*Intermember Expectations.* Much of the differentiation of members' roles and the emergence of leadership in an informal group comes about as a result of the mutual reinforcement of intermember expectations. Because of their initiative, interaction, and contributions to the group's task, some members reinforce the expectation that they will be more likely than other members to establish conditions that promote progress in the task, members' freedom and acceptance, and the group's cohesiveness. Other members, by compliance, reinforce the expectation that whoever has started and succeeded with it should continue in the leadership role; that is, "Don't change horses in midstream." Similarly, members build up expectations regarding the contributions that they are to make. The reactions of other members confirm the expectation that they are (or are not) to continue in the same role. The role system and the status structure of a group are determined by a set of such mutually reinforced intermember expectations. Thus in a verbal learning experiment, Bachrach, Candland, and Gibson (1961) observed that the members of the group differentially reinforced the behavior of other members. Such differential reinforcement accounts, in large part, for individual differences in role specialization and conformity to norms.

*Seeking Feedback.* Some people seek feedback; others shy away from it; still others ignore it when it is given to them. Subordinates have been found more likely to seek feedback if their leaders were perceived to be supportive, esteemed, expert, and transformational (Steelman, Williams, & Levy, 1996; Williams, Miller, Steelman, et al., 1999). Also, they were more likely to seek feedback from supervisors who were thought to be accessible, who clarified roles, and who had constructive intentions (Vancouver & Morrison, 1995; Levy, Miller, & Cobar, 2000). In addition to confirming many of these effects, Thibodeaux and Kudisch (2000) showed that feedback was more likely to be sought if the quality of LMX was high. But Dunford and Williams (1999) found that nurse supervisors were less likely to ask for feedback from the nurses in 200 nurse-supervisor pairs when there was stronger agreement between the nurses' and the supervisors' ratings of the nurses.

In the United States, information exchange is more direct and explicit. In East Asian cultures, it is more indirect and implicit, with more nonverbal nuances and symbolism (Hall, 1976). More cost in seeking feedback was seen by 167 Taiwanese university students than by 76 American counterparts; the Taiwanese noted greater effort and loss of face (Kung & Steelman, 2003). The norm is unlikely to encourage the Asian student to seek feedback (Ashford & Northcraft, 1992). Ashford and Tsui (1991) conducted a study of the feedback-seeking behavior of 387 managers from their superiors, peers, and subordinates. Some of the managers regulated their own performance by seeking negative feedback ("Tell me what I did wrong") and tended to increase the accuracy of their understanding of how their work was evaluated by the three sources. In turn, the three sources formed better opinions of the effectiveness of these negative feedback-seeking managers. But the sources tended to downgrade managers who sought positive feedback.

*Differing Leader Treatment of Subordinates.* Leaders do not deal with each of their subordinates in the same way. Leaders give more directions to followers who are performing poorly and monitor them more closely. The leaders are more considerate, cooperative, and tolerant when dealing with able subordinates (Podsakoff & Schriesheim, 1985). Leader-follower interaction and mutual support are seen among political leaders and their followers. The leaders activate and mobilize support for their objectives, control the communications media, and make use of intermediary opinion leaders. The followers may be actively interested and ready to be motivated to engage in political activity. Multilayered networks of leaders and followers are formed. Those below yield an aggregate of public opinion to support the aims of those at the top. The importance of such followers' support for leaders was seen by Pepinsky, Hemphill, and Shevitz (1958), who studied experimental groups working on construction problems. When the leaders were made to believe that they were accepted by the members, the groups were more productive and exhibited high degrees of satisfaction and participation. When the leaders were made to feel that they were rejected, the groups made

fewer and poorer decisions and exhibited less participation and satisfaction.

*Key Interactions.* Komaki and Citera (1990) conducted an experiment with 60 “manager-subordinate” pairs consisting of 160 female undergraduate students. Managers either were only monitors of subordinates’ performance or only directed the subordinates. Afterward, in comparison with the “directing manager” condition, managers who monitored spent much more time talking about the consequences rather than their own performance. Their subordinates spent more time talking about their own performance. The same interaction was stimulated in the next trial.

*Effects of Language.* More than direct cost-benefit calculations may lie behind an interaction between the leader and the followers. Drake and Moberg (1986) suggested that two adjustments in language can be made to change the cost-benefit calculations by a follower who is considering an attempt by a leader to influence him or her into compliance. First, *sedating* language, such as semantic indirectness, can be used in the leader’s attempt to keep the follower from considering the costs of compliance. For example, instead of giving a direct order, the leader can hint at the need for action or prompt the follower by saying, “It is getting warm in here” instead of, “Please turn down the heat.” Other sedative language includes teases and questioning: “I wonder what that’s all about?”

Second, the linguistic form may *palliate* the follower to protect him or her from loss of respect that might occur if a more straightforward order is used to correct a follower or to reverse a decision. Numerous positive polite strategies may be used as palliatives, such as expressing admiration, claiming common viewpoints, displaying concern for the follower, and desiring cooperation. With palliatives, the attempt to influence may be accompanied by efforts to reduce the difference in power between the leader and the follower. Instead of the direct order, “Check the switch again,” the leader suggests “You may want to try to check the switch again.” Other palliation includes disclaimers, hedging, appeals to suspend judgment, excuses, and justifications.

### ***Mutual Effects of the Task and Clarity of the Goal***

Under some circumstances, clarification of what needs to be done may depend on the subordinates’ participation with the leader in agreeing on the tasks and setting of the group’s goals. Critical experiments described by Locke, Latham, and Erez (1987) suggested that such participation by subordinates in setting goals is important to their understanding, commitment, and productivity if the leader is curt and unsupportive. The subordinates’ participation in goal setting is not necessary if the leader assigns goals in a friendly and supportive manner. This may explain why Dossett, Cella, Greenberg, and Adrian (1983) found in a laboratory study with 40 undergraduates that although, as was expected, productivity on a clerical task was highest when a supervisor set high, clear, standards for them and gave them friendly support, the subordinates’ participation in setting the goals did not contribute to their productivity by itself.

The failure of participation in setting goals to make a difference also may be explained by the character of the participation. Neider (1980) demonstrated, in a study of performance in retail stores, that positive outcomes were obtained from such participation only when the participation process clarified the linkage of effort and performance, and only when the rewards given for high performance were valued. The effects of clarification also depend on the competence of the leader. Podsakoff, Todor, and Schuler (1983) found that expert leaders who work at setting and clarifying goals did decrease their subordinates’ sense of role ambiguity. But the reverse was true for leaders who were inept; their efforts resulted in increasing their subordinates’ sense of role ambiguity.

In the previously mentioned longitudinal survey by Greene (1979b) of the mutual effects of leaders and subordinates, 60 subordinates from five manufacturing organizations, were queried. These subordinates had joined the management of their firms within the past three months and had never before worked for their

immediate superiors. Greene assumed that because these subordinates were newly appointed, their expectations were unclear and they were not yet fully compliant. The subordinates described their leaders' behavior and indicated their own expectations, compliance, performance, and satisfaction. The data were gathered three times at three-month intervals to permit path analyses. Consistent with path-goal theory (see [Chapter 27](#)), early role clarification by a leader directly resulted in greater satisfaction of and compliance by the subordinates three and six months later. Role clarification by the leader also was seen to enhance the subordinates' expectations that their greater effort would produce better performance.

*Compatibility.* It seems obvious that if leaders and their subordinates, individually or in groups, share the same approaches, values, and attitudes, they will be more satisfied with their relationship and experience less conflict and more mutual support. Such positive associations between the compatibility of the values of superiors and subordinates and satisfaction with their relationships were obtained by Duchon, Green, and Tabor (1986) in a field study of 49 Junior Achievement companies. Avolio and Howell (1993) showed in regression analysis of 76 senior executives and their 237 immediate direct reports that a match in personality (locus of control, innovation, and risk taking) contributed to the performance of their units.

Fuji (1977) conducted an experiment in which the independent variables were manipulated by simulating a division of a greeting card company. Eighty paid male volunteers participated as work-group leaders or workers in this unit. The followers' performance, based on merit ratings by the leaders but not on objective performance, was positively related to greater interpersonal compatibility between the leaders and the followers. Extrinsic satisfaction increased with leader-member compatibility. The relationship between leader-member compatibility and intrinsic and overall satisfaction was moderated by the amount of cooperation required by the task and the amount of experience with the task. Compatibility was positively related to relations-oriented leadership behavior, but less so to task-oriented leadership behavior.

McLachlan (1974) reported a study of group therapy with 94 alcoholic inpatients in which patients and therapists were matched for conceptual compatibility on the basis of Hunt's Paragraph Completion Test. Matched pairs of patients and therapists were positively associated with outcomes as evaluated by staff ratings 12 to 16 months later. Beutler, Jobe, and Elkins (1974) also investigated the effects of patient-therapist matching on attitudes. Matched attitudes were associated with self-rated improvement (although some dissimilarity of attitudes resulted in more attitudinal changes in patients). Similarly, Steiner and Dobbins (undated) conducted a laboratory study of 111 management students and their ostensible subordinates in which high and low intrinsic and extrinsic work-related values were the manipulated bases of matched and mismatched "superiors" and "subordinates." When superiors and subordinates matched each other in high extrinsic or high intrinsic work values, the superiors were more likely to attribute the subordinates' past good performance to internal rather than external causes.

Pulakos and Wexley (1983) examined 171 manager-subordinate dyads composed of the same and opposite sexes. Sex as such was not as important as perceived compatibility. The managers' leadership, particularly their facilitation and support of the work, was appraised higher by their subordinates when both the managers and the subordinates felt they were "similar kinds of people." Subordinates also were rated more favorably by their managers if they were perceived as similar. Conversely, lower performance appraisals occurred when the managers and subordinates were mutually perceived as dissimilar. When the subordinates saw themselves as similar to their managers, the managers gave higher dependability ratings to their female than to their male subordinates. When subordinates said they were dissimilar to their managers, managers rated both males and females uniformly lower.

*Actual Similarity.* The actual similarity between managers and their subordinates tends to correlate with the managers' appraisals of their subordinates' performance (Miles, 1964a; Senger, 1971); with the subordinates' evaluations of their managers; and with the subordinates' satisfaction with their managers (Weiss, 1977). Subordinates who perceive their superiors' attitudes toward work more accurately are rated more highly

by their superiors and are more satisfied with their superiors (Greene, 1972; Howard, 1968; Labovitz, 1972).

Subordinates are more satisfied in general if their descriptions of their manager's attitudes more accurately match the manager's self-description. In turn, subordinates receive higher evaluations from their manager if the manager's description of the subordinates' attitudes matches the subordinates' self-descriptions (Wexley, Alexander, Greenawalt, & Couch, 1980). As noted above, Avolio and Howell (1993) found that unit performance and satisfaction were higher when Canadian senior executives were matched rather than mismatched in locus of control, innovation, and risk taking.

### ***Interplay of Leaders' Style and Subordinates' Motivation and Personality***

Using Exercise Supervise (Bass, 1975c), approximately 3,500 managers in training workshops in 12 countries enacted one of three supervisory roles—authoritarian, persuasive, or participative—or one of three subordinate roles: highly involved, moderately involved, or uninvolved. Meetings took place between dyads composed of one supervisor and one subordinate. The three tasks were to decide which of 25 traits are most and least characteristic of lower, middle, and top managers. A Latin-Square design was completed so that data about all nine supervisory-subordinate combinations of role play emerged. As might be expected, the uninvolved, apathetic subordinate was least preferred by supervisors as a whole, and the participative supervisor was most preferred by subordinates as a whole. The fastest and most easily completed interactions took place between the authoritarian supervisors and the uninvolved, apathetic subordinates. Dissatisfaction of subordinates and supervisors tended to be greatest for highly involved subordinates meeting with authoritarian supervisors; satisfaction tended to be greatest for highly involved subordinates meeting with participative supervisors. The interaction effects of persuasive supervision and subordinates at the three different levels of involvement fell in between in satisfaction and speed of decision (Bass, Burger, et al., 1979; Thiagarajan & Deep, 1970).

Sales, Levanoni, and Saleh (1984) contrasted the reactions of 226 intrinsically and extrinsically motivated clerical, technical, and professional employees to two types of supervision. *General* supervision provided broad specifications of goals and gave subordinates the means of achieving them. *Close* supervision involved giving detailed instructions at each stage in the process of completing a task and checking to see that instructions were carried out. The investigators found that intrinsically oriented employees expressed more satisfaction with their supervisors under general supervision than under close supervision; extrinsically oriented employees indicated the opposite. Steiner and Dobbins (undated) experimented with the extrinsic and intrinsic work values of the subordinates of management students who were acting as their supervisors. Subordinates with high intrinsic work values were given more autonomy and more challenging assignments by their "supervisors" than were the other subordinates. W. W. Burke (1965) studied student leaders in 24 groups participating in an interfraternity contest. Each group performed a clerical and organizational task, as well as a decision-making task. Regardless of the task, followers with high need-achievement scores, working with relations-oriented leaders, reported more tension than followers with high need-achievement scores working with task-oriented leaders. Those with low need-achievement scores, working with task-oriented leaders, reported more tension than those working with relations-oriented leaders. The more relaxed situation occurred when the leader's personality met the needs of the group of followers. Misumi and Seki (1971) showed that Japanese subjects with low need for achievement demonstrated relatively high performance but low satisfaction with a task-oriented leader in experimental tasks. Subjects with high need for achievement were most productive and most satisfied under leaders with high task and relations orientation and performed worst under leaders whose task and relations orientations were low. Misumi (1985) also noted that high-anxiety subjects did better under a relations-oriented leader than under a task-oriented leader.

Superiors were viewed as less active and directive by hospital employees who were more concerned with

power, achievement, and independence (Niebuhr, Bedeian, & Armenakis, 1980). Engineering personnel with high self-esteem who were in dyads with superiors of long duration saw more initiation and consideration in their superiors' leadership behavior (Niebuhr & Davis, 1984). Greer (1960–1961) reported that authoritarian infantrymen and airmen worked better under authoritarian leaders whereas egalitarian men did better when led by egalitarians. A group's performance was positively related to followers' perceptions of the leader as a problem solver and the extent to which the leader met the followers' expectations. Weed, Mitchell, and Moffitt (1976) concluded, from a laboratory study, that supervision that was structuring generated higher performance by subordinates if the subordinates were higher in dogmatism. Considerate supervision generated higher performance in subordinates who were lower in dogmatism.

*Concerns for Task or Relationships.* Back (1948) analyzed the interactions of leaders and followers in two discussion groups—work-centered and “emotionally toned.” When the leaders emphasized work performance more than did the followers in the first period, the followers increased their work responses in the next period. When the leaders emphasized friendliness more than did the followers in the first period, the followers exhibited more friendly responses in the next period. The emotionally toned group devoted more time in the first period to establishing stable intermember relations and a group structure. The work-oriented group spent more time in strengthening goal-directed activities. In the next period, the emotionally toned group spent more time maintaining participation among members and with leaders. In the work-oriented group, the leader tended to lose importance, whereas interactions between members were strengthened. Bass and Duntzman (1963) studied sensitivity training groups that were composed of participants who were homogeneous in relations (interaction) orientation, task orientation, and self-orientation. Relations-oriented groups tended to be most satisfied with their highly relations-oriented leaders. The leaders who emerged in task-oriented groups tended to be even more highly task-oriented than the average member. However, the emergent leaders of the self-oriented groups were relatively low in self-orientation. Stimpson and Bass (1964) found that compared with task-oriented and self-oriented participants, relations-oriented participants in problem-solving groups made it more difficult for their work partners to attempt and succeed as leaders, to reach agreement, and to feel responsible.

Bass (1967c) observed task-oriented and relations-oriented oriented followers under coercive and persuasive styles of leadership. He found that task-oriented followers produced greater quantities of work under persuasive leadership and that relations-oriented followers produced more work under coercive leadership. The followers' satisfaction with the task was significantly higher under a directive relations-oriented leader than under a participative relations-oriented leader. Conversely, their satisfaction was lower under a directive than under a persuasive task-oriented leader.

## Summary and Conclusions

---

In their interaction with followers, leaders show what needs to be done, provide feedback to subordinates on how well it is done, communicate needed information, and act as models for their subordinates. They mediate between and connect their followers to their superiors. They are a source of feedback and serve as models for their subordinates. They need to have influence with those above them as well as those below them in the hierarchical organization.

Leadership and followership are reciprocal. Followers have an impact on their leaders. To be a good leader, one needs to be a good follower. Isolates, not followers, are the opposite of leaders. Followers are an important source of feedback to leaders. Followers' readiness, maturity, interests, competence, and compliance affect their leaders' performance. Followers' effects on leaders also depend on the leaders' and followers' explanations for the followers' dispositions and performance. Among the interactions of importance to performance are the

leader's style and the followers' motivation and personality. Another important effect is due to the interaction of the task and relations orientations of the leaders and their followers. Groups operate more successfully when the task, the leader's personality, and the follower's personality are compatible. For example, groups with task-oriented leaders perform better than do those with person-oriented leaders when followers are also task-oriented. Followers whose task orientation is low experience less tension under person-oriented leaders.

Leaders may treat each follower in a group the same or differently, depending on whether followers are members of the inner or outer circle. It is important to examine the quality of the dyadic leader-member exchange (LMX) as well as the leader-group exchange. Analysis of variance within groups may be as important as analysis of variance between groups.

Followers affect, to a considerable extent, what their leaders may do and can do. The exertion of this upward influence involves many different tactics ranging from ingratiation to establishing coalitions of influence. Important feedback can flow upward.

Still to be determined is whether the exchange relationship between the leader and subordinates becomes stable or remains variable in the long term.

<sup>6</sup> Hinkin and Schriesheim (1986) and Schriesheim and Hinkin (1989) reworked the original upward influence measures of Kipnis, Schmidt, and Wilkinson, which resulted in improving their factorial structure and content validity with a shorter set of 27 questionnaire items.

<sup>7</sup> Hersey and Blanchard's Life Cycle Theory of Leadership is built on this premise and will be discussed in detail in [Chapter 19](#).

<sup>8</sup> This comprehensive line of investigation grew from earlier theorization by Kelley (1973) and by Weiner, Frieze, Kukla, et al. (1971).

## PART IV

---

# Styles of Leadership

---

# Autocratic versus Democratic Leadership

The duality of autocratic and democratic leadership has been seen throughout history. How should people be led? How should people be governed? How should people be guided? Two views prevailed, based on opposing doctrines about human nature. For centuries, theologians and philosophers argued that human nature was cursed by original sin or that human nature was blessed with the inherent ability to find salvation. The former proponents of original sin advised that people were essentially bad; they had to be controlled, directed, and uplifted by authority. The proponents of inherent salvation set forth that people were essentially good and they must be given freedom in which to act, learn, grow, and overcome. Adam Smith, a moral philosopher as well as a political economist, saw both sides of human nature. He agreed with David Hume that self-interest required a distrust of human intentions and motives, but at the same time he also believed in the innate goodness of human-kind and the power of education to enlighten and liberate (Herman, 2001).

The framers of the U.S. Constitution recognized the benefits and the costs of an independent executive with authority and a democratic legislative body. They handled the dilemma posed by balancing the powers of the executive against those of a bicameral legislature: two senators from each of the 13 sovereign states and population-based representatives of each state's male, white, property-qualified electorate. This arrangement recognized the contribution of the democratic majority vote of statewide and electoral district representatives to the commitment, interests, and satisfaction of the various constituencies. At the same time, an indirectly elected president could provide the need for order and for the execution and maintenance of federal laws, foreign affairs, and national defense. Much authority and power for direction and control were given to the president, but with safeguards. The president was commander in chief of the armed forces, but he had to face reelection and could be removed from office by the legislature. He could veto the legislative decisions of the representatives, but the veto could be overridden by the legislature.

The same dilemma confronts organizational leaders today. They must balance the advantages of a more democratic approach, which ordinarily contributes to the commitment, loyalty, involvement, and satisfaction of followers, with a more autocratic approach, which contributes to order, consistency, and the resolution of conflict. Whitty and Butts (1989) argue that authoritarian and elitist leadership sets the rules and has the power to control behavior. But more culturally accepted principles encourage democratic sharing of influence to obtain higher productivity, friendly interpersonal relations, and group cohesiveness.

## The Two Opposing Approaches

---

Leaders and managers vary in how they deal with the dilemma of autocratic leadership at one extreme and democratic leadership at the other. These dichotomies are simplifications. Sweeney, Fiechtner, and Samores (1975) conducted a factor analysis of the leadership focus of 103 male employed part-time college students that corroborated the high degree of complexity to be found in examining autocratic and democratic leadership. The factors were: (1) authoritarian role preference, (2) authoritarian role pressure, (3) egalitarian role preference, (4) egalitarian role pressure, (5) balanced manager, (6) people-oriented manager, (7) assumed similarity between opposites, (8) contemptuous indulgence, (9) supportive values, (10) tolerance of people; and (11) organizational tolerance. Nevertheless, the same persons who engage in one type of autocratic

behavior when, say, initiating structure, are also likely to be seen as facilitating work and persuading. The same persons who engage in one type of democratic behavior are likely to be seen as supportive, considerate, and people-oriented as well, but the empirical correlations are far from perfect (Edwards & Rode, 1986).

### ***The Autocratic-Authoritarian Leadership Cluster***

The autocratic-authoritarian cluster encompasses being arbitrary, controlling, power-oriented, coercive, punitive, and closed-minded. The cluster has often been described in pejorative terms. Stripped of negatives (emphasized by so many social scientists), it means taking full and sole responsibility for decisions and control of followers' performance. Autocrats stress obedience, loyalty, and strict adherence to roles. They make and enforce the rules. They see that decisions are carried out (Smither, 1991). Powerful autocratic leaders throughout history have often been praised for their ability to develop reliable and devoted followers and to act as the principal authority figures in establishing and maintaining order.

Authoritarian sports coaches may be disliked by their players. But this dislike may evolve into respect, appreciation, and fondness. Players may hate autocratic coaches but play well under them (Bernath, 1991). A list of the toughest bosses in America is compiled regularly by *Fortune* magazine. They are described as merciless with people who tell them less than the truth. They are intensely persistent, imperious, unwilling to entertain ideas that don't fit with their own. They get the job done, but the cost to themselves and others may be high (Flax, 1984).

The dark side of autocratic behavior is abusiveness, creating fear and distrust, using arbitrary and unconditional punishment, ignoring subordinates' information and inputs to decisions, and relying exclusively on one's own judgment (Smither, 1991). Henry Ford II was described by Lee Iacocca (1984), who worked directly under him, as the consummate autocrat in control of Ford Motor Company. Ford was bigoted and hypocritical. He would fire people without reason or for trivial reasons such as not wearing the right clothes. But autocrats can also be considerate. Pope John Paul II was called a spiritual dictator; he declared autocratically, "The Church is not a democracy and no one from below can decide the truth" (November 20, 1998). Yet repeatedly, he could show personal concern and sympathy for others whether or not they liked or agreed with him (Bane, 2005).

Abusive leaders engage in hostile verbal and nonverbal behaviors (Tepper, 2000). Lyndon Johnson, exemplifying the autocratic taskmaster, abused and exhausted his staff. He paid them the lowest salaries and worked them the longest hours. He played favorites and publicly humiliated his loyal aides (Reedy, 1982). He was terrorizing (though he could be tender at times), ruthless, impatient, petty, bullying, devious, brutal, suspicious, and crafty. Yet he could sometimes also be caring, patient, devoted to family and friends, compassionate, and generous (Valenti, 1975). Another autocratic leader was a terminated former president of Kellogg Foods, who was abrasive, abrupt, unwilling to listen, and inclined to manage without being questioned (Manz & Sims, 1991). In a review of the literature, Smither (1991) conceived of authoritarian managers in work organizations as taking full responsibility for decisions and subordinate performance. They believe their assignment is to make decisions and see that the decisions are carried out. They do not share power. They may be exploitative or benevolent in their relations with others (R. Likert, 1961a). Wallechinsky (2003) listed as the 10 worst living political dictators those who suppressed freedom and human rights taken for granted in democracies, executed or jailed political opponents, tortured prisoners, caused their citizens to starve, and used violence domestically and to interfere in other countries. Joseph Stalin was a model adopted by Saddam Hussein (Montefiore, 2004).

Although investigations use many terms whose meanings do not entirely overlap, correlations generally will be high among descriptions of various authoritarian ways of organizing to get things done. That is, the same

leaders who are described as autocratic or authoritarian (Lewin & Lippitt, 1938) will also be described as directive (Bass & Barrett, 1981; Heller, 1969a), coercive and persuasive (Bass, 1960), concerned with production (Blake & Mouton, 1964), lone decision makers (Vroom & Yetton, 1974), initiators of structure (Fleishman, 1953c), production-centered (R. Likert, 1961a), goal emphasizees and work facilitators (Bowers & Seashore, 1966), task-oriented (Fiedler, 1967a), and concerned about performance (Misumi, 1985). Howard and Wellins (1994) listed five types of autocratic leader behavior in work settings: (1) The *controller* enforces a prescribed way of working. (2) The *commander* tells what to do and expects obedience. (3) The *ruler* considers decision making a privilege of management. (4) The *judge* evaluates subordinate performance and metes out rewards and punishments. (5) The *guard* protects turf and hoards resources.

The “bulls of the woods”—the early-twentieth-century shop foremen, exploitative autocrats, and punitive task-directed leaders—made the decisions for their groups and told workers what to do. They used physical force when necessary to cow their workers (Muszyk & Reimann, 1987). Such leaders discouraged subordinates from contributing to the decision process. They paid little or no attention to their subordinates’ needs. More modern and less punitive autocratic leaders still reserve decisions for themselves and remain more concerned about getting the job done than about the needs of their subordinates.

Autocratic leaders tend to initiate structure, provide information, determine what is to be done, issue the rules, promise rewards for compliance, and threaten punishments for disobedience. They use their power to obtain compliance with what they have decided. They depend on their knowledge of policies and regulations and their official rank to regulate the behavior of their subordinates. They use their technical knowledge to solve problems to gain their subordinates’ respect and willing compliance with their orders (Nelson, 1950). They are more often charismatic than consensual (Zaleznik, 1974). Autocratic leaders are ideologues who believe that people are basically lazy and must be driven and controlled by external rewards and punishments.

*The Warrior Model of Leader.* Nice (undated) has enumerated the characteristics of a subcategory of authoritarian leader. This model is of leadership related to conflict and to triumph over opposition. The flow of information is controlled. Results are more important than the methods used to achieve them. The warrior leader knows friend and foe. Battles are selected carefully and unnecessary fighting is avoided. Plans and preparations are made for future contingencies in a world seen as dangerous and hostile, in which few people can be trusted.

### ***The Democratic Leadership Cluster***

The democratic or egalitarian leadership cluster reflects concern about the followers in many different ways. Leadership is considerate (Fleishman, 1953c), democratic (Lewin & Lippitt, 1938), consultative and participative (Bass, 1976), consensual (Zaleznik, 1974), employee-centered (R. Likert, 1961a), concerned with people (Blake & Mouton, 1964), concerned with the maintenance of good working relations (Misumi, 1985), supportive and oriented toward facilitating interaction (Bowers & Seashore, 1966), relations-oriented (Fiedler, 1967a), oriented toward joint decision making (Heller, 1969a), and oriented toward group decision making (Vroom & Yetton, 1974). Democratic leaders are Theory Y ideologues (McGregor, 1960). They solicit advice, opinions, and information from their followers and share decision making with their followers. Democratic leaders use their power to set the constraints within which followers are encouraged to join in deciding what is to be done. Democratic leaders depend on their followers’ skills, as well as on their own interpersonal ability and knowledge of their followers’ individual needs, interests, and capabilities (Nelson, 1950). Democratic leaders believe that workers are internally motivated to do well, and seek autonomy and the opportunity to prove their worth. These leaders move decision making in organization hierarchies to lower levels, encourage questioning and ideas from below about better ways of doing things, are open to criticism, treat subordinates’

mistakes as learning opportunities, celebrate subordinates' accomplishments, and promote subordinates' ideas to higher authority (Howard & Wellins, 1994). But democratic leaders often need to do more to involve their followers in decision processes. Concerned with the corruption and shortcomings of democratic governance, Rost (1996) would reform it by changing the many passive followers in an organization or community into active collaborators who help their leaders to set the major policies of governance. According to Gill (1996), five principles govern all democratic societies: (1) personal responsibility, (2) empowering others to become leaders, (3) inclusiveness, (4) equality, and (5) full deliberation. Democratic leadership has internal conflicts and is often messy. It is not to be confused with laissez-faire leadership (discussed in [Chapter 6](#)), in which the leader abstains, withdraws, or abdicates responsibility and shows none of the concern seen in the authoritarian or democratic cluster.

Illustrating the meaningfulness of the clusters, Stanton (1960) reported higher scores for consideration and for a human relations orientation among managers of clerical employees of one firm that was known for more democratic supervision, compared with another firm that was known for more autocratic supervision. Conversely, the amount of initiation of structure was much higher in the autocratic firm than in the democratic firm.

### ***Latent or Underlying Structure***

Edwards and Rode (1986) asked 100 students, mainly in ROTC, to complete four different ways of measuring authoritarian and democratic leadership preferences. The Leader Behavior Opinion Questionnaire<sup>1</sup> assessed how frequently they should initiate structure as leaders and how considerate they should be. Blake and Mouton's (1978) Managerial Grid was used to describe a concern for people and a concern for production. Hersey and Blanchard's (1973) LEAD-Self questionnaire (Leadership Effectiveness and Adaptability Description) generated authoritative telling and selling scores and democratic, participating, and delegating scores. Fiedler's (1967a) Least Preferred Coworker (LPC) score was used to assess task and relations orientation.<sup>2</sup> The intercorrelations among the authoritarian task measures were positive but rather low. The same was true for the democratic measures. However, a path model of the intercorrelations, adjusted for measurement errors by Jöreskog and Sorbos (1978), indicated that the latent structure underlying the observed correlations was a continuum stretching from authoritative behavior at one end to democratic behavior at the other.

### ***Distinctions among Styles of Leadership***

This chapter and [Chapters 18, 19, and 20](#) will look at concepts of the differences in leadership styles or patterns of leadership behavior and their effects: the overarching concept of and evidence about autocratic versus democratic leadership (this chapter), participative versus directive decision making ([Chapter 18](#)), relations versus task orientation ([Chapter 19](#)), and consideration versus initiation ([Chapter 20](#)). Laissez-faire leadership versus motivation to manage was discussed in [Chapter 6](#). Autocratic-authoritarian versus democratic-egalitarian leadership is the most multifaceted issue. It refers to the way power is distributed, whose needs are met, and how decisions are made. Participative versus directive leadership refers primarily to how decisions are made. Relations-versus task-oriented leadership focuses on whose needs are met. Consideration versus initiation of structure is a behaviorally factor-derived dichotomy. Consideration and initiation refer to how decisions are made and to the structuring of tasks, goals, and role relationships. Laissez-faire leadership and motivation to manage refer to the extent to which leadership is either avoided or attempted. It should be kept

in mind that styles of leadership are distinguished not only by behavioral differences but also by differences in cognition and intentions. To the degree that leaders are consistent in what they think they ought to do, they will have a consistent style of leadership (Wofford & Goodwin, 1998).

## Authoritarian and Democratic Leadership

---

Why do we emerge with just two overarching clusters of leadership styles? Possibly because there are only two ways to change a follower's behavior (apart from using drugs or physical force). The leader alters either the follower's information, understanding, and ability to cope with the task at hand, or the follower's motivation to deal with the task. When the leader has more relevant knowledge than the follower, authoritarian, task-focused direction can transfer the information quickly. Powerful leaders can arouse follower motivation. But in many situations, followers have at least as much information as the leader. Power may be shared. Follower motivation can be enhanced by involving them in decisions about handling the task, their concerns about the task and themselves.

Misumi (1985) argued that two fundamental dimensions—the performance leadership function (P) and the maintenance leadership function (M)—underlie all the others in the clusters. Thus, for instance, participative and democratic leadership are situationally specific manifestations of the underlying maintenance function, whose aim is to promote social integration and group stability. The manifestation of the maintenance function may appear as consideration if it is directed primarily toward satisfying subordinates' needs.

### *Use of Power and Ability*

MacIver (1947) and Bass (1960) noted that authoritarian leaders may depend on their power to coerce and their ability to persuade. An able leader successfully persuades others to follow him or her because they expect that following the leader's suggestions will result in solving the problems the group faces. A powerful person successfully coerces others to follow him or her because the power of the leader's position or the power of the leader as a person makes others expect that the leader will reward them for compliance or punish them for noncompliance. An able leader can indirectly reinforce the behavior of others. Such a leader can provide the cues that help them attain their goals. A powerful leader can directly reinforce the behavior of others by granting or denying them rewards or punishments (Bass, 1960).

These types of authoritarian leadership were described by F. C. Bartlett (1926). He observed that leaders in any complex social group maintain their success either because of the social prestige of their position and their personal capacity to impress and dominate or by virtue of their personal capacity to persuade their followers. Blau and Scott (1962) described the authoritarian supervisor as one who, among other things, uses power to be strict rather than lenient, to supervise closely, and to ensure adherence to procedures. Using one-minute sampling to observe the spontaneous play of children in nursery school, Parten (1932) found two types of leadership possible in the situation: persuasive leadership, which uses diplomatic, "artful" suggestion; and leadership through personal power, which uses brute force to dominate others. Zillig (1933) observed the same two types of leadership in the German classroom—leaders who dominate and leaders who direct and guide.

Colin Powell (1995, p. 332) described how he used his power and ability when he was a senior official in the Department of the Army to make Policy Review Group meetings more effective. He was delegated responsibility by his boss, Frank Carlucci, to chair the interagency discussions. Frustrated by "endless, pointless, time-wasters," he used his legitimate power and perspicacity to structure the meetings highly. Everyone could contribute in advance to the agenda, but Powell controlled the final listing. No one else could change it. The meeting was to last only one hour. In the first 5 to 10 minutes, Powell reviewed its purposes and what had to

be decided. Participants could present their positions without interruption for the next 20 minutes, followed by open discussion until the last 15 minutes, when Powell spent 5 minutes summarizing everyone's positions, allowing the participants one minute each to critique the summary and reserving the last few minutes for himself to present the conclusions. Participants' objections could be taken up with their superiors and referred by them to Carlucci.

The processes of democratic leadership usually require maturity and some education. Some leaders may be identified as democratic on the basis of their use of parliamentary procedures and majority decision making. Others may consult; strive for consensus; and pursue an open, trusting, follower-oriented relationship. Such consensus leadership has deep roots in the American national character (Cooley, 1956). According to Zaleznik (1974), the idealized image of the leader in America is that of brother rather than father. The leaders are first among equals whose sense of timing may be more important than their expertise. Leaders may be more dependent on the followers than the followers are on the leaders. Compromise, caring, and a sense of responsibility and attachment to followers characterize the consensus leader.

## Effects of Autocratic and Democratic Leadership

---

### *Ideal Types*

In the first experiments—using instructed camp counselors leading preadolescent boys and girls—to contrast the authoritarian and the democratic leader, the authoritarian leader dictated what was to be done and was unconcerned about the group members' needs for autonomy and development. The democratic leader shared the decision making with followers and was concerned about their need to contribute to deciding what was to be done. The authoritarian leader was personal in praise or reproof of each follower; the democratic leader was factual and rational. The authoritarian leader emphasized his or her social distance from the followers; the democratic leader deemphasized social distance.

Following the earlier experiments with authoritarian and democratic leadership, subsequent studies tended to concentrate on one of four aspects of the distinction between authoritarian and democratic leadership: (1) whether the leader shared decision making, (2) whether the followers were of primary concern to the leader, (3) whether social distance was maintained, and (4) whether punishment and coercion were used.

It must be stressed that these are ideal types of authoritarian and democratic leadership. In practice, one is likely to find much variation and overlap. For instance, benevolent autocrats, although they are likely to be dictatorial, may also be considerably concerned about the needs of their followers. The democratic manager may encourage group decision making but may also emphasize getting the job done, as well as the needs of the group. The charismatic leader may rely on personal power and the followers' desire for identification, but also may choose to support democratic efforts and the attainment of prosocial goals. Some researchers have taken greater care than others to define and "purify" the patterns of leadership behavior to be studied. But often it is difficult to determine whether the pattern of leadership behavior examined was democratic, participative, considerate, relations-oriented, or some combination of these characteristics.

### *The Prototype Experiments*

Consistent with Kurt Lewin's ideas (1939) about the behavioral dynamics in groups, two seminal experiments were conducted (Lewin & Lippitt, 1938; Lippitt, 1940a) to explore the effects of democratic and authoritarian

atmospheres upon the behavior of group members. These studies were preceded by a report by Mowrer (1938) on how infractions of rules were reduced at the New Haven Children's Center in 1937 when a democratic approach was offered to the children (aged 4 to 12) to deal with problems, in contrast to the authoritarian staff control that had been in place before.<sup>3</sup> Reporting on the two experiments, Lippitt (1940) defined democratic and authoritarian leader behavior. By means of careful coaching and practice, the authoritarian leader was trained to (1) determine all policy for group members, (2) dictate the methods and stages of goal attainment one step at a time, (3) direct the actions and interactions of group members, and (4) praise the members in a personal manner. The democratic leader was trained to (1) encourage group members to determine their own policies, (2) give them perspective by explaining in advance the steps toward attaining the goals, (3) award them freedom to initiate their own tasks and interactions, and (4) praise them in an objective manner. The leaders were adult counselors. The group members were 10-year-old boys and girls, closely matched on several control variables. Two groups of five members each worked on hobby projects. The behavior of leaders and members was recorded by trained observers.

Both the leaders and the group members initiated more actions in the authoritarianled group. Members of the authoritarianled group had more submissive reactions to the leader, however, and treated him less as an equal than was the case in the democraticallyled group. In the authoritarianled group, members became progressively more submissive to the leader. Although they tended to respond to the leader rather than to initiate interaction with each other, they hesitated to approach him because to do so might further reduce their personal power and freedom of movement. The democratic form of leadership, on the other hand, tended to increase the freedom of action of group members. The members of the democratically led group exhibited less tension and hostility, and their subgroups were more cohesive and enduring than was the case for the authoritarianled group.<sup>4</sup> Curfman (1939) replicated (1940a) Lippitt's first experiment with two clubs of fifth- and sixth-graders, with similar results.<sup>5</sup>

### ***Implications and Contrary Points of View***

Research and development by Rensis Likert (1961a, 1967, 1977b) flowed from a direct inference from the prototype experiments that the democratic approach was to be advocated in organizations to foster effectiveness and satisfaction. In this, Likert was joined by the entire human relations movement (see, for example, Argyris, 1957; McGregor, 1960). In counteraction, joining with the classical "scientific managers," Miner (1968), among others, argued for an emphasis on the manager-leader as a task-oriented authority figure. Blake and Mouton (1964) pioneered the point of view that the best leaders and managers were highly concerned with both production and people and could integrate the two approaches. A fourth group of advocates, such as Fiedler (1967a), Vroom and Yetton (1974), and Hersey and Blanchard (1977), argued that which style was best depended on the situation.

As we shall see in this and succeeding chapters, there is some truth in all these positions. Evidence has accumulated that in specified circumstances, authoritarian direction may, in fact, result in heightened productivity, particularly in the short term; but overall, the democratic approach is likely to be more effective, particularly in the long run. And in general, under most conditions, working for a democratic supervisor will be more satisfying. This last conclusion is simplest to document.

Over 30 empirical laboratory experiments and 10 field studies on the subject were conducted between 1940 and 1975. Under democratic leadership, members' satisfaction with the leaders was the rule rather than the exception. On the other hand, more positive correlations were found between the authoritative leadership style and productivity in the laboratory experiments. Fortunately, a more rigorous meta-analysis, including some of these findings as well as more recent reports, provided a greater opportunity to be more specific about these

effects on productivity. In field studies, it could be concluded that a democratic style worked better. In the laboratory, the autocratic style resulted in more productivity.

Miller and Monge (1986) first conducted such a meta-analysis of short-term laboratory experiments of the effects on productivity and satisfaction of “employees” of contrived autocratic versus participative “supervisors” by Ivancevich (1974); Katzell, Miller, Rotter, and Venet (1970); McCurdy and Lambert (1952); and Shaw (1955). In these experiments, productivity was greater when the leader in the laboratory manipulation was more authoritarian than democratic. For the four short-term laboratory experiments in which the “supervisor” was trained to act autocratically or democratically, productivity was greater with authoritarian, directive supervision. The mean correlation between productivity and authoritarianism was .33.

However, Miller and Monge (1986) also completed a meta-analysis for 10 longer-term field studies. Consistent with what will be reviewed next, they found strong support in reports from 41 analyses. In such real-life settings, the mean correlation was .27 between democratic supervision and the productivity of the persons or groups supervised. The researchers also concluded that the more democratic supervisory styles correlated with the satisfaction of subordinates. The mean correlation was .34. Consistent with this conclusion is the massive survey evidence accumulated by R. Likert (1977b) and his colleagues. Despite the fact that in the short run, in brief laboratory experiments, authoritarian supervision pays off in more productivity than does democratic supervision, in the long run democratic approaches tend to generate bigger improvements in an organization’s productivity as well as in the satisfaction of its employees.

*When It Pays to Be an Autocratic Leader.* Jack Welch, CEO of General Electric, headed the 1984 *Fortune* list of the 10 toughest bosses in America (Flax, 1984). Yet he moved General Electric to the top of the list in earnings and successfully changed its line of products and competitive performance. Muczyk and Steel (1998) cite successful turnarounds by business executives. During organizational crises, despite the aversion to autocratic leadership, when organizations need to be turned around quickly, autocratic and directive leadership is needed. Sometimes unpopular decisions are required along with legitimate and reasonable goals and fair and respectful treatment of subordinates. Teachers, coaches, and religious leaders exert powerful influence over many followers who learn from them by being told what they should do (Smither, 1991). Not unexpectedly, the military tends to value the use of authority more favorably. In a survey of 30,735 U.S. Army superiors, peers, and subordinates of commissioned and noncommissioned officers, Penner, Malone, Coughlin, and Herz (1973) found that leaders who established a high level of discipline were likely to be rated much higher in their overall performance by their superiors. Consistent with this, Torrance (1959) reported that U.S. Air Force aircrews who were given feedback by highly authoritarian methods improved their performance more than those who were given feedback by less highly structured methods.

Supportive evidence was also found elsewhere. Hise (1968), studying simulated business groups, found that productivity was positively related to close rather than general supervision. M. E. Shaw (1955) obtained results indicating that the speed and accuracy of a group’s performance in a highly structured communications network were significantly higher under autocratic than under democratic leadership. In a study of groups in a formal organization, Shepherd and Weschler (1955) found that psychosocial distance between the leader and the followers was associated with fewer communication difficulties. Working closely together was related to greater difficulty in communication. Bergum and Lehr (1963) studied subordinates’ monitoring performance under different conditions of supervision. They found that the vigilance of subordinates could be maintained at fairly high levels under authoritarian conditions.

Whether authoritarian leadership pays off will depend on the extent to which the leader has more knowledge about what needs to be done as well as control of the necessary resources. This payoff can be routinely demonstrated in leadership training exercises. Authoritarian leadership can be productive if the trainee who is assigned the role of autocratic leader happens, by chance, to know more about the problem to be solved than does the person who is playing the role of subordinate (Shackleton, Bass, & Allison, 1975). When

autocratic leaders know the correct answer in such exercises, they can ensure highly accurate group outcomes better than can democratic leaders. But authoritative leaders with misinformation can lead their groups farther astray than can democratic leaders with the same degree of misinformation (Cammalleri, Hendrick, Pittman, et al., 1973). An increase in rules constraining managerial behavior was found salutary in Malaysia (Mansor & Ali, 1998).

*When Autocratic Leadership Is Worse.* The American public was led to believe that 11,500 unionized air controllers went on strike in August 1981 for unreasonable economic demands and because of peer pressure. However, a U.S. Department of Transportation task force discovered that they had struck because they wanted improvements in working conditions to alleviate job stress and because their managers put autocratic values and beliefs into practice (Bowers, 1983). In 1989, the newly formed union of air controllers made the same claim that morale was low because of autocratic management (Cushman, 1989). Ziller (1957) found group members to be least satisfied under autocratic leadership. In a study of personnel turnover, Ley (1966) found that the supervisor's authoritarian behavior was the factor most frequently associated with subordinates quitting their jobs.

More deleterious effects are likely when autocratic leadership takes the form of abusive, punitive, and disciplinary actions. The only U.S. Navy captain to be relieved of duty "for cause" as commander of a nuclear submarine was relieved for abusive treatment of the crew, resulting in their "despondency" and low morale (Ricks, 1997). Richman, Flaherty, Rospenda, et al. (1992) found that abusive supervision of medical students and medical residents was related to their sense of distress and dissatisfaction. Ashforth (1997) reported that belittling of subordinates and noncontingent punishment by their supervisors were correlated with subordinates' feelings of frustration, alienation, and helplessness. Tepper (2000) conducted follow-up surveys of 390 home telephone interviews of full-time employees of service, retail, manufacturing, and small-business organizations about their experience with abusive supervision. Abuse was infrequent on 15 items of behavior such as "Ridicules me" and "Puts me down in front of others" (1 = never uses this behavior; 5 = uses this behavior very often). The mean obtained was 1.38. Abusiveness correlated negatively with job satisfaction (−.35), organizational commitment (−.24, −.27), and positively with respondents' emotional exhaustion.

Cultural norms dampen enthusiasm for using autocratic leadership. In earlier chapters, we observed that supervisors tend to avoid disciplinary, punitive action even when confronted with poor performance by subordinates. Thus, for instance, Maier and Danielson (1956) reported that even when disciplinary rules call for punishment, supervisors tend to avoid it. They perceive that punishment will reduce productivity, even when it is used to control the violation of rules. In fact, Keller and Szilagyi (1976) found that punitive leadership, rather than improving performance, primarily increased role ambiguity. Day and Hamblin (1964) found punitive and close supervision to be connected with reductions in productivity and group harmony. They studied 24 quartets who had to follow elaborate blueprints to assemble models of molecules using pegs, springs, and colored balls. In this complex task, the members were subjected to either punitive or nonpunitive supervision, as well as to close or general supervision. Punitive and close supervision, in contrast to nonpunitive and general supervision, tended to increase the subjects' feelings of aggression toward their coworkers, as well as toward their supervisor, which significantly lowered their productivity.

Numerous other experiments point to the deleterious main and side effects of punitive supervision. French (1957) examined the effects of the "supervisor" who obtained compliance by using the power to fine paid participants who were working at a simple task—sorting IBM punch cards according to the total number of holes the cards contained. The assignment was supposedly part of a research project. Participants were fined for failure to maintain the standard of speed and accuracy. In comparison with participants who were rewarded with extra pay when they reached and maintained the standard, participants who were punished by fines for failure were more likely to show signs of resistance to maintaining production. After four working periods, punishment for failure became detrimental to speed and accuracy. The participants had a greater desire to leave

the work and were more likely to want to do something else and to make suggestions for changing the work situation. Furthermore, they showed greater feelings of aggression, liked their supervisor less, and were less likely to accept the supervisor as competent to evaluate their work. In a similar experiment, Raven and French (1958b) levied fines when participants failed to conform to the demands of “supervisors.” These fines led the participants to resist by overconforming to the suggestions of their supervisors. That is, metaphorically, if participants were ordered against their will to “polish the silverware,” they rubbed so hard that they rubbed off all the silver.

Experiments by deCharms and Hamblin (1960) yielded similar results finding that punitive supervision resulted in increased tension in “employees” and lowered their productivity. These studies of the effects of punitive supervision are consistent with the general psychological findings that severe punishment tends to be disruptive and anxiety producing. Mild punishment, however, may provide, under certain circumstances, more appropriate attention to the failure to comply with authority and serve as a way to eliminate undesired acts. Thus Georgopoulos (1965) observed higher productivity to be associated with a pattern of supervisors’ disciplinary behavior that employees regarded as “just right” and “not too strict.” Mild aversive reinforcements and negative feedback have their uses.

*When It Pays to Be a Democratic Leader.* Smither (1991) listed four conditions in which democratic leadership works best in organizations: (1) it is visibly supported by higher authority; (2) members are well-educated and support the organization’s goals; (3) leaders have the skills to conduct meetings with the members; and (4) time can be afforded for trust to develop. Comrey, Pfiffner, and Beem (1952) studied employees at six levels of organization in the U.S. Forest Survey. Supervisors of more effective departments were described as sympathetic, democratic, social, and willing to share information. Similarly, Comrey, High, and Wilson (1955a, 1955b) studied supervisors and workers in an aircraft factory. Supervisors of effective groups were characterized by adequate authority, communication downward, and sympathy; these supervisors were not arbitrary, and their attitude toward employees was not hypercritical. Argyle, Gardner, and Ciofi (1958) also reported higher rates of productivity, reduced personnel turnover, and reduced absenteeism under democratic, nonpunitive supervision in work groups in seven British factories. Zweig (1966) found that democratic supervisors were rated by higher management as being more effective than supervisors exhibiting less democratic styles of behavior. Similarly, Hall and Donnell (1979) reported that the managers whose career advancement was the fastest, compared with those who advanced more slowly, were less likely to subscribe to Theory X beliefs<sup>6</sup> that workers are lazy and immature, and need to be carefully monitored and controlled. Levy-Leboyer and Pineau (1981) obtained interview data from 151 French laboratory supervisors. The success of their laboratories was appraised subjectively and from research publication records. Leaders of more successful laboratories supervised less strictly, allowed for participation by technicians in decision making, and held more frequent meetings and evaluations.

In a federal agency, J. C. White (1972) observed that both the effective county office managers and the effective managers at headquarters used a more democratic style. The effectiveness of business supervisors and purchasing managers was also seen by H. C. White (1971a, 1972) to be associated with the extent to which they were more democratic and less autocratic. Hollman (1973) and Tanimoto (1977) found that the effectiveness of management by objectives, as seen by subordinates, was greater when practiced by a more democratic manager than by a more autocratic manager. Other studies have shown that democratic approaches in organizations have a favorable effect on the physical and mental health of the members (Caplan, Cobb, French, et al., 1975).

Ordinarily, satisfaction and morale are likely to be lower with autocratic supervision and higher with democratic supervision. Under autocratic leadership greater resentment, less loyalty, less commitment, less involvement, and less satisfaction are commonly found (Gouldner, 1954). Such subjective reactions to the supervisors and poorer relations with them affect the willing compliance of subordinates with their supervisors’

initiatives (Barnard, 1938). In both the short term and the long term, subordinates generally will be more satisfied with democratic leaders.

Beam (1975) showed that enlisted personnel in the U.S. Navy had a strong desire to be treated democratically, regardless of the level of technology or physical activity in which they were involved. Mohr (1971) obtained similar results in 144 work groups from 13 local health departments, as did Pennings (1975) in 40 branch offices of a large U.S. brokerage firm. The subordinates' satisfaction was strongly associated with democratic supervision in these as well as in many other large-scale field studies.

Baumgartel (1957) studied attitudes and motivations of scientists in governmental research-and-development labs under three leadership conditions (democratic, authoritarian, and laissez-faire). He found that scientists who worked under the democratic leadership held the most favorable attitudes and had a greater job motivation, whereas the least favorable attitudes were found among those who worked under the authoritarian leadership. Harnquist (1956) observed that group members tended to feel more satisfied under democratic than under autocratic leadership. Mullen (1965, 1966b) reported that the satisfaction of employees was associated with democratic supervision but saw no relationship between supervisory style and employees' requests for transfers.

Mandell and Duckworth (1955) reported that the overall morale of 64 trade employees in civil service was high if the employees said that their "supervisor lets them know how they are doing." In a series of surveys, R. Likert (1961a) found that employees of public utilities revealed higher job satisfaction when their supervisors were more "personal" than "institutional" in their dealings and more "downward" or employee-oriented, and when the supervisors trained the subordinates for better jobs. Supervisors of high-morale groups differed from supervisors of low-morale groups in that they reviewed their subordinates' work more frequently, welcomed the discussion of mutual problems with subordinates, carried on group discussions, and kept subordinates posted on new information.

D'Angelo (1973) found that sales managers who believed themselves to be practicing a democratic, human relations style brought about more change in their subordinates in an organizational development program than did those who believed they were practicing either authoritarian or "human resources" leadership. H. H. Meyer (1968) studied two plants, one managed according to Theory Y and the other managed according to Theory X.<sup>2</sup> Workers under the more democratic type of management (Theory Y) reported higher felt responsibility, risk, reward, warmth, and identity. Beehr and Gupta (1987) compared two manufacturing firms—one, formally democratic; the other, more traditional—that were similar in size and technology. They found that employees' perceptions, attitudes, and behavior were more favorable in the democratic firm.

Hendrix and McNichols's (1982) survey of 4,786 military and civilian personnel in the U.S. Air Force showed that managers who were described as self-enhancing, outspoken, and demanding and who used their authority as their primary means of influencing their subordinates were seen as contributing to a much less attractive organizational climate, to much less job satisfaction, and to much less perceived productivity than were other more democratic managers who tended to show concern for their subordinates and for group processes. Results were the same for three different work settings involving customer service, routine jobs, and unique jobs with a lot of autonomy.

Brollier (1984) surveyed 93 directors of departments of occupational therapy and 348 staff therapists. The directors' democratic leadership had much more of a positive effect on the staff's satisfaction than on the staff's performance. A survey by Field (1984) of 295 human services professionals indicated that democratic leadership tended to promote greater job satisfaction among the staff, particularly satisfaction with salaries and career advancement.

*When Democratic Leadership Is Worse or When Alternative Styles of Leadership Are Better.* Studebaker went out of business in 1964, after competing against other auto manufacturers that practiced less industrial democracy and less committee management (Clemens & Meyer, 1987). Contingent reinforcement

and transformational leadership may be more effective than the emphasis on either authority or democracy (Bass, 1998). Ziller (1957) observed greater problems among members who were led democratically. Neither autocratic nor democratic leadership was as effective as a type of *reinforcement* leadership that consistently approved the correct performance of members and made suggestions for improvements. Spector and Suttell (1956) demonstrated that this type of leader brought about better achievement by the group than did an authoritarian type who made decisions for the group or a democratic type who permitted maximum participation by members. D'Angelo (1973) reported that a *human resources* style, which involves "striving to continually expand the areas over which the manager's subordinates have self-direction and self-control," was associated with more effective work groups before and after an organizational development program for 103 sales managers and their 360 salesmen subordinates. Autocratic or human relations styles were less effective. Howell (1985) showed that in contrast to task-structuring and considerate leaders, actors who were trained as *charismatic* leaders were most effective in enhancing productivity in the face of normative resistance among subordinates.

Anticipating future interest in transformational leadership, Litwin and Stringer (1966) organized 45 business students into three "firms." The firms competed in the construction and marketing of "radar equipment" manufactured from Erector set materials. Three different business climates were created: (1) an *authoritarian-structured* business, with a strong emphasis on the careful definition of duties and the exercise of formal authority; (2) a *democratic-friendly* business, in which cooperative behavior, group loyalty, teamwork, freedom from punishment, and a loose informal structure were emphasized; and (3) an *achieving (transformational)* business, in which innovation was encouraged, competitive feedback was given, pride in the organization was fostered, a certain amount of risk taking was deemed desirable, and high personal goals were encouraged. The "president" of each company was a member of the research staff who adopted an authoritarian, democratic, or achieving leadership style. The achieving (transforming) style resulted in the greatest dollar volume, the most new products, and the most cost-saving innovations. The authoritarian style did succeed in producing the finished goods with the highest quality, primarily by never deviating from the specifications. Consistent with most other findings, students who were working with a democratic president were more satisfied with their jobs than were the students in the two other firms.

*When There Are No Differences.* Some studies have failed to find that democratic or autocratic supervision had any significant effect on satisfaction or productivity. Thus, with experimental groups of students, Hamblin, Miller, and Wiggins (1961) reported no relationship between authoritarian leadership and group morale. J. D. White (1963) examined whether the morale of boards of directors was affected by how they were led. Although the power of members was found to be higher on boards with democratic leaders than with autocratic leaders, morale was not related to the different styles of leadership. In the case of sports coaches, Browne and Mahoney (1984) concluded that it sometimes appears best for the coach to act in an authoritarian manner. At other times, it is best for the coach to be more democratic by talking to players with individualized consideration and by allowing them to participate in goal setting. Still other investigators found no significant differences in productivity between democratically and autocratically led groups. Thus Lyle (1961) and Spector and Suttell (1956) found no differences in the performance of groups under democratic and autocratic leadership. However, Lyle (1961) observed a tendency for democratic groups to work faster under restricted communication, whereas authoritarian groups worked faster under open communication. Results obtained by S. Adams (1952) indicated that bomber crews performed more effectively under medium than under high or low degrees of democratic leadership. Sales (1964) obtained no significant difference in the performance scores of groups with democratic and autocratic leaders. Johnson and Smith (1953) studied classes taught traditionally and under democratic leadership. They found no significant differences in achievement gains or in the students' evaluations.

Mullen (1965, 1966b) also failed to find that group productivity was related to supervisory style. Likewise,

T. A. Mahoney (1967) obtained no relationship between democratic supervision and measures of organizational effectiveness in a study of industrial organizations. Similarly, Swartz (1973) found that whether football coaches were autocratic, democratic, or laissez-faire was unrelated to their success in winning games. G. H. Graham (1969) conducted one class democratically according to Theory Y and another autocratically according to Theory X.<sup>8</sup> The two groups did not differ in examination scores. The top quartile of students did better when led by the democratic instructor, but the lower 75% of students got better grades under the autocratic instructor.

## Antecedent Conditions That Moderate the Effects of Autocratic and Democratic Leadership

---

[Chapter 7](#) noted that authoritarian leadership works better with authoritarian followers and in authoritarian cultures. Other potential personal and interpersonal modifiers were also discussed. [Chapters 25](#) through [29](#) will look at how situational conditions may affect the leader's style, and [Chapters 31](#) to [33](#) will examine how race, sex, and culture make a difference. Some of the findings will be introduced here that have demonstrated that the effects of authoritarian and democratic leadership depend on these antecedent conditions.

Taylor (1980) pointed out that immature, dependent, inexperienced subordinates are more likely to expect and accept authoritarian direction and that democratic leadership is likely to result in their more rapid development. Nisbett (1986) suggested that a more democratic leadership is desirable as the workforce becomes more educated and seeks greater participation, as business becomes more complex and requires a team of experts to deal with its problems, and as the use of high technology increases. The symphony conductor Daniel Barenboim (2001) felt that one could learn to live in a democratic society through experience in a symphony orchestra: "For when you do so, you know when to lead and when to follow. You leave space for others and at the same time you have no inhibitions about claiming a place for yourself." The fall of communism in Eastern Europe gave Luthans and Riolli (1997) the opportunity to compare managers in Albania at a fully privatized company starting over, a company slowly converting to privatization, and a large old-line state-owned enterprise. Most managers in the privatized company preferred and practiced a democratic style of getting everyone involved in decisions. Most in the slowly converting company preferred and practiced a consulting style, getting input from others. Most in the state enterprise practiced benevolent autocracy, explaining their decisions, but preferred a more consultative style.

### ***Effects of Followers' Expectations, Orientation, and Competence***

In examining the effects of followers' expectations about leadership, we need to take into account cultural changes that have occurred in the past 60 years. Earlier studies are likely to show willingness to accept autocratic leadership by many followers; later studies are less likely to show this. Nevertheless, Smither (1989) noted that in the right context authoritarian leadership can be effective in accomplishing organizational goals. Tough leaders can be effective, according to anecdotal evidence. Autocratic leadership may be what is required if employees are poorly educated and are uninterested in responsibility or in the organization's mission. Immediate productivity may be more important than employee satisfaction. Employees may have strong emotional ties to the leader and may not resent tough leadership.

According to French, Morrison, and Levinger (1960), autocratic leadership is likely to generate dissatisfaction and hostility in subordinates unless they see it as a legitimate part of the supervisor's role. Thus Foa's (1957) study of groups of Israeli workers under democratic and autocratic leadership found that groups

with authoritarian and democratic expectations were about equally well satisfied with democratic leaders. But when leaders were autocratic, crews with authoritarian expectations were better satisfied than those with democratic expectations. Hemphill (1949b) noted that arbitrary inconsistency and reversal of opinion by the leader are more readily tolerated in groups that lack well-established rules and regulations, well-defined goal direction, and strong cohesiveness among the members. Vroom and Mann (1960) studied industrial work groups that varied in size and in style of supervision. In the small work groups, high rates of interaction occurred between workers and supervisors, and egalitarian leaders were preferred. In the large work groups, members interacted less frequently with each other and with their leaders and exhibited more positive attitudes toward authoritarian leaders.

Tepper, Duffy, and Shaw (2001) found that constructive resistance to abusive supervision was greater if subordinates were conscientious. But resistance was dysfunctional if the subordinates were also agreeable. Tepper, Duffy, and Hoobler (2002) reported that for 176 employees, abusive supervision made a difference in how their coworkers' organizational citizenship behavior (OCB) affected these employees' job satisfaction. When abusive supervision was low, coworker OCB contributed to employee job satisfaction. When abusive supervision was high, coworker OCB had a negative impact on employee satisfaction.

Calvin, Hoffmann, and Harden (1957) constructed experimental groups that differed according to their members' scores on intelligence tests and the authoritarianism or egalitarianism of the leaders. The performance of groups composed of bright members did not differ under authoritarian and egalitarian leadership. But dull members in authoritarianled groups were more effective than were dull members in egalitarianled groups. McCurdy and Eber (1953) arranged for leaders to be coached in democratic and autocratic patterns of behavior. Authoritarian participants solved problems somewhat less speedily under democratic than under autocratic leadership.

*Circularity.* Kruglanski (1969) reported that managers tended to supervise less closely those subordinates whom they trusted. However, a circularity occurs. In an experiment, Strickland (1967) found that laboratory "supervisors" came to mistrust "subordinates" whom they were directed to monitor closely and increased their trust of "subordinates" whom they were not instructed to watch closely. In the same way, McFillen (1978) and McFillen and New (1978) failed to find any significant relationship between supervisory rewards or punishment and subordinates' performance, but subordinates' performance caused a difference in closeness of supervision. Low-performing subordinates were more closely supervised. McFillen and New (1979) demonstrated experimentally that not only is mistrust increased under close supervision, but the supervisor attributes more success to the closely supervised subordinate who succeeds than to the generally supervised subordinate who succeeds, and more failure to the closely supervised subordinate who fails.

### ***Immediate Task Demands***

Which leadership style works best depends on the task of the leader and the led. As Plato observed, there may be no time for a democratic vote on a ship in a storm. Sailors may not know as much about what to do as the captain. The captain's individual judgment may be better than the sailors' consensus. When the democratic management of Steve Jobs, which had promoted the creativity and innovation that launched Apple Computer, was no longer effective in competing with IBM's entry into the personal computer market, Jobs was replaced by the tough John Scully, a top-down decision maker (Clemens & Meyer, 1987).

According to Rudin (1964), a punitive style of supervision leads to good performance on simple tasks and to poor performance on complex tasks. Becker and Baloff (1969) suggested that the optimum style of leadership is likely to depend on whether the task involves information processing or the generation of ideas. In a laboratory experiment involving complex mechanical tasks under close or general supervision and punitive or

nonpunitive styles, Day and Hamblin (1964) found that close supervision produced a large increase in aggressive feelings toward the supervisor. Close supervision did not affect satisfaction with the task, but production was significantly lower. The punitive style also resulted in increased aggressive feelings toward the supervisor, but again without any effect on satisfaction with the task. As with close supervision, punitive supervision led to a decrease in production. However, Patchen (1962) obtained a positive relationship between close supervision and better performance in manual work when there was strong group cohesiveness and when the supervisor was seen as rewarding rather than punitive. Thus although close supervision is usually considered part of a more autocratic style, its effects may depend more on whether it also includes a punitive component. (A benevolent autocrat would be more rewarding and less punitive.)

The phase in the task also makes a difference. R. C. Anderson's (1959) survey of leadership in experimental groups disclosed that groups under authoritarian leaders required less time in the planning phases but were less efficient in the task-solution phases. Consistent with what was said earlier, democratic leadership resulted in greater satisfaction for members in both phases of problem solving. Subsequently, Doyle (1971) ascertained that egalitarian leadership was most effective in the analysis phase of group problem solving, but in the final synthesizing phase that required coordination, groups with powerful leaders were particularly effective.

### ***Falling Dominoes Again***

As was seen in [Chapter 16](#), managers' behavior toward subordinates depends on how the managers' superiors act toward the managers. Thus D. Katz (1951) found that highly productive groups had less close supervision from their supervisors, who in turn were less closely supervised by their superiors. Hunt, Osborn, and Larson (1975) observed that whether or not upper-level management was autocratic had an impact on what leadership style was most effective at lower levels. Morse (1953) studied employees and supervisors in an office situation. General supervision and delegation of authority facilitated the workers' satisfaction with the work group. Job satisfaction or satisfaction with the company was not fostered unless the supervisors' orientation toward employees was reinforced by higher management.

## **Large-Scale, Long-term Comparisons of autocratic and Democratic Systems**

---

Bowers (1997) argued that top-down hierarchical command of business is out of date—that decision making is needed at all levels of a firm. At all levels, leaders and subordinates need to work out decisions together, and a democratic model should replace command and control systems. The outstanding application of democratic as opposed to autocratic processes in organizations was an extensive effort at the University of Michigan. Strong evidence was accumulated from over 500 studies completed between 1950 and 1977 that in the long run, democratic leadership pays off in both higher productivity and greater satisfaction for employees. Katz, Maccoby, and Morse (1950) began the line of investigation in the home office of a large insurance company. Twenty-four work groups were studied; half were high and half were low in productivity. Each highly productive unit was matched with another unit that was low in productivity. Differences in supervisory behavior between the high-and low-productivity units were assessed by means of interviews with supervisors and their subordinates. Highly productive supervisors were more frequently employee-centered rather than production-centered. They were more likely to exercise general rather than close supervision, and they were more likely to differentiate their roles from those of their subordinates in terms of the duties they performed.

Next, Katz, Maccoby, Gurin, and Floor (1951) studied railroad maintenance-of-way workers. Again, the

more productive supervisors were found to be more employee centered and to exercise more general supervision than those whose units were less productive. However, no difference in role differentiation was found. The line of investigation was continued by Morse and Reimer (1956). They showed that although authoritarian methods contributed more to increased productivity in an insurance firm during the first year of an experimental effort to change, a sizable drop in performance followed in subsequent years because of the adverse impact of the authoritarian approach on human factors.

These studies led to the formulation of a rationale for organizational improvement. This rationale relied partly on democratizing the leadership patterns in the organization, predicated on the efficacy of democratic over autocratic processes.

## ***Rationale***

Borrowing heavily from the original experimental concepts and results of Lewin and Lippitt (1938), R. Likert (1961a) conceived of four systems of interpersonal relationships in large organizations: (1) exploitative autocratic, (2) benevolent autocratic, (3) consultative, and (4) democratic. These systems varied as System 1 to System 4 on a number of criteria. Likert proposed and demonstrated that moving organizations away from Systems 1 and 2 and toward Systems 3 and 4 would result, given sufficient time for effects to take place, in increases in both the productivity and satisfaction of employees.

## ***Method***

The Profile of Organizational Characteristics (POC) was constructed using 18 survey questions such as: “How much confidence and trust is shown in subordinates?” “How free do subordinates feel to talk to superiors about the job?” and “How often are subordinates’ ideas sought and used constructively?” An assessment was generated to indicate where the organization lay between System 1 and System 4. The correlations among the 18 scales of leader, peer, subordinate, and organizational behaviors ranged between .40 and .80. These correlations indicated that there was considerable consistency among the various questions. For leadership and influence in the autocratic Systems 1 and 2, the *exploitative autocrat* of System 1 emphasizes threats, fear, and punishment with some promise of reward. The *benevolent autocrat* of System 2 emphasizes more positive and less negative reinforcement. Top-down communication is stressed. Subordinates have little influence on goals and methods. Decisions and controls are centralized and are made person to person. The leadership and influence processes in the *consultative* System 3 and the *democratic* System 4 are such that supervisors and subordinates trust each other; and the supervisors are very supportive, very easy to talk to, and virtually always get subordinates’ ideas to try to make constructive use of them. There is an emphasis on economic and achievement motivation as well as on personal worth. The subordinates’ participation in goal setting is encouraged, along with bottom-up communication. Subordinates are influential in determining goals, tasks, and methods. Decisions and controls are decentralized. Virtually no confidence is shown by supervisors to subordinates in System 1 and a great deal of such confidence is shown in System 4.

