a higher level, and experience more positive affect when performing well than subordinates with low self-esteem (Taylor & Slania, 1981). Those with high self-esteem seek less information from others in making decisions and forming judgments. They are more self-reinforcing. Those with low self-esteem tend to be more dependent on social and environmental feedback (Weiss, 1977) and are more responsive to it. Inexperienced personnel prefer to receive feedback from their superiors, but experienced personnel prefer to be more self-reinforcing (Hillery & Wexley, 1974). However, in contrast to reinforcement only from the supervisor, a combination of both self-feedback and supervisory feedback, in which the subordinate first prepares a self-appraisal and then meets to compare it with the superior's feedback, appears to reduce the subordinate's defensiveness and to bring about greater subsequent improvement in the subordinate's performance (Bassett & Meyer, 1968). Whether the subordinate seeks feedback will also be affected by his or her role ambiguity and tolerance of ambiguity (Ashford & Cummings, 1981). Whether a subordinate will improve in performance after receiving negative feedback from the supervisor will depend on the subordinate's self-esteem as well as the supervisor's sources of power (Fedor, Davis, Maslyn, et al., 2001).

### ***Feedback Characteristics as Moderators***

Problems inherent in the feedback itself may cause it to fail to work as intended. In place of the summary ratings many supervisors use, Deets and Tyler (1986) introduced detailed feedback about the specific initiation and consideration behaviors<sup>7</sup> of supervisors at Xerox, along with interim evaluations of the supervisors' progress toward specific personal and professional goals that were given closer to the events involved. They found a marked improvement in attitudes toward the appraisal system and toward teamwork.

The accuracy, amount, distinctiveness, consistency, and method of giving feedback (oral, written, or face-to-face) may also matter (Duncan & Bruwelheide, 1985–1986). But in a study of 360 pairs of managers and subordinates from more than 50 organizations in three countries, Larson, Glynn, Fleenor, and Scontrino (1986) found it impossible to single out the specificity of feedback from other positive features of good-quality feedback, such as its timeliness, frequency, and sensitivity. However, Quaglieri and Carnazza (1985) found that most subordinates paid attention to multiple aspects of feedback, including its accuracy, timeliness, attractiveness, and specificity, as well as to the trustworthiness, expertise, and power of the source. Furthermore, these and other features of feedback could be experimentally manipulated. Earley (1986a) completed a field experiment in which 60 subjects believed they were in a working situation processing subscriptions. Positive feedback increased their expectations of successful performance more than did negative feedback, as expected. The subjects' performance was better than anticipated if the feedback was specific rather than general. In turn, specific feedback resulted in more planning by the subordinates, which contributed to the subordinates' better performance. However, the supervisors had less of an impact on the subordinates' performance than self-generated feedback retrieved from computer storage, particularly if the positive or negative feedback was general. Only when the supervisors' feedback was specific and negative did its effect match that of self-generated feedback. Mediating these effects was the extent to which the subordinates trusted the computer feedback more than they trusted the supervisors' feedback.

The credibility of the source of feedback is important. Feedback will be more effective if the leader is respected and trusted, if the subordinate regards the feedback as useful, and if it is delivered with consideration, tact, and support. Another important consideration is whether feedback from one source is discordant with feedback from other sources (Liden & Mitchell, 1985). When one colleague finds fault with a member's

behavior, the impact is much less if other colleagues do not agree.

*Coping with Unintended Consequences.* Contingent negative feedback may have unintended consequences. Reprimands may serve not only to increase clarity about what is undesirable behavior and to correct it (Reitz, 1971), but they can also generate unproductive anxiety. In turn, this anxiety can result in a variety of dysfunctional behaviors, such as reaction formation, guilt, and hostility, particularly in highly motivated subordinates who are already overloaded or under stress and who may interpret well-intentioned negative feedback as a personal attack (Bass, 1985a).

Komaki (1982) and Sims and Gioia (1984) suggested ways to cope with the unintended consequences and potential shortcomings of feedback processes and make better use of them. According to 60 professionals interviewed by Komaki, to increase the effective utilization of feedback the long-term benefits of reinforcement need to be emphasized. More positive feedback should be used, but it should not be limited just to delivering praise; it should include connections to the performance involved. Reinforcement schedules have to be adapted to fit busy schedules. Standards of performance and of performance appraisals need to be clarified.

To reduce self-serving bias among subordinates and to increase the subordinates' acceptance of negative feedback, Sims and Gioia proposed that the supervisor needs to recognize and expect the biased reaction to negative feedback for poor performance. The subordinate's acceptance of negative feedback should be positively reinforced, and efforts to cover up mistakes should be rejected. Emphasis should be placed on determining the causes of and remedies for the poor performance.

## Constraints on the Performance Appraisal Interview

---

### *Problems and Possibilities*

Contingent reinforcement may occur at the time the supervisor observes the subordinate's good or poor performance or in a performance appraisal interview. An annual appraisal review seems to be the norm in the United States. However, more frequent appraisal interviews are suggested for poor performers (Kay, Meyer, & French, 1965) and for subordinates in nonroutine jobs in which goals are set, progress is evaluated, and then goals are reset (Cummings & Schwab, 1973, 1978; McConkie, 1979). Numerous problems can impair the efficacy of the feedback in this interview. Reinforcement theory suggests that the feedback will be most reinforcing if it is given as soon as possible after the occurrence of the subordinate's good or poor performance. Yet the delay caused by waiting to provide the feedback in a formal interview increases the reliability of the evidence to be discussed by the supervisor and the subordinate. Such a discussion can also take into account broader systematic issues and longer-range goals and plans than could feedback given immediately after an incident. Since the supervisor and subordinate can both be better organized to give and receive the feedback, a more orderly, calm, and thoughtful exchange is possible than in the heat of the immediate operations. Of course, nothing precludes both timely feedback and feedback for an extensive period given during an appraisal interview in which the subordinates' performance during the six months or year preceding the interview is reviewed. In this formal meeting of the superior and the subordinate, the subordinate's performance during a preceding period is reviewed, evaluations are made, and suggestions for improvement are advanced. The meeting can involve the superior's and subordinate's sharing of information or it can be directed by the supervisor. The interview can be structured in a variety of ways around goals and their attainment or around traits and behavior.

Although it is an organized effort to provide positive reinforcement for good performance and negative

feedback for poor performance, the performance appraisal interview may fail to improve the subordinate's subsequent performance, for numerous reasons. First, the formal feedback process tends to be constrained in use and impact by, for example, the supervisor's lack of familiarity with the subordinate's job. Second, the superior may not encourage the subordinate's participation and two-way communication in the interview (Cederblom, 1982). Other reasons for ineffective feedback during a performance appraisal include a lack of supervisory support, a lack of goals, an unfocused discussion, and a failure to separate administrative and developmental feedback (Ivancevich, 1982). The performance appraisal interview may also fail to have an impact if no reward is linked to it (Burke, Weitzel, & Weir, 1978).

The lack of connection between performance appraisals and performance may be due to a variety of other goals that managers have in mind when they evaluate their subordinates (Longnecker, Sims, & Gioia, 1987). Supervisors may avoid discouraging subordinates or confronting them with their inadequacies, may seek favors from the subordinates, or may discourage a top-performing employee from demanding a commensurate increase in salary. Thus appraisals may be unrelated to performance even in the face of available objective evidence about the performance. For example, Leana (1984) discovered that the periodic evaluations of 98 claims adjusters by their 44 supervisors were not correlated with such objective measures of performance as the settlement ratio and the average cost of the claims that were settled.

### ***Supervisors' and Subordinates' Evaluations of the Process***

Lawler, Mohrman, and Resnick (1984) conducted a survey of over 300 supervisor-subordinate dyads regarding the extent to which the performance appraisal interviews fulfilled their purposes. They found that although 82% of the supervisors said that all important matters had been discussed, most subordinates thought there had been less than a full discussion of their development, work, planning, or pay. Furthermore, they thought that not enough attention was being paid to documenting their performance. On the other hand, supervisors in general were unenthusiastic about discussing decisions about pay or documenting subordinates' performance in these interviews. Presumably, both these matters would be extremely important for leaders to cover as means of contingent reinforcement (Mohrman & Lawler, 1983). Consistent with these findings was the survey by Greller (1980), which showed that supervisors actually overestimated the importance of the feedback they provided to subordinates and underestimated the value their subordinates place on feedback from sources under their own control such as the task and comparisons with the work of colleagues.

### ***Avoidance***

Many supervisors avoid conducting appraisal interviews. When forced by organizational policy, they often hold perfunctory general discussions with subordinates, which the subordinates do not consider to be the formal feedback of a performance appraisal interview (Meyer, Kay, & French, 1965). The failure to conduct high-quality performance appraisal interviews with optimal frequency may militate against these interviews' serving to provide effective contingent reinforcement. Most employees seek more such feedback opportunities than they receive (Ashford & Cummings, 1983).

### ***Other Aspects of the Process***

Frequent appraisals, however, particularly negative appraisals, may generate more resistance and defensiveness in subordinates (Burke, Weitzel, & Weir, 1978). If the feedback is not what the subordinate expected, it may

arouse resistance (Bernstein & Lecomte, 1979), or the subordinate may consider it less accurate (Taylor, 1981). If the feedback is not as positive as expected, it may reduce the subordinate's commitment to the organization (Pearce & Porter, 1986). Decreased commitment is likely to be common, since subordinates ordinarily give themselves higher evaluations than their superiors do (Bradley, 1978). Furthermore, subordinates' reactions to the performance appraisal interview will depend on their opinions about the supervisor's credibility, knowledge, and trustworthiness, which parallel their reactions to informal feedback from their supervisor, as was mentioned earlier. Ilgen, Fisher, and Taylor (1979) noted that subordinates' judgments of their supervisors' credibility as an appraiser will influence how the subordinates react in performance appraisal interviews. If the subordinates think their supervisor is knowledgeable about their job and performance, they will regard the interview as fair and accurate, but those who judge their supervisor to be less knowledgeable will think the interview is unfair and inaccurate (Landy, Barnes, & Murphy, 1978). And, as Ilgen, Peterson, Martin, and Boeschen (1981) observed, subordinates who trust their supervisor will be more satisfied with the appraisal interview process than subordinates who do not trust their supervisor.

Herold and Greller (1977) added a number of other characteristics of feedback that recipients can discern in the performance appraisal interview, such as whether the feedback is helpful or unhelpful, clear or ambiguous, important or unimportant, and formal or informal. The utility of the feedback appeared to be most strongly related to its frequency, helpfulness, and importance. In the interviews, ratings and discussions that focus on the past performance of the subordinates appear to be the most satisfactory to both superiors and subordinates (Fletcher & Williams, 1976; Mount, 1984). The subordinates' participation in the development of the rating forms also seems to help (Landy & Farr, 1980). Agreement on the meaning of scores and terms, such as "good" and "satisfactory," will help as well (Taylor, Fisher, & Ilgen, 1984). Supervisors who begin the interviews with positive feedback before giving negative feedback are seen as more accurate by the subordinates than supervisors who begin with the negatives before presenting the positive aspects of the subordinates' performance (Stone, Gueutal, & MacIntosh, 1984).

### ***An Ideal System***

Fox (1987–1988) enumerated guidelines for an improved performance appraisal system. First, credit should be given for good form. Second, emphasis should be on work-relevant behaviors that are known to be desirable and productive, rather than on outcomes that are often beyond the employee's total control. These behaviors should be determined from critical-incidents surveys of the occurrence of highly effective and highly ineffective job events. Third, the appraisals should be from multiple sources, not just from the boss. Fourth, ratings should be accompanied by evidence. According to Fox, improvement in an employee's performance would stem from an ongoing defining of behaviors that need to be changed, setting goals for change, and administering feedback and other reinforcements on appropriate schedules.

Following a comprehensive review of the literature, Biddle and Fisher (1987) described an ideal procedure for promoting such contingent reinforcement from performance appraisal interviews. First, there would be a preperformance meeting in which the supervisor and subordinate reached an understanding of exactly how the subordinate's future performance was to be assessed. If rating scales were to be used, the meaning of each dimension and anchor point would be clarified. A performance monitoring system would be set up to ensure that good data were available for the appraisal. The sources of feedback would be considered, and the supervisor would arrange to collect data, as needed, from these sources, such as peers and clients, as well as to gather his or her own data. The subordinate would also keep track of his or her performance and accomplishments through self-monitoring. Between interviews, the supervisor would give more frequent informal feedback and coaching, so that the formal performance appraisal interview would not bring up much

that was unexpected for the subordinate. The timeliness of the frequent informal feedback would allow the subordinate to learn from and correct his or her errors immediately. It also would afford opportunities to clear up differences in attributions for the same specific incidents of performance. In sum, the actual performance appraisal interview would begin with a self-appraisal, followed by the supervisor's sharing of his or her feedback with the subordinate as well as feedback collected from the other sources. Discussion should then center on how the subordinate might be able to do things differently and what additional support the superior might provide. Finally, new goals for the upcoming period would be discussed and established.

## Implicit theories of Leadership as Moderators of LMX

---

The perceived and actual descriptions of the quality of the exchange, the causes of the exchange, and the consequences of the exchange may be obscured or magnified by the implicit theories of leadership that are held by the leaders and subordinates who are involved in the relationship.

### ***Meaning of Implicit Theories of Leadership***

*Implicit Theories of Leadership as Cognitive Frameworks.* The implicit theories we hold about leadership and its antecedents and consequences join with our explicitly expressed attitudes, beliefs, values, and ideologies about leadership<sup>8</sup> to color our judgments of specific leaders we describe or evaluate. Implicit theories are cognitive frameworks or categorization systems that are in use during information processing to encode, process, and recall specific events and behavior. An implicit theory can also be conceived of as the personalized factor structure we use for information processing.

Both the leader and the led are affected in their exchange relationship by the implicit theories of leadership they carry around in their heads. If they both believe that leadership is mainly a matter of striking a deal for the payment for services rendered and monitoring the arrangements, then they are likely to judge that contingent reinforcement explains the motivation and performance of the leader and the subordinate. But if they believe that leadership is mainly an inspirational process, then they will judge contingent reinforcement as being of little or no consequence. Thus Eden and Leviatan (1975) noted that people have preconceptions about what constitutes appropriate behavior by leaders. Subordinates have expectations regarding the kind and amount of leadership behavior that is proper for given situations (L. R. Anderson, 1966b), as do the leaders themselves (Yukl, 1971). These preconceptions are important, according to Pfeffer and Salancik (1975), who obtained results showing that the leadership behavior of focal supervisors was affected by the expectations of both their superiors and their subordinates. In addition, subordinates attach their own individual specific value-laden meanings to the actions of their superiors (McConkie, 1984), whereas leaders may regard their performance as leaders to be a matter of their traits, their power, or the way they act.

Birnbaum (1987c) collected the definitions of leadership provided in interviews with 32 college and university presidents. Almost all of the presidents thought that leadership involved power, influence, and ways of behaving. About a quarter talked as well about traits of consequence, situational determinants, or the symbolism of leadership. Content analyses of the interviews suggested that about a third of the presidents believed that the goals of leadership stemmed from the mission of the institution; a few thought that the goals came from followers; and the rest thought that the goals came from the leaders themselves. Presidents saw themselves as either: (1) the heads of a bureaucracy; (2) collegial in their relations with the staff, faculty, and students; (3) political manipulators; or (4) occupants of a highly symbolic office. Some of the presidents had a single frame of reference about leadership, and about a quarter had multiple frames of reference (Bensimon,

1987). According to Bolman and Deal (1984), those with multiple frames of reference were better equipped to deal with the complexities of the modern college community.

*Effects on Raters of Leadership.* Implicit theories of leadership facilitate the assimilation of specific events and behaviors into a collective interpretation. They help raters to categorize their stimulus environment into less complex classifications. Implicit theories make it possible to simplify complex information by enabling raters to process that information automatically, as well as to add missing details not observed in the actual behavior of the leader (Lord, Foti, & DeVader, 1984). The raters' application of their own implicit theory to observed events affects the truth of their observations. The result is that their responses to the survey questions are closer to their own implicit theories than to the actual events they observed. The impact of these implicit theories is greatest when raters are asked to recall the behavior and events they observed sometime in the past.

Lord, Binning, Rush, and Thomas (1978) estimated that up to 40% of the variance in ratings of leadership can be accounted for by implicit theories. Thus instead of describing the actual behavior of the individual leader who is being judged, we respond in a way that is highly biased by our preconceptions about how leaders in general are supposed to behave. Support for this proposition first emerged when Eden and Leviatan (1975) applied D. J. Schneider's (1973) Implicit Personality theory to the study of leadership. Staw and Ross (1980) and McElroy (1982) provided additional support for the idea that the implicit conceptions we use in attributing what we observe to leadership seriously alter our attributions. Thus an exchange may take place between a supervisor and a subordinate. The subordinate is actually complying with the supervisor's request to gain a recommendation for promotion from the supervisor. But the subordinate has an implicit theory that says leaders are inspiring. The subordinate reports she is complying as a consequence of the way the supervisor inspired her to work with him. Thus an actual transactional exchange is reported as a transformational event. Or the reverse may occur. A subordinate is actually inspired to transcend her own interests. However, she holds an implicit theory that you get what you give, so she interprets her appraisal by the supervisor as compliance because she wants to be recommended by him for a promotion.

*Effects on Leaders' Behavior.* Supervisors are also clearly affected by the implicit theories of leadership they hold. Neubauer (1982) found, in a sample of 90 German supervisors, that implicit leadership theories are characterized by a belief in participative management and acceptance of informal leader-member relations for workers who live up to the supervisors' expectations. But for workers who fail to live up to expectations, not very helpful implicit theories emphasize the limiting of such workers to simple activities, the need for supervisory control, and the prevention of the development of informal leader-member relations.