R. Likert (1967) applied Bowers and Seashore’s (1966) four dimensions of leadership behavior to distinguish among autocratic and democratic leaders. He found that System 4 leaders were highest and System 1 leaders were lowest on the four dimensions of a leader’s behavior: (1) support—friendly, pays attention to what one is saying, listens to subordinates’ problems; (2) team building—encourages subordinates to work as a team and encourages the exchange of opinions and ideas; (3) goal emphasis—encourages best efforts and maintains high standards; and (4) helps with work—shows ways to do a better job; helps subordinates plan, organize, and schedule; and offers new ideas and solutions to problems.

## ***Overall Results***

Correlations of the respondents' mean scores on the POC with the quality and quantity of organizational performance ranged from .30 to .60 (R. Likert, 1977a). In other words, in the more than 500 studies completed by 1997, positive associations generally were found between measures of the organizations' performance. The modal system was System 3. Surveys before and after shifts upward from more autocratic to more democratic systems were reflected in improvements in organizational performance. For example, R. Likert (1975) reported that the shift from System 1 to System 4 between 1969 and 1970 at a General Motors plant resulted in substantial increases in direct labor efficiency in 1971 and 1972. Although indirect labor efficiency declined between 1970 and 1971, it increased sharply between 1971 and 1972. Particular effects cannot be attributed exclusively to changes in leadership style. However, given the pattern of large-scale, long-term changes reported by R. Likert (1977b), associated with changes in both leadership and other aspects of organizational development, it seems plausible to attribute many of these effects to the changes in leadership. By 1997, more than 500 studies had been completed in petroleum, automotive, pharmaceuticals, investment banking, insurance, delivery service, publishing, utilities, textiles, office equipment, packaging, paper making, and railroad companies. Research also had been conducted in governmental organizations, hospitals, schools, colleges, correctional institutions, military organizations, and voluntary organizations. Data were obtained from more than 20,000 managers at all hierarchical levels, and from more than 200,000 nonsupervisory employees.

### ***Immediate versus Long-Term Effects***

These results need to be understood in terms of the differential impact of authoritarian and democratic systems on immediate, compared with long-term, labor costs. When belt-tightening was autocratically imposed in three continuous-processing plants, it produced an immediate reduction in costs in one organization of 600. However, this reduction occurred at the expense of the employees' deteriorating motivation, dissatisfaction with company policy, and dissatisfaction with the leadership and was reflected in lowered quality and increased grievances, turnover, work stoppages, and failures to meet delivery dates. In one study, it took three or more years for these effects to show up clearly.<sup>9</sup> The immediate savings of \$250,000 actually produced losses of \$450,000 in the longer term, owing to the fact that employees became more hostile, less motivated, and less individually productive as a result of the autocratic imposition (R. Likert, 1977b). Consistent with this finding, Dunnington, Sirota, and Klein (1963) noted that when engineered work standards were imposed on managers and supervisors at an IBM manufacturing plant, the employees resented the pressure, and the same adverse trends occurred in the measurements of the human consequences. Yet Dunnington, Sirota, and Klein did find exceptions. When particular supervisors were more democratic, employees showed much less resentment of the engineered work standards than did employees whose supervisors were more autocratic. The employees who worked for democratic supervisors felt less resentful because the democratic supervisors were more likely to try to do something if an employee complained that the work standard was unreasonable.

Contingency research, to be discussed in [Chapter 25](#), supports the need for different organizational structures in different industries (see Lawrence & Lorsch, 1967a, 1967b; Woodward, 1965). Assembly plants (mass and batch production) have different organizational structures from oil refineries (continuous-processing). Nevertheless, Likert (1977b) noted that regardless of industry, the better-performing plant or department was likely to be closer to System 4 in its leadership processes, and the poorer-performing plant or department was likely to be closer to System 1 in its management system.<sup>10</sup>

*Effects on Business Organizations.* Results from 30 studies in 35 business firms involving some 260 sections, departments, or similar organizational units containing more than 50,000 employees were reported by R. Likert (1961a), Likert (1967), Likert and Likert (1976), and Likert and Fisher (1977). They demonstrated the efficacy of democratic as opposed to autocratic systems of management.

Nineteen of the studies, as summarized by Likert (1977b), were comparisons of more democratic organizations that were closer to System 4 in their leadership and management with organizations that were closer to the autocratic System 1. The differences in productivity and earnings favoring System 3 or 4 over System 1 or 2 ranged from 14% to 75%. In “before-after” studies, in which management shifted toward System 3, productivity and earnings improved from 15% to 40% one or two years after the shift. In two comparisons in which control groups were available, no such improvements were obtained for the control groups.

These improvements continued if the democratic shift was maintained. In departments of fewer than 200 employees, the improvement usually resulted in annual savings of \$50,000 to \$100,000. In a large plant of 6,000 employees, the annual saving was more than \$5 million. Guest (1962a) observed similar results for productivity, quality, and safety when a new manager of the poorest-performing of six plants shifted the organization toward democratic Theory Y leadership.

For 15 business firms, Taylor and Bowers (1972) reported the relations between the measures obtained from the POC and various organizational outcomes 6 months prior to the survey to 18 months afterward. Correlations between having a democratic climate and efficiency reached as high as .80. But correlations were somewhat lower with reductions in absenteeism, minor injuries, ill health, and grievances.

*Effects on Governmental Agencies.* Heslin (1966) found that the high-producing units in a federal government agency engaged in automatic data processing were closer to Likert’s System 4 than to System 1 in their management, as seen by the employees, than were the low-producing units. Operational bureaus of the Department of State were seen as providing better budgeting, space, travel, and personnel services if their management (according to their own subordinates) was closer to System 4 than to System 1 (Warwick, 1975). Similarly, Likert (1977b) reported that city managers, when asked to compare the highest-producing unit with a matched lowest-producing unit they knew well, described the highest unit as between Systems 3 and 4 and the lowest unit as pursuing benevolent autocratic (System 2) management. Bruns and Shuman (1988) administered the POC to 298 Arizona police sergeants and 67 police lieutenants. The modal leadership system in departments of large and medium size was System 2, benevolent-autocratic. The modal leadership system in smaller departments was consultative, System 3.

*Effects on Military Organizations.* In data from 20 ships and 18 shore stations of the U.S. Navy, Bowers (1975) found a strong relationship between an individual’s intention to reenlist (which is a good predictor of actual reenlistment) and the extent to which the ship or station was closer to System 4 and farther from System 1. Likert (1977b) reported that among 14 U.S. Navy crews, the absence of mishaps and operational failures was associated with supervisory facilitation of work and team development. D. E. Johnson (1969) found that of 93 U.S. Air Force ROTC units, those that were judged by higher authority to be operating closer to System 4 than to System 1 were also evaluated as better-performing units.

*Effects on Educational Institutions.* Summarizing 40 studies in school systems, R. Likert (1977b) concluded—from school POC surveys of members of boards of education, superintendents, central staff, principals, department heads, teachers, students, and parents—that school systems closer to System 4, compared with those closer to System 1, exhibited better communications, cooperation, and coordination (Lepkowski, 1970). They were more flexible and innovative (Broman, 1974)<sup>11</sup> and more effective overall (Ferris, 1965; Riedel, 1974). Their personnel felt a greater sense of self-actualization and satisfaction from their work (Wagstaff, 1970).<sup>12</sup> Furthermore, they were judged as achieving superior educational results. They had

better board-employee relations (R. C. Key, 1974) and union-management relations (Bernhardt, 1972; Haynes, 1972). Their students were more highly motivated and attained higher educational achievement for given IQ and socioeconomic levels (Belasco, 1973; A. K. Gibson, 1974). Their students had more favorable attitudes and were less likely to engage in disruptive behavior or acts of aggression against the schools (Cullers, Hughes, & McGreal, 1973; Morall, 1974).

For 12 studies of higher education, Likert (1977b) concluded that institutions whose administrations were closer to System 4 than to System 1 experienced more favorable outcomes. The faculty members were more satisfied with administrative decision making (A. B. Smith, 1971).<sup>13</sup> There was less need for collective bargaining (Cline, 1974), more innovativeness (Bowers, 1976; Hanna, 1973) and commitment to college objectives (T. G. Fox, 1973; Laughlin, 1973), and more favorable student outcomes (Bowers, 1976; Gilbert, 1972).

*Effects in Health Care Organizations.* On the basis of data from 351 nurses in 55 patient teams in eight hospitals, Munson (reported by Likert, 1977b) found that the closer the head nurse was to System 4, the more generally satisfied the nurses were. H. C. White (1971b, 1971c, 1971d) obtained similar results for peers who described effective and ineffective supervisors they had known. System 4 was seen to be more effective than System 1 in three outpatient clinics (National Tuberculosis and Respiratory Disease Association, unpublished) and by Ketchel (1972), who studied the effectiveness of volunteer health planning in 17 Ohio counties.

*Effects in Other Nonprofit Organizations.* In three community-based reintegration centers for ex-convicts in Ohio, McGruder (1976) concluded that in comparison with the most autocratic center on Likert's POC, the most democratic center was most effective, as measured by graduation rates and low rates of recidivism and reincarceration. Similarly, Marchant (1976) obtained data on Likert's POC from the staffs of 22 research-oriented university libraries. The closer the libraries were to System 4 and the farther they were from System 1, staffs were more satisfied, and faculty evaluations of service were higher. Haggard (as reported by Likert, 1977b) found that as management of a YMCA shifted away from System 2 toward System 4, the number of people served by the YMCA increased from 11,064 to 23,794, and the budget increased (from \$173,000 to \$303,000).

## ***Critique***

*Methodology.* Despite the amount of support attesting to the efficacy of democratic leadership in the long term, disquieting ambiguities remain. Thus among the reasons why Miller and Monge (1986) excluded the results of 15 journal articles from their meta-analysis was their determination that the democratic approach had not been clearly measured or experimentally manipulated. They found additional methodological problems in seven other studies.

*Differing Outcome Measures.* Other difficulties arise, reducing confidence in the reported conclusions, owing to the extent to which differences occur from one study to the next in the definition and measurement of the satisfaction of followers and the productivity of groups. Some studies measure global satisfaction, whereas others measure satisfaction with leadership, the job, the group, or the organization. Some researchers count units of output or rates of performance as measures of productivity. Others use ratings of quantity or quality of output as productivity measures.

*Circumstances.* Leadership style may be a product of circumstances rather than of personal preferences. Scully, Sims, Olian, et al. (1994) found in 56 high-tech business firms that when financial performance was poor rather than better, the CEOs tended to be tougher, more directive, and more punitive toward their top managers. Southern Baptist preachers become more authoritarian in response to ambiguity in their role

definition. Ingraham (1981) suggested that the ambiguity of the pastor's role in Southern Baptist churches results in the development of an authoritarian self-image among pastors. When the pastors are unsuccessful in influencing their congregations, they either withdraw from their attempts to lead or try to become manipulative authority figures.

*Effects on the Leader.* The leadership style that is adopted may affect the leader as well as the follower. Kipnis, Schmidt, Price, and Stitt (1981) randomly assigned 113 business students to act as authoritarian or democratic leaders of five-person work groups that manufactured model airplanes. They found that those who acted as democratic leaders perceived their group members to be more internally motivated to work effectively than did those who acted as authoritarian leaders. As a consequence, the democratic leaders gave the members more favorable evaluations, although their productivity was not necessarily higher.

*Confounding of Cause and Effect.* [Chapter 16](#) noted that followers condition a leader's behavior; that is, the leader of a productive group can afford to be more considerate to his or her subordinates than can the leader of a poorly performing group. In addition, Mitchell, Larson, and Green (1977) showed that subordinates' descriptions of a leader's initiation and consideration are erroneously confounded with the perceived quality of his or her group's success and morale. The error is compounded because the same source of information about the leader's behavior provides the indicators of perceived group success and morale. Under these conditions, the correlations between democratic leadership on the one hand, and group success and morale on the other, are inflated above the true correlations.

In interpreting the findings, which comes first, the chicken or the egg? A concurrent study of leadership and its consequences may in reality be a study of leadership and its antecedent conditions. Leaders may be authoritarian because their groups are unproductive, or can afford to be democratic because their groups are productive. The longitudinal studies are few; the concurrent studies are many. Even the efforts to move organizations in a democratic direction suggest that results may not be immediately apparent. One or two years may elapse before a change in leadership style has measurable effects on organizational performance.

*Reflection of Implicit Theories in Results.* The issue of cause and effect is complicated by the extent to which correlations reflect the raters' implicit theories of leadership. That is, a rater may assume that subordinates will be more productive under a particular pattern of supervision. They may make their report about the supervisor's style of behavior as a consequence of how they see the group performing (Rush, Thomas, & Lord, 1977). In Mitchell, Larson, and Green's (1977) study, knowledge that a group performed well caused increases in the rated consideration and initiating of structure of that group's supervisor, whereas knowledge that a group performed poorly caused large decreases in the supervisor's rated consideration and initiating of structure. These distortions in leadership ratings because of the knowledge of performance also occurred when raters of high-and low-performing leaders were exposed to identical and highly salient leadership behaviors (Lord, Binning, Rush, & Thomas, 1978).

## Summary and Conclusions

---

A large cluster of styles can be included in democratic leadership and member-related behaviors: employee-oriented, considerate, concerned with the satisfaction of needs, maintenance-oriented, rewarding and nonpunitive, supportive, relations-oriented, open, close, informal, warm, System 3 or System 4, and people-centered. Included in autocratic leadership or work-related behaviors are opposites of those just mentioned: job-centered, structuring, task-oriented, punitive, closed, distant, formal, cold, System 1 or System 2, and work-centered.

The positive effects of democratic approaches are most apparent if based on the results of large-scale field surveys and lagged productivity measurements rather than on small-group laboratory experiments with

immediate, concurrent effects. Generally, the patterns of behavior included in democratic leadership are more satisfying than those associated with autocratic leadership. But in the short term, productivity may be enhanced more by autocratic leadership than by democratic leadership. This is especially so when the democratic leadership ignores concern for the task and production goals. Nevertheless, in the long term, the positive effects of democratic leadership are evident, especially if the employees' development, commitment, loyalty, and involvement are important to productivity. But numerous conditions, such as the authoritarianism of subordinates or the nature of the task, increase the utility of autocratic methods, particularly in the short run.

Looking at their components provides a fuller appreciation of the autocratic and democratic styles of leadership behavior. Leaning toward the autocratic are direction, task orientation, and initiation of structure. Leaning toward the democratic are participation, relations orientation, and consideration for followers. These components are covered in the chapters that immediately follow.

<sup>1</sup> See [Chapter 20](#) and Fleishman (1960) for an extended discussion of the concepts and measurement of consideration and initiation of structure.

<sup>2</sup> For a discussion of the Managerial Grid, the LEAD-Self questionnaire, and the LPC score, see [Chapter 19](#).

<sup>3</sup> Mentioned in Fox (1954).

<sup>4</sup> Laissez-faire leadership was introduced as a third leadership style by Lippitt (1940a) in his expansion of the experimental investigation. Its effects were discussed in [Chapter 6](#).

<sup>5</sup> Mentioned in Fox (1954).

<sup>6</sup> McGregor (1960) formulated Theory X (autocratic beliefs about how workers needed to be led) and Theory Y (democratic beliefs about how workers needed to be led).

<sup>7</sup> See McGregor (1960).

<sup>8</sup> See McGregor (1960).

<sup>2</sup> There are many such examples of harmful effects on attitudes and performance—effects that linger long after an autocratic leader has left the organization. These effects of coercion often do not surface until the autocratic leader has departed, since one of his or her techniques may include using threats to repress dissent (see R. H. Solomon, 1976).

<sup>10</sup> Such results have been reported by R. Likert (1967); R. Likert and J. Likert (1976); Marrow, Bowers, and Seashore (1968); McCullough (1975); Mohr (1971); Roberts, Miles, and Blankenship (1968); and Toronto (1972).

### Directive versus Participative Leadership

In Ayn Rand's (1957) novel *Atlas Shrugged*, E. Locke found the prescription for heroic business leaders like Jack, who formulated rule for business leaders: face reality as it is, not as it was or as you wish it to be (Tichy & Sherman, 1993). Although the many current business scandals would suggest otherwise, honesty and candor are needed to avoid self-deception and unethical behavior. Failing executives refuse to face reality. Characteristics of business heroes, according to Rand and Locke, are independence, self-confidence, an active mind, vision, and competence. They also need sufficient intelligence to understand their markets and causal connections of consequence and the ability to accurately generalize from what they have observed. They need to have passion in their work. As was already noted in [Chapter 17](#) about autocratic leaders, these tough-minded, directive, task-oriented CEOs are best known for their success and effectiveness in turning around large, previously successful businesses that were encrusted with strong bureaucracies which failed to adapt to changes in their markets. Examples of business leaders illustrate that some whose style is directive and task-oriented may be successful and effective in reaching their goals and satisfying their constituencies. Other examples can be found of business leaders who were successful and effective by being more consultative, participative, and relations-oriented. Generally, they need to be both directive and participative as well as concerned about tasks and relationships.

The more directive leaders, such as Lou Gerstner at IBM and Jack Welch at General Electric, were likely to ask a lot of direct questions; they made some subordinates feel that a meeting was an inquisition rather than a consultation. They made shareholders happier but some employees unhappier. Lou Gerstner was described as tough, ferocious, and driven, yet respected by associates. At the same time, he contributed a great deal to philanthropies and worked hard to invigorate educational systems in many locations. He was a demanding boss, was highly disciplined, stayed focused, set very high standards, and could go beyond less important matters to get at key issues. He had earned a degree in engineering *magna cum laude* and had previously been a successful top executive at American Express and RJR Nabisco. He envisioned that giant IBM, as a smaller firm with fewer hierarchical levels, would be better able to adapt and compete in the world marketplace. He consolidated operations, closed plants, sold subsidiaries, and laid off many managers and a large number of employees. He wanted to take advantage of IBM's potential to offer consulting and a full range of services to provide an integrated information system for its business customers. He brought in 60 new executives and took the firm from bleeding losses back to profitability again (Waga, 1997). His legacy continued after he retired: IBM continued to divest itself of much of its computer manufacturing business and reduced its barriers to integrating its efforts with non-IBM programs and products.

Jack Welch of General Electric projected himself in his 1997 annual letter in which he said that grade A leaders have

a vision and the ability to articulate that vision so vividly and powerfully to the team that it also becomes their vision. ... [These leaders have] enormous personal energy ... and the ability to energize others ... [The leaders] have the ... courage to make the tough calls. ... [In engineering], they relish the rapid change in technology and continually re-educate themselves. In manufacturing, they consider inventory an embarrassment. ... In sales ... they emphasize the enormous customer value of the Six Sigma quality program that differentiates GE from the competition. In finance, "A" talents transcend

traditional controllership. The bigger role is full-fledged participation in driving the business to win. (Henry, 1998, p. 7a)

Welch made sure his frank and honest opinions on management and operations were known and were a guide to GE's future. Welch demonstrated his ability to change a large firm with strong historical institutions. He remained personally involved in everyday matters. He charted clear, specific directions for GE, emphasizing its core businesses and venturing into new businesses. He made GE fast and flexible. He invested heavily in R & D to ensure GE's future, reduced its top-heavy hierarchy, and reduced the number of its employees. In his first three years in office, he reduced GE's employees by 18%. Welch insisted on consolidating GE's 150 businesses into 15 lines, and these lines reduced to three circles: services, industrial automation and high tech, and manufacturing. Executives were under orders to make every business they ran either first or second in market share. Businesses without the potential to grow were divested and plants closed. They were replaced with others judged as having more potential. Many of the acquisitions were made in Europe and Asia. Under Welch, decisions were made more rapidly. He made it possible in 20 years for GE to become one of the largest and most successful multinational conglomerates (Lueck, 1985; Wall Street Transcript, 1985; Forbes, 1985).

Other examples of directive leaders are Jeffrey Immelt and Michael Armstrong. Jeffrey Immelt was appointed CEO of Welch's successfully restructured GE. Immelt took charge following the many financial scandals exposed among top corporate managers at WorldCom, Enron, Tyco, and elsewhere. With concern for ethical standards of top management, he reformed the board of directors by increasing the number of independent outsiders, strengthening its auditing committee, and removing directors with conflicts of interest. Directors were asked to visit two GE businesses each year, without HQ management, to have frank discussions with operating managers. Immelt emphasized consensual management and teamwork in his directiveness (Hymowitz, 2003). Michael Armstrong accepted the CEO position at Hughes Aircraft, informing the current top management team that he admired them but they should either accept his vision for restructuring Hughes or resign. Hughes then had a strong culture focused on product development. A need for restructuring had been recognized but not implemented. Armstrong successfully directed reorganization toward market needs and increased revenue growth (Cole, 1993).

## Making Decisions

---

Who decides? The leader? The led? Both? On what does the answer depend? What are the consequences? Should leaders give directions and tell followers how to do the work, or should they share with followers the need for solving problems or handling situations and involve them in working out what is to be done and how? Is there one best way? Eleanor Roosevelt (April 16, 1945) noted that international peace required both: "a leader may ... point out the road to lasting peace, but ... many peoples must do the building." Numerous humanistic researchers and writers support the need for participative leadership—in which the leader and the led jointly make the decision. The conventional wisdom is that participative leadership is preferred to directive leadership, and that participative leadership is more satisfying and effective than directive leadership. A survey of 485 upperlevel managers from 59 industrial firms agreed, but did not install participative systems (Collins, Ross, & Ross, 1989). As Wagner (1994) noted, in 11 meta-analytic reviews of studies, participation does have positive effects on performance and satisfaction, but the average size of these effects is small enough to raise questions about their practical significance. In many contexts, leader direction may still be of consequence. Depending on circumstances, leader direction may be effective (Hogan, Curphy, & Hogan, 1994). Furthermore, the same leader who is participative at times may also be directive at other times, with equal effectiveness. Their frequency is positively correlated rather than independent of each other.

# The Continuum

---

Most leaders, managers, and supervisors are both directive and participative, depending on the circumstances, but in different amounts. Tannenbaum and Schmidt (1958) suggested that direction and participation are two parts of a continuum, with many gradations possible in between. At one extreme of the continuum, *directive* leaders decide and announce the decision to their followers. They give directions and orders to followers without explaining why. These leaders expect unquestioning compliance; participation in the decision by followers is minimized. At the next gradation, leaders *sell* the decision. They accompany their orders with detailed explanations to persuade followers and manipulate or bargain with them. At the third gradation, (in between directive and participative leadership), leaders consult with followers before deciding what is to be done. They present ideas and problems and invite questions. At the fourth gradation, *participation* by both leaders and followers occurs. Leaders define limits and ask for a consensual decision. Followers join in deciding what is to be done. At the fifth gradation, leaders delegate to the followers what is to be done, and the leader's participation is minimized. At this gradation, within the established limits and constraints, the followers decide what to do; the leaders need to review what was delegated. At this extreme of the continuum, some leaders may completely abdicate their responsibilities.<sup>1</sup> Similar continua were advanced by many others (Hersey & Blanchard, 1969a, 1969b; Heller & Yukl, 1969; Sadler & Hofstede, 1972; Bass & Valenzi, 1974; Vroom & Yetton, 1974; Drenth & Koopman, 1984; and Scandura, Graen, & Novak, 1986). Scores could be generated to describe points on the continuum.

## ***Directive Leadership***

Directive leadership implies that leaders play the active role in problem solving and decision making, and expect followers to be guided by their decisions. There are two types of directive leadership. In one type, the leader makes the decisions for the followers often without an explanation and without consulting or informing them until he directs them to carry out his decisions. This type will be italicized (*directive*) when referred to. Other directive leaders play a more active role and try to persuade their followers to accept them. They gain acceptance of their proposals by using reason and logic (Berlew & Heller, 1983). They may assert an expectation or need and offer rewards, or they may coerce, threaten, and exert pressure to gain acceptance. They may generate charismatic identification to motivate and build commitment. They may try partial disengagement by backing away from time-consuming issues with a lower priority and by concentrating colleagues' attention on more important issues. Unlike participative leaders, directive leaders do not ask their followers to get involved in making decisions. They direct followers' activities and give permission to their followers to carry out duties as the leaders see fit to do (Muszyk & Reimann, 1987). If in a position of authority, the directive leader may make decisions for him-or herself and others. Directive leaders may be persuasive as they attempt to raise their followers' efficacy beliefs. Such persuasion will depend on the leader's rationale, the followers' confidence in the leader, and the leader's emotional, verbal and nonverbal expression (El Haddad, 2001). Directive leaders may decide, announce their decisions, and give orders without consulting followers and colleagues beforehand or after consulting with them.

## ***Participation***

Participation, when italicized (*participation*), refers only to sharing in the decision process. There are different types of participative leaders who may draw followers out, listen actively and carefully, and gain acceptance

through engaging colleagues in the planning or decision-making process (Berlew & Heller, 1983). Participation may refer to a particular way of leader-subordinate decision making in which the leader equalizes power and shares the final decision making with the subordinates. Consensus is sought. Participative leadership aims to involve followers in decision processes—in generating alternatives, planning, and evaluation. Such involvement is expected to enhance satisfaction and performance (Stewart & Greger sen, 1997), but such expectations do not always materialize. Wilson-Evered, Hartel, & Neale (2001) found participative decision making highly correlated with supportive leadership of 277 Australian hospital employees for their ideas and objectives.

Roberts and Thorsheim (1987) note that participative leaders express their doubts, concerns, and uncertainties; verbalize their problem-solving processes; ask questions of followers and listen to the answers; reflect feelings; and paraphrase, summarize, acknowledge, and use followers' ideas. Participative leaders use group processes to promote follower inclusion, ownership, involvement, consensus, mutual help, cooperative orientation, and free and informed choice. These leaders try to avoid unilateral control, hidden agendas, and inhibition of expression of feelings and relevant information. Additionally, according to West (1990), the leaders provide safety for followers by creating a nonthreatening environment in which the participants can be involved in decisions that affect them.

"Participative leadership" suggests that the leader makes group members feel free to participate actively in discussions, problem solving, and decision making. It implies increased autonomy for followers, power sharing, information sharing, and due process (Lawler, 1986). Participation implies that followers have a "voice" and influence in deliberations (Wright, Philo, & Pritchard, 2003). But freedom and safety to participate do not mean license. In *participative* decision making, the leader remains an active member among equals. The belief that it is safe to speak up depends not only on one's immediate supervisor but also on senior leaders higher in the hierarchy (Detert, 2003). In Europe, employee participation is seen as depending on the acceptance of varying rules of industrial democracy developed for middle management (Jaeger & Pekruhl, 1998).

Specific differences can be seen in the way directive and participative leaders communicate with their subordinates (Sargent & Miller, 1971). For instance, different uses would be made of palliatives and sedatives. The brisk directive leader is likely to say, "I want you to ..." The more sophisticated directive leader is likely to ask, "Would you be kind enough to ...?" The participative leader would ask, "Would it be a good idea if we ...?"

*Example: An Effective Leader Who Was Directive and Participative.* Horatio Nelson was both directive and participative. Clearly, Nelson made the decision how his fleet was to be positioned for the battle of the Nile, but prior to making the decision, he called all his captains aboard his flagship to obtain their opinions about the best way to station the ships of the line. He did not take a vote nor ask for consensus. The decision was his alone. Paramount was his vision of the overwhelming need to find and destroy the French fleet, even at the cost of many British lives, in order to cut off Napoléon and his troops, just landed in Egypt. As usual, Nelson's disposition of his ships was innovative. His fleet had been brought to a high state of readiness by his attention to continuous training and his own practice (unusual for the era) of "walking the talk"—conversing one-on-one with officers, seamen, and marines, and cultivating his own image of courage and bravery. Part of Nelson's orders delegated to each ship's captain the responsibility for making decisions when his ship had to engage in a general *melée* (Walder, 1978).

## ***Delegation***

When participation takes the form of delegation, it does not mean that the leader abdicates his or her

responsibilities. The leader may follow up delegation by reclarifying what needs to be done, giving support and encouragement, and making periodic requests for progress reports, as well as by giving praise and rewards for subordinates' successful efforts (Bass, 1985a). Delegation should not be confused with laissez-faire leadership. A leader who delegates still remains responsible for follow-up to see whether the delegation has been accepted and whether the requisite activities have been carried out.

Schriesheim and Neider (1988) distinguished among three types of delegation: advisory, informational, and extreme. In advisory delegation, subordinates share problems with their supervisor, asking their supervisor for his or her opinions regarding solutions; however, the subordinates make the final decisions by themselves. In informational delegation, the subordinates ask the supervisor for information, then make the decisions by themselves. Extreme delegation occurs when subordinates make decisions by themselves without any input from their supervisor. A factor analysis of a survey of 196 nurses and 281 executive MBA students disclosed the independence of these three kinds of delegation. That is, leaders who used one kind of delegation did not necessarily use the other kinds.

Delegation implies that a subordinate has been empowered by a superior to take responsibility for certain activities. The degree of delegation is associated with the trust the superior has for the subordinate. When a group is the repository of authority and power, it likewise may delegate responsibilities to individual members.

Delegation of decision making implies that the decision making is lowered to a hierarchical level closer to where the decision will be implemented. Such delegation is consistent with self-planning (see [Chapter 12](#)). Delegation is a simple way for a leader who is faced with a heavy workload to reduce time-consuming chores, and it provides subordinates with learning opportunities and multiplies the executive's accomplishments (Anonymous, 1978). It also increases latitude and freedom for subordinates (Strasser, 1983). The act of delegation is often directive, but it can be based on a prior participative decision. Nevertheless, Leana (1984) called attention to a need to avoid confusing the "power relinquishment" of delegation with the power sharing of participation. In agreement with Strauss (1963), Heller (1976), and Locke and Schweiger (1979), Leana (1987) also noted that delegation, compared with participation, is more concerned about subordinates' autonomy and individual development. According to 118 managers who were asked how to handle eight situations involving the assignment of a task to a subordinate engineer, some managers are willing to delegate regardless of the circumstances. But other managers are unwilling to delegate because of any one of three considerations: (1) Some do not delegate because they do not feel confident in the capabilities of their subordinates. (2) Some avoid delegating because they think the task is too important to be left to the subordinates. (3) Some are unwilling to delegate because of the technical difficulty of the task (Dewhirst, Metts, & Ladd, 1987).

## Aspects of Direction and Participation

---

### ***Token Participation and Misuse of Participation***

When executives call meetings ostensibly to reach shared decisions but actually to announce their own decision to subordinates (Guetzkow, 1951), they are practicing token participation. They are also practicing this when they invite the wrong people to participate, knowing in advance that these people lack genuine interest or have conforming tendencies. Halpern and Osofsky (1990) criticize management by objectives (Drucker, 1954)—which purports to be participative—as unrealistic; they say that it fails to protect employees against managers' manipulation, arbitrariness, and retaliation for speaking out about problems. Furthermore, employees may lack incentives and the necessary expertise to evaluate issues.

Holding frequent group meetings does not necessarily imply participative leadership. Guetzkow and Kriesberg (1950) found that leaders may use meetings to sell and gain acceptance of their own solutions, as well as to explain their own preferences. These executives see meetings as a way to transmit information and to make announcements, rather than as an opportunity to share information and opinions or to reach decisions. According to Rosenfeld and Smith (1967), subordinates recognize this phony participation and respond negatively to it.

If one can assume that followers in formal organizations appreciate autonomy, one should expect that leaders who say they delegate freely will be described as considerate. Employee satisfaction should also be highly related to delegation. But the effects obtained by Stogdill and Shartle (1955) were marginal. Subordinates often feel that their superiors do not really delegate to them the authority to accompany the responsibilities they are given. Subordinates feel that superiors delegate work they don't want to do themselves. Superiors may believe they are delegating, but their subordinates may see this as abdication—a most unsatisfying state of affairs for subordinates.

Some leaders risk participative decision making (consultation, *participation*, or delegation) only when a high-quality solution is not needed. Other leaders push for participation regardless of the need for it and despite the extra time it takes (Wright, 1984–1985). Participation has become an ethical imperative for some of its advocates, but Locke, Schweiger, and Latham (1986) argued that it should be seen as a managerial procedure which is appropriate in only some situations, because its effects—although possibly satisfying to followers—may fail to contribute to productivity. In some circumstances, directive leadership may result in both higher productivity and greater satisfaction. Participation is usually thought to enhance subordinates' compliance with decisions to change (Carson, 1985; Kanter, 1983); however, direction may be better for envisioning what needs to be changed. Some studies have reported that neither directive nor participative leadership made much difference in outcomes. McCurdy and Eber (1953) observed that groups in which free communication and decision making were practiced did not perform more effectively than groups in which the leader made all the decisions. Similarly, neither Spector and Suttell (1956) nor Tomekovic (1962) found differences in productivity between participative and nonparticipative groups.

In a study of 20 small shoe-manufacturing firms, Willits (1967) found that neither the degree of delegation by the president nor the extent of participation by executives in decision making was related to measures of the companies' success. Heyns (1948) and W. M. Fox (1957) also found no differences of consequence.

### ***Contextual Aspects of Participation***

Lawler (1986) argued that participation is a way for U.S. business to offset foreign competition and to deal with increasingly specialized work and the higher labor costs associated with some of it. But clearer goals and directions could also help. The pressure for more participation in the workplace and involvement in decisions about work has been fostered in the United States by workers' greater expectations for upward mobility and their desire for more interesting work, but Lawler (1985) pointed out that education has not equipped many to participate effectively at work. Participative management requires an appropriate organizational design, as well as a design that is relevant to the employees' backgrounds, motivation, and abilities. Employees with more education are more concerned about participating in decisions that affect their work (Wright & Hamilton, 1979). In the shift of the management of libraries from direction to participation, Sager (1982) noted that the roles of management and staff at all levels needed to be shifted, along with essential changes in regulations and policies.

### ***Conceptual Distinctions and Empirical Overlaps***

Tannenbaum and Schmidt (1958) thought that participation and direction were based on how much authority the superior used, relative to how much freedom the subordinates were permitted. Bass (1960) noted that participative leadership required leaders with power who were willing to share it. With their power, such leaders set the boundaries within which the subordinates' participation or consultation was welcomed. In contrast, with the powerless leader, as in the leaderless group, a struggle for status occurred among group members.

Graves (1983) noted that two of the three categories of concepts used by students to cluster 23 supervisory behaviors indicated their implicit theories of leadership. They dealt first with task direction ("Sets goals for employee performance") and second with participation ("Asks employees for opinions and suggestions"). The third category of concepts dealt with reward ("Praises those who perform well"). Although conceptually independent, the dimensions of task direction and participation correlated .53 for the students' implicit theories of leadership.

Similarly, Bass, Valenzi, Farrow, and Solomon (1975) found that according to subordinates' descriptions of their superiors, *direction* and persuasive negotiation were positively correlated. Even more highly intercorrelated were democratic consultation, *participation*, and delegation. However, 46 judges, using response-allocation procedures, could readily and reliably discriminate among the specific behaviors involved in (1) *direction* and (2) negotiation, as well as among the behaviors involved in (3) consultation, (4) *participation*, and (5) delegation. The five styles were found to be conceptually independent, although they were correlated empirically. For instance, the judges clearly saw consultation as a different pattern of behavior from, say, delegation; nevertheless, the same managers who were most likely to consult were also more likely to delegate, according to their subordinates' descriptions (Bass, Valenzi, Farrow, & Solomon, 1975). Similar results were reported by Filella (1971) for 77 Spanish managers, as well as in Saville and Holds-worth's OPQ manual (Anonymous, 1985) for 527 British professionals and managers.

Nevertheless, three styles—consultation, *participation*, and delegation—are distinct and may, to some degree, have different antecedents and consequences. Factorial independence of each of the styles would make research with them easier; however, maintaining conceptually distinct but correlated styles remains viable and useful. (In the same way, analyses of body height and body weight continue to be separated, although height and weight are also empirically correlated. In general, tall people are heavier than short people, but it remains useful to talk about how people differ in height and how they differ in weight, as well as how they differ in stature or body mass, the combination of height and weight.)

### ***Vertical versus Shared Leadership***

With growing use of teamwork and empowerment of team members has come leadership behavior by the formal head of the team and shared leadership by team members. The team leaders do considerably more than members to empower the members and are more directive than the members themselves. Leaders and members appear otherwise to display similar participation in aversive, transactional, and transformational leadership behavior (Pearce & Sims, 2002).

### ***Empirical Interrelations among Styles***

Additional evidence that the same managers empirically exhibit many of the conceptually different styles of decision making is obtained from examining the intercorrelations in style found in survey studies. Consultation, *participation*, and delegation are highly intercorrelated. That is, consultative managers also tend

to be highly *participative* and delegative. The intercorrelations were above .60 for a sample of 343 to 396 respondents who described their organizational superiors. Even the extent to which managers are *directive* tends to correlate positively with the extent to which they are manipulative or negotiative, .25; consultative, .31; *participative*, .28; and delegative, .13. Consultation, the most popular style observed among 142 assistant school superintendents in Missouri, correlated highly with *participation* (.64) and delegation (.47). Actually, all five styles have active leadership in common, and all are the opposite of inactivity and laissez-faire leadership.

Despite these intercorrelations, Wilcox (1982), using the Bass-Valenzi Management Styles Survey, reported systematic differences for the independent contributions of direction, consultation, and delegation to satisfaction with and the effectiveness of leadership, even after the effects of many other organizational and personal variables of the leader and the led were removed. Chitayat and Venezia (1984) conducted a smallest-space analysis for 224 Israeli managers and executives from business and nonbusiness organizations and attained patterns for the Bass-Valenzi survey measures showing that direction and negotiation (persuasion and manipulation) were closer together but distant from delegation, *participation*, and consultation—which, in turn, were closer to each other in usage by the respondents. Consistent with the reports of Bass, Valenzi, Farrow, and Solomon (1975) and Wilcox (1982) about subordinates' descriptions of their superiors' styles, intercorrelations of .41, .33, and .51 were found among delegation, *participation*, and consultation, and .23 was found between direction and negotiation for the Israeli managers. The correlations between decision styles within the two clusters were close to zero.

Some leaders and managers may lean toward inactivity. Whereas any of the preceding styles require activity, laissez-faire leadership—or abdication of responsibility and avoidance of leadership—does not. Laissez-faire leadership calls for doing little or nothing with subordinates, remaining passive, or withdrawing, as was discussed in [Chapter 6](#). Such passivity correlates with passive managing by exception, in which the leader waits for problems to arise before taking any corrective action. This is in contrast to active managing by exception, in which the leader monitors follower performance and makes corrections as needed (Bass & Avolio, 1991).

### ***Related Leadership Behavior***

*Negotiative Leadership.* The leader bargains with the follower who has a different interest or point of view. Differences are settled with persuasive arguments and agreements.

*Manipulative Leadership.* The leaders act shrewdly or deviously to enhance their own advantage and gain, and to exploit the followers. Manipulation can shade into falsification (see [Chapter 7](#)).

*Close Supervision.* Directive leadership is more likely to be exhibited by the same leaders who are also close supervisors, who do a lot of structuring, and who are manipulative and persuasive. This persuasive, manipulative emphasis has been seen in political tactics: withholding information, bluffing, making alliances, publicly supporting but privately opposing particular views, compromising, and using delaying and diversionary tactics.<sup>2</sup> Participation is likely to be seen with general, rather than close, supervision; with the equalization of power; and with nondirective leadership.

*Considerate Leadership.* Participative decision-making leadership includes many elements. One of these, consideration, calls on the leader to ask subordinates for their suggestions before going ahead, get the approval of subordinates on important matters, treat subordinates as equals, make subordinates feel at ease when talking with them, put subordinates' suggestions into operation, and remain easily approachable. Graves (undated) found that implicit task direction correlated .61 with the factor of initiating structure, and implicit participation correlated .81 with consideration, one of the two important dimensions of the Leader Behavior Description Questionnaire (LBDQ). Many elements of direction are to be found on the LBDQ scale of the

initiation of structure, such as making attitudes clear, assigning subordinates to particular tasks, and deciding in detail what shall be done and how.<sup>3</sup>

*Social Factors.* Bass (1968c) contrasted MBA students' and managers' beliefs about how to succeed in business. Two social factors emerged: sharing decision making and emphasizing candor, openness, and trust. The factors involved making open and complete commitments, establishing mutual goals, and organizing group discussions. The factors coincided with ideal participative decision making as proposed by Argyris (1962) and Bennis (1964).

*Transformational and Transactional Leadership.* As noted in [Chapter 22](#), contrary to many misconceptions about transformational and transactional leadership, such leadership can be directive and participative. The intellectually stimulating leader can issue instructions and participatively arouse curiosity. The inspiring directive leader can state that conditions are improving greatly. The inspiring participative leader can ask for all to merge their aspirations and work together for the good of the group (Bass, 1998).

*Warrior Leadership.* Related to directive leadership, the *warrior style*—as already discussed in [Chapter 17](#)—is most likely to emerge when conflict and opposition are present, the world is seen as dangerous and hostile, people cannot be trusted, and direction is needed. Flows of information are controlled. Results are more important than the methods used to achieve them. There is an emphasis on knowing the people that the leader is seeking to defeat or lead. Battles are selected carefully, and unnecessary fighting is avoided. There is planning and preparation for future militant contingencies (Nice, undated).

*Persuasive Rhetoric.* Directive leadership through persuasive rhetoric was a theme of Aristotle and much of classical instruction in general. Orators from Martin Luther to Martin Luther King Jr. have followed Aristotle's prescription for persuasion: identify the discontent among audiences, name the enemy, and provide the needed response. Give the restless a voice, a motive, and legitimacy (Monty, 2004).

*Forcing, Coercing, and Controlling.* These forms of directive influence involve pressure or persuasion by a leader to induce follower compliance and avoid undesired outcomes. Ordinarily, continued use of force by a leader is likely to generate ill feelings and resistance. However, Emans, Munduate, Klaver, et al. (2003) showed that 145 police officers complied effectively with supervisory orders if forcing influence was interspersed over time with non-forcing influence. Hard tactics of persuasive direction are employed, such as giving orders without explanation, threatening unsatisfactory performance evaluations, and getting the backup of higher authority, when the persuader has the power to do so, when resistance is expected, or when the subordinate is violating norms. Soft tactics of persuasion are employed, such as acknowledgment of the subordinate's goodwill and ability, when the influencer is at a disadvantage. Rational tactics of persuasion are employed if power is balanced, if no resistance is anticipated, and benefits for compliance will be mutual (Kipnis & Schmidt, 1985). *Tight or loose controls* are likely to coincide with the leadership styles of direction and participation. As Avolio (1999) noted, leaders will maintain tight controls if they don't trust their subordinates. There are reciprocal effects. When employees are allowed to participate more fully in decisions, they are likely to feel that they are more trusted by their leaders. They may confirm this by showing better organizational citizenship behavior (OCB). Van Yperen, van den Berg, and Willering (1999) demonstrated in a study of employees from 10 departments in a Dutch company that employee participation in decision making fostered better employee OCB.

## ***Frequency of Usage***

A popular stereotype of the ideal leader is the decisive, directive, heroic order giver. The prototypical supervisor in the workplace of MBA students with full-time jobs had these directive transformational characteristics (Bass & Avolio, 1989). Yet in the behavioral science literature, participative decision making is most commonly

advocated. And managers themselves are most likely to favor a consultative style. Actually, Heller and Yukl (1969) and Bass and Valenzi (1974) have shown that neither extreme direction nor extreme participation is reported most frequently by subordinates in describing their superior. Rather, subordinates most often see their superior as consulting with them. Thus on a scale of frequency ranging from 1 (never) to 5 (always), according to over 400 subordinates from a variety of organizations, the average frequency with which superiors were observed to exhibit each of the styles on many items of supervisory decision-making behavior was as follows: consultation, 3.10; participation, 2.65; delegation, 2.46; direction with reasons, 1.97; direction without reasons, 1.90; and manipulation, 1.88 (Bass & Valenzi, 1974). In agreement, H. R. Gillespie (1980) concluded, from self-reports of 48 manufacturing executives, that participation, particularly consultation, was more frequent, especially among executives at the top level. Kraitem (1981) likewise found that consultative leadership was favored in the self-reports of top executives in financial institutions and that there had been a shift away from more directive approaches.

Manipulation and negotiation were reported to occur least frequently, perhaps because of the greater subtlety of manipulative behavior, which is more difficult to discern when it happens. The most artful manipulative behavior is that which is misperceived as participative. There is less reliability in judgment about manipulation than in judgment about other decision-making styles. Subordinates feel they are being manipulated when they think managers know in advance what they will decide and what they want the subordinates to do. These managers strike bargains and play favorites. Such manipulative behavior tends to be exhibited by directive managers but not by managers who generally tend to be participative (Bass, Valenzi, Farrow, & Solomon, 1975).

### ***Multiplicity of Styles***

For followers, a leader who is a consistently autocratic or consistently laissez-faire leader in all situations is likely to be least satisfactory and least effective. Generally, followers will favor participative leadership over directive leadership. Nonetheless, subordinates may agree with their superior that supervisory *direction* is called for in a crisis and that consultation is indicated when subordinates are knowledgeable, experienced, and expert. Followers are likely to applaud their superior's flexibility in being directive in the first situation and consultative in the second. In fact, few leaders use only a single style; most use a variety of styles, ranging from extreme direction to extreme participation. Among 124 middle-and first-level supervisors, W. A. Hill (1973) found that only 14% of the supervisors were seen as likely to use the same one of four styles in four different hypothetical situations.

Bass and Valenzi (1974) obtained sharper results with 124 subordinates who described how frequently their superiors actually used six styles, ranging from deciding without explanation to delegating decisions to subordinates. A manager was classified as exhibiting a *single* style if the subordinate indicated that only one of these styles was displayed by the manager "very often" or "always," and the remaining styles "never" or "seldom." Managers were classified as exhibiting a *dual* approach if they were described by their subordinates as displaying two styles "very often" or "always," and the other styles "never" or "seldom." Managers were classified as exhibiting a *multi-style* approach if they were described as displaying three or more of the six styles "sometimes," "fairly often," "very often," or "always." Of 124 subordinates, less than 4% indicated that their superior exhibited a single style or a dual approach; 117, or almost 95%, indicated that their boss exhibited a multistyle approach.<sup>4</sup> Consistent with Bass and Valenzi's findings, Hollander (1978) noted that although political leaders, in particular, often try to project a consistent image to a wide audience, based on a particular style that is uniform across situations, most change their style after they are elected; they also change their style from one constituency to another.<sup>5</sup> History is replete with examples illustrating that the most powerful

dictators may also be strong advocates of consultation.

Lenin, according to his biographers, frequently consulted his immediate subordinates (Bass & Farrow, 1977a). Mao Zedong urged party leaders to be consultative and instructed them carefully on how to carry out a doctrine stressing consultation: “We should never pretend to know what we don’t know, we should not feel ashamed to ask and learn from people below, and we should listen carefully to the views of the cadres at the lower levels. Be a pupil before you become a teacher; learn from the cadres at the lower levels before you issue orders” (Burns, 1978, p. 238). But in his later years, Mao could also be ruthless as a leader, unleashing his Cultural Revolution on the Chinese population.

*Differences in Problems.* The overwhelming tendency for managers to use multiple decision-making styles is seen most clearly in studies of how the same managers use different styles depending on the nature of the problem. Thus McDonnell (1974) found that when 226 respondents were asked whether they would be autocratic, consultative, *participative*, or *laissez-faire*, each chose a different style depending on which of 12 problem situations was presented for consideration. Heller and Yukl (1969) and Heller (1972a) demonstrated that a senior manager varies his or her style according to the nature of the required decisions. For example, prior consultation was the modal style for decisions that were critical to individual staff members but not to the organization. Participation in all three forms was most frequent for decisions of importance to subordinates and least frequent for decisions of importance to the company. Supervisory delegation and supervisory decision making without explanation were most frequent for decisions that were unimportant to both the leader and the subordinates. Using a different method (to be detailed later in this chapter), Vroom and Yetton (1973) came up with similar results. Several thousand managers indicated the decision-making style they would employ if confronted with different kinds of cases requiring or not requiring high-quality solutions and subordinates’ acceptance. Only about 10% of the variance in response could be attributed to the personal tendencies of the managers to be more directive or more participative; 30% of their responses depended on whether high-quality solutions and subordinate acceptance were required. Hill and Schmitt (1977) tested a shortened version of Vroom and Yetton’s method and found that 37% of the variance in the leaders’ decision-making style was due to ease-requirement effects and only 8% was due to the effects of the respondents’ individual dispositional differences. These results tended to be relatively insensitive to the hierarchical levels dealt with in the cases presented to the managers (Jago, 1978a). This was so despite the fact that, as was noted in [Chapter 14](#), both the authority to be directive and the authority to be delegative increase as one rises in the organizational hierarchy (Stogdill & Shartle, 1955). Such increased authority makes it possible for superiors to delegate more responsibilities to subordinates. But it also allows the superiors to be more participative.

### ***Discrepancies between Self-Descriptions and Others’ Descriptions***

In Wilcox’s (1982) dissertation, agreement was quite close between the school superintendent’s self-descriptions of their directiveness, participation, and delegation and the descriptions provided by their subordinates. But the superintendents believed they were more consultative and less negotiative than their subordinates thought they were. Generally, when managers’ self-rated styles are contrasted with descriptions provided by their subordinates, one is likely to find many more managers who see themselves as favoring their subordinates’ participation than subordinates who see such participation occurring. Also, many authoritarian leaders would be surprised to learn that their subordinates say they are far more directive than they believe themselves to be. Harrison (1985) studied 30 supervisors and their 234 college-educated subordinates in a large social service organization. There was little correspondence between the subordinates’ feelings of participation in decision making and the supervisors’ tendency to see themselves as participative. For the superiors, participation meant interacting with subordinates; but for the subordinates, it also meant that the subordinates

could both send and receive information related to their own desires. Moreover, the subordinates' judgments of the extent to which their superior was participative correlated .61 with the interpersonal support they received from the superior, .59 with the team-building activities led by the superior, and .30 with the accuracy of the information they felt they received from the superior. The superior generally failed to recognize that any of these actions was connected to being participative.

A Harris (1987) poll revealed still another aspect of the discrepancy between managers and white-collar workers. Although 77% of the workers considered it very important to be allowed to participate in decisions that controlled their working conditions, only 41% of their superiors agreed with them. Some samples of leaders subscribed to direction rather than participation. None of 450 interviewed Australian managers rated their executive superiors as collaborative in organizational development. They regarded the high and medium performers as more tough and directive in style when it came to making organizational changes. The lower performers were viewed as careful, timid fine-tuners (Heller, 1994).

## Antecedents of Direction and Participation

---

As was already noted, different studies using a variety of methods showed that leaders in organized settings said they preferred to be consultative and were most often seen by their subordinates as consultative. Such consultation involved their subordinates to some extent in the decision process, but the supervisors reserved the final decision for themselves. At the same time, a given leader was seen to use the whole range, from *direction* to delegation, in varying amounts. However, different patterns of usage were revealed—some leaders were more directive on the whole, whereas others were more participative. Both deductive and inductive research point to a variety of factors that predispose leaders to pursue one style rather than another. These antecedent conditions include the attributes of the leader and of the subordinates; their preferences, goals, tasks, and assignments; and the organizational and external environment.

### ***Personality or Situation?***

Some argue that direction or participation will depend on the nature of the situation; others state that it depends on the leader's judgment of the situation (Hersey & Blanchard, 1977; Vroom & Yetton, 1973). Still others find that the predispositions of the leader are most significant (Fiedler, 1967a).

Situations have an obvious impact. On the one hand, crisis conditions may make any leader directive. On the other hand, a leader of a project team that is composed of experts from different fields will most likely benefit the project by being participative. Nevertheless, it may be that personality has more of an effect on a leader's being directive, but the situation has more of an effect on the leader's being participative (Farrow & Bass, 1977). Both the contingency and the noncontingency theorists may be right. Frequency of directiveness may be mainly a matter of personality; frequency of participation may hinge mainly on contingent factors. Farrow and Bass (1977) found, for 77 managers who were described by their 407 subordinates, that situational factors, as seen by the managers or by the subordinates, were irrelevant in determining whether a manager would be *directive*. Path analyses indicated that managers who were most frequently *directive*, according to their subordinates, were highly assertive and regarded people as fundamentally unfair. Such managers were highly satisfied with their own jobs. If the managers had short-term rather than long-term objectives, their subordinates saw them to be manipulative and negotiative. These results went beyond various organizational, intrapersonal, and personal attributes of the subordinates. However, the amount of participation seen by subordinates depended on the extent to which the manager perceived that the subordinates had discretionary opportunities and highly interdependent tasks.

## *Personal Antecedents: Effects of the Leaders Themselves*

Self-confidence and a personal sense of security were likely to have a strong effect on a leader's tendencies to be directive or participative (Bass & Barrett, 1981). Vroom (1960a) found that managers with authoritarian personalities, as measured by the *F* Scale of Adorno, Frenkel-Brunswik, Levinson, and Sanford (1950), were more directive. The lower the managers' need for independence and the higher their degree of authoritarianism, the higher was their directiveness. Belief in the legitimacy of the manager's prerogative to plan, direct, and control had similar effects. Managers who characterized themselves on personality inventories as unwilling to believe that people are fair-minded were more likely to be *directive*, according to their subordinates. This finding was consistent with the proposition that managers will be directive because they believe in Theory X: that employees cannot be trusted (McGregor, 1960). Conversely, those who felt people were fair-minded tended to be participative (Farrow & Bass, 1977). Among 122 undergraduates, dominance correlated with effectiveness as directive leaders. Dominance and supportiveness correlated with effectiveness as participative leaders (Sorenson & Savage, 1989).

Educational background also made a difference. Bass, Valenzi, and Farrow (1977) found a correlation of .37 between the educational level of 76 managers and their tendency to be participative. If leaders were women, more participative leadership was expected of them (Pelletier, 1999).

*Myers-Briggs Types.* There is a consistent linkage between one's thought processes and the tendency to be directive or participative. For example, according to a study of 55 managers and executives by O'Roark (1986), who correlated scores on the Myers-Briggs Type Indicator with the Bass-Valenzi preferred management styles, *thinking* types were most directive and feeling types were least directive; *sensing* types were least negotiating and *intuitive* types were more consulting. Schweiger and Jago (1982) reported that among 62 graduate business students, Myers-Briggs intuitive types tended to choose fewer participative solutions to the problem set of Vroom and Yetton (1974), whereas *sensing* types tended to choose more such participative solutions. Overall, personality seemed less important than situational determinants in the choices that were made.

*Risk Preferences and Propensities.* Whether managers delegate certain duties to subordinates may depend on whether the managers enjoy doing the tasks themselves, as well as on their willingness to take risks and wait for others to succeed (Matthews, 1980). Managers also need to feel secure and confident in themselves and in their subordinates (Hollingsworth & Al-Jafary, 1983). The riskiness of a decision to a supervisor is decreased if it is to be implemented on a trial basis. In a simulation with 143 bank employees under such conditions, Rosen and Jerdee (1978) found the leaders to be more willing to engage in participation when decisions were to be implemented on a trial basis than when decisions implied permanent solutions. The risk of decisions is increased for top managers who face intense competition from the marketplace. In such situations, the top manager tends to be more *directive* and highly controlling in some decisions—say, about production, purchasing, and cost control—and more *participative* in others, such as those dealing with raising capital, research and development, policy changes, and marketing strategies (Khandwalla, 1973).

*Power.* Leaders with power can be more directive. Leaders who are esteemed and valued by subordinates, who are acknowledged as experts, and who are seen by subordinates to control rewards (that the leaders can allocate among the subordinates) have the power to be directive (Mulder, 1971; Raven, 1965b). In addition to the effects of expert, reward, and referent power on being directive, there are also effects of coercive and legitimate power. If the power of leaders is suddenly increased in an experiment, the amount the leaders can be directive is also increased, and in fact the leaders do tend to increase their directiveness (Shiflett, 1973). But, paradoxically, leadership power is required to create participative circumstances. Whether power results in direction or participation depends on other factors. The results are decidedly mixed. Chitayat and Venezia

(1984) noted that in Israeli business organizations, leaders' self-reported power contributed to their being *directive*, but the reverse occurred in the Israeli armed forces and governmental agencies. In such bureaucratic organizations, powerful leaders were more participative because the rules and procedures required directiveness, and only executives with more power could be participative if they chose to be. However, Hord, Hall, and Stiegelbauer (1984) found that more powerful school principals were more directive than were their less powerful assistant principals, teachers, or curriculum coordinators.

*Experience.* Heller and Yukl (1969) reported, in a study of 203 British managers at all hierarchical levels in 16 organizations, that despite their greater power and status, senior managers, particularly those who had been in their positions for a considerable time, were more likely than junior managers to share in decision making with their subordinates. Seversky (1982) found that more delegation was practiced by school superintendents who had more experience in their jobs. Likewise, Pinder, Pinto, and England (1973) found that older managers tended to be more participative, whereas younger managers tended to be more directive. Age, however, was unrelated to participativeness in a study of 48 manufacturing executives (H.R. Gillespie, 1980).

*Ideological Beliefs.* Locke and Schweiger (1979) provided academic and management advocacy for the moral reasons for participative leadership. The humanist movement argued that participative leadership was right and good. Directive leadership was questionable (Maslow, 1965). Likewise, participative leadership was regarded by some leaders as morally correct in a democratic society. Some extremists, such as Rost (1993), suggested that engaging followers (relabelled "collaborators") as participants in decisions is *always* the right thing to do. For Rost, the old paradigm to be discarded was doing what the leader wishes. The new paradigm to replace it was doing what both the leader and the collaborators wished to do. Nonetheless, Sagie (1997) pointed out that although a directive, tell-and-sell strategy of assigning goals could be as productive in performance and the quality of decision making (Sagie, 1994), and that assigning goals could be as effective as participation in goal setting (Locke & Latham, 1990), the continuing arguments for participation were based on ideological reasons (Dickson, 1982) rather than empirical evidence.

### ***Effects of the Superiors of the Leaders***

As was noted in [Chapter 14](#), there is a clear linkage between what a U.S. Navy executive officer of a ship can and does do and the responsibility, authority, and delegation of his immediate superior—the commanding officer. Stogdill and Scott (1957) correlated the responsibility (R), authority (A), and delegation (D) scores (RAD scores; see [Chapter 14](#)) of commanding officers and executive officers with the average RAD scores of their junior officers on submarines and landing ships. The executive officers tended to delegate more freely to their subordinates on both types of ships when their commanding officers exercised wider scopes of responsibility and authority and delegated more freely. Commanding officers could increase or decrease their executive officers' workload and freedom of action. Subordinates tended to tighten their controls as superiors increased their own responsibility and freedom of action. However, responsibility and authority did not flow without interruption down the chain of command. The responsibility, authority, and delegation of subordinates were more highly influenced by the subordinates' immediate supervisors than by the subordinates' higher-level officers.

### ***Effects of the Followers***

Some degree of agreement between the leader and the led about procedures, interests, and norms is necessary before effective participation can take place (Heller, 1969). In addition, they must concur that participation is

relevant. Yukl and Yu (1999) reported that participative leadership with subordinates—like consultation and delegation—depended on the competence of the follower, task objectives shared with the leader, status of the follower as a supervisor, and favorable relations between the leader and the follower.

*Relevance of Participation.* Subordinates or followers vary in how much they would like to participate in decisions. As was noted earlier, Heller (1972a, 1976) found, in a number of samples in several countries, that managers used participation more frequently when decisions were more important to their subordinates than to the firm. In an overall review of the literature, Hespe and Wall (1976) demonstrated that although workers wanted to participate more than they actually were given the opportunity to do, they expressed the greatest interest in participating in decisions that were related directly to the performance of their jobs, followed by matters concerning their immediate work units. They expressed little interest in participating in general policy decisions. This finding was corroborated by Long (1979), who asked workers in a Canadian trucking company that had become wholly owned by its employees about their participation in company affairs after the employee takeover. According to Maier (1965), subordinates will prefer participation rather than direction if they are seeking personal growth, if they are striving to be more creative, and if they are highly interested in the objectives of the task. On the other hand, they may prefer a great deal of direction, guidance, and attention from their supervisor until they have mastered the job, particularly if the job does not involve much creativity but requires only attention to routine details that must be learned (Bennis, 1966c).

*Followers' Personality.* Abdel-Halim (1983a), Abdel-Halim and Rowland (1976), and Vroom (1960a), among others, found that the personality traits of subordinates are of consequence to the participatory process. Just as authoritarian leaders wanted to be directive with their subordinates, so their authoritarian subordinates wanted to be directed by authoritarian leaders. Followers with authoritarian attitudes were likely to reject participative leadership. Highly authoritarian personalities wanted powerful, prestigious leaders who would strongly direct them.<sup>6</sup>

*Followers' Competence.* Raudsepp (1981) suggested that managers need a comprehensive inventory of subordinates' capabilities before deciding what duties they can delegate to subordinates and in which areas subordinates need further experience. Managers will consider participative approaches too risky when they have reservations about the competence and commitment of their lower-level employees (Rosen & Jerdee, 1977). Lowin (1968) showed that subordinates who perceived that they were not competent in the tasks to be completed were more appreciative of directive supervision than were those who thought of themselves as competent. Similarly, Heller (1969a) found that whenever managers reported a big difference in skills between themselves and their subordinates, they were more likely to use *direction*. The differentials in skills that were of particular importance were technical ability, decisiveness, and intelligence. Managers were more likely to engage in participation when they esteemed the subordinates for their expertise and personal qualities. Heller (1976) also found that participative leadership was favored at senior organizational levels when the competence of subordinates was high. Similarly, on the basis of a study of members of 144 work groups in 13 local health agencies, Mohr (1977) concluded that supervisors favored participation when their subordinates had more training and were at higher technical and professional levels. Sinha and Chowdhry (1981) found, in a survey of 135 Indian executives, that the executives tended to be participative if they believed their subordinates were better prepared but were more directive with subordinates who they felt were less well prepared. Locke and Schweiger (1979) also concluded that leaders are more likely to be participative when they believe their subordinates have the necessary information to contribute to the quality of decisions. In a mass role-playing experiment, Maier and Hoffman (1965) observed experimentally that the "foreman" who regarded his "subordinates" as men with ideas was more likely to lead his crew toward an integrated solution to their problem on the basis of their participation in making the decision. However, if the "foreman" thought he was dealing with difficult employees, he was more likely to direct them toward a solution he favored than to involve them extensively in the decision-making process.

In their prescriptive model, Vroom and Yetton (1973) deduced that leaders need to consider being more participative if they think they lack information that their subordinates are likely to have. The Hersey and Blanchard (1977) model assumed that the subordinates' competence is the most important determinant of whether and when a manager should be directive or participative (see [Chapter 19](#)). Leana (1987) reported a correlation of .42 between the willingness of insurance supervisors to delegate responsibilities to their 122 subordinate claims adjusters and their judgment of the capabilities of these subordinates. Tendencies to delegate correlated .27 with the subordinates' appraised trustworthiness. As was mentioned before, Dewhirst, Metts, and Ladd (1987–1988) found strong indications that managers were less willing to delegate if the subordinates were incompetent or the tasks were difficult and highly technical.

## ***Superior-Subordinate Relations***

The interplay of the superior and the subordinate contributes to the superior's tendency to be directive or participative. Thus in an Israeli study, Somech and Drach-Zahavy (2003) reported that demographic similarity in age, tenure, education, and sex and the quality of the leader-member exchange (LMX; [Chapter 16](#)) were conducive to participative leadership.

*Differences in Power and Information.* Bass and Valenzi (1974) proposed that the frequency with which a particular leadership style is used could be accounted for by the differences in power between the manager and the subordinates and by the differences in their competence or the information available to them. Shapira (1976) confirmed, through smallest-space analysis, the validity of Bass and Valenzi's deductions. Given the managers' power ( $P_m$ ), the subordinates' power ( $P_s$ ), the managers' information ( $I_m$ ), and the subordinate's information ( $I_s$ ), then *direction* is more likely if  $P_m > P_s$  and  $I_m > I_s$ . Manipulation or negotiation is more likely if  $P_m < P_s$  and  $I_m > I_s$ . Consultation is more likely if  $P_m > P_s$  and  $I_m < I_s$ . Delegation is more likely if  $P_m < P_s$  and  $I_m < I_s$ .

*Effects of the Quality of the Exchange Relationship.* An analysis of 58 superior-subordinate paired questionnaires by Scandura, Graen, and Novak (1986) revealed that the quality of LMX further complicates matters. Regardless of their competence, as rated by their superiors, subordinates who perceive they are in a more satisfying exchange relationship with their superiors also believe that their superiors allow them to participate much more in decision making. But subordinates who think they are in a dissatisfying relationship will perceive such participation only if their performance has been rated highly by their superiors. If the relationship with superiors is poor and the subordinates' performance has been rated low, the superiors will be seen as much more directive. Superiors agree with this description of the exchange relationship and its effects.

## ***Situational Antecedents: Constraints and Objectives***

Policies, goals, task requirements, and functions constrain how directive or participative a leader can be. They also furnish objectives that the leader will see as being met more satisfactorily by either direction or participation. Both the leader and the subordinates may be constrained by rules, regulations, and schedules, demands on their time, and fixed requirements for methods and solutions over which they have no control. The requirements of a decision may be highly programmed. Greater acceptance and change by the group may be desired or required. The manager may consider the objectives to be long-range rather than a quick payoff—that is, the development of subordinates or the creation of a capable and effective operation for the long run may be more important than immediate profitability. According to Vroom (1976a), it “seems unlikely” that the same leadership style would be appropriate when the objective was to save time than when the objective

was the long-term development of subordinates. If the cost of the time required of subordinates is more expensive than the value of the outcomes of their participation, directive approaches are more likely (Tannenbaum & Massarik, 1950).

Musczyk and Steele (1998) reviewed the characteristics of “turnaround” executives. When organizations are faced with crises, such executives are brought in to prevent the organization from failing. Directive leadership is required. Unpopular decisions have to be made. Subordinate autonomy and participation may have to be reined in.

*Organizational Function.* Chitayat and Venezia (1984) found, in their previously cited investigation of 224 Israeli executives, that differences in the frequency of use of leadership styles were associated with differences in organizational norms, climate, and structure.

Since marketing is usually under shorter time constraints than research, a directive style may be appropriate more often in work units in marketing than in research (Lawrence & Lorsch, 1967a, 1967b). Heller and Yukl (1969) found that production and finance managers tended to use directive decision making, whereas general and personnel managers were more participative.

In a study of 155 managers of police (Kuykendall and Unsinger, 1982), the managers stated that they would avoid delegating, regardless of the problem faced. Like managers in accounting, finance, and production, managers of police supervise more standardized, programmed types of jobs that permit less freedom, less flexibility, and less meaningful participation by subordinates. Nevertheless, when faced with unprogrammed personnel decisions, they could be more participative. Similar findings appeared for accountants. A study of 212 chief accountants (McKenna, undated) found that although they were generally more likely to be directive than participative, they were more likely to use consultation and *participation* than *direction* or delegation when they had to make unprogrammed rather than programmed decisions. This was also true when they had to make decisions dealing with personnel rather than with tasks. Similarly, as noted above, the police managers were more likely to be participative than directive when faced with such decisions. Service managers thought that they generally faced more unprogrammed decisions. Child and Ellis (1973) found, in a study of 787 managers in service organizations, that these managers saw their roles as less formal, less well defined, and less routine than did managers in manufacturing organizations. Miner (1973) concluded that participative management was most likely to be found in organizations of professionals. Miller (1986) advocated participativeness with R & D professionals whose work was less programmed.

Woodward (1965) studied the impact of technology on decision-making processes in 100 British firms. She concluded that in companies involved in mass or batch production, decision making was more likely to be directive but usually did not set precedents. However, in continuous-processing industries such as petroleum refining, decisions were more likely to be made by committees with considerable participation by subordinates, and these decisions had long-term implications.

*Organizational Level.* Stogdill and Shartle (1955) reported correlations between the tendency to delegate and the self-rated authority and responsibility of managers on the RAD scales in 10 organizations (Stogdill & Shartle, 1948). On the average, delegation correlated .17 with responsibility and .23 with authority. Since greater authority and responsibility naturally went with higher-level positions, it was not surprising to find that delegation was also higher among managers in those positions. Moreover, delegation must be practiced at higher levels because organizations cannot afford to pay high-level executives to spend their time carrying out activities that could be performed by the lower-paid staff (Major, 1984). Using the RAD scales ([Chapter 14](#)) to study large governmental organizations, Kenan (1948) also found, as expected, that executives in higher-level positions described themselves as having a greater tendency to delegate than those in lower-level positions. Browne (1949) noted that executives' salaries related positively to their estimates of how much they delegated. D. T. Campbell (1956) reported that delegation was positively and significantly related to one's level in various types of organizations, as well as to one's military rank, time in one's position, and regard for being in a

position of leadership.

Blankenship and Miles (1968) observed that the level of one's position was more important than the span of control or size of the organization in determining delegation by managers. Compared with managers at lower levels, upper-level managers not only reported greater freedom from their superiors with regard to decisions but tended to involve their subordinates more in decisions. H. R. Gillespie (1980) agreed, finding that among 48 manufacturing executives, those at the top level were more participative than were those at the next two levels below them.

A higher organizational level brings with it many of the conditions that promote greater participation, and lower organizational levels do the reverse. Senior executives are concerned with longer-range problems and policies, norms, and values. They are dealing directly with more creative, more educated, higher-status subordinates, who expect more opportunities to participate and have a greater interest in long-term commitments and in their own development. Directive practices are more prevalent at lower levels, since managers are dealing with more routine types of work, more clearly defined objectives, and less well-educated subordinates of lower status who have fewer expectations about participating in the decision-making process (Selznick, 1957). Thus in their intensive study of workers on the assembly line, Walker and Guest (1952) emphasized that supervision was likely to be more directive, particularly if the tasks were routine.

*Tasks.* The nature of the work may determine whether the leader will need to be more directive or participative. If the tasks are simple, direction may be more acceptable than when tasks are complex. Although Ford (1983) argued that there must be some way to measure the outcomes of tasks if tasks are to be delegated, Mohr (1971) found that the degree of "task manageability" did not increase a manager's participatory style, but the task interdependence of the manager's subordinates did. Understandably, Leana (1986) reported that supervisors with heavier workloads were more likely than supervisors with lighter loads to delegate work to their insurance claims adjusters.

*Phase.* The phase in the work or decision process will affect whether leadership should be directive or participative. Wilson-Evered, Dall, and Neale (2001) noted that direction from the top may facilitate the initiation of innovative tasks; participation may generate more support for new ideas, their diffusion, and their implementation. Heifetz (1994) used the example of the physician-patient relationship in the diagnostic-treatment process to illustrate when direction or participation should dominate. In the first phase of diagnosis and treatment, the work is technical and the physician is primarily responsible for the work. When the patient is under stress, the flow of diagnostic and prognostic information to him or her may need to be paced and sequenced. The second phase, implementation, is technical but also requires the patient to learn and adapt. Here responsibility needs to be shared between physician and patient. In the third phase, as the relationship continues, the patient needs to learn to take on more responsibility than the physician. Heller, Drenth, Koopman, et al. (1988) studied the phases in 56 decisions in three Dutch organizations. Management dominated the first (start-up) phase and the third (finalization) stage. Professional staffs and middle management were most influential in the second (developmental) phase. Participation by lower organizational levels was limited to the fourth (implementation) phase. Richard Nixon saw participation as limited to the first phase of decision making and direction as mandatory in its finalization. "I would not think of making a decision by going around the table. Of course, I like to hear everyone, but then I go off alone and then decide. The decisions that are important must be made alone" (Schecter, 1982, pp. 18, 19).

*Perceived Importance of Outside Environmental Influences.* Managers differ in what aspects of the outside environment they regard as most important to their work, and as a consequence they behave differently inside the organization. Bass, Valenzi, and Farrow (1977) asked 76 managers to describe the importance of economic, political, social, and legal influences on the work of their 277 immediate subordinates. These subordinates, in turn, described the frequency with which their own manager displayed *direction*, negotiation, consultation, *participation*, and delegation. Managers who tended to see economic events, such as inflation

and taxes, as having strong effects on their work situation were more likely to be *directive* or negotiative. Managers who tended to see political, social, or legal issues as more important were more likely to be consultative or *participative*.

*Higher Authority.* If rules and regulations that are set by a higher authority or the central administration restrict subordinates' decisions, then supervisors dominate the group and make the decisions (Hemphill, Seigel, & Westie, 1951). A higher authority can indirectly prevent subordinates' participation in decisions by demanding immediate answers from supervisors and allowing the supervisors no time or opportunity to consult their subordinates. In addition, whether supervisors can be participative with their subordinates depends on the extent to which the higher authority requires the employees to be secretive about products, techniques, and business strategies. If people in the organization are supposed to know only "what they need to know," employees cannot be consulted about some decisions because much of the information required to discuss and consider such decisions cannot be revealed to them (Tannenbaum & Massarik, 1950).

The number of hierarchical levels at which participation is encouraged by policy will increase the tendency of supervisors to be participative throughout the system. The acceptance and promotion of the participative ideology by the sponsors of the organization and its top management are particularly important (Marrow, Bowers, & Seashore, 1968).<sup>7</sup> The efforts of chief executive officers (CEOs) at General Motors, National Intergroup, and W. L. Gore & Associates demonstrated that participative leadership could be increased throughout their systems through the transformational leadership of their CEOs. The CEOs articulated a corporate mission and philosophy to encourage participation. They worked to gain acceptance of the approach by other key top executives, then the acceptance of those at lower levels. Participation at all levels was encouraged by changing the corporate culture, developing trust at all levels, and building the necessary skills for effective participation. These actions of top management resulted in increased employee commitment, job satisfaction, and role clarity (Niehoff, Enz, & Grover, 1989). If top management is transformational, there will be more support for participation at lower levels, according to the survey of 485 upper-level managers by Collins and Ross (1989). Board and top management pressure to promote from within may also increase the need for and importance of delegation at all levels in the organization to develop personnel for higher-level positions. The effectiveness of such delegation depends on setting early expectations about the results that are desired.

L. B. Ward's (1965) large-scale survey of top management in the United States suggested strongly that (at the time) the religious affiliation of the top managers in a firm affected the firm's personnel policies. Leadership at lower levels was more likely to be participative when the top management was not restricted to members of one religious group. When the top management was restricted to one religion, participation was most likely in all-Jewish-led firms and least likely in all-Catholic-led firms. These findings need replication in the early twenty-first century.

*Organizational Size.* Blankenship and Miles (1968), McKenna (undated), and Wofford (1971) reported systematic trends between the size of the organization and the leadership style observed in it. On the whole, managers in larger firms exhibited more participation and less directiveness. However, a third variable may have been responsible, such as more education among managers of larger firms, differences in policies, and so forth.

The results for small naval vessels differed markedly from those obtained for larger ships (Stogdill & Scott, 1957), particularly for delegation. The effects of delegation continued unbroken down the chain of command in the large organizations of the bigger vessels. On the small ships, the delegation process was broken or reversed in the third echelon down from the top. Characterized by a high rate of face-to-face interaction, the personnel of the small ships were subject to greater interpersonal stresses and strains than were crews of the large ships. The formalized interactions in highly stratified larger organizations appeared to reduce some of the tension found in the smaller organizations, where personal interaction is conducted less formally. A formalized interaction structure had the effect of enlarging members' area of freedom of action, whereas the context

inherent in face-to-face interaction tended to restrict freedom of action for some group members.<sup>8</sup>

## General effects on Benefits and Costs of Directive and Participative Leadership

---

So far, this chapter has identified the attributes of the leader and the led, as well as the constraints and objectives of the task and surrounding conditions, that influence whether a leader will be directive or participative. This section examines the effects of direction or participation on follower acceptance of leadership, their satisfaction and morale, their involvement and commitment, the quality of decisions reached, and innovation and productivity.

The evidence does not automatically favor one leadership style over the other. Even the leadership that emerges in self-managed work groups, according to observations and group interviews by Manz and Sims (1984), needs to balance a hands-off with a directive style if it is to be effective. When asked about what managers do to appear fair, group members saw both direction with explanations and participative decision making as important. A survey of 815 managers by Greenberg (1988) found that to be seen as fair, 81% of the managers thought they needed to announce all pay raises and promotions; 76% thought they should explain how raises are determined; 43% thought they should explain why work assignments are made; and 55% said that subordinates should be allowed to participate in decisions. Yukl (1998, p. 126) concluded from 40 years of research evidence that “participative leadership sometimes results in higher satisfaction, effort, and performance, and at other times it does not.”

A meta-analysis by Spector (1986) found the following average correlations of employee outcomes with amount of participative leadership: involvement, .65; job satisfaction, .44; motivation, -.43; commitment, -.43; intention to quit, -.20; role ambiguity, -.54. Average correlations of the amount of participativeness with employee performance was .23; with turnover, -.38; and with role conflict, -.42. Despite this evidence, a variety of contingencies must be taken into consideration with regard to the benefits and costs of participation. Early on, Miner (1973, p. 348) suggested that the costs of participation may outweigh the benefits in many circumstances:

The change in value[s] ... required to implement participation on a large scale can be costly. ... Many managers must be retrained to the participative leadership style; many others will find change difficult and end by seeking other employment. Among these latter may be individuals with considerable talent in aspects of the management process ... such as planning, coordinating, and controlling. ... Individuals whose opinions are rejected ... can become alienated. ... [P]articipation may yield a sense of closeness and belonging ... that is mobilized behind objectives not in the best interest of the organization. ... [P]articipative decision making is a slow process which may not be adequately responsive to rapid changes in an organization's environment.

Lawler (1986) strongly advocated participation as a means of decreasing workers' resistance to changes in procedures and increasing the flexibility of assignments. Nonetheless, he expected that salary and training costs would increase, as would resistance by some staff personnel and line managers to participative decision making. A sampling of evidence on the general effects of directive and participative leadership follows. Then evidence about contingencies that moderate the effects will be presented.

### ***Effects on Acceptance and Agreement***

In general, the available evidence supports the contention that participative leadership promotes the acceptance

of decisions and agreement to a greater extent than does directive leadership. When participative leadership is practiced in a group, R. Likert (1961a, 1961b) found that each member has the opportunity to gain recognition and a sense of self-worth. This type of leadership also creates conditions that allow each subordinate to observe how everyone else in the group feels about a matter under consideration. Such conditions reduce the individual's resistance to suggestions and changes of opinion. Thus Bennett (1955) obtained results indicating that students were much more likely to volunteer as experimental subjects if they perceived that almost all other members of their class had volunteered. Observing near-consensus and the opportunity to make public decisions increased volunteering more than did the opportunity for discussion. In a more tightly controlled experiment, Pennington, Haravey, and Bass (1958) showed that the followers' acceptance and change were greatest when both discussion and group decision were permitted; less when only group discussion or announcements of group opinion were allowed; and least when only secret balloting was used.

In a seminal experiment, "participatory leaders" were instructed primarily to inhibit hasty decisions and domination of the group by any one member. They were contrasted by Preston and Heintz (1949) with "supervisory leaders," who were instructed to keep the group on the task. With more shared participation under participatory leaders, members as a whole showed more agreement with each other than did members without the opportunity to interact as much. The latter were more likely to be coerced, in that they showed less acceptance of decisions privately than publicly. Pennington, Haravey, and Bass (1958) found that experimental groups under participative leadership achieved greater coalescence and changes in opinion than did groups who were denied the opportunity to discuss and decide. Bovard (1951a, 1951b) observed that group-centered teams shifted their perceptions toward a common group norm more readily than did leader-centered teams. Hare (1953) found that although both participative and supervisory (directive) styles of leadership produced significant changes in the amount of agreement among group members, participative leaders were more in agreement with the group's rankings than were directive leaders. Likewise, Levine and Butler (1952) found participative leadership and group decisions to be more successful in producing behavioral change than did a lecture or control condition.

T. P. Wilson (1968) reported that prisoners make a better cooperative adaptation to prison life under participative rather than under bureaucratic management. Similarly, French, Kay, and Meyer (1966) observed that lower-level managers' participation in an appraisal system facilitated their acceptance of the goal, the group's cohesiveness, and favorable attitudes toward the appraisal procedures. Jacobson, Charters, and Lieberman (1951) showed that workers who were involved in decision making by their foremen but not by their shop stewards tended to share the values and goals of management, whereas workers who were involved in decisions by their stewards but not by their foremen tended to share the goals and standards of the union.

In a demonstration of how to change housewives' meat-buying behavior (from steaks and chops to kidneys and liver) during World War II, Lewin (1947b) pointed the way toward the use of participative leadership to overcome resistance to change. Coch and French (1948) illustrated how a combination of participation in goal setting and the redesign of jobs resulted in increased productivity of three groups of garment workers with no such change obtained for a control group. Participation remains a key tool for those who cope with resistance to change (Lawler, 1986).

### ***Effect of Opinionated Leaders***

In an experiment with 47 executives, Bass (1967a) reported that the simulated advisory staff of a department head shifted and coalesced more if the department head announced his opinion, particularly if he did so at the beginning of the problem-solving meeting. Anderson and Balzer (1988) showed for 19 teams in a university

residence hall who were dealing with various problems, that if the leaders immediately stated their opinions instead of withholding them until later in the discussion, fewer alternatives were proposed. Presumably, this was indicative of greater acceptance of the leader's point of view. However, T. A. Hill (1973) found that in student groups, consensus was more likely to be achieved when the leader was least opinionated. More will be said about the effects of directiveness on acceptance in the discussion of how contingencies modify the effects of participation and direction.

### ***Effects on Satisfaction and Morale***

Participation in all its forms has generally been found to increase subordinate satisfaction. However, evidence has been gathered that direction and persuasion can also be satisfying to followers, although to a lesser extent. And examples can be cited for situations in which participation fails to be satisfying to subordinates.

Preston and Heintz's (1949) previously mentioned study revealed the greater satisfaction of subordinates under participatory than under supervisory (directive) leaders. Similarly, Bass, Burger, et al. (1979) found that for an international sample of 1,641 managers who were engaged as subordinates in a training simulation, 51.7% preferred working again with a *participative* rather than with either of two kinds of directive supervisors (the choice by chance was 33.3%). Zimet and Fine (1955) contrasted the results of lectures given to 15 chief school administrators with those of group-centered participative discussions. Although the administrators were initially more defensive in the discussions, subsequent sessions reduced their hostility and yielded increased warm, friendly behavior and more favorable attitudes toward themselves and others outside the meeting. Likewise, Ziller (1954) found that aircrews were more satisfied with decisions concerning simulated problems if they discussed the problem and their participative leader stated his opinion after the discussion. They were less satisfied when the decision was made authoritatively by a more directive leader. According to Aspegren (1963), participatory leadership produced higher levels of satisfaction and task motivation among group members than either directive or laissez-faire leadership. Storey's (1954) study of groups with participative leaders and groups with directive leaders found that members of participative groups were better satisfied with the group procedures, the decisions reached, and intermember acceptance, although no significant differences were found in satisfaction with the leadership.

*Effects of the Opportunity to Participate.* A. S. Tannenbaum (1963) reported greater satisfaction among 200 clerks as a consequence of their increased opportunity to participate. Morse, Reimer, and Tannenbaum (1951) noted increased satisfaction with a new organizational arrangement that promoted more self-determination and group decision making by lowering by one echelon the authority to make and execute various decisions. What the supervisor had previously decided was now delegated to subordinates. Mann and Baumgartel (1952) found that employees who felt free to discuss job-related and personal problems with their supervisors were better satisfied with the company, exhibited less absenteeism, and enjoyed membership in more cohesive work groups. Baumgartel (1956, 1957) obtained results showing that scientists in research laboratories exhibited higher degrees of task motivation and job satisfaction under participatory than under directive supervisors. In a large metropolitan social service agency, Harrison (1985) found correlations of .42 and .47, respectively, between the extent to which the 30 superiors used participative decision making and the 233 subordinates' desire to continue interacting with their leaders. Likewise, Mann, Indik, and Vroom (1963) reported that workers' satisfaction was highly related to their participation in decision making; their satisfaction and task motivation were especially low under directive supervision. Absences of white-collar workers were related to how free they said they felt to discuss their job with their supervisor. Of the employees who were absent four or more times during a six-month period, only 29% said they felt very free to talk with their boss; 57% to 69% of those who were absent less often said they felt very free to hold such discussions (R. Likert,

1961a).

In a Dutch study, Drenth and Koopman (1984) obtained correlations for 175 municipal transport employees, 154 railway employees, and 153 steelworkers of .44, .57, and .35, respectively, between the employees' participation in decision processes and the employees' satisfaction with the processes. Early participation in the decision process was particularly important to satisfaction. In Australia, Wilson-Evered, Dall, and Neale (2001), found that for 277 employees, participative leadership correlated with their morale and their support for team objectives. Weschler, Kahane, and Tannenbaum (1952) found that a research group led by a directive leader was less satisfied with its job. Alutto and Belasco (1972) reported that dissatisfaction and job tension were associated with "decision making deprivation."

*Effects of Directive Leadership on Satisfaction.* Direction may also be satisfying. Farrow, Valenzi, and Bass's (1980) analyses of approximately 1,400 subordinates' descriptions of their 350 managers in the Bass-Valenzi Management Styles Survey found that the managers' *direction* was positively correlated with satisfaction (.17 and .18). For the same sample, consultation correlated .34 with the subordinates' satisfaction with their jobs and .53 with the subordinates' satisfaction with their supervisors. The managers' *participation*, as seen by the subordinates, correlated .25 with their job satisfaction and .41 with their satisfaction with the leader. Comparable correlations of delegation with satisfaction were .32 and .46. Only negotiation or manipulation was negatively related to job satisfaction (2.16) and satisfaction with the leader (2.16). Using the same Bass-Valenzi instrument with 147 assistant school superintendents' descriptions of their superintendents, Wilcox (1982) obtained similar results. The rated superintendents' frequency of *direction* by the assistants correlated .50 with their satisfaction with the superintendents' leadership, although only .25 with their job satisfaction. The superintendents' frequency of *participation*, according to their assistant superintendents, correlated .37 with the assistants' job satisfaction and .41 with their satisfaction with the superintendents' leadership. In both Farrow, Bass, and Valenzi's study and Wilcox's study, consultation (in which the leader seeks advice from subordinates but makes the final decision) and delegation (in which the decision is left to the subordinates) were seen as more satisfying leadership styles than was *participation* (in which the decision is shared between the leader and the subordinates). Thus Wilcox obtained a correlation of .58 between consultation and satisfaction with the superintendents' leadership and .43 between delegation and such satisfaction. *Participation* and satisfaction correlated somewhat lower. A similar pattern of correlations with the same instrument translated into Turkish was obtained by Ergun and Onaran (1981) for 107 subordinates' descriptions of their supervisors in the Turkish Electrical Authority.

Berkowitz (1953b) observed decision-making groups in business and governmental organizations and found that group cohesiveness and the members' satisfaction decreased with participative leadership and increased with directive leadership. Although one would expect to find that leaders who say they delegate a great deal generate greater satisfaction among their subordinates, often the subordinates fail to appreciate the delegation (Stogdill & Shartle, 1948). The subordinates may not appreciate it because they believe they lack the authority to go along with the responsibilities that have been delegated to them. Also, superiors may believe they are delegating, but their subordinates may see the same behavior as dumping undesirable assignments on them. Or, they may think the delegation is marred by overly close monitoring; the resources necessary to carry out the delegated task may not be provided; or the leader's instructions may be ambiguous. Conditions that contribute to the failure of participation to be satisfying to subordinates can be a consequence of contingencies such as whether the participation is for the short or long term. For instance, Cotton, Vollrath, Froggatt, et al. (1988) showed that short-term participation failed to contribute to either employee satisfaction or productivity. Participation required more time to be effective.

Compared with a nondirective leader, a directive leader is more satisfying. Page and McGinnies (1959) showed a motion picture to groups of subjects who discussed the film under two styles of leadership—directive and nondirective. The directive leader was rated by the members as significantly more interesting,

satisfying, purposeful, frank, industrious, and persuasive than the non-directive leader. Levy (1954a, 1954b) also found that the satisfaction of members was higher under directive than under nondirective leadership.

### ***Effects on Involvement, Commitment, and Loyalty***

According to D. Katz (1951), workers tend to enter groups or withdraw psychologically from groups as a function of their ability to make decisions in those groups. Many commentators (see, for example, Tichy & Devanna, 1986) have noted that the participation of employees is critical for the reorganization of a firm or agency and its successful implementation.

Kahn and Tannenbaum (1957) and Tannenbaum and Smith (1964) surveyed organized workers and members of women's clubs. The members' participation was facilitated by leaders who encouraged consultation and participation in activities. The members' loyalty to the organization was also strengthened by participation in activities. Likewise, in a study of technicians and laboratory testers at the Tennessee Valley Authority, Patchen (1970) found that participative management led to increased individual integration into the organization. Individuals became more involved in the work project when they were engaged in participative decision making. Siegel and Ruh (1973) reported similar results in a study of manufacturing employees; participative leadership was positively related to the employees' involvement in their jobs.

The opportunity to participate can be a mixed blessing. According to a nationwide survey by Gurin, Veroff, and Feld (1960), participation in the decision-making process increases both one's involvement in one's job and one's frustration with it. A. S. Tannenbaum (1963) studied 200 clerks who were given greater responsibility to make decisions. Despite their general increase in satisfaction, the clerks felt less sense of accomplishment at the end of the workday and were less satisfied with their present level in the organization. In acquiring an increased feeling of responsibility for the work, the clerks developed standards of achievement that were harder to satisfy.

Locke (1968) began a long line of investigation by questioning whether the mere directive assignment of hard goals to people was sufficient to generate heightened commitment and productivity; the people did not have to participate in the decision to set the hard goals. Considerable experimental support was obtained in U.S. studies (Latham & Baldes, 1975). Likewise, feedback appeared more important than participation in a study of the safety practices of 150 U.S. workers by Fellner and Sulzer-Azaroff (1985). But in Israel, Erez and Arad (1986) noted that involvement and commitment were required for the heightened productivity to occur, and such involvement and commitment could be obtained only if the experimental subjects participated in setting the goals. These differences between the United States and Israel appear to have been resolved (Locke, Latham, & Erez, 1987) when it was discovered that participation was unnecessary in the United States for the required commitment to be achieved, because the commitment seemed to have been gained by the friendly, supportive behavior of the experimenter in assigning the goals. In Israel, the experimenter who assigned the goals was curt and abrupt. Here, only with participation in goal setting, was it possible to obtain the expected commitment and subsequent heightened performance. Thus relations-oriented leadership, a subject of [Chapter 19](#), may substitute (as in the U.S. experiments) for actual participation in gaining the commitment of subordinates.

### ***Effect on Task Performance***

Generally, both participation and direction can affect subordinates' task performance and task outcomes. For example, Nutt (1986) examined 84 cases from service organizations, such as hospitals, governmental agencies, charities, and professional societies, in which managers had sponsored efforts to implement planned changes. In

16 cases, the directive managers first acquired the necessary authority and then demonstrated or justified the changes with appropriate information; their implementation efforts were successful in 100% of these 16 cases. In another 14 cases, the participative managers first stipulated the needs, opportunities, and objectives and then set up task forces to develop recommendations; overall success occurred in 84% of these 14 cases. In 35 cases, managers used persuasion to sell the planned changes after the changes had been formulated by the staff or consultants; here the success rate was 73%. In the remaining 19 cases, implementation was by management edict and least success was found. Here, the sponsor of the change used positional and personal power to issue directives ordering the changes; this approach achieved a success rate of 71%.

Bass (2000) suggested that directive supervision was more effective when supervising novices working on routine tasks, especially if the supervisor was experienced, knowledgeable, and esteemed. According to Portin and Shen (1998, p. 96), “the school principal remains the singular individual at the nexus of leadership in the school ... [with] a mandatory responsibility [to deal with] the increasing complexity of schools and school administration.” Smither (1991) argued that, to be effective, managers may need to be authoritarian and directive. Tetrick (1989) provided supportive evidence with data from 422 naval personnel and their immediate supervisors. Informative and controlling supervisors enhanced their subordinates’ role clarity, motivation, and felt influence. P. J. Burke (1966a, 1966b), as well as Katzell, Miller, Rotter, et al. (1970), found that directive leadership could enhance group cohesiveness. Thiagarajan and Deep (1970) studied groups in which supervisors played three roles: *directive*, *persuasive*, and *participative*. The *directive* leader was more influential on coalescing agreement of follower and leader than the *persuasive* leader, and the *persuasive* leader was more influential than the *participative* one. Several meta-analytic reviews found that directive leadership could be as effective as participative leadership in increasing worker productivity (e.g., Sagie, 1994). Sagie (1997) offered three explanations:

1. As Muczyk and Reimann (1987–1989) suggested, participation is called for in making an effective decision; direction is concerned with executing the decision effectively once it has been made.
2. Since the superior is more knowledgeable about strategic issues, and the subordinates are more knowledgeable about tactical operations, direction should be used for strategic decisions and participation for tactical decisions.
3. For effectiveness, a coupling is needed between participatory goal setting and directive leadership that sets the framework for action, structures the interaction, and urges subordinates to contribute.

Sagie (1996) demonstrated that the third explanation was most accurate for 183 experimental team members required to solve problems in the least amount of time.

### ***Effects on the Quality of Decisions***

Experiments generally show that group decisions are superior to decisions reached by the average member of a group, although it is also true that the group decision may not be as good as that of the best member of the group. But how often is the supervisor the best? If it could be guaranteed that the supervisor was always the best, then the quality of the decision might be better when decisions were made by the supervisor alone (Bass, 1960).

When 66 U.S. Air Force officers wrote decisions before a discussion and then met as an ad hoc staff to write the decisions, the decisions written by the staff were superior to the average quality of the decisions written by individuals without a discussion. But the quality was the same after the discussion, whether the decision was written by the staff or by the commander who had listened to the staff’s discussion. Group discussions contributed to better decision making whether the final decision was written by the group or by the person leading the group (Lorge, Fox, Davitz, & Brenner, 1958). Many others have also studied the improved quality

of decisions made by discussion groups.<sup>2</sup>

The quality of the decision was higher under participation than under a directive style of leadership that discouraged discussion. Lanzetta and Roby (1960) found that both time and error scores were better under participative than under directive leadership.

Leana (1983) engaged 208 undergraduate students in a role-play of a business problem. In the four-person groups, if the “vice president of operations” (the formal leader of the group) was participative rather than directive, the group generated and discussed significantly more alternative solutions. Directive leaders tended to produce premature closure of the search for solutions, which presumably reduced the quality of the final decision. These effects were independent of the groups’ cohesiveness. Watson and Michaelsen (1984) demonstrated that participative leadership in a role-playing setting with 35 four-person student groups generated more effective problem solving than did directive leadership.

However, numerous other studies can be cited in support of directive leadership. Katzell, Miller, Rotter, and Venet (1970) studied small problem-solving groups. More directiveness by leaders was positively associated with the groups’ greater effectiveness. Kidd and Christy (1961) found that avoidance of errors was greatest under directive leadership. Schumer (1962) obtained evidence indicating that both the quality and quantity of results were enhanced by a directive form of leadership. Torrance (1952) contrasted five types of critiques following 16 minutes of problem-solving activity by air crews in survival school to see which resulted in the greatest improvement in the ability to solve subsequent problems. The largest gains were made when an expert directed the critique; the next largest gains with guided discussion (participative leadership); and the least gain with free discussion (*laissez-faire* leadership) in which no control was exerted.

Schlesinger, Jackson, and Butman (1960) found that committees are more effective in solving problems under directive than under nondirective leadership. Stagner (1969), who studied a large sample of corporation executives by questionnaire, observed that corporate profits were associated with more formality, more centralization of decision making, and less personalized management.

### ***Effects on Productivity***

If one searches for universal answers about the immediate effects of participation and direction on productivity, almost every possible alternative emerges. From a review of the results of laboratory, correlational, and univariate field studies of the effects of leadership style on productivity, Locke and Schweiger (1979) concluded that they could find no overall trend favoring participative or directive leadership. As for field studies with multiple antecedent conditions and outcomes, they thought that other factors, such as training and reward systems, often could account for effects on productivity that were attributed to participation. Likewise, Erez and Arad (1986) demonstrated that appropriate information and involvement in goal setting were needed for a participative group discussion to generate higher-quality performance. Nonetheless, Miller and Monge’s (1986) meta-analysis confirmed the significance of participative leadership to productivity. In a seminal experiment (detailed in [Chapter 12](#)), Coch and French (1948) demonstrated that the participation of pajama-manufacturing workers in decision making generated higher productivity and a lower turnover of personnel than did nonparticipation by a control group. A subsequent replication yielded comparable results (Marrow, Bowers, & Seashore, 1968). With groups of employees of a large supplier of aerospace electronics, Hinrichs (1978) obtained production increases of 20% to 30% and reductions in errors of 30% to 50% in 27 of 40 employee groups who were encouraged to participate over a four-year period.

R. Likert (1977b), aiming toward long-range effects, involved various business and industrial groups in management by group objectives (MBGO), which generates the participative sharing of data and the setting of a group’s goals. A 27% increase in profits over the previous year was reported from a retail sales division. Such

participation by teams of foremen resulted in a rise in productivity of 15% and a decrease in scrap of 7% to 14% in an auto assembly plant. In an early study reported by the Survey Research Center (1948), work groups were more productive among those first-level supervisors in an insurance company who encouraged their workers to participate in decisions. Indik, Georgopoulos, and Seashore (1961) showed that among 975 deliverymen at 27 parcel delivery stations, the ease and freedom they felt in communicating with their superiors at a station correlated between .39 and .48 with the average deliveries the men completed daily in relation to the standard time allotted for completion.

R. J. Solomon (1976) demonstrated the greater effectiveness of participative library directors. The immediate subordinates of these directors evaluated the effectiveness of the services supplied by other departments. For instance, personnel in the acquisition departments evaluated the effectiveness of the circulation departments. Directors who were consultative and participative were the most conducive to high ratings of effective departments under them, and directors who were manipulative were the least conducive. Similarly, Reeder (1981) employed path analysis to show that participative leadership by supervisors of U.S. Army clerks and programmers was more causally related to the subordinates' productivity than to the supervisors' knowledge of their subordinates' work. Programs of management by objectives (MBO) imply participative setting of goals. Gains in productivity occurred in 68 of 70 studies, but the average gain was 56% when top management was committed to the program and only 6% when it was not committed, according to a meta-analysis by Rodgers and Hunter (1991).

In still other studies, participation and direction were seen to have similar effects on task performance. According to Weschler, Kahane, and Tannenbaum (1952), a research group with a directive leader perceived itself to be less productive than one with a participative leader. However, the leaders' boss thought the group led by the directive leader was more productive. Lange and Jacobs (1960) and Lange, Campbell, Katter, and Shanley (1958) found that directive patterns of leadership and encouraging participation were positively and significantly related to the performance ratings of groups. Similarly, Farrow, Valenzi, and Bass (1980) found that effectiveness correlated positively with the amount of *direction* (.23) by about 250 managers, as seen by 1,400 subordinates. Effectiveness also correlated positively with various participatory approaches: consultation (.23), *participation* (.23), and delegation (.22). Only negotiation or manipulation by managers was negatively related to effectiveness (−.25).

### ***Effects on the Manager's Rate of Advancement***

Hall and Donnell (1979) calculated the rate at which managers had been promoted by comparing their organizational level with their age. Over 2,000 subordinates indicated the extent to which the 731 managers allowed and encouraged them to participate in making and influencing work-related decisions. Although slowly and moderately advancing managers were seen to permit or encourage very little participation, faster-advancing managers did a lot of it. But Farrow, Valenzi, and Bass (1981) determined, for more than 1,200 managers and their subordinates, that the managers whose salaries were higher than would have been predicted from their function, their organization, their sex, and their seniority were seen by their subordinates to be persuasive, manipulative, and negotiative. Such managers were downgraded in effectiveness by their subordinates but evidently were pleasing to their bosses, who awarded them higher-than-expected salaries. Managers who were favored by their subordinates for their frequent consultation, *participation*, delegation, and *direction* were not similarly awarded salaries above the norms.

### ***Models in Support of Participation***

Support for participative leadership can be built into cognitive, affective, and contingent models (Miller & Minge, 1986). *Cognitive* models propose that participation contributes to subordinates' satisfaction and productivity because it improves the interchange of important information in the organization. For example, Anthony (1978) argued that workers have more knowledge than do their managers and that their participation increases the information needed for high-quality decision making. Furthermore, as Melcher (1976) noted, people will work better under the requirements for implementing decisions if they have participated in the decision-making process. In a study of 12 high-technology R & D projects, McDonough and Kinnunen (1984) found that in the more successful projects, there was more discussion among the different levels of management about the projects' goals and more constant distribution of information about progress.

The satisfaction of employees is a side effect of such participation (Ritchie & Miles, 1970). Since the distribution of information is the crucial aspect of participation, Miller and Monge (1986) deduced that stronger effects should occur with the participation of employees in decisions about the design of a job than in companywide policy decisions. Satisfaction should occur only after the feedback of information about the consequences of participation. Participation should not necessarily pay off in greater satisfaction merely for working in a participative climate or for a participative leader. It should pay off only when the exchange of knowledge is relevant to the decisions.

The *affective* model, strongly endorsed by the human relations school of thought (see, for example, Maslow, 1965; McGregor, 1960), posits that participation generates the satisfaction of higher-order needs in subordinates, which, in turn, increase the subordinates' motivation, satisfaction, and quality and quantity of performance.

The third or *contingency* model stresses the importance of the perception of participation. Another contingency is the felt opportunity to participate. Still another contingency is the number of issues involved. From all 41 weighted and adjusted estimates of the relation between the amount of participative leadership and the satisfaction of subordinates, Miller and Monge (1986) obtained a mean correlation of .34 in their meta-analysis. The results were similar for students and organizational respondents. The correlation rose to .48 when the respondents *perceived* themselves to be participating on a multiplicity of issues (see, for example, Obradovic, 1970). It dropped to .21 if only a single specific issue was involved (see, for instance, Alutto & Acito, 1974). The correlation was only .16 between actual participation and satisfaction. What makes participative leadership satisfying for subordinates is not so much their actual participation in the decision-making process as their feeling that they genuinely have the opportunity to participate if they want to contribute to making a decision. Only about 50% of the American electorate actually votes in presidential elections; the rest are satisfied to remain on the sidelines. Yet if they were denied the ballot, strong protests, cries of dictatorship, and a great increase in dissatisfaction with the system would ensue.

From 25 studies, the Miller-Monge meta-analysis yielded a mean of .15 between participative leadership and the productivity of subordinates. The mean rose to .27 for field studies (in contrast to laboratory settings). As was reported earlier, in the laboratory studies in which participants were subject to participative or directive leadership, the mean correlation was  $-.33$  (productivity was higher with direction). When a friendly supervisor subjected the participants to arbitrarily assigned goals or to participation in setting the goals, the mean correlation with productivity was  $-.01$ . It made no difference in these temporary conditions with a friendly experimenter whether arbitrary direction or participation was used.

Miller and Monge did not find a change in these mean results for managers compared to lower-level employees, or in different kinds of organizations; nor could they test the effects of personality. They concluded that with reference to such contingencies, they had found more support for the affective model than for the cognitive or contingent models. They reasoned in favor of the affective model because (1) they had found stronger effects between participation and satisfaction than between participation and productivity and (2) they

had found stronger effects of a participative climate on the satisfaction of subordinates who were involved in multiple issues rather than in a single issue.

With reference to another contingency, they obtained mean correlations of  $-.33$  versus  $.27$  between participation and productivity in the laboratory versus the field studies. They inferred that directive leadership contributed to productivity in the laboratory because laboratory tasks tend to be simpler and to have clear objectives and outcomes. They thought that participation yielded more productivity in the field because tasks in the real-life work setting are likely to be more complex and to have unclear objectives and outcomes.

Wagner and Gooding (1987) uncovered another contingency. If single-source bias is present, in that the same respondent provides the data on participation and outcomes, mean correlations range from  $.34$  to  $.42$ . But if one source provides the measure of participation and another source provides the data on outcomes, the range of correlations lowers to between  $.09$  and  $.21$ . Overall, the impact of participation per se on performance and satisfaction is evident.

Additional support for the contingent model stems from the fact that, as was noted earlier, a majority of managers actually are directive or participative, depending on the nature of the decision to be made. With this fact in mind, Hambleton and Gumpert (1982) found that for 65 managers, their 189 subordinates, and their 56 supervisors, the adaptable, flexible manager who made a greater use of the variety of styles appropriate to different situations, according to the Hersey-Blanchard model (1977),<sup>10</sup> emerged with significant and practical gains in the subordinates' performance.

*Integration of Models.* Lawler (1986) integrated the models, suggesting that the effective participative process requires a multiplicative combination of the adequate flow of information, the requisite knowledge by employees of what needs to be done, shared power to decide, and satisfactory rewards for implementation. If any one of these elements is missing, the process will fail.

## Additional Contingent Effects of Directive and Participative Leadership

---

R. Likert (1977a) argued that if long-term measures of effectiveness are the criteria of consequence, then a democratic approach, including shared participative decision making, is universally more effective as long as the leader is task oriented. There are few contingencies for Likert. Blake and Mouton (1964) presented similar arguments for an integrated task-and relations-oriented approach. On the other hand, Bass and Barrett (1981) noted in reviewing the literature that participative leadership is contraindicated in situations with short-term perspectives when interaction is restricted by the task, when the higher authority disapproves, when maximum output is demanded, when subordinates do not expect to participate, when leaders are unready for participation, and when emergencies occur. Many comparable theories have been advanced on the basis of the postulate that effective leaders use participation or directive leadership styles to fit the situation. (See, for example, Austin's [1981] style-flex model.) And countless commentaries and the inspirational management literature of the 1980s repeated the virtues of the life-cycle theory (Hersey & Blanchard, 1969a) that the key situational factor for leaders to consider is the maturity of their subordinates (Carbone, 1981).

The evidence so far is that although the meta-analytic effects are not as large as some commentators expect, generally participative leadership enhances performance, the quality of decisions, and satisfaction, but in the short run, at least, it may be less conducive to productivity than is directive leadership. Various contingencies have already been mentioned, which must be taken into account to predict and understand more fully the impact of direction and participation. What follows further elaborates on the effects of contingencies such as the differences between leaders and their followers and the constraints under which they must operate.

Three bases for understanding exist. First, one can draw empirical inferences from surveys in which

correlations have been run between the style of the leader and outcomes under different contingencies. Second, one can draw further inferences from experiments in which each leadership style has been introduced under each contingency. Third, beginning with several acceptable assumptions that are consistent with what was said earlier about the impact of participation on outcomes, it becomes possible to prescribe which style of leadership is likely to be more effective. Empirical data supporting or refuting the propositions derived from the models can also be presented.

### ***Effects of Superior Subordinate Competence, Motivation, and Personality***

*Ability and Motivation.* Whether direction or participation is more effective as a leadership style has been found in a number of investigations to depend on the competence, motivation, and personality of the leaders and their subordinates. Probably the single most emphasized modifier in determining whether participative or directive leadership will be more effective is the competence of the subordinate relative to the leader, and the information each possesses (Hersey & Blanchard, 1977). Mulder (1971) and Miner (1973) pointed out that it may be counterproductive for leaders to be participative in style if they are much more expert than their subordinates on the matters to be decided. What is important to whether direction or participation will work better is how much training and information the leader and the subordinate have (Filley, House, & Kerr, 1979; Locke & Schweiger, 1979).

Blades and Fiedler (1976) and Fiedler and Garcia (1987) demonstrated that whether directive leaders are more effective depends on the leaders' task ability and their subordinates' support and motivation. The followers' performance is better if the leaders are expert and intelligent and the followers are supportive and motivated. If the followers are more intelligent and motivated, then nondirective leadership is more effective. Thus Bons and Fiedler (1976) found that among 138 U.S. Army squad leaders, the leaders' intelligence correlated .44 with their squads' performance of tasks. Yet the correlation fell to .04 when the squad leaders failed to be directive. Similar results were obtained by Fiedler, O'Brien, and Ilgen (1969) in a study of 41 small public health teams in Honduras. When the leaders' direction was high, their intelligence correlated .48 with community developments. When the leaders' direction was low, the correlation fell to  $-.20$ . More intelligent, informed, technically competent leaders—both when contrasted with the competence of their followers and when contrasted with less competent leaders—are more effective if they are directive rather than nondirective and if their subordinates are already highly motivated and supportive of their efforts (Fiedler, 1982; Murphy, Blyth, & Fiedler, 1992).

Latham and Baldes (1975) provided the strongest evidence to support the contention that both the ability and motivation of the leader, combined with the ability and motivation of the subordinates, determine what style of leadership will prove more effective. Latham and Baldes studied 49 groups of U.S. Army enlisted cooks. The cooks operated mess halls, each of which was led by a mess steward who was either directive or nondirective, according to behavioral descriptions of the steward by the group on such items as, "The mess steward decides what shall be done and how it shall be done." The tendency of the steward to enforce standards was measured by such items as, "The mess steward maintains definite standards of performance." Motivation was measured by responses to such questions as, "How hard do you work and do as good a job as possible?" The ability of the stewards and cooks was obtained from a 50-item test. Measures of the quality of mess hall services were obtained from weekly inspections made by food service officers. Nondirective participative leadership worked better when the cooks were higher in both ability and motivation. However, directive leadership resulted in a much more effective food service when the stewards were higher in ability and the cooks were highly motivated. Such directive leadership resulted in lower inspection ratings if the steward was lower in ability and the cooks were lower in motivation. Enforcement of standards by the steward

generated the best food inspection ratings when the cooks were either high in both ability and motivation or low in both ability and motivation. Particularly deleterious was the enforcement of standards when the cooks were high in ability but low in motivation.

The steward's tested intelligence contributed to the effectiveness of the mess halls, but only when the steward was directive and the cooks were highly motivated. Furthermore, with highly motivated cooks, nondirective leadership resulted in a correlation of .56 between the cooks' level of ability as cooks and the effectiveness of operations. But here, directive leadership generated an opposite correlation of  $-.48$  between the cooks' ability and effectiveness. With nondirective leadership, if the cooks' motivation was low, the cooks' ability correlated  $-.45$  with the effectiveness of the mess halls; with directive leadership, the correlation was  $-.20$ . Parallel results were obtained when the tested intelligence of the cooks was used as an indicator of their ability.

### ***Effects of Training***

Blyth (1987) randomly assigned leaders to four conditions: the leaders were either trained or untrained in the use of survival gear and were instructed to be either directive or participative with their groups. Only the directive leaders who had been trained to use the survival gear had groups that performed well; participative leaders with the training performed no better than did those without training. When Blyth trained the group members but not the leaders to use the gear and then instructed the leaders to be directive or participative, the groups with participative leaders performed better than those with directive leaders.

### ***Effects of Centrality***

Communication network experiments reported in [Chapter 29](#) demonstrated that if leaders are at the center of a network, they are likely to be most informed, since they are in two-way contact with all the people at the periphery. Their network will be more effective if they are directive. On the other hand, if the leaders occupy peripheral positions, their network will be most effective if they are more participative (Shaw, 1954a).

### ***Effects of Task Relevance***

Bass and Ryterband (1979) reported a study in which 18 wives of managers were asked to meet individually with a male manager (not their own spouse) to reach decisions about either company affairs or household affairs. The managers were instructed to be either directive or participative as the leaders in a counterbalanced design. The women felt responsibility for the household discussion regardless of the leader's style, but felt responsibility for the discussion about the company only with the participative leader—not with the directive leader. The wives reported considerable hostility toward the directive leader in the discussions of household affairs, and such meetings were the least satisfying experience for them. In contrast, the wives did not react negatively when leaders directed the decision-making process if the problem concerned company issues.

### ***Effects of Personality***

Mitchell, Smyser, and Weed (1975) showed that for workers, locus of control determined whether a directive or participative supervisor was more satisfactory as a leader. For workers with an external locus of control, satisfaction with work was higher with directive supervisors and lower with participative supervisors.

Conversely, for those with an internal locus, satisfaction was higher with participative leaders and lower with directive leaders.

In Vroom's (1959) study of 108 supervisors in a retail parcel-delivery service, productivity was found to correlate with felt influence on decisions among egalitarians much more than among authoritarians. Satisfaction on the job was increased by participation, but only for subordinates with egalitarian attitudes. A. S. Tannenbaum (1958) noted that followers who were predisposed to participation tended to be satisfied under conditions of increased involvement. Those who were predisposed to dependence, however, reacted adversely to increased participation. Runyon (1973) and Mitchell, Smyser, and Weed (1975) found that, as might be expected, internally controlled subordinates were more satisfied with participative supervisor, but externally controlled subordinates were more satisfied with directive supervisors.

Passive followers favored a more directive leader in Page and McGinnies's (1959) comparison of discussion groups led by directive and participative leaders. Likewise, in simulations (Bass, Burger, et al., 1979), apathetic subordinates were found to be relatively more comfortable with *directive* supervisors.

Saville (1984) proposed that supervisors who favored some form of direction or participation could be matched with subordinates who complemented them to maximize supervisor-subordinate compatibility and to minimize the development of serious problems between them. Receptive, dependent subordinates should be matched with *directive* supervisors; more reciprocating types of subordinates complement negotiative supervisors; more innovative, critical subordinates should be assigned to consultative supervisors; more affiliative, democratic subordinates should be matched with *participative* supervisors; and more self-reliant subordinates will fit best with delegative supervisors.

Bass, Valenzi, and Farrow (1977) found that for 244 managers and their 992 subordinates, judged effectiveness by both managers and subordinates correlated positively with delegative supervision (as seen by the subordinates) if the managers tended to regard the world as fair minded and if the subordinates were introspective but not assertive. The same was true for the effectiveness of *participative* leadership. In addition, it helped if the manager had an assertive personality. Consultation was more effective with introspective, unassertive subordinates and assertive managers. Manipulation and negotiation were more effective with introspective managers and subordinates. The personalities of the managers or the subordinates were of no consequence to the effectiveness of *direction*. In a consumer finance firm, Tosi (1970) failed to find that the subordinates' personalities made any difference.

## ***Effects of Organizational and Interpersonal Relations***

Commitment by top business management played a crucial role in the effectiveness of participative leadership at hierarchical levels below them (Rodgers & Hunter, 1991). Renn (1998) showed that while task performance was not directly enhanced by the participation of 200 employees in a goal-setting program, it was enhanced by goal acceptance, which was a direct consequence of participation. In a related experiment, Li and Butler (2004) found that persuasive rationales for goals were particularly important to effective outcomes and sense of procedural justice when goals were assigned rather than set by means of participation. In a military setting (Virginia Military Institute), Atwater, Lau, Bass, et al. (1994) found that subordinates' effectiveness rankings of their cadet leaders correlated .33 with the frequency of *direction* of the leaders and .19 with the frequency of their persuasion but only .09 with their frequency of *participation* and .12 with frequency of consultation. Colquist, Noe, and Janz (1998) surveyed 230 employees from 27 work teams in information systems departments of Fortune 500 firms in six industries. When the employees strongly identified as team members, felt interdependent, were satisfied with their jobs, and were in small teams, there was less need for participative leadership to generate cooperation among them. There was more need for participative leadership when the

reverse conditions prevailed. Bass, Valenzi, and Farrow (1977) developed discriminant functions for 244 managers and 992 subordinates in work groups who were above and below the median in effectiveness who had responded to a questionnaire about the system of inputs, relations, and outputs under which they perceived themselves to operate. They found that the effectiveness of operations was higher if harmony and trust were higher. A greater amount of harmony made consultative leadership even more conducive to effective operations, and a greater amount of trust in the organization contributed more to the impact on effectiveness of the leader's participation.

*Power.* Kipnis (1958) studied groups of children under different conditions of leadership, reward, and threat. Both reward and threat produced more public compliance than did the control condition. Participative leadership induced more children to change their beliefs when leadership was associated with the power to reward. When the children were threatened with punishment for noncompliance, significantly fewer of them changed their beliefs under participative leadership than under lecture conditions. The participative leader was better liked than the lecturer if he did not threaten. Similarly, Patchen (1962) found that directive supervision resulted in a group's high output only if the group was also cohesive and directed by a supervisor who was seen to be a rewarding figure.

Ergun and Onaran (1981) found that Turkish supervisors who were more active in either direction or participation were judged more effective when both the managers and the subordinates lacked power. Activity appeared to be a substitute for power.

Pelz (1951) observed that participative leadership by Detroit Edison managers generated satisfaction among employees only when the managers had influence "up-stairs." But House, Filley, and Gujarati (1971) failed to replicate this finding for R & D managers in another firm.

*Falling Dominoes Effects.* The effectiveness of participatory leadership at lower levels in an organization will depend on the practice of such leadership at higher levels, as well as in adjacent departments. Otherwise, conflict emerges (Lowin, 1968). Such conflict may be avoided if R. Likert's (1967) organization of overlapping groups is used. Here, every manager is a linchpin that connects the participatory group of the manager and his or her subordinates with the participatory group of the manager's boss, the manager's peers, and the manager.

*Constraints and Goals.* Hemphill (1949b) found that directive behavior by leaders is most readily accepted in groups with a closely restricted membership, a stratified status structure, and members who are dependent on the group. But Murnighan and Leung (1976) obtained results indicating that participation helped performance only when subordinates thought the task was important. According to Ergun and Onaran (1981), the effectiveness of the unit, organization, and supervisor increased, particularly if the leader used direction when constraints were low, goals were clear, and the interdependence of tasks was high. Participation correlated more highly with effectiveness for interdependent work teams that had clear objectives and considerable discretionary opportunities.

*Task Requirements.* Shaw and Blum (1966) found that directive leadership was more effective in structured task situations, whereas nondirective leadership was more effective in less structured conditions. Roby, Nicol, and Farrell (1963) obtained indications that problems requiring a reaction to environmental changes were more quickly solved under participative conditions, but that problems necessitating coordinated action were solved more efficiently under directive leadership.

The leadership decision-making style in an organization is influenced by whether the organization must deal with a stable or turbulent market. Firms that operate in turbulent markets are more effective if they encourage participation and decision making at the lowest possible levels (Emery & Trist, 1965). Burns and Stalker (1961) contrasted the relatively stable environment of a rayon mill with the more unstable conditions faced by firms in the electronics industry. For the mill, in its stable environment, a "mechanistic" system with directive supervision was most effective. In the electronics industry, with its rapidly changing environment, a more

participative, “organic” system seemed most effective.

Similar conclusions were reached by Lawrence and Lorsch (1967a, 1967b). For a container firm with a stable environment, effective decision-making processes within the firm were likely to be directive; in a plastics firm facing a more turbulent environment, effective decision-making processes were more likely to be participative. Nonetheless, Wagner and Gooding’s (1987) meta-analysis of 118 correlational analyses on the extent to which the interdependence and complexity of tasks and performance standards moderate the effects of participation on employees’ performance, motivation, satisfaction with decisions, and acceptance of decisions revealed few differences in the effects of participation on outcomes if the task was complex rather than simple, if the task involved independence or interdependence, and if performance standards were present or absent.

*Objectives.* Korten (1968) observed that if the final product of a task was practical, more directive supervision was in order; but if the outcome was theoretical, participation was more useful. However, participative leadership needs to have a focus if it is to affect productivity. Lawrence and Smith (1955) studied checkers and mail openers over a five-week period. Groups of each type of employee held participative discussions either about their work or to set the group’s goals. Only the goal-setting groups showed increased productivity, although both types of meetings were equally satisfying to the participants.

The increased productivity of the goal-setting groups was probably connected to the importance attached to the meeting in which the participative leadership occurred. Thus Cosier and Aplin (1980) concluded, from an experiment with 84 undergraduate business students, that having the freedom to choose objectives about a task of prediction was important to them, but having the freedom to schedule the procedure to be used was not. Delegation to them of the choice of objectives yielded a much better performance than assignment of the objectives, but delegation or assignment of the schedule to be followed made no difference to them. Similarly, Drenth and Koopman (1984) reported that among 56 Dutch employees, satisfaction with decisions was enhanced most by opportunities to participate for those employees who were unclear about their goals. For these same employees, however, satisfaction with the outcomes and implementation of the decisions correlated between .26 and .40 if the decisions were about tactical matters of consequence to them. But the parallel correlations ranged from  $-.11$  to  $.13$  if the decisions were about organizational strategies that the employees did not think were of direct consequence to them. This finding lent confidence to arguments by Bass and Shackleton (1979) that participative management should be restricted to decisions that are of direct concern to employees. Consultation with production employees about financial and marketing decisions may make little sense, in contrast to consultations about overtime policies.

When leaders overstep their authority by forcing an arbitrary decision on their groups, the expected resistance and hostility may fail to materialize if the leaders’ behavior actually facilitates the achievement of the groups’ goals. Whether leaders reach their objectives depends on whether the style of leadership they choose meets the needs of their subordinates to attain their goals and whether it clarifies for the subordinates the paths to achieve the goals (House & Mitchell, 1974). Participation may meet subordinates’ needs but may fail to clarify goals without some direction from the leaders.

*Time Perspective.* If the supervisors’ time perspective is short—that is, if they have some immediate objectives to attain—they are likely to find it most effective to be directive. Alternatively, if an important objective is the long-term efficiency of their groups, participation is more likely to pay off (Hahn & Trittippoe, 1961).

### ***Other Contingent Effects***

The passage of time itself may make a difference in the efficacy of early participation. Ivancevich (1976)

demonstrated that over time, the positive effects of involvement in goal setting may dissipate. Employees may become immersed in the job itself and forget their earlier involvement in decisions. It is possible that some individuals in a group may be satisfied with a participative leader and some with a directive leader, although the group as a whole may be more satisfied with participation. Yammarino and Naughton (1992) conducted a Within-and-Between Groups Analysis (WABA) of the responses of 70 officers in a law enforcement agency about the outcomes of their participation in decisions. Included were the director and his lieutenants as well as investigators, patrol officers, and dispatchers. Both the groups and the individuals who reported high levels of participative decision making were those who felt that they had respect and status and were satisfied with their work. But commitment was not affected.

Although research on virtual team leadership is in its infancy, direction or participation may be favored for the same contingent reasons as with face-to-face leadership. For example, directive decisions will be more effective when the leader is expert and the followers are novices. Participation will result in more effective outcomes when the followers are sources of information, knowledge, and experience.

Followers may get bored, weary, and frustrated with continuing participation. The amount of participation by subordinates seems to reach an optimum. If actual participation is greater than expected, R. Likert (1959) noted that dissatisfaction will result. Ivancevich (1979) found that there could be too much as well as too little participation. Performance suffered when participation was above or below optimum. However, e-leadership may benefit from participative leadership. Yukl (1998) pointed out that quantitative studies in which measures of leadership and effective performance were obtained from the same source tended to favor participative leadership as more effective. Evidence is much more modest when different sources are used about the leaders and about their effects. Case studies of participation also tend to be favorable, but plenty of successful, tough, directive leaders who are effective are cited in the popular press.

## Deduced Models for achieving Decision Quality or Subordinate acceptance

---

Among the prescriptive models that indicate when leaders should be directive and when they should be participative, two have been particularly popular—that by Hersey and Blanchard (1977) and that by Vroom and Yetton (1974). Each model details the situations in which practicing managers should be directive and those in which they should be participative to maximize satisfaction and effectiveness. The former model is derived from empirical studies, the latter from more rigorous deduction. The former is supported mainly by observation and commentaries of users and is seen as fuzzy in its prescription and application; the latter is supported (and sometimes refuted) by controlled empirical surveys and experiments. Nevertheless, early on, the Vroom-Yetton model was criticized for its lack of parsimony and its inapplicability to management (Filley, House, & Kerr, 1976). Yet unlike the Hersey-Blanchard model, the Vroom-Yetton model was more intellectually rigorous and lent itself more readily to empirical testing of its validity, although, as shall be seen, it is not without serious flaws. The Vroom-Yetton model is examined in detail here; the Hersey-Blanchard model is discussed extensively in [Chapter 19](#).

### ***Description of the Vroom-Yetton Model***

The leadership decision style that is most conducive to effectiveness in the Vroom-Yetton model depends on the demand characteristics of the situation. Particularly important is whether the leader is aiming for a high-quality decision or for the subordinates' acceptance of the decision. Efforts have been made to show an

adequate correspondence between deductions derived from the model and what can be induced empirically from managers' preferred and actual styles in dealing with problems containing various combinations of the demand characteristics.

*The Direction-Participation Continuum.* Vroom and Yetton (1973, p. 13) laid out the direction-participation continuum as follows:

- AI: You solve problem or make decision yourself using information available to you.
- AII: You obtain necessary information from subordinates, then decide on the solution to the problem yourself. Subordinates are not asked to generate or evaluate alternative solutions.
- CI: You share the problem with relevant subordinates *individually*, getting their ideas and suggestions. Then you make the decision, which may or may not reflect your subordinates' influence.
- CII: You share the problem with your subordinates *as a group*, collectively obtaining their ideas and suggestions. Then you make the decision, which may or may not reflect your subordinates' influence.
- GI: You share the problem with relevant subordinates *individually*. Together you generate and evaluate alternatives and attempt to reach a solution. You do not try to influence the subordinate to adopt "your" solution and you are willing to implement any solution reached.
- GII: You share the problem with your subordinates *as a group*. Together you generate and evaluate alternatives and attempt to reach a solution. You do not try to influence the group to adopt "your" solution, and you are willing to accept and implement any solution which has the support of the entire group.

Thus CI and CII are consultative leadership either with each subordinate alone or all together. Similarly, GI and GII are *participative* either with each subordinate alone or all together. Subsequently, Vroom and Jago (1974, p. 745) added another choice:

- DI: You delegate the problem to one of your subordinates, providing him with any relevant information that you possess, but giving him responsibility for solving the problem by himself. Any solution which the person reaches will receive your support.

The choice of AI is *directive*. AII is also directive and CI and CII are consultative. GI and GII are *participative* and DI is delegative.

*The Situational Demands.* The situational-demand characteristics and the requirements of the problem for the leader depend on whether the answers to the following seven questions are "yes" or "no":

- A. Is there a quality requirement such that one solution is better than another?
- B. Does the leader have sufficient information to make a high-quality decision?
- C. Is the problem structured?
- D. Is the subordinates' acceptance of the decision critical to effective implementation?
- E. If the leader were to make the decision by himself or herself, is it reasonably certain that the decision would be accepted by the subordinates?
- F. Do subordinates share the organizational goals to be obtained in solving this problem?
- G. Is conflict among subordinates likely in preferred solutions?

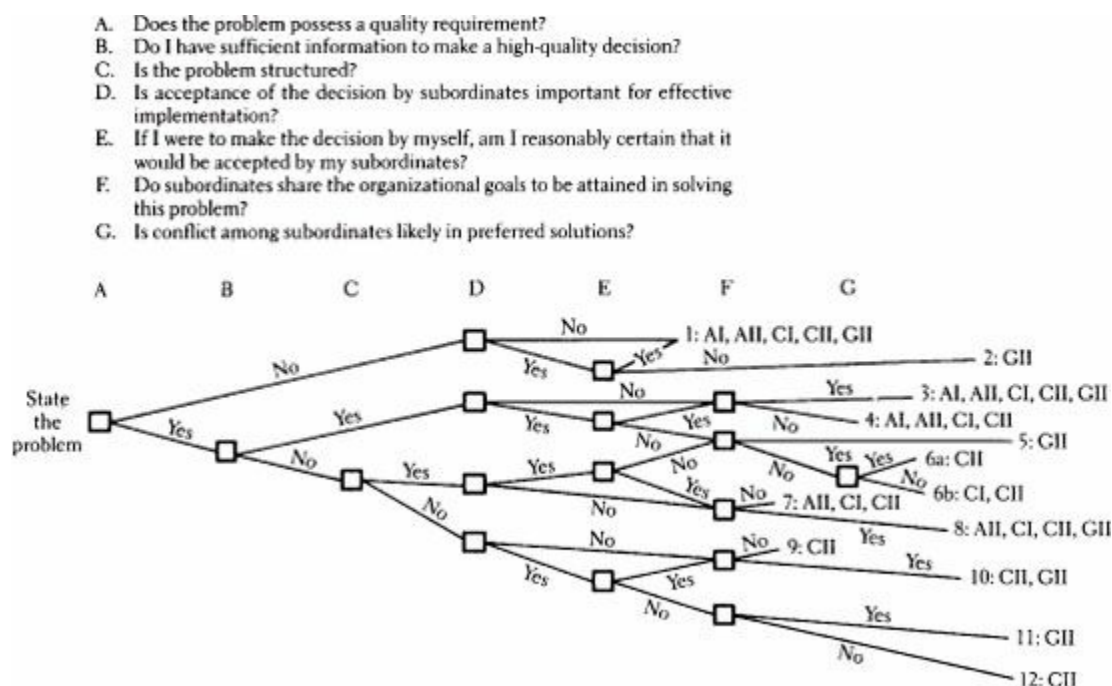

*The Feasible Sets.* Seven rules are imposed to limit various styles of leadership to those feasible sets that can be deduced to protect the quality of the solution and acceptance of the decision: (1) AI is eliminated as a possible choice for the leader when the quality of the solution is important and the leader lacks information; (2) CII is eliminated from the feasible set of leadership styles if quality is important and subordinates do not share organizational goals; (3) AI, AII, and CI are eliminated when quality is important, the leader lacks information, and the problem is unstructured; (4) AI and AII are eliminated from the feasible set if the subordinates' acceptance of the solution is critical; (5) AI, AII, and CI are eliminated (a group approach is necessary to resolve conflicts) if the subordinates' acceptance is critical and subordinates are likely to disagree

about the solution; (6) AI, AII, CI, and CII are eliminated if acceptance but not quality is critical; and (7) AI, AII, CI, and CII are eliminated if acceptance is critical and subordinates share the organization's goals. Shared *participation*, GII, is deduced to be the only suitable leadership style.

Figure 18.1 shows the decision tree that must be followed, given the situational characteristics and the rules for eliminating choices of leadership styles. For example, in this flowchart, if the leader's answer to question A is that the problem does not require a high-quality decision, the leader's next decision is about whether the subordinates' acceptance is important (question D). If a directive decision is seen to be unacceptable (question E), the appropriate style for the leader to choose is GII, *participation* of the leader and all subordinates together in making the decision.

## Development of the Diagnostic Procedure

An initial roster of managers were asked to describe, in writing, a recent problem that they had to solve in carrying out their leadership role. The managers then specified the style (AI, AII, CI, CII, or GII) that came closest to the one they had actually used in dealing with that problem. They described the problem in terms of its quality and its situational-demand characteristics. The diagnosis of the situation determined what styles the leaders used. There was considerable correspondence between what the managers said they had done and what was prescribed by the decision tree (Vroom, 1976) based on Vroom and Yetton's (1973) model.

The problems disclosed by these managers were used to prepare 30 to 54 standardized cases that were then given to several thousand managers to diagnose in terms of the seven questions and to decide which style they would use. Most of the differences in the styles used depended on case differences rather than individual differences among the managers. Vroom and Yetton (1973) concluded that, on the average, managers said they would (or did) use exactly the same decision style as the decision-tree model in about 40% of the situations. In two-thirds of the situations, the managers' behavior was consistent with the feasible set of styles proposed in the model. In other words, in only about one-third of the situations did their behavior violate at least one of the seven rules underlying the model.

Nevertheless, Vroom and Yetton also noted that the model called for more variance in style than the average

manager recalled or proposed. Thus if managers used the model as the basis for choosing their leadership styles, all would become both more directive and more participative. They would use direction more frequently in situations in which their subordinates were unaffected by the decision. They would use participative approaches more frequently when their subordinates' cooperation and support were critical or their subordinates' information and expertise were required.

*Individual versus Group Problems.* The frequency of the choice of process reflects strongly whether the problem concerned the group or its individual members. [Table 18.1](#) shows how 98 managers, military officers, and heads of research departments dealt differently with individual and group problems they faced. With group problems, managers more frequently chose CII and GII; with individual problems, they more frequently chose AI, CI, GI, and DI (Vroom & Jago, 1974). Consistent with the survey research summarized earlier in the chapter (Bass & Valenzi, 1974), the consulting styles CI and CII were the most popular solutions to the various problems presented. But a clear need was evident to distinguish between consulting with one's group or with individual members, depending on whether the problems concerned the group as a whole or particular members.

Vroom (1998) reported that over a 25-year period, there has been a rising choice among managers for the participative processes.

### ***Evidence of Validity***

Evidence to support or refute the validity of the model has been gathered in the field from numerous studies based on self-reports<sup>11</sup> and in the laboratory by Field (1982).

In Vroom and Jago's (1978) study of 96 managers from a variety of organizations who were unaware of the decision-tree model, the managers described 181 situations and their leadership behavior in these situations. The model was then used to predict the ratings of the technical quality, the subordinates' acceptance, and the overall effectiveness of the final leadership styles chosen by the managers. The managers noted the extent to which their chosen leadership style in the situation they described had resulted in a high-quality solution and the subordinates' acceptance. The logical Vroom-Yetton (1973) model and decision tree (Vroom, 1976) came

up with prescribed leadership styles that matched what the managers reported they actually did in 117 (65%) of the 181 situations. Among these 117 situations, 80 (68%) were judged to be effective in the situation and 37 (32%) were judged to be ineffective. In 64 instances, the chosen leadership style was outside Vroom and Yetton's feasible sets for the situation described. In those cases, only 14 (22%) were seen by the managers to be effective leadership behavior and 50 (78%) were seen as ineffective. The more often Vroom and Yetton's seven rules were violated, the solution was regarded as less effective, particularly when the subordinates' acceptance was involved.

Pate and Heiman (1981) reported the results of a survey of 530 mostly female supervisors, middle managers, and top administrators from seven hospitals. Three specially developed problem cases that were generated by the nurses and personnel directors were likely to call for autocratic (A), consultative (C), and delegative styles (D). When the respondents employed the Vroom-Yetton model and decision tree, 71% of their choices were within the model and 29% were outside it. These results were close to those of Vroom and Jago (1978) and Vroom and Yetton (1973).

A field validation was provided by Paul and Ebadi (1989) based on a survey of the job satisfaction and performance of 216 sales employees in a service organization. The leaders who used decision-making styles that agreed with the Vroom-Yetton model had more productive subordinates, and these subordinates were more satisfied with their coworkers.

*Experimental Support.* Field (1979) thought there was a need to examine the validity of the Vroom-Yetton model in circumstances that did not depend on the self-reports of managers. He conducted an experimental test in which 276 business students in four-person groups solved five decision-making problems. However, the students also were instructed to use different decision processes of the model for each problem. This forced more solutions that diverged from the Vroom-Yetton feasible set. Field found that decisions fitting with the Vroom-Yetton feasible set were significantly more effective than decisions outside the feasible set. Of the 105 decisions in which the leader's behavior agreed with the feasible set, 51 (49%) were effective, whereas only 31 of 87 decisions (36%) outside the feasible set were effective. One of three quality rules and three of four acceptance rules had effects as predicted. Pace, Hartley, and Davenport (1992) validated the standardized cases in the Vroom-Jago (1988) scenarios in three laboratory studies. Both leaders and subordinates were aware of the need for situation-specific behaviors. Subordinate evaluations of leader effectiveness were most favorable when leaders made correct use of participative methods.

*Scaling of Participation.* According to Vroom and Yetton's (1973) model, the leadership decision styles could be judgmentally scaled according to the greater opportunities for subordinates to participate and to influence outcomes. The scale that emerged was roughly as follows: AI = 0; AII = 1; CI = 5; CII = 8; GII = 10. Jago (1978a) scored the amount of participativeness by leaders from 0 to 10 in choices of leaders' responses to 72 problems. He found that, as expected, subjects who used a variant of the model displayed less participativeness (4.1) when the leader in a stated problem had all the information required to make a high-quality decision than when he did not (5.9). More participativeness occurred (7.6) when the subordinates' acceptance was required and was not likely to result from an autocratic decision. Less participativeness occurred if such acceptance was likely to result from an autocratic decision (5.0) or when such acceptance was irrelevant (3.3). Also, more participativeness occurred when subordinates expected to share organizational goals (5.8) than when such goal congruence was not expected (4.9).

*Caveat.* Mixed support for the model came from Clement (1983), who found that only the sixth rule—the subordinates' acceptance is more critical than the quality of the decision—contributed significantly to the model's validity. Clement also found that the seventh rule—subordinates share organizational goals—undermined the validity of the model in matching its prescribed leadership behavior with responses chosen by financial executives and managers of nonprofit organizations.

Although Field acknowledged the possibility that subordinates may accept autocratic leadership in dealing

with some of the Vroom-Yetton problems, experimental evidence gathered by Heilman, Cage, Hornstein, and Herschlag (1984) suggested that this may not occur. The latter researchers conducted two experiments in which a leader's reported actions were either correct or incorrect according to the Vroom-Yetton model. Nevertheless, no matter what the circumstances, subjects who took the subordinate's point of view favored a participative solution even when the model prescribed an autocratic one. This finding is consistent with Sinha and Chowdhry's (1981) study, which found that although the Vroom-Yetton and Hersey-Blanchard models prescribe that leaders be more directive with less well-prepared subordinates, such autocratic leadership was detrimental to the group's efficiency and the subordinates' satisfaction.

## ***Alternative Models***

*Model of Randomness.* Pate and Heiman (1981, pp. 8–9) suggested that the level of matching of the model prescriptives with outcomes could have been due to random responding. They advised that

By selecting a style at random it is possible to trace the style backwards through the model and compute the probability that a style will be "within" the model ... When this is done, the following probabilities result: .563 (A1 & A2), .680 (C1), .813 (C2), .750 (D), and .711 (any style). Thus, if a group of people chose any style and answered the decision rule questions blindfolded, 71.1% of their responses would be "within the model."