### ***Managing the Effects of Implicit Theories***

Implicit theories of leadership can be manipulated in advance to get raters to assess the same observed leadership behavior differently. If we are told that a leader is effective and believe the leader to be effective in carrying out his or her assignment, this will influence how much and what type of leadership we judge to exist in the subsequent performance we observe. In a laboratory study by Gioia and Sims (1985), subjects viewed videotapes of contingently reinforcing leadership behavior by managers in action. When managers were presented to the subjects as effective leaders before the subjects saw the tapes, the subjects described the managers subsequently as being significantly higher in initiating structure than the managers who were presented to the subjects as ineffective before the same tapes were viewed. Similar results were reported by Rush, Thomas, and Lord (1977).

Other conditions can be arranged to increase the effect of implicit theories of leadership. Thus the more ambiguous a leader's actual behavior, the more implicit theories will affect how we describe or evaluate it

(DeNisi & Pritchard, 1978). Also, implicit theories of leadership will have more of an impact in less structured situations (Gioia & Sims, 1985). *Halo* effects can also be connected with implicit theories (Nathan & Alexander, 1985). In addition, subordinates are likely to fall back on their implicit theories of leadership when they lack information about a situation (Schriesheim & DeNisi, 1978).

Implicit theories of leadership need to take into account the causal expectations that leaders have about themselves and their followers, as well as the complementary theories held by the followers. The extent to which leaders will modify their reactions to the good and poor performance of subordinates, depending on whether they attribute the performance to the subordinates' competence or motivation, to external causes, or to luck, has already been addressed. The leaders are also likely to respond according to their own beliefs about the value of promises of reward for compliance or threats of punishment for noncompliance. As a consequence, one supervisor may praise a subordinate for an effort to reach desired standards that failed because of uncontrollable obstacles, and another supervisor may reprove the same subordinate for the failure despite the obstacles.

Larson (1980) suggested that supervisors vary in the implicit theories they have about feedback in general, as well as their theories about the consequences of feedback to specific subordinates. Some supervisors may think that reprimands invite retaliation and that praise lacks credibility. Disapproval is more likely if rationality, objectivity, and certainty are regarded as more important than adaptability; if security is valued as more important than affiliation; and if the leaders see themselves as aiming for homogeneity, regularity, standardization, safety, or consolidation (Quinn & Hall, 1983). Subordinates will use various tactics to try to influence their leaders, according to the subordinates' beliefs about the likely effects on the leader of reason, ingratiation, excuses, and coalitions, as well as the implications for the subordinate's self-image involving his or her integrity and self-esteem. The organizational role the subordinate believes he or she expected to play is also important.

### ***The Prototypical Leader***

Phillips and Lord (1981) concluded that implicit theories of leadership could best be understood in terms of cognitive categorization processes. ("In my head, Joe comes across as a dynamic leader. Dynamic leaders are a category containing 'such and such attributes.' Therefore, Joe has these attributes.") The researchers demonstrated this experimentally by using 128 undergraduates to view one or another of two videotapes of a four-person problem-solving group in which the leader's salience and the group's performance were manipulated. Furthermore, Lord, Foti, and Phillips (1982) argued that implicit theories reflect the cognitive categories used to distinguish leaders from nonleaders. Such categories can be applied to explaining which information is connected to designated labels of leadership (Cronshaw & Lord, 1987; Lord, Foti, & Phillips, 1982).

For most people from the same culture, a common set of categories fits the image of what the typical leader is like. These categories describe the "prototypical" leader. A prototypical leader is *actively participating*; an "anti-prototypical" leader *remains withdrawn*. Perceiving someone as a leader involves a relatively simple categorization of the stimulus person as a leader or a nonleader. Such a categorical judgment, according to Rosch (1975), is made on the basis of the similarity between the stimulus person and the "prototype" of the category. The prototype (in this definition) is an abstract representation of the most representative features of members of the category.

Foti, Fraser, and Lord (1982) asked students to rate the extent to which phrases like "bright" or "sides with the average citizen" (taken from a Gallup poll) fit their image of a leader, a political leader, an effective leader, or an effective political leader. The students' different prototypical categorizations helped considerably to

account for changes in Gallup poll results of public support for President Jimmy Carter at different times during his administration. If Jimmy Carter acted more like the students' prototype of an effective political leader, he received more support from the public. The mere social desirability of the categorizations was not as predictive.

People simplify rather than describe or evaluate their leaders in terms of many specifications. People form mental images of categories of leaders. As was noted before, they rapidly judge whether their leader falls into these categories according to their beliefs about the leader and how they see the leader acting (Phillips & Lord, 1981, 1982). Lord, Foti, and DeVader (1984) conducted three studies that used 263 undergraduates to specify the internal structure of these leadership categories and how they relate to prototypicality. These studies showed how properties of the categories can be used to facilitate information processing, such as recalling information about a leader, and to explain simplified perceptions about leadership.

In the first study, different students were each given five minutes to generate attributes of a particular type of leader or nonleader in 11 different situations: (1) business, (2) education, (3) finance, (4) labor, (5) politics, (6) the mass media, (7) the military, (8) minorities, (9) religion, (10) sports, and (11) at the world level. Master lists of attributes of the frequency of mentions of specific clusters of traits were then assembled. *Intelligence* was seen as highest in "family resemblance," that is, attributed generally to leaders in almost all of the 11 situations. Other categories with relatively high family resemblance for leaders included *honesty*, *outgoing*, *understanding*, *verbal skills*, *aggressiveness*, *determined*, and *industrious*. Most of the other 59 attributes, such as *caring*, *authoritarian*, and *decisive*, were limited to just one or two types of leaders.

In the second study, a different set of students judged how much these attributes were "prototypical" for leadership. The students rated the categories according to how well they "fit my image of a leader or a nonleader." Attributes "fitting the image of leader" included *intelligence*, *honesty*, *verbal skills*, *determined*, *informed*, *strong character*, *believable*, *concerned*, *goal-oriented*, and *disciplined*. The family resemblance of these attributes correlated .40 with the attributes of the prototypical leader. A correlation of .42 was found between the speed of reaction in judging these attributes and their fitting the image of the prototypical leader. Such attributes of prototypicality were thus linked to implicit theories as reactions "off the top of the head."

In the third study, Lord, Foti, and DeVader presented vignettes about a district store manager. One vignette ascribed to the manager four or five attributes of the prototypical leader, such as "provides information" and "talks frequently." Another vignette ascribed to the manager neutral attributes, such as "seeks information" or "explains actions." Still another vignette ascribed to the manager "antiprototypical" attributes, such as "admits mistakes" and "withholds rewards." Those who read the vignette containing the prototypical, rather than the neutral or antiprototypical, attributes perceived that the manager displayed more leadership and made much more of a contribution to the store's effectiveness and to the successful merchandising of a new product. The investigators inferred that attributes of causes and responsibility were a retrospective rationalization of events in which "leadership" was the central construct stimulated by the few prototypical attributes embedded in the vignette. However, Lord and Alliger (1985) did not find that prototypicality weightings of the 12 functional leadership behaviors of members of small task groups had much impact on the frequent correlation between the sheer frequency of activity of group members and the leadership ratings they received.

*Prototypicality and Contingent Reinforcement.* Bass and Avolio (1988) asked 87 part-time MBA students to describe their full-time supervisors' transactional and transformational leadership behavior with the Multifactor Leadership Questionnaire. They also had the students complete the prototypicality ratings developed by Lord and his associates about the attributes that "fit my image of a leader." They found that contingent reinforcement was less highly correlated with the prototypicality of the leader than was charismatic leadership, individualized consideration, or intellectual stimulation. When the prototypicality ratings were statistically controlled by partial correlation, only charismatic leadership remained correlated significantly with effectiveness of operations (.34) and continued satisfaction with the leadership (.68). The partial correlation

with contingent reinforcement was reduced to close to zero. Bass and Avolio concluded that the positive contribution that contingent rewarding by a leader is often seen to make to perceived effectiveness may be accounted for by the image of leadership held by the raters. The same may be true for the transformational effects of intellectual stimulation and individualized consideration. However, the charismatic effect cannot be accounted for in this way. Complicating these results may be the extent to which the followers' motivation affects their image of the ideal leader.

*Imagined Ideal Leader and the Followers' Needs.* Singer and Singer (1986) reported that among male undergraduates in New Zealand, the extent to which contingent-reinforcement leadership was desired in an imagined ideal leader did not depend on the men's motivation. But those who had a higher need for affiliation were more likely to prefer transforming, charismatic, and considerate leaders. Nonconformists were more likely to prefer transforming intellectually stimulating leaders.

## Summary and Conclusions

---

Leadership can be understood as a transaction or exchange of material, social, and psychological benefits. In a fair and profitable exchange, the benefits to both the leader and the follower exceed their costs. In the transactional process, leaders and followers reinforce each other's behavior with either reward or punishment—preferably reward, and preferably reward that is contingent on fulfilling the transacted role arrangements. But the exchange may be less rewarding; it can involve management by exception or punitive discipline. In the dynamics of the exchange relationship, competence and early acceptance of the group's norms are important, as a follower builds the idiosyncrasy credit of a member, making it more likely that his or her attempts to lead will be successful. With enough idiosyncrasy credit, one can begin to stand out in the group and be successful in introducing new ideas. But those with credit need to avoid violating the norms and expectations of the group.

Leaders' rewarding and punishing may be contingent or noncontingent, depending on followers' performance. Management by exception may be active or passive. Leaders may treat each follower differently or in the same way. Within-group and between-group analyses can show how much leaders vary in these respects.

Reinforcement can be manipulated in experiments to determine who emerges as a leader. Reinforcement can be used to increase different members' attempts to lead and to affect whether their attempts will be successful in influencing other members. To understand many individual and organizational outcomes of leadership, it is necessary to focus attention on the dyadic leader-member exchange, for the same leader is likely to have different expectations and reactions about his or her different subordinates. These different perceptions and behaviors of leaders result in different levels of performance by subordinates—who are working for the same leader—that cannot be captured by looking only at leader-group relationships. However, this is not an either-or matter.

The combination of dyadic and group effects can be teased out.

Contingent reward may be effective for leaders in many situations, but it has limitations. Rewards for performance and disciplinary actions for failures may not work as expected, for numerous reasons ranging from the leader's lack of control over what the followers are seeking to the overriding impact of group norms. The carrot-or-stick approach may make the subordinate feel denigrated and less than an adult person. What can be accomplished with feedback depends on its timeliness, accuracy, attractiveness, and judged importance, as well as the trustworthiness, expertise, and authority of the source. Negative feedback is often distorted by both the leader who sends it and the subordinate who receives it. Many other factors related to superiors and subordinates will moderate its effects and generate unintended consequences. Systematically affecting the

meaning, interpretation, and understanding of the leader's efforts to provide contingent reinforcement will be the leader's and followers' implicit theories about leadership. Important here are the prototypical leaders that fit the followers' images of what leaders are like. Leaders and followers have been likened to two sides of the same coin. The behavior of each can serve to reinforce the other.

<sup>1</sup> As will be seen in [Chapter 27](#), if the task is already highly structured, then little or no clarification by the leader will be needed.

<sup>2</sup> The studies included those of Bateman, Strasser, and Dailey (1982); Bigoness, Ryan, and Hamner (1981); Hunt and Schuler (1976); Keller and Szilagyi (1976); Podsakoff and Todor (1983a, 1983b); Podsakoff, Todor, Grover, and Huber (1984); Podsakoff, Todor, and Skov (1982); Reitz (1971); and Sims and Szilagyi (1975).

<sup>3</sup> More about this will follow in [Chapter 16](#), which examines limitations of and constraints on the use of contingent reinforcement to shape subordinates' and leaders' behavior.

<sup>4</sup> First known as vertical-dyad linkage theory (Dansereau, Cashman, & Graen, 1973), the theory of leader-member exchange implies that there is a different exchange relationship between each individual member and the leader. An analysis of the leader's relationship with the average member or the group cannot account for the differences in these exchanges. Leader-member exchange is likely to be coded as LMX in the literature, to contrast it with theory and analysis based on the average group member's relation with the leader (ALS).

<sup>5</sup> Many other empirical studies support this finding. See, for instance, F. S. Hills (1979), W. J. Kearny (1979), and H. H. Meyer (1975).

<sup>6</sup> It will make a difference if the negative feedback is sought by the recipient.

<sup>7</sup> Detailed more fully in [Chapter 20](#).

<sup>8</sup> Enumerated by Bass and Barrett (1981).

# Followers and Mutual Influence on Leadership

[After making profuse apologies for disturbing the Minister, ... the civil servant] indicated that some urgent matters has arisen as a result of the day's business in the House, and the Minister must take certain decisions which would then be implemented in time for the question hour the next day. The civil servant ... had brought the file so the Minister could study the questions, before [deciding]. But ... all the Minister said was: 'Where do I sign?' A pen was produced by the civil servant, the places for signature were indicated, and with [deference and more apologies, he] ... backed out of the room. Bailey, 1969, p.

73

Successful leaders influence their followers and bring about changes in their followers' attitudes and behavior. In the same way, by accepting, modifying, or rejecting the influence, followers influence the leader's subsequent behavior and attitudes. Sometimes, subordinates lead and superiors follow.

Leaders and followers matter to each other, as do the quality of relations between them. "Governments and laws cannot work without people in authority, and those in authority are powerless without support, cooperation, and obedience from the people they govern" (Sarsar & Stunkel, 1994). Leaders and followers are similar in many ways. The antitheses of leaders are not followers, but alienated, apathetic isolates and rejectees. Like good leaders, good followers are transformational, committed to principles and purposes beyond themselves. Like leaders, followers use both hard and soft tactics. Hegel suggested that to be a good leader, one needed to be a good follower. "The school for leadership is indeed follower-ship, a followership that is fully preserved within leadership, but transformed for having moved beyond itself" (Litzinger & Schaefer, 1982). Nevertheless, the study of followers has always played second fiddle to the study of leaders.

According to critical incidents obtained from 81 respondents, good leadership is distinguished from bad leadership by the quality of the leaders' relations with the followers (Hollander & Kelly, 1990). Leaders need to be helped by their followers to understand the tasks and challenges they face. Followers need to learn to challenge their leaders while respecting the leaders' authority (Hirschhorn, 1990). Leaders need to engage followers in satisfactory mutual pursuits. Followers give or withdraw support of their leaders (Hollander, 1997). The exchanges vary considerably in nature and amount. Different leaders have different relations with their followers; likewise, followers have different relations with their leaders. According to a survey in three British companies, the organizational culture affects what types of leaders are dominant, and the leaders in turn affect what types of followers are dominant (Brown & Thornborrow, 1996). Leaders command more attention, but followers affect and constrain what the leaders can do (Hollander, 1992). "Leadership is not what the leader does but what the leaders and collaborators do together to change organizations" (Rost, 1993, p. 92). Bennis (1999) agrees, stating that effective change in organizations requires an alliance between the leaders and the led.

This chapter examines the roles of both the leader and the led in the exchange that takes place between them. Specifically, it looks at the antecedents and consequences of the leader's downward influence on the subordinate, the subordinate's upward influence, and their mutual influence.

## The Leader's Influence

---

Leaders can be found who exert little discretionary influence on their followers. These leaders are the rule-governed, fully programmed administrator; the paper-pushing absentee supervisor; and the token officeholder without power. They are glorified doormen, whose behavior is almost fully determined by others. Other leaders use a lot of discretionary influence as disciplinarians, rule makers, active monitors, and instrumental purveyors of praise, reward, or penalties. They also use discretionary influence to be considerate, stimulating, informative, and inspirational. As a consequence of their influence, their followers can perform better and be more fully informed. These followers can avoid mistakes. Their interests may be enlarged. Their expectations may be developed, their preference for taking risks may be altered, and their satisfaction with their roles may be enhanced. The emphasis that followers believe their leaders place on self-guiding performance determines whether or not the followers persist at working on unsolvable problems (Brown, 2000). But followers fail to benefit from leaders' successful influence when it is not effective in achieving goals of consequence.

In the formal organization, the performance of individual subordinates or groups depends on their energy, direction, competence, and motivation. They perform what is required to reach the objectives of their positions in the system. The leader may contribute to the adequacy of their performance by: (1) clarifying what is expected of the subordinates, particularly the purposes and objectives of their performance; (2) explaining how to meet such expectations; (3) spelling out the criteria for the evaluation of effective performance; (4) providing feedback on whether the individual subordinate or group is meeting the objectives; and (5) allocating rewards that are contingent on their meeting the objectives.

Effective leadership develops understanding and agreement about the leader's and subordinate's roles in this process. For instance, if the leader engages in management by objectives, leadership may take the form of periodic discussions between the leader and the subordinate. A review of past performance and obstacles to effectiveness is the basis for setting mutually acceptable objectives for the next period. Legitimacy for the roles of both the leader and the led is provided by organizational policies that declare and support the roles.

### ***The Downward Influence Tactics of Leaders***

Influence tactics are behaviors designed to change another person's values, attitudes, beliefs, or behaviors (Hughes, Ginnett, & Curphy, 1993). Yukl and Falbe (1990) used the Influence Behavior Questionnaire (IBQ) to measure nine tactics of influence upward, laterally, or downward, conceptually originated by Kipnis and Schmidt (1982) and assessed with the Profile of Organizational Influence Strategies (POIS).

The transactional leader may introduce a proposal with: (1) the tactic of *ingratiation*: "Mary, I know you can do this job;" (2) An *exchange* may be offered: "George, you can leave early if you get this work done;" (3) Another tactic is a *personal appeal* from the leader: "Bill, I need your help;" (4) Another influence tactic is *pressure*: "Jenny, if you want to stay out of trouble, you had better finish this now;" (5) A *legitimizing* tactic is: "Carl, I am an attorney here to represent you;" (6) A *coalition* tactic is: "Eleanor, let's join forces to confront the opposition."

A transformational<sup>1</sup> leader may use intellectual stimulation for *rational persuasion*: "Martha, considering the alternatives, it is the treatment with the least risk." *Inspirational appeal* is another transformational tactic: "We must give until it hurts!" A tactic of considerate leadership is *consultation*: "Ann, before the decision, I need to know what you think about it."

Although ingratiation, exchange, and personal appeal yielded task commitment from subordinates and pressure reduced it, the tactics that were actually effective were the transformational ones, according to a survey of 128 managers and their 526 subordinates from five companies in diverse industries (Yukl & Tracey, 1992). When "critical influence" incidents were gathered by 215 night MBA students, Yukl, Kim, and Falbe (1996) found that managers with lack of referent power used more pressure tactics ( $r = -.33$ ), which tended to

damage their relations with subordinates and peers. Managers with more referent power were less likely to use pressure tactics. Multiple regression analyses indicated that strong rational persuasion, inspirational appeal, and consultation were more likely to result in desired outcomes. Followers accord more discretionary opportunities to leaders who are seen as more competent, legitimate, and expert in solving problems (Lord & Maher, 1991). In a study of 78 leaders and their 156 subordinates, Tepper (1990) showed that less controlling downward influence tactics were displayed by follower-oriented than self-oriented leaders.

*Hard* tactics such as pressure and legitimizing are used when the user is powerful and resistance is expected; *soft* tactics such as ingratiation or personal appeal are used if the user lacks power or will personally benefit from a successful attempt (Hughes, Ginnett, & Curphy, 1993).

### ***Leaders as a Source of Feedback***

Feedback about a subordinate's performance is the most common contingent reinforcement provided by a leader. Supervisory feedback often is required to improve the subordinate's performance and can affect either the subordinate's ability or his or her motivation to do the job (Locke, Latham, Saari, & Shaw, 1981; Payne & Hauty, 1955). Cook (1968) found that improvement in the attitudes and performance of managers who participated in a business simulation game was directly related to the frequency with which reports of their performance were fed back to them.

Rewarding when positive, feedback can be highly punitive when negative. However, negative feedback may quickly come to be interpreted as rewarding if it is seen as intended to be helpful and if it actually results in improved performance. Subordinates will see negative feedback about their failures as fair and accurate if the causes are attributed to bad luck or external circumstances rather than to their lack of ability or motivation, and if the feedback is about the task, not about them (Liden, Ferris, & Dienesch, 1988). Nevertheless, when subordinates suspect that they are doing poorly, they will seek feedback to short-circuit the buildup of negative feedback in order to uphold their self-esteem. They can arrange how and when feedback is given, and they can mitigate blame (Larson, 1989). Feedback can also be neutral and non-reinforcing, as when the superior merely acknowledges, without evaluating it, he or she has seen a subordinate's behavior or has heard a subordinate's statement.

According to a survey of 360 supervisor-subordinate dyads by Glynn, Larson, Fleenor, et al. (1985), supervisors differ from each other in the timeliness, specificity, frequency, and sensitivity of their feedback. But these four dimensions are highly intercorrelated. Furthermore, negative feedback that is prefaced by the Drake-Moberg (1986) sedative or palliative statements will be accepted by subordinates with less sense that they are being negatively reinforced ("It's probably not necessary to say this, but ..." or "I know it's hard, but ...").

*Types of Feedback.* Supervisory feedback can range from a formal annual appraisal interview (see [Chapter 35](#)) to a grunt of acknowledgment of a message received or a pat on the back for a job well done. The grunt or pat has the advantage of occurring soon after the behavior about which the feedback is being given. The appraisal interview has the advantage of being systematic and of couching the feedback in the context of goals, needs, and plans for future action.

*Impact of Feedback.* It is important that subordinates accept and agree with the performance feedback their supervisors believe they are giving them (Ilgen, Fisher, & Taylor, 1979). Naturally, agreement and acceptance are more likely if the feedback is positive (Jacobs, Jacobs, Feldman, & Cavior, 1973). Agreement and acceptance are also more likely if the feedback is clear, convincing, credible, and frequent.<sup>2</sup> The credibility of the superior's feedback is likely to be enhanced if the subordinate believes the superior is highly knowledgeable about the subordinate's job and has had sufficient opportunities to observe the subordinate's performance.<sup>3</sup> The context in which feedback is delivered will affect whether subordinates interpret it as

positive or negative. For example, if feedback is solicited, it may be received more positively than if it is volunteered unexpectedly.

Pavett (1983) illustrated the positive effects of feedback on the performance of 203 staff nurses. Komaki, Collins, and Penn (1982) found feedback to have a positive impact beyond giving instructions. They monitored the safety performance of 200 employees over 46 weeks. After a baseline was established, safety rules were clarified at meetings in which considerable supervisory-subordinate interaction occurred. In contrast to the baseline record of performance, modest improvements occurred in two of four departments as a consequence of the clarification efforts. Then safety performance feedback graphs were introduced. It was this feedback that produced significant improvements in safety over the baseline. Whether the feedback was delivered once a week or twice a week did not seem to matter. According to a similarly designed investigation by Chhokar and Wallin (1984), similar effects of feedback on improvements in safety occurred among 58 employees over a 10-month period.

### ***Leaders as Communicators***

In addition to giving feedback, the leaders' words and actions convey meaning. Their communications distinguish leaders who are successful and effective from those who are not. "Understanding and consensus ... at an operational level are indispensable ... to gain success [in] global competition" (Testa, 1998, p. 32). As was noted in earlier chapters, emergent leaders contribute strongly to the interactions in their groups. They initiate more ideas, express more opinions, and ask more questions than members who do not emerge as leaders (Bass, 1954a; Morris & Hackman, 1969). Elected and appointed leaders would be expected to do likewise in discussions with their groups, as well as in separate dyadic interactions with each of their team members (Watson, 1982).

In a survey, chief executive officers (CEOs) of large businesses ranked face-to-face communication as the most important source of their effectiveness (Anonymous, 1978). An intensive study of nine senior executives by S. Carlson (1951) over a four-week period noted that they spent approximately 80% of their time talking with others. A detailed study of four departmental-level managers also found that more than 80% of their time was spent in conversation. Zelko and Dance (1965) stated that when managers were asked how much of their work-day was spent in communicating, their replies ranged from about 88% to 99%, with most saying that it was above 90%.<sup>4</sup>

According to Baird (1980), the credibility of managers' communications depends on their competence, esteem, personality, dynamism, character, and perceived intentions. Empirically, Klauss and Bass (1982) established strong positive linkages between the trustworthiness and informativeness of supervisors and their careful communications to subordinates; their two-way rather than one-way communications; and their attentive listening. In turn, the trustworthiness, informativeness, and care of supervisors contributed to their subordinates' role clarity, satisfaction with their supervision, and to the effectiveness of their groups.

Hain (1972) reported that in four General Motors plants, productivity and profitability increased most in the plant that also showed the greatest improvement in communications. Similar parallel improvements in other General Motors plants were reported by Widgery and Tubbs (1975) and Tubbs and Widgery (1978). Hain and Tubbs (1974) found greater efficiency, fewer grievances, and lower absenteeism to be associated with employees' ratings of the effectiveness of their supervisors' communication. The effectiveness of supervisors' communication was the best predictor of low grievance activity in still another General Motors automotive assembly plant (Tubbs & Porter, 1978). Such effective communication included agreement that supervisors were friendly, were easy to talk to, listened with interest, paid attention to what others said, were willing to listen to others' problems, were receptive to ideas and suggestions, and showed how performance could be

improved. These various communication behaviors are usually included in measures of leadership. It is not surprising that Klauss and Bass (1981) found correlations as high as .65 between the various communication styles of supervisors and the supervisors' leadership styles as described by their subordinates.

### ***Leaders as Models for Their Subordinates***

Porter and Kaufman (1959) devised a scale for determining the extent to which supervisors described themselves as similar to top managers. Self-perceptions similar to those of top managers were associated with patterns of interaction that peers of the supervisors perceived to be similar to the interaction patterns of managers in top-level positions. Katz, Maccoby, and Morse (1950) noted that supervisors in an insurance firm tended to model their tendency to be coercive or participative on whether their bosses were coercive or permissive. Likewise, R. Cooper (1966) showed that workers tended to pattern their own task behavior after that of their supervisors. Task-oriented leaders supervised groups in which workers made fewer errors in their work and had lower rates of absenteeism and tardiness than was true of groups whose leaders did not have a task orientation. According to a study by Kern and Bahr (1974) of approximately 100 staff personnel in the Washington State Division of Parole, parole officers who interacted a lot with their supervisors used their superiors as models for the way they supervised their parolees. But such modeling did not occur when the parole officers interacted less frequently with their supervisors. H. M. Weiss (1977) studied 141 superior-subordinate pairs of leaders, obtaining from each member of the dyad a self-description of his or her supervisory behavior, along with the subordinate's evaluation of the superior's competence and success. These items were then correlated with the degree of similarity found in the self-descriptions of the superior-subordinate dyads. Weiss found that subordinates tended to choose for role models those superiors they saw as more competent and successful. Although transformational leaders are more likely to serve as models for subordinates who identify with them, transactional leaders may also serve as models.

Adler (1982) found that the characteristics of superiors whom subordinates chose as models depended on the subordinates' self-esteem. Among the subordinates of 66 Israeli heads of bank departments, those with high self-esteem were more likely to model themselves on the heads whom they perceived to have reward and coercive power; those subordinates with low self-esteem were more inclined to model themselves on heads whom they perceived to have referent power. Regardless of the subordinates' self-esteem, modeling was also more apparent of heads who displayed more initiation and consideration in their leadership behavior. Behavioral contagion is less obvious modeling. A crude boss can spawn crude subordinates. The subordinates unconsciously adopt the boss's spoken expressions, intonations, and peculiar nonverbal mannerisms.

*Leaders as Cues.* Followers may come to depend on their leader's view of reality as their prime source of information and expectations. Beyond followers' modeling of their leader's behavior, Graen and Cashman (1975) noted that followers also enlarged their interests to match those of their leader more closely. Followers attempt to increase their esteem in the eyes of their leader to ingratiate themselves with the leader (E. E. Jones, 1964). Friedlander (1966b) asked members of a research and development organization to describe various aspects of members' interaction and the group's performance. The effectiveness of the group was associated with open discussion and with the leader's suggestion of new approaches to problems. At the same time, a member's influence on other members was associated with his or her influence on the leader. Members accepted the leader's influence when policies were clear-cut and group tensions were low. The members tended to play their expected roles and discuss divergent ideas when the leader was oriented toward productivity and efficiency.

Daniels and Berkowitz (1963) experimentally varied supervisor-worker dependence for the attainment of goals, the degree of liking, and the time required for a supervisor to learn of a worker's performance. They

found that workers tried hardest under independent conditions when they believed that the supervisor would learn about their performance quickly. They also worked hardest when they had to depend on a supervisor whom they liked. Similarly, Katzell (1987) showed, from the results of a survey, how complex is the impact on the morale, involvement, and performance of employees of the extent to which supervisors help employees achieve intrinsic and extrinsic rewards. The extent to which they do so is linked to the extent to which they cue the employees by setting goals for them, maintaining normative standards, and preserving equity.

*Falling Dominoes: Modeling or Alternating?* Do strong leaders at one hierarchical level alternate with weak leaders at the level below them? Or does the style of leadership cascade from one management level to another through modeling and other processes? Do subordinates at each descending level below the boss imitate their boss, or do they complement their boss's leadership with compliance to fit it? If A kicks B, will B kick C or will B become solicitous of C after being kicked by A? Do modeling and matching one's superior make a difference, or is alteration from one level of supervision to the next more likely to be productive? The modeling of transactional leadership behavior is supported in a number of ways. When a manager's boss rewards the manager for performance or allocates requested resources to him or her, some of these rewards and resources make it easier for the manager, in turn, to reward his or her subordinates for their performance. Discipline applied by the boss usually will require similar disciplinary action by the manager. Subordinates will be safer targets of the manager's displaced hostility, which is sparked by the hostility of the boss toward the manager. The boss's clarification of goals for the manager provides the means by which the manager clarifies goals for his or her subordinates. On the other hand, the threatening boss may create a manager who is attentive to rewarding subordinates in exchange for their support against the threatening boss. The inefficiencies of the boss who practices non-contingent reinforcement with the manager may result in the manager rejecting the boss's style in favor of contingently reinforcing his or her subordinates. In the case of transformational leaders, J. M. Burns (1978) argued for the former point of view, but Tichy and Ulrich (1984) argued for the latter position. According to Burns, dedication, caring, and participation are multiplied outward from the leaders through their disciples; the leaders become the models to be imitated by successive expanding layers of followers. Tichy and Ulrich (1984) suggested that organizational changes envisioned by top management require lower-level managers to adopt leadership behavior supporting the practical implementation of their superiors' vision.

Most evidence supports modeling rather than alternating. Bowers and Seashore (1966) found that leadership behavior patterns exhibited by executives in insurance agencies were reflected in similar behavioral patterns by the supervisors below them. The supervisors' emphasis on the facilitation of goals and interaction with their subordinates was related to the extent to which the executives did the same. Similarly, Stogdill (1955) obtained data to indicate that participatory leadership at lower levels in an organization was dependent on its being practiced at higher levels. Ouchi and Maguire (1975) found that subordinates tended to use the same methods of control as their superiors in dealing with their own subordinates. Summarizing his studies of Japanese managers from the 1960s onward, Misumi (1985) reported that the supervisory style of a manager, with emphasis on either performance or maintenance, tended to be similar to the style found above and below the manager in the organizational hierarchy.

Bass, Waldman, Avolio, and Bebb (1987) collected self-rated and subordinate-rated leadership descriptions of second-line managers, their first-line supervisors, and their subordinates in New Zealand. A cascading effect of leadership behavior emerged. The amount of transformational and transactional leadership behavior observed at one level of management tended to be seen at the next lower level as well. The leadership patterns of subordinate-superior dyads tended to match each other. The correlation of the actual leadership observed among the levels was highest ( $r = .51$ ) for the transactional exchange involved in providing contingent rewards.

To examine whether modeling of one's superior made a difference in the performance of one's group, Misumi (1985) calculated the capital growth rate in two Japanese banks with 25 and 54 branches, respectively.

Pairs of high-producing and low-producing branches with similar socioeconomic characteristics were compared. First-level and second-level superiors were identified as being low or high in performance (P) and in maintenance (M) orientation. In one bank, 38% of the first-and second-level superiors matched each other in orientation in both the more productive and less productive branches; but in the second bank, 77% of the first-and second-level superiors in the less productive branches matched each other's orientation and 33% did so in the productive branches. The probability of matching on a chance basis was 25%. If the matching was high in P and M at both levels, effects were salutary; but if the matching was low in P and M, effects were counterproductive.

The alternating approach was observed indirectly when the same performance by commanding officers of ships and their executive officers appeared to produce opposite effects. In a study of shipboard organizations, D. T. Campbell (1956) found that although the leadership scores and sociometric interaction scores of the commanding officers were positively correlated with measures of shipboard efficiency and morale, the leadership and sociometric interaction scores of the executive officers, the commanders' closest aides, were negatively correlated with shipboard efficiency and morale.

### ***Superleaders: Leading Followers to Lead Themselves***

Manz and Sims (1987) first studied self-leading and discussed its theory, constraints, and effectiveness (Manz & Sims, 1990). It could replace the leaders' providing orders, promises, or objectives about what needed to be done. Power was to be shared with followers. Followers would provide more direction for themselves. Their commitment would be higher because they "owned" how they proceeded. The superleaders would model self-leadership for the followers, create positive thought patterns, and use contingent reinforcement of the self-leading individuals, teams, and cultures (Manz & Sims, 1991). Manz, Keating, and Donellon (1990) discussed the transition from traditional supervisor to superleadership of teams of self-leaders. Self-led teams and self-management have become popular practices and are discussed further in [Chapter 26](#), with regard to what conditions further the success or failure of self-leadership and self-management.

### ***Complementary Linkages***

The leader's relations with followers can depend on his or her relations with others, such as superiors and peers. In many organizations, the CEO and the chairman of the board work closely together to make corporate decisions. Gronn (1999) presented the case of close coupling, for over 10 years, of the founder, J. R. Darling, and the first head, E. H. Montgomery, in leading Timbertop, an Australian school. Another prominent leadership couple is the platoon leader and the platoon sergeant. The platoon leader is usually a commissioned officer and the platoon sergeant, a noncom. The officer is in charge, but the sergeant often is more experienced. Together, they provide the leadership of the platoon. According to a study of 72 light infantry platoons in near-combat testing for 11 missions, when the relations between the leaders and sergeants were good rather than poor, the platoons were rated much higher in effectiveness by pairs of independent observers of the platoons in action (Bass, Avolio, Jung, & Berson, 1999).

*Importance of Supervisors' Influence with Higher-Ups.* Pelz (1949, 1951, 1952) noted that when supervisors who had influence with their superiors took the side of their subordinates, the subordinates tended to feel more satisfied. But when a supervisor without such influence identified with the subordinates' interests, the subordinates tended to be more dissatisfied. Closeness to subordinates and taking their side increased the subordinates' job satisfaction only when the supervisors had enough influence with their superiors to provide conditions that could result in the fulfillment of the subordinates' expectations. Jablin's (1980) results

concurred with Pelz's findings, particularly for supportive supervisors with upward influence rather than nonsupportive supervisors with upward influence. Nahabetian (1969) found that in general, group members were better satisfied under leaders who had influence with their superiors than under leaders without such influence. Influential leaders were seen to facilitate the group's task, whereas those without influence higher up were seen as hindering it. Ronken and Lawrence (1952) reported similar findings. Anderson, Tolson, Fields, et al. (1990) demonstrated the Pelz effect in a study of 195 nurses and 201 clerical employees who were more satisfied with their jobs and felt more upward control if they perceived that their superiors had more influence with higher authority.