Wedley and Field (1982) examined the feasible-set choices of 102 undergraduates and 51 managers. However, the different branching that occurred to reach the various options was by no means random. In fact, the students and managers tended to prefer, to a high degree, the same particular branching of the decision tree leading to GII (participation with all subordinates together). This was only one branching among the 23 they could have followed.

*Constructive Controversy.* Tjosvold, Wedley, and Field (1986) proposed that a single concept, *constructive controversy*, could account for the greater effectiveness of the decision making. Constructive controversy encompasses cooperation ("We seek a solution that is good and acceptable to all"), controversy ("Persons express their own views fully"), confirmation ("Persons feel understood and accepted by each other"), collaboration ("We all influence each other"), and differentiation ("All ideas are expressed before we began to evaluate them"). The investigators completed a study of 58 managers who retrospectively examined two previous problems. One decision was decidedly successful; the other was a failure. The managers applied the Vroom-Yetton model and described, on a 15-item questionnaire, how much constructive controversy had occurred in dealing with each of the two problems. Constructive-controversy scores accounted for 45% of the tendency to achieve a successful rather than a failing decision. Only 5% was attributable to the Vroom-Yetton model.

*Model B.* The original model, referred to here as Model A, is "time-driven" (Vroom, 1998). It is predicated on the short-term objective of minimizing the time of the leader and the subordinates. A somewhat different model, Model B, is required if long-term objectives for the subordinates' development are involved. Vroom (1998) now refers to the model as "development-driven." A sample situation in which Model A or B is used is illustrated below with a problem case (paraphrased).

You manage a region for an international consulting firm with a staff of six consultants. One of them is the subject of complaints from several clients that the consultant is not doing an effective job, although the clients are not explicit about what is wrong. For his first four or five years, the consultant's performance was superb. Now he has a "chip on his shoulder" and has lost identification with the firm and its objectives. You need to deal with the problem quickly to retain the client who most recently complained. What should you do?

The decision tree analysis is as follows:

- A. (Quality?) = Yes
- B. (Leader's information?) = No
- C. (Structured?) = No
- D. (Acceptance?) = Yes
- E. (Prior Probability of Acceptance?) = No
- F. (Goal Congruence?) = No

Given the fact that the problem is about an individual, not the group, the synthesized model A and model B solutions are these.

Feasible Set	CI, GI
Model A Behavior	CI (Individual Consultation)
Model B Behavior	GI (Individual Consultation)

*Maier's and Field's Models.* Field (1979) suggested returning to an earlier, simpler fourfold model, developed by Maier (1970b) on the basis of earlier creativity and problem-solving experiments.<sup>12</sup> According to the model, a Type I problem has a quality requirement, acceptance is likely to be obtained easily, and the decision should be made by the leader. Type II problems do not have a quality requirement, but acceptance is critical; therefore, these problems should be resolved by group decision. Type III problems do not have quality or acceptance requirements and should be decided by tossing a coin; participative approaches with this type of problem generate unnecessary conflicts. Type IV problems require both quality and acceptance and are solved by using persuasion or, better yet, by group discussion. Field also noted that in [Figure 18.1](#), the decision CII is in the feasible set for 19 of the 23 situations included in the four types of problems. But in the four situations in which CII is not in the feasible set, GII is in the feasible set. A more parsimonious rule that Field (p. 256) proposed to protect the quality of the decision and the acceptance of subordinates is this: "If acceptance of the decision by subordinates is critical to effective implementation and it is not reasonably certain that subordinates would accept an autocratic decision, but they share organizational goals (or decision quality is not important), use GII; otherwise, use CII." This simple model uses only four situation-demand characteristics instead of seven, and only two leadership styles, CII or GII, instead of the five in the Vroom-Yetton model. Also, this simple model offers a balance between the short-term time-efficient Model A and the long-term group-development model B. Field concluded that what needs to be prescribed is either consultation with the group of subordinates or shared participatory leadership with the group, unless it is certain that a directive decision would be acceptable to subordinates.

Jago and Vroom (1980) ran a comparative test of the Vroom-Yetton prescriptions with those of Field (1979) as well as those of Maier (1970b). For each prescription, the actual reported behavior of 96 managers dealing with 181 cases was collected. Sixty-five percent conformed to the Vroom-Yetton model, 79% conformed to Maier's prescriptions, but only 33% conformed to Field's. Of the 117 decisions that conformed to the Vroom-Yetton model, 80% fit Maier's model and 50% fit Field's. Furthermore, the Vroom-Yetton model provided more predictive power of effectiveness, quality, and acceptance of the decision by subordinates beyond what Maier's and Field's prescriptions did. Jago and Vroom (p. 354) concluded that although Field's

formulation guarantees conformity to the Vroom-Yetton prescriptions, yet his rules presumably are easier to learn and apply because they involve fewer situational variables and fewer normative contingencies. However, the apparent attractiveness may be misleading. The behavior of untrained managers violates Field's prescriptions substantially more often than such behavior violates the prescriptions of either Maier's model or the Vroom/Yetton model. Because its highly participative prescriptions represent a large departure from the decision-making style of most managers, implementing Field's model would require some rather dramatic behavioral changes that may meet with some

resistance. Although its prescriptions are indeed easy to learn, Field's model may be quite difficult for some managers to internalize and practice. On the other hand, the Vroom/Yetton model may be more difficult to learn initially but more easily internalized and implemented.

### ***Individual versus Situational Differences***

Another issue that has been looked at extensively is how much the Vroom-Yetton situational requirements determine which choices of leadership style will be made and how much individual differences arise. For instance, will authoritarians be autocratic in choosing a response to any Vroom-Yetton problem, regardless of the prescriptive rules and the nature of the problem? Vroom and Yetton (1973), Hill and Schmitt (1977), and Clement (1983) all demonstrated that situational main effects accounted for almost half the variance in choices, whereas individual differences were likely to account for less than 15% of the results. In dealing with problems about groups, 35% of the decisions were determined by the situation and 12% were due to individual differences in the preferences of the managers. In dealing with problems about individuals, 44% were due to situational elements and 9% to consistent individual differences among the managers (Vroom & Jago, 1974). Vroom and Yetton thought that these results suggested the need to talk more about autocratic and participative situations, rather than autocratic and participative persons. However, Jago (1978b) concluded, from an analysis of differences among managers in the rules they used, that there was a need to focus on autocratic versus participative decision-making rules. Furthermore, Jago's results indicated that the decision maker cannot be fully represented as a linear processor who handles the rules in a simple additive fashion. Rather, the decision maker's choices interact, to some degree, so that a more complex configuration may provide a better portrait.

*Vroom-Jago Model.* Vroom (1984) summed up some of the strengths and weaknesses of the model's fit with actualities. Generally, the model was supported by consistencies between decision-making styles and superiors' and subordinates' perceptions of decision-making requirements based on characteristics of the decision process. Nevertheless, he pointed to several deficiencies for practical application, owing to the simplicity in defining the variables that influence the decision-making process. Along with developing a differentiation for the group and individual problems faced by a manager (Vroom & Jago, 1974) and to take account of the failure of the original model to consider the importance of subordinates' knowledge, external influences outside the immediate work group, and the matter of time constraints, Vroom and Jago (1984) added the following questions to a determination of the feasible sets.

H. Do subordinates have sufficient information to make a high-quality decision?

I. Does a severe time constraint limit your ability to involve subordinates?

J. Are the costs involved in bringing together geographically dispersed subordinates prohibitive?

According to a simulational analysis by Vroom and Jago (1984), the subordinates' knowledge, lack of time constraints, or lack of geographic dispersion greatly increased the expanded model's prescription for participative rather than directive leadership.

Vroom and Jago (1988) created a new model with considerably greater validity than the original Vroom-Yetton model by adding a number of objectives, such as cost reduction, that could be sought by the leader. Further, five-point ratings were substituted for the yes/no responses. Multiple regression replaced deductions of the feasible sets. Effectiveness and commitment were introduced as alternative outcomes that might be sought by the leader. Also, they created conditions to encourage reflection on past decisions.

## **Summary and Conclusions**

Decisions are made by the superior, the subordinate, or both. Conceptual distinctions can be clearly maintained between *direction*, negotiation, *participation*, and delegation. But empirically, most leaders exhibit all these modes with different patterns of frequency. Many antecedent conditions add to the variance found in these patterns. Participative leadership works best when the subordinates' acceptance, satisfaction, and commitment are important and when subordinates have the required information. But directive leadership can also be effective, especially when structure is needed, when the leader (but not the followers) has the necessary information, and when the quality of the decision is more important than the commitment of the followers. Leaders will increase their delegative tendencies if they have confidence in their subordinates' competence. Empirical and rational models are available for specifying the conditions under which either more direction or more participation is appropriate. Direction may often work as well as or better than participation in short-term laboratory studies, but greater payoff from participative leadership appears in the field for longer-term relations and outcomes, although the effects are small when subjected to meta-analyses. Whether the leader, the led, or both will decide is affected by the importance of the relations among them and by what needs to be done, as will be seen next.

<sup>1</sup> This has been discussed in [Chapter 6](#) as laissez-faire leadership.

### Task versus Relations Orientation

Most executives who make it to the top of their organizations are highly task-oriented. But many are also inclined to be concerned with their relationships. Ten CEOs and managing directors of divisions in a large, multinational firm were identified by a group of senior executives at the firm's headquarters. Vansina (1982) carried out a qualitative description of the 10 leaders using semistructured taped interviews that were subsequently content-analyzed. The 10 leaders were selected for their consistently "excellent performance in different business situations in different parts of the world" (p. 2). Vansina inferred that the leaders worked through people for whom they cared. They wanted to create an operating climate in which employees at every level in their organization knew what they were working for and what tasks needed to be done. Concerns about tasks and relationships were to be met by providing members with the appropriate means, authority, knowledge, and resources. The leaders had a keen interest in spotting and developing young talent and a low tolerance for poor performers. To establish organizational commitment, they saw their need to develop personal and professional relationships and collaboration through personal example, consultation, and removal of obstructions and incompetent people. They kept actions simple and followed them up to monitor progress. They carefully managed the linkages between headquarters and key persons, and between business objectives and social responsibilities. They were self-confident, responsible, and open-minded. They learned the local language and had direct contact with employees.

Concern for task and relations was illustrated by Andrew Grove, CEO of Intel, known for his innovation in the design and manufacture of computer chips. His egalitarianism came from his escape from Hungary during the Nazi occupation. For him, America was symbolized by respect for intellect and for others as human beings. The culture of Intel he initiated combined informality in relationships, high standards, and hard work (Tolkoff, 1998). Also equally concerned about tasks and relationships, Robert E. Wood changed Sears from solely a mail-order business into a chain of retail stores with a strategy of meeting customer needs, buying to specification, building good relations with suppliers, and creating an image of each store as local rather than as part of a chain. He instituted a radically different hierarchy for a large organization. There were only five echelons between the salesclerk and the CEO. His belief in decentralization was buttressed by the need for employees and managers to grow and learn from their mistakes (Worthy, 1984).

### Task, Relations, and Change Orientation

---

Leaders differ from each other in their focus of attention. Some focus more on the task to be accomplished, others more on the quality of their relations with others (Blank, Weitzel, & Green, 1990), and still others more on change. Bergan (1986) observed leaders concentrating on their group's working methods or on mutual trust building. Ekvall and Arvonen (1991) added that leaders may also concentrate on making changes. Effective leaders do any of these things, or all three. For instance, when Berkowitz (1953a) asked members of air crews to describe their commander with a behavioral description inventory, a factor analysis of the results revealed factors concerned with both task and relationships, including maintaining standards of performance, acting on an awareness of situational needs, maintaining coordination and teamwork, and behaving in a nurturant manner. The conceptualizations may be universal. Thus Shenkar, Ronen, Shefy, et al. (1998)

reported that the Chinese manager's role could be partly accounted for by attention to task-related and relations-oriented activities.

### ***Task-Oriented Leadership***

Task-oriented leaders differ in their concern for their groups' goals and the means to achieve the goals. They engage more in task roles (Bass, 1967b; Fiedler, 1967a). They are more concerned with production (Blake & Mouton, 1964) and need for achievement (McClelland, 1961; Wofford, 1970). They are identified as achievement oriented (Indvik, 1986b), production oriented (Katz, Maccoby, & Morse, 1950), production-emphasizing (Fleishman, 1957a), goal achieving (Cartwright & Zander, 1960), work facilitative, goal emphasizing (Bowers & Seashore, 1966), performance planning and performance pressuring (Misumi, 1985; Peterson, Smith, & Tayeb, 1993). The leaders' assumptions about their roles, purposes, and behavior reflect their interest in completing assignments and getting the work done. A high task orientation underlies selected types of leaders, such as Birnbrauer and Tyson's (1984) hard driver and persuader or Reddin's (1977) autocrat. Purely task-oriented leaders are likely to keep their distance psychologically from their followers and to be more cold and aloof (Blau & Scott, 1962). When coupled with an inability to trust subordinates, their concern for production is likely to manifest itself in close, controlling supervision (McGregor, 1960). Successful task-oriented leaders are instrumental in contributing to their groups' effectiveness by setting goals, allocating labor, and enforcing sanctions (Bales, 1958a). They initiate structure for their followers (Hemp-hill, 1950a), define the roles of others, explain what to do and why, establish well-defined patterns of organization and channels of communication, and determine how to accomplish assignments (Hersey & Blanchard, 1981). [Chapter 18](#) provided illustrations of executives—Jack Welch and Lou Gerstner—who were highly task-oriented and less concerned about interpersonal relationships.

*Conceptions.* Task-oriented leadership can be a source of expert advice and challenging motivation for subordinates. Misumi (1985) conceived of task-oriented leadership behavior as performance leadership—behavior that prompts and motivates the group's achievement of goals. For example, when deadlines are necessary, the leader clearly specifies them and has a good grasp of how work is progressing. According to Cleveland (1980), such a focus on the task is seen in strategic thinking, in projecting patterns of collective behavior, and in considering the whole situation. It is also seen in the leader's manifest curiosity about issues and methods and the system that can connect people and things to achieve objectives. Akin and Hopelain (1986) described a "culture of productivity" in three highly productive organizations. Immediate supervision, combined with management as a whole, can foster a shared image of a highly productive work setting in which supervisors, managers, and workers alike focus on the work being done and how to maintain successful operations.

*Purposes.* Yukl (1994) proposed five purposes of task-oriented leader behavior: (1) to propose an objective, introduce a procedure, present an agenda, and redirect attention to the task; (2) to stimulate communication, seek specific information, or encourage the introduction of new ideas; (3) to clarify communication, reduce confusion, ask for interpretations, and show how different ideas are related; (4) to summarize accomplishments, to review or ask for reviews; and (5) to test for consensus about objectives, interpretations, evaluations, and readiness for decisions.

*Caveat.* Although the various conceptualizations of task orientation have similar-sounding labels, their inter-correlations are not necessarily high. In fact, they may point to different attributes of an individual. Thus the direct assessment of the task orientation of 81 Polish industrial personnel—using the Orientation Inventory (ORI), which directly asks examinees for their preferred activities—correlated only .32 with the need for achievement as measured by the Thematic Apperception Test, an assessment of the projected fantasies of

the same examinees (Dobruszek, 1967). Similarly, Fiedler's (1967a) determination of task orientation, based on the leaders' rejection of the coworker with whom they found it most difficult to work, did not correlate as highly with other approaches to measuring task orientation. (In fact, the least preferred coworker, or LPC, measure seems so unlike any other that it will be treated separately in this chapter.) Thus it is necessary to review results in the light of variations that are due to how task orientation and relations orientation are measured.

### ***Relations-Oriented Leadership***

*Concept.* Relations-oriented leadership is expressing concern for others, attempting to reduce emotional conflicts, harmonizing relations among others, and regulating participation (Yukl, 1994). Relations-oriented leadership is likely to contribute to the development of followers and to more mature relationships.

Leaders differ in the extent to which they pursue a human relations approach and try to maintain friendly, supportive relations with their followers. They are identified as relations-oriented (Katz, Maccoby, & Morse, 1950), concerned for maintenance (Misumi, 1985) or group maintenance (Cartwright & Zander, 1960; Wofford, 1970), concerned for people (Blake & Mouton, 1964), people centered (D. R. Anderson, 1974), interaction facilitative and supportive (Bowers & Seashore, 1966), interaction oriented (Bass, 1967b), employee emphasizing (Fleishman, 1957a), and in need for affiliation (McClelland, 1961). Such leaders are expressive and tend to establish social and emotional ties (Bales, 1958a). Dansereau and Yammarino (2002) have used the term *individualized leadership* to describe relations among leaders and subordinates that reflect an exchange of leader support for subordinates' feelings of self-worth and the subordinates' satisfactory performance. The relationship is revealed in the extent the leaders relate similarly or differently to each of their subordinates in the component of individual differences in WABA analysis. Dasborough and Ashkanasy (2003) suggest that leaders can shape affective events by positive uplifts or negative hassles. The negative hassles are more likely to be recalled by subordinates. Usually associated with a positive relations orientation are the leader's sense of trust in subordinates, less felt need to control them, and more general rather than close supervision of them (McGregor, 1960).

A strong relations orientation is the basis of Reddin's (1977) "missionary" and "developer" types of leader. Relations-oriented leadership is associated with consideration for the welfare of subordinates (Hemphill, 1950a). For Hersey and Blanchard (1982a, b), it is linked to relationship behavior: maintaining personal relationships, opening channels of communication, and delegating to give subordinates opportunities to use their potential. It is characterized by involved support, friendship, and mutual trust. It is leadership that is likely to be more democratic and employee-oriented rather than autocratic and production-oriented. Misumi (1985, p. 11) saw it as maintenance-oriented leadership behavior "directed toward dispelling excessive tensions that arise in interpersonal relations within a group or organization, promoting the resolution of conflict and strife, giving encouragement and support, providing an opportunity for minority opinions to be expressed, inspiring personal need fulfillment and promoting an acceptance of interdependence among group members."

Relations-oriented supervision is seen in the communication patterns of supervisors and subordinates. Kirmeyer and Lin (1987) arranged for observers to record an average of 107 face-to-face interactions with the supervisors of 60 randomly chosen police radio dispatchers. Communications with the dispatchers' supervisors were facilitated if the dispatchers felt they were receiving social support from their superiors. Felt support correlated .33 with the dispatchers' communications about work to their superior and .48 with communications to their superiors about other matters. It correlated .55 and .26 with observed face-to-face communications from the superiors to the dispatchers about work and nonwork matters.

*Quality of Relations.* Kottke and Sharafinski (1988) and Hutchison (1997) defined the quality of the

relations of employees with their immediate supervisor according to how much the employees felt that their supervisors supported and cared about them. It was correlated with the quality of leader-member exchange (LMX) but could be distinguished from LMX, and from perceived organizational support. However, a Belgian-French study of 293 university alumni respondents found a correlation of .55 between perceived supervisory and perceived organizational support (Stinglhamber & Vandenberghe, 2001). A similar positive correlation was found between enacted supervisory and environmental support by Slack, Etchegary, Jones, et al. (2002). A high quality of relations might be found in self-sacrificing leadership (Choi & Mai-Dalton, 1999).

*Organizational Systems.* The concern for relations is manifest in different ways with different organizational systems. Such concern and effort are involved in shifting organizations from autocratic systems 1 and 2 to democratic systems 3 and 4 (Likert, 1977b) and in contributing to industrial democracy and participative management.<sup>1</sup> The concern for relations is central to humanistic management (Daley, 1986), which is dedicated to promoting the personal significance of work, the autonomy of employees, and fairness in appraisals. In Taiwan, it is seen as a matter of doing favors. It is seen in Britain with Theory P, a deemphasis of traditional management-employee relationships in favor of management's increased awareness of employees' needs, increased involvement in the community, and increased use of consultation (Jaap, 1982). It is seen in Japanese management and Theory Z, with its emphasis on long-term employment, unhurried evaluation and promotion processes, wide-ranging career opportunities, and consensual decision making. Theory Z leadership beliefs represent a mix of task direction and relations orientation; generating commitment, loyalty, and involvement in the organization; and treating followers as members of a family (Ouchi, 1981).

*Examples: Relations-Oriented Executives.* Herb Kelleher was credited by Wall Street analysts as the major reason for Southwest's continuing profitability after the first two years of business. Southwest often generated larger earnings than any of its competitors, which as of 2005 had registered increasing losses or gone bankrupt. Kelleher was a cofounder of the airline in 1971 and introduced low-priced, frequent point-to-point service instead of the hub-and-spoke service of the major airlines. He used a fleet of one type of aircraft, the Boeing 737, instead of the many types found among his competitors. His cost per available seat mile, employees per aircraft, and employees per passenger were as low as 50% to 75% of his competitors'. But he also ensured employees' and customers' satisfaction. In addition to providing employees with 15% of the net profits and matching up to 100% of individual employee contributions to their 401(k) retirement plans, his unusually good labor-management relations and his unusually friendly personality resulted in strong loyalty to the company. Employees were willing to do whatever was needed. (I was surprised, at a stop on my first trip on Southwest, to see the flight attendants cleaning up the aircraft cabin.) Pilots might help out as ticket agents, and ticket agents as baggage carriers. Individualized consideration, kindness, and spirit were nurtured. Recruits were selected for their sense of humor. "Employees are our most important resource" may be a cliché, but it is a major principle at Southwest. Kelleher is like the very funny father of a family and the center of formal and informal festivities (Labich, 1994).

Ben Cohen and Jerry Greenfield, founders of successful Ben and Jerry's, were extremely egalitarian and focused on the human side of the enterprise, with a strong sense of social responsibility. Before selling their homemade ice cream company, they ran it like a human service agency. They practiced walk-around management and had fun with their employees and at their annual meetings. They formed a committee to put more joy into employees' work and decrease stress. They created an organizational culture of charity, goodwill, and respect for the community and kept their top salaries to five times the lowest employee base pay (Levine, 1988; Severance, 1988).

Other CEOs have showed that they cared about their employees in a variety of ways. Jack Stack of Springfield ReManufacturing emphasized teaching employees the financial aspects of the business. Patricia Gallup of PC Connection nurtured her more than 800 employees and interacted directly with them by e-mail.

Mary Kay Ash of Mary Kay, Inc. felt she had compassion for her people and viewed them as more important than the bottom line.

### ***The Need for Both Task and Relations Orientation***

Blake and Mouton (1964), Cleveland (1980), and many others have strongly advocated leadership that integrates both task orientation and relations orientation. Leaders have to be strong and decisive, yet sensitive to people (Calloway, 1985). Blake and Mouton (1964) argued that maximum leadership effectiveness occurs only when the leader is highly concerned for both production and for people and integrates the human and task requirements of the job. The exclusively task-oriented manager is seen to treat employees as machines, to the detriment of their commitment, growth, and morale. The exclusively people-oriented manager is viewed as running a “country club,” to the detriment of productivity.<sup>2</sup>

Leaders exhibit both task and relations orientation. Kaiser and Kaplan (2001) reported that although 46% of managers they sampled in their consulting work were highly task oriented and 19% were highly relations oriented, 6% were versatile in that they displayed just the right amount of both task and relations orientation. The remaining 30% were disengaged (*laissez-faire*). Further complicating matters are the “switch-hitters.” The autocratic leader is likely to be directive and caught up with getting the work done and the democratic leader is likely to be participative and concerned about maintaining relationships; nevertheless, some benevolent autocrats, who pursue a patronizing leadership style, are still likely to be concerned about their relationships and the needs of their followers. Likewise, highly task-oriented democratic leaders may encourage participation in decision making for the sake of reaching high-quality decisions. Presumably, they would be characterized as R. Likert’s (1977b) System 4 leaders.

### ***Change-Oriented Leadership***

Given the increased efforts required to keep up with rapid technological, societal, and market changes, Mintzberg and James (1985) suggested that leaders needed to have an “umbrella” strategy, concerned with getting new ideas accepted and implemented. Morgan (1986) proposed that it was important to focus on challenging constraints. Ekvall (1988) in Sweden and Lindell (1989) in Finland revealed an orientation toward change that they found factorially independent of task and relations orientation (Ekvall & Arvonen, 1989). The change-oriented leader was interested in innovation, creativity, new ways to accomplish old tasks, and new ways to relate to others. The change-oriented leader engaged in Argyris’s (1982) double-loop learning and attention to feedback. In a Swedish factor study of 502 respondents in four manufacturing and five service firms, Lindell and Rosenqvist (un-dated) were able to confirm a three-factor model for 502 respondents to a 36-item questionnaire about their superiors’ behavior and orientation to task, relations, and change. In a sample of 711 mainly middle managers attending management training centers in Sweden, Finland, and the United States who each described their boss, Ekvall and Arvonen (1991) extracted three ortho-gonal factors: change-centered, employee-centered, and production-centered. (Nationality was inconsequential.) The change-centered boss was rated as a promoter of change and growth (pushes for growth; initiates new projects), had a creative attitude (saw possibilities rather than problems, offered ideas, encouraged thinking about new and creative ways and tried them), was a risk taker and was particularly willing to take risks in decisions, made quick decisions when necessary, and was visionary—engendering thoughts and plans about the future.

*Relationship of Change Orientation to Concern for Task and Relation.* As noted earlier, leaders may emphasize both task and relationships or neither. Observers can accurately discriminate among the ratings for emerging task and socioemotional leadership earned by interacting members of experimental task groups

(Stein, Geis, & Damarin, 1973). Hermigar and Taylor (1980) found that the assessed receptivity to change of 80 middle-management administrators of public schools was high if the administrators were either highly concerned for people or highly concerned for productivity. But a lack of concern for either was connected with a lack of openness to change. Experience in leading change affected orientation. Tullett (1995) noted that 133 managers in charge of change projects in Britain were more likely to be innovative in their score on the Kirton Adaptation-Innovation Inventory than managers in general.

## Antecedents of Task-, Relations-, and Change-Oriented Leadership

---

As with the tendencies toward and preferences for direction or participation, task, relations, and change orientation tend to depend on the leader's personal characteristics as well as situational contingencies. These contingencies include the characteristics of the follower, the organization, the task, the goals, and the constraints.

### ***Personal Antecedents***

Along with Bales (1958a) and Etzioni (1965), Downton (1973) surmised that *instrumental* (task-oriented) and *expressive* (relations-oriented) modes of leadership are assumed by individuals with different temperaments. Instrumental leaders are seen to be more aggressive, more able to tolerate hostility, and more anxious to be respected. Expressive leaders are more accommodating, less able to tolerate hostility, and more anxious to be loved. A variety of surveys and experiments demonstrated this linkage of personality to leadership orientation. For instance, Klebanoff (1976) used observers' and peers' rankings of the task- or relations-oriented behavior displayed by 160 participants in 40 small groups working on various tasks. Task-oriented leaders were more likely to have been firstborn children; they felt more personal autonomy and tended to be more actively involved. Menon (2003) found that among 370 managers, those who were more task-focused, goal-oriented, and persistent despite difficulties or distractions were more satisfied with their jobs. Task-focused students were more conscientious and emotionally stable and less hesitant and preoccupied. Konovsky (1986) analyzed the extent to which supervisors of 484 hospital subordinates were seen by their subordinates as providing emotional support and as helping to solve the subordinates' problems. Supervisors offering such support and assistance also scored higher in personal competence, sociability, emotionality, and altruism.

Helmich and Erzen (1975) surveyed 108 corporation presidents and found that task-oriented leaders lacked fulfillment as presidents. The needs of relations-oriented presidents were better met by their assignment. According to a study of 194 employees in a human service organization, persistence at tasks was greater if the employees perceived themselves to be self-efficacious (Seltzer & Miller, 1990). Bolino, Turnley, and Bloodgood (2002) argued that employees' favorable attitudes toward organizational citizenship provided organizations with social capital that contributed to better relationships and better performance.

*The Orientation Inventory (ORI)*. Preferences of highly task-oriented examinees on the ORI (Bass, 1962c) included to be wise; to have the feeling of a job well done; to have bright, interesting friends; and to be a leader who gets things done. For interaction-oriented (relations-oriented) examinees, preferences included to have fun with friends, to have helpful friends, to work cooperatively, to make more friends, and to be a leader who was easy to talk to. According to scores on various personality inventories, personal factors significantly correlated with task orientation, as assessed by the ORI, included being more highly self-sufficient, resourceful,

controlled in willpower, aloof, not sociable, sober-serious, tough-realistic, and aggressive-competitive (Bass & Duntzman, 1963). Task-oriented leaders were more likely to show more restraint, ascendance, masculinity, objectivity, thoughtfulness, endurance, need for achievement, and heterosexuality (Bass, 1967b).

Task orientation as assessed by the ORI was higher among men than among women and among those with greater maturity, education, status, and technical training. Task-oriented students were more likely to volunteer and to persist at tasks voluntarily until the tasks were completed (Frye & Spruill, 1965). They were self-reinforcers (Marston, 1964) and more likely to be seen as helpful to others in sensitivity training groups (Bass & Duntzman, 1963). In a Polish study, task orientation on the ORI was found to correlate positively as high as .41 with intelligence, as measured by a Polish version of the Army General Classification Test. Interaction (relations) orientation correlated negatively as low as  $-.32$  with tested intelligence (Dobruszek, 1967). Relations orientation was higher among examinees who, according to various personality inventories, were warm, sociable, in need of affiliation, and dependent on the group (Bass & Duntzman, 1963). Relations orientation was also correlated with wanting to be controlled by others, to be close to others, to receive affection from others, to include others, and to be included with others (Bass, 1967b).

*Immutable Conditions?* These personal factors, seldom mentioned in the prescriptive literature of the past two decades, call attention to Fiedler's (1967a) argument that one often needs to find or change the situations to fit the leader's personality. These personal factors make managers and administrators skeptical about the possibilities of training and developing leaders to be both relations and task oriented and about those who say they already are. Nevertheless, the correlations of task and relations orientation with personality and intelligence are modest. Much can be changed in leadership orientation and behavior through learning, role modeling, and experience, reinforced by socialization processes and organizational culture.<sup>3</sup>

### ***Situational Antecedents***

Leaders will be more concerned about the task when their superiors want them to remain focused on it. Managers who are under the gun to produce immediate results are more likely to be task oriented and less likely to devote time and energy to their relationships. Brady and Helmich (1982) found, in a survey of chief executive officers (CEOs) and their boards of directors, that the CEOs were more task oriented than relations oriented if their boards were made up of outsiders. The reverse was true if the boards were composed of insiders. Relations-oriented leaders are likely to emerge when leaders are more attentive to pleasing their followers than their superiors and, by definition, when they are more concerned about the needs of their followers.

In utilitarian hierarchies, organizational level makes a difference in orientation. For 6,434 subordinates in 13 countries describing their superiors, change orientation was most prevalent at the top and production orientation was most common at the bottom; relations orientation was about the same at both echelons (Arvonen, 1992). Nevertheless, senior managers seriously underestimate how much they are distrusted by lower-level employees (Howard & Wellins, 1994). Relations orientation is to be expected in communal organizations, such as the Israeli kibbutzim, whose espoused beliefs emphasize providing for members according to their needs. Socioeconomic differences between communities of workers are also likely to be of consequence. Thus Blood and Hulin (1967) reported that workers in communities in which one would expect adherence to middle-class norms (for example, small suburban communities) tended to favor a human relations style of supervision. Strong organizational policies supporting either a relations or a task orientation (or both) particularly coincide with a top management that provides role models for lower management and engenders task, relations, or change orientations among the individual managers and supervisors. Also, the leaders' orientation is likely to be affected by those below them.

*Subordinates and Their Performance.* Earlier chapters noted that poor performance by subordinates appears to cause much of the observed punitiveness of leaders. But good performance by subordinates appears to increase leaders' tendency to be relations oriented. In a study of routine clerical workers and their supervisors at a life insurance company, Katz, Maccoby, and Morse (1950) found that supervisors of high-producing sections were significantly more likely to be employee oriented than production-oriented. Barrow (1975) showed that increasing the performance of subordinates in a laboratory setting resulted in the leader becoming significantly more supportive. Decreasing the subordinates' performance caused the leader to become more task-oriented. This finding is consistent with Bass, Binder, and Breed's (1967) findings about the performance of a simulated organization (discussed below).

Farris and Lim (1969) showed that if the performance of groups was good in the past, the groups' leaders subsequently tended to be more relations-oriented. The leaders were more sensitive to the needs and feelings of the members and had more trust and confidence in the members. These leaders allowed members more freedom and autonomy in their work. Members were encouraged to speak out and were listened to with respect. The leaders gave recognition for good work, communicated clearly, stressed pride in the group, and emphasized teamwork. The leaders of high-performing groups were also more task oriented than were the leaders of low-performing groups, in that they maintained high performance standards without being punitive. They were less likely than the leaders of low-performing groups to be critical of their groups' performance and less likely to exert unreasonable pressure for better performance.

Jones, James, and Bruni (1975) could not separate cause and effect in a study of 112 engineering employees. But the results suggest the followers' influence on their leader's orientation and behavior, although the reverse possibility is also tenable.<sup>4</sup> Jones, James, and Bruni obtained correlations of from .41 to .55 between employees' confidence and trust in their supervisors and the extent to which their supervisors were seen as high in support, emphasis on goals, facilitation of work, and facilitation of interaction. As was noted in [Chapter 7](#), Sanford (1951) found, in a survey of Philadelphia residents, that egalitarians wanted leaders who were warm and generally supportive, but authoritarians preferred leaders who would serve their special interests. Indirectly, one may infer that more relations-oriented leadership would be demanded by highly self-oriented followers, by followers with personal problems, by followers in need of nurturance, and by followers seeking affection. As will be detailed later, the "psychological and job maturity" of subordinates dominates the Hersey-Blanchard (1977, 1981) prescriptions for determining whether leaders should be relations or task oriented or both in their behavior toward subordinates.

*Prior Effectiveness of the Organization.* Commonly observed as well as deplored (see, for instance, R. Likert, 1977b) is the extent to which human relations concerns are abandoned when an enterprise's profits are seriously eroded. In such situations, akin to a stress response, task orientation is increased at the expense of relations orientation. Bass, Binder, and Breed (1967) demonstrated this phenomenon in a simulated budgeting exercise. The concern of decision makers for the satisfaction and well-being of employees and their willingness to accept more employee-centered solutions to problems in the areas of safety, labor relations, and management development were strongly influenced by whether the company had just finished a profitable year. In this exercise, MBA students were given one of three firms' year-end profit-and-loss statements. One firm showed a net loss of \$86,000; the second firm's statement showed that moderate profits had been earned; the third firm reported large profits. Three-quarters of the students in the profitable circumstances recommended buying safety equipment. Only half of the students in the moderately profitable enterprise and only 25% of those in the firm that lost money were willing to spend the required funds to settle a strike quickly. The goals emphasized in the most profitable situation were the welfare, goodwill, and satisfactory operations of employees. The goals stressed in the firm that had experienced a loss were meeting competition and raising profits.

# General Consequences of Relations-Oriented, Task-Oriented, and Change-Oriented Leadership

---

Three kinds of evidence are available: (1) the extent to which relations-oriented and task-oriented leaders are seen to be more or less meritorious by others; (2) the differential impact of these orientations on the satisfaction of subordinates; and (3) the differential effects of these orientations on the performance of groups. Care must be maintained about the validity of the evidence. Consistently, one sees managers who describe themselves as both more task oriented and more relations oriented than their subordinates perceive them to be (see, for example, Rees & O'Karma, 1980).

## *Evaluations as a Leader*

Reports on correlations of evaluations as a leader and relations or task orientation have generally found both orientations to be of positive importance. Followers' values affected the extent to which they favored leaders of one kind or another. Ehrhart and Klein (2001) reported that employees who were more interested in extrinsic rewards for performance favored more relations-oriented supervisors whereas employees who preferred more structure and security in their work favored more task-oriented supervisors. Mathieu (1990) found that among 298 ROTC cadets, those high in need for achievement preferred instrumental (task-oriented) leadership; those low in need for achievement preferred relations-oriented leadership.

*Relations Orientation.* Shartle (1934) used interviews and questionnaires in a comparative study of supervisors who were rated as either effective or ineffective. Effective supervisors did not differ from their ineffective peers in technical skills, but they were found to excel in their ability to interact effectively and in their interest in people. Similarly, Katzell, Barrett, Vann, and Hogan (1968) found that executives whose roles emphasized administrative, rather than technical, performance received higher performance ratings from their superiors.

Mann and Dent (1954b) studied supervisors who were rated for promotability by higher-level managers. Highly promotable supervisors were described by their employees as being good at handling people; approachable; willing to go to bat for employees; letting the employees know where they stand; pulling for both the company and the workers, rather than just for one or the other; and using general, rather than close, supervision. In turn, the highly promotable supervisors saw their own superiors as being good at handling people, letting the supervisors know where they stood, and permitting the supervisors the freedom to make decisions.

H. H. Meyer (1951) observed that effective supervisors regarded others as individuals with motives, feelings, and goals of their own and did not avoid interactional stress. Similarly, Kay and Meyer (1962), using both questionnaire and observational methods, found that higher-rated foremen were less production oriented and gave general, rather than close, supervision. Likewise, Walker, Guest, and Turner (1956) observed that effective supervisors established personal relationships with employees, stuck up for them, and absorbed pressure from higher levels of authority. A. N. Turner (1954) reported that workers regarded supervisors as good if the supervisors did not pressure their subordinates unnecessarily; were fair, friendly, and understanding; and did not tell subordinates to quit if they did not like the conditions.

Among the 17 Americans on the 1963 Mount Everest expedition, all of whom were highly task oriented, those who were most interaction oriented and highest on FIRO-B (Fundamental Interpersonal Relations Orientation-Behavior) expressed inclusion were rated highest in leadership. Lester (1965, p. 45) noted,

The results pointed to the importance ... of being emotionally responsive, affectionate and warm,

inviting in manner, or placing primary value on the emotional give-and-take in face-to-face relations. The men reacted negatively to emotional constriction, to too much emphasis on method, efficiency, productivity, and the imposition of high impersonal standards.

However, when interaction-orientation scores are high at the expense of task-orientation scores—as when *ipsative scoring*<sup>5</sup> is used—task orientation, rather than interaction or relations orientation, is likely to correlate with merit as a leader.

*Task Orientation.* Rubenowitz (1962) reported that job-oriented supervisors were regarded by higher management as more effective than person-oriented supervisors. Shortly afterward, Kelly (1964) found that the technical features of executives' behavior outweighed the effects of personal style.

According to Duntzman (1966), task orientation, as measured by the ORI, correlated with promotability ratings based on three days of assessment of 96 supervisors (but correlations were negative among the younger, temporary supervisors and the journeymen who were so assessed). For both 66 first-level and 27 second-level supervisors, task orientation significantly contributed to their high on-the-job performance ratings by their supervisors (Duntzman & Bass, 1963). Rutherford (1984) reviewed studies of the success of elementary school principals. In attempts to implement new programs or to improve the schools, the successful principals appeared highly task-oriented. They made strong instructional efforts; set clear, high expectations for teachers and students; and monitored performance. They actively intervened when intervention was needed. The successful principals also paid attention to relationships, remaining in close contact with the teachers.

Many other studies, enumerated in [Chapter 27](#), have found that leaders who are concerned about the task in situations in which such a concern is relevant are likely to be evaluated highly by others. Furthermore, the plethora of studies of the need for achievement<sup>6</sup> provide additional evidence of the positive association of task orientation and success as a leader.

### ***Impact on Subordinates' Satisfaction***

Supervisors' attention to relationships was seen early in several investigations focused on the impact on subordinates' satisfaction of psychological and social closeness or distance, a component of relations orientation. Julian (1964) found that job satisfaction was higher when there was psychological closeness between the leader and the led. However, Blau and Scott (1962) and E. R. Shaw (1965) reported that the cohesiveness of the group was strengthened by the social distance between the leader and the followers, and Sample and Wilson (1965) found cohesiveness to be unrelated to social distance. Still, the majority of reports from both field studies and laboratory experiments have indicated that subordinates' satisfaction with their leaders was linked to the leaders' relations-oriented attitudes and behavior. Particularly important for follower satisfaction, performance, and willingness to follow the leader is the extent to which the leader evinces support for the followers' feelings of self-worth (Dansereau, Yammarino, Markham, et al., 1995). A supportive change-oriented supervisory attitude also lies behind subordinates' efforts to innovate (Delbecq & Mills, 1985) and to be creative (Langley & Jones, 1988).

*Field Studies.* Hoppock's (1935) analysis of the early literature on job satisfaction indicated that workers tended to feel more satisfied when supervisors understood their problems and helped them as needed. In a survey of more than 10,000 managerial, supervisory, and hourly personnel, Ronan (1970) obtained similar results, as did Roberts, Blankenship, and Miles (1968). Stagner, Flebbe, and Wood (1952) found that railroad workers were better satisfied when their supervisors were good at handling grievances and communicating with employees. Likewise, Bose (1955) observed that workers under employee-centered supervisors had more pride in their groups than those under work-centered supervisors. Mann and Hoffman (1960) found that in two plants—one automated, the other not—employees were more satisfied with supervisors who were considerate

of their feelings, recognized good work, were reasonable in their expectations, and stood up for the subordinates.

Stampolis (1958) showed that the more employees rated their supervisor as fair, able to handle people, giving credit, ready to discuss problems, and keeping employees informed, the less the employees expressed a desire for their company to be unionized. Bass and Mitchell (1976) reported similar results for professional and scientific workers. The United Auto Workers had difficulty organizing the highly relations-oriented Japanese-owned automobile plants in the United States (Gladstone, 1989).

Wager (1965) found that a supportive style of leadership assisted the supervisor in fulfilling and satisfying the employees' role expectations. In an aircraft factory, where team leaders devoted much of their time to facilitating the work of the teams and attending to the members' personal problems, indicators of dissatisfaction, such as absenteeism and turnover, were lower (Mayo & Lombard, 1944).

York and Hastings (1985–1986) asked 172 employees working in North Carolina social services to complete the Survey of Organizations (D. G. Bowers, 1976). At all levels of the assessed maturity of workers, facilitative and supportive performance of supervisors was associated with the subordinates' satisfaction and motivation to work. A review of nursing studies by Maloney (1979) concluded that people-oriented leaders generally were more satisfying to their employees. In addition, employees' grievances and turnover were lower when the leaders were seen as relations oriented.

When the socioemotional and task-oriented leadership of residence hall leaders were measured separately by MacDonald (1969), both were linked to the satisfaction of students. However, the effects of task orientation on subordinates' satisfaction have usually been found to be somewhat less consistent. Task-relevant behavioral measures, which contain elements of the leaders' punitiveness, will generate dissatisfaction, grievances, and turnover (Schriesheim & Kerr, 1974). In a survey of several thousand employees, R. Likert (1955) found that job satisfaction decreased as the supervisors' pressure for production increased. However, it is not uncommon to find positive correlations for both the task-and relations-oriented behavior of supervisors and the satisfaction of their subordinates. Generally, for nurse supervisors, for example, a strong task orientation that is not coupled with a high relations orientation results in less satisfied subordinates (Maloney, 1979). Gruenfeld and Kassum (1973) showed that nurses were satisfied with highly task-oriented supervisors, but only if the supervisors' people orientation was high as well. The strong task orientation of supervisors was dissatisfying when coupled with a medium or low orientation to people. But Arvonen (1995) found, in Swedish forest-product manufacturing, that supervisor task orientation—as revealed in their structuring, clarification, and ordering of work—did not produce dissatisfaction among blue-collar employees, as it did among white-collar employees and managers.

In a very large undertaking of over two decades, Misumi (1985) conducted studies of over 150,000 Japanese employees working in banks, post offices, coal mines, shipyards, transportation, utilities, and manufacturing, under supervisors with different performance (P) and maintenance (M) orientations. The supervisors were classified as P-type (above the median in performance alone), M-type (above the median in maintenance alone), neither type (pm), or both types (PM). The subordinates of a PM supervisor had a more favorable attitude toward their supervisor than did the subordinates of an M-type or P-type supervisor. The least satisfying supervisors were those who were pm types. In a bank that had branches in Okinawa, Misumi and Mannari (1982) surveyed an average of 1,325 subordinates who described their 303 superiors' leadership. The P and M leadership orientations of the supervisors, as well as the subordinates' morale (interest in work and satisfaction with supervision), were collected five times at 15-month intervals. The supervisors were changed in 287 groups but not in 159 groups. There was less change in morale from interval to interval if the supervisor did not change. However, the morale of the subordinates rose if the P and M leadership orientation of the supervisor's successor was higher than that of the former supervisor. The previous morale of the subordinates had less of an effect on the incoming supervisor's leadership than vice versa.

Along with relations and task orientation ( $r = -.33$ ), change orientation also appears to contribute to satisfaction. Arvonen (1995) collected survey data from 781 employees in two production plants of a Swedish forest-products firm. Dissatisfaction and lack of well-being were less if supervisors were structure-oriented ( $r = -.27$ ), relations-oriented ( $r = -.33$ ), and change-oriented ( $r = -.25$ ).

*Laboratory Experiments.* Experiments may provide additional convincing evidence of the relationship between a leader's relations orientation and subordinates' satisfaction. As with the field studies, most experimental studies have concluded that satisfaction of subordinates was positively associated with the leader's relations-oriented behavior. Wischmeier (1955) found that group-centered, rather than task-centered, discussions resulted in a warm, friendly group atmosphere. T. Gordon (1955) found that group-centered discussion was associated with members' sense of belonging, respect for others, ability to listen to and understand others, and loss of self-defensiveness. Similarly, Thelen and Whitehall (1949) and Schwartz and Cekoski (1960) reported that follower-oriented leadership enhanced satisfaction. Maier and Danielson (1956) reported that an employee-oriented solution to a disciplinary problem produced greater satisfaction in groups of problem solvers than a solution bound by legalistic restrictions.

Heyns (1948) coached one set of leaders to play a positive, supportive role that emphasized agreement, mutual liking, and cooperation. Leaders in another set were coached to play a negative role in which they overtly displayed a misunderstanding of the members and made no effort to develop their groups' cohesiveness. Although the two styles produced no significant difference in the quality of the groups' decision or the members' satisfaction, the groups with positive leaders exhibited evidence of greater cohesiveness. W. M. Fox (1954) used scenarios to coach leaders in a positive relations approach or a "biased, diplomatic, persuasive" role. Groups with positively supportive leaders exhibited higher degrees of cohesiveness and members' satisfaction but were slower in solving problems. With a different group of participants, W. M. Fox (1957) also found that supportive leadership was associated with the members' satisfaction and the groups' cohesiveness.

### ***Impact on the Group's and Members' Performance***

Zaleznik (1997) lamented the extent that attention to the task has suffered from too much concern for relationships. He attributed this to the increased complexity of the organization, in which managers and executives have to play many roles; and to the success of the human relations movement. This movement emphasized the need for cooperation and workplace harmony and had "an unhealthy preoccupation with process at the expense of productivity" (p. 7). The substantive hard work of business was displaced by psychopolitics; by "smoothing over conflict, greasing the wheels of human interaction" (p. 7); and by driving out the necessary "real" work of cutting costs and creating products. However, generally, we shall see that effectiveness is greatest when leaders attend to both task and relationships.

It may be difficult to separate the impact of the leader's orientation on the members' satisfaction from its impact on the members' and the group's effectiveness. For example, Medalia and Miller (1955) observed that human relations leadership and employees' satisfaction interact to influence the group's effectiveness. And although a leader's relations orientation and task orientation are both generally found to be positively associated with the group's productivity, the group's attainment of goals, and followers' performance, there are exceptions. Some situations may call for more relations-oriented leadership and others for more task-oriented leadership. However, it may be that in a vast majority of circumstances, strong doses of both types of leadership orientation are optimal.

When positive associations are found, it is usually inferred that the relations orientation or task orientation of the leader resulted in the improved performance of subordinates. But the reverse may be equally true. Few

of the findings have been causal. That is, the previous performance of subordinates is as likely to affect the orientation of the leader as the leader's orientation is likely to influence the subsequent performance of the subordinates (Bass, 1965c). Farris and Lim (1969), as was previously mentioned, showed that the past good or poor performance of groups determined, to a considerable degree, the task and relations orientation of their leaders.

*Relations-Oriented Leadership and Follower Performance.* Pandey (1976) reported that groups with relations-oriented leaders generated more ideas than groups with task-oriented leaders. Katz, Maccoby, and Morse (1950) and Roberts, Miles, and Blankenship (1968) found that the performance of groups was higher under an employee-oriented style than under a more disinterested style of supervision. Philipsen (1965a, 1965b) also found that human relations leadership correlated positively with group effectiveness. But in a study of skilled tradesmen, Wison, Beem, and Comrey (1953) established that supervisors of both high-and low-performing shops were described as more helpful, sympathetic, consistent, and self-reliant than were those in medium-performing shops. Slack, Etchegaray, Jones, et al. (2002) reported that supervisory-espoused support was linked to enacted support. Enacted supervisory support was linked to employee performance because the employees perceived a supportive environment. Bliese, Bienvenu, Castro, et al. (2002) found that a supportive leadership climate played an important role in determining whether the stress of the work overload of soldiers on assignment in Kosovo could be buffered by job control.

Abdel-Halim (1982) showed how much of subordinates' role conflict and role ambiguity—which affected their intrinsic satisfaction with, involvement in, and anxiety about their jobs—were moderated by the support they received from their supervisor. In the report by Konovsky (1986), supervisors who were judged by their 484 subordinates as helpful and emotionally supportive contributed to the subordinates' commitment to their hospital organization and to the supervisors' judged interpersonal effectiveness. Riegel (1955) found that employees' interest in their company's success increased when their supervisor was seen to help them with their difficulties, to give necessary training and explanations, and to “take an interest in us and our ideas.”

Indik, Georgopoulos, and Seashore (1961) studied the employees of a transportation company. Their results indicated that high levels of group performance were associated with satisfaction with the supervisors' supportiveness, open communication, mutual understanding, and workers' autonomy on the job. As documented in [Chapter 17](#), R. Likert (1967a, 1967, 1977b) concluded, from many surveys, that supportive attitudes toward employees, combined with the group's loyalty toward management, were associated with increased productivity and a desire for responsibility by the employees. With the introduction of a human relations approach to management, as well as high performance goals, long-term gains in productivity were achieved. Similarly, Daley (1986) surveyed 340 employees of Iowa public agencies and obtained uniformly positive associations between their perceptions of relations-oriented, humanistic management practices and their evaluations of the effectiveness and responsiveness of their organizations to the public. Stinglhamber and Vandenberghe (2001) obtained correlations of .44 and .38 between perceived supervisory supportive relations and employee satisfaction with job conditions.

Supportive leadership increases the likelihood that organizations can police and correct themselves. Near and Miceli (1986) found that the felt support from their leaders was the most important factor in protecting employees from retaliation for calling attention to observed wrongdoing. Conversely, in a random sample of 8,600 federal employees the perceived likelihood of retaliation for whistle-blowing correlated with the lack of support from their supervisors and higher management. This perception was realistic. Honest whistle-blowers were actually more likely to be punished than their corrupt senior managers in the Department of Housing and Urban Development under Samuel Pierce from 1981 to 1988.

Ramus and Steger (2000) surveyed 353 employees in 12 countries in large environmentally-proactive companies with headquarters in Europe. The survey disclosed that employees who perceived management support were willing to promote self-described environmental initiatives. Without such perceived support,

they were unlikely to do so.

Deluga (1988) noted that faculty members in a school of higher education, when negotiating a second time, reduced their bargaining and use of authority as influence strategies if the leadership was perceived as relations-centered.

*Correlations of Task-Oriented Leadership with Performance.* In contrast to the above in Deluga's study of influence strategies, faculty member bargaining, assertiveness, coalition formation, and reference to higher authority emerged if the leadership was perceived as task centered. R. Likert (1955) reported that a survey of several thousand workers indicated a tendency for productivity to be higher in the presence of higher pressure by supervisors for production. Similarly, Litwin (1968) noted that experimental groups whose leaders had a strong need for achievement were much more productive than groups whose leaders had a great need for affiliation or power. Dunteman and Bass (1963) studied foremen who had an interaction orientation or a task orientation. Groups who worked under task-oriented leaders were more productive than those under interaction-oriented leaders. Mann, Indik, and Vroom (1963) showed that the productivity of workers was associated with the supervisor's task orientation. R. Cooper (1966) also reported that first-level supervisors whose bosses judged them to be higher in "task relevance" tended to have more productive and more task-motivated subordinates.

For 14 U.S. Navy airplane-maintenance groups, R. Likert (1977a) reported a strong association between the extent to which supervisors facilitated the work by helping with advanced scheduling and offering new ideas to solve problems in the job, and the extent to which airplanes serviced by the groups were not involved in accidents or disasters because of operational failures.

*Effects of Change/Development Orientation.* Lin-dell and Rosenqvist (undated) reported results for change and development styles for 502 Swedish cases from four manufacturing and five service companies. Management change correlated .67 with managerial competence, .73 with comfort with the manager, and .17 with comfort with the employees' own tasks. The comparable correlations for managerial development were .67, .53, and .24. For task orientation, the correlations were .59, .52, and .26. LaPolice and Costanza (undated) found that a three-factor model, which included change-related leadership along with task and relations orientation, was the best predictor of the behavior of 16,795 employees from 16 government agencies. Analyses were based on the Office of Personnel Management's Organizational Assessment Survey.

*Effects of a Combined Task and Relations Orientation.* There is considerable theoretical and empirical support for the idea that regardless of circumstances, the effectiveness of leadership is greatest when the leaders are both task oriented and relations oriented in attitudes and behavior. Thus Patchen (1962) reported that the leader who maintained high performance norms, encouraged efficiency, and attempted to obtain rewards for followers was likely to have a high-performing group. However, the maintenance of high performance standards alone and attempting to obtain rewards for followers alone each had a negative effect on productivity. These two patterns of behavior had to be combined to have a positive impact on productivity.

Numerous other studies and lines of investigation have supported the utility of a combined high task-and relations-oriented approach to leadership. Tjosvold (1984b) demonstrated, in an experiment with 56 college students, that the students were most productive in completing a subsequent task if they had experienced beforehand a leader who nonverbally conveyed warmth and who was directive about what was to be done. The experience of the warm leader, along with the absence of direction, was satisfying but was least conducive to subsequent productivity. Similarly, Klimoski and Hayes (1980) found that the effort, performance, and satisfaction of 241 assistants in the production department of a large information-processing firm were enhanced if the supervising editors were task centered in being explicit in their expectations and consistent in their demands, as well as supportive of their employees. Daniel (1985) found that subordinates perceived that they were working in a more productive organization if their managers were concerned both about tasks and about people. Hall and Donnell (1979) conducted a survey study of 2,024 subordinates who described their

managers' attention to the demands of the task and concern for the quality of manager-subordinate relationships. The managers who were high in both earned high "career achievement quotients." (The quotient reflected the speed with which they had climbed their organizational ladder.) They were also the most collaborative in their leadership style. These results were consistent with findings by Blake and Mouton (1964) and J. Hall (1976) for large samples. The moderately successful managers had a low relations orientation but a high task orientation, while those whose career success was lowest were low in both task and relations orientation.

Erez and Kanfer (1983) argued that the relations orientation implied in allowing subjects to participate in goal setting enhanced the task-oriented impetus for more goal setting than did assigning goals to subjects without permitting them to participate in setting the goals. Erez, Earley, and Hulin (1985) obtained experimental evidence to show that such participation increased acceptance of the goals and hence increased productivity. However, Erez (1986) found that the organizational culture from which the participants were drawn affected the need for such participation: subjects from the Israeli private sector did better with assigned goals; subjects from the kibbutz sector did better with group participation in setting goals.

As described earlier in discussing the utility of participation, Locke, Latham, and Erez's (1987) critical experiment tried to understand why, in their respective investigative efforts and using the same standardized experimental conditions, assigning goals to subjects generated more productivity in the United States (Latham & Steele, 1983), while allowing the subjects to participate in goal setting generated more productivity in Israel (Erez & Arad, 1986). The one difference that turned out to account for the highly significant difference in productivity was that the Israeli experimenter was curt and unsupportive in giving instructions, but the U.S. experimenter was friendly and supportive. The friendly, supportive experimenter's instructions facilitated the subjects' acceptance of the assigned goal without their having participated in setting it.

Misumi (1985), and Misumi and Peterson (1985), consistently found, in the previously mentioned studies of 150,000 Japanese employees in business and industry, greater productivity by employees under PM supervision than under pm supervision—that is, under managers who were above rather than below the median in both performance orientation and maintenance orientation. In one of these studies, P and M were systematically manipulated for coordinated first-level and second-level supervision in an experiment with 15 postal trainees working in trios. The PM-type first-level supervision generated more productivity than did either P or M alone. Second-level supervision, present only in the form of written instructions to the subjects from the second level, had the same effects, although with less statistical significance. For 215 of 500 groups of coal miners, when the second-level supervisor was actually present, the PM pattern at both the first and second level of supervision was most typical for the high-producing groups. For 186 working groups of about 10 employees each, involving a total of 2,257 workers in a Mitsubishi shipyard, evaluations of group meetings were most positive under PM-type leaders (evaluation mean = 17.5), followed by M-type (mean = 16.4), P-type (mean = 15.3), and pm-type (mean = 14.5) leaders.

The rated performance of 92 squads in a bearing manufacturing firm was most often high under PM leadership and least often high under pm leadership. The results for ratings above the median for P alone or above the median for M alone were in between. The same pattern emerged in a tire-manufacturing firm, where the success or failure rate of 889 project managers was strongly associated with their style of leadership: PM, P, M, or pm. The success rate was highest (52%) and the failure rate was lowest (5%) with the combined PM style.

Peterson (1988) concluded that introducing PM theory and practice in China and the West may need modification. For instance, more attention may need to be paid to merging self-interests with working hard. Peterson, Smith, and Tayeb (1993), in a British and in a U.S. plant, found results consistent for M but unlike those in Japan. "Pressuring" leadership was negatively related to interpersonal cooperation. This was confirmed when Royal Australian Air Force service personnel and blue-and white-collar employees were questioned about

how much they liked or disliked supervisory pressure statements such as, “Hurry up, you have to work harder” and “There are a number of tasks I want you to complete today” (p. 263). As will be noted in [Chapter 20](#), such pressuring for production had to be eliminated from the “initiation of structure” factor assessment in the Leadership Behavior Questionnaire to improve its prediction of subordinates’ satisfaction and performance (Fleishman, 1973). In order to be palatable to Australian subordinates, such statements had to be preceded by socioemotional supportive statements such as, “You have been doing a good job” and “I appreciate the extra effort you have been making” (p. 263).

*Negative Evidence.* A number of additional exceptions to the positive effects of task or relations orientation on productivity have been reported, particularly in short-range analyses. Andrews and Farris (1967) found no evidence that innovation was higher when supervisors of scientific personnel were high in both task and human relations functions. Human relations skills had little moderating effect on the generally positive relationships between the leader’s carrying out task functions and innovation. The most innovation occurred under supervisors who were neither high nor low in their attention to human relations, regardless of the task functions that were completed.

Lundquist’s (1957) results indicated that regardless of whether supervisors were worker-oriented, the sheer frequency of their interaction with workers increased their effectiveness. Weitz and Nuckols (1953) found that supervisors’ scores on a test measuring human relations orientation were not related to the productivity of the group or to the turnover of personnel. MacKinney, Kavanagh, Wolins, and Rappaport (1970) found that both production-oriented and employee-oriented management were unrelated to the satisfaction of employees. Carp, Vitola, and McLanathan (1963) showed that supervisors of effective postal teams maintained their social distance from subordinates, an attitude that reduced the surfacing of emotional problems. Fernandez and Vecchio (1997) found little descriptive utility in the Hersey-Blanchard predictions of the performance of university employees. However, they did find that supervisory monitoring had a positive impact on lower-level employee performance, and supervisory consideration had a positive impact on higher-level employee performance.

In a study of simulated management groups, Kaczka and Kirk (1967) established that the profitability of teams was associated with relations-oriented leadership. But this type of leadership also resulted in less pressure to accomplish tasks and less cohesiveness in the groups. C. A. Dawson (1969), studying the achievement of schoolchildren, observed that the children performed equally well under “cold” or “warm” leadership.

## Blake and Mouton’s Grid theory

---

Among the models of task and relations orientation of the past 40 years with the power to survive into the twenty-first century are Blake and Mouton’s (1964) Grid, Hersey and Blanchard’s (1969 a, b) Situational Leadership, and Fiedler’s (1964a, 1967) Contingency Model. Fiedler and Hersey and Blanchard emphasized that what the leader should do to be effective depended on diverse circumstances. But Blake and Mouton (1964) prescribed the integration of task and relations orientations as the one best way to achieve effective leadership. Their managerial grid (see [Figure 19.1](#)) is based on the concept that managers and leaders vary from 1 to 9 in their concern for people (the vertical axis of the grid) and from 1 to 9 in their concern for production (the horizontal axis). The measurement of these concerns is based on a manager’s endorsement of statements about management assumptions and beliefs. But these concerns are interactive rather than independent. They are manifested in the five styles shown on the grid as published in 1985 (Blake & Mouton, 1985) and “softened” in a later version by Blake and McCanse (1991), with concern for production replaced with concern for results.

The revised grid and its expected effects are shown in [Figure 19.1](#). Further elaboration was provided by

Blake and McKee (1993).

9,1: *Authority-Compliance Management*. Efficiency in operations results from arranging conditions of work so that human elements interfere to a minimum degree. Expected effects: Productive, but quality suffers. Strong conflict, resentment, antiorganizational creativity, and efforts to “beat the system” are high.

1,9: *“Country Club” Management*. Thoughtful attention to the needs of people for satisfying relationships leads to a comfortable, friendly organizational atmosphere and work tempo. Expected effects: Low productivity, indifferent quality, low conflict, easygoing and pleasant atmosphere.

Figure 19.1 Managerial Grid

SOURCE: Blake and Mouton, *Managerial Grid III: The Key to Leadership Excellence*. Houston, TX: Gulf Publishing, 1985.

1,1 *Impoverished Management*. Exertion of minimum effort to get required work done as appropriate to sustain organization membership. Expected effects: Low productivity and quality, poor creativity, low conflict, low involvement.

5,5: *Middle-of-the-Road Management*. Adequate organizational performance is possible through balancing the necessity to get out work with maintaining morale at a satisfactory level. Expected effects: Acceptable performance based on the status quo, moderate quality, good team players who go along to get along, low creativity.

9,9: *Team Management*. Work accomplishment from committed people; interdependence through a “common stake” in organization, purpose leads to relationships of trust and respect. Expected effects: High productivity, quality, and creativity stimulated by internalized goals and objectives; commitment to goals, resulting in a high degree of interdependent cooperation; conflict is productive confrontation. 9,9 can take the form of paternalism if the leader fails to integrate the concerns for people and results—that is, if the two are kept in logic-tight compartments. The leader cares as father or mother for dependent subordinates, from whom unconditional loyalty is expected.

Opportunistic leaders use several styles interchangeably, depending on the persons with whom they are

dealing Sometimes leaders masquerade as 9,9s when they really are paternalists or opportunists hiding behind facades.

The leader's dominant style is likely to be backed up by other styles. Thus, for instance, the 1,9 leader may begin a meeting in a casual, friendly way but quickly become a tough, no-nonsense 9,1, which is his or her dominant style (Blake & Mouton, 1985c).

Team leadership (9,9) is prescribed. It is attained by behavioral science principles that involve participation, openness, trust, respect, involvement, commitment, open confrontation to resolve conflicts, consensus, synergistic utilization of the human resources represented by the leader and followers, mutually determined management by objectives, mutual support, and change and development through feedback (Blake & Mouton, 1981a).

According to a study reported by Blake and Mouton (1985c), prior to a seminar on the subject, 68% of the managers saw themselves as 9,9; 10% as 9,1; 19% as 5,5; and 2 to 3% as 1,9 or 1,1. After the seminar, a modal 41% admitted to being 5,5 and another 36% saw themselves as 9,1. Only 16% now believed they were 9,9. Blake and Mouton thought that these changes in results indicated the self-deception that occurs if understanding is impaired and feedback is not provided.

According to Blake and Mouton (1978), a 9,9 orientation has consistently proved to contribute positively to a variety of performance criteria in organizational development studies. In one of these studies, two matched subsidiaries of the same company were involved in a pre-post comparison over 10 years. One subsidiary engaged in an extensive organizational development program that stressed 9,9 management; the other was not involved in any comparable program. The experimental subsidiary increased its profitability by 400% over the matched control.

In a study of 716 managers from a single firm, Blake and Mouton (1964) found (after correcting for age differences) that 9,9-oriented managers were more likely than those with other dominant styles to advance further in their careers. J. Hall (1976) replicated these findings with an independent sample for 731 managers from a variety of companies.

Blake and Mouton (1985b) determined that the 9,9 style of team-management orientation characterized the leadership of the twentieth-century U.S. presidents who had performed with greatness, in contrast to those who had not. This style was inferred from contemporary writings about the presidents' different ways of decision making, exercising initiatives, analyzing problems, taking advocacy roles, dealing with conflicts between themselves and their subordinates, and using critiques to increase their effectiveness in achieving results with and through subordinates.

## Situational Contingencies affecting Outcomes

---

Blake and Mouton did not leave much room for exceptions. Nevertheless, in a substantial number of investigations of the impact of task and relations orientation the findings have been mixed or negative. Explanations have been sought in situational contingencies. These situational contingencies need to be examined for their moderating effects on the impact of relations-and task-oriented leadership on the satisfaction and productivity of followers. For instance, Miner (1982a, 1982b) suggested that high-task, high-relations leadership orientation is most likely to be effective when organizations are a mix of systems of hierarchies and groups. The task orientation fits the hierarchies; the relations orientation fits the groups.

One example of a moderated result was the upward influence tactics used by subordinates who were subjected to task-or people-centered leadership in Deluga's (1987b) study of 48 faculty members at a school of higher education. Deluga found that in the faculty members' first attempt to influence their superiors, only the superiors' relations orientation was of consequence. The faculty members said they were less likely to bargain

or appeal to a higher authority if their superiors were more people centered. But if their first attempt failed to influence their superiors, the task orientation of the leaders became important in the second attempt. Here, the faculty members said that the more they thought their superior was task-centered, the more likely they would be to try friendliness, bargaining, assertiveness, appeals to a higher authority, and forming coalitions.

### ***The Subordinate as a Moderator***

Although relations-oriented leadership was expected to generate more satisfaction among subordinates, moderating effects were seen in a number of investigations. In a study of community hospitals, F. C. Mann (1965) observed that the satisfaction of the nurses was related to the human relations skills of their supervisors, but the satisfaction of the nursing supervisors was related to the administrative skills of their superiors. The satisfaction of the hospital technicians was related to their supervisors' technical and human relations skills. Tannenbaum and Allport (1956) studied two departments of women workers. One department was given more responsibility and authority for work and for decisions about the work, and the second department emphasized top-down line authority. A personality test was administered initially and scored as to the suitability of the workers' personality to the situation in which they worked. One year later, an attitude test was administered. The results of the test revealed that significantly more suited than unsuited workers in the situation with more authority and responsibility wanted the situation to continue. However, suited and unsuited workers did not differ in their attitudes toward the program if they had not been given authority and responsibility. In another large-scale field study, Seashore (1954) found that supportive leadership with cohesive work groups paid off in higher productivity. However, the same group cohesiveness also resulted in lower productivity when the groups' supervisors were unsupportive.

A number of investigators saw the followers' need for achievement as making a difference in the way the followers reacted to particular styles of leadership. W. W. Burke (1965) discovered that followers with a high need to achieve who had socially close leaders rated their situation as more tense than did those with a high need to achieve who were under socially distant leaders. Followers with a low need to achieve who had socially close leaders rated their situation as more tense than did followers with a high need to achieve who had socially distant leaders. Followers with a high need to achieve rated socially close leaders high in authoritarianism; those with a low need to achieve did the same for socially distant leaders. Misumi and Seki (1971) also studied the effects of leadership style on the performance of students with a high or low need to achieve. Those who were achievement oriented performed best under a PM leader. In groups whose members had a low need to achieve, performance was best under a P-type leader.

### ***Constraints and Goals as Moderators***

Several studies obtained results suggesting that the style of supervision interacted with situational variables to influence productivity and satisfaction with the job. For example, Lundquist (1957) reported that foremen who are worker oriented produce better results in small groups than in large groups. In an Indian study of officers in central government departments, Srivastava and Kumar (1984) demonstrated that high task and high relationship styles of leadership both contributed to the effectiveness and adaptability of the middle-level officers; however, they did not do so for the junior-level officers. Nealey and Blood (1968) showed that among nurses in a Veterans Administration hospital, task-oriented first-level supervisors received higher performance appraisals, but it was the people-oriented second-level supervisors who received such higher performance appraisals. Although the subordinates' job satisfaction was correlated significantly at both levels with the supervisors' people orientation, task orientation contributed to the nurses' job satisfaction at the first

but not at the second level of supervision.