*Combined Effects of Multiple Hierarchical Levels.* Misumi (1985) showed the combined effects of two layers of supervision on the performance of banking subordinates. Hill and Hunt (1970) observed that although the leadership behavior of supervisors one level removed from the employees was not related to the employees' satisfaction, the combined behavior of first-and second-level supervisors did affect their satisfaction. Much initiative by both first-and second-level supervisors was significantly related to the employees' satisfaction with their own esteem and autonomy. George (1995) found that the contingent reward behavior of leaders was correlated at successive levels of sales management.

As evidence of the systematic connections between subordinates, supervisors, and their superiors, Stogdill and Goode (1957) concluded that when supervisors interacted frequently with their superiors, their subordinates thought the leaders should spend more time than they did in interviewing personnel and in coordination. According to Stogdill and Haase (1957), more impersonal performance by superiors, such as inspection, kept subordinates away from superiors. When superiors spent little time in preparing procedures and much time in technical performance, their subordinates tended to interact with peers; but when superiors spent more than an average amount of time in supervision, subordinates tended to interact with them. A high rate of communicating and integrating behavior by superiors enlarged the total number of interactions initiated and received by their subordinates, increased reciprocated interactions within the subgroups, and decreased interactions with members outside the subgroups.

Stogdill (1955) studied the effects of interactions among three hierarchical levels of organization members—subordinates, supervisors, and the superiors of the supervisors. The supervisors tended to interact more with their own subordinates when their superiors interacted more with them. The interactions of these supervisors with members outside their own subgroups were affected by whether their superiors were the initiators or the recipients of interactions within their own subgroups of supervisors. If their superiors were initiators rather than recipients of interaction with the subgroup of supervisors, the supervisors tended to interact less frequently with members outside their own subgroups. When their superiors interacted frequently with members outside the subgroups of supervisors, the supervisors also interacted with members outside this unit, but the supervisors interacted less often with their superiors.

When superiors interacted with the supervisors' peers, the supervisors tended to initiate more interactions with their superiors but received fewer interactions in return. In general, the superiors' interactions with the supervisors induced similar patterns of interaction between the supervisors and their subordinates. The supervisors' interactions with their superiors exerted the strongest effects in restricting the area of interaction of their subordinates.

In the previously mentioned study of three hierarchical levels of organization members (Bass, Waldman, Avolio, & Bebb, 1987), lower-level leaders who were seen by their subordinates as more charismatic, in turn, required less, not more charisma, in their superiors. It appears that charismatic leaders would rather not have a charismatic superior with whom they may have to compete.

*Other Combinatory Effects.* Stogdill and Goode (1957) observed also that leaders who interacted frequently with peers had subordinates who believed that their leaders had too little responsibility, were less active than they ought to be in representing their subordinates, and spent too much time in planning. When

leaders interacted extensively with people outside their own units, their subordinates reported having to delegate and represent their groups too much. These followers also thought they ought to spend more time than they did in inspection, planning, and preparation. In a study of a large naval organization, Stogdill and Haase (1957) found that the more time superiors actually spent in highly personal interactions with others, such as interviewing personnel, the less their subordinates actually interacted with their peers and initiated interactions with members of other subgroups with whom their interactions were reciprocated. On the other hand, Greenberg and Barling (1999) reported that the more supervisors monitored subordinates, the more hostility and aggression were found among 136 full-time employees, particularly when the monitoring was seen as unfair workplace surveillance. In a survey of 116 employees, Fedor, Davis, Maslyn, et al. (2001) found that the sources of a supervisor's power and the recipient's self-esteem made a difference in how much negative feedback affected subordinate performance.

*Explanations.* The multilevel and falling-dominoes effects may be due to differential selection as well as modeling. Lower-level supervisors can be either self-selected, selected by their second-level manager, or selected by the organization. It is not a matter of chance that they may be stylistically compatible with their superior. It is also possible that certain leadership behaviors are reinforced by the norms of organizational subunits; therefore, the cascade effects may be due to the subculture of norms, beliefs, and values within which the leaders operate. In the same way, the environmental and technical demands in one subunit may generate common job requirements and therefore dictate the differential leadership observed and required at the different levels of the subunit. Thus Smith, Moscow, Berger, and Cooper (1969) found weak support for the hypothesis that under conditions of slow organizational change, good interpersonal relations between managers and superiors were associated with good relations between managers and subordinates. But strong support was found for the hypothesis that under rapid organizational change, good relations between managers and their superiors changed into poor relations between the managers and their subordinates. The greater need for rapid change put pressure on the managers to push their subordinates for better performance and faster response. Superiors encouraged the managers in this regard; subordinates were disturbed by it.

## Followers' Impact on Leaders

---

According to regression analysis, in eight organizations social distance and demographic divergence were important influences on 213 followers' relations with their leader (Boccialetti, 1995). Followers come in three types, according to Boccialetti. *Helpers* show deference and comply with the leadership; *independents* distance themselves from the leadership and show less compliance; and *rebels* show divergence from the leader and are least compliant. Among other types of followers, moderate in compliance, are *diplomats*, *partisans*, and *counselors*. The types differ in how they put up with their leaders as authority figures, accept responsibility, seize initiatives, and stay informed. Barbuto (2000) formulated a framework for predicting follower compliance from the leader's bases of power, the self-concept of the follower, the follower's intrinsic and extrinsic motivation, and the follower's zones of resistance to requests.

Heller and Van Til (1982, p. 405) argued that "leadership and followership are linked concepts; neither can be comprehended without understanding the other." The compliance of followers is the mirror image of successful leadership. Just as successful leadership may be seen to influence the completion of tasks and socioemotional relations, so the compliance of followers can be seen as instrumental to the completion of tasks and both public and private socioemotional acceptance of the leadership effort. It also seems obvious that by their performance, subordinates control the nature of feedback from their superior (Jablin, 1980). In the same way, just as the leader can influence subordinates by initiatives and information, the subordinates can complete the process and influence their leaders by giving feedback to them. Hegarty (undated) demonstrated that

feedback of subordinates' ratings to supervisors resulted in positive changes in the supervisors' behavior. The employees of the 58 supervisors in the experimental and control groups completed an information opinion survey. The survey results were used to prepare feedback reports for the experimental supervisors but not for the control supervisors. A second survey was conducted 10 weeks later to measure change. After adjusting for the initial scores, Hegarty found that all 17 measures of change shifted more in the expected direction in the experimental than the control supervisors, six significantly so. Such feedback has become common in many organizations as a means for improving the effectiveness of leaders and their operations.<sup>5</sup>

### ***Followership and Leadership***

In the political arena, both immediate followers and grassroots citizens make a difference to what a leader can accomplish. Karl Rove, President George W. Bush's close advisor, influenced the president as much as or more than the president has influenced Rove. President Bill Clinton's Universal Health Plan of 1994 was defeated in Congress because of failure to gain public understanding and grassroots support. Active followers matter, as does their relationship to their leaders (Hollander, 1996). Followers increase their respect for a good leader and lose their respect for a bad one. A supportive, clearly communicating, and rewarding leader develops and strengthens the relationship with the follower and enhances the follower's satisfaction and performance. Unsupportive, harsh, and demeaning leaders create poor relations with followers, who then withhold information, become passive, withdrawn, and discouraged, and consider quitting (Hollander, 1996).

Followers' expectations affect the performance of their leaders. Followers' perceptions of their leaders' motives and actions constrain what their leaders can succeed in doing (Stewart, 1982b). Followers allow more discretionary opportunities for leaders who are seen to be more competent, legitimate, and expert in solving problems (Lord & Maher, 1991). From an analysis of a representative sample of 100 Swedish managers and their subordinates, Norrgren (1981a) found that the subordinates' levels of education and aspirations affected the managers' beliefs, intentions, and evaluations, particularly those of the younger managers. Furthermore, although older subordinates and subordinates with high aspirations and substantial seniority were most specifically favorable toward managers who had beliefs and intentions to allow the subordinates to participate in decisions, it was the younger subordinates who reacted most negatively to managers with beliefs and intentions that were opposed to such participation (Norrgren, 1981b).

The compliance of subordinates is not automatic; it depends on the active cultivation of the leader's legitimacy. A leader's management style is affected by how the subordinates respond to it. The subordinates can actively work to undermine it, or they can work hard to support it because it serves their own interests or the "greater good." Self-interest, according to Biggart (1981), may have accounted for the strong loyalty of most of Ronald Reagan's subordinates, despite his hands-off management style when he served as governor of California and later as president of the United States. Cabinet officers resign when they can no longer support the policies of a prime minister. As will be noted below, good followers go beyond their self-interests for the good of their group, organization, or society.

The follower's influence on the leader also means that, contrary to popular notions, followership and leadership are highly similar, as are followers and leaders. Hollander and Webb (1955) showed that the same peers who are nominated as most desired leaders are also nominated as most desired followers. Nelson (1964a) found that among 72 men on a U.S. Antarctic expedition, the characteristics that made the men liked were about the same for the leaders as for the followers.

There are no sharp boundaries between the roles of leader and follower (J. M. Burns, 1978). Both roles always must be played in any group. Leaders cannot exist without followers; nor can followers exist without leaders. Moreover, leaders and followers exchange roles over time and in different settings. Many persons are

leaders and followers at the same time. But the interaction between the leader and the follower is not symmetrical. K. M. Watson (1982) coded the antecedent acts of dyadic interactions of subordinates and leaders. When the leaders attempted to initiate structure, the subordinates were most likely to comply with deference. However, when the subordinates attempted to initiate structure, the most common reaction of the leaders was to resist by responding with efforts to try to structure the situation differently rather than to comply with the subordinates' initiative (Boccialetti, 1996).

*The Good Follower.* James (1995) argued that we need to pay more attention to the good follower. Kelley (1988) enumerated many elements that go into being a good follower. These elements are similar in many respects to what makes a good leader. The differences between the effective leader and the effective follower are mainly in the different roles they play. Good followers are active, independent, critical thinkers who can manage themselves. They are committed to the organization and to persons, principles, or purposes beyond themselves. Their personal and organizational goals are aligned. They are competent and avoid obsolescence by pursuing continuing education and development. They disagree agreeably. They build credibility. They can move easily into the leadership role and return again to the role of follower. Campbell (2000) adds that the follower who is proactive is not only competent, interpersonally effective, and organizationally oriented but also has integrity and is enterprising. Such followers are good "organizational citizens" who willingly contribute to the firm's effective functioning. They volunteer for assignments and put forth extra effort. They take the initiative to expand their role and take on new tasks. Albino (1999), a college president, agreed with Kelley (1992) that good followers are essential in higher education. Good followership is a discipline that requires going beyond self-interests. Effective leadership requires good followership. Effective leaders know how and when to follow. Laotzu suggested that to lead people, one must walk behind them. The effective leader follows the lead of the group (Rinne & Karl, 1990). According to 37 supervisors at retail stores and 58 bank supervisors, satisfactory subordinates (among a total of 274) helped to get things done.

One example is the turnaround in IBM in 1994 from a complacent manufacturer of mainframe computers and PCs that had been recognized by *Fortune* as a "most admired" company in the mid-1980s. In the three years preceding 1994 it had accumulated \$15 billion in losses. David Grossman, a midlevel IBM programmer, was one of the first people to download the Mosaic browser and experience the Web. IBM was the highly advertised technology sponsor of the 1994 Winter Olympics, providing raw results on television. But when Grossman surfed the Web, he found that newcomer Sun Microsystems presented the results as a Sun contribution. Grossman drove to IBM headquarters with the necessary equipment to show the Internet to John Patrick, a senior marketing executive manager on IBM's strategic task force. Grossman and an associate built a primitive intranet for IBM, and Patrick published a document extolling uses of the Web, from replacing paper communication to e-commerce, and giving every employee an e-mail address. The new CEO was highly supportive. By 1996, IBM's Web site was able to earn \$5 million from its e-commerce and launch into an effective changeover, becoming a consulting business (Hamel & Schonfeld, 2000).

*The Susceptible Follower.* According to Shamir and Howell (1999), followers who are more susceptible to the influence of a leader, particularly a directive and charismatic one, are likely to be unstable, uncertain, and inconsistent about their own self-concept. They do not have a clear, consistent self-concept that could guide their behavior. Furthermore, susceptible followers' values and identities are congruent with those of their leader. They will also be more readily influenced by a leader who seemingly has the support of majority opinion.

*Antitheses of Leaders.* If not the followers, then who are the opposites of leaders? They are those barred from the process (for instance, the underage, who cannot vote). They are the isolates, the rejectees, and the anomic. They are those who exclude themselves from participation—the apathetic and the alienated. The apathetic may be too busy with other affairs or too busy just surviving. The alienated may reject and resist

participation; they believe that the power to lead is in the hands of others, for the benefit of others. The anomic feel powerless, normless, and aimless, and see leaders indifferent to their needs (J. M. Burns, 1978). These nonleaders-nonfollowers, by their lack of involvement, can have a negative impact on their groups, organizations, and societies. Quoting deJouvenal ("A society of sheep must in time beget a government of wolves"), Gardner (1987b) noted that those who fail to follow but remain the antithesis of leadership invite the leader's abuse of power.

## ***Upward Influence***

Despite the asymmetry of the relationship, followers exert considerable upward influence on their leaders (Gabarro & Kotter, 1980). Followers can actively affect leaders in many important ways (Hollander, 1992). Upward feedback was provided by subordinates to their managers in a quasi-experimental Australian study. Compared with the managers' initial performance and a control group, managerial performance was improved considerably six months later, particularly if the managers had an orientation toward the goal of learning (Heslin & Latham, 2004). Farmer and Maslyn (1999) confirmed three styles of upward influence first typed by Kipnis and Schmidt (1988): *bystander*, *tactician*, and *shotgun*.

Acts of moral courage by elected political leaders can be strongly pressured by constituencies, economic blocs, and organized letter writers (Paige, 1977). Reed (1996) argued that civic followers are actually leaders as they monitor the affairs of society and react accordingly. On tour, President Woodrow Wilson was first shocked, then braced, by hearing a voice from the crowd shout, "Attaboy, Woody" (Davies, 1963). After they have been elected, U.S. presidents may try to ignore their own campaign rhetoric or reinterpret it to fit their preferred policies. But when public opinion is sufficiently aroused, the presidents become responsive and usually adopt the opinion of the strong public majority as their own. In 1983, public opinion polls indicated that the public did not find much reason for placing U.S. Marines at risk in Lebanon in the exercise of a presidential policy that had been in effect for at least a year. Despite the continuing lack of public approval, days before the terrorist bombing of the Marine barracks President Reagan publicly expressed his opinion that we would never "cut and run." Days after the bombing and the loss of life, which greatly aroused public opinion against the policy, the Marines were "redeployed offshore" (Gwertzman, 1983). President Clinton was sensitive to the results of daily public opinion polling. But like Reagan, President George W. Bush was less responsive to adverse domestic or foreign public opinion about American military forces and kept accusing the Democrats of wanting to "cut and run" from Iraq. Still, suddenly, in June 2006, Bush accepted a plan for a staged withdrawal from Iraq, which subsequently did not occur.

Upward influence is seen as an important contribution to organizational effectiveness (Gabarro, 1979) and a key to understanding organizational politics (Porter, Allen, & Angle, 1981). Subordinates have the responsibility to exert upward influence on their bosses for their mutual benefit and the benefit of the organization as a whole. Subordinates should challenge their superiors' proposals and help them avoid mistakes, but subordinates can do so only if they have contributed to building trust between their superiors and themselves. The subordinates must provide adequate information and account for their performance in carrying out delegated assignments. Effective subordinates will actively invite review, support, and feedback from their superiors (Crockett, 1981).

*The Tactics of Upward Influence.* Upward influence tactics used by subordinates were identified and scaled by Kipnis, Schmidt, and Wilkinson (1980) as: assertiveness; reasoning; bargaining about the exchange of benefits; appealing to a higher authority; forming coalitions; or trying friendliness, ingratiation, and flattery.<sup>6</sup> The list of items was refined and the subscales confirmed by Schriesheim and Hinkin (1988). For Schilit and Locke (1982), upward influence tactics included logical or rational presentation of ideas; informal exchange

not related to performance, such as ingratiation or praising the superior; promising rewards or threatening sanctions; adhering to rules; manipulating matters so that the superior is unaware of being influenced; mobilizing coalitions of support among coworkers and higher-ups; and being persistent or assertive.

Supervisor-focused upward influence tactics by subordinates such as ingratiation and impression management aim to increase being liked by the supervisor. They result in receiving higher performance ratings from the supervisor (Wayne & Liden, 1995). Job-focused upward influence tactics are self-promoting and self-serving distortions to increase the appearance of competence (Dulebohn & Ferris, 1999).

*Hard, Soft, or Persuasive?* Like leaders, followers may use tactics of upward influence that are hard (assertiveness), soft (friendliness, ingratiation), and rational (persuasive). In a national sample of 225 mainly women employees of 60 branches of a nonprofit health and advocacy organization, Fedor, Goodman, and Maslyn (1992) found that hard tactics of upward influence were used more frequently by respondents higher in Machiavellianism; soft tactics were used by those higher in internal locus of control and self-monitoring. Followers were also more likely to use soft tactics with leaders perceived to have more control of rewards and punishments. Rational tactics were used more by followers if their leaders were valued and esteemed with referent power. Deluga (1991a) found that 102 bank employees high in self-monitoring used all three kinds of tactics for upward influence, particularly if they also were high in deceiving others. According to another survey by Deluga (1988), soft upward influence tactics such as reason and friendliness were used more frequently by 70 managers and employees from various departments when they rated their leaders as transformational. In still another survey by Deluga (1991b), 82 hospital personnel were shown to contribute to their managers' felt interpersonal stress by using hard upward influence tactics ( $r = .72$ ) and reduced such stress by using rational influence tactics ( $r = .52$ ). Assertiveness, coalition, and bargaining were used less frequently. Epitropaki and Martin (2001) found that "to get their way with their manager" 271 employees in one service company and six manufacturing companies said they were more likely to use soft and rational tactics with a transformational manager and less likely to use hard tactics. They were also less likely to use hard or rational tactics with transactional leaders. According to Deluga and Souza (1991), 117 police officers reviewing scenarios were more likely to choose rational upward influence as more appropriate if the supervisor were transformational rather than transactional. Elsewhere, Deluga (1988) noted that when leaders were rated as transactional, fewer if any upward influence tactics were tried.

*Impression Management.* Followers practice impression management with defensive tactics such as trying to justify inadequate performance with excuses and apologies, or with proactive tactics such as self-promotion to appear competent and dependable so as to attract their boss's attention or to obtain authorization for changes. They may also do personal favors for the boss and ingratiate themselves with the boss in other ways (Wayne & Ferris, 1990; Yukl, 1998). From 67 manager-subordinate pairs, Rao, Schmidt, and Murray (1995) obtained the managers' appraisals of the subordinates and the subordinates' styles of influence. Coalitions resulted in favorable impressions and appraisals of the subordinates, but subordinate ingratiation and assertiveness did not. Wayne and Liden (1995), in a study of 111 supervisor-subordinate dyads, found path coefficients of .40 and .33 between the subordinates' supervisor-focused impression management and the supervisors' liking of and perceived similarity to the subordinate. This in turn yielded a path coefficient of .21 for appraised subordinate performance when demographic similarity was taken into account.

*Usages.* All 123 salaried employees in a metal fabricating firm surveyed by Deluga (1986) used ingratiation, flattery, reason, and assertiveness much more frequently when trying to influence their superiors than they used bargaining and appeals to coworkers or to a higher authority. Deluga (1988) reported that when their first efforts to influence their transactional but not their transformational superiors did not work, 117 managers and employees of a northeastern manufacturing firm subsequently displayed significantly less friendliness and assertiveness toward their superiors and appealed less to a higher authority. According to Schmidt and Kipnis

(1984), staff managers were more likely than line managers to attempt more upward influence to achieve individual goals.

*Purposes.* Subordinates' goals will determine which tactics they use. To affect policy, subordinates will be more likely to use reasoning and the rational presentation of ideas (Kipnis, Schmidt, & Wilkinson, 1980; Schmidt & Kipnis, 1984). Mowday (1978) found that elementary school principals who were power motivated were more likely to attempt upward influence. In a study in India, the need for power determined the particular power strategies that 96 managers from the public sector said they used to influence their superiors. Most of the strategies they used were "soft and subtle" (Singh, Kumari, & Singh, 1988). To promote self-interests, to attain personal goals, and to obtain benefits, the Indian administrators were more likely to try ingratiation and promises for a satisfactory exchange with their superior based on their evaluation of the superior's preferences. In looking at the specific reasons why subordinates attempt to ingratiate themselves with their bosses, Ralston (1985) argued that ingratiation was more likely to be used by Machiavellian subordinates with autocratic superiors in an ambiguous setting. In an experiment in India, Pandey and Bohra (1984) confirmed that subjects who acted as subordinates were likely to endorse ingratiating tactics with executives who liked to have admirers around them; who preferred employees who supported their views, praised their ideas, and conformed to their policies un-critically; who used subjective criteria in making decisions about employees' requests for benefits; and who rewarded those whose behavior flattered and pleased them. In contrast, ingratiation was less likely to be suggested as a viable tactic if one was working for an executive who had the opposite tendencies.

*Successful Upward Influence.* Schilit and Locke (1982) asked employees and supervisors about more and less successful ways for subordinates to influence their superiors. Both subordinates and supervisors agreed that subordinates used logical presentations more than any other tactic in attempts at upward influence and agreed that the substance of the effort determined its success. But they disagreed on what caused attempts at upward influence to fail. Although the supervisors attributed failure to the substance of the attempt, subordinates attributed failure to the closed-mindedness of the supervisors. In an analysis of the diaries of 60 middle-level managers over a two-month period, Schilit (1987) found that the managers high in tested need for power thought they had more upward influence on strategic decisions. Such felt upward influence coincided with a high need for achievement, self-control, and experience with their superiors. As a whole, the managers tended to believe themselves to be successful in their attempts at upward influence, particularly in attempts involving less risky strategic decisions. Rice (1986) offered suggestions on how to cope with a difficult boss: subordinates should observe how others succeed in getting along with the boss; they should offer to be helpful; they need to keep track of their boss's mood swings, discussing his or her mistreatment of them in private, when the boss is calm; subordinates should avoid seeking the boss's approval when it is not required, but they should not dispute the boss's legitimate authority even if they disagree with his or her judgments.

*The Subordinate as a Source of Feedback.* Considerable upward influence may occur in the course of the subordinate's feedback to the superior. For effective superior-subordinate relations, feedback must flow both ways; a loop must be maintained. In their attitudes and behavior, leaders can hinder the flow or help close the loop from the subordinates back to them (Kaplan, Drath, & Kofodimos, 1985). Hegarty (1974) showed that subordinate ratings of supervisors could improve supervisors' behavior. Reliability and validity of upward appraisals was likely to be higher than appraisal from a single boss, since multiple subordinates are available to rate each supervisor (Harris & Schaubroeck, 1988). Improvements in managerial performance were found over a five-year period for 252 managers who received feedback from their direct reports and discussed their previous year's feedback, compared with managers who did not (Walker & Smither, 1999). Subordinate upward appraisals were found to be among the best predictors of managerial performance (McEvoy & Beatty, 1989).

*Facilitators and Inhibitors.* The willingness of 153 employees in a university affairs office to provide feedback to their supervisors was greater if they felt it was beneficial ( $r = .52$ ), if they did not fear retaliation ( $r = .39$ ), if they perceived organizational support ( $r = .39$ ), if they felt it was appropriate to their role ( $r = .26$ ), if they were knowledgeable about upward feedback ( $r = .23$ ), and if they sought feedback themselves ( $r = .22$ ; Smith, Kudisch, & Thibodeaux, 2000). At a research university, 411 of 1,135 faculty members who participated in anonymous upward appraisals were more confident about the accuracy of the ratings, felt they did not have to bias ratings, felt more secure in rating superiors, and perceived that more effects would accrue from the process (Westerman & Rosse, 1997).

Superiors prevent their subordinates' criticism from reaching them by monopolizing conversations, by developing an abrasive style, by emphasizing their own power and status, and by "adopting the mantle of their office when interacting with lower level managers" (Bruce, 1986). Leaders who receive positive feedback do not seem to evaluate subordinates differently, but they do evaluate less active subordinates less favorably if the feedback is negative (Elgie, Hollander, & Rice, 1988). They avoid discussing issues until they are ready to make a decision. They distance themselves from subordinates and become isolated and insulated from feedback from below by selecting subordinates to bolster their own thoughts and feelings.

Channels of communication dry up as one moves upward in an organization. Information is increasingly filtered, as it must flow through more levels. To promote the upward flow of information, superiors need to reduce perceived differences in power, make themselves more accessible, and open informal channels (Bruce, 1986). They need to reward—not punish—messengers who bring bad news or disturbing opinions. They need to be aware that despite the greater pressure to communicate upward than downward, their subordinates are quite reluctant to risk their displeasure by being seen as critics of the current state of affairs or as bearers of unpleasant messages. Superiors can encourage systematic surveys of subordinates' attitudes that are a formal medium for upward feedback. They can institute a policy, as did the British Army in World War II, that each commander must pay frequent visits to all the unit commanders at the level immediately below. They can practice "walk-around" management, in which managers visit employees' work stations. This policy can promote upward feedback informally if the employees recognize that their superiors, particularly those at high levels in the organization, may feel out of touch with those at the lower levels and would appreciate receiving positive, supportive feedback as well as constructive criticism. The higher-level receivers must make it clear that they are open to accept feedback; the lower-level senders must be ready to provide feedback that is free of the distortion commonly observed in upward messages in which subordinates tell the superiors what they believe the superiors want to hear (Jablin, 1980).

In addition to such motivated distortion, there is cognitive distortion because of the different meanings that superiors and subordinates attach to the same words and their different perceptions and broader views about the same issues (Smircich & Chesser, 1981). When upward feedback was provided to supervising officers in a police agency, the extent to which they reacted positively and took steps to improve depended on their organizational cynicism (Atwater, Waldman, Atwater, et al., 2000). When subordinate feedback is given as part of a 360-degree appraisal program, the upward feedback is perceived as useful if there is organizational support for it (Facteau, Facteau, Schoel, et al., 1998).

### ***Maturity of Followers***

An axiom of learning theory and counseling is that a learner needs more guidance early in training and less guidance later in training. In the same way, the novice subordinate requires more direction and the mature subordinate requires less. Less can be delegated to the novice; more can be delegated to the mature subordinate. The subordinates' readiness and competence determine how much and what kind of leadership can be

efficacious.<sup>7</sup>

*Readiness and Maturity.* Followers strongly affect the likelihood of a leader's success in influencing them as a consequence of whether they are ready for the leader. J. M. Burns (1978) suggested that followers could be ripe for mobilization by a leader or, on the contrary, imprisoned by fixed beliefs that would make it impossible to lead them. In the same vein, Heller (1969a) pointed out that some level of agreement about procedures, interests, and norms among followers is necessary for effective participatory leadership. Nie, Powell, and Prewitt (1969) found five sets of attitudes that were of consequence to such readiness among political followers in Germany, Italy, Mexico, the United States, and Britain: (1) a sense of duty; (2) information about politics; (3) a stake in political outcomes; (4) a sense of political efficiency; and (5) attentiveness to politics. According to L. L. Moore (1976), fully effective leadership tends to depend on mature followership. Moore developed a maturity index based on observations of verbal and nonverbal behavior of followers in task groups. Dimensions of maturity were perspective, position, awareness, activity level, dependence, motivation to achieve, ability and willingness to take responsibility, task-relevant education or experience, and variety of behavioral interests. The leader's knowledge of the followers' maturity can facilitate and modify the followers' and the leader's behavior.

One's readiness to accept the suggestions of leaders will depend on one's immediately preceding experiences. For instance, negative arguments that were introduced before an attempt to persuade students to volunteer for civil defense work were found more likely to reduce the success of the positive arguments than were the negative arguments that came later (Feierabend & Janis, 1954). Another antecedent to determining the readiness of subordinates for a subsequent attempt to lead them is the extent to which the attempted leadership fits with previous experiences. Weiss and Fine (undated) found that groups who were first subjected to failure and insult were more influenced by suggestions to be punitive; groups first subjected to rewarding experiences were more likely to respond to suggestions to be lenient. Also important is the followers' sense of security—whether the followers have a general trust of others and are comfortable with others. The insecure are anxious and avoid attachments (Hazen & Shaver, 1987). Among 127 undergraduate management students who ranked themselves as followers in their small class groups, Berson and Yammarino (1998) found that on scales of implicit leadership, the secure students ranked their ideal leader high if the leader was charismatic and considerate. They ranked low a leader who tried to initiate structure but did not lead. Insecure students ranked their ideal leader as a nonleader low in consideration. Lord, Brown, and Frieberg (1999) suggested that the working self-concepts of followers are changed by the leader through the development of schemas and are influenced by the leader's self-schema.

*Effects on the Leader of the Follower's Interest and Competence.* What subordinates seek in their jobs affects what their supervisor can and will do (Maier, 1965). Jones, James, and Bruni (1975) showed that the degree to which trust and confidence of 112 engineering employees correlated with the behavior of their supervisors was affected by whether the employees were involved in their work. If the subordinates preferred to avoid risk, if they did not wish to become involved in the task, if they were uninterested in the task, and if their interest was of no relevance to getting the job done, leaders became directive. But if subordinates wanted to be involved and were interested in what happened, more supervisory leadership occurred to engage them. Thus when the British managers who were surveyed by Heller (1969a) saw a decision as being important to subordinates but not to the company, they used a high degree of power sharing. Conversely, when a decision was a matter of concern to the company but not to subordinates, they preferred the centralization of power.

If the time required for subordinates to participate in decision making is more expensive than the value of their contribution, effective supervisors will be more directive than participative (Tannenbaum & Massarik, 1950; Lowin, 1968). On the other hand, if the supervisors value the competence of their subordinates, they will be more participative (Likert, 1959). Thus Hsu and Newton (1974) found that supervisors of unskilled employees in a manufacturing plant were more directive than were supervisors of skilled employees in the same

plant. Similar results were obtained experimentally by Lowin and Craig (1968) with students who thought themselves to be in part-time jobs. When the students thought they lacked competence for the tasks to be done, they were more appreciative of close, directive supervision than when they considered themselves competent. Likewise, Heller (1969a) reported that whenever managers considered their technical ability, decisiveness, and intelligence much greater than those of their subordinates, they were more likely to use autocratic decision methods. But when the subordinates were valued for their expertise, they were more likely to be invited to share in the decision process with their supervisors.

Ashour and En gland (1971) found, in experimental teams of supervisors and secretaries, that the perceived competence of followers was the major determinant in assignment of discretionary tasks. Supervisors allowed competent secretaries more discretion than they permitted incompetent secretaries. Another effect of the competence of subordinates on superiors was seen by Kim and Organ (1982) using an in-basket simulation. "Supervisors" were more likely to initiate noncontractual social exchanges with competent "subordinates." Scandura, Graen, and Novak (1986) showed, in this regard, that supervisors were more willing to involve competent subordinates in nontrivial decisions, particularly subordinates with whom they had good relations. However, the competence of followers could produce resistance. Thus Mausner (1954a) showed that participants with a past history of positive reinforcement in a given type of judgment were less influenced by their partners in a group-judgment situation than were participants with a history of negative reinforcement. Nevertheless, effective followers are those who, despite their own competence, can avoid being overly resistant to influence from others because of the followers' capacity and willingness to learn from others. They listen, discriminate, and are guided by others without feeling threatened or fearing loss of status (J. M. Burns, 1978).

The competence of followers affects how they view their leaders' initiation and consideration. Cashman and Snyder (1980) reported systematic differences in the factor structure of 475 descriptions of supervisors by more competent and less competent subordinates. Snyder and Bruning (1985) found that the competence of 815 employees of federally funded social service organizations correlated .24 with their evaluations of the quality of the dyadic linkage with their superiors. The same correlation was obtained by Bass (undated) for 220 manufacturing employees who were sorted by their supervisors into "best" and "less than best" and the employees' satisfaction with their supervision.

Subordinates' competence may affect their ability to comply. Numerous studies have shown, as seems obvious, that the compliance of subordinates affects their superiors' attitudes and behavior toward them. In a laboratory experiment, Price and Garland (1981) demonstrated that when the group members were low in competence, they were much more willing to comply with their leader's suggestions. Nevertheless, in some situations, compliance can suffer because the member is unable to comply, rather than unwilling. Kessler (1968) hypothesized that highly rated subordinates in a governmental agency would be highly motivated to act in accord with their superiors' expectations; instead, Kessler found that these subordinates were most independent. Consistent with this, Simmons (1968) observed that in a business game, students who were rated as very low, low, or average in performance complied more closely with the managers' expectations than did those who were rated high in performance. Evidently, the competent, highly valued subordinates felt greater freedom than did the less highly valued subordinates to deviate from managers' expectations.

## ***Performance of Followers***

*Effects of Followers' Good or Poor Performance.* The quality of the subordinates' performance—good or poor—has obvious effects on whether their leaders will be supportive or punitive toward them (Podsakoff & Schriesheim, 1958a, b). The evidence in this regard is overwhelming. Barrow (1976) and Herold (1977) found that leaders rewarded good performers and behaved more punitively toward poor

performers. Farris and Lim (1969) agreed. They divided 200 male graduate management students into 50 groups to play a business discussion game. Some leaders, appointed at random, were told that they had high-producing groups, and other leaders were told they had low-producing groups. Leaders who were told that their groups were high producers were significantly more likely to be seen by their groups as sensitive, nonpunitive, maintaining high standards, exerting less pressure to produce, allowing freedom, and emphasizing teamwork than were leaders who were told their groups were low producers. The subordinates in the high-performance condition were better satisfied, felt they had more influence, and described their groups as more cohesive.

In a laboratory study, Lowin and Craig (1968) artificially established the level of subordinates' performance as either high or low. "Poor" performing subordinates tended to elicit from their appointed leader close supervision with frequent directions and checking. The ideas of the "poor" subordinates were ignored. These subordinates were held closely to prescribed procedures, viewed by their leader as irresponsible, and treated with less consideration. The laboratory "supervisors" of the "poorly" performing subordinates criticized them more for their work and for taking unauthorized breaks, ordered them to return to work, and showed them less support than did supervisors of "high-producing" subordinates. In studying the behavior of 82 coaches of boys' baseball teams, Curtis, Smith, and Smoll (1979) found that compared with the behavior of winning coaches, proportionally more of the behaviors of coaches on losing teams were reactions to players' mistakes and misbehaviors. (Of course, players on losing teams usually make more mistakes.) But more important, players perceived the coaches of losing teams to be more punitive and less supportive than winning coaches. With teams of older boys, such perceptions by team members became more significant to their continuing performance as winners or losers.

Lanzetta and Hannah (1969) found that trainers were rewarding when trainees responded correctly, but the trainers were punitive when the trainees responded incorrectly. Bankart and Lanzetta (1970) found that reward and punishment were systematically related to observed performance; rewards were given for good performance and punishments for poor performance. Kipnis and Vanderveer (1971) concluded that "managers" in a simulated work setting rewarded superior performers more than average performers and average performers more than poor performers. Fodor (1973a) also reported that superior performers were given more rewards than average workers. Chow and Grusky (1980), in a laboratory study, observed that supervision was less close for productive workers than for unproductive workers. Sims and Manz (1984) studied laboratory subjects who served as the appointed supervisors of "subordinates" who actually were confederates of the experimenters. The subjects tended to provide positive verbal rewards for the "subordinates'" good performance and punitive and goal-setting verbal comments when the "subordinates'" performance was poor. More of the subjects' supervisory activity dealt with clarifying how the task could be accomplished than with evaluations of the subordinates' efforts.