### ***The Task as a Moderator***

W. W. Burke (1965) found that a group's performance of a coding task was completed more effectively under a production-oriented leader, but the completion of a decision task was carried out more effectively under a relations-oriented leader. Weed, Mitchell, and Moffitt (1976), among others, found that it was necessary to take the tasks into account to uncover the moderating of the linkage between a leader's relations orientation and the subordinates' satisfaction as a consequence of the subordinates' personality and orientation. Overall, they studied the effects of task versus relations orientation on a group's performance and satisfaction with supervision as a function of the subordinates' personality and orientation. They compared leaders who scored high in human relations orientation and high in task orientation, low in human relations orientation and low in task orientation, low in human relations orientation and high in task orientation, and high in human relations orientation and low in task orientation. Each leader worked with subordinates high or low in dogmatism. Subordinates varied in their task and relations orientations as well. Regardless of their personality and orientations, the subordinates were significantly more satisfied with leadership behavior that was high in human relations orientation. But Weed, Mitchell, and Moffitt had also varied the ambiguity and difficulty of the tasks. The interacting effects of the leadership style—relations or task oriented—and the subordinates' relations or task orientation were strongest on difficult and ambiguous tasks than on clear and easy tasks. That is, the compatibility of the leader's and follower's personality made a difference only if the task was difficult and ambiguous.

Wofford (1971) obtained results indicating that a relations-oriented manager is likely to be more effective in terms of the productivity and morale of the group in simple, centralized, structured operations. Shaskin, Festinger, Willerman, and Hyman (1961) generated somewhat different and more convincing evidence in an experiment with work groups matched in age, productivity, seniority, and disciplinary records. For three weeks, managers were friendly and helpful to the favored group, which they praised. To the unfavored group, they were threatening, reproofing, and deliberately annoying in their demands. The favorable and unfavorable relations ceased at the end of three weeks, when minor changes in work were instituted. [Table 19.1](#) shows the percentage of assembled units requiring repair during each phase of the experiment. When the employees continued to work on old, familiar tasks, the unfavorable supervision had only slight effects on their performance. But when a changeover occurred that required work on new, unfamiliar tasks, the repair rates of the unfavored group jumped much higher than those of the favored group. Equally important, although the favored group rapidly returned to its normal repair record by the end of the third week after the changeover, the unfavored group continued to exhibit a repair rate that was three times worse than its normal record before the onset of the unfavorable supervisory relations. Unlike the results of surveys, this experiment demonstrated that unfavorable supervisory human relations cause decrements in performance primarily when new learning is required, not when accustomed tasks are performed.

### ***Management Functions as Moderators***

Woodward (1958) reported that friendly supervisors were rated as more effective in service departments but less effective in production departments. Consistent with this finding, B. Schneider (1973) noted that in social service agencies, supervisors set examples of how they expected their subordinates to relate to clients. Satisfied clients coincided with friendly, concerned, supervisory relations with subordinates. Schneider also found that good customer relations at a bank reflected good relations between the bank tellers and their superiors.

Relations-oriented supervision thus would seem to be particularly indicated in service operations.

Table 19.1 Quality of Work Done Before and After the Changeover of Work Groups That Were Subjected to Favored and Unfavored Supervisory Treatment

<i>Phase of the Experiment</i>	<i>Percentage of Assembled Units Requiring Repair</i>	
	<i>Favored Group</i>	<i>Unfavored Group</i>
During the first week of contrived disturbance	10.6	11.8
During the second two weeks of contrived disturbance	11.7	14.7
The first week after the changeover	21.1	31.4
The second week after the changeover	13.8	28.0
The third and fourth weeks after the changeover	11.6	29.0

SOURCE: Schachter, Festinger, Willerman, and Hyman (1961), p. 206.

The manager and the coach of English football teams differ greatly in function. The manager has little continuous contact with the players, whereas the coach maintains a high degree of contact. Cooper and Payne (1967) found a correlation of .72 between the task orientation of the team coach and the success of the teams in winning games, but the correlation was close to zero for managers.

### ***Interrelations with Other Leadership Behaviors as Moderators***

The effects of other types of behavior by the leader moderate the impact of the leader's task or relations orientation. Thus Larkin (1975) showed that task-oriented elementary school teachers created high morale among pupils, regardless of how much they also resorted to power. But teachers whose task-oriented behavior was low and who used power generated rebellious pupils. Among supervisors of technical personnel, participative approaches (the provision of freedom) resulted in the most innovation if the supervisors were low in task or human relations orientation (Andrews & Farris, 1967). In an experiment with small groups of ROTC students, Anderson and Fiedler (1964) found that those under task-oriented leaders were most productive and satisfied when the leaders were participative, but the students' satisfaction was greater when relations-oriented leaders were directive. Similarly, Pandey (1976) showed that the behavior and effectiveness of relations- and task-oriented leaders of discussion groups depended on whether the leaders were appointed, elected, or rotated: the elected and rotated leaders tended to be more participative than the appointed leaders.

A number of models of situational or contingent leadership have been constructed to provide advice to leaders on when they should be task-oriented and hence directive and when they should be relations oriented and hence participative. The Hersey-Blanchard situational leadership model has been widely applied but has received less research support than the Fiedler contingency model, which has been more widely researched than applied.

## **The Hersey-Blanchard Situational Leadership theory (SLT)**

---

### ***Basis***

The Hersey and Blanchard (1969a) situational leadership model was built on propositions that were based on Hersey and Blanchard's understanding of prior empirical research:

1. Leadership styles vary considerably from leader to leader (Stogdill & Coons, 1957).

2. Some leaders' behavior primarily involves initiating structure to accomplish tasks; other leaders behave to build and maintain good personal relationships; and still others do both or do neither (Halpin, 1956a).
3. The most effective behavioral style of leaders is one that varies with the situation (Fiedler, 1967a; Korman, 1966).
4. The best attitudinal style is a high task orientation and a high relations orientation (Blake & Mouton, 1964; Reddin, 1967).
5. The job maturity and psychological maturity of the followers are most crucial in determining which behavioral style of leaders will result in the most effectiveness (Argyris, 1962).
6. Maturity relates to the stage in a group's life cycle or to the previous education and training of the followers. Just as parental leadership of offspring must change to reflect the life cycle (infancy, adolescence, and adulthood), so must leading groups reflect the life cycle of followers from novices and newcomers to experts and people with experience.

## Prescriptions

According to Hersey and Blanchard (1969a, 1969b, 1977, 1982a), as shown in [Figure 19.2](#), depending on the maturity of subordinates, a manager should be task oriented and tell or sell subordinates regarding what to do; or a manager should be relations oriented and *participate*<sup>7</sup> with subordinates in joint decision making; or the decision should be delegated to them. What to do should depend on the subordinates' task-relevant job maturity (capacity, ability, education, and experience) and their psychological maturity (motivation, self-esteem, confidence, and willingness to do a good job). The maturity manifests itself in the subordinates' performance of their jobs. Newly appointed, inexperienced employees seek task-oriented direction from their superiors; they should be told what to do. As their life cycle on the job continues and their experience increases, they have to be sold to continue their performance. Later, with the subordinates' further development, relations orientation and *participation* become most efficacious in order to engage both their knowledge and their maturation. Finally, fully mature subordinates work best when the leaders delegate what needs to be done. The most effective leadership is conceived of as depending on whether the leader's task-oriented or relations-oriented behavior matches the subordinate's maturity.

Figure 19.2 Hersey-Blanchard Model of the Relationship between Leader Style and Maturity of Followers

SOURCE: Hersey and Blanchard, *Management of Organizational Behavior: Utilizing Human Behavior*, Copyright 1977, p. 170. Adapted by

*LASI or LEAD.* The Leader Adaptability and Style Inventory (LASI)—later renamed the Leadership Effectiveness and Adaptability Description (LEAD)—provides brief vignettes of 12 situations, each with four alternatives (Hersey & Blanchard, 1974). Maturity of the subordinates is at one of four levels in the situations. Each level involves a different combination of attention to relations and task.

For example, in one of the situations, you supervise a group with a fine record of accomplishment whose members respect the need for change. You indicate from among four choices what supervisory action you would take to deal with the problem. One alternative, under answer C, is to delegate by allowing the group to work out the solution itself. This delegation is leadership behavior that is low in task orientation and low in relations orientation. The response adds 2 points to your self-rated delegation score. It also adds to your flexibility score, for it best matches the requirements of the particular situation according to the model. The next best answer is A—to be *participative*, to allow the group to be involved in the change, and is scored 11 for flexibility. It is a moderately adaptive leadership response, low in task orientation and high in relations orientation. The next best answer, D—to be persuasive by directing the change but incorporating the group's recommendations—is scored 21 for flexibility; it is a response that is high in task orientation and high in relations orientation. Finally, the worst and least flexible answer is B—announce the changes and implement them with close supervision. This is a highly *directive*, high-task–low-relations response; it is scored 22 for flexibility. Subordinates and colleagues can also complete the form, indicating what they believe the focal manager would do. Their responses can provide useful feedback to the focal leader (Hersey & Blanchard, 1981).

A curvilinear relationship between a leader's task and relations orientation and the subordinates' maturity was postulated by Hersey and Blanchard (1977), as displayed in [Figure 19.2](#). Unwilling and unable subordinates should be told what to do; willing but unable subordinates should be sold; unwilling but able subordinates should participate; and willing and able subordinates should be delegated assignments.

### **Positive Evidence**

Despite problems with the model, some supportive empirical evidence has emerged for it along with contrary findings. Hersey, Angelim, and Carakushansky (1982) obtained support for the model as an approach to improve learning. The participants in their study were 60 managers who attended a management-training seminar. The experimental groups were trained in four stages; a control group was not trained. Early on, the instructor engaged in a great deal of *direction*. The instructor next did some selling and then *participated* with the trainees in the learning process. Finally, the instructor delegated the responsibility for learning to the trainees but remained available to support them. Thus as the maturity of the trainees increased, the instructor decreased the task-oriented direction. The final examination at the end of training showed that the experimental group learned significantly more than did the control group.

Jacobsen (1984) found that LASI ratings by colleagues of the appropriate flexibility of the style of 338 managers correlated significantly with the progress of the managers' careers, as well as with selected performance criteria. Although the maturity level of their subordinates was found to moderate between the managers' behavior and effectiveness, it was less important than other situational variables. For 209 supervisors and managers from five organizations, Haley (1983) obtained positive correlations between the subordinates' LASI assessments of the adaptability of their superiors' styles and the subordinates' ratings of the effectiveness of their own work groups. Hambleton and Gumpert (1982) found a statistically significant and practical gain in the job performance of 189 subordinates when their 56 supervisors applied the Hersey-Blanchard model correctly. High-performing managers rated higher than low performers on the effectiveness of their leadership and the flexibility of their style, both in their self-reports and in the appraisals by their subordinates and

superiors. They also showed greater knowledge and use of the model of situational leadership.

Kohut (1983) found that the flexibility of 281 women managers, as measured by LEAD, was related to their effectiveness and sex-role identity. Vecchio (1987) surveyed 303 teachers from 14 high schools with the less controversial Leader Behavior Description Questionnaire (LBDQ), to be discussed in [Chapter 20](#). Consistent with the Hersey-Blanchard model, Vecchio concluded that recently hired teachers, compared with those with more experience, may need and appreciate more initiation of structure from their supervisors. A replication with seven supervisors and 91 nurses reached similar conclusions (Norris & Vecchio, 1992); but another replication with 332 university employees and 32 supervisors (Fernandez & Vecchio, 1997) failed to find support for Situational Leadership Theory (SLT). Stirling (1998) obtained support for SLT by examining leadership in condominium and homeowner associations. Highly active members serve on committees and volunteer their time. Moderately active members participate in elections and occasionally attend meetings. Apathetic members expect a maintenance-free life and efficient management of the association. Stirling anticipated finding that apathetic members would be more satisfied with communication and decision making if the annually elected leader was task-oriented, telling, and a one-way communicator. Moderately active members were expected to favor selling and participative leadership. Highly active members were expected to want the leader to encourage participation and delegate responsibilities. Satisfaction of members was somewhat higher the more the leader adopted an appropriate style to match the perceived activity level of the member.

### ***Negative Evidence***

Consistent with other studies using other instruments, such as leaders' self-ratings on the LBDQ (Weissenberg & Kavanagh, 1972), Haley (1983) found response bias, low reliability, and lack of correlation between self-ratings and others' LASI ratings of the focal managers. Narayanan, Venkatachalam, and Bharathiar (1982) could find no relation between the LEAD self-reports of 30 owners of small Indian hosiery-knitting units and their employees' descriptions of the owners' styles. Nor could these researchers find any connection with the productivity of the units.

Goodson, McGee, and Cashman (1989) tested the Hersey-Blanchard propositions about effective leadership using 459 employees from 100 stores in a retail chain. The effectiveness of the style of leader behavior was unrelated to follower maturity; nor was the ranking of usefulness of the four styles from delegation to telling relevant to employee outcomes in commitment, satisfaction with the supervisor, or effectiveness in the different situations. York and Hastings (1985–1986) surveyed 172 employees in three North Carolina social service departments to ascertain the effects of the supervisors' behavior on their subordinates' performance in the context of the subordinates' level of maturity. They found that regardless of the level of the subordinates' maturity, supervisors' supportive and work-facilitation behavior, as measured in the Survey of Organization, contributed in the same way to the subordinates' performance.

Blank, Weitzel, and Green (1990) examined the situational leadership performance of 27 directors of residence halls (full-time professionals) who were responsible for 353 resident advisers (part-time paraprofessional students) in two large midwestern universities. A psychological maturity index was developed for the advisers, starting with 40 items about independence, the ability to take responsibility, and the motivation to achieve. Several factor analyses resulted in a refined single-factor scale of 11 items, such as "Acts conscientiously on the job," "Follows through on job tasks," "Takes care to do the job right," and "Works hard on the job." Peer ratings using the items were obtained from other advisers to measure the psychological maturity of the advisers (the subordinates of the directors). Satisfaction with their work and supervision were obtained from the advisers, along with ratings of their performance by their directors. The psychological

maturity of the advisers correlated .40 with the directors' ratings of their job performance. As predicted by the model, for those low in psychological maturity, work satisfaction increased linearly with the task-oriented, directive, and persuasive behavior of their directors. However, work satisfaction was much higher in advisers whose psychological maturity was high, regardless of the leadership behavior of their directors. The investigators concluded that their analyses as a whole lent little particular support for the Hersey-Blanchard model, although they agreed that further exploration of the relationship between the maturity of subordinates and the behavior of leaders would be useful.

## *Critique*

The curvilinear model ([Figure 19.2](#)) has been roundly criticized because of the lack of internal consistency of its measures (Aldag & Brief, 1981), its conceptual contradictions, and its conceptual ambiguities (Graeff, 1983). The model appears to have no theoretical or logical justification (Graeff, 1983); nevertheless, the model has intuitive appeal. As was already noted, Blake and Mouton (1981a) argued that although situational leadership as such may be interesting, a preponderance of the empirical evidence supports their one best way: leadership that integrates both task and relations orientation. For example, in the research by Blank, Weitzel, and Green, the advisers' satisfaction with their supervision correlated .41 and .54, respectively, with the task and relations behavior of their directors, regardless of the advisers' maturity. To this, Hersey and Blanchard (1982b) replied that Blake and Mouton deal with attitudinal models, while they deal with a behavioral model. Conflict occurs only when behavioral assumptions are drawn from the analysis of attitudinal models. Blake and Mouton (1981a, 1981b) countered with other difficulties of the Hersey-Blanchard model. They noted the extent to which task and relations orientation and behavior tend to be interdependent rather than uncorrelated with each other. Merely adding high task concerns to high relations concerns makes for benevolent paternalism, not teamwork. Qualitative differences at different ends of the continua in orientation and behavior need to be taken into account. For example, a high relations orientation that achieves high productivity (9,9) is characterized by openness, trust, respect, understanding, and mutual commitment. A high relations orientation that results in low productivity (1,9) is warm, friendly, and harmonious. To demonstrate this issue, Blake and Mouton (1981a, 1981b, 1982a) revised each of the 12 LEAD situations by adding fifth choices that reflected their 9,9 style. In paraphrase, the first Hersey-Blanchard situation was as follows:

A group is not responding favorably to our friendly conversation and concern for their welfare. Their performance is going down quite quickly.

The prescribed Hersey-Blanchard answer is a high task–low relations orientation, with the leader behaving according to response A. The least desirable choice is response D.

- (A) Stress and apply uniform procedures and the need for accomplishing the task.
- (B) Keep yourself on hand for discussion, but don't pressure subordinates to involve you.
- (C) Set goals for subordinates after talking with them.
- (D) Demonstrate your intentions by not interfering.

For this situation, Blake and Mouton thought the 9,9 style was the most efficacious: initiate a critique session with the entire group to diagnose the underlying problems responsible for this rapidly declining production and to decide what to do about it. From Blake and Mouton's point of view, the prescribed Hersey-Blanchard answer, A, is 9,1 behavior: telling subordinates what to do and pushing for production (Blake & Mouton, 1982a, 1982b).

One hundred experienced managers from 41 organizations completed the revised form without prior knowledge of the controversy. They ranked the choices for each of the 12 problems from most effective to least effective. The managers chose the fifth alternative, which reflects Blake-Mouton's 9,9 behavior

(integration of the task and relations orientations) between 72% and 90% of the time to handle each of the 12 situations. The managers chose the 9,9 alternative for situations at the four levels of the maturity of followers, from lowest to highest, 79%, 86%, 76%, and 78% of the time, respectively. They chose the appropriate alternative presented by Hersey-Blanchard to reflect the followers' maturity only 9%, 7%, 11%, and 5% of the time, respectively. Similar results were obtained with 36 mental health professionals.

In line with these results, Slocum (1984) suggested that the emphasis on the maturity of subordinates to determine when direction or participation is appropriate is of minor importance, in contrast to a number of other variables: the subordinates' tasks, the technology employed, the information required, the managerial control and coordination systems in place, the amount of self-control that is possible, and the extent to which the decision is operational and complex. Norris and Vecchio (1992) attributed to chance effects the occasional theoretically correct matches of leader style and subordinate readiness.

### ***Efforts to Improve the Hersey-Blanchard Model and Its Measures***

Nicholls (1985) suggested correcting the model's logical flaws by requiring a smooth progression of the leader from the *parent* style of high task orientation–high relations orientation to the *developer* style of low task–high relations. In this developmental progression, the leader will maintain a balanced emphasis on both the task and relationships as long as the ability and willingness of the group are developing symmetrically. If ability and willingness develop asymmetrically, the leader may find it more appropriate to act highly task-oriented, like a *coach* or a *driver*.

Boone (1981) improved the LEAD by modifying its scoring. The reliability of the LEAD self-report was increased by changing it from forced-choice scoring to scoring that captures the intensity of the endorsement of each alternative. In this way, a study of 249 managers from South Africa and the United States obtained more satisfactory test-retest reliabilities, ranging from .66 to .79.

*Leader Behavior Analysis (LBA)*. Blanchard, Hambleton, Zigarmi, et al. (1982) developed a revised instrument, Leader Behavior Analysis (LBA), with 20 incidents, to improve on the 12-incident LASI or LEAD. The LBA was constructed recognizing that effective task orientation and effective relations orientation were not independent of each other. Three of the four principal leadership styles were relabeled in 1985. *Telling* became *directing*; *selling* was seen as manipulative and became *coaching*; and *participating* became *supporting* for purposes of clarification and retention (Blanchard, Zigarmi, & Zigarmi, 1985). *Readiness* and *maturity* were also relabeled, as *development level*, to change the implication from age and status to mastery of necessary skills for task accomplishment and competence. The lowest developmental level of followers was changed from being *unwilling and unable* to being *committed but unable*. At the second level of development, followers were conceived to be low in commitment but somewhat competent. An *effectiveness* score could be calculated from the extent to which the chosen responses to the 20 incidents matched what was required according to the revised Situational Leadership model.

*Evidence of the Effectiveness of the Revised Model*. Using the LBA, Wilkinson (1990) compared 116 high-and low-scoring leaders in a government agency. Compared with low scorers, high scorers were rated by their subordinates as significantly more satisfying as supervisors. Stoner-Zemel (1988) obtained significant positive correlations between LBA effectiveness of supervisors according to others and the perceptions by 293 employees of their high productivity ( $r = .25$ ), alignment ( $r = .28$ ), and feelings of empowerment ( $r = .34$ ). Duke (1988) also reported a positive correlation for nurses between LBA effectiveness scores of supervisors and subordinates' sense of empowerment. Zigarmi, Edeburn, and Blanchard (1993) compiled results for 552 employees for whom morale was higher, tension was lower, and felt opportunities for growth were higher if the employees' LBA descriptions of their manager generated high rather than low effectiveness scores. Price

(1993) found positive correlations between effectiveness scores and various managerial competencies as found in the Boyatzis' (1982) model.

### ***Should Leaders Be Consistent or Flexible?***

*Measurement.* A *flexibility* score can be calculated based on the extent to which the leader or rater reported use of varying styles to handle the 20 LBA incidents. The most inflexible score would describe a leader who used the same single style to deal with all 20 incidents. Use of the LBA and the flexibility score could further understanding of the importance of leadership constancy and flexibility.

*Effects.* If leaders recognize that different circumstances call for different actions on their part, do they risk being downgraded for being inconsistent and unpredictable? Do they cause subordinates to feel unsure about what is expected? The evidence is mixed. Bruce (1986) reported that CEOs placed a premium on being consistent and predictable in word and action. Staw and Ross (1980) asked 95 practicing managers and 127 undergraduates to read one of several case descriptions of administrators who were consistent or flexible and ultimately successful or unsuccessful in their actions. Although both sets of respondents assigned the highest ratings to administrators who were consistent, particularly those who also were successful, the practicing managers valued consistency more than did the undergraduates. Block and Kennedy (1986) asked 133 employees to rate leaders who were described as consistently autocratic or participative rather than flexible and varying in their style depending on the circumstances. The employees opted most often for the consistently participative manager than for the more flexible one. Graves (1985) obtained similar results for 141 undergraduate leaders. Those who persisted in one particular way were evaluated more favorably than were those who varied in their responses, despite the different levels of complexity with which they had to cope. Also supporting the utility of consistency, Aldag and Brief (1977) obtained strong negative correlations between an index of the variability of leaders' behavior and measures of subordinates' satisfaction, involvement with their jobs, organizational commitment, and experienced meaningfulness of the work. Thus Blake and Mouton's (1982a) arguments for a consistent 9,9 leadership style have more empirical support than do Hersey and Blanchard's notions about how leaders must vary their style according to the situation.

Some exceptions need to be noted. James and White (1983) showed that 377 U.S. Navy managers were in favor of flexibility and varied their leadership behavior toward their subordinates depending on their perceptions of what specifically caused these subordinates to perform inadequately. When 159 undergraduates judged systematically differing leadership descriptions, Knight (1984) found that the perceived competence among managers was more important in evaluating them than whether they were consistent or flexible.

One factor that seemed to account for the differences in support for consistency or flexibility was whether the evaluators were the superiors or subordinates of the leaders. According to a simulation used by Heilman, Hornstein, Cage, and Herschlag (1984), appropriate flexible responses were more likely to be favored if the evaluator was a superior of the leader; consistent participativeness was more likely to be favored if the evaluator was a subordinate. In addition, it seems that flexible leadership will be judged favorably if the shifts in a leader's style or behavior are meaningful and explainable to those who are evaluating the leader as shifts to accommodate the requirements of the circumstances. If no such change in requirements is perceived, consistency will be prized in a leader because it is predictable and fits with colleagues' expectations.

### ***Why Is the Hersey-Blanchard Model So Popular?***

The Hersey-Blanchard model has had remarkably widespread intuitive appeal to practicing managers and to leaders of management-training programs. An understanding of its popularity with management may require

an analysis of the sociology of knowledge, not of the model's theoretical or empirical validity.

Situationalism may be popular because it provides freedom from principles ("You can do your own thing as you see fit"). Principles are more complex to learn and practice. Situationalism allows a leader to keep all options open (Blake & Mouton, 1982b). Although LEAD lacks the desired level of reliability, and its validity remains in doubt, its situations and choices seem to provide interesting discussion material for training. The simplicity of this instrument makes it possible to retain its prescriptions on a single small card. This simplicity may also give managers a sense of quick mastery of a complex problem. For the personally authoritarian manager, the model calls attention to the need for a flexible response. To the personally democratic manager, it gives legitimacy to being directive at times.

## Fiedler's Contingency Model of Leadership

---

Fiedler's contingency model (1967a) avoids the problem of a leader's consistency in the face of situations with different requirements. Leaders are conceived to have a personally consistent style of task or relations orientation. Either different types of leaders need to be chosen for various situations, or leaders need to change the situations to suit their particular personal style. According to the heavily researched contingency model of leadership, leaders with high "least preferred coworker" (LPC) scores do best in situations moderately favorable to them; low-scoring leaders do best in situations extremely favorable or extremely unfavorable to them. This model is presented here as part of the discussion of relations-and task-oriented leadership. Nevertheless, controversy continues about whether Fiedler's LPC questionnaire measures task orientation or something else. The controversy, in turn, affects our ability to understand LPC's contribution to effectiveness in different situations. On the surface, LPC measures how much each of 16 to 18 attributes reflect respondents' feelings about a person with whom they can work least effectively.

### *Development of the LPC Measurement*

Starting in the early 1950s, Fiedler (1953a, 1953b, 1953c) began studying the success of psychological therapists as a function of their accuracy and assumed similarity to their patients. This research was then extended to leaders and the effectiveness of their groups (Fiedler, 1954a, 1954b, 1955, 1956). A measure of Assumed Similarity between opposites (ASo) was developed. ASo scores were obtained by computing the difference between two sets of semantic differential ratings. One set was the leader's description of his or her least preferred coworker (LPC). The other set consisted of ratings of the leader's most preferred coworker. ASo scores were viewed as indicators of leadership style, and were correlated with the performance of groups. Success in accurately predicting performance of outcomes from ASo scores was mixed.

Eventually, the most preferred coworker was abandoned as an assessment, and attention was focused on LPC. In its standard version, the examinee is asked to think of everyone with whom he or she has ever worked and then to describe the one person with whom he or she could work least well. This description of one's LPC is made by marking 16 items, as shown in [Table 19.2](#). The favorable pole of each scale is scored as 8 and the unfavorable pole is scored as 1 (Fiedler, Chemers, & Mahar, 1976). The sum of the scale scores of items constitutes the individual's LPC score. A relatively high LPC score (favoring the LPC) was most generally conceived by Fiedler (1967a, 1970b) to indicate a relations-motivated person, whereas a low LPC score (rejecting the LPC) was conceived to indicate a task-motivated person.

### *Measurement Properties of LPC*

A good deal of evidence is available concerning the internal consistency and stability of the LPC, but its validity remains a complex question.

Table 19.2 Least Preferred Coworker Scale

Think of the person with whom you can work *least* well. This person may be someone you work with now or someone you knew in the past. This person does not have to be the person you like least well, but should be the person with whom you had the most difficulty in getting a job done.

Please describe this person as he or she appears to you by putting an "X" in the appropriate space on the following scales.

Pleasant	_____	Unpleasant
Friendly	_____	Unfriendly
Rejecting	_____	Accepting
Helpful	_____	Frustrating
Unenthusiastic	_____	Enthusiastic
Tense	_____	Relaxed
Distant	_____	Close
Cold	_____	Warm
Cooperative	_____	Uncooperative
Supportive	_____	Hostile
Boring	_____	Interesting
Quarrelsome	_____	Harmonious
Self-Assured	_____	Hesitant
Efficient	_____	Inefficient
Gloomy	_____	Cheerful
Open	_____	Guarded

SOURCE: Fiedler (1967), p. 41.

*Internal Consistency.* Do the same people respond in the same way to the different items of the LPC scale? For earlier versions of LPC, Rice (1978a) obtained a mean split-half reliability of .88 for a variety of investigations. Fox, Hill, and Guertin (1973); Shiflett (1974); and Yukl (1970) discovered separate interpersonal and task factors in these earlier LPC scales, but the secondarily scored task factor was seen to be relatively unimportant. Therefore, a newer 18-item scale was designed to minimize task-factor items and, as a consequence, was somewhat higher in internal consistency (Fiedler, 1978). In five studies with the newer 18-item version, shown in [Table 19.2](#), Rice (1979) reported coefficient alphas of .90, .91, .79, .84, and .89.

*Stability.* Do people's LPC scores remain the same over time? Rice (1978a) found 23 reports of test-retest reliability ranging from .01 to .91, with a median of .67. Stability indexed by high test-retest correlations was obtained by Chemers and Skrzypek (1972)<sup>8</sup> when the test and retest were separated by at least several weeks. However, the time between the test and retest did not affect stability (as might have been expected), according to an analysis of studies in which the intervals between the test and the retest ranged from several days to over two years (Rice, 1978a). Hence, stability can be maintained over extended intervals of time. Bons (1974) obtained a test-retest reliability of .72 for 45 higher-level army leaders over a five-month period, and Prothero and Fiedler (1974) obtained a test-retest correlation of .67 for 18 faculty members at a school of nursing over a 16-to 24-month period. However, Fox (1976) found a decline in reliability when the retest was obtained nine weeks instead of four weeks after the test. With intervals of three to five weeks, test-retest reliabilities ranged from .73 to .85. With intervals of eight to nine weeks, they ranged from .23 to .68. When the interval was 130 weeks, the test-retest reliability was only .45. Fox (1976) found that stability was reduced if the same LPC was not described in the test and in the retest.

Thus, LPC is not necessarily as invariant an attribute of an individual as is a personality trait, such as sociability. Offerman (1984) and other investigators<sup>9</sup> obtained results suggesting that the LPC is more like a transitory attitude. For example, in a comparative experiment with male and female undergraduates who led opposite, mixed, or same-sex groups, Offerman (1984) found significant differences among the leaders as a consequence of the sex composition of the groups. The LPC scores of females who had just led male groups were most task-oriented; the LPC scores of males who had just led female groups were most relations-oriented.

Temporary shifts also can be induced by unsatisfactory work experiences in laboratory experiments. When

instability has been found in such experiments, it has been attributed to “implicit instructions” of training interventions as to how one should adapt toward poor coworkers (Rice, 1978a). The LPC also appears sensitive to major life changes, such as being subjected to stressful contact assignments (Bons, Bass, & Komorita, 1970). In spite of the satisfactory median test-retest results, Schriesheim, Bannister, and Money (1979) remained unconvinced of the stability of LPC because of the wide variation in test-retest results within the various reported analyses. For instance, Schriesheim and Kerr (1977a) noted that a significant proportion of persons also changed category from high to low LPCs, or vice versa.

*Parallel-Form Reliability.* Do LPC scores remain the same if different attributes are included in the items? For instance, in one form, the choice may be between dull and bright. In the parallel form, the choice may be between stupid and smart. Rice (1978a) reported one study in which scales whose items had different content and different formats were fairly well correlated with each other. Different versions of the LPC have contained various numbers of task-oriented items, which may reduce their parallel-form reliability. This difference may account for some of the variations in correlations of the LPC version used with other tests and measures of the effectiveness of groups in attempts to determine the meaning of LPC (Schriesheim, Bannister, & Money, 1979). But Rice (1979) argued that since correlations of .79, .78, and .66 were obtained when items and formats to assess LPC had been changed, correlated parallel forms could be constructed successfully.

*Content Validity.* Are the items of the LPC scale biased? If LPC is a measure of the degree to which task-oriented individuals are negative about those with whom they cannot work—an attitude reflected by ascribing negative values to the LPCs on such attributes as pleasant-unpleasant, which are not necessarily related directly to their work—then task-oriented items, such as bright-dull, reduce the content validity of the LPC, since brightness and dullness are directly related to getting the work done (Schriesheim, Bannister, & Money, 1979). An 18-item version that omits such clearly task-relevant items is now operative. As was noted earlier, Shiflett (1974) and Yukl (1970), among others, demonstrated that the earlier versions of the LPC contained two factors, one associated with interpersonal relations items, the other with task-oriented items. Studies by Fiedler (1967a) and Schriesheim (1979b) have found LPC scores to be relatively free of social desirability, unlike so many other personality measures.

*Construct Validity.* What is really being measured by the LPC? How does the LPC logically and empirically link with other known entities? Fiedler and Chemers (1974, p. 74) observed that “For nearly 20 years, we have been attempting to correlate [LPC] with every conceivable personality trait and every conceivable behavior observation score. By and large these analyses have been uniformly fruitless.”

But Rice (1978b), who sampled 66 out of 114 studies involving over 2,000 empirical relationships between the LPC and other variables, thought he could lay out the nomological network of empirical relationships of the LPC and other measures. He concluded more optimistically that although it remains unclear whether the LPC is a measure of social distance, personal need, cognitive complexity, or motivational hierarchy (as will be discussed later), the LPC score as a measure of interpersonal relations versus task orientation is not in doubt.

The inconsistent results can be seen if one examines the correlations of LPC with biographical data and then compares what Bass (1967b) reported about the correlations of direct measures of relations orientation and task orientation. In agreement with Bass’s review, a low LPC score (task orientation) was higher with increasing age (Fiedler & Hoffman, 1962) and with experience (Bons, Bass, & Komorita, 1970). But opposed to Bass’s conclusions, a high LPC score (relations orientation) was positively correlated with managerial level (Al-pander, 1974) and with Protestant rather than Catholic affiliation (Fiedler & Hoffman, 1962). Above and beyond these results, no significant relations of biodata and LPC were found by Eagly (1970) or numerous other investigators.<sup>10</sup>

Schriesheim and Kerr (1974) have critically noted, as new evidence has emerged, that the LPC has been redefined as an orientation toward work, as an attitude, as a cognitive complexity measure (E. J. Frank, 1973), as the ability to differentiate conceptually (Foa, Mitchell, & Fiedler, 1971), or as an index of a hierarchy of

goals (Fiedler, 1972a). However, this redefinition could be a virtue rather than a fault. (Theoretical constructs, like ether, should wither away, leaving behind empirical facts, like the electrical discharge in lightning.) But critics fail to see that the new data justify the new interpretations (Hosking, 1978). For example, Evans and Dermer (1974) correlated the LPC scores for 112 business students, managers, and systems analysts with two measures of cognitive differentiation and cognitive complexity and found that low LPC scores were associated with cognitive simplicity. Nevertheless, high LPC scores were not unequivocally related to cognitive complexity.

*LPC as a Measure of Relations and Task Orientation.* A number of studies have supported the contention that a high LPC score is connected with relations orientation and a low LPC score is connected with task orientation.

Fiedler (1964, 1967a) proposed that high-LPC people have a strong need to attain and maintain successful interpersonal relationships, whereas low-LPC people have a strong need for successful task performance. Four sets of data generally gave some support for this interpretation (although many reversals were noted). The behavior of low-LPC leaders tended to be task oriented, and the behavior of high-LPC leaders was generally relations oriented. Members of groups with high-and low-LPC leaders tended to exhibit task-oriented and relations-oriented leadership. Higher levels of satisfaction and lower levels of anxiety were found among groups with high-LPC leaders. Finally, data suggested that low-LPC people gained self-esteem and satisfaction from the successful performance of tasks and high-LPC people gained self-esteem and satisfaction from successful interpersonal relations.

Fiedler (1978) inferred that for an individual who describes his or her LPC in negative, rejecting terms, the completion of the task is of such overriding importance that it completely colors the perception of all other personality traits attributed to the LPC score. Fiedler's interpretation was as follows: "If I cannot work with you, if you frustrate my need to get the job done, then you can't be any good in other respects. You are unfriendly, unpleasant, tense, and distant, etc."

The relationship-motivated individual who sees his or her LPC in more positive terms says, "Getting a job done is not everything. Therefore, even though I can't work with you, you may still be friendly, relaxed, interesting, etc.—in other words, someone with whom I could get along quite well on a personal basis." Thus a high-LPC person looks at his or her least LPC in a more differentiated manner and is more interested in the personality of the individual than merely in whether this is or is not someone with whom one can get a job done (p. 61). But Hare, Hare, and Blum-berg (1998) found among 20 groups of managers that leaders who were both relations-and task-oriented were prone to give lower ratings to their LPCs.

*LPC and Other Relevant Measures of Orientation.* Vroom and Yetton (1973) and Sashkin, Taylor, and Tripathi (1974) reported that high LPC scores related to the preference for participation in resolving conflict. Nebeker and Hansson (1972) found that high LPC scores correlated with support of giving children the freedom to use facilities. Alpaender (1974) obtained results indicating a positive relationship between high LPC scores and the judged importance of people-oriented management functions. Similarly, Ayman and Chemers (1986) found that high-LPC Mexican managers described the ideal leader as a "people person" and low-LPC managers described the ideal leader as a taskmaster; low-LPC managers were also more self-monitoring. However, Singh (1983) failed to find support, in experiments with 53 Indian engineering students, that high-LPC students would place greater importance on the equity of the distribution of rewards whereas low-LPC students would emphasize performance. Contrary to expectations, Steiner and McDiarmid (1957) found that a high LPC score coincided with authoritarian beliefs, and Evans and Dermer (1974) and others<sup>11</sup> found LPC to be unrelated significantly to authoritarianism or dogmatism.

*LPC and Observed Leader Behavior.* Observers and other group members found that a low LPC score coincided, as expected, with initiating structure and task-oriented leadership behavior, and a high LPC

score coincided with relations-oriented behavior in a number of studies.<sup>12</sup> But complete reversals (Nealey & Blood, 1968) and negative results were also reported.<sup>13</sup> Interactions with situations had to be considered.<sup>14</sup> LPC scores did not relate much to decision-making styles. McKenna (undated) obtained correlations between LPC and style of decision making of 22 chief accountants, as follows: directive without explanation,  $-.12$ ; *directive* with explanation,  $-.01$ ; consultative,  $.06$ ; *participative*,  $.03$ ; delegative,  $.13$ .

Mitchell (1970a) found that, as expected, high-LPC leaders gave more weight to interpersonal relations. Gottheil and Lauterbach (1969) studied military cadets and squads who were competing in field exercises and found that a leader's low LPC score was associated with a group's performance, whereas leader's high LPC score was associated with a group's morale. But contrary to expectations, LPC scores were higher for leaders working in the short term than in the long term (Miller, 1970).

Such complete reversals of results and the weakness of LPC scores as indicators of leadership behavior led Vroom (1976b) to suggest caution in characterizing leadership style on the basis of LPC score alone. According to Fiedler (1967a), leadership style depends on combining LPC scores with measures of the situation in which high-or low-LPC people find themselves. A high LPC score, Fiedler (1978) noted, does not always predict that a leader will behave according to a relations orientation. Nor will a low LPC score always predict that the leader will push for production, for completion of the task, or for more structuring. At any rate, although LPC may prove to discriminate among leaders in ways that are of consequence to their effectiveness in different contingencies, LPC is not directly symptomatic of the other styles of leadership behavior discussed earlier or yet to be discussed. Hence the results with LPC must stand alone. In fact, some question remains about whether LPC is measuring task and relations orientation or something else.

### ***Alternative Meanings of LPC***

LPC has gone through a series of reinterpretations based on empirical studies of its characteristics. It has been conceived as a measure of social distance, cognitive complexity, motivational priorities, and a value attitude.

*LPC as a Measure of Social Distance.* At first, Fiedler (1957, 1958) interpreted LPC—then called ASo, an index almost perfectly correlated with LPC—as a generalized index of psychological closeness. Low-LPC people were conceived to be more socially or psychologically distant from other group members than were high-LPC persons. The assumed similarity data were drawn from person-perception research conducted in therapeutic settings. Fiedler (1953a, 1953b) inferred that respondents showed greater assumed similarity between themselves and group members they liked than between themselves and members they disliked. Analyses suggested that LPC was a measure of emotional and psychological distance, since high-LPC people conformed more in the face of social pressure and were more closely involved with other group members. But following a review of studies of the reactions of others to high-and low-LPC persons, Rice (1978b) concluded that the data were contradictory.

*LPC as a Measure of Cognitive Complexity.* Foa, Mitchell, and Fiedler (1971) and Hill (1969a) argued that compared with low-LPC people, high-LPC people are more cognitively complex, favoring the abstract over the concrete and using less broad categorizations. These researchers based their proposal on positive correlations they found between LPC and several measures of cognitive complexity. In addition, the intercorrelations among the factor scores of the LPC scale were lower for high-LPC persons; and greater responsiveness to interpersonal factors was observed in the judgments and behavior of high-LPC persons.

Although LPC was found to be correlated significantly with intelligence in only 1 to 14 analyses, in several of 11 other analyses LPC was related to specific cognitive tendencies. Thus Mitchell (1970a, 1970b) found that high-LPC leaders gave more weight to power and structure in making discriminations, whereas low-LPC leaders gave more weight to interpersonal relations. Foa, Mitchell, and Fiedler (1970) observed that the high-

LPC leader performed better in situations that presented difficulties in either interpersonal or task relations and thus that required a high degree of cognitive differentiation between them. Jacoby (1968) found positive correlations between LPC and scores on the Remote Associates Test, a test of creativity. Similarly, Triandis, Mikesell, and Ewen (1962) reported a possibly positive correlation between LPC and the judged creativity of two written passages. Singh (1983) also obtained data to support LPC as a measure of cognitive complexity by demonstrating that high-LPC engineering students did better than low-LPC students in obeying the precise prescriptions of a model for the equitable distribution of rewards.

The findings for cognitive complexity dealing with field independence-dependence, as measured by the Embedded Figures Test, were less consistent (Gruenfeld & Arbuthnot, 1968; Weissenberg & Gruenfeld, 1966). Furthermore, a number of other studies<sup>15</sup> found no evidence to support LPC as a measure of cognitive complexity.

*LPC as a Measure of a Motivational Hierarchy.* To account for so much variation in results, Fiedler (1972a) saw the need for a “hierarchical” conceptualization of LPC. Since, according to Fiedler, the high-LPC person needs to be related and socially connected to others, he or she will show concern for good interpersonal relations when the situation is tense and anxiety arousing and when relations with coworkers seem tenuous. But when the goals of being related are secure, the relationship-motivated high-LPC person will then seek the self-oriented admiration of others and the attainment of prominence. In work groups, such goals can be attained by showing concern for the task-relevant aspects of the groups’ interaction. The major objectives of the low-LPC person are to accomplish a task and to earn self-esteem by doing a good job (D. W. Bishop, 1964). But when the completion of a task presents no problem, the low-LPC person will seek friendly, good interpersonal relations with coworkers, partly because he or she believes that good interpersonal relations are conducive to accomplishing the task (Fiedler, 1971b).

Nevertheless, this interpretation, like previous interpretations, remains controversial. Green and Nebeker (1977) presented data to support it. But evidence by Rice and Chemers (1975) failed to confirm predictions based on a motivational hierarchy. Rather, LPC as a measure of cognitive complexity better fit their results. Kunezik (1976a, 1976b) found no support for the motivational hierarchy in studies of the relationship of ASO to various personality measures among 1,590 German army recruits and 148 group leaders. Schriesheim and Kerr (1977b) concluded that neither sufficient theoretical nor empirical support had emerged for this interpretation of LPC.

*LPC as a Measure of a Value Attitude.* On the basis of a review of available evidence, Rice (1978b) agreed that the data did not support the shift in orientation required by the motivational hierarchy concept of LPC. According to Rice, the data fit better with a simpler conceptualization of LPC as a value and an attitude, for LPC was more consistently and strongly related to attitudes and judgments than to behavioral manifestations. Therefore, LPC was seen as an attitude that reflects differences toward interpersonal relations and the accomplishment of tasks. One can make some general statements about the behavior of high-and low-LPC leaders, but situational variables have a strong influence.

How can Fiedler and Chemers’s (1974) beliefs in the uniqueness of LPC be reconciled with Rice’s conclusion that LPC is a value-attitude assessment? One problem was Rice’s strategy of building his summary around published relationships that were statistically significant at the 5% level. As David Bakan quipped in a private communication, significant relationships are more likely to be published than nonsignificant ones. The total universe of studies is probably far greater than what Rice compiled. And with so many studies in the significant pool at the margin of significance, with no attention paid to the strength of the relationships that were found, it is difficult to accept Rice’s evidence as compelling. However, Rice (1978b) concluded, as a consequence of his analysis of 313 reported relationships, that LPC was more strongly linked (that is, significant results at the 5% level were obtained) with values and attitudes. But even here, only 27% of the 313 relationships were significant. Yet even among these, certain expected and reasonable inferences could be

made with some conviction. Thus, as would be expected from relations-oriented individuals, high-LPC people were found to make more favorable judgments of other group members—the leader, coworkers, and followers in general<sup>16</sup>—than low-LPC persons did in 18 of 20 analyses. Low-LPC people tended to be more favorable than high-LPC people in judgments of their best friends, more preferred coworkers, and loyal subordinates.<sup>17</sup> But negative results were also reported.<sup>18</sup>

Rice (1978b) concluded from these studies that low-LPC persons discriminated more sharply than high-LPC persons among other group members on task competence. Also, LPC was related to judgments about oneself; low-LPC persons judged themselves significantly more favorably than did high-LPC persons in 34 of 102 analyses, particularly in direct evaluations (88% of the relationships were statistically significant).<sup>19</sup> A complete reversal (not necessarily unexpected) occurred in a Japanese study (Shima, 1968), and negative results were reported by others.<sup>20</sup>

Evidence that low-LPC persons value the successful completion of tasks was seen in the defensiveness of their attributions about the cause of the failure of a task and their evaluation of the task-relevant ability of the group. In addition, low-LPC persons were found to be more optimistic about succeeding in a task and about earning important rewards as a consequence. High-LPC persons were more optimistic about succeeding at interpersonal relationships and expected that such success would lead to important outcomes (Fiedler, 1967a, 1972a).

Taking everything into account, Rice (1978b), on the basis of these mixed results, agreed with Fiedler that low-LPC persons value being successful in tasks and high-LPC persons value interpersonal success. But Fiedler concluded that any interpretation of the meaning of LPC must take into account situational considerations in determining how LPC will manifest itself in effective leadership. That is, Fiedler (1978) believed that the main effects of LPC on a leader's behavior are weak, in comparison with the effects of the interaction of LPC with the favorableness of the situation to the leader.

### ***Situational Favorability for the Leader***

In Fiedler's (1967a, 1978) exposition of his model, lowLPC (task-oriented) leaders performed better and led more effective groups when the quality of leader-member relationships, the degree of task structure, and the positional power of the leader are either altogether highly favorable or altogether highly unfavorable to the leader. High-LPC (relations-oriented) leaders are most effective when favorability is neither high nor low; that is, high-LPC leaders are expected to be most effective in moderately favorable circumstances. Fiedler envisaged eight situations (octants I through VIII), one for each combination of poor or good relations with group members, low or high structure of the group, and weak or strong power of the leader. The extremes of octants I and VIII are clearly determined by their location at the ends of the dimension of situational favorability. In octant I, leader-member relations are good, the task is highly structured, and the leader's positional power is strong. In octant VIII, leader-member relations are poor, the task is unstructured, and the leader's positional power is weak. But octants II and III, for instance, would exchange places on the dimension of favorability if the leader's position power was considered the second horizontal dimension and structure was considered the third horizontal dimension. The eight octants of the situational favorability dimension are shown along the horizontal axis of [Figure 19.3](#).

*Weighting.* The relative importance of the three situational factors to the leader's situational favorability was reflected in a continuous scale constructed by Nebeker (1975). Nebeker's scale weighted standardized scores for each of the three situational variables so that the leader's situational favorability = 4 (leader-member relations) 1 2 (task structure) 1 (positional power).

Figure 19.3 The Contingency Model of Leadership Effectiveness Based on Original Studies

SOURCE: Fiedler (1967a).

The theoretical combinations required by Fiedler for octant analysis fit the empirical multiple regression analyses conducted by Nebeker (1975). Beach and Beach (1978) also reported findings that supported an independent, additive view of the three variables of leader-member relations, task structure, and leader's positional power. Beach and Beach (1978) asked students to estimate the probability of success and the situational favorability of a series of hypothetical leadership situations. These situations were presented as involving either good or poor leader-member relations, high or low task structure, and the leader's high or low positional power. A correlation of .89 was obtained between the estimated probability of the leader's success and the degree of situational favorability. A multiple correlation was then compared with situational favorableness as the criterion and the three situational favorability subscales as predictors. The beta weights obtained were .45 for leader-member relations, .33 for task structure, and .11 for positional power, comparable to the Nebeker formula of 4:2:1.

Earlier, situational favorability had been defined in terms of how much control the leader had in the situation. Support for the linkage of situational favorability and situational control came from a study by Maidalton (1975) in which participants were asked to complete a leader's in-basket test. The study found that high-LPC leaders tended to be most effective and were most likely to ask for additional information in moderate-control situations, whereas low-LPC persons engaged in the most information-searching behavior in high-control situations.

*Determination of Situational Characteristics.* In Fiedler's original studies, the quality of interpersonal relations was measured by sociometric choices and related measures of liking. Open-hearth steel crews were judged to be highly structured and boards of directors or transient student groups were judged to be highly unstructured. The leader's power was judged to be high for managers of gasoline stations and to be low for the informal leaders of basketball teams. Subsequently, Fiedler developed specific scales to provide measurements of the three situational variables for any leader-group situation. Other situational variables that have been assumed to determine the leader's situational control included stress, cultural and linguistic heterogeneity, and the amount of experience.<sup>21</sup>

To measure leader-member relations, an eight-item group-atmosphere scale was developed that correlated .88 with earlier methods of estimating these relations. Respondents rated how much the situation was friendly or

unfriendly, accepting or rejecting, satisfying or frustrating, etc. To measure task structure, a scale was created to obtain judgments about whether the goal was clearly stated, whether there was only one way to accomplish the task, whether there was one correct answer, and whether results were easy to check for correctness. To measure a leader's positional power, a scale asked whether the leader could evaluate subordinates and recommend rewards, punishments, promotions, and demotions (Fiedler, Chemers, & Mahar, 1976). Schriesheim (1979a) found the group-atmosphere scale to be free of social desirability, but the positional-power scale correlated .42 with social desirability.

*Meaning of Situational Favorability.* For Fiedler (1978), situational favorability implied that leaders were certain that their decisions and actions would have predictable results, would achieve the desired goals, and would satisfy the leaders. At the favorable extreme and the unfavorable extreme, the leaders know where they stand in relation to their groups. In between, relations are more cloudy for the leaders.

Schriesheim and Hosking (1978) found a number of problems with the measurement of situational favorability. The three variables were assumed to interact in a relatively simple way to determine the amount of influence the leader had over the group, an assumption subsequently supported by Beach and Beach's (1978) results. However, although Fiedler (1978) acknowledged the importance of other variables, he relied on just the aforementioned three among the many possible variables of consequence (Filley, House, & Kerr, 1976).

### ***Situational Favorability and LPC***

Between 1953 and 1964, Fiedler and his associates studied the effectiveness of leadership in a variety of groups and tested a contingency hypothesis from the results of those studies. Fiedler (1964) plotted the correlations and their medians between LPC scores (actually ASo) and group performance for the different octants—the different levels of situational favorability. Each plotted point in [Figure 19.3](#) represented an obtained correlation between the leaders in a particular study in a designated octant of situational favorability for the leaders and the effectiveness of their groups. A positive correlation indicated that high-LPC (relations-oriented) leaders coincided with more effective groups. A negative correlation showed that low-LPC (task-oriented) leaders ran more effective groups. A positive median correlation for all analyses completed in a designated octant denoted the extent to which high-LPC leaders performed more effectively than low-LPC leaders. A negative median correlation disclosed that the low-LPC leaders were superior for a designated octant. Fiedler theorized that the curvilinear relation (as seen in [Figure 19.3](#)) was an indication that low-LPC leaders were more effective than high-LPC leaders in very favorable and very unfavorable situations (e.g., octants I and VIII), whereas high-LPC leaders were more effective in situations of intermediate favorability (e.g., octants IV and V).

### ***Validity of the Model***

Early on, Fiedler (1971b, 1978) was able to review efforts to validate the contingency model.<sup>22</sup> The empirical investigations included field studies, field experiments, laboratory experiments, and octant analyses. Many more reviews followed (among them Ayman, 2002).

*Field Studies.* Field tests validating the model were completed with basketball teams, student surveying teams, bomber crews, tank crews, open-hearth shops, farm-supply cooperatives, training groups, departments of a large physical science research laboratory, a chain of supermarkets, and a plant that manufactured heavy machinery. W. A. Hill (1969a) reported analyses in a large electronics firm with assembly-line instructors. Fiedler, O'Brien, and Ilgen (1969) worked with public health volunteer groups in Honduras. Shima (1968) studied Japanese student groups; Mitchell (1970b), participants in a church-leadership workshop; and Fiedler (1971c), trainees in an executive development program.

An example of the operational support of applied findings was Loyer and O'Reilly's (1985) study of Ontario community health supervisors. In favorable situations on the group-atmosphere scale, units led by low-LPC (task-oriented) supervisors were more effective (according to nursing directors' evaluations of the units) than were groups led by high-LPC supervisors. As predicted by the model, groups led by high-LPC (relations-oriented) supervisors, compared with those led by low-LPC (task-oriented) supervisors, were more effective in situations that were moderately favorable to the supervisors. A similar confirmatory pattern was reported by Wearing and Bishop (1974) for the LPC scores of leaders of U.S. Army combat-engineer training squads.

Kennedy (1982) reanalyzed data from 697 fire and military personnel in 13 studies. As the contingency theory postulated, low-LPC leaders did best, according to supervisors' and observers' evaluations, in very favorable and very unfavorable situations, and high-LPC leaders did best in the moderately favorable situations. However, Kennedy also observed that leaders whose LPC scores were intermediate were generally more effective than those whose LPC scores were high or low; and their effectiveness was relatively unaffected by the favorability of the situation.

Conclusions supporting the validity of the contingency model were most likely to be reached if the criterion measure of effectiveness was limited to superiors' evaluations of the performance of high-and low-LPC persons in carrying out their tasks as leaders. Rice (1978b) reviewed the relevant correlations by octants and found that almost all predictions fit the model. [Table 19.3](#) presents Rice's results. However, Giffort and Ayman (1988) found that the contingency model was also supported when they used subordinates' satisfaction with coworkers as a criterion of effective leadership. The outcomes were dependent on situational favorability, as expected, but two other measures of subordinates' satisfaction (with the job and with supervision) failed to be sensitive in the same way.

Table 19.3 Extent to Which the Contingency Model Fits Obtained Correlations of LPC and Superiors' Appraisals as a Function of Situational Favorability in Eight Octants

Total number of analyses	17	1	18	—	12	1	2	16

SOURCE: Rice (1978b).

*Field Experiments.* A number of experiments and controlled field studies also tested the model. Fiedler (1966) studied 96 experimentally assembled groups of Belgian sailors, half of which were led by petty officers and half by recruits. Half the groups began with structured tasks (routing a ship convoy through 10 and then 12 ports); the other half began with unstructured tasks (writing a recruitment letter). The results were consistent with the contingency model. In a controlled experiment conducted by Chemers and Skrzypek (1972) at West Point, leaders were chosen on the basis of sociometric choices by the members to determine in advance whom the members would choose as a leader. Then half the groups were assembled with preferred leaders and half with nonpreferred leaders. This study, with carefully preselected leaders, replicated the predicted median correlations. The generally supportive results are displayed in [Figure 19.4](#). Fiedler (1978) concluded that the results of field research on work groups almost uniformly supported the model but that the results of experimental group research were somewhat less supportive

Figure 19.4 Median Correlations between Leader's Performance and Group Performance for the Original Studies, Validation Studies, and the Chemers and Skrzypek (1972) Study

SOURCE: Fiedler (1997b).

**Laboratory Experiments.** Gruenfeld, Rance, and Weissen berg (1969) studied leaders under high, medium, or low support in experimental groups. They found that low-LPC leaders behaved in a more dominant manner than did high-LPC leaders, regardless of the level of group support, but especially under medium support.

Exceptions to the predicted relations were found in octant II (good leader-member relations and structured, weak power of the leader), where the correlations between LPC and group effectiveness in the laboratory studies were positive, rather than negative as predicted. The same results occurred in laboratory experiments by Hardy (1971, 1975) and Hardy, Sack, and Harpine (1973), who obtained LPC scores one or two weeks before their experiment. In two of these studies, leader-member relations were experimentally manipulated by assigning subjects to groups on the basis of preassessed sociometric scores. Rice, Bender, and Vitters (1980) conducted a laboratory study of 72 four-person temporary groups of West Point cadets using female and male leaders. The LPC scores related significantly to the groups' performance of tasks, according to the contingency model, in several cases, although the investigators qualified their findings because they lacked direct measures of situational favorableness.

Singh, Bohra, and Dalal (1979) conducted four experiments with male Indian engineering students and demonstrated that a much better fit with the contingency model could be obtained if the situational favorability of the octants was placed on the horizontal axis according to how much the ratings of the quality of leader-member relations, task structure, and position actually contributed to situational favorability. They discovered that ratings of the power relations declined in importance to situational favorability, and ratings of leader-member relations increased in importance to situational favorability. They attributed the changes in the importance of the components of situational favorability to India's return to democracy after the emergency rule by Indira Gandhi, which coincided with the repeated data collection. These shifts called into question Nebeker's (1975) 4:2:1 fixed scheme for weighting the three variables that contribute to situational favorability.

**Comparisons of the Octants.** As shown in [Table 19.3](#), a large number of studies have assessed the hypothesized relationships for designated octants. In these studies, usually efforts were made to select or create and compare two of the eight octants and to note the LPC of the leader in relation to the group's effectiveness. Thirty-eight of these studies have been generally supportive of the contingency model.<sup>23</sup>

Supportive analyses of selected octants include dissertation studies of 122 child-study teams and their

chairpersons in public schools (Jacobs, 1976), 64 groups of secondary-school juniors (Smith, 1974), and 40 task-oriented three-person experimental groups (Maher, 1976). Beebe (1975) manipulated the leader's positional power by instruction, structure, and task assignments. Only good leader-member relations were involved to determine the effectiveness of 37 three-person groups for octants II and IV. The correlation of LPC and group productivity was .01 in octant II and .40 in octant IV, both nonsignificant. Nevertheless, the result for octant IV was near the usual results obtained in many other studies.

*Unsupportive Results.* Along with the field, laboratory, and octant studies that support the validity of the contingency model, there are a number of studies that have failed to find support for it. Lanaghan's (1972) analyses of the effectiveness of 59 Illinois elementary schools and their principals and of the satisfaction of the teachers as a function of the behavior of the principals provided support for Fiedler's contingency-model predictions in only six of the 80 situations analyzed (at the 5% level of confidence). In seven other situations, results for relations and task orientation were opposite to what would have been predicted by the model. Shiflett and Nealey (1972) compared the performance of three-man college groups with very high intellectual ability and with moderate ability in creative tasks in octants III and IV (weak and strong positional power). The results of the moderate-ability groups supported the prediction of the model, but those of the very-high-ability groups were contradictory and nonsignificant.

Two laboratory experiments by Graen, Orris, and Alvares (1971) and a field study by Fox (1982) of tax examiners in the Internal Revenue Service also failed to find the expected outcomes. But Fiedler (1971a) and Chemers and Skrzypek (1972) attributed these failures to methodological manipulations that were inadequate to test the model. The results obtained by Utecht and Heier (1976) and Vecchio (1977) also failed to support the model, but Fiedler (1978) found that Vecchio's assignment of leaders to mixes of classmates whom the leaders ranked favorably and unfavorably was an invalid manipulation of good and poor relations. Isenberg (1981) found no support for the model in a study of communications. When the LPC scores of 62 Indian woolen mills supervisors were combined with task-structure and positional-power ratings of situational favorableness by Upmanyu and Singh (1981), they suggested that there was a need to reclassify the octants. A review by Rice (1981) concluded that followers were more satisfied when there were low-LPC (task-oriented) leaders in favorable situations and high-LPC (relations-oriented) leaders in unfavorable situations. Furthermore, contrary to the usual expectation that homogeneity of the leader and followers would be more satisfying to the followers, Rice noted that the followers' satisfaction was highest when they and the leader had dissimilar LPC scores.

Some unsupportive studies only indirectly tested the contingency model. Fiedler (1977b) pointed out that much research designed to test the model failed to use favorable and unfavorable situations sufficiently different from each other to provide a valid test.

### ***Criticisms of the Contingency Model and Rejoinders***

In studies that used only an approximate classification of situations—favorable, intermediate, or unfavorable to the leader—26 of 35 correlations of LPC and group effectiveness were as predicted by the model (Fiedler, 1971b). But critics faulted these conclusions. Some correlation coefficients were based on subsamples in the same study in which one subsample may have had good and the other may have had poor leader-member relations (Ashour, 1973a, 1973b; Graen, Alvares, Orris, & Martella, 1970).

A more general criticism was that most of the validations were based on concurrent measurements of LPC, leader-member relations, and group performance scores. Measures of leader-member relations and even LPC scores might be affected by the group's performance (Vroom, 1976b). This cause-effect criticism could be leveled at a considerable percentage of research on leadership, not just at studies that have tested Fiedler's model

(Kerr & Schriesheim, 1974), but Katz and Farris (1976) actually found specific evidence that group performance could cause variations in leaders' LPC scores.

Among 140 significant relations reported in the literature, Rice (1976) could find only one clear significant pattern relating the leader's LPC score to the group's effectiveness. When the leader described leader-member relations favorably, low-LPC leaders were clearly more effective; 23 of 26 significant effects (88%) under such conditions showed low-LPC leaders to be more effective than high-LPC leaders. When leaders described leader-member relations as poor, there was no clear pattern. This finding could be considered evidence that the group's performance affected the leader's judgment of the quality of relations with members. But a longitudinal study by Konar-Coldband, Rice, and Monkarsch (1979) of eight intramural basketball teams over a nine-week season concluded that previously assessed LPC scores of the leaders and the groups' initial atmosphere did predict the groups' subsequent performance according to the contingency model. Increments in effective performance beyond the initial levels were most likely for groups with low-LPC leaders and a good group atmosphere. An additional 7% of the variance in effective performance was accounted for by the interaction of the groups' previous atmosphere and leaders' LPC scores. The investigators also found that 10% of the increment in the groups' atmosphere beyond the initial levels was accounted for by LPC interacting with the groups' initial performance. They concluded that a systems approach that allows cause and effects to flow in both directions is required.

*Differences in Octants.* As was noted earlier, octant II, in toto, yielded mixed and widely diverging results. However, Fiedler (1978) argued that octant II, which requires a structured task with a powerless leader, may be created experimentally but is unlikely to exist in the field. Fiedler (1978) suggested that leaders who are placed in such circumstances will find the situation unmanageable. This suggestion, of course, fails to explain what is causing the varying results of octant II. A more important question is this: why is octant II, for example, less favorable to a leader than is octant III, since in both octants two of three variables favor the leader? What is required is differential weighting of the variables. The difference in task structure between octant II and octant III must be given more weight toward favorability than the leader's positional power as weak or strong. This weighting was provided by Nebeker (1975) and Beach and Beach (1978). However, except for permitting the graphics to remain the same, a rationale and evidence are needed to support the logic that task structure is twice as important to a leader's situational favorability as the power of the leader's position. The same problem exists between octants IV and V, for which leader-member relations must be given more weight than task structure (as has been done).

*Variations in Results.* Empirically troublesome to some critics is the wide divergence of individual correlation coefficients in each octant, as can be seen in [Figures 19.3](#) and [19.4](#). The median correlation for octant IV, for instance, may be .40, but the results that contribute to the median may range from .00 to .71. Another problem for which explanations are offered, but not necessarily accepted, is how to interpret some of the sudden shifts—say, from octant III to octant IV of the median correlation of  $-.29$  to the median correlation of .40. Hosking (1978) believed that the most supportable inference about all octants except octant I is that the median correlations are random departures from a true correlation of zero. Schriesheim and Kerr (1977b) agreed, in a review of additional studies. Schriesheim and Hosking (1978, p. 500) concluded:

When the relevant studies are critically examined, and a distinction [is] drawn between those that constitute adequate tests of the model and those that do not, the results are far from encouraging. Examining both the size and direction of the correlations in each of the eight octants of the situational favorableness dimension, reveals that Fiedler's model really has little empirical support.

However, Strube and Garcia (1981), using R. Rosen-thal's (1978, 1979a) meta-analyses of the contingency model, thought that all but octants III and VII in Fiedler's original validation were supportable, but they ignored octant VI. Strube and Garcia identified 33 analyses from which the model was built and 145 subsequent tests of the validity of the model. A meta-analysis of these data strongly supported the model's

validity. Vecchio (1983) believed that Strube and Garcia had used a biased sample of studies and suggested a need to qualify the conclusions they had reached, but Strube and Garcia (1983) rejected Vecchio's criticisms. Then, a less extensive meta-analysis by Peters, Hartke, and Pohlmann (1985) provided additional but somewhat less strong support for the validity of the model than Strube and Garcia obtained. Finally, after including almost twice as many validation correlations as had been listed by Strube and Garcia (1981) and Peters, Hartke, and Pohlmann (1985), Nathan, Haas, and Nathan (1986) rejected the earlier supportive conclusions of both previous meta-analyses. Nathan, Haas, and Nathan based their rejection on the fact that the set of validity coefficients within each octant varied much too much. They stated:

The confidence intervals are too broad to allow any one to expect, as the theory predicts, that low LPC leaders would be effective when situational favorability was good and high LPC leaders would be effective when situational favorability was moderately poor. Worse, the fairly stable finding in Octant II, that when situational favorability is very good, high rather than low LPC leaders will be effective is directly opposite to what the theory predicts. At best, one can conclude that over half the time, correlations are above and below zero as predicted. (p. 10)

Fiedler (1971a, 1971b, 1973, 1978) systematically dealt with many of the earlier criticisms of his methodology. These included the statistical strength of evidence, of the conceptual meaning of the three variables defining situational favorability, and of the construct assessed by the LPC scales. He even anticipated many of the criticisms (Mitchell, Biglan, Oncken, & Fiedler, 1970). As T. R. Mitchell (1972) noted, if the validity of the hypothesized curvilinear relationship is to be tested, all eight octants must be assessed in a given study. Despite the difficulty of obtaining sufficient participants when the group, rather than the individual, is the unit of analysis, research designs must have adequate sample sizes and resulting statistical power (T. R. Mitchell, 1972).

Although the contingency model may still appear to be supported by a wide array of studies, the meaning of LPC remains unclear and controversial, and no adequate theoretical explanation of its effects has been presented. Moreover, the variability of the findings and the reverse results with octant II continue to undermine confidence in it. Yet analytically, the model compares favorably with alternative models.

*Comparison with Alternative Contingency Models.* Schriesheim, Tepper, and Tetrault (1988) compared two alternative contingency models with Fiedler's contingency model. In the declining-octant model (Shiflett, 1973), the performance of both high-and low-LPC leaders should decline systematically from octant I to octant VIII as the situation becomes less favorable to the leader. In the declining-zone model, octants I, II, and III are most situationally favorable; octants IV, V, VI, and VII are the next most favorable; and octant VIII is the least favorable to the leader.

Fiedler's contingency model predicts that high-LPC leaders will be more effective in octant IV than in octant I, II, III, or octant VIII. Four tests of the significance of the difference can be made to compare octant I with each of these other octants (II, III, and VIII). Four such tests can also be made for octants V against octants I, II, III, and VIII. Also, four such tests can be made for octant VI and four more for octant VII. A comparable number of tests across pairs of octants can be made for low-LPC leaders who are predicted by the contingency model to be more effective in octants I, II, III, and VIII and less effective in octants IV, V, VI, and VII. Similar tests can be made for the rival models. In the declining-octant model, effectiveness is expected to decline from octant I to octant VIII. Since octant I is the most favorable situation, it should coincide with the leader's being more effective than in each of the other octants; octant II should yield better performance than each of the remaining octants; and so on.

Each octant was compared individually with each other relevant octant by Schriesheim, Tepper, and Tetrault (1988) using meta-analytical procedures. The data came from a variety of published investigations. Of 245 tests of the differences between pairs of octants, 62% fit the contingency model; of 281 tests, 54% fit the declining-octant model; and of 274 tests, 51% fit the declining-zone model. The investigators concluded that,

overall, these results supported the greater validity of Fiedler's contingency model than of the proposed alternatives.