Continued punishment may lead to a downward spiral in performance. Moreover, *learned helplessness* can occur. A particular area of poor performance will be dealt with even more punitively than usual if a subordinate is generally viewed as a poor performer (James & White, 1983). Overall performance will deteriorate further (Peterson, 1985a). However, there is some buffering against the downward spiral. Rothbart (1968) found that when the use of rewards in a prior trial in an experiment produced improved performance, the administrator had a strong tendency to use reward again. But if punishment on a previous trial led to increased performance, it was unlikely to be used in the next trial.

*Effects of the Causes Supervisors Attribute to Subordinates' Performance.* Calder (1977) and Green and Mitchell (1979) proposed that to understand how a subordinate's performance affects a supervisor's reactions requires a determination of the cause of the subordinate's good or poor performance as identified by the supervisor.<sup>8</sup> Four causes were seen as possibilities: competence, effort, luck, and external causes within or outside the subordinate's control. Competence and effort were causes internal to the subordinate; luck and

uncontrollable causes were external. Knowlton and Mitchell (1980) demonstrated, with 40 undergraduates who were ostensibly supervising confederates of the experimenter, that if supervisors attributed the good performance of their subordinates to the subordinates' efforts, they evaluated the subordinates more highly than ordinarily. But this did not happen if the good performance was attributed to the subordinates' competence. Ilgen and Knowlton (1980) reached similar conclusions. Mitchell (1981) and Brown and Mitchell (1986) found that supervisors were more likely to blame subordinates for a poor performance and its consequences than for external causes. In doing so, the supervisors gave more weight to information about the subordinates' lack of effort than to the subordinates' lack of ability.

For supervisors in a role-playing simulation conducted by Liden and Green (1980), the poor performance of subordinates in missing a deadline was described as being due either to their taking an overextended lunch break (an internal cause) or to a delay in receiving materials (an external cause). The supervisors attributed taking too much time for lunch to the subordinates' personal character and failure to take responsibility for their action. Supervisors were more intense in their punitive reactions to the subordinates who missed the deadline because they took a long lunch. The supervisors thought they should do something more punitive than just talking to the subordinate about the matter, but the subordinates thought that such a discussion was sufficient. The supervisors were less likely to carry out stated corrective policies when the failure was due to an external cause—the delay in receiving materials.

In similar studies, supervisors generally were found to be more punitive when they attributed poor performance to internal causes—subordinate ability or effort—rather than to external causes. If lack of effort was the diagnosed cause, punitive action was more likely than if lack of ability was seen as the cause. If lack of ability was regarded as the cause of the subordinate's poor performance, then training or replacement of the subordinate was indicated (Mitchell & Wood, 1980; Wood & Mitchell, 1981). Employees who were described as succeeding because of their ability were seen to have more potential for top management positions than those who were thought to be successful because of their efforts, external conditions, or good luck (Heilman & Guzzo, 1978).

Brown and Mitchell (1986) reported that attributions of internal causes increased if poor performance was detected in just one of several employees. The employees did not have to be working on interdependent tasks for this to happen. However, in a laboratory experiment with undergraduates, Offerman, Schroyer, and Green (1986) showed that leaders advocated reward or punishment for actual success or failure rather than for the reasons they attributed for the subordinates' performance. The leaders also increased their talking to subordinates whose success they attributed to luck, as well as to subordinates whose poor performance was attributed to a lack of effort. Attributions by leaders of the causes of followers' failures also affected their talking and negative comments (Offerman, Schroyer, & Green, 1998). Heneman, Greenberger, et al. (1989) found that the reported quality of leader-subordinate exchanges by 188 supervisors in 37 organizations was increased by how much they attributed competence and effort to their subordinates' performance, but not by how much they attributed the performance to luck or other external causes.

*Effect of Supervisory Experience.* In a laboratory experiment and in a field study with military officers, Mitchell and Kalb (1982) found that the superiors' experience made a difference. Experienced supervisors were more likely to emphasize external causes than internal causes as the reason for the subordinates' poor performance. Liden (1981) obtained similar findings for bank managers' explanations of the poor performance of subordinates; again, more experience resulted in more external attributions. On the other hand, Mitchell and Kalb argued that if the subordinate had performed poorly on the same task before, if the subordinate also performed poorly on other tasks, and if coworkers were performing well on the task, supervisors would be expected to attribute the subordinate's poor performance to the subordinate rather than to external causes, and to act accordingly. Gioia and Sims (1986) demonstrated with 24 experienced managers, each interacting with four different subordinates in simulated performance appraisal interviews, that the interviews resulted in a

more lenient appraisal of the subordinates afterward. The managers attached less blame to their subordinates for failure and more credit for success after the meeting than before it.

*Effects of Subordinates' Accounts.* If subordinates apologize or provide an explanation of the external causes for their poor performance, they can affect their supervisor's interpretation and reaction. In an experiment with 109 nursing supervisors, Wood and Mitchell (1981) showed that although both tactics may work to reduce the supervisor's blame of the subordinate, explanations were much more effective than were apologies. In another study, Mitchell and Liden (1982) established that a supervisor's punitive action for a subordinate's poor performance might be moderated by the subordinate's social skills and popularity. Lenient reactions of supervisors, according to a study in Israel by Bizman and Fox (1984), may result because supervisors see good acts by subordinates—such as avoiding waste; not squandering resources; performing duties with precision and thoroughness; and making efficient and practical use of information—as being more stable in occurrence than bad acts by subordinates, such as setting up difficulties in planning and organizing work, creating unpleasantness, and not following supervisors' instructions.

Martinko and Gardner (1987) traced different likely outcomes from the combined attributions of leaders and subordinates about the subordinates' failure to perform adequately. If both the leader and the subordinate consider that the subordinate's failure was due to bad luck, the leader will take no action and the subordinate will not change. If the leader attributes the subordinate's failure to a lack of effort, if the subordinate does likewise, and if the leader reprimands the subordinate, the subordinate will increase his or her effort. However, if subordinates continue to perform poorly or if the leader continues to punish them, they will attribute the continued failure to external conditions, including the leader's punitiveness.

### ***Followers' Compliance***

*Effects on Leaders of Compliance or Noncompliance.* It is evident from the previous section that leaders tend to react to their subordinates' compliance or non-compliance. As expected, Hinton and Barrow (1975) found that supervisors rewarded subordinates for compliance with the supervisors' requests and were punitive when subordinates did not comply. Fodor (1974) demonstrated, also as expected, that leaders became more authoritarian when faced with a disparaging and disruptive subordinate. Naturally, they rated such a subordinate lower and gave the subordinate less pay than they did subordinates who did not engage in such behavior. In an experiment by Crowe, Bochner, and Clark (1972), male management students were asked to play the role of a leader. Each was confronted with accomplices of the experimenters who served as subordinates and acted either *democratically* or *submissively*. "Democratic" subordinates showed initiative by putting forth ideas and trying to set their own goals. "Submissive" subordinates avoided taking any initiative and asked for detailed instructions, which they followed without question. The student subjects' leader behavior was affected accordingly. For example, the students were more autocratic with the submissive subordinates and more democratic with the democratic ones. Chow and Grusky (1980) found that in laboratory-simulated organizational settings, subordinates' compliance generated employee-oriented supervision, whereas subordinate's aggressiveness resulted in punitive supervision.

In a longitudinal field survey, Greene (1979a) reported that the subordinate's compliance exerted considerable subsequent influence on the supervisor. If the subordinate was more compliant and performed better early on, the supervisor in the following three months displayed more considerate, supportive, and participative leadership. However, if the subordinate's performance was poor early on, the supervisor initiated more structure and role clarification later. Poor subordinate performance, particularly noncompliance, generated the leader's greater use of punishment three or six months later.

Better supervisors in real life tend to look for and to reward independent action in subordinates, whereas less

effective supervisors tend to reward conformity and group action. The better supervisors are also less lenient (Kirchner, 1961; Kirchner & Reisberg, 1962).

*Effects of Contrasting Subordinates.* A supervisor's reactions to a subordinate's compliance appears to depend on the failure of other subordinates to comply. In a field study of the performance of clerical workers, Grey and Kipnis (1976) found that the supervisors' evaluations of compliant workers were higher in work groups with more noncompliant workers. Evaluations of noncompliant workers tended to be lower in work groups with more compliant workers. Goodstadt and Kipnis (1970) and Kipnis and Vanderveer (1971) found that in the presence of a poorly performing subordinate with a bad attitude, subjects allocated nearly twice as many pay raises to compliant workers as they did when the poorly performing subordinate was seen as simply inept, rather than disparaging.

## Leader-Member exchange (LMX)

---

### *Inner Circle versus Outer Circle*

The concept of leader-member exchange (LMX) originated with the phenomenon that leaders of a group or work unit tend to perceive each member as *in-group* or *out-group*. The leaders pay more attention to the inner core and maintain different relations with the "inners" and "outers." They "incorporate some members into the inner life of an organization but exclude others" (Sparrowe & Liden, 1997). Leaders' relations (LMXs) with the inner and outer circles differ. They evaluate members of the inner circle less critically (Duarte, Goodson, & Klich, 1994). According to LMX theory, the development of the members' roles will be differentially reinforced because the leader does not have the time to give all members equal attention. Furthermore, the leader differentially values subordinates and fosters the success of those he or she values most (Chassie, 1984). The leader also initiates more exchanges with highly competent subordinates (Kim & Organ, 1982) and establishes a close relationship with only a few key members—the inner group. Subordinates who are similar to their leader in the leader's perceived use of power, and in the subordinates' use of negotiation, choose to enhance their closeness to the leader. Those not in the inner circle use distancing tactics with leaders seen as dissimilar, according to an analysis of 230 supervisor-subordinate dyads by Townsend and Jones (2000). For dealing with the outer group, the leader relies on formal authority (Graen, 1976). Hollander (1978), among others, observed that it is commonplace in groups and organizations for an inner clique to form with whom the leader has closer relations than with the rest of the group. The inner clique gets more attention and more approval and possibly more status but is expected to be more loyal and committed to the leader and the group. The envy of members of the outer circle is likely to be aroused, and the inner clique must share more blame for the leader's failures. According to Mayfield and Mayfield (1998), the performance of members of the inner group is about 20% higher than that of members of the outer group.

*Differences in Influence.* Dansereau, Graen, and Haga (1975) interviewed 60 leaders and their individual subordinates four times over nine months. For members of the inner group, the leader-subordinate dyadic exchange was seen as a partnership that was characterized by reciprocal influence; extracontractual behavior; mutual trust, respect, and liking; and a sense of a common fate. For the members of the outer group, the exchange was characterized by downward influence, role-defined relations, and a sense of loosely coupled fates. The leader was seen as an overseer. The higher quality of the vertical-dyad linkage for the inner group than for the outer group was correlated with the leader's greater attention to the inner group. The energy and effort of the inner group were greater; they had fewer job problems. Duchon, Green, and Tabor (1986) found that members of the inner group were more compatible with the leader and had better relations with the leader

than did members of the outer group, although outer-group members were not necessarily less satisfied with their leader or with their influence. Graen and Schiemann (1978) obtained results indicating that leader-member dyads in the inner group agreed more on the meaning of shared experiences than did leader-member dyads of the outer circle. In a study of first-level supervisors and their immediate superiors by Liden and Graen (1980), the outer-group members reported spending less time in decision making and were less likely to volunteer for special assignments and extra work.

*Effects.* Where outcomes have been based on criteria other than self-reports of the leaders and the members, the findings about membership in the inner and outer circles have been mixed. For instance, when the performance of the inner and outer circles was measured objectively, the expected differences were not found among bank tellers or for enlisted airmen completing small-group tasks. Nor was there a significant correlation between the quality of the leader-subordinate relationship and the turnover of the bank tellers (Vecchio, 1982, 1985). Rosse and Kraut (1983) studied 433 managerial dyads and found that the exchange that gave subordinates considerable latitude in negotiations was positively correlated with the subordinates' job satisfaction and was negatively related to their having job problems. But these researchers failed to confirm other predictions about job performance.

The quality of LMXs and productivity did improve as expected with special training among 106 governmental form-processing employees (Graen, Novak, & Sommerkamp, 1982). Also, for 45 supervisor-subordinate dyads in a business organization, Vecchio and Gobdel (1984) found that leader-member dyadic exchanges in the inner circle were of a higher quality and were associated with the members' higher performance ratings, better actual job performance, lower tendency to quit, and greater satisfaction with supervision. Inner-group members become trusted lieutenants. For a sample of 83 administrators in a large midwestern hospital, Mael (1986) showed that such lieutenants had more latitude in negotiations in their dyadic exchange relationship with their leader and were more satisfied than were others with their job and their leader's performance.

### ***Life-Cycle Model for LMX Development***

Graen and Scandura (1987) proposed a life-cycle model for a high-quality relationship of superior and subordinate. First, leader and member of a group or work unit test the attitudes and resources each has to offer the other and what to expect from each other. Then mutual trust, respect, and loyalty are developed. Finally, the relationship matures into mutual commitment. The relationship begins with the self-interest of transactional leadership and matures into the transcending self-interest of transformational leadership. Although the relations may be different with each subordinate, the leader can maintain mutual trust and loyalty with all of them. The leader develops a different partnership with each subordinate. The dyadic relations grow into an organizational system (Graen & Uhl-Bien, 1991). Leadership becomes less important than dyadic relationships to the system (Graen & Uhl-Bien, 1995). Schriesheim, Castro, and Cogliser (1997) found 182 journal publications, dissertations, and other research reports on LMX between 1972 and 1997, beginning with Graen, Dansereau, and Minami (1972).

### ***Measures of the Exchange***

To quantify the quality of the exchange, the leader rates the quality of the relationship with each member on a set of items. Each member does the same for the relationship with the leader. (See Scandura, Graen, & Novak, 1986, for an example.) Unfortunately, over the three decades of research and application of LMX, the number of items that have been the basis of LMX scores has ranged from 1 to 40, and the items have involved at least

six kinds of content: liking, mutual support, trust, latitude, attention, and loyalty (Schriesheim, Castro, & Cogliser, 1997). In all, at least 16 different versions of LMX measurement have been used in reported studies. However, in 36 of 86 studies meta-analyzed by Gerstner and Day (1997), seven items were used. This version is increasingly the favorite. Although Scandura, Graen, and Novak (1986) found only a correlation of .24 between the LMX ratings of leaders and their subordinates, Dienesch and Liden (1986) noted that three dimensions were needed to account for LMX: contribution, loyalty, and affection. Graen and Wakabayashi (1992) obtained a different three-dimensional factor structure to describe the necessary content of LMX: respect, trust, and obligation. Liden & Maslyn (1998) created a multidimensional measurement of four factors (LMX-MDM): affect, loyalty, contribution, and professional respect. The average relationship for the leader (ALX) ordinarily is not as informative as LMX, nor predictive of various outcomes, since the leaders have different relations with different subordinates. Some relations are mainly role-defined and downward in influence; others involve reciprocal influence with mutual respect and trust. There may be less agreement than desired between a supervisor and a subordinate about the quality of their relationship, but according to a survey of 166 newly hired university employees and their direct supervisors, LMX appears to be reasonably stable. Employee LMX ratings made at the end of two weeks and six weeks, respectively, correlated .66 and .47 with their LMX ratings at the end of six months. For supervisors, the comparable correlations were .65 and .38 (Liden, Wayne, & Stilwell, 1993).

There is a need to obtain LMX from the point of view of the leader as well as the subordinate. Gerstner and Day (1997) found an average uncorrected correlation of .29 based on the leader as the only source of information about LMX and the subordinate as the only source of information. According to analyses of 422 matched supervisor-subordinate dyads by Ford and Greguras (2001), incremental validities were obtained beyond using only those from supervisor or from subordinate in predicting such criteria as subordinate job involvement by using both supervisor and subordinate ratings of LMX.

### ***Quality of the Exchange***

The “quality” of the leader-member exchange—the satisfaction of either or both parties with it—should be a determinant of subsequent outcomes. A high-quality LMX is a social exchange based on high trust, respect, support, mutual obligation, and latitude. A low-quality LMX is a social exchange that depends on a formal contract providing service for reward or avoidance of punishment (Dienesch & Liden, 1986). For 41 LMX dyads studied by Liden and Graen (1980), members with higher-quality relationships with the leader assumed more responsibility for their jobs, contributed more to their units, and were rated higher in performance than their colleagues who reported lower-quality relationships with their leader. According to Dienesch and Liden (1986), the quality of the exchange may be affected by the mutual trust of the leader and the member, mutual loyalty, their influence on each other, the competence of one or the other, the perceived equity of the exchange, and the interpersonal attraction of the leader and member.

*Dimensions of Quality.* Dienesch and Liden (1986) suggested three theoretically and methodologically appropriate dimensions that should be considered:

- (a) Perceived contribution to the exchange—perception of the amount, direction, and quality of work-oriented activity each member puts forth toward the mutual goals (explicit or implicit) of the dyad;
- (b) Loyalty—the expression of public support for the goals and the personal character of the other member of the [leader-member exchange] dyad; ...
- (c) Affect—the mutual affection members of the dyad have for each other based primarily on interpersonal attraction rather than work or professional values. (pp. 624–625)

Liden and Maslyn (1998) obtained three factors—contribution, loyalty, and affect—in validation studies of

LMX with 302 working students and 249 employees, along with a fourth factor, professional respect. The three dimensions also appeared to be conceptually distinct, according to judges, but were empirically correlated (Dienesch, 1985). Each of the three dimensions would be expected to have a different impact. Mutually perceived contributions should result in the undertaking of more challenging assignments and joint efforts. Mutual loyalty should be reflected in more shared confidences. Interpersonal attraction should generate greater warmth in the workplace and emotional support for nonwork problems.