### ***Other Moderating and Mediating Variables***

In a cross-cultural situation, Chemers (1969) trained leaders in the culture of their followers or in the geography of the country. Low-LPC leaders were more supportive and developed a more enjoyable group atmosphere in the culture training situation than high-LPC leaders did in the geography-training situation. These findings agreed with Fiedler's model in that in favorable situations, high-LPC leaders should tend to be concerned with the task whereas low-LPC leaders should tend to behave in a relationship-oriented manner. In unfavorable situations, the high-LPC leaders should be concerned with relations and the low-LPC leaders with tasks (Cummins, 1970).

*Arrangements.* Whether members of groups were co-acting (performing side by side) or interacting did not seem to influence the findings of Hunt (1967) or W. Hill (1969a), which were generally supportive but nonsignificant.

*Verbal Behavior.* The behavior, as well as the effectiveness of followers, depends on the favorability of the situation and the leader's LPC. Fiedler (1967a) found that group members made more task-related comments in favorable situations and fewer such comments in unfavorable situations under a high-LPC leader. The reverse was true for group members under the low-LPC leader. Furthermore, the group made more person-related comments in the unfavorable situation and fewer such comments in the favorable situation under the high-LPC leader.

*Followers' LPCs.* The followers' LPCs also may make a difference. Schuster and Clark (1970) studied first-and second-level supervisors in post offices. Under high-LPC second-level supervision, high-LPC first-level supervisors were better satisfied than their low-LPC peers. With low-LPC second-level supervisors, the satisfaction of high-and low-LPC first-level supervisors did not differ.

Hunt (1971) assembled groups—each with a manager, two supervisors, and two workers—to play a business game. Although the effects of manager-supervisor interaction did not account for variance in the teams' performance, the effects of the manager and supervisor alone were each significantly related to the performance of the workers. Low-LPC managers and high-LPC supervisors had the best-performing groups; high-LPC managers and low-LPC supervisors had the poorest-performing groups. The two-level interaction effect also predicted the satisfaction of workers better than did either LPC effect alone.

*Leaders' Self-Monitoring.* Ayman and Chemers (1991) found that among 83 Mexican middle-level managers, the predictions of the contingency model were valid only if the managers were low in self-monitoring. The managers rated their self-monitoring behavior. Their 184 subordinates rated satisfaction with the supervisors, coworkers, and the work. The predictions from the model failed to work when the managers rated themselves high in self-monitoring, but the results did conform to the contingency model when managers rated themselves low in self-monitoring.

*Leaders' Experience.* The leaders' experience with leadership changes the situational favorability (Bons & Fiedler, 1976). With continued experience, tasks become more routine and leaders get to know their subordinates and usually can work better with them. In addition, the leaders learn the expectations of the higher authority.

Although the effectiveness of leaders, as a whole, does not necessarily improve with experience (Fiedler, 1970a, 1972a), the contingency model predicts that leadership experience will have different effects on the performance of high-and low-LPC leaders. In a study of infantry squads by Fiedler, Bons, and Hastings (1975), 28 sergeants who served as squad leaders were evaluated at the time the units were formed and after

they had five months of experience. The sergeants' judgments about their situational favorability increased over the five months, as expected. The high-LPC leaders performed better at first when they had little experience and situational favorability than they did five months later. As predicted by the model, the low-LPC leaders performed relatively better after they had five months' experience and gained situational favorability. Similar results were found by Godfrey, Fiedler, and Hall (1959) for the general managers of 32 consumer cooperatives; by McNamara (1968) for Canadian elementary and secondary school principals; and by Hardy and Bohren (1975) for college teachers. Furthermore, the training of leaders based on the contingency model generates similar dynamics and results (Chemers, Rice, Sundstrom, & Butler, 1975; Fiedler, 1972a).<sup>24</sup>

*Organizational Shifting.* Changes in organization can have similar effects on situational favorability, as can increased experience. Bons and Fiedler (1976) tested the contingency model using experienced leaders of army squads who were given new subordinates, new bosses, or new jobs.

In the stable condition of continuing with the same bosses, subordinates, and jobs, the experienced leaders who were low in LPC were unaffected, but the performance of experienced high-LPC leaders declined. When a change of boss, subordinates, or job moved leaders from moderate situational favorability to low situational favorability, the low-LPC leaders again did relatively better.

## ***Implications***

Fiedler's Contingency Model offers a remedial plan for increasing the effectiveness of leaders that is different from all other theories of leadership. Blake and Mouton (1964), Hersey and Blanchard (1969b), R. Likert (1977a), and Vroom and Yetton (1974) would see a need to educate leaders to improve their styles. For Blake and Mouton, improvement would be toward the one best style: 9,9. For Hersey and Blanchard, it would depend on the stage in the group's life cycle and the followers' maturity. For Likert, it would be toward a democratic style. For Vroom and Yetton, the decision process to use would depend on the problem situation. But Fiedler (1978) suggested an entirely different course of action. Because a leader's LPC is what matters, and because LPC is not very changeable, either one must identify and select leaders of high or low LPC to fit given situations, or leaders need to know their LPC scores and in what situations they are most effective—then they can try to change the situation, rather than themselves. Fiedler argued that changing leader-member relations, the structure of the task, or a leader's positional power is easier than changing a leader's personality. Leader Match (Fiedler, Chemers, & Mahar, 1976), a training program that tries to do so, is discussed in [Chapter 34](#). The contingency model also has implications for leadership under stressful conditions, which is examined in [Chapter 28](#).

## **Summary and Conclusions**

---

In general, the leader who is more highly rated by superiors and peers, who is most satisfying to subordinates, and whose approach results in the good performance of the group is likely to be both relations-oriented and task-oriented in an integrated fashion. Blake and Mouton's theory is the strongest endorsement of this conclusion.

However, many situational contingencies have been found to moderate the effects. These contingencies include the makeup of the subordinates and the organizational constraints, tasks, goals, and functions in the situation. The popular but underresearched and controversial Hersey-Blanchard model has focused on the followers' psychological maturity and job experience as the most important contingencies affecting the leader's need to be task-oriented or relations-oriented.

According to Fiedler's widely researched contingency model, (1) task orientation (as measured by LPC) works best in situations which are either extremely favorable or extremely unfavorable to the leader, or in which the leader has very high or very low control; and (2) relations orientation works best in situations that are moderately favorable to the leader or in which the leader has moderate control. Despite a vast array of publications on the reliability, validity, and meaning of LPC and situational favorableness, and despite tests supportive of the model, the validity of the model continues to be disputed. Less controversial are the equally widely researched concepts and behavioral measures of the leaders' consideration of their subordinates and the leaders' initiation of structure for their subordinates, the subject of [Chapter 20](#).

<sup>1</sup> See [Chapters 15](#) and [21](#).

<sup>2</sup> Kahn and Katz (1953), R. Likert (1977a), and Oaklander and Heishman (1964), among many others, came to similar conclusions.

<sup>3</sup> See [Chapter 34](#).

<sup>4</sup> See Katz, Maccoby, and Morse (1950), whose results are mentioned later.

<sup>5</sup> In ipsative scoring, the task score and relations score sum to a fixed total—say, 100. If the task score is 65, then the relations score must be 35.

<sup>6</sup> See [Chapter 8](#).

<sup>7</sup> As defined in [chapter 18](#), *participation* (italicized) refers only to sharing in the decision process. Participation (roman) includes consulting, sharing, and delegating. *Direction* (italicized) refers only to giving orders with or without explanation. Direction (roman) includes ordering, persuading (selling), and manipulating.

### Initiation versus Consideration

In 1945, C. L. Shartle (1950b) launched the Ohio State Leadership Studies. He was influenced by his work on gathering occupational information to describe tasks, jobs, and occupational requirements in all echelons of industry, government, and the military. He focused on defining and classifying work done in each of the 30,000 occupations that had appeared originally in the 1939 *Dictionary of Occupational Titles* and in the *U.S. Military Occupational Specialties*. He and his colleagues now applied this background to the study of leaders. This was different from the emphasis in previous leadership research, which had sought to identify the traits of leaders. Reviews by Bird (1940), W. O. Jenkins (1947), and Stogdill (1948) had concluded that the personality-traits approach had reached a dead-end, for several reasons: (1) attempts to select leaders in terms of traits had had little success; (2) numerous traits differentiated leaders from followers; (3) the traits demanded of a leader varied from one situation to another; and (4) the traits approach ignored the interaction between the leader and his or her group. Attention was shifted to what leaders did.

Needed were descriptions of individuals' actions when they acted as leaders of groups or organizations. Hemphill (1949a) had already initiated such work at the University of Maryland. After joining the Ohio State Leadership Studies, Hemphill and his associates developed a list of approximately 1,800 statements that described different aspects of the behavior of leaders, such as "He insists on meeting deadlines." Most statements were assigned to several subscales. However, staff members agreed on 150 statements that could each be assigned to only one subscale. These statements were used to develop the first form of the Leader Behavior Description Questionnaire, or LBDQ (Hemphill, 1950a; Hemphill & Coons, 1957). On the LBDQ, respondents rated a leader by using one of five alternatives to indicate the frequency or amount of a particular behavior that was descriptive of the leader being rated. Responses to items were simply scored and added in combinations to form subscales on the basis of the similarity of their content. These subscale totals were then intercorrelated and factor-analyzed (Fleishman, 1951, 1953c; Halpin & Winer, 1957). "Consideration" and "initiation of structure" were primary factors identified by Halpin and Winer (1957) with regard to Air Force officers, and by Fleishman (1951, 1953c, 1957) with regard to industrial supervisors. They emerged in successive factor studies (Fleishman, 1973) as the two most prominent factors that described leaders according to questionnaires completed by themselves and others.

### Descriptive Factors

---

#### *Consideration*

This first factor describes the extent to which a leader exhibits concern for the welfare of the other members of the group. The *considerate* leader expresses appreciation for good work, stresses the importance of job satisfaction, maintains and strengthens the self-esteem of subordinates by treating them as equals, makes special efforts to help subordinates feel at ease, is easy to approach, puts subordinates' suggestions into operation, and obtains subordinates' approval on important matters before going ahead. Considerate leaders provide support that is oriented toward relationships, friendship, mutual trust, and interpersonal warmth. Participation and the

maintenance of the group accompany such support (Atwater, 1988). In contrast, the *inconsiderate* leader criticizes subordinates in public, treats them without considering their feelings, threatens their security, and refuses to accept their suggestions or to explain his or her actions.

### ***Initiation of Structure***

This second factor shows the extent to which a leader initiates activity in the group, organizes it, and defines the way work is to be done. Initiation of structure includes such leadership behavior as insisting on maintaining standards and meeting deadlines and deciding in detail what will be done and how it should be done. Clear channels of communication and clear patterns of work organization are established. Orientation is toward the task. The leader acts directly without consulting the group. Particularly relevant are defining and structuring the leader's own role and the roles of subordinates in attaining goals. The leader whose factor score in initiating structure is low is described as hesitant about taking initiatives in the group. He or she fails to take necessary actions, makes suggestions only when members ask for it, and lets members do the work the way they think best.

## **Psychometric Properties**

---

### ***Three Leader Behavior Description Questionnaires***

The LBDQ, consisting of 40 statements, was designed to measure the two factors of consideration and initiation (Hemphill & Coons, 1957). An industrial version, the Supervisory Behavior Description Questionnaire (SBDQ), followed (Fleishman, 1972), as did LBDQ—Form XII, hereafter referred to as LBDQ-XII (Stogdill, 1963a). Each of the LBDQs had instructions such as these:

The following ... are items that may be used to describe the behavior of your leader or supervisor. Each item describes a specific kind of behavior, but does not ask you to judge whether the behavior is desirable or undesirable. This is not a test of ability. It simply asks you to describe, as accurately as you can, the behavior of your supervisor or leader. *Group* refers to an organization or to a department, division, or other unit of organization that is supervised by the person being described. ... *Members* refer to all the people in the unit of organization that is supervised by the person being described.

THINK about how frequently the leader engages in the behavior described by the item.

DECIDE whether he (A) *always*, (B) *often*, (C) *occasionally*, (D) *seldom*, or (E) *never* acts as described by the item.

Typical items were: "He lets group members know what is expected of them." "He is friendly and approachable."

The intentions of the developers of the LBDQs and the SBDQ, particularly with regard to initiating structure, differed somewhat in the construction of the different versions. The LBDQ contained a subset of 15 items that asked subordinates to describe the actual structuring behavior of their leader. This structuring behavior was the leader's behavior in delineating relationships with subordinates, in establishing well-defined patterns of communication, and in detailing ways to get a job done (Halpin, 1957b). The Supervisory Behavior Description Questionnaire (SBDQ) consisted of 20 items that included asking subordinates about their leader's actual structuring behavior. Initiating structure, as measured by the SBDQ, was intended to reflect the extent to which the leader organizes and defines interactions among group members, establishes

ways to get the job done, schedules, criticizes, and so on (Fleishman, 1972). The SBDQ items for the factor of initiation of structure included a wider variety of structuring behaviors drawn from the loadings on this factor. Several were close to Misumi's (1985) *Production Pressure*. Items on the LBDQ came mostly from original conceptualizations about communication and organization (Schriesheim, House, & Kerr, 1976). The revised LBDQ-XII had 10 items that measured initiation of structure in terms of the actions of leaders who clearly define their own role and let followers know what is expected of them (Stogdill, 1963a).

### ***Reliability and Validity***

As noted, ratings of the consideration and initiation of structure by leaders are highly stable and consistent from one situation to another (Taylor, Crook, & Dropkin, 1961; and Philipsen, 1965a). According to Schriesheim and Kerr's (1974) review of the psychometric properties of the LBDQ and SBDQ, the descriptions maintain the high internal consistency that was the basis for their construction. That is, items on the "consideration behavior" in each instrument correlate highly with all the other consideration items and do not correlate with items on the "initiation behavior" factor. Conversely, items on the "initiating structure" factor are independent of the "consideration" items and are highly intercorrelated with all the other structuring items. Using a sample of 308 public utilities employees, Schriesheim (1979a) found that consideration and initiation were so psychometrically robust that it did not make much difference in a supervisor's scores whether one asked a subordinate to describe how the supervisor behaved toward him or her personally (the dyadic approach) or how the supervisor behaved toward the whole work group (the standard approach).

Nonetheless, the factor scores left a lot to be desired. They suffered from halo effects and were plagued by a variety of other response errors, such as leniency and social desirability, as well as a response set to agree rather than to disagree (Schriesheim, Kinicki, & Schriesheim, 1979). It was not known whether they were valid measures of true consideration and initiation of structure. Most important, as research with the original LBDQ and SBDQ instruments continued, it became apparent that some of what leaders do had been missed. A great deal of the behavior of leaders was being lost in the emphasis on just two factors to account for all the common variance among items describing this behavior. Therefore, for LBDQ-XII, various additional factored scales were constructed, possibly lacking complete independence from structuring and consideration, yet likely to include much of the missing information of consequence.

*Comparison of the Three Forms.* All three versions—LBDQ, SBDQ, and LBDQ-Form XII—have been used extensively, and each has been subjected to additional factor analyses (Bish & Schriesheim, 1974; Szilagyi & Sims, 1974a; Tscheulin, 1973). A direct comparison of all three became possible after a survey and factor-analytic study of 242 hourly employees by Schriesheim and Stogdill (1975). This comparison study was necessary, since, as Korman (1966) and others had noted, the content of the scales varied, which caused differences in outcomes. The original LBDQ and particularly the SBDQ contained several items such as "Needles subordinates for greater effort" and "Prods subordinates for production" that measured punitive, arbitrary, coercive, and dominating behaviors and that affected the scores for initiation of structure. The LBDQ-XII was considered to be most nearly free of such autocratic items (Schriesheim & Kerr, 1974). As has usually been found, internal consistency reliabilities were high for scores on both factors that were derived from the items drawn according to their use in the LBDQ, SBDQ, or LBDQ-XII. For consideration and initiation, reliabilities were .93 and .81 for the LBDQ, .81 and .68 for the SBDQ, and .90 and .78 for the LBDQ-XII. (The reliability of .68 for initiation of structure on the SBDQ was raised to .78 when three SBDQ punitive items were removed from the scoring of the scale.) The primary factors that were extracted indicated that all three versions contained some degree of arbitrary punitive performance ("The leader demands more than we can do"). But, as expected, the pattern was most marked in the SBDQ. A hierarchical factor analysis disclosed

the existence of a higher-order factor of rater bias, which appeared in all three questionnaires.

According to Schriesheim and Kerr, the items loading highest on the SBDQ in initiating structure were: “He insists that he be informed on decisions made by people under him” (.60), “He insists that people under him follow standard ways of doing things in every detail” (.65), and “He stresses being ahead of competing work groups” (.64). In fact, Atwater (1988) found that two items—“Demands a great deal from his workers” and “Pushes his workers to work harder”—correlated highest with the SBDQ factor she obtained and labeled *demanding behavior*. But on the LBDQ, the two items loading highest on initiating structure were: “He maintains definite standards of performance” (.59) and “He lets members know what is expected of them” (.54).

Matters further were complicated because many researchers deleted items or modified the wording of items for use in a particular study, as Podsakoff and Schriesheim (1985) found in their review of studies that used the LBDQ. Also, many researchers failed to specify which version of the LBDQ they had used or how they had modified the scales (Hunt, Osborn, & Schriesheim, 1978).

### ***Other Psychometric Issues***

The items ask how the leader acts toward the work group rather than toward specific individuals. Critics, such as Graen and Schiemann (1978), assume that there are large variations in the leader’s behavior toward different individual members of a work group, and therefore that the wording of items should allow for this. Individual differences among raters also underlie the ratings. Although WABA analysis could handle this, it was not introduced until 1984 (see [Chapter 16](#)). The previously cited findings of Schriesheim (1979a) suggested, however, that the matter may be overblown. D. M. Lee (1976) asked 80 students to judge the initiation and consideration of their English professors over an eight-week period. The results indicated that the individual students differed widely in the cues they used as the basis of their ratings of the same professors. The questionnaires fail to weight the timing, appropriateness, importance, and specificity or generality of responses. They may assess the circumstantial requirements of the job, rather than the leader as a person with discretionary opportunities to behave in the manner indicated.

*Leniency Effects.* Seeman (1957) reported that the LBDQ scales suffered from halo effects. Even making items more detailed was of no help in reducing the halo. Schriesheim, Kinicki, and Schriesheim (1979) completed five studies of the extent to which consideration and initiation of structure were biased by leniency effects. They inferred from the results that leniency response bias—the tendency to describe others in favorable but probably untrue terms—did not particularly affect descriptions of initiation of structure. But even though consideration and leniency are conceptually distinct, they concluded that (1) consideration items were not socially neutral and were susceptible to leniency, (2) consideration reflected an underlying leniency factor when applied in a field setting, and (3) leniency explained much or most of the variance in consideration. Leniency may explain why consideration tends to correlate higher with other evaluative variables than does initiation of structure (Fleishman, 1973).

*Implicit Theories.* D. J. Schneider (1973), among others, suggested that respondents express their own implicit theories about and stereotypes of leaders and leaders’ behavior, rather than the behavior of the specific leader they are supposed to be describing with the LBDQ. That is, respondents describe their idealized prototype of a leader, rather than the actual leader they should be describing (Rush, Thomas, & Lord, 1977). Eden and Leviatan (1975) noted that leader-behavior descriptions of a fictitious manager using the Survey of Organizations resulted in a factor structure highly similar to that obtained from descriptions of real managers reported by Taylor and Bowers (1972).<sup>1</sup> Rush, Thomas, and Lord (1977) found a high degree of congruence between factor structures obtained from descriptions of a fictitious supervisor using LBDQ-XII and

descriptions of real leaders from a field study by Schriesheim and Stogdill (1975). In both studies, the authors concluded that since practically identical factor structures emerged for fictitious and specific real leaders, the actual behavior of a leader is relatively unimportant for behavioral descriptions, because descriptions are based mainly on implicit theories or stereotypes.

One might suggest that this tendency to project or to use implicit theories tells more about the subordinate than about the leader. But the tendency is a consequence of ambiguity and of a lack of specific information about the leader to be rated. Schriesheim and DeNisi (1978) studied 110 bank employees and 205 workers in a manufacturing plant who used the LBDQ-XII to describe supervisors in general after first describing their own supervisors. The investigators, as expected, found comparable factors emerging from the general and specific descriptions when each was analyzed separately. However, separate real and imaginary factors emerged when the combined data were subjected to an analysis that provided an opportunity for statistical differentiation. As before, in both real and imaginary descriptions, initiation of structure and consideration was correlated above .50, with reliabilities ranging from .84 to .87.

Schriesheim and DeNisi discovered that although satisfaction with one's real supervisor correlated between .51 and .75 with descriptions of the actual consideration and initiation of the real supervisors, it correlated only .23 and  $-.03$  with scores for initiating structure and consideration for the stereotypes of supervisors. This was a particularly important finding.

Subsequent experimentation by Schriesheim and DeNisi (1978) with 360 undergraduates strongly supported the contention that as more specific information became available to them, the respondents' LBDQ responses became more accurate and were less likely to depend on implicit theories. These results are consistent with those of Bass, Valenzi, Farrow, and Solomon (1975), who found that subordinates describing the same real leader were in much more significant agreement with each other than with subordinates who described other leaders.

*Self-Ratings Unrelated to Subordinates' Ratings.* As many researchers reported for self-rated directive versus participative leadership, for autocratic versus democratic leadership, and for task-versus relations-oriented leadership,<sup>2</sup> little relation was obtained between leaders' self-descriptions of their own initiation and consideration and their subordinates' descriptions on the LBDQ. Similarly, there was only a weak relation between what leaders say they should do, according to scores on the Leadership Opinion Questionnaire, and what they actually do, according to their subordinates' descriptions of them on the LBDQ (Schriesheim & Kerr, 1974).

### ***Relationship between Consideration and Initiation of Structure***

Theoretically, given the original orthogonal factor structure, consideration and initiation of structure should be independent, but this is not the case. Schriesheim, House, and Kerr (1976) reexamined Weissenberg and Kavanagh's (1972) review of the data, along with work published subsequently. In 11 of 13 studies using the LBDQ, a positive correlation was reported. The median correlation for the 13 analyses was .45. Likewise, for the LBDQ-XII for 10 studies, the median correlation was .52 between consideration and initiation of structure. The correlation was even higher in situations where job pressure was strong. In addition, the correlations between consideration and initiation were positive both when group-by-group values were correlated and when the scores for individuals within the groups were correlated (Katerberg & Hom, 1981). Of the 16 studies that used the SBDQ, which includes some "autocratic" items, 11 studies yielded some significant negative correlations between consideration and initiation. However, the median correlation was  $-.05$ . Without the punitive items, consideration and initiation on the LBDQ tend to correlate more positively. A comprehensive review (Fleishman, 1989a), which included 32 studies with the SBDQ, found a median

correlation of  $-.02$  between the score for consideration and the score for structure.

## Alternative and Additional Scales

---

### *Industrial Examples*

Oldham (1976), among others, developed alternative and additional scales to provide a more detailed profile of leader behavior. The scales included behaviors such as these: personally rewarding, personally punishing, setting goals, designing feedback systems, placing personnel, and designing job systems. These scales were higher in relation to effectiveness than were measures of consideration and the initiation of structure. Seltzer and Bass (1987) found that the transformational leadership factors of charisma, individualized consideration, and intellectual stimulation added substantially to the effects of consideration on subordinates' satisfaction and effectiveness. Seltzer and Bass conceived of consideration and initiation of structure as primarily transactional.

Halpin and Croft (1962) also were not convinced that the behavior of leaders could be adequately described with just two factors. Using items containing additional content about school principals, as well as items from the LBDQ, they extracted four factors to account for the common variance in the obtained descriptions of school principals' behavior: (1) aloofness, formality, and social distance; (2) Production emphasis—pushing for results; (3) Thrust—personal hard work and task structure; and (4) Consideration—concern for the comfort and welfare of followers. These factored scales for describing the behavior of school principals were supplemented by the following four scales used to describe the behavior of teachers: (1) Disengagement—clique formation, withdrawal, (2) Hindrance—frustration from routine and overwork, (3) Esprit—high morale, enthusiasm, and (4) Intimacy, mutual liking, and teamwork.

When Halpin and Croft classified 71 schools into six categories according to climate, they found that an open school climate was associated with the esprit of teachers under a principal who was high in thrust. An autonomous climate produced intimacy in teachers under an aloof principal. A controlled climate resulted in hindrance in teachers under a principal who pushed for production. A familiar climate was associated with the disengagement of teachers under a considerate principal. A climate with potential but with the disengagement of teachers resulted in a principal who exhibited consideration, along with an emphasis on production. A closed climate, also with the disengagement of teachers, was associated with an aloof principal. These results yielded considerably more insight into the dynamic interplay among the climate of schools, the behavior of leaders, and the response of teachers than could be produced by the use of just two factors to describe the behavior of leaders.

### *Leadership Behavior Description Questionnaire—Form XII*

The most direct expansion from consideration and initiation of structure to a broader array of leader-behavior dimensions was the development of LBDQ-XII.

On the basis of a theoretical analysis of the differentiation of roles in groups, Stogdill (1959) proposed 10 additional patterns of behavior involved in leadership, conceptually independent of consideration and initiation of structure, to be included in the LBDQ-XII along with consideration and initiation of structure. These patterns were: (1) Representation—speaks and acts as the representative of the group; (2) Reconciliation—reconciles conflicting organizational demands and reduces disorder in the system; (3) Tolerance of uncertainty—is able to tolerate uncertainty and postponement without anxiety or upset; (4) Persuasiveness—uses

persuasion and argument effectively; exhibits strong convictions; (5) Tolerance of freedom—allows followers scope for initiative, decisions, and action; (6) Role retention—actively exercises the leadership role, rather than surrendering leadership to others; (7) “Production emphasis”—applies pressure for productive output; (8) Predictive accuracy—exhibits foresight and the ability to predict outcomes accurately; (9) Integration—maintains a close-knit organization and resolves intermember conflicts; and (10) Influence with supervisors—maintains cordial relations with superiors; has influence with them; strives for higher status. Subsequently, these patterns became the 10 scored factors of LBDQ-XII. The conception of the persuasiveness pattern anticipated the more recent focus on the measurement of charismatic and inspirational leadership.

*Interdescriber Agreement.* In a study of a governmental organization by Day (1968), high-ranking administrators were each described by two male and two female subordinates. Correlations were computed to determine the extent to which pairs of subordinates agreed with each other in their descriptions of their immediate superiors. The greatest agreement was shown by pairs of female subordinates describing their female superiors. Their correlations ranged from .39 (integration) to .73 (retention of the leadership role). The least agreement was shown by pairs of male subordinates describing their female superiors. Their correlations ranged from  $-.02$  (tolerance of freedom) to .53 (retention of the leadership role). Pairs of female subordinates tended to exhibit higher degrees of agreement than male subordinates in descriptions of male superiors on 8 of the 12 scales. The four exceptions occurred for representation, production emphasis, integration, and influence with superiors. The scales with the highest degrees of interdescriber agreement across groups of raters, male or female, were demand reconciliation, tolerance of uncertainty, persuasiveness, role retention, predictive accuracy, and influence with superiors. The scales with the lowest degrees of agreement across samples were representation, tolerance of freedom, and integration.

*Divergent Validities.* To test the divergent validities of several scales of the LBDQ-XII, Stogdill (1969), with the assistance of a playwright, wrote a scenario for each of six scales (consideration, structure, representation, tolerance of freedom, production emphasis, and superior orientation). The items in each scale were used as a basis for writing the scenario for that pattern of behavior. Experienced actors played the roles of supervisor and workers. Each role was played by two actors, and each actor played two different roles. Motion pictures were made of the performances. Observers used LBDQ-XII to describe the “supervisor’s” behavior. No significant differences were found between two actors playing the same role. Still, the actors playing a given role were described as behaving significantly more like that role than the other roles. Stogdill concluded that the scales measured what they purported to measure.

*Factor Validation of LBDQ-XII.*<sup>3</sup> Data collected by Stogdill, Goode, and Day (1963a, 1963b, 1964, 1965) used nine of the LBDQ-XII scales to obtain descriptions of the leadership behavior of U.S. senators, corporation presidents, presidents of international labor unions, and presidents of colleges and universities. For leaders in each setting, the scores for the scales were intercorrelated and factor-analyzed. In general, the results suggested that each factor was strongly dominated by a single appropriate scale. For example, in all four analyses the representation factor emerged with only the representation scale correlated highly with it. The representation scale correlated, respectively, with the representation factor, .80, .94, .92, and .92, in the four locales. Similarly, the role retention subscale correlated only with its own role retention factor, .89, .93, .81, and .92. However, production emphasis tended to load highly on initiation of structuring as well as on production emphasis.

“Reconciliation of conflicting demands” failed to emerge as a factor differentiating college presidents, presumably because they all were described similarly highly in this behavior. “Orientation to superiors,” of course, did not fit with the role of senators; nor did union presidents differ from each other in orientation to a higher authority. The differences in predictive accuracy generated the factor “predictive accuracy” for only the corporate and union leaders, not the senators or college presidents.

Slightly different results emerged when all the items of the LBDQ-Form XII were intercorrelated and

factor-analyzed for three additional locales. Eight factors emerged: (1) General persuasive leadership; (2) tolerance of uncertainty; (3) tolerance of followers' freedom of action; (4) representation of the group; (5) influence with superiors; (6) production emphasis; (7) structuring expectations; (8) retention of the leadership role. In addition, two distinct factors of consideration were extracted.

The most numerous and most highly loaded items on general persuasive leadership, aside from measures of persuasiveness, were scales with items about the reconciliation of conflicting demands, structuring expectations, retention of the leadership role, influence with superiors, consideration, and production emphasis. These items represented the followers' general impression of the leaders. In fulfilling these functions, leaders were seen as considerate of their followers' welfare. Each of the remaining factors tended to be composed of items from a single scale, but some contained stray items from other scales. Consideration broke down into two separate factors, to be discussed later in connection with J. A. Miller's (1973b) hierarchical factor analysis.

The first nine factors showed similar loadings for senators, union leaders and college presidents. But "retention of the leadership role" appeared as a separate factor only in the ratings of the state senators. All scales except those dealing with tolerance of uncertainty, tolerance of freedom, and representation contributed some items to the general factor. However, all scales except persuasiveness and the reconciliation of conflicting demands emerged in separate factors differentiated from each other. These findings indicated that the behavior of leaders is indeed complex in structure and that followers are able to differentiate among different aspects of behavior. The general persuasion factor provided valuable additional insight into the nature of leadership, strongly suggesting that this general factor may be particularly useful given what was said in [Chapter 6](#) about its opposite, laissez-faire leadership.

*Initiation and Consideration as Higher-Order Dimensions.* A. F. Brown (1967) used the LBDQ-XII to obtain scores on each of the 12 factors for 170 principals described by 1,551 teachers in Canadian schools. He found that two higher-order factors accounted for 76% of the total factor variance for the 12 primary factors. When the loadings for the two factors were plotted against each other, "production emphasis," "structuring expectations," and "representation of the group" clustered about an axis of "initiation of structure" and "tolerance of uncertainty." "Tolerance of freedom" and "consideration" clustered about an axis of "consideration." The loadings for the remaining factors fell between the clusters at the extremes of these two orthogonal axes. A plot of factor loadings obtained for descriptions of university presidents on the LBDQ-XII (Stogdill, Goode, & Day, 1965) produced similar results. "Representation," "structuring expectations," "emphasis," and "persuasiveness" clustered around the first axis and "freedom," "uncertainty," and "consideration" clustered around the second axis. Marder (1960) obtained a somewhat different pattern of loadings when military rather than educational leaders were studied. The data consisted of 235 descriptions of U.S. Army officers by enlisted men. "Productivity emphasis" and "initiation of structure" centered on one axis and "tolerance for freedom" and "tolerance for uncertainty" clustered around the other. "Consideration" was displaced toward the central cluster of items.

### ***Psychometric Outcomes as Dependent on Factor Theory***

There are different schools of thought regarding the use of factor analysis. One school maintains that as much of the total factor variance as possible should be explained in terms of a general factor. Another school holds that rotational procedures, such as the *varimax* that reduces the magnitude of the general factor, are legitimate. The former school, while admitting that systems of events in the real world may involve a variety of factors, maintains that human perception contains a large element of bias and halo that should be removed in the general factor before any attempt to determine the structure of measurements representing the real world. The second school argues that the apparent halo in the general factor has its equivalent in the opacity of

the real world and that the purpose of research is to reduce this opacity by making full use of all the structure differentiated by human perception. The structure that is perceived should not be permitted to remain hidden in the general factor.

If one prefers a two-factor theory of leadership behavior, initiation of structure, production emphasis, or persuasiveness can define one of the factors; consideration, tolerance of freedom, and tolerance of uncertainty can define the other. A two-factor solution, which leaves a considerable amount of the total variance unexplained, can always be obtained in the analyses of descriptions of leaders' behavior. However, a multifactor solution should not be rejected until its consequences have been thoroughly explored and it has been proved untenable. Furthermore, the dilemma can be reconciled, as J. A. Miller (1973b) and Schriesheim and Stogdill (1975) showed, by recourse to hierarchical factor analysis. The former used rotation and differentiation; the latter, the general evaluative bias factor. Finally, the positive association routinely found (as noted earlier) between consideration and initiation of structure, as measured by LBDQ-XII, suggests that a single, general factor solution may be warranted. Nevertheless, with reference to the contents of the LBDQs, the two-factor framework for describing leadership behavior—consideration and the initiation of structure—emerges consistently from factor analyses when no additional constraints are placed on the analyses, such as first requiring the isolation of a general factor that, no doubt, has strong connections with the respondents' prototypes of leaders.

### ***Refining Initiation and Consideration***

Consideration and initiating structure can be finely factored in a number of ways by adding detailed behaviors, other than those found on the LBDQ-XII, and pursuing reconceptualizations about consideration and initiation. As was just noted, Stogdill (1963a) added new content dealing with different domains of leadership behavior to obtain the 10 additional scales for LBDQ-XII. More detail about initiation and consideration can also intensify the analysis of the basic content of initiation and consideration and related measures. Yukl (1971) demonstrated the feasibility of a three-factor approach (consideration, initiation of structure, and centralization of decisions). Saris (1969) offered "responsibility reference" and Karmel (1978) offered "active engagement" as a third factor. Another three-factor approach—initiating structure, participation, and decision making—was pursued by R. H. Johnson (1973). Wofford (1971) expanded the framework of leadership behavior to five factors: (1) group achievement and order, (2) personal enhancement, (3) personal interaction, (4) dynamic achievement, and (5) security and maintenance.

Using several thousand members of a nationwide business fraternity, who described their leaders on both a new instrument (FFTQ) and the comparable scales of the LBDQ-XII, Yukl and Hunt (1976) demonstrated some degree of communality between factors and scales purporting to deal with similar dimensions; yet overall, unfortunately, the scales were not equivalent.

*Hierarchical Factor Analysis.* Because of earlier reported findings that the LBDQ and supposedly similar instruments were not equivalent,<sup>4</sup> J. A. Miller (1973b) assembled 160 items from nine frequently cited standard instruments used in published research concerning leadership behavior described in this and preceding chapters. The objective was to gain a better understanding of similarities and differences in the measures of consideration and initiation of structure. The original pool included items from the following: the LBDQ (Halpin & Winer, 1957), Survey of Organizations (Taylor & Bowers, 1972), interaction process analysis (Bales, 1950), the Job Descriptive Index (Smith, Kendall, & Hulin, 1969), the Orientation Inventory (Bass, 1963), scale anchors used to describe a "continuum of leadership behavior" (Tannenbaum & Schmidt, 1958), six categorical statements describing a continuum of decision-making styles (Vroom & Yetton, 1974), five bases of social power (French & Raven, 1959), and adjectives used by Fiedler (1967a) for measuring the least

preferred coworker (LPC). Miller drew 73 nonduplicative items from the pool of 160 that were most specific and that were descriptive, rather than evaluative, and then collected data from 200 respondents from 10 organizations, including social agencies, industrial firms, and military organizations.

The first step in the hierarchical solution was a factor analysis stipulating a two-factor solution. Then the process was repeated with a stipulated three-factor solution, then a four-factor solution, and so on (Zavala, 1971). Miller then successively rotated all 12 principal components, using the varimax (orthogonal) rotation algorithm. At each level, interpretable solutions reflecting familiar leader-behavior factors emerged. The two-factor solution clearly paralleled consideration and initiation of structure. Other clearly identifiable factors that had been discovered in previous research emerged when an additional factor in each successive level of analysis was called for. Production, goal emphasis, and close supervision split apart as subfactors of initiation of structure in the four-factor solution. Participation emerged at level 6, information sharing at level 7, and supporting (the narrowly interpersonal interpretation of consideration) at level 8. Enforcing rules and procedures emerged as a subfactor of close supervision at level 9, and so forth. The emergence of the factors and the hierarchical linkages are shown in [Figure 20.1](#). Here, the two-factor solution appears at level 2, the three factor solution at level 3, and so on. A subsequent higher-order factor analysis, based on an oblique solution, obtained a higher-order factor of consideration and another of initiation of structure.

It can be seen from [Figure 20.1](#) that consideration includes behavior ordinarily regarded as concern for the welfare of subordinates, such as supportive behavior and sharing information, but it also appears linked to participative group decision making, to abdication, and to delegation.

## Behavioral Descriptions of the Ideal Leader

---

### *Ideal Form—What a Leader Should Do*

Hemphill, Seigel, and Westie (1951) developed and Halpin (1957c) revised an ideal form of the LBDQ that asks respondents to describe how their leader *should* behave—not, as on the LBDQ, how they see their leader actually behaving. For example, in a study of 50 principals, J. E. Hunt (1968) found that teachers described principals as lower in actual consideration and structure than the teachers believed to be ideal. Such discrepancies between subordinates' descriptions of what their leaders should do and what the leaders actually do are more highly related to various measures of group performance than are desired or observed leadership behavior alone. Such discrepancies are measures of dissatisfaction with the leaders' performance and, as a consequence, are more strongly related to various group outcomes.

Stogdill, Scott, and Jaynes (1956) studied a large military research organization in which executives and their subordinates described themselves—and subordinates described their superiors—on the real and ideal forms of the LBDQ. When superiors were really high in initiation of structure, according to their subordinates, the subordinates described these superiors on the ideal forms as having less responsibility than they should, as delegating more than they should, and as devoting more time than they should to teaching. When superiors were really high in consideration on the LBDQ, according to their subordinates, the subordinates said on the ideal form that they expected the superiors to assume more responsibility than they perceived the superiors to assume, devote more time than necessary to scheduling, and devote less time to teaching and mathematical computation. When superiors were really high in initiating structure, as seen by their subordinates, the superiors perceived themselves to be devoting more time than they should to evaluation, consulting peers, and teaching and not enough time to professional consultation. When superiors were described as actually high in consideration, subordinates perceived themselves as having more responsibility than they should. The

subordinates also reported that the superiors ought to devote more time to coordination, professional consultation, and writing reports but less time to preparing charts. The leaders' initiation of structure was more highly related to subordinates' actual work performance. The leaders' consideration, by contrast, was more highly related to subordinates' idealization of their own work performance.

SOURCE: J. A. Miller (1973b).

In a similar type of study, Bledsoe, Brown, and Dalton (1980) showed that the actual behavior of school business managers, as described by 132 school superintendents, principals, and school board members, tended to differ considerably from the ideal for initiation and consideration. Board members tended to describe the ideal school business managers as actually more considerate than did the school principals. Ogbuehi (1981) surveyed 270 Nigerian managers' and administrators' self-descriptions of their ideal behavior using the LBDQ-XII. The results were consistent with their superiors' judgments of their effectiveness.

Vecchio and Boatwright (2002) examined the preferences of 1,137 employees in three organizations regarding leaders' structuring and consideration. More highly educated and tenured employees preferred less structuring in their leaders; women preferred more consideration.

### Leadership Opinion Questionnaire (LOQ)

Fleishman's (1989a) LOQ differs from the ideal forms of Hemphill, Seigel, and Westie (1951). It asks the leaders themselves to choose the alternative that most nearly expresses their opinion on how frequently they should do what is described by each item on the questionnaire, and what they, as a supervisor or manager, sincerely believe to be the desirable way to act. The LOQ also differs from the ideal form in that the LOQ scale for initiation of structure contains several items that Stogdill, Goode, and Day (1962) later found to measure production emphasis. Production emphasis correlates with initiating structure but is not identical with it.

Following a review, Schriesheim and Kerr (1974) concluded that the test-retest reliability of the LOQ had

been adequately demonstrated over a one-to three-month period. Internal consistency reliabilities are also high (Fleishman, 1960, 1989b). In 60 studies, the median correlation between consideration and structure on the LOQ was  $-.06$ , with 57 of these correlations below  $.19$  and only 9 above  $.20$  found significant (Fleishman, 1989). According to a review of 20 LOQ validation studies (Fleishman, 1989b), a number of studies showed that supervisors higher in both consideration and structure were more likely to be higher on criteria of effectiveness, such as performance ratings, staff satisfaction, low stress, and less burnout of subordinates.

## Antecedents and Correlates of Consideration and Initiation of Structure

---

The internal consistency and test-retest reliability of the various scales of leader-behavior descriptions may be satisfactory, but to understand their effects, differences in content make it mandatory to distinguish whether the measures were based on the LBDQ, SBDQ, LOQ, or LBDQ-XII. This is essential in reviewing the antecedent conditions that influence the extent to which a particular behavior is exhibited and concurrent conditions are associated with such behavior.

*Interpreting Concurrent Analyses.* Most of the available research consists of surveys in which leadership behavior and other variables in the leader or the situation were measured concurrently. However, it seems reasonable to infer that a relatively invariant attribute such as the intelligence of the leader is an antecedent to the leader's display of consideration or initiation as rated by their colleagues. The national origin of the leader's organization is antecedent to the leader's behavior; but the average leader's behavior in the organization cannot affect its origin. Likewise, the leader's educational level is obviously antecedent to his or her behavior, but that behavior cannot cause a change in the leader's educational level. Similar inferences can be made about situational influences on the leader's behavior with less confidence, because the leader often can influence the situation, just as the situation is influencing the leader. If an association is found between company policy and the behavior of first-line supervisors, it seems reasonable to infer that the policy has influenced the supervisors, but the policy may also reflect the continuing behavior of the supervisors and may be a reaction to it. If an association is found between the leader's behavior and conflict in the work group, it is likely that the leader is a source of the conflict; but the continuing conflict is likely to be influencing the leader's behavior as well.

Suppose that a positive association is found between a leader's consideration and an absence of conflict within a group. The most plausible hypothesis is probably that the leader's behavior contributes to the absence of conflict; but the harmony within the group makes it possible for the leader to be more considerate. Therefore, in examining concurrent results, the reader will have to decide what meaning to draw from the reported associations. Such criteria of effectiveness as the subordinates' productivity, satisfaction, cohesion, and role clarity can be seen to be a consequence of the leader's behavior, yet they may influence the leader's behavior as well.

### ***Personal Attributes Related to Initiation and Consideration***

In a study of ROTC cadets, Fleishman (1957a) found that their attitudes toward consideration and initiation on the LOQ were not related to their intelligence or to their level of aspiration. But among school principals described by 726 teachers, Rooker (1968) found that principals with a strong need for achievement were described as high in tolerance of freedom and reconciliation of conflicting demands on the LBDQ-XII. However, Tronc and Enns (1969) found that promotion-oriented executives tended to emphasize initiation of structure over consideration to a greater degree than executives who were less highly oriented toward

promotion. And Lindemuth (1969) reported that for college deans, consideration was related to their scholarship, propriety, and practicality.

Experience and sex have been correlated with LBDQ scores. For 124 managers of state rehabilitation agencies who were described by their 118 subordinates, Latta and Emener (1983) found that initiation of structure on the LBDQ increased directly with experience. Serafini and Pearson (1984) reported that at a university initiation of structure was higher only among the 208 male nonadministrative supervisors and managers. For the female leaders, consideration was higher. This is consistent with the expectation that females are likely to be more relations-oriented.

*Personality, Values, and Interests.* Although one might expect authoritarianism to coincide with initiation of structure, this does not appear to occur. For example, Fleishman (1957a) observed that the leader's endorsement of authoritarian attitudes was negatively related to initiation of structure on the LOQ, but it was unrelated to consideration. Stanton (1960) also found no relation between consideration and authoritarianism. Flocco (1969), who studied 1,200 school administrators, showed that consideration and initiation of structure, as indicated by subordinates' responses to the LBDQ, were unrelated to the administrators' scores for dogmatism on a personality test.

Fleishman (1957b) also found that supervisors who favored consideration tended to have high scores on a personality scale of benevolence, whereas those favoring initiation of structure were more meticulous and sociable. Also, Fleishman and Peters (1962) obtained results for supervisors indicating that the trait of independence was correlated negatively with both initiation of structure and consideration, and the trait of benevolence was positively correlated with initiation of structure and consideration. Consideration was more highly related than initiation to ratings of social adjustment and charm (Marks & Jenkins, 1965). Litzinger (1965) reported that managers who favored consideration tended to value support (being treated with understanding and encouragement), whereas those who favored initiation of structure tended to place a low value on independence. Atwater and White (1985) reported that certain personal characteristics significantly correlated with demanding (SBDQ structuring) behavior by first-line supervisors; these included being inflexible, aggressive, uncooperative, harsh, strict, tense, ambitious, and unforgiving.

Newport (1962) studied 48 cadet flight leaders, each described on the LBDQ by seven flight members. Leaders who were rated high in both consideration and initiation of structure differed from those who were rated weak in desire for individual freedom of expression, resistance to social pressure, desire for power, cooperativeness, and aggressive attitudes.

In line with expectations, R. M. Anderson (1964) found, in a study of nursing supervisors, that those who preferred nursing-care activities were described as high in consideration but those who preferred coordinating activities were described as high in initiation. According to analyses by Stromberg (1967), school principals with emergent value systems were perceived by teachers as high in initiating structure, whereas those with traditional value orientations were perceived as high in consideration. Durand and Nord (1976) noted that 45 managers in a midwestern textile and plastics firm were rated by their subordinates as higher in both consideration and initiation of structure if the managers were externally, rather than internally, controlled—that is, if the managers believed that personal outcomes were due to forces outside their control rather than to their own actions.

Fleishman and Salter (1963) measured empathy in terms of supervisors' ability to guess how their subordinates would fill out a self-description questionnaire. They found that empathy was significantly related to employees' descriptions of their supervisors' consideration but not their initiation of structure. L. V. Gordon (1963a) showed that personal ascendancy was positively related to initiating structure but negatively related to consideration. Neither score was related to responsibility or emotional stability, although sociability was correlated with initiating structure (but not with consideration). Rowland and Scott (1968) failed to find any relation between consideration on the LOQ and the social sensitivity of supervisors. Pierson (1984) failed

to find any significant relations between the Myers-Briggs Indicator of perceptual and judgmental tendencies and consideration or initiation. Numerous other investigators<sup>5</sup> also failed to find LBDQ and LOQ scores related to any of the personality measures they used. Situational factors, to be discussed later, may override or eliminate the effects of personality on initiation and consideration.

*Cognitive Complexity.* A number of studies of the influence of cognitive complexity on leadership behavior have obtained positive findings, particularly when the additional LBDQ-Form XII factors have been used. W. R. Kelley (1968) reported that school superintendents who were high in cognitive complexity were also described as high in predictive accuracy and in reconciliation of conflicting demands. Streufert, Streufert, and Castore (1968) found significant differences between emergent leaders whose scores on perceptual complexity varied in a negotiations game. Leaders who were lower in cognitive complexity scored higher on initiating structure, production emphasis, and reconciliation. Leaders who were higher in cognitive complexity scored higher on tolerance of uncertainty, retaining the leadership role, consideration, and predictive accuracy. Results obtained by Weissenberg and Gruenfeld (1966) indicated that supervisors who scored high in field independence endorsed less consideration than those who scored high in field dependence. But Erez (1979) found that the self-described consideration of 45 Israeli managers with engineering backgrounds was positively related to field independence and to social intelligence, whereas initiating structure was negatively related to these two factors.

*Preferences for Taking Risks.* Rim (1965) studied risky decision making by supervisors and reported that male supervisors who scored high on both consideration and initiating structure and head nurses who scored high on initiation of structure tended to make riskier decisions. Men and women who scored high on both tended to be more influential in their groups and to lead the groups toward riskier decisions. However, Trimble (1968) found that for a sample of teachers who described their principals as being higher in consideration than in initiating structure, neither of the principals' scores was related to the principals' perceptions of their own decision-making behavior.

*Personal Satisfaction.* Initiation and consideration are greater among more satisfied leaders, whose tendencies to make decisions and attempts to lead are also related. To some degree, these tendencies may be consequences rather than antecedents of initiation and consideration. Managers who are more satisfied with their circumstances tend to have higher LBDQ scores, according to Siegel (1969). Similarly, A. F. Brown (1966) reported that better-satisfied school principals were described as higher than dissatisfied principals on all subscales except tolerance of uncertainty.

### ***Relationship of Initiation and Consideration to Other Leadership Styles***

Democratic versus autocratic, participative versus directive, and relations-oriented, task-oriented, transactional, and transformational leadership styles are discussed in [Chapters 17](#), [18](#) and [19](#). It should come as no surprise that consideration and initiation are related to these other leadership styles. Miner (1973) noted that concepts used in other studies—such as providing support, an orientation toward employees, human relations skills, providing for the direct satisfaction of needs, and group-maintenance skills—are akin to consideration. Concepts similar to initiating structure include facilitation of work, production orientation, enabling the achievement of goals, differentiation of the supervisory role, and the utilization of technical skills. Miner further pointed out that with its emphasis on organizing, planning, coordinating, and controlling, initiating structure has much in common with the ideas of classical management.

*Democratic and Autocratic Styles.* Although factorially independent, the various scales of consideration and initiation contain the conceptually mixed bag of authoritarian and democratic leadership behaviors. Each scale contains a variety of authoritarian or democratic elements. Although empirically these

elements cluster on one side or the other of authoritarian or democratic leadership, they are conceptually distinct. The industrial version, SBDQ, added strongly directive behaviors ("He rules with an iron hand") to its factor of initiating structure (House & Filley, 1971).

Yukl and Hunt (1976) correlated Bowers and Seashore's (1966) four leadership styles of support, the facilitation of interaction, emphasis on goals, and the facilitation of work with the LBDQ for 74 presidents of business fraternities. Support correlated .66 with consideration and .61 with initiation of structure. On the other hand, the emphasis on goals correlated .64 with consideration and .76 with initiation. Facilitation of work correlated .56 with consideration and .64 with initiation of structure. Clearly, a large general factor of leadership permeates all these measures, and leadership generally is or is not actively displayed. Karmel (1978) drew attention to the ubiquity of initiation and consideration in the study of leadership and in efforts to theorize about it. What she primarily added was the importance of the total amount of both kinds of activity by leaders, in contrast to inactivity.

This general factor becomes most apparent when the LBDQ rather than the LOQ is used. Weissenberg and Kavanagh (1972) concluded from a review that although managers think they should behave as if consideration and initiating structure are independent, in 13 of 22 industrial studies and in eight of nine military studies, a significant positive correlation was found between these two factors of leadership behavior on the LBDQ as completed by subordinates. This was especially so when LBDQ-XII was the version used in the survey (Schriesheim & Kerr, 1974). Seeman (1957) noted that a school principal's overall leadership performance was seen to be a matter of how much consideration and initiation of structure were exhibited. When Capelle (1967) asked 50 student leaders and 50 nonleaders to fill out the LOQ, he found that leaders scored significantly higher than did nonleaders on both consideration and initiation of structure. However, G. W. Bryant (1968) did not find that appointed and sociometrically chosen leaders (college students in ROTC) differed significantly in their conceptions of the ideal leader on the LOQ. These results fit with the general contention that, *conceptually*, initiation of structure is readily distinguishable from consideration, just as autocratic and democratic or relations-oriented and task-oriented leadership can be conceptually discriminated. But *empirically*, the same leaders who are high on one factor are often high on the other as well.

*Task and Relations Orientation.* Initiation of structure emphasized concern with tasks ("Insists on maintaining standards," "Sees that subordinates work to their full capacity," "Emphasizes the meeting of deadlines"), as well as directiveness ("Makes attitudes clear," "Decides in detail what should be done and how it should be done"). Consideration emphasized the leader's orientation to followers ("Stresses the importance of people and their satisfaction at work," "Sees that subordinates are rewarded for a job well done," "Makes subordinates feel at ease when talking with them"), as well as participative decision making ("Puts subordinates' suggestions into operation," "Gets approval of subordinates on important matters before going ahead"). Social distance was also minimized for considerate leaders ("Treats subordinates as equals," "Is easy to approach"). Conceptually opposite to initiation of structure is destructuring behavior (J. A. Miller, 1973a)—that is, reducing the request for consistent patterns of relations within the group. The lack of initiation of structure implies allowing conditions to continue without structure, avoiding giving directions, and avoiding being task-oriented. Conceptually opposite to consideration is leadership behavior that is exploitative, unsupportive, and uncaring (Bernardin, 1976).

Among 55 corporation presidents according to ratings by a staff member, a correlation of .55 was found between task-oriented production emphasis and initiating structure. Similarly, these presidents' consideration correlated .49 with the relations-oriented representation of their subordinates' interests and .41 with toleration of freedom of action for their subordinates (Stogdill, Goode, & Day, 1963a). W. K. Graham (1968) found, as predicted, that high-LPC (relations-oriented) leaders were described as higher in consideration and initiating structure than low-LPC (task-oriented) leaders. Yukl (1968) also noted that low-LPC leaders tended to be described as high in initiation and low in consideration. However, Meuwese and Fiedler (1965) reported that

leaders who were high and low on LPC tended to differ significantly only on specific items of the LBDQ, not in the total scores for consideration and initiating structure. Yukl (1971) and Kavanagh (1975) concluded that task-oriented behavior is implicit in initiating structure, but subordinates can still influence their superior's decisions. Misumi's Production and Maintenance (PM) style of leadership uses maintenance items that correlate highly with consideration. Production has two components: pressure and planning. Pressure correlates highly with initiation of structure when measured by the original SBDQ, which contained items such as "Prods for production" but is less correlated with initiation of structure as measured by the LPDQ without such autocratic items (Peterson, Smith, & Tayeb, 1993).

*Power, Authority, and Responsibility of the Leader.* Martin and Hunt (1980) obtained LBDQ evaluations by 407 professionals and quasi-professionals of their first-line supervisors in the construction and design units of 10 state highway department districts. Related data on morale were also collected. The expert power of the supervisors correlated .44 and .41 with their initiating structure and .48 and .51 with their consideration; but the other sources of power—referent, reward, coercive, and legitimate—correlated close to zero with the leadership measures. Foote (1970) found that members of the managerial staffs of television stations who tended to describe themselves on the RAD scales<sup>6</sup> as high in responsibility and authority also tended to be described on the LBDQ-XII as high in tolerance of freedom. Those who delegated most freely were described as high in production emphasis and low in representation orientation toward superiors.

Attempts to lead, manifest in one's emergence as a leader in a leaderless group discussion, were negatively related to consideration and positively related to initiation of structure (Fleishman, 1957a).

*Transactional and Transformational Leadership.* Cheng (1994) suggested that transformational school-teachers could be innovative and could demand clear rules in managing the classroom (structuring) as well as provide support to the students (consideration). Seltzer and Bass (1987) found that for 294 MBAs with full-time jobs who described their immediate supervisors' Initiation of Structure on the LBDQ-XII correlated .53, .55, and .59, respectively, with charisma, individualized consideration, and intellectual stimulation on the Multifactor Leadership Questionnaire (MLQ); and .48 and .06, respectively, with the transactional measures of contingent reward and management by exception on the MLQ. However, consideration on the LBDQ-XII correlated .78, .78, and .65, respectively, with the same MLQ transformational leadership measures and .64 and -.23, respectively, with the same MLQ transactional leadership measures. Evidently, active leadership is common to initiation, consideration, and transformational and transactional leadership behavior, and there are particularly strong associations between transformational leadership and consideration. Miliffe, Piccolo, and Judge (2005) reported correlations of .46 and .27, respectively, of transformational leadership with consideration and initiation. Furthermore, adding the transformational scales to initiation and consideration increased substantially the prediction of outcomes of the rated effectiveness of leaders and satisfaction with leadership. Similar results were reported for 138 subordinates and 55 managers (Seltzer & Bass, 1990).

Peterson, Phillips, and Duran (1989) found that the MLQ scale of charismatic leadership correlated higher with measures of consideration than measures of initiation in a study of 264 retail chain-store employees describing their supervisors. Thus charismatic leadership correlated .48 with maintenance orientation and .74 with support but only .16 with pressure for production and .22 with assigning work.

### ***Epitome of Consideration: The Servant Leader***

Greenleaf (1977, 1991), an AT&T executive, conceived the idea of the servant leader from Herman Hesse's *Journey to the East*. Leo, the servant to a band of men on a mythical journey, does their menial chores but also sustains them with his spirit and song. Leo disappears. The group falls apart and the journey is abandoned.

It turns out later that Leo is the titular head of the order that sponsored the journey. For Greenleaf, as for Hesse, the leader is the servant, first. The leader ensures that the highest priorities of followers are met. He first listens and questions before suggesting initiatives. Instead of coercion and manipulation, the servant leader depends on awareness, empathy, and foresight. To illustrate:

John Woolman visited Quaker communities for 30 years asking Quaker slaveholders about what ... slave-owning did to them morally. ... What were they passing on to their children? Non-judgmental persuasion followed. The Quakers became the first religious group in America to denounce and forbid slavery among its members. (Greenleaf, 1991, p. 21)

Servant leaders encourage skill and moral development in followers. They are sensitive to the needs of organizational stakeholders and hold themselves accountable for their actions (Graham, 1991). Servant leadership can be a model for higher education. Faculty members need to curtail and redirect their ego and image. Power needs to be shared with students. They become collaborators in an ethic of collective study. "The faculty member who has never learned from his students is a failure" (Buchen, 1998, p. 130). In Block's (1993) replacement of leadership with stewardship, service is chosen over self-interest. As noted by Heuerman (2002), caring about others, seen in servant leaders, underlies considerate leadership behavior. Followers are regarded as real people, not machines or expense categories. For leaders who care, service is an obligation, not a burden. At the extreme of the leader as servant, leaders sacrifice themselves for the perceived good of the group. In experiments with 357 students and 157 industrial personnel, Choi and Mai-Dalton (1998) found that self-sacrificing leaders were seen as more charismatic and legitimate, and generated intentions to reciprocate. Self-sacrificing leaders were also judged as more competent by the students. Block (1993) argued that self-interest, dependency, and control of others should be replaced by organizational stewards with service, responsibility, and accountability.

The self-sacrificing servant leader has to be a good steward. Abraham Feuerman was praised for continuing to pay full wages to his employees at Malden Mills from reserves and insurance during the period it was out of operation after it burned down. He might have been expected to use the money to rebuild overseas to make use of cheaper labor, as other textile companies had done. Instead, he continued to pay his employees, who were able to return with high morale to a beautiful new plant, for which he became extensively indebted. Unfortunately, his competitors used the time to catch and pass Malden Mills and gain some of its customers. Product leadership was lost. Bankruptcy ensued. In attending to the needs of his people, the servant CEO had not fully taken care of his organization's financial future.

### ***Situational Factors in Initiation and Consideration***

The organization, the immediate group that is led, and the task requirements affect the extent to which a leader initiates structure, is considerate, or both. For instance, when faced with a complex task and need for planning, a leader is likely to be more structuring in a group of low diversity. Structuring and the leader's planning skills contribute to the quality and originality of the plans, according to a study of 195 participants working in 55 groups (Daniels, Leritz, & Mumford, 2003).

*Organizational Policies.* A clear example of the impact of the organizational context on the behavior of individual leaders within it was provided by Stanton (1960), who described two medium-size firms. In one company, which was interested only in profits, authoritarian policies were dominant, and subordinates had to understand what was expected of them. The personal qualities of leadership were emphasized, and all information in the company was restricted to the managers except when the information clearly applied to an employee's job. The second firm, which had democratic policies, stressed participation as a matter of policy and was concerned about the employees' well-being as well as about profits. This firm made a maximum

effort to inform the employees about company matters. Supervisors in the firm with democratic policies favored more consideration, whereas supervisors in the firm with authoritarian policies favored more initiation.

The importance of the higher authority represented by the organization and its policies also can be inferred indirectly from results obtained in a progressive petrochemical refinery and in a national food-processing firm, where the extent to which supervisors felt they should be considerate was positively correlated with how highly they were rated by their superiors (Bass, 1956, 1958). Yet in other companies no such correlation was found (Rambo, 1958). Supervisors' perceptions of their superiors' and subordinates' expectations affect their leadership behavior. That is, supervisors will be more supportive or more demanding, depending on what they perceive their superiors and subordinates expect of them (Atwater, 1988).

*Organizational Size.* Vienneau (1982) examined the LBDQ scores of 33 presidents of amateur sports organizations, obtained from the responses of 85 members of their executive committees. Although the presidents' sex or language was of no consequence, both consideration and initiation were higher in the larger of the amateur organizations. The presidents agreed on what was required of their ideal leader on the Ideal Leader Behavior Questionnaire regardless of other organizational differences.

*Functional Differences.* D. R. Day (1961) found that upper-level marketing executives were described on the LBDQ-XII as high in tolerance of freedom and low in structuring, but upper-level engineering executives were described as low in tolerance of freedom and high in initiation. In the same firm, manufacturing executives were rated high and personnel executives were rated low in tolerance of uncertainty.

*Military versus Civilian Supervisors.* Holloman (1967) studied military and civilian personnel in a large U.S. Air Force organization and found that superiors did not perceive military and civilian supervisors to be different in observed consideration or initiation of structure, although they expected military supervisors to rank higher than civilian supervisors in initiation of structure and lower in showing consideration. Unexpectedly, Holloman found that subordinates—both military and civilian—perceived the military supervisors to be higher in consideration as well as in initiating structure than they did the civilian supervisors. Thus in comparison with civilian supervisors, military supervisors were seen to display more leadership by both their civilian and their military subordinates.

Halpin (1955b) administered the *ideal* form of the LBDQ to educational administrators and aircraft commanders. Subordinates described their leaders on the *real* form of the LBDQ. The educators exhibited more consideration and less initiation of structure than did the aircraft commanders, both in observed behavior and in ideal behavior. But in both samples, the leaders' ideals of how they should behave were not highly related to their actual behavior as described by their subordinates.

*Attributes of Subordinates.* Atwater and White (1985) and Atwater (1988) found that supportive (considerate) behavior by supervisors correlated highly with the subordinates' loyalty and trust. Kerr, Schriesheim, Murphy, and Stogdill (1974) concluded, from a review of LBDQ studies, that if the subordinates' interest in the task and need for information are high, less consideration by the leader is necessary and more initiation of structure is acceptable to them. Consistent with this conclusion, Hsu and Newton (1974) showed that supervisors of unskilled employees were able to initiate more structure than were supervisors of skilled employees in the same manufacturing plant. In a large sample survey of employees, Vecchio (2000) found that less mature employees were more inclined to favor structuring by leaders.

Chacko (1990) noted in data from 144 department heads in institutions of higher education that subordinates were more likely to be assertive and appeal to higher authority when their supervisors were low in structuring and in consideration. Gemmill and Heisler (1972) and Lester and Genz (1978) analyzed the impact of subordinates' locus of control—internal or external—on their perceptions of their supervisors' leadership and their satisfaction with it. Internally controlled subordinates tended to see significantly more consideration and initiation in their supervisors' behavior (Evans, 1974). Although internally controlled subordinates in a textile and plastics firm tended to see their supervisors as initiating more structure, they also felt that their

supervisors were less considerate (Duran & Nord, 1976). But Blank, Weitzel, and Green (1987) found correlations close to zero between the psychological and job maturity of 353 advisers of residence halls and the initiation and consideration, respectively, of their 27 residence-hall directors.

## General effects on Productivity, Satisfaction, and Other Criteria

---

Except for a few cross-lagged analyses and experiments, most of the results reported here come from concurrent surveys of leadership behavior and criteria such as subordinates' satisfaction and productivity. For instance, Brooks (1955) found that all the items measuring consideration and initiation of structure differentiated managers rated as excellent from those rated as average or below average in effectiveness. Although one tends to infer that productivity and satisfaction are a consequence of leadership behavior, the effective outcomes modify the leader's behavior to some extent as well. Greene and Schriesheim's (1977) longitudinal study suggested that more consideration early on by a leader can contribute to good group relations, which in turn may later result in higher group productivity. In any event, Fisher and Edwards (1988), in a series of meta-analyses, established that subordinates were more satisfied with work and supervision if their supervisors were high in consideration.

Using an early version of the LBDQ scales, Hemphill, Seigel, and Westie (1951) found that leaders' organizing behavior (initiating structure) and membership behavior (consideration) were both significantly related to the cohesiveness of the group. Likewise, Christner and Hemphill (1955) noted that subordinates' ratings of the leaders' consideration and initiation were positively related to ratings of the effectiveness of their units, but leaders' self-descriptions of consideration and initiation were not.

A sample of 256 MBA students who were working full-time in many different organizations described the initiation and consideration of their immediate supervisors at work. They also completed a "burnout" questionnaire. Although their leaders' initiation correlated only  $-.15$  with the respondents' feeling of being burned out, the leaders' consideration correlated  $-.55$  with this feeling. Thus considerate supervision appears to reduce substantially the sense of burnout in subordinates (Seltzer & Numerof, 1988). Considerate supervision also promotes creativity, according to Oldham and Cummings (1996). They found that supportive and noncontrolling supervision of 171 employees in two manufacturing plants correlated with subordinates' pattern disclosures, contributions to suggestion programs, and rated creativity. But Williams (2001) reported that the amount of structure supervisors initiated reduced the divergent thinking of their subordinates.

In an extensive analysis of 27 organizations involving more than 1,300 supervisors and 3,700 employees, Stogdill (1965a) ascertained that supervisors' consideration was related to the employees' satisfaction with the companies and to measures of the cohesiveness of the groups and the organizations. But as with authoritarian and democratic leadership, neither the supervisors' consideration nor their initiation of structure was consistently related to group productivity. Organizational differences had to be considered. The contribution to effectiveness of initiation and consideration appears quite variable and hence requires further examination of the context in which the data are collected.

### ***Business Studies***

*Leader Behavior.* Fleishman (1989a) reviewed more than 20 validity studies of the SBDQ. Fleishman, Harris, and Burt (1955) found that production foremen rated higher in performance by their managers were higher in initiation of structure and lower in consideration. But absenteeism and turnover were greater in work groups that had foremen with this pattern. Many other studies with the SBDQ have confirmed this strong relation between leader consideration and worker job satisfaction in industry (Badin, 1974; Fleishman &

Simmons, 1970; Skinner, 1969), hospitals (Szabo, 1981; Oaklander & Fleishman, 1964), educational settings (Petty & Lee, 1975), and government organizations (Miles & Petty, 1977).

The relationship between initiation of structure, as measured by the SBDQ, and performance criteria tended to vary with situations. Thus both initiation of structure and consideration were positively related to proficiency ratings in nonproduction departments (Fleishman & Harris, 1955). Using the SBDQ, Hammer and Dachler (1973) showed that the leader's consideration was positively related to the subordinates' perceptions that their job performance was instrumental in obtaining the desired outcomes. However, the leader's initiation of structure was negatively related to such perceptions. Likewise, Gekoski (1952) found that supervisors' initiation of structure, but not their consideration, was related positively to group-productivity measures in a clerical situation.

Lawshe and Nagle (1953) obtained a high positive correlation, for a small sample of work groups, between group productivity and employees' perceptions of how considerate their supervisor was. In a study of the leadership of foremen, Besco and Lawshe (1959) found that superiors' descriptions of a foreman's consideration and initiation of structure were both related positively to ratings of the effectiveness of the foreman's unit. However, subordinates' descriptions of foremen's consideration, but not initiation of structure, were positively related to such effectiveness.

In later studies, the LBDQ or LBDQ-XII was more likely to be used. Trieb and Marion (1969) studied two chains of retail grocery stores. They found that the supervisors' consideration, as described by the workers, was positively related to productivity, cohesiveness, and satisfaction in both chains. The supervisors' initiation of structure was related positively to the productivity of subordinates and to cohesiveness in one chain, but not in the other. In a study of two companies, House and Filley (1971) found that the supervisors' consideration in both companies related significantly to the subordinates' satisfaction with the company and with their jobs as well as to their freedom of action. In both companies, initiating structure was also related significantly to the subordinates' satisfaction with the company and their jobs, along with favorable family attitudes toward the company and their jobs. Fleishman and Simmons (1970) showed that the effectiveness of Israeli supervisors was positively related to their initiation of structure and consideration.

M. G. Evans (1968) reported that supervisors' consideration and initiation of structure were positively related to the importance of the goal to workers and to their job satisfaction. Under high supervisory consideration, a strong positive relationship existed between the supervisor's initiation of structure and the group's performance. In a later study, M. G. Evans (1970a) found that the supervisors' consideration and initiation were related to the workers' perception of opportunities to satisfy their need for security but not to their actual satisfaction with their job security. Weiss (1977) demonstrated that subordinates tended to be more likely to share values with their supervisors if the supervisors displayed considerate behavior toward them. Marks and Jenkins (1965) reported that initiation of structure was more highly related than was consideration to global ratings of effectiveness. However, supervisors' initiation of structure and consideration were unrelated to the satisfaction of subordinates' needs for social esteem, autonomy, and self-actualization.

In a study of insurance sales supervisors, W. K. Graham (1970/1973) found that supervisory consideration was positively associated with group performance. In a similar setting in seven retail discount department stores, Hodge (1976) obtained results for 21 second-level managers as reported on the LBDQ by 188 first-line managers. Satisfaction of subordinates' needs was positively associated with the higher-level managers' initiation of structure. But there was an unexpected negative correlation with consideration. These results were similar to what Patchen (1962) found for the supervision of manual workers, but contrary to what was reported by Fleishman and Harris (1962) for similar types of workers.

The source of the criteria makes some difference. Kofman (1966) reviewed research in which industrial supervisors' scores for consideration and initiating structure were related to various criteria of the supervisors' effectiveness and the work groups' performance. Generally, he found that the peer ratings of the groups'

performance were unrelated to the peer ratings of the supervisors' consideration and initiation of structure. However, evaluations of the supervisors' effectiveness by superiors and subordinates, as well as evaluations based on objective criteria, tended to relate positively to the supervisors' initiation and consideration as described by subordinates.

A number of industrial studies were completed using the additional scales of LBDQ-XII. D. R. Day (1961) obtained 165 ratings of executives in an aircraft manufacturing firm. The effectiveness of leaders correlated with a general factor, as well as with the predictive accuracy of LBDQ-XII, persuasiveness, role enactment, and the reconciliation of conflicting demands. According to R. E. Hastings (1964), leaders who were rated high in initiating structure and production emphasis supervised research teams that were rated high in the volume of work they completed. If the leaders were rated high in orientation to superiors, their groups were rated low in harmony. Leaders who were rated high in representation and role retention tended to supervise teams that were rated high in enthusiastic effort. Leaders who were high in persuasiveness supervised teams whose quality of work was rated as high. Even after the effects of many other morale variables were removed, freedom and consideration by supervisors on LBDQ-XII were important contributors to the amount of innovative behavior displayed by 309 federal R & D aerospace scientists and engineers (Dalessio & Davis, 1986).

M. Beer (1964) used the LBDQ-XII to test McGregor's (1960) hypothesis that employees become motivated and are enabled to satisfy their higher-order needs (for autonomy, esteem, and self-actualization) only when supervisors allow them freedom from organizational structure and pressure. He found support in that the employees' satisfaction of the need for autonomy, esteem, and self-actualization was positively related to the supervisors' consideration and tolerance of freedom. However, contrary to his hypothesis, the leaders' considerate behaviors that resulted in the satisfaction of higher-order needs were not the ones that led to employees' strong striving for the needs. Rather, the leaders' initiation of structure was the leaders' behavior associated with such striving.

*Leaders' Opinions and Attitudes.* As with the effects of leaders' behavior on effective and satisfying outcome, findings about the effects of leaders' attitudes were also mixed. Bass (1956) found that the effectiveness ratings by superiors of 53 supervisors were significantly related to their opinion scores on consideration but not on initiation expressed two years previously on the Leadership Opinion Questionnaire (LOQ). In a replication, a significant correlation of .32 was found between sales supervisors' attitudes toward consideration and effectiveness ratings by superiors three years later (Bass, 1958). But Bass (1957a) also reported that neither attitudes toward consideration nor attitudes toward initiation of structure were related to peer ratings of sales supervisors on criteria such as popularity, problem-solving ability, and value to the company. Fleishman and Peters (1962) found no relation between LOQ measures of supervisors' attitudes toward leadership and their rated effectiveness as supervisors. Rowland and Scott (1968) also noted that LOQ measures of supervisory consideration were unrelated to employees' satisfaction. According to T. C. Parker (1963), 1,760 employees of a wholesale pharmaceutical company in 80 decentralized warehouses were more satisfied with their supervision, their recognition, and their job security when their supervisors felt that consideration and initiation were important, as measured by the LOQ. The correlations of subordinates' satisfaction and supervisors' attitudes were .51 with supervisory consideration and .22 with supervisory initiation. Although there was no relation of the supervisors' attitudes to such objective measures of group performance as productivity and errors in filling orders, the supervisor's favoring of initiating structure correlated .23 with pricing errors of the unit being supervised. Spitzer and McNamara (1964) also reported that managers' attitudes toward consideration and initiation were not related to salary as a criterion of the managers' success; nor were such attitudes related to superiors' ratings of the managers' success. However, Weissenberg and Gruenfeld (1966) found that supervisors who had favorable attitudes toward consideration and initiation were also more favorably inclined toward the personal development of their subordinates. Generally, satisfactory supervisors reveal this "hi-hi" pattern (Fleishman, 1989b), and it has been found to be

related to low stress and low burnout among subordinates (Duxbury, Armstrong, Drew, & Henly, 1984).

## ***Military Studies***

In the first extensive use of the LBDQ with U.S. Air Force personnel, Christner and Hemphill (1955) found that changes in the attitudes of crew members toward each other over time were related to the leadership behavior of the crew commander. When crew members rated their commander as high in consideration, they increased their ratings of each other's friendliness, mutual confidence, conversation on duty, and willingness to engage in combat. Crews that described their commander as high in initiation of structure increased their ratings of each other's friendship and confidence. But Halpin (1954) found that superiors tended to evaluate positively those aircrew commanders they rated high in initiating structure and to evaluate negatively those rated high in consideration. In training, the satisfaction of crew members was positively related to rated commanders' consideration ( $r = .48$ ) and negatively related to commanders' initiating structure ( $r = -.17$ ). In combat, however, commanders' consideration ( $r = .64$ ) and initiating structure ( $r = .35$ ) were positively related to the same crew members' satisfaction. In a later study, Halpin (1957a) found that superiors' ratings of the commanders' effectiveness in combat were unrelated to crew members' descriptions of their commander's consideration. However, superiors' ratings, as before, were positively and significantly related to the commander's initiation of structure. Significantly, crew members' ratings of their commander on confidence and proficiency, friendship and cooperation, and morale and satisfaction were positively related to both consideration and the initiation of structure by their commander.

Fleishman (1957a) found that the consideration and initiation scores of ROTC leaders were positively and significantly related to peers' ratings of the leaders' value to their groups, but superiors' ratings were not related to either pattern of behavior. In a study of trainee leaders in the military, Hood (1963) ascertained that the trainees reported more affiliation and less communication when their superiors were higher in initiating structure and consideration. Enlisted personnel attained higher scores on a pencil-paper test of military leadership when their leaders structured the situation and pushed for production. However, such higher attainment by the enlisted personnel was not related to their leaders' consideration.

Hooper (1968/1969) obtained results with the LOQ indicating that the attitudes of U.S. Air Force cadets toward consideration and initiation were not significantly related to their effectiveness ratings. However, the two factors differentiated significantly between those scoring high and those scoring low on a composite leadership criterion.

*Group Effects.* C. H. Rush (1957) reported the effects of leadership behavior on other dimensions of the performance of 212 aircrews. Crew members described the leadership behavior of the crew leaders and conditions in the crews on Hemphill and Westie's (1950) Group Dimension Descriptions. The leaders' consideration was associated with more intimacy and harmony and less control and stratification in the crews. The leaders' high rating on the initiation of structure was related to greater harmony and procedural clarity and to less stratification in the crews.

In examining the satisfaction and the initiation and consideration of their leaders, according to 672 U.S. Army National Guardsmen in the study by Katerberg and Hom (1981), it was necessary to account statistically for both the group effects and the individual dyadic effects of LBDQ ratings of the first sergeants and the company commanders on the guardsmen's satisfaction with the sergeants and commanders. First sergeants and commanders who earned high mean LBDQ scores on initiation and consideration from their collective unit of subordinates also had units with higher mean satisfaction. But beyond this, within the groups, individual subordinates were more satisfied if they saw their leader exhibiting more initiation and consideration. The adjusted correlations between satisfaction and the initiation and consideration scores on the

LBDQ were .37 and .47 for the group-by-group analyses for the first sergeants and commanders, respectively. The individual-within-group analyses added substantially to the correlations between leadership and satisfaction. Although there were problems with Katerberg and Hom's failure to separate the group and dyadic effects completely (Dansereau, Alutto, & Yammarino, 1984), the strong associations with satisfaction found for both initiation and consideration in the military were supported by similar LBDQ evidence obtained for 30,000 U.S. Army personnel in 63 national and overseas installations (Marsh & Atherton, 1981–1982).

### ***Educational Studies***

Various investigations of the leadership behavior of college administrators, school administrators, school principals, and classroom teachers have been conducted. Hemphill (1955) used the LBDQ to study the leadership of heads of academic departments in a university. The department head's reputation for administrative competence correlated .36 with consideration and .48 with initiation of structure. But Lindemuth (1969) failed to establish any relationship between a college dean's initiation of structure and various measures of organizational climate. Superintendents who were rated as effective leaders by both their staff and school board members were described as high in both consideration and initiation of structure (Halpin, 1956a). H. J. Bowman (1964) asked school principals to describe the leadership behavior of higher-level school executives and themselves. Principals perceived themselves as exercising high degrees of responsibility and authority and as delegating extensively when they described their own superiors as being high in consideration but not in initiation. Among the school administrators studied by Flocco (1969), those described by subordinates as higher in consideration and initiation of structure were rated more effective. Those administrators who described themselves as being higher in consideration and initiation than their staff subordinates described them were rated ineffective.

*School Principals.* A. F. Brown (1967) and Greenfield (1968) concluded from reviews of Canadian studies that the performance of pupils was associated with the principals' LBDQ scores. Keeler and Andrews (1963) studied the relation of principals' leadership to the performance of pupils and the cohesiveness of staffs in Canadian public schools. Both consideration and initiation of structure by principals, as described by teachers, were significantly and positively related to the pupils' examination scores on a province-wide examination. Initiation of structure by the principals was positively related to the cohesiveness of their staffs, but consideration was not. Nevertheless, A. F. Brown (1966) reported that effective principals generally scored higher on the LBDQ-XII scales. Seeman (1957) found performance evaluations of the school principals' leadership positively related to consideration, initiation of structure, communication, and willingness to change, and negatively related to domination and social distance. According to Fast (1964), consideration and initiation of structure by principals, as described by teachers, were positively related to the teachers' satisfaction, although expected behavior was not. Stromberg (1967) obtained a significant relation between teachers' morale and the attitudes of their principals toward consideration and initiation of structure.

C. C. Wall (1970) studied four effective and four ineffective principals in terms of their dialogue, decision making, and action. Effective principals were described by their teachers as higher than ineffective principals in consideration and tolerance of freedom on the LBDQ-XII. Ineffective principals were scored high in production emphasis. Teachers in seven of the eight schools studied believed that the principals ought to initiate more than they were perceived to do. Teachers in the ineffective schools believed that the principals should exhibit more persuasion and demand more reconciliation and more integration of the group than they were perceived to do. Mansour (1969) found that these discrepancies between the expected and actual behavior of principals were negatively relative to teachers' job satisfaction and participation. Fast (1964) also obtained results indicating that the greater the discrepancy between the teachers' expectations and observations of

principals' behavior, the lower the teachers' satisfaction.

Among different schools, Punch (1967) found that the principals' initiation of structure was positively related and the principals' consideration was negatively related to a measure of bureaucracy in the school. Mathews (1963) reported that principals' initiation of structure and consideration were significantly related to Hemphill and Westie's (1950) measures of their staff's stratification, control, homogeneity, cohesiveness, hedonic tone, and participation.

Hills (1963) obtained descriptions by 872 teachers of 53 principals. Both consideration and initiating structure were highly correlated with two representative functions of the principals: (1) representing the teachers' interests to higher levels of the organization and (2) representing the teachers' interests to pupils and their parents. Hills concluded that consideration and initiation of structure were not solely concerned with internal leadership but were reflected in how the principals, as leaders, dealt with outsiders and higher levels of authority.

However, Rasmussen (1976) failed to establish any significant relationship between the success of 25 elementary schools, the satisfaction of teachers, and the behavior of principals described on the LBDQ. Bailey (1966) studied four principals who were described by their superintendents and four teachers as higher in consideration than in initiating structure and four other principals who were described as being higher in initiating structure than in consideration. Each principal and four teachers played a decision-making game. Although the principals' consideration was found to be significantly related to the teachers' satisfaction with the decision and support of it, neither the principals' consideration scores nor their initiating structure scores were significantly related to the ability of a group to arrive at a decision or to perceptions that teachers had helped make the decisions.

*Classroom Teachers.* Using the appraisal of the performance of their classroom teachers by 2,084 business students, Baba and Ace (1989) extracted stable initiation factors as well as factors of evaluation and effort. Class size and course level made no difference. In another large-scale Canadian study, Greenfield and Andrews (1961) obtained results indicating that consideration and initiation of structure by classroom teachers were positively and significantly related to the scores of their pupils on achievement tests. Cheng (1994) found that teachers high in initiating structure and consideration were more influential as a consequence of their greater expertise and attractiveness. Their classrooms had a more positive social climate.

### ***Health Organization Studies***

In a study of nurses and their supervisors, Nealey and Blood (1968) found that the satisfaction of subordinates was related to the consideration scores of both their first- and second-level supervisors. The supervisors' initiation of structure contributed to the subordinates' job satisfaction at the first, but not at the second, level of supervision. Oaklander and Fleishman (1964) observed that when hospital administrators endorsed both high consideration and high initiation of structure on the LOQ, stress was lower in the units they supervised.

A path analysis by Sheridan and Vredenburg (1979) for the descriptions by 372 nurses, practical nurses, and nursing aides of the behavior of their head nurses disclosed a positive effect of the head nurses' initiation of structure on the subordinates' group relations. But these group relations did not affect the subordinates' performance or turnover rates. Good group relations also reduced the subordinates' felt job tension. However, such job tension had only a slight positive association with job performance or turnover rates. Yet the head nurses' consideration had a direct positive effect, as well as an indirect effect, on the subordinates' performance. It also reduced the subordinates' felt job tension. This result fits with Weed, Mitchell, and Moffitt's (1976) laboratory finding that the leader's consideration makes for a pleasant working situation, although it may not necessarily contribute to the group's productivity.

The critical importance of the leader's initiation and consideration to the performance of subordinates in health organizations was confirmed by Dagirmanjian (1981), Blaihed (1982), and Denton (1976). On the basis of a data analysis, Dagirmanjian (1981) concluded that the supervisors' initiation of structure and consideration were the central links between the organizational structure in mental health services and the staffs. Blaihed (1982) obtained the LBDQ-XII scores of chief executive officers (CEOs) and staffs of hospitals in Los Angeles and related the results to criteria of hospital performance furnished by the California Health Facilities Commission. Initiation of structure by the CEOs and staffs contributed to the efficiency of the hospitals and the quality of care they provided, as did a number of the other scale scores of the LBDQ. Similarly, for 80 professional mental health workers and their directors, Denton (1976) found significant, direct relationships between supervisors' consideration and initiation of structure, on the one hand, and the workers' job satisfaction and satisfactory relations with clients on the other. Conversely, Duxbury, Armstrong, Drew, and Henly (1984) found that head nurses with low consideration and high initiation scores on the LOQ had the lowest staff satisfaction and highest staff burnout.

### ***Studies in Other Not-for-Profit Organizations***

Bernardin (1976) found that for 501 police officers in a metropolitan department, consideration by supervisors was positively and linearly related to the police officers' satisfaction but not to their performance or absenteeism. To account for the results more adequately, additional descriptive data about the supervisors were required, such as the supervisors' specific reward orientation and punitiveness.

Stogdill (1965a) studied 10 regional organizations in a department of a state government. He noted that throughout the 10 organizations, executives who described their superiors as high in representation on the LBDQ-XII tended to manage groups that were rated high in support of the organization, and their subordinates tended to be satisfied with their pay. Tolerance of uncertainty by their superiors was related to harmony in the groups. Superiors who were rated high in initiating structure had subordinates who were satisfied with the organization. When the state employees described their first-line supervisors, Stogdill found that those first-line supervisors who were rated high in initiation of structure, consideration, and "influence upstairs" tended to have subordinates who were satisfied with the organization and groups that were rated strong in drive. Employees who described their supervisors as tolerant of freedom expressed satisfaction with their own freedom on the job. Klepinger (1980) collected LBDQ and outcome data from a stratified sample of 35 executive directors of social service departments who were rated by their 227 employees. Directors who scored high in initiation and consideration were also seen as highly effective managers, but their leadership behavior did not influence their employees' job satisfaction.

Hood (1963) found that business trainees reported more affiliation and less communication when their leaders were rated high both in initiating structure and in consideration. Furthermore, the trainees attained higher scores on a paper-and-pencil test of performance when their leaders structured the situation and pushed for production. But such increased attainment was not related to the leaders' consideration. Cunningham (1964) observed that the most effective agricultural agents and 4-H club agents were above the median in both consideration and initiation of structure on the LBDQ. Similarly, Osborn and Hunt (1975a, 1975b) obtained data indicating that most aspects of the satisfaction of members in 60 chapters of a business fraternity were positively associated with their presidents' initiation and consideration. But Yukl and Hunt (1976) reported that in 74 chapters the correlations between LBDQ assessments of the chapter presidents' initiation and consideration and the chapters' efficiency in fulfilling specified requirements were only .12 and .10, respectively.

## Meta-Analyses

Fisher and Edwards (1988) completed a meta-analysis of studies in the computer abstracts of *Psychological Abstracts*. These studies presumably were published mainly after 1968. As can be seen in [Table 20.1](#), after the mean findings were corrected for sample size, restriction in range, and unreliability, the adjusted mean correlation of leader consideration on the LBDQ with job performance ranged from .27 to .45. The adjusted correlations of employee job performance with LBDQ initiation of structure were similar, but this was not true of the SBDQ measure of initiation with its punitive elements.

Except for the SBDQ measure of leaders' initiation, considerably higher adjusted correlations were obtained, as expected, between leaders' initiation, consideration, and outcomes in job satisfaction, and satisfaction with supervision, as shown in [Tables 20.2](#) and [20.3](#).

Table 20.1 Mean Correlations of Leader Consideration and the Initiation of Structure with Job Performance

			Mean Correlation	
Leadership Measure	Number of Respondents	Number of Correlations	Unadjusted	Adjusted
<i>Consideration</i>				
LBDQ	1,486	19	.19	.45
SBDQ	1,953	21	.19	.46
LBDQ-XII	1,424	11	.13	.27
<i>Initiation of Structure</i>				
LBDQ	1,486	19	.20	.47
SBDQ	1,953	21	-.02	-.06
LBDQ-XII	1,424	11	.09	.22

SOURCE: Adapted from Fisher and Edwards (1988), p. 202.

The patterns of results lent support to Larson, Hunt, and Osborn (1976), who concluded after examining 14 samples of first-line supervisors involving 2,474 respondents that the multiple regression additive or interactive combining of initiation and consideration was unwarranted, since it did not add sufficiently to the prediction of outcomes beyond what each measure could do alone. Part of this lack of augmentation of one measure by the other was due to the mean intercorrelation of .52 between them found for 10 samples on the LBDQ-XII by Schriesheim, House, and Kerr (1976). For four samples, Schriesheim (1982) obtained results indicating that consideration alone accounted for most of the effects on the satisfaction of subordinates. For samples of 230 hourly employees, 178 college seniors and graduate students with employment experience, 96 middle managers, and 258 clerks and middle managers who described their supervisors' leadership behavior by means of the LBDQ and the SBDQ, Schriesheim found that the supervisors' consideration alone correlated between .62 and .77 with satisfaction with the respondents' jobs and with their supervisors. The results for the supervisors' initiation of structure, in multiple regression analysis, added only from 2% to 4% to the consideration effects in accounting for satisfaction. However, while Nystrom (1978) reached the same conclusion about consideration and the satisfaction of subordinates' needs, with a sample of 100 junior and senior managers, he noted that managers who were high in initiating structure and in consideration had relatively lower salary levels and progressed more slowly in their careers. Low initiation of structure, rather than high consideration, contributed the most to higher salaries and career advancement. Nystrom's results may say much about the culture and policies in the firm from which the 100 managers were drawn. Contingent factors need to be considered.

Table 20.2 Mean Correlations of Leader Consideration and Initiation of Structure with Overall Job

SOURCE: Adapted from Fisher and Edwards (1988), p. 203.

Judge, Piccolo, and Remus (undated) conducted three meta-analyses involving over 20,000 cases of 209 correlations from 154 samples in 103 publications and dissertations; 203 correlations from 151 samples in 99 studies; and 181 correlations from 166 samples in 78 studies. The SBDQ, LBDQ, LBDQ-XII, LOQ, and other measures of initiation and consideration were included. The estimated true score correlation was .48 between consideration and measures of follower satisfaction with job, motivation, leader, and leader effectiveness. The highest correlation was with satisfaction with the leader ( $r = .78$ ). The somewhat lower estimated true score correlation was .24 for initiation of structure with follower performance. The comparable estimated correlation between consideration and initiation of structure was .17, supporting their factorial independence. Although there was variability, the results were generalizable across many conditions. These were negligible for SBDQ, lower at supervisory than middle or upper hierarchical levels, and lower for cross-sectional compared with longitudinal studies. The consideration estimated correlations were higher for studies in the public sector and colleges ( $r = .56$ ,  $r = .53$ ) and lower in business and the military ( $r = .43$ ,  $r = .40$ ). The initiation estimates were higher in the military studies ( $r = .46$ ) and lower elsewhere ( $r = .29$ ,  $.28$ ,  $.25$ ).

## Contingencies in the effects of Consideration and Initiation

---

Generally, the consideration of supervisors seems to be associated with subordinates' satisfaction with the

supervisors, fewer absences, and less likelihood of quitting. But, as we have just seen, the correlations between a leader's initiation of structure and the satisfaction and productivity of subordinates vary, in outcome, depending on the instruments used to measure them. The constraints and goals in the situation also make a difference. The personnel involved may be particularly important. Followers in a wide variety of groups consider it legitimate for the leader to exercise influence on matters related to the performance of tasks and the work environment (Fleishman & Peters, 1962). At higher executive levels, initiation of structure is seen in planning, innovation, and coordination; at lower levels, it is seen in the push for production (Brooks, 1955).

Although too much initiation often increases the likelihood of grievances, absenteeism, and turnover (Fleishman & Harris, 1962), a certain amount of pointing out the "paths to successful effort" (Bass, 1965c) is characteristic of the effective supervisor. This yields the greatest effectiveness and satisfaction in the work group—especially when workers are untrained, unmotivated, or both, for example, or when the group lacks cohesiveness. Untrained personnel need more help; trained people prefer less help.

The variety of mixed results noted in reviews<sup>7</sup> of the effects of consideration and initiation suggests that to gain a better understanding of these effects, researchers need to specify the measures used and the conditions involved (House, 1971; Kerr, Schriesheim, Murphy, & Stogdill, 1974). For example, initiation of structure usually has been found to be associated with subordinates' role clarity, but somewhat less frequently with subordinates' performance. The correlation with subordinates' satisfaction varies considerably from study to study (Fleishman, 1973). The leadership climate under which the supervisors work has been found to be related to the supervisors' own consideration and initiating structure behavior and attitudes (Fleishman, 1953b).

## ***Instrumentation***

As noted earlier, variations in results depend to some degree on whether the LBDQ, the SBDQ, the LBDQ-XII, or the LOQ has been used.

Schriesheim, House, and Kerr (1976) did a masterful detective job in reconciling the mixed results obtained with the various versions of the LBDQ and SBDQ in measuring initiation of structure. First, they pointed out that the LBDQ of Halpin (1957b) contained 15 items asking subordinates to describe the actual initiating structure behavior of their leader to establish well-defined patterns of communication and to set up ways to get the job done. But the revised LBDQ-XII (Stogdill, 1963a) contained 10 items for measuring initiation of structure that dealt with the actions of the leaders in clearly defining their own roles and informing followers about what was expected of them. Even more substantial differences were found in the leadership behavior tapped by the SBDQ and the LBDQ in a comprehensive item-by-item analysis of 242 employees' descriptions of their supervisors. In addition to role clarification by the leader, as was noted earlier, the SBDQ included a cluster of items measuring punitive, autocratic, and production-oriented behaviors, such as "He rules with an iron hand" and "He needles those under him for greater effort." Thus the three questionnaires—SBDQ and the earlier and later versions of the LBDQ—differed markedly in content. The initiation items of the LBDQ versions largely reflected communication and organization elements; the SBDQ initiating structure, however, contained domination and production pressure items.

An essential component of initiation of structure in all the instruments involved role-clarification behaviors. A specific aspect of role clarification—establishing methods to get the work done—is mentioned in the LBDQs, but other aspects, such as scheduling and criticizing, are found only in the SBDQ. Schriesheim, House, and Kerr (1976, p. 301) concluded:

When measured by the SBDQ, leader Initiation of Structure is generally positively related to performance ratings by superiors of manufacturing first-level supervisors' subordinates.<sup>8</sup> This

generalization also holds with regard to noncommissioned ... infantry officers and air force officers<sup>9</sup> ... with Initiating Structure being measured in these studies by a form containing items similar to the autocratic behavior items of the SBDQ. A similar although much weaker pattern of relationships has been found concerning non-manufacturing supervisors of clerical workers doing routine tasks ... using selected items from the SBDQ in a laboratory experiment.<sup>10</sup> When the revised LBDQ Initiating Structure scale is used to measure leader behavior of first-line supervisors of non-manufacturing employees performing routine tasks, correlations with subordinate satisfaction are positive, although generally [lower] ... using a very modified version of the revised LBDQ.<sup>11</sup>

Meheut and Siegel (1973) demonstrated the differences by dividing the items on initiation of structure in the SBDQ into those concerned with role clarification and those concerned with the autocratic behavior of leaders. They obtained a correlation of .26 between leaders' role clarification and subordinates' satisfaction, but a correlation of  $-.21$  between leaders' autocratic behavior and subordinates' satisfaction.

Another source of error that accounts for variations in results with the SBDQ, according to Schriesheim, House, and Kerr, is the SBDQ's failure to provide opportunity for respondents to describe the timing or appropriateness of the structuring of the particular task or of the context in which respondents work, even though empirical evidence indicates that timing may be more important than the frequency of specific leadership behaviors (see, for example, W. K. Graham, 1968; Sample & Wilson, 1965). In addition, leaders who have adequate knowledge of the demands of their subordinates' tasks may vary the amount of initiation of structure and the kind and timing of the structure they provide. Some tasks require more structure during the goal-setting (goal-clarification) stage, whereas others require more path clarification and feedback on performance. Furthermore, some subordinates need more administrative structure to relate their work to other employees. Other subordinates could benefit more from technical guidance. Leaders may have no control over standards. Their initiation of structure may depend on circumstances outside their purview. "He decides what shall be done and how it shall be done" may be physically impossible for leaders in some situations. Other items on initiation of structure, such as "He tries out his ideas in the group," are less likely to be affected by circumstances.

Some items deal with specific behavior, and others deal with general tendencies. Such initiation of structure items as "He schedules the work to be done" refer to specific actions; items like "He encourages overtime work" relate to general practices. Even farther removed from specific behaviors and more concerned with the skills, traits, and personality attributed to the leader are such items as "He makes accurate decisions" and "He is a very persuasive talker."

## ***Organizational Contingencies***

The impact of a leader's initiation and consideration will depend on the organization in which they occur. House, Filley, and Gujarati (1971) found that both the leader's consideration and the leader's initiation of structure moderated the employees' satisfaction with freedom on the job, job security, and family attitudes in one firm, but not in another. Similarly, Larson, Hunt, and Osborn (1974) found that in one state mental health institution, the leaders' consideration was related to the performance of different groups of personnel, but that in another institution, initiating structure was more highly related to over-all groups' performance. The report by Marsh and Atherton (1981–1982) of the results of a study of 30,000 U.S. Army personnel concluded that whether a military unit was *mechanistic* or *organic* moderated the extent to which the leader's initiation or consideration was related to the subordinates' satisfaction.

*Differences in Function and Task.* Fleishman, Harris, and Burt (1955) noted that the leader's greater initiation of structure contributed to absences and grievances of subordinates in manufacturing departments

and to heightened rates of turnover in nonmanufacturing departments. At the same time, Fleishman, Harris, and Burt found that supervisors in manufacturing departments or in other departments that were working under time constraints were likely to receive higher merit ratings from their own supervisors if they tended to exhibit more initiation of structure, whereas the reverse was true for supervisors in service departments. In addition, in the nonmanufacturing service departments, the more considerate supervisors were seen as more proficient. "Pressure for production" was the moderator.

In Cunningham's (1964) study of county agricultural agents and 4-H club agents cited earlier, the agricultural agents' consideration was significantly related to effectiveness, but initiation of structure was not. In contrast, initiating structure was significantly related to the effectiveness of 4-H club agents, but consideration was not. However, as was noted earlier, the most effective agents in both organizations were those who were described as above the median in both consideration and initiation. Mannheim, Rim, and Grinberg (1967) reported that manual workers tolerated more initiation of structure by their supervisors than did clerical workers. Only clerical workers tended to reject the high-structuring supervisor when they expected the initiation of structure to be low. When high consideration was expected, both groups chose the leader who conformed to their expectations.

Hunt and Liebscher (1973) showed that leaders' consideration was more strongly associated with subordinates' satisfaction in a construction bureau than in a bureau of design of a state highway department; the leaders' initiation of structure did not vary as much in its effects on satisfaction. Dagirmanjian's (1981) study of 126 mental health service personnel showed that when organizational differentiation was in force, the leaders' consideration generated employee satisfaction with supervision, but when organizational integration was involved, the leaders' initiation of structure generated such satisfaction.

*Leaders in the Middle.* Although Rambo (1958) failed to find any significant differences in the initiation and consideration of executives in different echelons of the hierarchical structure, Halpin (1956a) saw such hierarchical differences when he examined the reactions of organizational members at different levels to the leader in between them in level. Halpin studied the leadership of school superintendents described by staff members, school board members, and themselves on both the real and ideal forms of the LBDQ. He found that the board members agreed among themselves and the staff members agreed among themselves in their descriptions of the superintendents' behavior, but the two groups differed significantly in their perceptions. Staff members saw the superintendents as less considerate than the superintendents saw themselves or the board members saw the superintendents. The board members described the superintendents as being higher in initiating structure than did the staff members or the superintendents. The staff members and the board members differed significantly regarding how considerate the superintendents should be, but they did not differ significantly about the extent to which superintendents should initiate structure. The board members expected the superintendents to act in a more considerate manner than the staff members considered ideal. There was a nonsignificant tendency for board members to expect more initiation of structure than either the staff members or the superintendents considered ideal.

Other studies in educational institutions by raters of a leader in the middle were conducted by Sharpe (1956), Carson and Schultz (1964), and Luckie (1963). Sharpe studied the leadership of principals as described by teachers, staff members, and the principals themselves. The three groups held similar ideals of leadership behavior, but the teachers and staff members perceived the principals as deviating less from the ideal norms than did the principals themselves. Occupants of high-status positions perceived the principals as deviating more from the ideal norms than did those in lower-status positions. Carson and Schultz (1964) obtained descriptions of junior college deans by college presidents, department heads, student leaders, and the deans themselves. The greatest discrepancies were found between the presidents' and student leaders' perceptions and expectations of the dean's behavior. The evidence suggested that the greatest source of role conflict for the deans was the discrepant expectations of their behavior. Luckie (1963) obtained 434 descriptions of 53

directors of instruction by superintendents, staff members, and the directors themselves. The results indicated that the instructional directors actually behaved at a lower level of consideration than superintendents, the directors themselves, and the staff members rated as ideal. The superintendents and the staff members expected the directors to exhibit higher degrees of initiating structure than the directors considered ideal.

The conflict of the leader in the middle seems to reside in the question of how considerate to be, not how much structure to provide. Graen, Dansereau, and Minarm (1972b) obtained data indicating that at lower organizational levels, both superiors and subordinates evaluated the leader in between them more highly if the leader initiated more structure. But the leader's consideration had more of an impact on subordinates than on superiors.

Lawrie (1966) used real and ideal consideration and initiation in a study of superiors' and subordinates' expectations of foremen in two departments. The convergence between real and expected behavior, as described by subordinates, was not related to ratings of the foremen's effectiveness. However, in one of the two departments, the foremen's ability to predict the superiors' expectations and the congruence between the foremen's and the superiors' expectations were related to ratings of the foremen's effectiveness.

*Influence "Upstairs."* Leaders' influence with higher authority has been found to affect the impact of their initiation of structure and consideration on their subordinates' satisfaction and performance. Consideration often involves promises of tangible rewards, and leaders may need influence "upstairs" to deliver on their promises. Initiation of structure involves setting forth goals and plans; influence "upstairs" adds to the leaders' ability to do so with authority and credibility. In one of two companies studied, House, Filley, and Gujarati (1971) found the expected strong positive relation between a supervisor's influence with a higher authority and an increase in the correlation of the supervisor's consideration with the subordinates' satisfaction. As Wager (1965) found earlier, in both the companies studied, the greater a supervisor's influence with higher authority, the greater was the supervisor's tendency to be considerate. Presumably, the influential leader could offer support and rewards with more certainty of providing them. The more influential supervisor exhibited more initiation of structure in only one of the firms studied, but, generally, employees were more satisfied with most aspects of their jobs if their supervisors were more influential with higher authority.

*Falling Dominoes Again.* The falling dominoes effect, discussed at length in earlier chapters, was observed by Hunt, Hill, and Reaser (1973) for results with the LBDQ-XII. In a school for the mentally retarded, an increase was found in the association of considerate supervision and the performance of aides when the LBDQ scores of the second-level and first-level supervisors were combined. Hunt, Osborn, and Larson (1975), with data from three mental institutions, showed that leaders' consideration had more of a positive impact on their groups' performance if the leaders' superiors were high in authoritarianism. However, group performance was higher if the leaders' initiation of structure was low, whether the leaders' superiors were authoritarian or egalitarian.

In his first study with the LOQ, Fleishman (1953a) found that the higher the supervisors' positions in the hierarchy of a plant, the less considerate the supervisors thought they should be and the more structure they thought should be initiated. These attitudes had an impact on those below them. Foremen whose superiors expected them to lead with less consideration and with more structuring revealed high grievance rates among their subordinates.

*Size of Group Led.* Ordinarily, one would expect that when a group is enlarged, a leader would have to display more initiation of structure to be as effective as before the unit was enlarged (Bass, 1960). It would be expected that the leader would find it increasingly difficult to maintain the same level of consideration for the concerns of all subordinates as the group enlarged. Corollary results that are consistent with this expectation were found by Badin (1974), who showed that in the smaller of 42 work groups of 489 manufacturing employees, the initiation of structure by the leader correlated negatively with productivity, but that the amount of a supervisor's initiation of Structure was unrelated to productivity in the larger groups.

Osborn and Hunt (1975b), in their previously cited study of presidents of chapters of a business fraternity, found that the size of a chapter moderated the positive effects of initiation and consideration on the members' satisfaction. However, Sheridan and Vredenburg (1979) failed to find any relation between the size of units led and the head nurses' leadership behavior, although size correlated with perceived job tension, which, in turn, was related to the subordinates' performance.

*Structure of the Work Group.* J. A. Miller (1973a) deduced that more initiation of structure would be contraindicated in a highly structured setting. Thus for a supervisor to tell skilled crafts personnel how to do their job was expected to be detrimental to their performance. Consistent with this expectation, Badin (1974) found that when first-line supervisors initiated structure a great deal in the previously mentioned 42 work groups at the manufacturing firm, effectiveness was reduced in the groups that were already most structured. In these highly structured groups, the correlation of group effectiveness and the supervisors' initiation of structure was  $-.56$ . But in the less structured work groups, the effectiveness of the groups was correlated  $.20$  with the extent to which their first-line supervisors initiated structure.

Also consistent with Miller's argument, Jurma (1978) demonstrated, in an experimental comparison, that workers in 20 discussion groups were more satisfied when leaders provided discussants with task-related information, gave guiding suggestions, helped groups to budget their time, and established group goals. This was especially true when the workers were faced with a debatable, ambiguous discussion task rather than one with clear choices for making a decision.

*Dyadic versus Group Relationships.* By the late 1970s, considerable research had concentrated on the dyadic leader-subordinate relationship (Graen & Schie-mann, 1978), instead of on the leader and the primary work group (Hunt, Osborn, & Schriesheim, 1978). Substantive differences in results from standard leader-group investigations have failed often to emerge. Thus, for example, in the case of the LBDQ, for 308 managerial and clerical employees in 43 work groups in a public utility, C. A. Schriesheim (1979a) found correlations of  $.77$  and  $.89$  between dyadic and group LBDQ descriptions of supervisors for initiation and consideration, respectively. Nevertheless, Yammarino (1990) collected LBDQ-Form XII data in 13 groups from 54 members of a campus police department at various hierarchical levels from patrol officers and dispatchers to lieutenants and directors. Each group reported to a single superior. Yammarino found for that for initiation of structure, individual member and group correlations of supervisory control and satisfaction with rewards were due to differences between the groups but not within them. Individual supervisors were the reason. The same was true for the correlations between consideration and role ambiguity and effort. But the correlations of the LBDQ assessments with satisfaction with supervision were a matter of individual differences.

*Cohesion.* Among 308 low-and middle-level managerial and clerical employees, J. F. Schriesheim (1980) used a modification of the LBDQ-XII. She asked subordinates to indicate how their superiors acted toward them as individuals rather than toward the group as a whole. In line with her expectations, she showed that when the cohesion of the work group was low, the leader's initiation of structure was positively related to the subordinates' satisfaction with supervision, role clarity, and self-rated performance. But when cohesiveness was high in the work group, the leader's consideration was positively related to the measures of satisfaction, clarity, and performance.

*Alignment with Objectives.* The contribution of initiation and consideration to productivity will depend on the extent to which the group of subordinates is supportive of the objectives of the productivity. In Howell's (1985) experiment, detailed in [Chapter 21](#), the leader who initiated structure generated more than average actual productivity in the experimental subject if the confederate fellow worker established high norms for productivity. The experimental subject produced much less if the confederate induced low norms for productivity. The leader's consideration had the same effect, but to a lesser extent. Similar results occurred for the effect of initiating structure on satisfaction and freedom from role conflict, but here the effects of

consideration were not moderated by productivity norms set by the confederates of the experimenter.

Hernandez and Kaluzny (1982) studied the leadership and performance of 20 work groups of public health nurses. They found that the supervisors' initiation of structure had a strong positive relationship to productivity but that consideration did not. Likewise, satisfaction was enhanced by the supervisors' and peers' initiation of structure. Instead of the amount of communication flow and group processing correlating positively with the groups' productivity and satisfaction, the reverse occurred. The explanation of these results lay in the lack of support by the nurses for the appropriateness of the services they offered.

*Group Conflicts.* Various kinds of conflict between the group and external agents, as well as within groups, moderate the extent to which consideration and initiation will be effective. R. Katz (1977) found that considerate leadership was most effective when the group faced external conflicts but that initiation of structure by the leader was most effective in dealing with internal interpersonal conflicts.

Stumpf (undated) completed a path analysis for questionnaire data from 144 professionals in a government R & D organization. Leadership behavior was not directly related to the subordinates' job satisfaction or performance, but it was related through two moderating or intervening variables that linked the leader's consideration and initiation to subordinates' job satisfaction and performance. The leader's initiation of structure correlated with the subordinates' skill-role compatibility, which in turn correlated with the subordinates' job satisfaction. Thus the R & D professionals' satisfaction with their jobs depended on the extent to which their skills were not in conflict with the demands of their roles, which in turn depended on the structuring of the situation by their supervisors.

*Curvilinear Effects.* Skinner (1969) obtained results indicating that supervisors who scored high in consideration experienced lower than average grievance and turnover rates among their subordinates. As did Fleishman and Harris (1962), Skinner concluded that the consideration of supervisors bears a curvilinear relationship to turnover and grievances of employees. As consideration increases, grievances decrease to a point and then level off. Supervisory initiation also had a curvilinear relationship to grievances.

*Interaction of Effects.* The interacting effects of consideration and initiation of structure were observed to vary, depending on the situation. Thus considerate foremen could initiate structure without increasing turnover or grievances (Cummins, 1971). Fleishman and Harris (1962) found in using the SBDQ that consideration and initiation of structure by foremen interacted to affect the grievances and turnover of employees. Medium and high degrees of consideration, along with low degrees of initiation of structure by foremen, were associated with the lowest rates of turnover and grievances of employees. Graen, Dansereau, and Minami (1972a) found, among 660 managers of a large corporation, that for those managers who saw their leader as either extremely high or extremely low in initiating structure, the relationship between the leader's consideration behavior and the managers' performance evaluation was positive. But for those managers who saw their leader as intermediate in initiating structure, the relationship between the leader's consideration and the managers' performance was near zero.

But other studies failed to establish any interaction effects of initiation and consideration on outcomes. Filley, House, and Kerr (1976) studied three companies to test Fleishman and Harris's (1962) hypothesis that the leader's initiation of structure acts as a mediator of the relationship between the leader's consideration and employees' job satisfaction. Initiating structure was positively and significantly related to satisfaction with the company in all three organizations. Consideration was significantly related to satisfaction with the company and freedom of action in all three organizations. The data failed to support the mediating hypothesis. Similarly, as will be examined more fully in [Chapter 27](#), M. G. Evans (1970a) tested the path-goal hypothesis in two organizations. He found that consideration and initiation of structure did not interact in path-goal facilitation but, rather, that consideration and initiation of structure each acted separately to enhance path-goal instrumentality. The mixed findings suggest that the occurrence of the interaction effect depends on particular circumstances.

*Contingent Aspects of the Subordinates.* As might have been expected from what has been presented regarding the effects of autocratic leader behavior compounded with authoritarian subordinates, Weed, Mitchell, and Moffitt (1976) found that leaders who initiated structure more with dogmatic subordinates were likely to achieve higher levels of performance; leaders who exhibited more consideration yielded greater performance among less dogmatic subordinates. In the path analysis by Sheridan and Vredenburg (1979), greater job experience of the nursing personnel was found to be related to less considerate leadership from the head nurses, which, in turn, increased the subordinates' tension and had mixed effects on their performance.

M. Beer's (1964) industrial study of the effects of leadership behavior on subordinates' fulfillment of needs disclosed that subordinates whose need for self-actualization, esteem, autonomy, production emphasis, and consideration was high were positively motivated by the leader's initiation of structure, contrary to the hypothesis that the leader's consideration would be more effective in motivating subordinates. Abdel-Halim (1981) collected data from 89 lower-and middle-level manufacturing managers and demonstrated that the subordinates' locus of control moderated the effects of the ambiguity and complexity of tasks on the effectiveness of initiation and consideration.

*Contingent Aspects of the Leaders.* The effects of initiation or consideration appear to depend on whether the leader has a strong need for achievement. Leaders with a high need for achievement who initiated structure obtained a better performance from their subordinates than did leaders with a low need for achievement who also initiated structure (T. Mayes, 1979). Another illustration of a contingent effect that is due to the leader was provided by Miklos (1963), who observed that the longer the tenure of school principals who were high in the initiation of structure, the greater the consensus among teachers in their role expectations for teachers and the greater the agreement between teachers and principals. Agreement between teachers and principals was highest when principals were rated high in both consideration and initiation of structure.

The expert power of the leader also moderated the effects of initiation and consideration. Path analyses by Martin and Hunt (1980) that initiation and consideration, when combined directly or indirectly with expert power, linearly enhanced the group's cohesiveness, job satisfaction, and intentions to remain on the job. Podsakoff, Todor, and Schuler (1983) helped to explain this effect of expert power and leadership. They collected data from 101 employees of a large nonprofit organization who used modified LBDQ scales to describe their supervisors. As the supervisors' initiation of structure increased, if the supervisors were highly expert, the role ambiguity of the subordinates decreased. However, if the leaders who were high in initiation were low in expert power, the reverse occurred—the role ambiguity of the subordinates increased. A similar though less extreme pattern emerged with the increasing consideration of the leaders. Expert considerate leaders generated less role ambiguity in their subordinates, whereas inexperienced considerate leaders generated more role ambiguity.

## Causal effects

---

### *Cross-Lagged Analyses*

The limitations of the results of LBDQ surveys in ascertaining whether the described leadership is a cause, a consequence, or a coincidence of group effectiveness, satisfaction, or other valued outcomes has already been noted. Do considerate and structuring leaders promote the satisfaction and productivity of subordinates, or do leaders of satisfied and productive subordinates show them more consideration and tend to initiate less structure? Cross-lagged analyses suggest that the causality is reciprocal. Leaders affect subsequent outcomes, and outcomes affect the leaders' subsequent behavior (Greene, 1973, 1974, 1975, 1979a).

Greene (1975) asked first-level managers in insurance, marketing, finance, and research and engineering to describe their own consideration and initiation of structure on the LBDQ. Two subordinates of each of the managers rated their own work satisfaction. Peers of these subordinates rated the subordinates' productivity. The measures were picked up on successive occasions one month apart. Cross-lagged comparisons were made of the leaders' behavior at time 1 correlated with the subordinates' satisfaction or productivity at time 2 and contrasted with the subordinates' satisfaction or performance at time 1 correlated with the leaders' behavior at time 2. The results strongly suggested that considerate leadership resulted subsequently in the increased satisfaction of subordinates. At the same time, the subordinates' productivity resulted subsequently in their managers' increased consideration for them. Finally, the subordinates' productivity subsequently resulted in a reduction in the managers' initiation of structure.

### ***Experimental Effects***

Even greater confidence about the cause and effects of initiation and consideration comes from the rare experiment in which the leader's initiation or consideration (or both) is arbitrarily manipulated experimentally and measurements are taken of the subsequent effects on subordinates. Some results were obtained to support the argument that initiation or consideration causes the subsequent improved performance or increased satisfaction of subordinates. Dawson, Messé, and Phillips (1972) arranged for teachers to increase their initiation of structure deliberately. They found that their students' work group productivity improved as a consequence. When the teachers subsequently increased their consideration deliberately, the students' work-group productivity again increased as a consequence. In a laboratory experiment by Gilmore, Beehr, and Richter (1979), 48 participants were subjected to either low or high consideration and low or high structure by specially coached student supervisors who were working with groups of four members each. The LBDQ completed by the members failed to discriminate the behavior of the four types of supervisors, even though the leadership behavior itself had differential effects on the quality of the participants' performance. The quality of the participants' performance was highest with leaders who were high in initiation of structure but low in consideration. But neither the amount of initiation nor the amount of consideration was related to various measures of satisfaction of the participants. Finally, as mentioned before, Howell's (1985) experiment demonstrated that if group norms were supportive of high productivity, the leaders' initiation and consideration resulted in a rise in productivity and satisfaction.

## **Summary and Conclusions**

---

Hundreds of statements about leaders' behavior formed two factors—consideration and initiation of structure—but it was recognized that some important elements in leadership might still be left out. Twelve factors were found to exhaust the list. To initiation and consideration were added representing, reconciling, tolerating uncertainty, persuasiveness, tolerating (followers') freedom, role retention, production emphasis, predictive accuracy, integrating (of organization), and influence with supervisors. Although factorially and conceptually independent, the leader's consideration and initiation of structure factors were ordinarily found to correlate moderately with each other in their revised measurement with LBDQ-Form XII scales.

The two factors are systematically affected by many personal and situational variables. Initiation of structure becomes more important when the group is not already highly structured. Psychometric reviews of results using the original and revised LBDQ and the SBDQ indicate that the generally negative associations between task-oriented initiation of structure, as measured by the SBDQ, and satisfaction and morale become positive when the coercive elements are removed. But leniency is likely to continue to bias the results, along with halo

effects when single sources of variance are used to evaluate both leadership and outcomes. Self-ratings seem unlikely to indicate what leaders do according to their subordinates. Moreover, many contingencies can be cited as moderators of the relationships. A variety of expanded and alternative factor structures are available for a more detailed study of leadership behavior with the LBDQ-XII.

Causal analyses by cross-lagged surveys and experimentation suggest that consideration both increases the satisfaction of subordinates and is increased by it. Initiation of structure by the leader (if structure is low) improves the subordinates' performance, which in turn increases the leader's subsequent consideration and reduces the leader's initiation of structure.

Several components that are variously involved in the different versions of scales that measure the leader's initiation of structure must be taken into account for a full appreciation of their antecedents and their effects on the subordinates' performance. The elements of role and task clarification are likely to have positive effects on satisfaction and productivity; the autocratic elements in the earlier LBDQs may have negative effects, especially on satisfaction. Consideration, likewise, may contribute differently in different situations to satisfaction and effectiveness as a consequence of its several components, including participatory and consultative decision making and concern for the welfare of subordinates. As we shall see next, together initiation and consideration can account for the transactional exchange between the leader and the led, but much more is involved when the leadership is transformational.

## PART V

---

# The “New” Leadership: Charismatic and Transformational Leadership

# Charismatic Leadership

---

In trying to understand the rise of the Prussian bureaucracy early in the twentieth century, the German sociologist Max Weber (1924/1947) introduced the formerly religious concept of *charisma* to the study of leadership and organizations. Coordination in organizations required authority, either rational-legal, traditional, or charismatic. This became of interest in the sociological study of social and political movements as well as in psychoanalytical interpretations of historical leadership. Sociologists such as Parsons (1937) suggested that there is usually some charismatic leadership preceding the development of traditional and legal authority. Early on, psychoanalysts including Sigmund Freud (1922/1939) and Eric Fromm (1941), began explorations of individual charismatic leaders and their impact on followers. But into the 1970s, charismatic leadership still had not become a subject for much survey, experimental, or behavioral research (Stark, 1977).

## Concepts of Charismatic Leadership

---

*Weber's Concept of Charisma.* Weber's concept of charisma was an adaptation of the theological concept, which involves endowment with the gift of divine grace. Weber's (1922/1963) charismatic leader was a mystical, narcissistic, and personally magnetic savior with extraordinary capabilities and a doctrine to promote. Such a leader arose in times of crisis.

Weber (1924/1947) applied the concept of charisma to explain the development and maintenance of complex organizations in which the gift of extraordinariness as a person was now bestowed by colleagues and subordinates instead of by God. According to Weber, charismatic leaders inspired the development of organizations, which subsequently came to be traditionally or bureaucratically managed. Charismatic offices, such as pope, king, or hereditary chief, could arise and then become traditional. Routinization would finally occur and managerial bureaucrats would take charge. The charismatics formulated the basic purposes and principles for bureaucratic administrators to live by.

Trice and Beyer (1986) summed up Weber's conceptualization as having five components: (1) a person with extraordinary gifts, (2) a crisis, (3) a radical solution to the crisis, (4) followers who are attracted to the exceptional person because they believe that they are linked through him to transcendent powers, and (5) validation of the person's gifts and transcendence in repeated experiences of success. According to Beyer (1999), leaving out any of these components was a "taming" of charisma.

*Post-Weberian Charisma.* For some writers, charismatic leadership implied radical innovation (Stark, 1969); for others, it implied pathology (Davies, 1954). Its conversion from an extremely unusual character was "tamed" (Beyer, 1999) by House (1977), Bass (1985) and Conger and Kanungo (1988) and became accessible for leadership research in everyday life. House (1977) theorized that leaders deserved to be called charismatic if they exerted various effects and influences on their followers such as followers' trust in the leader's beliefs, unquestioning obedience and acceptance of the leader, identification with the leader, emotional involvement with the mission, elevated goals, self-efficacy, and collective efficacy. Bass held that charisma was a component of transformational leadership (see [Chapter 22](#)). Conger and Kanungo held that charisma was a set of behaviors and attributions such as being unconventional, visionary, and willing to take risks. DiThomasso (1993) faulted these neo-Weberian conceptions as ignoring the tensions involved in the emergence and development of the

charismatic leader.

Closest to Weber is the continued conception of charisma as an institutional phenomenon. It deals with how social changes are introduced by charismatic leaders and formalized into organizational arrangements, routinization, and the leadership succession (Bryman, 1993). The post-Weberian charismatic leader was conceived by House (1977) in terms of particular behaviors and attributes.

Another conception was psychoanalytical, concerned mainly with the predispositions of dependent followers and charismatic leaders. Charismatics exude confidence, dominance, a sense of purpose, and the ability to articulate the goals and ideas for which followers are already prepared psychologically (Fromm, 1941). The response of followers is likewise extreme. It is both cognitive and emotional as well as devoted and unquestioning. Charismatic leaders have extraordinary influence over their followers, who become imbued with moral inspiration and purpose. The followers experience a magnetic attraction that transcends their usual experience. They become disciples and zealots.

Charisma also may be viewed as a reciprocally interdependent but asymmetric relationship of a powerful leader and dependent followers (Bryman, 1992). Other post-Weberian conceptions include finding charismatic leadership in some everyday situations; at all organizational levels; in the complex interaction between leader, followers, and situation; and in a mission bonding leader and followers (Jermier, 1993).

Although most attention had been paid to charismatic leaders in the religious, political, and societal arenas, such leaders are also studied increasingly in business, educational, and military settings (Handy, 1976). On the basis of his observations of such successful leaders, Lawler (1982) concluded that their leadership occurs "through a combination of factors" that can be captured by words like "vision," "communication," "symbols," and "charisma." Such leaders are more concerned with doing the right thing than with doing things right. Charismatic leaders often emerge in times of crises as prospective saviors who by their magical endowments will fulfill the unmet emotional needs of their completely trusting, overly dependent, and submissive followers. If successful, charismatic leaders can bring about radical transformations in their groups, organizations, or societies.

*Weber's Legacy.* Although contradictions were seen in Weber's conceptualization (Downton, 1973), charisma has continued to figure strongly as an explanatory concept in sociology, political science, and psychoanalysis, and more recently in organizational psychology and management studies. Weber's original concept has been modified, expounded on, and extended in numerous sociological, political science, and psychoanalytic treatises.<sup>1</sup> Charisma plays a major role, conceptually, in the psychoanalytical offshoot of psychohistorical analysis (Demaue, 1982). Weber's lead was also followed by a number of organizational theorists, who found charisma among some officeholders in complex organizations, particularly at higher levels.<sup>2</sup> Such charismatics were likely to be at the center of institutional structures and have the power to radicalize them (Berger, 1963).

The revisers of Weber's concept have seen a need to account for Weber's conception of the charismatic leader's break with continuity, as well as his or her dealing with the aftermath. They have also questioned the relative importance and meaning of charisma to democratic politics (Schiffer, 1973). According to Weber (1924/1947), the charismatic leader is obeyed because of the moral authority with which he is endowed, not because of democratic consent.

Some commentators take a severely restricted view of charisma. Friedrich (1961) would limit charisma to inspirational leadership characterized by the charismatic having a call from God for his or her mission. Trice and Beyer (1986) wanted to see all five Weberian components present before a condition was accepted as charismatic. They rejected labeling any leadership as charismatic merely because it was inspiring or dynamic. Berlew (1979) had identified three characteristics of charismatic leadership: confidence building, shared vision, and creating valued opportunities. But Trice and Beyer argued that these were "rather incomplete and pale in

comparison to Weber's conception of charisma" (p. 122). They also dismissed Solomon's (1977) discussion, which they said was about personalized, autocratic leadership, not charisma. And although George Washington has often been considered charismatic because he embodied the values of his society (Schwartz, 1983), they concluded that he was not charismatic, because he and his situation lacked some of the other Weberian features.

Other extremists, such as Bradley (1984), have argued that intense cohesiveness of the group would result in endowing leaders with charismatic qualities. By contrast, Dow (1969a) emphasized, almost exclusively, the exceptional individual and his ideas rather than the social or political scene. Willner (1984) saw charisma as a consequence of both context and individual personality. Likewise, Erickson (1958) thought that people would seek a charismatic leader when they were faced with cultural shock, fears, anxieties, and identity crises.

### ***Toward a Pragmatic Concept of Charisma***

As with definitions of leadership, absolutists have insisted that their definition of charisma is the only proper one. In fact, however, definitions should be formulated for their operational and explanatory utility (Bass, 1960). Nor does the meaning of charisma have to remain fixed with Weber and his interpreters. Some of the variance in the phenomenon of charisma is due to the exceptional individual, some to the exceptional situation, and some to the interaction of the exceptional individual and the exceptional situation.

There have been and continue to be a considerable number of exceptional people. For example, it is likely that there were many other charismatic reformist preachers who were contemporaries of the more famous ones from Martin Luther to Martin Luther King Jr. Although these others were less publicized, each had dedicated followers, radical solutions, a mission, and self-confidence. In all walks of life and at all organizational levels, we are likely to encounter charisma and charismatic interactions between confident, gifted leaders with seemingly radical solutions to critical problems and followers who are unquestioningly and magnetically attracted to these leaders (Smith, 1982). Such leadership is not merely inspiring or dynamic; it involves unusual reactions by the followers. For purists, we may need to talk about the charismalike behavior of leaders or the charismalike devotion of followers. For the purposes in this chapter, the Weberian requirements and those of some revisionists will be regarded as sufficient, but not all are necessarily essential in each instance. In the hi-tech industry, strong substantive arguments may be characteristic of charismatic leaders and their immediate technical subordinates, who never accept these leaders unquestioningly. Continued unquestioning acceptance of the leader is not an absolutely essential consequence of charismatic leadership. As Tucker (1970, p. 4) noted:

Followers can be under the spell of a leader and can accept him as supremely authoritative without necessarily agreeing with him on all occasions or refraining from argument with him. In the highly argumentative atmosphere of a modern radical party, for example, a leader can be both charismatic and contested on specific points, as Lenin often was by his close followers. Indeed, he can even manifest some of his charisma in the inspired way in which he conquers dissent by the sheer power of his political discourse. Immense persuasiveness in argument may, in other words, be one of the extraordinary qualities by virtue of which a leader acquires charisma in his followers' eyes.

The charismatic relationship can appear in the absence of a crisis. For instance, dynamic leaders of financial investing have devoted, unquestioning followers. The leaders provide these followers with an exhilarating mission—to grasp an opportunity for improving the followers' portfolios (even though the followers are often already wealthy). The followers show every indication of wanting to identify with the leaders and their ideas. Does the fact that there is no crisis mean that these leaders must be something other than charismatic? Boal and Bryson (1987, 1988) agree that visionary charismatics need no crisis.

What do we call charismatic leaders who have all the Weberian attributes except success? Early in their careers, Mao Zedong and Yasir Arafat suffered one defeat after another. Perhaps it was their successful escapes that were emphasized. What about the charismatic leader who is incompetent? Schiffer (1973) suggests it is easier for many followers to identify with a charismatic leader who lacks talent, just as they do.

As the concept of charisma spread from sociology and political science to psychoanalysis and psychology, increasing attention was paid to the followers' need to identify with the leader and to the endurance of the charismatic leader, rather than to the routinization of the organization that was to follow, according to Weber. It also has been observed that the charismatic leader inspires opposition and hatred in those who strongly favor the old order (Tucker, 1970). This view argues strongly for dyadic, rather than group, analyses of charismatic leader-follower relationships. One can see the subordinates of a single charismatic supervisor divided in the extent to which they love, fear, or hate him or her. The very behaviors and qualities that transport supporters of the charismatic into extremes of love, veneration, and admiration may send opponents into extremes of hatred, animosity, and detestation (Bass, 1985a). President George W. Bush generated such contrasting reactions between his socially conservative political supporters and his liberal opponents.

Charismatic leaders vary greatly in pragmatism, flexibility, and opportunism, and adopt different styles to achieve their impact. Charles de Gaulle, for instance, was always more concerned about being right than achieving immediate results and spoke of his "contempt for contingencies." Generally, his attitude was unbending (Hoffman & Hoffman, 1970). He became pragmatic only when forced to do so in order to resolve the Algerian crisis. Other inflexible charismatics of our time have included Muammar al-Qaddafi of Libya and the Ayatollah Khomeini of Iran. In contrast, John F. Kennedy and Franklin Delano Roosevelt avoided speaking out, to sidestep political battles that they thought they might lose. Lenin also was a practical activist and a pragmatic organizer ready to reverse course when necessary (Tucker, 1970).

Another reason to look at the charismatic leader as exemplifying some but not all of the Weberian characteristics is that the move toward routinization of leader-follower relations may have been initiated by charismatic leaders rather than by their successors. Marshal Tito of Yugoslavia is a case in point, as are Augustus, Joseph Stalin, and Jawaharlal Nehru, who, respectively, continued the routinization begun by the charismatic Julius Caesar, Lenin, and Mahatma Gandhi, and who had many, if not all, the charismatic qualities of their predecessors. Were not the successors as charismatic as the founders, even though cumbersome bureaucracies emerged under them?

## ***Types of Charismatics***

*Personalized versus Socialized Charismatic Leaders.* Howell (1988) distinguished between ideal types of *personalized* and *socialized* charismatic leaders. Charismatics can foster antisocial or prosocial behavior. Personalized charismatic leaders are dominant, self-interested, and authoritarian. Freud similarly (1922) distinguished between *totemic* leaders, who could be worshipped as idols to satisfy the fantasies of their followers; and *true* charismatics, who directed their followers toward more worthy transcendental purposes. Personalized charismatic leaders use their powers of persuasion to obtain their followers' obedience and submission (McClelland, 1975). Such leaders are self-aggrandizing and maintain psychological distance from their followers; this distance increases their magical, supernatural, charismatic image. In contrast, socialized charismatic leaders are oriented toward serving others. They develop shared goals with their followers and inspire the attainment of these goals. Psychological distance between socialized leaders and followers is reduced, enhancing the followers' expectation of an equalization of power and mutual stimulation.

Socialized charismatic leaders are socially constructive, are egalitarian, and serve collective interests. They perpetuate their influence by the continued relevance of their ideas and their mission to the followers' intrinsic

satisfaction. That is, followers accept the influence of socialized leaders' ideas because these ideas are intrinsically rewarding (Howell, 1988). Socialized leaders are similar to Lipman-Blumen's (1996) "third stage" connective leaders, who use the right gestures and perfect symbols and rituals to underscore their messages. Like a magnet, their dramatics attract followers to their cause. "Untainted by a self-serving addiction to power, their leadership is dedicated to the well-being of the group" (p. 230). To some degree, socialized charismatic leadership—with its emphasis on the mutuality of goals and contribution to the greater good, rather than on the followers' unquestioned identification with the leader—fits with what will be discussed later in this chapter as inspirational leadership. Their Leadership Motive Patterns (LMP) of high power need coupled with *high* activity inhibition is directed toward using social influence in socially desirable ways and for collective benefit rather than for self-aggrandizement (House & Howell, 1992).

Followers accept the influence of *personalized* charismatic leaders in order to identify with them. Following is intrinsically rewarding (Kelman, 1958). Howell deduced that to continue to remain influential, personalized charismatic leaders must maintain a physical or psychological presence and a satisfying relationship with their followers. On the basis of extensive research by McClelland (1985) on the LMP, House and Howell (1992) inferred that personalized leaders were likely to have a high *need for power* combined with *low activity inhibition*. Such leaders responded to the Thematic Apperception Test (TAT) by telling stories that concentrated on dominating and winning at someone else's expense. House and Howell also expected personalized charismatic leaders to score high in Machiavellianism (Christie & Geis 1970), narcissism (Raskin & Hall, 1979), and authoritarianism (Altemeyer, 1981).

*The "Office Charismatic" and the Personal Charismatic.* Etzioni (1961) and Hollander (1978) noted that charismalike leadership could be a property of one's position as well as one's person. An American president has luster, some of which he loses after he leaves office. "Office charismatics" attain high status by virtue of the strong public image they have as holders of a valued role. Personal charismatics like Betty Friedan or Simone de Beauvoir, prominent figures in the women's movement, gained high esteem through their writings and speeches. Their followers had faith in them as persons. Furthermore, personal charismatics may be in high-or low-status positions. A personal charismatic can occupy the highly valued office of president, but a charismatic like Saint Francis or a Hindu *sadhu* can attract people because of their sacrificial renunciation of all worldly power and possessions.

Etzioni (1961) suggested that although charismatic office frequently has to be achieved, "office charisma" is ascribed. Regardless of their ability or performance, incumbents obtain it with the office. Charisma can attach to any high social status, achieved or inherited, as is seen in the public reactions to a visit, marriage, or divorce of the Prince of Wales. The charisma as well as celebrity status goes with the role.

*Celebrities.* One cannot ignore the vicarious effects on a mass audience of the superstar who can be only an image and a name to identify with. For example, enlistment rates can go up substantially after a popular star appears in a war movie. Psychological projection and identification play important roles in the process of charismatic influence at a distance. As Schiffer (1983, p. 9) noted:

To most people ... political figures ... are just like box-office attractions in the field of entertainment despite the fact that many politicians are often bearers of ideals and ideologies. ... We embrace the images ... [of] popular actors, actresses, and musicians who, above and beyond their talents, have been given charismatic status despite—or perhaps because of certain flaws in their character or theatrical skills.

Weber believed that the personal charismatic creates a charismatic office to be filled by an uncharismatic successor. However, Etzioni (1961) pointed out that personal charisma may be revealed more forcefully when the holder of the office is an incumbent who follows un-charismatic predecessors in the same office—as was the case with Franklin Delano Roosevelt, who followed Warren Harding, Calvin Coolidge, and Herbert Hoover. Also, nothing seems to preclude one charismatic succeeding another.

Publicly celebrated charismatics may have little charisma in their private lives. As Etzioni (1961, p. 316) put it, “Top executives, heads of state, and kings, who have charisma in the eyes of the public ... may have little or [none] in the eyes of [their] private secretaries, valets, and cabinet ministers.”

*Close and Distant Charismatic Leaders.* Shamir (1995) called attention to the fact that some charismatic relationships were close, directly connected, usually face-to-face: supervisor and subordinate, teacher and student, physician and patient. Other relationships involved, for example, CEOs, presidents, prime ministers, mass movement leaders, generals, and church leaders, who were socially distant from their followers. Followers connected only indirectly to distant leaders, through the media or through layers of intermediaries. The followers could observe and interact personally only with the close leaders. The closest they could come to the distant leader was on television or at a public meeting. Katz and Kahn (1978) suggested that for the leader to be viewed as charismatic, some distance was required between the leader and the led. Shamir disagreed: he found that close as well as distant leaders could be identified as charismatic by 320 Israeli students. Although both types of charismatic leaders were described by these students as self-confident, dominant, willing to sacrifice, and willing to set personal examples, the traits and behaviors attributed to the leaders were somewhat different. For instance, the close charismatics were identified as sociable, open, and considerate; the distant charismatics had rhetorical skills. Also, different effects were attributed to close and distant charismatic leaders. Task-related motivation was more frequently attributed to the close leader; substantive achievements were more frequently attributed to the distant leader. A follow-up by Yagil (1998) with 554 Israeli combat soldiers found that although they described close charismatic platoon commanders and distant charismatic battalion commanders as having extraordinary traits, only the close platoon commanders were seen as having confidence in individual and exemplary behavior.

*Individualized and Group-Assessed Charisma.* To the extent that charismatic leadership is an attribution based on questionnaire ratings, the individual followers’ ratings can be averaged regardless of whether they report to the same or different leaders; or we can average the results for each group of ratings for each leader. Avolio and Yammarino (1990) collected data from the Multifactor Leadership Questionnaire (MLQ): the charismatic leadership behavior scores of 111 line and staff managers based on ratings by their 375 subordinates. Within-and-between groups analysis (WABA) suggested that for practical purposes individual differences among subordinates, regardless of their group, gave a more valid assessment of the leaders than did the group averages. Charisma was in the eye of the individual beholder, not in the eyes of a group of beholders. However, Klein and House (1995) argued that a full explanation of the emergence of charisma required looking at the interaction of the individual leader, each group of followers, and the situation.

*Absolute, Normative, Executive, and Policy Charismatics.* Zablock (1980) was able to order four kinds of charismatic leadership in communes according to the completeness of the issues covered by the leadership.<sup>3</sup> *Absolute* charismatic leadership was commonly found in selected religious communes. These communes concentrated authority about meanings, goals, strategies, norms, and alternatives. *Normative* charismatic leadership occurred in other religious communes that were similar except that authority about alternatives was missing. *Executive* charismatic leadership was found in some psychological, counterculture, and political communes in which one or several leaders concentrated authority about meanings, goals, and strategies, but not about norms or alternatives. *Policy* charismatic leadership was particularly salient in counterculture and political communes in which authority was concentrated only about meanings or only meanings and goals.

### ***Alternative Concepts Similar to Charismatic Leadership***

*Inspirational Leadership.* Charismatic leadership? Inspirational leadership? What’s the difference?