Following Sparrowe and Liden's (1997) suggestion, Uhl-Bien and Maslyn (2000) identified positive and negative reciprocal relationships in 36 work groups with 29 managers and 280 subordinates in a sample from 1,100 employees in a division of an international firm. These relationships included immediacy (time for reciprocating in an exchange between manager and subordinate), equivalence (elements of equal value are exchanged), and motive (the exchange involves self-interests, mutual interests, and other interests). *Negative reciprocity* is characterized by extreme equivalence, extreme immediacy, and self-interest; *balanced reciprocity* by high equivalence, high immediacy, and mutual interest; and *generalized reciprocity* by low equivalence and low immediacy and concern for others (Sparrowe & Liden, 1997). The reciprocity of "strangers" ordinarily needs immediate equivalency and self-interest. The reciprocity of partners needs mutual interests and tolerates lengthy delays and only in-kind equivalence (Uhl-Bien & Maslyn, 2000).

*Effects of the Quality of LMX.* The quality of the leader-member exchange and the satisfaction of either or both parties with it should be determinants of subsequent outcomes of joint efforts. For example, for 41 such leader-member dyads studied by Liden and Graen (1980), members with higher-quality relationships with the leader assumed more responsibility for their jobs, contributed more to their units, and were rated higher in performance than were their colleagues who reported lower-quality relationships with their leader. In a large firm when the leaders and subordinates were high rather than low in self-efficacy, LMX was found to be higher in quality among 56 leader-subordinate dyads. Performance was also better (Murphy and Ensher, 1999).

Gerstner and Day (1997) concluded from their meta-analysis that LMX quality was related to better job performance, higher overall satisfaction, more commitment, less role conflict, more role clarity, competence of leaders and followers, and less intention to quit.

Compared with low-quality LMX, high-quality LMX was often found, along with better task performance (Dansereau, Graen, & Haga, 1975), conducive to subordinate innovation (Basu, 1991). Murray and Markham (undated) obtained results with 25 managers paired with their 110 subordinates showing that high-quality LMX was related to performance effectiveness when there was agreement about this quality within each manager-subordinate dyad. Tierney, Farmer, and Graen (1999) found that among 191 nonclerical employees in R & D, those with higher LMX scores earned higher ratings for creativity from their supervisors, submitted more high-quality "invention-disclosures," and did more research reports. (Results were moderated by the employees' cognitive styles.) Deluga (1991) showed that among 376 managers, professionals, and white-and blue-collar personnel, higher LMX correlated with more leader effectiveness and greater satisfaction with the leadership. The Gerstner and Day (1997) meta-analysis reported a mean corrected correlation of .41 for 17 studies of LMX scores and organizational commitment, as did Green, Anderson, and Shivers (1996). Gerstner and Day also reported a mean corrected correlation of 2.35 for 10 studies of LMX and role conflict, .34 for 14 studies of LMX and role clarity, and only 2.13 for LMX and turnover. But mixed and insignificant results were found for LMX and turnover by Vecchio & Norris (1996).

*Individual Differences.* Kinicki and Vecchio (1994) reported a correlation of .32 between LMX and members' locus of control. They also found a correlation of .48 of LMX with felt time pressure. Murphy and Ensher (1999) observed that among women supervisors, self-efficacy correlated with subordinates' LMX. House and Aditya (1997) suggested that LMX would probably be lower among members with a low need for growth and authoritarianism, and with a desire for autonomy. Basu and Green (1995) found that good

“organizational citizen” behavior was correlated with high-quality LMX. However, the meta-analysis by Gerstner and Day (1997) noted a lack of correlation between antecedents such as age, education, and sex and quality ratings of LMX. Member competence correlated only .12 with high-quality LMX in 13 studies. As might be expected, mutual liking by members was highly predictive of LMX (Engle & Lord, 1997).

*Expectations and Effort.* Liden, Wayne, and Stilwell (1993) demonstrated for 166 supervisor-subordinate dyads that mutual expectations of competence and future achievement correlated with high-quality LMX. Maslyn and Uhl-Bien (2001) showed with 232 manager-subordinate dyads that higher-quality LMX was reported by subordinates when the judged effort of the leader correlated with the subordinate’s own effort. But according to the leader, if LMX was high in quality as seen by the leader, and leader effort correlated with subordinate effort, leader effort could be lower with higher LMX. If one’s effort to develop quality relations with a partner was high, and the partner’s was low, the quality of the relationship would be low. In a Dutch firm, 170 employees with an orientation of mastery displayed higher job performance, innovation, and job satisfaction. In contrast, those employees with a performance orientation were the same or lower in these outcomes (Janssen & Yperen, 2004).

*Communications.* A total of 537 students viewed videotapes of the facial expressions of leaders giving simulated performance appraisal feedback to subordinates. The participant rated the likely LMX quality of the consequences of positive and negative communications and coordinated actors’ facial expressions. Positive performance evaluations and “message-congruent” facial expression yielded ratings of higher-quality LMX (Ashkanasy & Newcombe, 2000). Kacmar, Witt, and Zivnuska (2001) conducted three experiments showing that subordinates in a high-LMX relationship who communicated frequently with their supervisor received higher performance ratings. Subordinates in low-LMX relationships interacted less frequently with their supervisor. Those with high LMX scores also were more likely to communicate by telephone and face-to-face than by memos and e-mail. When LMX relationships were poor according to the supervisors, the subordinates made more use of memos and e-mail than telephone and face-to-face communications with the supervisors. Communications between leader and subordinate increase in frequency and quality if LMX is high rather than low (Crouch & Yetton, 1988).

*Tactics.* The quality of the exchange relation between a leader and followers (LMX) affected the upward tactics used by the followers. In a sample of 376 employees, when the exchange relation with their leader was lower in quality, they were more likely to use hard tactics: assertiveness, cultivation of relations with higher authority, and coalition with colleagues (Deluga & Perry, 1991). Upward influence tactics such as ingratiation and impression management by subordinates added to the positive contribution of LMX to performance and commitment in an analysis of 150 manager-subordinate dyads of 75 managers. Each manager was coupled with one highly performing and one poorly performing subordinate (Schriesheim, Castro, & Yammarino, 1994).

*Similarity.* Similarity of attitudes and education of supervisor and subordinate correlated with LMX among dyads composed from 223 subordinates and their 58 supervisors (Basu & Green, 1995). Similarity of cognitive style correlated with LMX for 142 pairs of managers and their subordinates in two British manufacturing organizations (Allison, Armstrong, & Hayes, 2001). Likewise, similarity of ratings about supervisors’ power and subordinates’ negotiation in 230 supervisor-subordinate dyads correlated .77 with LMX according to the subordinates and .23 with LMX according to the supervisors (Townsend & Jones, 2000). Ashkanasy and O’Connor (1997) obtained similar findings for 160 members of 30 Australian work groups between LMX and the congruence of five personal values. For 42 dyads of different racial or ethnic background and 67 of mixed gender, LMX correlated .71 with perceived similarity of subordinates’ and leaders’ values and attitudes, .31 with speed of forming the relationship, and .33 with the similarity in age of the leader and member. The same investigators obtained a correlation between LMX and speed in forming the relationship among dyads of 83 sales representatives and their 13 managers (Hepperlen & Reiter-Palmon,

2000, 2001). In all, in their meta-analysis, Gerstner and Day (1997) reported that for 28 studies, LMX correlated .34 with agreement by the leader and member.

*Person-Organization Fit.* To assess how closely schoolteachers' personal attitudes fit those of their school, Erdogan, Kraimer, and Liden (2002) calculated the correlation of the individual culture profiles of 524 teachers with the organizational profiles of their 30 schools. The fits were uncorrelated with LMX of teacher and supervisor. However, when LMX was low, job and career satisfaction remained high if the fit between teacher and school was good. When LMX was high, job and career satisfaction could remain high even if the fit between teacher and school profile was low: LMX could make up for the lack of fit in personal attitudes with the school norms.

*Health.* For 312 retail and health care managers and professionals, Rose and Nelson (1998) found that LMX correlated positively with job satisfaction (.63) and negatively with job burnout (–.39), medical problems, personal impatience and irritability (–.24).

*“Organizational Citizenship” Behavior.* Manogran and Conlon (1993) and many others have found that high-quality LMX is correlated with organizational citizenship behavior (OCB). A meta-analysis by Hackett, Farh, and Song (2003) found an average correlation of .29 between LMX and OCB. High-quality LMX was also associated with more rapid movement up the corporate ladder (Wakabayashi, Graen, Graen, et al. 1988) and with more favorable perceptions of the organizational climate (Kozłowski & Doherty, 1989). But contrary to expectations, felt empowerment did not mediate the correlations of LMX and organizational commitment and other such outcomes, according to a survey of 337 employees and their immediate superiors (Liden, Wayne, & Sparrowe, 2000). The meta-analysis by Gerstner and Day (1997) reported for 10 and 30 studies, respectively, a mean corrected correlation of .37 of LMX and performance ratings according to leaders and .29 according to members. Mean satisfaction with supervision correlated .74 with LMX in 25 studies. Effects last and remain strong (Crouch & Yetton, 1988; Mayfield & Mayfield, 1998).

*Leadership Style.* The quality of LMX was higher if there was a match between leaders' and subordinates' styles of implicit leadership (Engle & Lord, 1997). Kuhnert and Lewis (1987) contrasted the quality of leader-member relationships in terms of three levels of the leader's perspective—how meaning is made from the regularities of social interactions. At the lowest level, leaders are transactional and self-interested. At the middle level, they focus on mutual rewarding, looking out for both their own and their subordinates' interests; there is positively reinforcing interaction between leaders and subordinates. The highest level is transformational: the interaction goes beyond the self-interests of both parties. Howell and Hall-Merenda (1999) reported positive correlations of LMX with both transformational and contingent reward leadership but not management by exception. Transformational, especially charismatic and individually considerate leaders, had higher-quality exchanges (Deluga, 1991; Deluga & Perry, 1991). Deluga (1992) found that LMX correlated with *individualized consideration*, a component of transformational leadership. Schriesheim, Neider, and Scandura (1998) found that when LMX was higher in 106 dyads, delegation by leaders was higher, as was subordinate satisfaction and performance. They also showed, for 183 dyads of managers, that rated performance, promotion, and salary progress were greater with higher LMX scores—independent of mentoring, which also contributed to the criteria of managerial success. In India, Aryee, Tan, and Budhwar (2002) obtained results for 161 subordinates and their 40 supervisors indicating that if LMX was of high quality, the correlation with willingness to initiate actions was higher (.36), particularly when subordinates felt a sense of autonomy.

### ***Critique of LMX***

Given the continuing problems with the meaning of LMX, the variations in the content of its measurements,

the variations in its effectiveness outcomes, biased design flaws, the need to control for individual differences, and the need to consider individual differences and numerous mediating variables, many questions about LMX still require answering, although methods and measurements are converging. House and Aditya (1997) concluded that LMX and performance outcomes may reflect common biases. The results depend as much on the characteristics and behavior of the subordinates as of the leaders. Thus LMX may be a better explanation of the development of superior-subordinate relationships than of the effects of the leaders on their subordinates. Also, LMX theory may be about dyadic relationships and their subjective consequences rather than about leadership effects on followers. The positive relations of LMX and organizational citizenship behavior may be over-stated. One question not fully answered concerns the level of analysis.

### ***Group or Dyadic Analysis?***

*The Case for Group Analysis.* Some investigators remain unconvinced that much is added by substituting dyadic relationships for the group's average relationship with the leader. For example, Fujii (1977) found that analyses of leader-subordinate relations in an experimental setting based on dyads did not differ greatly from analyses based on mean group results. Proponents of *leader-group exchange* argue that most measures remain reliable and valid even though they are couched in terms of leader-group rather than leader-member relationships (for example, "He shows the group what to do," not "He shows me what to do"; Schriesheim, 1979a). Variations among members within a group are merely individual differences in describing the same leadership behavior (Nachman, Dansereau, & Naughton, 1985). In a study of public utility employees, Schriesheim (1979a) found little difference in the correlations of descriptions of leader-member relations and outcomes, compared with correlations of leader-group descriptions and these same variables. Schriesheim concluded that distinguishing between leader-member and leader-group measurements, although theoretically meaningful, may have little practical utility; however, he favored continuing to use available leader-member descriptions rather than leader-group descriptions for theoretical purposes.

*The Case for Dyadic Analysis.* Graen (1978) and Graen and Cashman (1975), among others, provided evidence to support the importance of studying the dyadic exchange relationship (LMX) instead of the average exchange (ALX). Graen, Liden, and Hoel (1982) showed that a group analysis alone might fail to detect important outcomes. For example, in an information systems department, although the average way a leader related to the group did not predict the turnover of group members, the quality of the dyadic leader-member exchange did predict the tendency of 20 out of 48 individual members to quit. Ferris (1985) replicated this finding and showed again that the differences of the dyadic-exchange quality scores of the individual members within the groups predicted turnover. But the quality of the average exchange relationships of the groups and the leaders did not.

Graen, Orris, and Johnson (1973) found that supervisors established effective dyadic exchange relationships with some newly hired employees and established ineffective relationships with others. Early on, the supervisors thought they could predict which newcomers would stay and which would leave within a few months, and they fulfilled their prophecy by acting on it. They invested most of their time and energy in the development of those who they thought would stay. The newcomers who were expected to leave early remained unclear about what their supervisors expected of them, whereas those who worked for the same supervisors but were expected to remain were quite clear after the first week of employment. These results could not have been captured by analyzing only the supervisor's relation to the group of newly hired employees. Crouch and Yetton (1988) looked at 323 manager-subordinate dyads in Australia in which 78 managers were involved. The same manager maintained a different relationship with subordinates, depending on the subordinates' performance. High-performing subordinates whose experience with the managers was

friendly had more task contact with the managers; low performers had less contact and experienced less friendliness.

In the previously mentioned nine-month study of a management hierarchy by Dansereau, Graen, and Haga (1975), most of the dyadic relationships were new at the beginning of the study. The same manager developed different dyadic relations with different subordinates. These relations ranged from mentor-protégé to overseer-peon. The quality of each dyadic exchange relationship remained stable from the first month onward and could forecast career outcomes. Graen and Cashman (1975) showed over a nine-month period of study that the different quality of the dyadic relationship of different subordinates with the same superior determined the role assignments of the subordinates. Subordinates who had a high-quality relationship with the manager carried out less routine activities. They had more responsible administrative discretionary opportunities. They also had more resources at their disposal. The dyadic exchange was not just in the perceptions of the superior and subordinate who were directly involved. Peer observers tended to agree with the particular superior and subordinate about the quality of that relationship.

This is not an either-or question. Both analyses are needed. Dyads can be examined within groups. They may be viewed as independent of the group of which they are a part. Most supervisors have learned to praise subordinates in public and to reprove them in private. We should expect that the extent to which a leader praises subordinates will be seen in the same way by the subordinates (whichever description is used), since praise is likely to be a public affair. In this case, the average member of the group of employees will provide a description of the leader that is equal in accuracy to the description provided member by member. But to describe the leader's contingent punishment, dyadic analysis should prove more fruitful, since such contingent punishment is more likely to be a private one-on-one exchange. In some circumstances, the effects on the group are likely to be more important; in others, individual exchanges will be more important. Much more multiplex examinations are required to take into account both possibilities as well as their statistical interaction (Dansereau, Alutto, Markham, & Dumas, 1982).

In an effort to examine both group and individual effects, Dansereau, Alutto, and Yammarino (1984) created a theory and methodology for analyzing variance in leadership along with covariance in leadership outcomes of leader-member relations and their effects for the dyad, the group, and higher organizational levels of analysis. Dansereau, Alutto, and Yammarino's DETECT computer program facilitated an examination of what had heretofore not been fully analyzed—variances and covariances within the same group and in a set of groups as opposed to variance and covariances among these groups. Dansereau, Alutto, and Yammarino's strategy and analysis program determined whether the relationships were a function of: (1) different styles of leaders described by their average differences in perceptions by their subordinates; (2) leadership processes that occur only within groups; or (3) individualized differences in perceptions of the same leader's behavior.

Along with demonstrating that inner and outer circles of subordinates are likely to be working for the same superior, researchers have built a case for focusing on LMX, in contrast to the average exchange relationship between the leader and the group (Graen, 1978; Graen & Cashman, 1975).

Graen, Cashman, Ginsburgh, and Schiemann (1977) showed that managers who developed higher-quality dyadic linkages with their bosses produced greater resources for their subordinates than did those managers who developed lower-quality linkages. Liden and Graen (1980) obtained the same results with first-level supervisors. Some supervisors appeared to collaborate with their bosses on unstructured tasks and to receive appropriate resources in return; others who were led by the same bosses did not collaborate or obtain desired resources.

## ***Theory of Variance***

Katerberg and Hom (1981) correlated the satisfaction and role perceptions of 672 National Guardsmen and their leadership descriptions of their first sergeants and unit commanders. Between-units leadership effects were based on the usual correlations between scores averaged for each unit. Within-unit effects were obtained by means of a hierarchical regression analysis in which unit means were entered as the first step and the remainder were then regarded as being due to within-group effects. Considerable increases in explanatory covariance emerged when the within-group component was added to the leadership-satisfaction outcomes, despite the fact that the instrument used to assess leadership, the Leadership Behavior Description Questionnaire, was couched in terms of group, not individual members. This preliminary effort was followed shortly by the work, mentioned on page 427, of Dansereau, Alutto, and Yammarino (1984).

Members' ratings of their leader or of outcomes within a group may be similar but differ from the ratings of the average members of other groups about their own leaders and outcomes. These *whole-group* differences lie between and not within groups. There are *intergroup* differences in responses, coupled with the *homogeneity* of responses within the groups. This condition fits with the average-member-exchange approach to studying leadership based on the average member of each group. For instance, the reinforcing style used by a leader with all the group members correlated with the leader's sense of security and personality (Hinton & Barrow, 1976).

Another possibility is that in a *group-parts* condition, individuals' responses differ from one another within a group, but their average does not differ from the average responses provided by the members of other groups. Differences lie within groups, not between groups. There are *intragroup* differences, and there is *heterogeneity* among the members within the groups. The LMX approach is necessary to study the leadership and outcomes.

A third alternative is that the reports of the individuals may differ reliably and consistently both within or between the groups. This condition is *equivocal*, for the ratings are *codeterminable* from both sources. Individual implicit theories may dominate an equivocal condition.

A fourth possibility is that members may respond not as a group but only independently; thus their identity as a member of a particular group or the set of groups under analysis may be irrelevant. Here the results of interest are *inexplicable*, accounted for neither by systematic differences among individual member differences nor by the groups. There are no reliable differences among individuals within or between groups, and thus a null case is demonstrated.

*Dyadic and Group Possibilities.* Yammarino (1995) pointed out four types of supervisor-subordinate dyads: (1) *Dyads within groups* can be examined to see if they are different in a group, if the same differences in supervisor-subordinate relations appear in other groups but aggregated, and if the supervisors show up the same across the groups. (2) *Independent dyads* are not influenced by which group they are in. The supervisor-subordinate relationships differ from each other without reference to their group association. (3) *Independence within dyads* occur if the supervisors and subordinates differ from each other regardless of their group membership. (4) *Cross-level dyads* occur when each leader and subordinate in a dyad are in agreement but dyads within groups differ from each other. Independent dyads become dyads within groups.

*Some WABA Results.* Variance theory is tested empirically by within-and-between analysis (WABA) of variance and covariance. Yammarino and Naughton (1987) completed within-and-between analyses of the variances in LBDQ initiation and consideration scores (WABA I) of 70 members of a law enforcement organization on a university campus. Each member of the different hierarchically arranged units described his or her own immediate superiors. The investigators also completed corresponding analyses of within-and-between analyses of the covariances in the leadership-outcomes descriptions (WABA II). Outcomes included satisfaction with supervision, satisfaction with rewards, supervisory control, adequacy of communications, efforts of subordinates, and stress on subordinates. The results for the WABA I analyses of variance indicated the existence of an equivocal or codeterminable condition. There was significant variance both within and

between groups; also, consistent individual differences in perceptions were at work here, rather than just differences between leaders. On the other hand, the WABA II analyses of covariance generally supported the conclusion for 10 of the 28 relationships that leader-outcome differences between whole groups dominated. This supported the acceptance of the average leadership style or *whole-group* approach. For example, members' satisfaction with rewards and the leader's initiation of structure correlated .67 among groups led by the different leaders and only .09 for members within groups led by the same leader. It did not matter if the descriptions were correlated in *group* terms ("The leader rewards the group if ...") or in *individual* terms ("The leader rewards me if ..."). In the case of six variables, an equivocal condition was seen. For example, satisfaction with supervision emerged as codeterminable; there were covarying differences between leaders and outcomes as well as among members' descriptions of their leader within the groups. The correlations between initiation and consideration were particularly likely to emerge as equivocal in interpretation. Finally, in the case of 12 variables, such as leadership and communications, the results were inexplicable. There was no statistically significant between-or-within covariance.

Table 16.1 Correlations between Leader-Members and Leader-Group Satisfaction and Rewards

<i>Member's Satisfaction with Rewards</i>	<i>Initiation</i>		<i>Consideration</i>	
	<i>Leader-Group Relation Described</i>	<i>Leader-Member Relation Described</i>	<i>Leader-Group Relation Described</i>	<i>Leader-Member Relation Described</i>
Between Leaders	.67	.57	.42	.30
Within the Same Leaders	.09	.03	.27	.26

SOURCE: Yammarino and Naughton (1987).

[Table 16.1](#) illustrates the importance of both a dyadic and group account of leader-outcome relationships based on members' descriptions. We need to ask the same questions about such relationships in two ways, dyadic and group. We need to examine both within-and-between covariances. As is seen in [Table 16.1](#), satisfaction is correlated modestly with rewards and with considerate leadership (.26 to .42), regardless of the analytic component (between or within leaders) or type of description (leader-group or leader-member). Differences between leaders in initiation correlate with the average members' satisfaction with rewards. The same results apply for all the members, regardless of their group. However, the leaders' perceived use of initiation correlates with satisfaction only between the leaders' groups, not within the leaders' groups.

In the replication of the Graen, Liden, and Hoel (1982) study, it was concluded that the group effect was also of consequence when 81 registered nurses who quit or remained described their supervisors, although the dyadic effect on turnover was still the stronger (Ferris, 1985). However, Yammarino, Spangler, and Dubinsky (1998) analyzed individual, dyadic, and group results for 111 subordinates and their 34 superiors in a sales organization, who formed 111 dyads in 34 groups. The Multi-factor Leadership Questionnaire (MLQ) was used by the respondents to measure transformational leadership and contingent reward along with satisfaction with job and leadership. WABA I and WABA II results were of consequence for the MLQ and satisfaction, but only at the individual level, not the dyadic or group levels. In a sample of 285 employees of a county library system, work-unit size, cohesiveness, organizational climate, and leader power all predicted the quality of leader-member exchanges (LMX), but WABA also found individual differences—that is, effects at the level of the individual employee (Cogliser & Schriesheim, 2000). A sample of 83 sales personnel and their supervisors in a chain of retail stores rated their relationships. According to WABA, in comparison with effects at the group and individual levels, differences between the 83 dyads were most significant. But for a second sample of 116 dyads composed of insurance sales personnel and their supervisors in 37 organizations, the most significant differences were at the level of individuals (Yammarino & Dubinsky, 1992).

Although the group, dyadic, or individual approach may be appropriate in some instances, only analyses that take all the possibilities into account are likely to explain more fully what is happening. Schriesheim, Castro, and Yammarino (2000) examined the quality of LMX ratings of 75 managers, each paired with a high-performing and a low-performing subordinate. Generally, individual differences appeared more important than the group or dyadic effects implied by the span of supervision, efforts at upward influence, and commitment of the managers or subordinates.

### ***Behavioral Interdependence of Dyads***

The preceding research examined the processes through which leaders affect their followers or the processes through which followers affect their leaders. In fact, of course, both processes are occurring simultaneously and may be discussed as two-way dynamics. For example, Graen (1976) examined the dyadic relation between the leader and each member of the group. He noted that the dyads formed a behavioral interdependence between the respective roles. This interdependence included the dyadic “partnership” engaged in reciprocal influence, its extracontractual behavioral exchanges, its role-defined relations, and its loosely coupled fates (Dansereau, Graen, & Haga, 1975). Graen and Schiemann (1978) observed that the manager’s and subordinate’s agreement about the relationship was higher if the quality of their behavioral interdependencies was high. Such interdependence of the manager and the subordinate is necessary for the leader to give and the subordinate to receive opportunities for growth on the job (Graen & Scandura, 1986). Subordinates with high need for growth are more likely to collaborate in a closer and better-quality relationship with superiors on tasks that provide opportunities for growth.

But behavioral interdependence has its dark side. A superior and subordinate can share a delusion—a folie à deux—when both have a strong need to be dependent and are in an isolated position, say, on a space exploration mission. The delusion is likely to occur in more everyday settings if mutual trust and closeness are lacking. The subordinate may have the need to depend on the superior, but this need is frustrated if he or she cannot depend on the superior. In turn, the superior may want to depend on the subordinate but feels it unwise to do so. The world becomes dangerous, and the danger is compounded by the superior’s and subordinate’s lack of trust in each other. Each can trust only a few people, but not each other. The superior and subordinate can elaborate their mistrust of each other into a common fantasy about an organizational betrayal of both of them. Thus they become trapped by their shared delusion (Kets de Vries, 1984).

## **The Reciprocal Relationship**

---

### ***Individualized Leadership***

[Chapters 17](#) through [20](#) will present consistent styles of leadership that describe how leaders relate in the same way to all their followers. But according to Dansereau (1995), when previously the variations in a leader’s behavior toward different individuals in a group were treated as statistical error, WABA theory and WABA allowed for a leader to regard each subordinate as an independent, unique individual. To be successful, the leadership efforts must vary within *and* between work groups (Dansereau, Yammarino, Markham, et al., 1998). Perceptions of the same leader differ from one subordinate to another. Nevertheless, if the leader supports the individual subordinate in exchange for satisfactory performance, the leader will reinforce the subordinate’s sense of self-worth. The knowledge, skills, and abilities of both the supervisor and the

subordinate set the stage for *individualized leadership*. Individualized leadership is expected to correlate positively with LMX (Yammarino & Dansereau, 2002). This result was found by Paul, Scheyns, and Rigotti (2001).

## ***Psychological Contracts***

Psychological contracts are the expectations and obligations of the leaders and the led toward each other, their unit, and the organization (Argyris, 1960; Schein, 1965). The concept was accepted but little empirical work on it was completed until the 1990s.

Building on a 13-nation survey of psychological contracts by Rousseau (1995) and Rousseau and Schalk (2000), Van den Brande, Janssens, et al. (2002) analyzed survey data from structured interviews with 1,106 Belgian employees from public, private, for-profit, and nonprofit agencies. Formal written legal contracts and statutes also covered their employment. The employees' expected entitlements generated five factors: long-term involvement; tangibility, clarity, and transparency of obligations and rights; treatment as a person, not an economic resource; carefulness about arrangements; and equal treatment of all employees. The employees' expected obligations factored into: loyalty; open attitude; high personal investment; flexibility and tolerance for internal organizational changes; and respect for authority. On the basis of their high and low entitlement and obligation factor scores, employees formed the following six clusters of types of contracts:

1. Contractual loyalty—high long-term involvement, equal treatment, loyalty, and low personal investment. The employee perceives loyalty in his or her contract. He or she is a poorly educated, low-paid blue-collar employee or civil servant in a large organization with a personal investment and flexibility but lower expectations about the operational job.
2. Contractual instrumentality—high expectations but low obligations. The employee is a poorly educated, low-paid white-collar or blue-collar employee in a medium-size organization with reasonable job opportunities elsewhere.
3. Contractual investing—higher employee. The psychological contract is as perceived by a highly paid executive in senior management in a small company.
4. Contract strength—high on all dimensions. The psychological contract is that of a young, highly educated, highly paid white-collar employee or executive, holding a professional or senior management position in a small or medium-size organization and readily marketable.
5. Contract weakness—low scores on all dimensions of expected entitlements and obligations. Reasonably employable elsewhere with an average education and jobs at all hierarchical levels. The employee perceives a weak contract and is average in pay for his or her level in the hierarchy.
6. Contractual lack of attachment—low scores on all dimensions, particularly involvement and loyalty. These psychological contracts were typical of young, highly educated, highly paid executives or white-collar employees in professional or senior management jobs in small or medium-size organizations.

Rousseau (1995) suggested that psychological contracts may appear as: (1) *Transactional*: Short-term, economically focused, specific and clear about expected performance and rewards, as in seasonal work; (2) *Transitional*: Short-term, uncertain, and ambiguous with unspecified mutual obligations, rewards, and performance expectations, as in jobs in radical reorganizations, mergers, and takeovers; (3) *Balanced*: Long-term, economically focused, with clear and specific terms, as among structured work team members. Psychological contracts may be also said to be in balance when the obligations of employees and employers are at relatively the same level (Shore & Barksdale, 1998); or (4) *Relational*: Long-term, ambiguous, and lacking tangibility, as in a family business.

As might be expected, personality affects the type of psychological contracts formed. For example,

individuals with high self-esteem would be expected to form balanced psychological contracts; individuals with low self-esteem, transitional psychological contracts (Raja, Ntalianis, & Johns, 2002). Among 210 graduate business students with two years of work experience, varying in attachment style, those who were avoidant were less likely than those secure or anxious in attachment to ask others for contractual information. The secure seek more information about various aspects of their psychological contract than do others and are most likely to believe their employers will fulfill their obligations. The insecure, avoidant, and anxious are most pessimistic about the probability that employers will fulfill obligations. If violations occur, those with a secure attachment style are most likely to speak out against contractual violations by higher authority. Again, the insecure are less likely to do so (Bendapudi, Bendapudi, & Ballam, 2002).

### ***Models of Mutual Influence***

Crouch (1987) and Zahn and Wolfe (1981) started with different assumptions and used different methods to construct different models to describe how mutual influence develops between superiors and subordinates. Crouch (1987) assumed that manager-subordinate relationships stem from the influence that the subordinates can exert in solving unstructured problems that they and the manager face. Over time, the model predicts the emergence of stable relationships. Either high-or low-performing groups will be developed to deal with outside demands on the groups. Zahn and Wolf (1981) provided Markov mathematical states-events models to deduce the continuing interplay of the superior and the subordinate, showing how their emerging task and interactional relationships can predict future outcomes. Unexpected results appeared. Contrary to Crouch, the model predicted long-term behavior to be highly variable and versatile, rather than stable. The mutual biases of the superior and the subordinate were most salient in effect; both were likely to contribute to the cyclical maintenance of their relationships.

### ***Two-Way Impact***

Considerable empirical evidence is available to provide a cross-sectional picture of the two-way impact—the combined effects of the leader's and the follower's competence and compatibility, the interplay of the leader's style and the follower's personality and motivation, and the combined effects of the leader's and follower's concerns for the task and for their relationship with each other. Pratt and Liambalvo (1982) showed that an understanding of the leadership of accounting auditors in working with their auditing assistants required consideration of aspects of the auditor, the assistants, and their interplay. Outcomes depended on the personal dominance of the auditors, the intolerance of ambiguity by the assistants, and the match between the perceived complexity of the task for the auditor and the assistants and the assistants' job experience.

Rao (1982) conducted an experiment in which the leader could reward the subordinate. In one setting, the leader was to receive a bonus based on the subordinate's performance. The results were the leader's increased rewarding of the subordinate, large improvements in the subordinate's performance, and greater stability and cooperativeness between the leader and the subordinate. These results were different from those in the situation in which the leader was not offered any bonus for the subordinate's good performance.

The two-way nature of leadership and followership was investigated by Herold (1974), who carried out a double-substitution laboratory experiment in which both leaders' and subordinates' actual behaviors were intercepted and substituted with fully programmed supervisory and subordinate behaviors. Thirty-two groups of three persons each, consisting of one leader and two subordinates, were balanced in treatment so that the subordinates were powerful in half the groups and the leaders were powerful in the other half. The experimental task consisted of proofreading manuscripts and finding errors. The leader of each group received a

“good product” from one of the subordinates and a “bad product” from the other. Within each group, one subordinate received a punitive communication following the performance, while the other received a supportive communication. Herold found strong mutual effects on the attitudes of the leaders and followers toward each other and toward the situation. Whether the leader received a good or bad product from a subordinate strongly affected what the leader did, but whether the subordinate received a punitive or a supportive communication from the leader had somewhat less of an impact on the subordinate. The leader’s power was important in its effects on subordinates, but the subordinates’ power was not significant in affecting the leader’s behavior.

This lack of symmetry was also seen by G. J. Palmer (1962a, 1962b), who studied leaders and followers in a difficult task situation. Palmer concluded that follower-ship in such a situation is explained largely by the lack of ability. Leadership, on the other hand, requires a more complex explanation involving both individual and situational variables. For instance, the joint competence of the leader and the subordinate has to be considered. This conclusion was confirmed by Rohde (1958), who observed different combinations of qualified and unqualified leaders and followers under four conditions of reward and punishment. The leader’s ability to perform the task was found to be more highly related to the group’s performance than to the group’s motivation. Not unexpectedly, the poorest performance was exhibited by groups with both unqualified leaders and unqualified followers. Almost equally poor were groups with qualified leaders and two unqualified followers.

Blades (1976) studied the joint effects of leaders’ and subordinates’ competence on their group’s performance in servicing U.S. Army mess halls. Ratings of the group’s performance by inspectors were correlated with ratings by 102 mess hall personnel of the intelligence, ability, and behavior of the leader. Blades found that the subordinates’ intelligence, ability to perform the task, and motivation correlated positively with their performance only under participative management and when the subordinates were highly motivated. The leader’s intelligence correlated positively with the group’s performance only under directive management with highly motivated leaders and subordinates. The leader’s ability to perform the task and the leader’s motivation correlated positively with the group’s performance only with directive supervision of highly motivated subordinates. Blades concluded that competent, motivated subordinates can be led best if they are allowed to participate in the decision-making process, and that competent, motivated leaders do best with a directive style if their subordinates’ competence is limited.

### ***The Leader-Follower Exchange***

The leader and the follower depend on each other because each stimulates and reinforces the other’s behavior. The leader initiates, questions, or proposes; the follower complies, resists, or ignores. Leadership and follower-ship are mutual activities of influence and counterinfluence. Leaders and followers both give and both receive benefits. The relationship is maintained by this social exchange and this mutual influence (Hollander, 1978). As Hollander and Julian (1969) noted, when leaders are effective, they give something and get something in return. This transactional approach to leadership involves trading of benefits. The leader provides a benefit by directing the group toward desirable results. In return, the followers provide the leader with status and the privileges of authority, influence, and prestige. However, the leader may demand from the followers what they regard as an excessive expenditure of energy. The followers’ compliance may be tempered if desired outcomes do not match the perceived effort required. As members become less involved in the group’s success, they complain less about obstacles to such success but more about demands for expending their time and energy (Willerman, 1954). Bass, Gaier, and Flint (1956) observed that ROTC cadets who were strongly motivated to enter advanced training complained about the difficulty of the test used to screen applicants, whereas those

whose motivation was low complained about having to take the test rather than about its difficulty.