According to Downton (1973), the difference is in the way followers accept and comply with the leader's initiatives. If there are no dynamics for the followers' identification with the leader, and if the followers are drawn to the leader's goals and purposes but not to the leader per se, then the leader is inspirational but not charismatic. Followers believe that they share a social philosophy with the inspirational leader. If the followers feel that they are more powerful as a consequence of the leader's exhortations because the leader has pointed out desirable goals and how to achieve them—not because the powerful leader is their model—then the leader is inspirational, not necessarily charismatic (McClelland, 1975). Followers impute God-given powers to charismatic leaders and are incapable of criticizing such leaders. But although followers may regard inspirational leaders as symbols of beliefs and shared problems, they can also roundly criticize them more than those whom they regard as charismatic leaders (Downtown, 1973).

*Heroic Leadership.* Burns (1978) preferred to speak about *heroic* leadership, believing that the term “charisma” had been overworked. The highly esteemed individual is a hero. There is

a belief in [heroic] leaders because of their personage alone, aside from their tested capacities, experience, or stand on issues; faith in the leaders' capacity to overcome obstacles and crises; readiness to grant to leaders the powers to handle crises; mass support for such leaders expressed directly—through votes, applause, letters, shaking hands—rather than through intermediaries or institutions. Heroic leadership is not simply a quality or entity possessed by someone; it is a type of relationship between leader and led. A crucial aspect of this relationship is the absence of conflict. (p. 244)

The heroic, transcending leader excites and transforms previously dormant followers into active ones. For example, leaders of an exodus heighten the followers' motivation, purposes, and missionary zeal. Followers become proselytizers, who, in turn, act as leaders as a consequence of their exalted awareness.

*Visionary Leadership.* Envisioning an attractive future is often seen as a component of charisma but it is not limited to charismatics. Sashkin (1988) suggested that visionary leadership does require dealing with change, ideal goals, and working together. (This will be elaborated in [Chapter 22](#).)

*Value-Based Leadership and Idealized Influence.* House (1997a) introduced this concept to replace charismatic leadership as a relationship between a leader and followers based on internalized ideological values espoused by the leader. Bass and Avolio (1994) substituted the term “idealized influence,” with the same meaning as charismatic leadership. In both cases, the authors wanted to abandon the term “charisma” because of its popular connotations of celebrity and popularity and its widespread usage. As Bensman and Givant (1975) noted, charisma is the name of a perfume, a shirt brand, a pop tune, and a laundry, an attribute of any popular politician.

*Outstanding Leadership.* Outstanding leaders achieve outstanding results, compared with ordinary leaders. Their behaviors are a compilation of all those associated with charismatic, visionary, heroic, transformational, and inspirational leadership, all of which tend to be highly correlated (House & Podsakoff, 1994).

*Maximum Leadership.* Zaleznick and Kets de Vries (1975) conceived of *maximum* leaders who were charismatic, creative institution builders as a consequence of their personalities and early childhood development. They were highly self-confident. They led with strength and vision. In contrast, *minimum* managers were more concerned about the opinions of their peers and followers, and followed such opinions instead of leading.

*Transformational Leadership.* Leaders motivate their followers by raising their followers' concerns from security and belonging to achievement and self-actualization, and by moving them beyond self-interest to concerns for their group, organization, or society (Burns, 1978). Components are charisma or idealized influence, inspirational leadership, intellectual stimulation, and individualized consideration (Bass, 1985a). [Chapter 22](#) is about transformational leadership.

*Charismatic/Transformational Leadership.* House (1995), Hunt (1999), and others believe that

charismatic and transformational leadership are one and the same and prefer to use the term “charismatic/transformational leadership.” So do Behling and McFillan (1996), who created a synthesis of the two concepts in which the leader’s words and actions both demonstrate empathy, empower followers, project self-assurance, dramatize the mission, and affirm collective efficacy.

## The Charismatic Relationship Theories

---

Post-Weberian explanations of the charismatic relationship abound. There is reciprocity, in that the leader’s vision tends to be congruent with the followers’ values and identities, and the followers tend to support a leader who shares their beliefs (Yukl, 1998). Explanations differ in their emphases on motivation, antecedents, and the mechanisms they postulate. They also differ in their dependence on attributions, self-concepts, symbolism, and psychoanalysis (Shamir, 1991).

Historical essays, surveys and several experiments have examined the charismatic relationship, as have psychoanalytical accounts (Zaleznik, 1990). Behavioral models and theories also emerged to explain charismatic leadership (House, 1977). For example, Behling and McFillan (1996) proposed operationalizing a *syncretic* model combining the effects of the leader’s empathy, mission, and assurance and the followers’ awe, inspiration, and empowerment.

*Behavioral Theories and Findings.* As noted above, House (1977) launched a theory to account for what the charismatic leader did to motivate the observable behaviors of followers. It was an effort to take some of the mystery out of charismatic effects. The theory was subsequently revised by House, Shamir, and Smith (1992) and Shamir, House, and Arthur (1993) to better fit findings. The charismatic leader connects the followers’ self-concepts to the collective mission and makes it valued as an aspect of the followers’ self-concepts. The leader engages the followers’ motivation for self-expression, self-esteem, self-worth, and self-consistency. The charismatic leader changes followers’ perceptions of what the group needs to do, proposes an appealing vision of the future, strengthens collective identity and frame alignment, and increases individual and collective efficacy. The specific messages of the charismatic leader, compared with those of the noncharismatic leader, make more references to values, moral justifications, history, distal rather than proximal goals, more positive references about the followers’ worth, and more expressions of high expectations for self and followers. Jacobsen and House (2001) matched 16 sets of data about six “clearly charismatic” leaders to verify a six-stage model of the charismatic relationship: (1) identification with the leader, (2) arousal of follower activity, (3) commitment, (4) disenchantment, (5) depersonalization, and (6) alienation. The model accounted for 76.7% of the variance in the data.

Shamir, Zakay, Breinein, et al. (1998) obtained generally supportive findings in data collected in 50 Israeli army companies. The charismatic leader’s ideology, emphasis on collective identity, and display of exemplary behavior resulted in the followers’ trust and identification with the leader. Also enhanced were the followers’ identification, intrinsic motivation, efficacy with the task, willingness to sacrifice in performing the task, and attachment to their group.

Conger and Kanungo (1988) listed behaviors of the charismatic leader as: radical, unconventional, risk taking, visionary, entrepreneurial, and exemplary. Of the elements associated with the charismatic relationship, two appeared essential. The first was the pattern of abilities, interests, and personal traits that is common to most char-

ismatic leaders. The second was the strong desire by followers to identify with the leader. Charismatic leaders have strong referent power. Often, but not always, leaders present concise and radical solutions to crises. The followers’ belief in the solutions comes as a consequence of their faith in the charismatic leader. If the effect of the emotion-driven charismatic relationship is to endure, it must therefore give way to a more rationally driven

routinization. Conger and Kanungo (1998) theorized that the charismatic relationship develops in three stages. First, the leader critically evaluates the followers' inclinations and the existing situation. Second, when the time is right, the leader formulates and articulates a vision (an idealized goal) that makes her or him worthy of identification. Third, the leader demonstrates how the goal can be achieved by setting a personal example, taking risks, and applying unconventional expertise. The leader who impresses followers with total dedication, commitment, exemplary acts, and personal investment earns the attribution of charismatic leader.

## Characteristics of Charismatic Leaders

### *Requisite Abilities*

Although followers endow a leader with charisma to fulfill their situational needs, they do not endow just anybody. The person who is so endowed must have abilities that are relevant to the situation. Thus according to historians, charismatic presidents, compared with noncharismatic presidents, were more highly esteemed by their contemporaries and were able to accomplish more during their administrations (Maranell, 1970). Pitman (1993) found that 245 white-collar workers' ratings of their supervisors in charismatic leadership on the Multifactor Leadership Questionnaire (MLQ)<sup>4</sup> correlated .36 with their supervisors' rational and technical competence. The correlation was .27 with verbal dominance. The equivalent correlation between the Conger-Kanungo overall scale of charismatic leadership and these abilities were .37 and .32.

At Federal Express, the superiors of 54 managers rated the managers significantly higher in judgment, quality of decision making, financial management, communication, persuasion, and risk taking if the managers were described by their 306 subordinates as more charismatic. No such significant correlations were found when the managers were described by their subordinates as practicing transactional contingent reward (Hater & Bass, 1988). Similar results were reported by Yammarino and Bass (1988) in a representative sample of junior officers in the surface navy.

Table 21.1 Correlations between Ratings of Transformational and Transactional Leadership Factors and of Specific Performance as a Manager, According to Superiors for 54 Managers Rated on the Multifactor Leadership Questionnaire by 306 Subordinates<sup>a</sup>

Subordinates' Description	Superior's Appraisal				
	Judgment and Decision Making	Financial Management	Communication	Persuasion	Risk Taking
Charismatic Leadership	.33**	.36**	.32*	.33*	.45**
Intellectual Stimulation	.23	.35**	.29*	.24	.18
Contingent Reward	-.08	-.07	.18	.08	.01

\* $p < .05$ .

\*\* $p < .01$ .

<sup>a</sup>These data are from a sample of high performers and from a random sample drawn from a larger population. Differences between the samples have been removed by a partial correlation analysis.

### *Personal Traits*

Several empirical studies of charismatic and noncharismatic leaders revealed patterns of systematic differences consistent with the profile of the charismatic that has emerged from historical and sociological analyses. Hall (1983) conducted a study of 10 leaders in the Atlanta area who were nominated for their charisma; in particular, these leaders described themselves as less accepting of authority than did 99% of a normative

population. Labak (1973) asked 9,609 students to rate the charisma of the faculty at the University of Northern Colorado on a standardized questionnaire; 26 teachers, identified as charismatic, were matched with noncharismatic teachers. On standardized self-report inventories, the charismatic teachers described themselves as more enthusiastic, self-actualized, and tolerant of ambiguity, and less defensive. Wilson (1975) reported that charismatic heroes were high in self-esteem, self-possession, generosity, openness, honesty, and concern for others. Conger and Kanungo (1988, 1994) suggested that above and beyond their task orientation and relations orientation, leaders described as charismatic were also rated as highly sensitive to the needs of followers, strongly articulate, willing to take personal risks, agents of radical change, and idealistic in their vision of the future. Levit (1992) noted that charismatic leaders had a strong purpose in life. Sosik and Dworakivsky (1998) found that manager's self-monitoring correlated with the charisma attributed to them by their subordinates, but only when they had a strong purpose in life. Crant and Bateman (2000) showed that among 156 managers, self-rated *proactive personality* added to the prediction of their charismatic leadership as rated by their immediate supervisors. This was above and beyond that accounted for by the five NEOAC personality factors. In a Dutch study, De Hoogh, Den Hartog, Koopman, et al. (2005) coded interviews with 73 CEOs and found that the *power motive* correlated positively with 125 subordinates' ratings of the CEOs' charismatic leadership. Charismatic leadership also contributed to the subordinates' positive attitudes toward their work.

Charismatic leaders are likely to display high levels of emotional expressiveness, self-confidence, self-determination, freedom from internal conflict, and are likely to have a strong conviction of the moral righteousness of their beliefs (House, 1977). Biographies, case studies, anecdotal material, and quantitative research provide evidence of these characteristics. One example is Anita Roddick, founder and head of The Body Shop International, who was a champion of human rights, animal rights, and recycling of refuse. The Body Shop comprises more than 2,100 stores in 55 countries selling cosmetics. The chain actively champions environmental quality; human, civil, and animal rights; AIDS awareness; and other causes. Much of the success of The Body Shop has been attributed to Roddick. An article about her in the popular press said that she exuded "intelligence, energy, humor, spontaneity, impatience, and [passion] ... [She was] uncompromising when it [came] to her core values" (Gaines, 1993, p. 348). Roddick was seen as exceptional by her followers, had a mission that attracted followers, and inspired commitment in them (Bryman, 1993).

Charismatics can be on the bright side of charismatic leadership without being personally lovable. At the Diet before the Holy Roman Emperor, Martin Luther, charged with heretical writings and rejection of the authority of popes and church councils, recanted nothing, concluding with, "Here I stand, I can do no other." Then he walked out alone unsure about how much protection he might receive from the German electors. In addition to possessing determination, he was willful, intolerant, contemptuous of art and learning, and driven by his own vision of a pure Christianity (Manchester, 1992).

*Expressive Behavior.* Friedman, Prince, Riggio, and DiMatteo (1980) suggested that charismatic leadership manifests itself in nonverbal emotional expressiveness. Expressive people can use verbal and nonverbal cues "to move, inspire, or captivate others" (p. 133). Such expressiveness can be assessed with the self-reporting Affective Communication Test. Items on the validated test include: "I often touch friends during conversations," "I can easily express emotion over the telephone," "I [don't] usually have a neutral facial expression," and "I am [good] at pantomime in games like charades." Expressiveness is related to dramatic flair and experience in acting and in politics. Females score higher in emotional expressiveness, just as they tend to be seen as more charismatic than comparable males (Avolio & Bass, 1989). Emotional expressiveness correlates .60 with the need for exhibition and .45 with the need for dominance—personality attributes of the charismatic leader.

Table 21.2 Correlations of Subordinates' Ratings of Leadership Behavior and Superiors' Ratings of

Subordinates' Ratings of Officers' Leadership Behavior	Superiors' Ratings of Performance	
	Cumulative Fitness-Report Evaluations	Cumulative Recommendation for Early Promotion

\*\* $p \leq .01$ .

<sup>a</sup> $N = 186$ ;  $r \geq .14$ .

SOURCE: Adapted from Yammarino and Bass (1988).

Bensman and Givant (1975) and Willner (1968) describe charismatic leaders as projecting a powerful, confident, dynamic presence. The leaders' tone of voice is engaging and captivating, and their facial expressions are animated, yet they remain relaxed (Friedman & Riggio, 1981). Not only do they maintain direct eye contact, but their eyes have a magnetic attraction (Wilner, 1968). Riggio (2002) showed that extroverted and charismatic females were facially expressive; as a result, they were evaluated more favorably than their nonexpressive counterparts. Spontaneously expressive females received more positive evaluations from judges, but similarly expressive males did not; the judges viewed the *emotional control* of males in a more favorable light. Expressive cues included fluid, outward-directed cues, such as rate and fluency of speech, outward-directed gestural fluency, and smiles; and of body emphasis, contact with the body, and inward directed gestures. Appealing rhetoric is characteristic of charismatics.

*Self-Confidence.* Charismatic leaders display complete confidence in the correctness of their positions and in their capabilities (Hoffman & Hoffman, 1970), and they make this confidence a clear aspect of their public image. Even when personally discouraged and facing failure, they are unlikely to make such feelings public (Tucker, 1968). Such elevated self-esteem helps charismatics to avoid defensiveness in conflicting interpersonal situations and to maintain the confidence that their subordinates have in them (Hill, 1976). Charismatics tend to project onto like-minded loyal followers their continuing confident opinion of themselves (Bass, 1985a). They are great actors—always onstage, projecting to their followers their extreme self-confidence and convictions, so they become larger than life. They must be able to present themselves as miracle workers who are likely to succeed when others would fail (House, 1977).

*Self-Determination.* Weber (1924/1947) considered charisma as first a personal attribute of some leaders whose purposes, powers, and extraordinary determination set them apart from ordinary people. Friedrich Nietzsche's (1883/1974) superman had some of the same characteristics: inner direction, originality, self-determination, sense of duty, and responsibility for the unique self. Nietzsche said that ordinary men conformed to the expectations of others, but the superman could free himself from the expected. He was a point of contact with the future, and created new values and goals. He was also a highly self-oriented narcissist. Weber's charismatic could also be a mystical ascetic, concerned with himself rather than involved with others, and interested in promoting ideas for their own sake rather than for material gain. According to Weber, the determined charismatic leader would set aside normal political life.

But self-determination can also imply obstinacy. Instead of being open to new ideas, some charismatic leaders may become closed-minded, dogmatic, and rigid. They may announce that they have provided the only true way to enlightenment. They think that their continued development is unnecessary, and regard differences

of opinion as heretical (Stark, 1969).

*Insight.* The charismatic leader can arouse, as well as articulate, feelings of need among followers and find radical solutions to their problems. Gorbachev's glasnost (openness) and perestroika (restructuring) were radical solutions aimed at removing the problems of secrecy, censorship, and rigidity in the Soviet Union's planned economy. Charismatics have insight into the needs, values, and hopes of followers (McClelland, 1975) and the ability to build on them through dramatic and persuasive words and actions. According to Gardner (1961), they are able to "conceive and articulate goals that lift people out of their petty preoccupations." Such leaders can unite people to seek objectives that are "worthy of their best efforts." According to Yukl (1981), charismatics can say things publicly that followers feel privately but cannot express. Charismatic leaders move the change process by first breaking frames (interpretive schemes) through negation; next, by including in the frames' referents like "we" instead of "I"; and finally, endorsing and affirming the changes (Fiol, Harris, & House, 1999).

*Freedom from Internal Conflict.* Charismatic leaders maintain their confidence and determination, despite serious setbacks and defeats, through a self-assurance that is "at one with their inner images" (Kets de Vries, 1984, p. 117). The confidence and determination of charismatic leaders stem from their greater freedom from the internal conflict that ordinary mortals are more likely to experience between their emotions, impressions, and feelings (Freud's id) and their controlling conscience (superego). Freedom from the id-superego conflict makes for strong ego ideals and assuredness about what the leader values as good, right, and important. Convinced of the goodness, rightness, and importance of their own point of view, charismatic leaders are likely to be more forthright and candid in reprimanding subordinates and can maintain a clear conscience if they feel they must replace a subordinate (Keichel, 1983). (Ronald Reagan was an exception in this respect. Like Richard Nixon, he avoided such confrontations.) By contrast, ordinary managers are victimized by self-doubt and personal trauma in such circumstances, regardless of the extent or success of their careers (Levinson, Darrow, Klein, et al., 1978).

*Eloquence and Rhetoric.* Martin Luther King Jr.'s powerful oratory made him larger than life and an even more charismatic leader of the black movement than he really was. Carson (1987) noted that the "great man" mythology exaggerated King's importance to the civil rights movement and distorted his considerable contributions to the effort. His moral and intellectual oratory was an inspiration for many activists, but King did not receive unquestioning obedience from them. He was seen by them as outstanding among many prominent ideologues, strategists, and institutional leaders. His strategy of nonviolence was never fully accepted by the masses in the movement and was at odds with their beliefs. Many of the most important initiatives in the movement, such as the Montgomery bus boycott and the student sitins, were started and guided by local leaders. Many ideas first surfaced among the grassroots followers. King was a great conciliator among the activists, and he mobilized supporters through continuous involvement in the network of black churches and other black institutions. He certainly was a charismatic leader, although he was not the superhuman he became in retrospect.

Because we are now in an era of speechwriters, we can no longer readily attribute the emotional flair for expressive language to the leaders who use it. But the highly charismatic Mario Cuomo did write his own colorful, incisive, inspiring speeches, such as the famous one he gave at the 1984 Democratic convention. Cuomo could respond extemporaneously to telephone questions in the same dynamic way. This facile use of language helped him win a record landslide vote in 1986, when he was reelected as governor of New York.

The *content* of charismatic messages is simple, focuses on the collective identity of the speaker and the audience, and evokes a response from the audience (Bord, 1975). In addition, charismatic speeches allude to the individual worth of the followers, their collective efficacy, their collective history, the continuity of the past, present, and distant future, and the similarities of the followers and the leader. The speeches provide moral justifications, long-term goals, and the importance of faith and hope (Shamir, Arthur, & House, 1994).

The *delivery* of political charismatic leaders (Willner, 1984) and organizational charismatic leaders (Conger, 1989) make heavy use of metaphors, rhythm, and alliteration. The language they use is modified to fit the nature of their audience. Charismatic leaders attract and sustain audiences with arousing, novel rhetoric, and remote associations in unusual combinations. They use high-action verbs, short pauses between phrases and sentences, and reiteration in their speeches. Compared with noncharismatics, they favor words and ideas that are image-based rather than abstract. For example, they use words such as “root” instead of “source,” “rock” instead of “dependable” and “path” instead of “alternative” (Emrich, Brower, Feldman, et al, 2001). Often, nonverbal gestures and cues reinforce the emotional appeals (Den Hartog & Verburg, 1997). Awamleh and Gardner (1999) presented to 304 undergraduates a videotape of one of six supposed speeches by a CEO of a software company: visionary or nonvisionary, with good or poor organizational performance, and with strong or weak delivery. The students attributed charismatic leadership to the CEO mostly as a consequence of strong rather than weak delivery, and much less as a consequence of the speech’s vision or lack of vision, or of good rather than poor organizational performance. Likewise, two experiments by Holladay and Coombs (1993, 1994) showed that strong delivery of a speech was more important than the content in managing the impression of a leader as charismatic. Greater vocal fluency, natural body gestures, and extensive eye contact made for a stronger delivery and the attribution of charisma. Although content was less significant than delivery, visionary speech did produce more attributions of a charismatic leader than nonvisionary speech.

Howell, Neufeld, and Avolio (undated) found in a survey of 343 employees that among 125 managers, those who scored high in charismatic leadership on the MLQ were more likely to use communication styles (Klaus & Bass, 1982) that were open two-way, carefully transmitted, and frank. While openness and care contributed to business unit performance, frankness was contraindicated. This was mainly true for managers at a physical distance from, rather than close to, their listeners.

*Activity and Energy Levels.* Leaders tend to be more active than followers, and charismatic leaders are even more so. Grant and Bateman (2000) showed that for 156 managers, those who scored themselves as more *proactive* were also rated by their supervisors as more charismatic. The relationship was greater than could be accounted for by the “Big Five” personality variables, social desirability, or in-role performance. According to a three-year survey by the Group for the Advancement of Psychiatry (1974), the charismatic qualities needed by candidates for 100 vacant medical school psychiatry chairs were a high energy level, optimism, fatherliness, and a capacity to inspire loyalty. Previously collected opinions of political historians demonstrated that charismatic presidents were more active and took significantly stronger actions than did noncharismatic presidents (Maranell, 1970).

*Self-Sacrificial Disposition.* Sacrifices may involve voluntary giving up of power, privileges, or personal resources; or going into harm’s way for the benefit of other individuals or the group, organization, or society. House and Shamir (1993) expected that charismatic leaders might make sacrifices to build trust and show loyalty. Javidan (1992) suggested that charismatic leaders might make sacrifices to encourage followers to do the same to reduce followers’ fears of an uncertain future, and to gain followers’ acceptance of the leader’s vision. Yorges, Weiss, and Strickland (1999) demonstrated that if leaders were willing to endure hardships for the expression of their beliefs, they would be more likely to be perceived as charismatic and more influential than if they personally benefited from their actions. In two experiments with 157 industrial participants and 457 students, Choi and Mai-Dalton (1998) found that followers were more likely to attribute charisma to a self-sacrificial leader described in different scenarios, especially if the leader was described as competent rather than incompetent. Unexpectedly, the outcomes were unaffected by whether or not the organization’s future was uncertain.

## ***Envisioning and Charismatic Leadership***

The vision charismatic leaders articulate contains an idealized perspective shared with their followers. It calls for radical change yet is within the latitude of acceptance. To achieve the vision, charismatics express a willingness to go beyond their self-interests, to make personal sacrifices, and to take high risks. Charismatic leaders search for and envision opportunities and threats to their organization or movement. They use the vision to frame the alignment of the members and to implement actions to try to make the vision come true (Conger & Kanungo, 1998). Transformational leaders are motivated to accomplish the vision and to persuade others to agree with it. They act according to a vision specifying a better future state; communicate with references to the vision; articulate the vision and the accomplishments needed to attain the vision. They influence followers to make decisions in line with the vision and role model the values implied by the vision. However, unlike the ideologue, the authentic transformational leader will change the vision to better fit with the needs of followers (Mumford & Strange, 2002). The charismatic's vision and effects differ from the ideologue's in other ways. According to a biographical analysis of 60 notable leaders by Mumford and Mowry (undated), the charismatic's or transformational's vision is broad; the ideologue's is narrow. Ideologues are more likely than charismatics to direct punitive influence tactics toward followers who diverge from their vision.

## Characteristics of Followers

---

So far, we have concentrated on the leader as the source of the charismatic relationship. But increasingly detailed attention has been paid to followers in their relationship with charismatic leaders (e.g., Weierner, 1997). Tritten (1995, p. 85) declared, "The fundamental determinate of a 'charismatic leader' is the perception of 'charisma' and the response of followers." Uncertainties and anxieties upset followers' sense of mastery and efficacy, and they look to a hero or charismatic leader to guide them (Lipman-Blumen, 1996). They will see leaders as the cause of events even if the events were due to other reasons. Shamir (1992) found that respondents high on Meindl and Erlich's (1987) Romance of Leadership Scale were more likely to regard leaders as charismatic. The novelty to the follower of the leader's message will increase the follower's attention to it. The follower's uncertainty in the current situation will also increase attention to the leader's message (Avolio & Bass, 1988).

Such followers want to identify with the charismatic leader and mission. They place their trust in him to lead them to the promised land. Followers differ in their preferences for charismatic leaders. In reviewing scenarios of district managers, those who preferred to work with charismatic managers described the managers as encouraging, inclusive, success-oriented, goal- and team-oriented, creative, adaptive, committed, and energized. Those low in preference for charismatic managers felt that such managers were ambitious, zealous, arrogant, overbearing, too pushy, too enthusiastic, overconfident, all-talk, narrow-minded, and forceful (Ehrhart & Klein, 2001). Conger, Kanungo, and Menon (2000) found that 252 managers gave higher ratings of charismatic leadership on the Conger-Kanungo questionnaire if they strongly revered the leader they were rating. Follower reverence mediated their trust in and satisfaction with the leader.

### ***Followers' Susceptibility to Charismatic Leaders***

Shamir and Howell (2005) suggested reasons why some followers are more susceptible than others to the influence of charismatic leaders. Followers in distress and with low self-esteem and an unclear self-concept are more susceptible. They do not have a well-defined negative view of themselves but rather an uncertain, unstable, inconsistent self-concept (Campbell, Trapnell, Heine, et al., 1996). Freemesser and Kaplan (1976) found that young people who joined a charismatic cult were lower in self-esteem than a comparison sample;

these young people's self-esteem was raised in 6 to 12 months by membership in the cult. Still, followers of charismatic entrepreneurs who may be highly self-confident and who accept calculated risks for large potential gains also may readily accept the influence of a charismatic leader (Conger, 1993). Galanter (1982) suggests that managers with low self-esteem would be unlikely to be promoted into senior executive positions led by a charismatic chief. To reach such a position they would need a reasonable amount of self-confidence and self-esteem. Least likely to accept the charismatic leader are those followers who are independent-minded or counterdependent.

Shamir and Howell (1999) note that followers are more ready to comply with the charismatic leader if they have a *collectivistic* rather than an *individualistic* orientation, if they have an expressive rather than an instrumental orientation to work and life, if they have a *principled* rather than *pragmatic* orientation toward the leader, and if the leader appeals to the susceptible follower's values and identity. Charismatic leaders increase the importance of specific values already held by those who can be influenced and for whom the values can be connected to what is to be done. Charismatic leaders appeal to followers with matching ideological goals and those seeking intrinsic satisfaction. Such followers internalize the charismatic influences (Shamir, House, & Arthur, 1993).

In a study using Boccialetti's (1995) inventory of follower-authority relations and the Conger-Kanungo scale of charisma, Arsenault (1998) compared the perceived charismatic leadership in six small organizations ranging from 17 to 55 members (a family-owned business, a microbrewery, an adoption agency, a sports team, a mayor's office, and an inner-city church). Of 209 respondents, 66% were typed as accommodating, 26% as adversarial, and 8% as autonomous. Followers perceived more charisma if they felt closer in social and physical distance to the leader ( $r = .52; .28$ ). They were more likely to agree with their leader about goals and achieving them ( $r = .20$ ) and to agree that their organization was transformational ( $r = .27$ ). Preference for a charismatic leader was significantly higher for 261 to 267 university students if they valued participative leadership ( $r = .23$ ), achievement ( $r = .16$ ) and self-esteem ( $r = .16$ ; Ehrhart, 2001).

### ***Followers' Desire to Identify with the Charismatic Leader***

Weber (1924/1947, p. 328) wrote about the followers' "devotion to the specific and exceptional sanctity, heroism or exemplary character of an individual charismatic person, and of the normative patterns or order revealed or ordained by him." Willner (1968) saw followers as having an intense emotional and cognitive attraction to charismatic leaders above and beyond ordinary esteem, affection, admiration, and trust; this attraction involves "devotion, awe, reverence, and blind faith" (p. 6). Followers have an unqualified belief in the "man and his mission about what is, what should be, and what should be done" (p. 9). Nonetheless, more important than what charismatics do or say is what their prospective followers feel about them. The same words or actions by a would-be leader can seem charismatic and extremely influential to ardent disciples but humbug to others. According to Madsen and Snow (1983), charismatic leadership depends as much on the "magnetizability" of the followers as on the magnetism of the leader. Those who are in psychological distress are prone to join a charismatic leader's coterie, according to Galanter's (1982) review of clinical evidence. For example, although Charles Manson had been in prison for two decades, this magnetic murderer still could maintain a devoted following of misfit personalities on California's Russian River. Similarly, the "Moonies," ardently devoted to their charismatic leader the Reverend Sun Myung Moon, showed more feelings of helplessness, cynicism, and distrust of political action and less confidence in their own sexual identity, their own values, and the future than did a sample of college students (Lodahl, 1982). Charismatic gurus and leaders of sects attract insecure and lonely people, who join other followers and relinquish their right to make decisions in exchange for strict, protective boundaries and security. The magnetism of the gurus often has a

strong sexual component (Newman, 1983). Freemesser and Kaplan (1976) observed in interviews that those who joined a charismatic religious cult had lower self-esteem than a comparable sample.

Corsino (1982) argued that the charismatic leadership of Malcolm X was due to his personality traits and to the intellectual, moral, and emotional predispositions of his followers, who could identify with his experiences and who projected their own frustrations with white society onto him. After a content analysis of statements that followers made about Adlai Stevenson and Dwight D. Eisenhower during the 1952 presidential election campaign, Davies (1954) concluded that compared with other voters, those who attributed special qualities to their leader had a higher intolerance for indecision and crisis, applied rigid categories of good and evil, and felt that other people were more in agreement with them than was actually the case.

*Personal versus Social Identification.* Followers who may personally identify with a charismatic leader do so for personal reasons. Such followers have low self-esteem, a weak self-concept, weak self-identity, and a strong need to depend on authority figures.

*Social identification* is based on seeing oneself as a member of a group, organization, or society. Values, ideologies and role identities are shared with other members, and the charismatic leader reinforces them with symbols, rituals, ceremonies, and by calling attention to the successes of the past (Shamir, House, & Arthur, 1993).

*The Identification Process.* Shamir, House, and Arthur (1993) emphasized that charismatic leadership changes the self-concept of followers. The followers find in the charismatic leader an affirmation of their sense of identity, and changes in their perceptions about the future and about what is to be done. A stronger shared and collective identity and efficacy emerge (Shamir, 1991). Their self-concept is tied by the charismatic leader to the goals and collective experiences of their missions “so that they become valued aspects of the followers’ self-concept” (Conger, 1999, p. 155).

According to Freud (1922), the follower’s identification with and commitment to the charismatic leader are ways for the follower to resolve ego-superego conflicts. Downton (1973) agreed, seeing that we resolve the conflict between our self-image and what we want and think it should be by making the leader the embodiment of our ego ideal. By accepting a leader with transcendental objectives, followers can fulfill their desires to go beyond their own self-interests and to become more noble and worthy. The leader is idealized and becomes the model of behavior to be emulated—the embodiment of the follower’s aspirations. Commitment is directed to the person of the charismatic leader (whether the leader’s goals are self-aggrandizing or prosocial). Through the leader, the follower can achieve the strongly desired ideal self (Marcus, 1961). Obedience to new attitudes and goals develops from the effort to emulate the leader’s example and adopt the leader’s mission. At the same time, the follower’s capacity to criticize the leader is impaired (Weber, 1924/1947).

Erikson (1968) conceived *identity confusion* as deriving from a failure to mature in adolescence and young adulthood and a failure to develop a strong ego ideal because of oppressive, weak, or absent parents. The lack of an ego ideal to guide one’s behavior and interpersonal relationships arouses uneasiness and a sense of drift (and more susceptibility to the blandishments of the charismatic leader). Downton (1973) held that identifying with the charismatic leader was a way of coping with such identity confusion, as well as with the conflict between the ego and the ego ideal. As a consequence, the charismatic leader benefits the follower by providing him or her with new goals and a positive identity, and by enhancing the follower’s self-esteem. The charismatic leader gives the follower a second chance to attain maturity. Young women’s identification with Mother Teresa, who devoted herself to the poorest of the poor, can give them an enhanced self-image and make them agents of contribution to a worthy cause. Identification with the maniacal murderer Charles Manson can also enhance a follower’s self-image, but in this case the contribution would be to a most unworthy cause.

Charisma, as an endowment of spiritual grace from God, was converted by social science into an endowment of leaders by their followers with a high degree of esteem and referent power. The value,

popularity, and celebrity that others attribute to a leader engenders in followers strong emotional responses of affection and the leader's generalized influence beyond the immediate situation and beyond the ordinary exchange of compliance for promises of reward or threats of punishment. The vicarious satisfaction obtained from basking in the glory of the charismatic may be as sufficient a reward for the star-struck as doing God's work is for the pious. Admiration of the charismatic leader and the desire to identify with and emulate him or her are powerful influences on followers. Charisma is in the eye of the beholder and, therefore, is relative to the beholder. Nevertheless, the charismatic leader actively shapes and enlarges his or her audience through energy, self-confidence, assertiveness, ambition, and seized opportunities (Bass, 1985a).

### ***The Dynamics of the Charismatic Leader-Follower Relationship***

House (1977) described the dynamic process involved as follows: confident of their own competence, convinced of their own beliefs and ideals, and strong in the need for power, charismatic leaders are highly motivated to influence their followers. Their self-confidence and strong convictions increase their followers' trust in leaders' judgments. Charismatics engage in impression management to bolster their image of competence, increasing their subordinates' compliance and faith in them. They relate the work and mission of their group to the strongly held values, ideals, and aspirations that are part of their organization's culture. In organizational settings, they vividly portray for their subordinates an attractive vision of what the outcomes of their efforts could be. This portrayal provides subordinates with more meaning for their work and arouses their enthusiasm, excitement, emotional involvement, and commitment to the group's objectives. Roles are defined in ideological terms that appeal to the subordinates. What makes this process more than just inspirational is that charismatic leaders use themselves as examples for subordinates to follow. Thus cadets at the U.S. Air Force Academy said they most wanted to emulate those squadron commanders whom they had described as highly charismatic on the MLQ (Clover, 1989).

In some instances, their very lack of talent may make popular but untalented charismatic figures easier for their uncritical followers to identify with; such followers gain vicarious satisfaction from their own frustrated ambitions (Schiffer, 1973). Unlike Freud's (1922) Moses-like charismatic leader, who orients followers toward personal and moral growth and transcendental purpose and mission, pseudocharismatic *totemic* leaders are idols who are easy to identify with at a superficial level because they cater to the whims and fantasies of the followers. Token identity and perfunctory rituals satisfy the followers' need to belong (Faucheux, 1984). Logic-tight compartments in the followers separate what is not wanted in the leader from what is wanted—they repress the former and enhance the latter. Charisma depends on a regression to imagery. The childlike image of the faultless leader replaces a realistic appraisal (Schiffer, 1973). Even when the leader's faults are recognized, as was the case with Ronald Reagan and George W. Bush, supporters see them as illustrations of greater humanity and find it easier to forgive them their shortcomings. This leniency connects with the fact that in evaluating their superiors, subordinates often do not rate them as they have been asked to do; rather, they rate their own mental prototypes of a generalized leader.

Followers tend to perceive charismatic leaders as ideal leaders. Bass and Avolio (1987) obtained a correlation of .83 between subordinates' behavioral descriptions of the charismatic leadership of their superiors on the MLQ and the subordinates' ratings of the prototypical leader using the Lord, Foti, and Phillips (1982) prototypically scale. Correlations of prototypicality with other leadership styles were much lower; prototypicality correlations fell to .61 with practicing contingent reward and .38 with practicing management by exception.

At the crux of the phenomenon of charisma is the emotional response of the follower. Schiffer (1973, p. 3) describes the charismatic rally:

Commonly ... some specific ... unique personality is supposedly the true source of the process. ... TV cameras and commentators ... lend luster and dimension to the whole happening; a strange hypnoid state begins to infiltrate the most vulnerable minds.

... The social scientist looks for economic and cultural factors ... to explain the new “miracle”; the intelligentsia dissect the personal mystique of the hero.

Charismatic leaders reduce the followers’ resistance to change by arousing emotional rather than rational responses. The cost of such emotional responding may be impaired judgment and uncritical acceptance of the leaders.

*The Mystique.* The magical and the fantasy aspects of charisma and their costs need to be considered more fully. The dependence generated by charismatic leadership is evident when the loss of an inspiring, charismatic leader is accompanied by demoralization and disruption among the followers (Hays & Thomas, 1967). Charismatics are not merely self-confident, determined, and convinced of their own beliefs. They may believe they have supernatural missions and purposes. Martin Luther King Jr. really had a waking dream of what he was to accomplish. Downton (1973, p. 230) noted that “the charismatic relationship can be a two-way exchange in which the leader comes to see himself as charismatic and lives from day to day on the deferential treatment he sees as rightfully his.”

Followers do not merely have favorable perceptions of the leader; for them, the charismatic leader may be larger than life, with eyes that seem to mesmerize. The leader may be a superhuman hero to followers, someone to be worshipped as a spiritual guide. Furthermore, followers can act as if they have been mesmerized, suspending their ability to make critical judgments. If we cannot have the loved object, we may try to imitate and emulate it to gain its approval and to meet its standards and expectations (Kets de Vries, 1984, 1988).

The sense of reality of both the charismatic leader and the followers can be distorted by psychodynamic mechanisms, such as projection, transference, regression, and disassociation. For instance, the followers can project their processes and needs onto the charismatic leader, who may become the catalyst for the followers’ rationalizations. President John F. Kennedy is a case in point:

John F. Kennedy ushered in a new Camelot complete with his Queen Guinevere and knights ready to do battle in Cuba, Berlin and Vietnam with the villainous foes of freedom, the Cuban devils and Soviet dragons. The depth of the public depression resulting from Kennedy’s assassination can only be explained by the strong, emotional idolization of the image of Kennedy as dragon slayer, savior, and creator of a new life on earth for the disadvantaged. In reality, he was an astute politician who changed a fictitious Soviet superiority in missiles—the so-called missile gap—into the beginning of a new arms race led by the United States. ... His statesman-like qualities grew with his experience in office. But for the mass of the U.S. public, his image was that of the youthful world leader who was lifting the U.S. out of the stodgy Eisenhower years with the focus of a future of U.S. leadership among the nations of the world and in space. (Bass, 1985a, pp. 56–57)

### ***The Transformation of Followers***

The charismatic (as well as inspirational) leader concretizes a vision that the follower views as worthy of effort, thereby raising the follower’s excitement and effort. However, people who seek to identify with the leader but who are distant from him or her may become only passingly aroused and committed, and may not take action to conform to the leader’s initiatives. Nevertheless, if they are free to act and are not constrained by other commitments or the lack of opportunity, they will actually become committed to leaders even at a distance. Presaging Burns (1978), Downton (1973, p. 230) described this process as *transformational* rather than

*transactional*, noting its greater likelihood of taking effect:

In the formation of a charismatic commitment, the opportunity for action is apt to be greater than strictly transactional relationships because the follower who identifies with a leader can transform his behavioral pattern without necessarily exchanging tangible goods with the leader. For example, the follower ... can act when the leader initiates a new moral code that can be put immediately into practice, no matter how distant the leader and the opportunities for organizational activity.

Tension is reduced in the follower who strongly identifies with the charismatic leader. Since the leader has come to substitute for the follower's ego ideal, continuing and uncritical acceptance of the leader's initiatives is a way of bringing the ego into line with the ego ideal. In the case of identity confusion, when the follower has been unable to "find himself" and to decide who he is and what he wants to be, the follower's intolerance of criticism of the leader counteracts the problems of identity. The follower protects the idealized identity of the leader as a defense. Such criticism is a challenge to the person who is defending the image, since it is by identifying with that image that the person develops a sense of who he is and what he wants to become.

*Behavioral Contagion.* The nonverbal expressive behavior of 84 college students in a simulated campaign speech where charisma was introduced—with more smiling, more intense smiling, and longer and more frequent attention to the audience by the speaker—resulted in more of the same expressive behaviors in the audience. In a second study, audiences were shown videos of a 1992 pre-election presidential debate between the more emotionally expressive, charismatic Bill Clinton and the less emotional George H. W. Bush. The audience exposed to Clinton showed more emotionally expressive reactions than the audience exposed to Bush (Cherulnik, Donley, Tay, et al., 2001).

## The Emergence of Charisma

---

### *Crises and Their Solutions*

Some explanations of the charismatic relationship have emphasized that social crisis is the root cause of its emergence. According to this viewpoint, the charismatic appears in times of great societal distress to save society. This salvation from distress engenders "special emotional intensity of the charismatic response. ... followers respond to the charismatic leader with passionate loyalty because the [promise of] salvation ... that he appears to embody represents the fulfillment of urgently felt needs" (Tucker, 1970, p. 81).

In work in organizations, threat, distress, and crises contribute to the emergence of the importance of charismatic leadership (Pillai & Meindl, 1991). Pillai (1995) found, in a survey of 101 units of a health organization, that the more charismatic the 454 workers in the units rated their supervisor as charismatic, the less they felt stressed by their job ( $r = -.27$ ) or in crisis in the past three months ( $r = -.24$ ). Crisis was measured by responses to five items: response uncertainty, time pressure, surprise, frequency, and resolution.

Among the five sociopolitical factors that accounted for half the variance in the degree to which charismatic leadership was attributed to twentieth-century heads of state, Cell (1974) isolated such factors as a national social crisis and disruptive youth. Not only acute crisis brings out the charismatic leader. Charismatic leadership also arises when the crisis is chronic, as when the ultimate values of a culture are being devalued and radical social change is occurring (Hummel, 1973). Charisma carries with it a challenge to the old order; a break with continuity; a risky adventure; and continual movement, ferment, and change (Bass, 1985b). The empowered leaders can continue to influence these feelings to maintain their position, but they need to provide new, usually radical, solutions to the crisis or to relate it "to a higher purpose that has intrinsic validity" for the followers (Boal & Bryson, 1987). The charismatic leader can also promote unlearning and a search for new

actions. In highly ambiguous situations, such new solutions may be chosen precipitately (Hedberg, 1981). Earlier, I noted the development of the revolutionary, reform, and counterrevolutionary leaders as well as charismatic leaders, which leaders of sociopolitical movements tend to be. In democracies, radical leaders, usually leftists, push for more active citizen participation, equality, and community involvement (Alinsky, 1971). Radical rightists argue for less government intervention for libertarianism, and for a return to earlier practices, privileges, and values. The initiators of the movement provide rational and emotional arguments for discrediting opposing beliefs and replacing them with new ones. Zealots and dogmatists join the cause and become the leaders of action (Hoffer, 1951).

Individuals who feel that they have lost control over their environment are more ready to accept the authority of a charismatic leader (Devereux, 1955). People become “charisma hungry” owing to the decline of old values and rituals; shocks to the culture; and growing fears, anxieties, and identity crises. For example, Mahatma Gandhi satisfied such “hunger” in Indians by giving them a new collective identity and new rituals (Erikson, 1969). Adolf Hitler arose as the savior of Germany in response to the disappointments of military defeat and social, political, and economic distress. Despite Italy’s final victory in World War I, the rise of Benito Mussolini to power in 1922 illustrated the same theme of distress (Fermi, 1966). Martin Luther King Jr. and Jesse Jackson stirred disadvantaged blacks to believe that their personal efforts, combined with collective action, could reshape American society to advance their place in it, ultimately for the benefit of all Americans.

When organizational cultures are in transition, charismatic leaders appear. They arise when traditional authority and legal, rational, and bureaucratic means cannot meet the organization’s or society’s need for leadership. Old, highly structured, successful organizations are unlikely to need such leadership. Charismatic leaders are more likely to appear in failing organizations or newly emerging ones that are struggling to survive. In such organizations, charismatic leaders can radicalize from within, rather than in response to a challenge from outside (Berger, 1963). They create new cultures for their supporters by creating new meanings and beliefs for them.

In the absence of threats and any need for new strategies or reorientation, toward the existing order and organizational culture can be maintained by institutional processes and by symbolic acts of the leaders’ reaffirmation of the organization’s values and standards. But when the organization must change to survive, its reorientation requires substantive changes in the distribution of power, interruption of previously established commitments and beliefs, and management of the development of a new set of values, norms, beliefs, and rationalizations (Romanelli & Tushman, 1983). During the 1980s, many colleges were faced with declining enrollments and declining resources, coupled with increasing competition for available public and private funds. Charismatic presidents were needed. Delson’s (1986) analysis of interviews in and news clippings from five schools suggested, among other things, that such presidents had to have a sense of purpose and had to recognize the need to build for the future. They had to choose strong deputies, gain the active involvement of public officials, and seize opportunities that arose.

Rapid changes in the nature of work and organizations may give rise to new types of charismatic labor leaders, although such leaders may have particular difficulty institutionalizing changes in their unions (Spector, 1987). Charismatic political leaders create crises. Serbian leader Slobodan Milošević started the breakup of Yugoslavia in 1989, and wars with Croatia, Bosnia, and the Albanians in Kosovo. Hitler’s rise to power was marked by one crisis after another, which he created. Whether spurred by a crisis or an ideology, the charismatic leaders’ solutions can take opposite directions. The dedicated follower of one charismatic can be uplifted and moved to a new and better life; the dedicated follower of another can be moved to murder or suicide. Thus charismatic leadership can be beneficial or deleterious to society and to organizational life, depending on whether the followers’ needs are authentic or contrived and whether the leader has prosocial or antisocial goals.

*Experimentation with Crises.* Crises are relatively rare. Experimental studies and simulations provide an opportunity to study causality in these situations and to reveal the most effective leadership approaches (D. J. Brown & Lord, 1999). Pillai and Meindl (1991a) had 125 undergraduate management students read one of four contrived scenarios about the 10-year performance of a fast-food company. Then they rated the mean charismatic score of the supposed CEO using the scale from the Multifactor Leadership Questionnaire (MLQ; Bass & Avolio, 1989). The mean charismatic leadership score for the CEO with each of the company's performance scenarios exhibited a significant linear trend from a crisis followed by decline, no crisis but a steady decline, no crisis but a steady growth, and a crisis followed by a turnaround to steady growth. As predicted by the Romance of Leadership theory (Meindl, 1990), the "CEO" received higher leadership ratings if perceived to be heading a firm that successfully turned around from a crisis, with steady growth rather than steady decline. The same investigators, Pillai and Meindl (1991b), manipulated crisis or no-crisis conditions for 96 undergraduates in 16 sextets by extremely positive or extremely negative feedback of their task performance as individuals and groups. The feedback, particularly the negative feedback, was ostensibly to contribute substantially to their grades. Members chose their leaders and afterward rated them using the MLQ. Again, charismatic leadership was significantly higher in the crisis condition than the noncrisis condition. Path analyses indicated that there was no direct path from crisis to satisfaction and effectiveness of the leader. Rather, crisis generated a path coefficient of .27 with the emergence of charismatic leadership, which in turn generated a path coefficient of .79 with rated satisfaction and effectiveness of the leader. But elsewhere, Pillai (1993) reported that a crisis was not always necessary for charismatic leadership to emerge. Hunt, Boal, and Dodge (1999) conducted an experiment in which 191 upper undergraduate students (juniors or seniors) were in a contest to cut costs and enhance revenue to improve a university's standing. The participants were or were not subjected to serious time and task load pressures introduced unexpectedly to simulate a crisis. Scripted leaders (confederates) used one of three styles: visionary, exchange (transactional), or unexpressive (laissez-faire). The visionaries began as such: the crisis-responsive leaders began unexpressively and started to behave as visionaries only after the crisis was introduced. Three weeks later, all participants worked on a counterbalanced equivalent task under unexpressive leadership. Manipulation checks confirmed that the crisis and noncrisis conditions were perceived by the participants as intended, as were the three styles of leadership. Both visionary leaders and crisis-responsive leaders received similar attributions from the participants: that they were charismatic and performing beyond expectations. However, after the crisis abated, the effects of crisis-responsive leadership as a source of charismatic leadership lingered.

*Cultural Expectations.* Charismatics appear in societies with traditions of support for them and expectations about their emergence. Thus charismatic prophets and messiahs could arise in ancient Israel because they fit with a long prophetic tradition. They were being awaited. The intense spiritual relationship of the charismatic leader and his followers is distinctive in modern Islam, which flowed out of the Judeo-Christian tradition. The prophet is an extraordinary personality who emerges in a social crisis, carrying a messianic message that becomes legitimated and routinized (Dekmejian & Wyszomirski, 1972). In the absence of such tradition in ancient and modern China, the emergence of such charismatics is somewhat less frequent. Mao Zedong was an exception. In determining leader-follower relations in China, hierarchy continues to be more important than the possibility that charismatic leaders will arise. For the charismatic leader to resort to particular psychological mechanisms in his appeals, the followers must have shared norms. Since sinfulness is a shared norm in the Judeo-Christian world, the western charismatic leader can stimulate guilt among followers. The importance of "face" is a shared norm in the Orient; the Oriental charismatic leader has to focus on shame (Hummel, 1972).

According to Tsurumi (1982), an important aspect of the introduction of quality-control circles in Japan was the American consultant Charles Protzman's emphasis on the need for a charismalike manager to "secure the faith and respect of those under him by his being an example of high purpose, courage, honor and

independence.” This focus conformed with the Japanese tradition of leaders as men of exemplary moral courage and self-sacrifice. In India, charismatic status can come from practicing asceticism, passive meditation, and physical austerity, which may or may not translate into leadership and does not depend on a crisis (Singer, 1969).

*Organizational Level.* Executives at the top of the organization are expected to be concerned with its ultimate purposes. Such leaders must reflect on long-term issues and be sensitive about keeping their organization in tune with the external environment (Watson, 1988). A correlation of .23 was found for 45 New Zealand professionals on the MLQ between subordinates’ descriptions of the charisma of their leader and the leader’s level in the organizational hierarchy (Bass, 1985a). Bass, Waldman, Avolio, et al. (1987) reported similar results for the mean charismatic behavior described and required by subordinates of their leaders at two successive levels of the organization. However, such differences in the MLQ failed to be found when junior and senior officers in the U.S. Navy were compared (Yammarino & Bass, 1988) and when majors were compared with colonels in the U.S., Canadian, and German armies (Boyd, 1989a).

*Charisma without Crisis.* Charismatic effects can emerge not only in crises, but as a consequence of the charismatic’s vision and its articulation, which create a sense of need for action by the followers. The *visionary* charismatic begins with ideological fervor and moves to action, unlike the *crisis* charismatic who begins with solutions to a crisis and then develops ideological justifications for them (Boal & Bryson, 1987). In a study of charismatic business entrepreneurs, Conger (1989) observed that they were stimulated into action as a consequence of opportunity and optimism rather than a distressful situation. Change can be driven by opportunity as well as threat. The business opportunities present in changing market demands and technological developments can bring forth calculated risk taking and charismatic leadership of consequence, and can result in necessary organizational changes. Charismatic leaders identify trends and assess resources and constraints in dealing with needed changes (Howell, 1997). An alienated organizational membership may be led by a charismatic leader who creates a compelling new vision for them of a more attractive future better attuned to fulfilling their values and purposes (Boal & Bryson, 1988).

Charismatic leaders may emerge in the absence of crisis if the organization is organic rather than mechanical (Bass, 1985a), and if it is flexible and innovative (Koopman, 1991). Charismatic leaders may arise if the tasks are unstructured and collective, and if goals are ambiguous (House, Spangler, & Woyke, 1991). Since different threats and opportunities exist at every organizational level, it is not surprising that charismatic leadership can be revealed at any level without crisis conditions. Charisma without crisis deteriorated faster compared to continuous visionary leadership with or without crisis conditions.

Whether spurred by a crisis or an ideology, the charismatic leaders’ solutions can take opposite directions. The dedicated follower of one charismatic can be uplifted and moved to a new and better life; the dedicated follower of another can be moved to murder or suicide. Thus, charismatic leadership can be beneficial or deleterious to society and to organizational life, depending on whether the leaders are authentic leaders have prosocial or antisocial goals.

## ***Routinization***

History is replete with charismatic leaders whose revolutionary changes endured. As Bass (1985a, p. 41) noted:

The world from the Danube to the Indus was remade socially, culturally and politically by Alexander the Great in his own brief career. Simon Bolivar’s efforts had lasting political effects on much of Latin America. Mohammed’s lasting effects transformed societies stretching from Morocco to Indonesia and left lasting effects on cultures from Spain to the Philippines.

What makes for the lasting effects of charismatic leaders? Weber (1924/1947) attributed them to

routinization. Focused on the expressive and the emotional, the relationship between the charismatic leader and the led is basically unstable, Weber thought; it must be routinized by the development of organizational rules and arrangements to achieve stability. The charismatic leader's mission can be routinized in several ways. For example, unless the leader is replaced by an equally charismatic successor, an administrative apparatus is created, along with rites and ceremonies, to provide continuity of the message and mission. Or oral and written traditions emerge to enable the charismatic's effects to endure. The charismatic revolutionary hero Napoléon Bonaparte became the Emperor Napoleon, with a new court, new legal codes, a new educational system, and a new administration. Mao Zedong, the "permanent revolutionary," was succeeded by Deng Xiaoping, the administrator, who sought to maintain most of the bureaucratic political system created by Mao, but not as much of Mao's economic system. The charismatic founder of Mothers Against Drunk Driving, Candy Lightner, succeeded in arousing the public with her moral expressiveness and moral mission and was able to obtain funding for a national organization. But conflict within the organization between the functionaries required to run a rational administration and the charismatic Lightner resulted in her replacement as leader (Weed, 1993).

The charismatic leader is a hard act to follow. Institutional practices and the cultural imperatives built by the charismatic leader must replace him after he is gone. Marshal Tito of Yugoslavia planned carefully for the succession after his death but was not optimistic that any associate could accumulate the personal authority that his charisma had given him (Drachkovitch, 1964). For a while, the structures that the Croat Tito had created remained in place in Yugoslavia. These generally favored the Serbs; but the ethnic divisions, aided and abetted by a new aggrandizing dictatorial leader, the Serbian President Milošević, caused the Yugoslav republics to fly apart after three wars between Serbia and Croatia, the Bosnian war, and the war in Kosovo.

Continuity is also provided by key groups of believers and by distinctive practices and imagery in the form of visual art, ceremonies, and stories. In the survival and growth of Alcoholics Anonymous and the National Council on Alcoholism, founded by charismatic leaders in 1935 and 1946, respectively, Trice and Beyer (1986) noted: (1) the development of an administrative apparatus that puts the charismatic's program into practice; (2) the transfer of charisma to others in the organization by rites and ceremonies; (3) the incorporation of the charismatic's message and mission into the organization's traditions; and (4) the selection of a successor who resembles the charismatic founder and has the esteem to achieve the charismatic's personal influence.

Government bureaucracies are highly routinized. Charismatic leadership is seldom seen. Impersonal rules provide standardization. There is little latitude for "creative administration." Nonetheless, at times creative administrators do manage to decide which rules to apply and how to interpret them in order to accomplish their objectives legally and without censorship. Reforms do occur in response to clients and political pressures (Kamensky, 1996). Politically well-connected agency directors with experience know how to use or go around the rules for their own ends.

*Charisma May Emerge from Routinization.* The office may make the leader. Apart from "office charisma," the demands of the office may greatly elevate the esteem of the officeholder. For instance, in Shakespeare's play, the profligate Prince Hal develops into the charismatic Henry V in response to the demands of kingship.

Charisma grows from administrative routine. This interesting reverse effect was demonstrated by Scott (1978). Rather than supporting Weber's thesis that charismatic authority eventually results in routinization, Scott found that routinization, as evidenced by years of tenure in a bureaucratic office, contributed to one's charismatic authority. In a random sample of Kentucky school superintendents, Scott found a correlation of .52 between their years in office and their charismatic authority. Not until the thirteenth year of their tenure was the superintendents' charismatic authority rated consistently high. A peak of charismatic authority was reached after 13 years of tenure and continued through the twenty-first year of tenure before declining slightly,

just before the superintendents' retirement.

Using Mao Zedong as an example, Chang (1982) argued that the emergence of a charismatic leader is a long-term process of interaction between the leader and followers and their collective ability to accumulate political power. Mao's charismatic leadership was legitimated, reinforced, and maintained through institutional efforts. After Mao, a powerful political bureaucracy maintained itself, but the bureaucratic hold on the Chinese economy was relaxed. We need to allow for various possible relations between charismatic leaders, their immediate colleagues, and the environment that may result in a more personalized leadership, rather than routinization of the leadership over time.

### ***Loss of the Charismatic Relationship***

Since the relationship depends on followers and conditions as well as the leader, leaders may lose their charisma in the eyes of their followers if changes occur in the followers and conditions. Yukl (1999) argued that charismatic leadership theory and research provided little insight about how and why charisma is lost. He suggested that the attribution of charisma might fall away if the crisis conditions disappear, if followers become more competent, if the leader fails or betrays the followers, or if rivals appear who are more credible and more attractive. Paradoxically, charismatic leaders may be victims of their own success in founding and building organizations. The charismatic founders may be replaced as the organization becomes more professional and bureaucratic, because their expertise is no longer unique and their emotionally appealing, unconventional behavior is no longer functional.

## **The Charismatic Leader in Complex Organizations: A Conceptual Examination**

---

The concept of the charismatic relationship is now used to understand leaders and leadership in a wide variety of organizations and political, social, and religious movements. Numerous theorists have used the concept to account for organizational members' emotional responses to work-related stimuli, for their trust and confidence in their leader, and for their adoption of the leader's values, which results in their heightened motivation to perform.

### ***Widespread Distribution***

Charismatic leader-follower relationships are widely found in political life, social movements, and complex organizations. They appear not only "in extravagant forms and fleeting moments, but in an abiding, if combustible, aspect of social life that occasionally bursts into open flame" (Geertz, 1977, p. 151). Charismatic relationships have been reported in such diverse organizations as suburban school systems, communes, utopian communities, colleges, Alcoholics Anonymous, the National Council on Alcoholism, the Chippewa Nation, a maternity home, a British manufacturing firm, and Tanzanian labor unions (Trice & Beyer, 1984). Some of the most prominent charismatic leaders in the United States have been leaders of labor movements and labor unions, such as Bill Haywood of the Industrial Workers of the World (IWW), Rose Schneiderman of the Women's Trade Union League (WTUL), A. Philip Randolph of the Brotherhood of Sleeping Car Porters (BSCP), Cesar Chavez of the United Farm Workers (UFW), and John L. Lewis of the United Mine Workers (UMW), cofounder of the Congress of Industrial Organizations (CIO). They tended to be dedicated, visionary, determined, mission-oriented, magnetic, inspirational, and articulate (Dubofsky & Van Tine, 1987).

As Shils (1965), Dow (1969a), and Oberg (1972) had observed earlier, Bass (1985a, pp. 56–57) found in empirical surveys that charisma is widely distributed as an interpersonal relationship and is not limited only to world leaders or to founders of movements or heads of organizations:

[Charisma] shows up with ... Lee Iacocca at Chrysler convincing workers, suppliers, Congressmen, and customers that Chrysler could be turned around and doing it; the young Robert Hutchins recasting the prestigious University of Chicago in his own image; Hyman Rickover, taking on the whole Navy Department with an idea, the nuclear submarine, whose time had come. ... [Much] of what the Iacoccas, Hutchinses and Rickovers can do from the top of the organization, can occur in varying amounts and degrees all through complex organizations. Such charismatic effects can be studied and found or developed in supervisors at all levels of the complex organization.

Charisma, in turn, is a component—the most general and important component—of the larger concept of transformational leadership. In this regard, it is to be found, to a considerable degree, in industrial, educational, government, and military leaders at all organizational levels. In questionnaire surveys, many followers described their military or industrial superiors as persons who made everyone enthusiastic about assignments, who inspired loyalty to the organization, who commanded respect from everyone, who had a special gift of seeing what was really important, who had a sense of mission, and who excited subordinates. Some of these subordinates had complete faith in the leaders with charisma and felt good to be near them. They were proud to be associated with the charismatic leaders and trusted the leaders' capacity to overcome any obstacle. The charismatic leaders served as a symbol of success and accomplishment for their followers (Bass, 1985a).

Charismatics may be more likely to appear in political and religious movements than in business or industry (Katz & Kahn, 1978), but they also appear at various levels in the complex organizations of business executives, educational administrators, military officers, and industrial managers. According to Zaleznik (1983), charisma distinguishes the ordinary manager from the true leader in organizational settings. The true leader attracts intense feelings of love (and sometimes hate) from his or her subordinates, who want to identify with him or her. Feelings about ordinary managers are bland, but relations are smoother and steadier. However, like most intimate relationships, the relations between the charismatic leader and his or her followers tend to be turbulent. Such “commando leaders” emerge to accomplish challenging and exhilarating tasks that need to be undertaken in an organization. Although they are highly effective, they may be “glamorous nuisances” (Handy, 1976).

Katz and Kahn (1978) argued that the charismatic relationship is strengthened to the degree that leaders distance themselves from their followers. This idea fits with Hollander's (1978) inference that charismatic leadership is less likely to emerge in complex organizations because of the close contact of superiors and subordinates, which prevents the maintenance of the magical properties of charisma. But many charismatic leaders, such as Vladimir Lenin and Lyndon Johnson, had close, immediate, lifelong subordinates who worshiped them with intense devotion. Social distance between leaders and followers is not essential for the maintenance of the charismatic relationship. In fact, Howell (1988) argued that socialized charismatics do not maintain such a distance.

Yukl (1981) attributed the presumed scarcity of charismatic leaders in business and industry to the lack of managers with the necessary skills. Berlew (1974) thought that many managers have the skills but do not recognize the opportunities. Bass (1985a) suggested that such managers may be less willing to risk standing out among their peers in organizations when they believe that conformity may be more important for success. Nevertheless, House (1977) proposed that charismatics may be found throughout complex organizations. Evidence of their effects on their followers includes the followers' trust in the correctness of the leader's beliefs, followers' beliefs that are similar to the leader's, unquestioning acceptance of the leader, affection for the leader, willingness to obey the leader, emotional involvement in the mission of the organization, heightened goals for performance, and belief by the followers that they are able to contribute to the success of the organization's

mission.

## ***Utility of Charismatic Leadership in Organizations***

Weber (1946) noted that charismatic leadership is a way to provide order and direction in complex organizations that were not bureaucratized or operated according to traditions. To meet the challenges of a rapidly changing workforce, markets, and technologies in the past few decades, productive organizations increased their efforts to avoid bureaucratic and traditional rigidity by using ad hoc groups, temporary systems, and organicity (Robbins, 1983). Elaborate formal coordination and planning were replaced with teamwork and devoted, intense efforts by members. Increasingly, leader-subordinate relationships displayed more charismatic characteristics (Quinn & Cameron, 1983).

Shamir, House, and Arthur (1993) suggested that charismatic leaders generate more effort in their subordinates in a number of ways. These leaders enhance, for their subordinates, the intrinsic worth of the goals and of the activities required to reach the goals; instill in them faith in the future and the belief that the goals are beyond ordinary, rational purposes; and, in the process, raise subordinates' self-esteem.

The charismatic prophet's antiestablishment preaching can be destructive, but it also may contribute to organizational renewal. Etzioni (1961) suggested that more charismalike leadership is needed in organizations to induce subordinates to accept guidance in expressive matters, in value judgments, and in decisions about purpose. Less charisma is needed to achieve agreement about instrumental means that usually are based on facts and rationales. More charisma is also needed if compliance depends on moral involvement; less is needed if it depends on material rewards or the avoidance of penalties. According to Etzioni, personnel in the lower ranks are instrumental performers, decisions about means are relegated to personnel in the middle levels, and charismatic concerns for the ends should be restricted to the top levels. Thus lower-level charismatic leadership would be dysfunctional in service and production bureaucracies: "Development of charisma on levels other than the top is not only unnecessary but is likely to undermine the rational processes required to maximize organizational effectiveness" (p. 317).

Nevertheless, Etzioni saw that when decisions about ends remain important—as they do for priests, shop stewards, and junior military combat officers and noncoms who are lower in the hierarchy of their organizations—charismatic leadership still has utility. Greater amounts of charismatic leadership were seen by the surveyed subordinates of U.S. Army combat officers than among combat-support officers (Bass, 1985a). Etzioni's argument that decisions about values, objectives, goals, and missions should be limited to the top organizational levels can be countered by the argument that participation in aspects of such decisions should be encouraged among leaders at all levels. Subordinates in lower organizational ranks who describe their immediate supervisors as charismatic also think their units and their organization are more productive. And opinions about the effectiveness of lower-and middle-level charismatic leaders are shared by their superiors (Hater & Bass, 1988; Yammarino & Bass, 1988).

*Negative Utility.* Nadler and Tushman (1990) pointed out possible negative effects of the charismatic leader. Expectations may be created that are unrealistic or unattainable. Everyone else will avoid taking the initiative and will remain dependent on the leader. Next-lower levels of management may be unable to exert any leadership. They will be reluctant to disagree with the charismatic leader's suggestions. When things fail to go as planned, followers may feel betrayed. The charismatic leader's magic may wear off, and he or she may take foolish steps to try to regain the loyalty of followers.

## ***Differences in the Behavior and Accomplishments of Charismatics***

Weber did not pay much attention to individual differences in the personalities of charismatic leaders but saw only that routinization would follow from the development of the charismatic's religious, political, or organizational authority. However, some charismatic leaders' sense of omnipotent personal power may prevent the institutionalization of charismatic authority into procedures and routines to be managed by subordinates and successors (Mitscherlich, 1967). This situation seems to have occurred with Kwame Nkrumah of Ghana but not with Jomo Kenyatta of Kenya. Both leaders were charismatic, but only Kenyatta could accept political opposition (Dow, 1969b). Thus charismatic leaders may differ considerably from each other in what they do and what they can accomplish.

Charismatic mentors will guide and support the personal growth of their disciples. Equally charismatic patrons will exchange support, protection and security for loyalty and service, keeping their clients in the same continued state of dependency. Charismatic teachers will provide intellectual stimulation; charismatic celebrities who lack the intellect will not. Charismatic junior army officers with their cry of "follow me," will ... [stimulate soldiers] to take action; charismatic ascetics or mystics will foster [followers'] escapism and lethargy. (Bass, 1985a, p. 52)

*When Charismatic Leaders Fail.* The situation may cause the charismatic leader to fail. For example, charismatic conductors of symphony orchestras will be seriously constrained by the unionization of the musicians they direct, as well as by the evaluation and control of employers, patrons, critics, business managers, and audiences (Kamerman, 1981). But more often, their personal weaknesses may lie behind their failure.

Despite their self-confidence, self-determination, and freedom from inner conflicts, some charismatics will fail ... as a consequence of particular deficiencies or exaggerated tendencies. Sometimes they may fail due to the overwhelming constraints they face and how they try to cope with them. Thus, how leaders with a sense of mission, self-confidence, ambition and other attributes of charisma handle the organizational constraints that frustrate their aims also makes a difference in whether they succeed in transforming organization managements, or fail in a dissatisfying standoff between what they want to see done and what can be done. (Bass, 1985a, pp. 50–51)

What McCall and Lombardo (1983) discovered in "derailed" promising young executives is illustrative. Unpredictability, insensitivity to others, the betrayal of trust, the failure to delegate to staff effectively, and the failure to build a team halted these executives' move up the organizational ladder. A political leader who operates at a distance from colleagues and constituents may get away with cronyism and extreme ambitiousness; but for industrial executives, too many such flaws create strong antipathy to their subsequent promotion among their more powerful colleagues.

Charismatic leaders tend to generate both love and hate in followers. Brown and Keeping (1999) observed that leaders obtaining higher scores on the MLQ were liked better than those earning lower scores. It may be that some charismatic leaders fail because they are more disliked than liked by their diverse followers. In a study of fire department personnel, Bramwell (1991) demonstrated that teams dealing with a first simulated task that was familiar were more effective if led by unseen charismatic leaders. Compared to suitable controls, the teams did worse on an unfamiliar second simulated task when they could see the nonverbal behavior of the charismatic leaders. If strong identification with a charismatic leader produces dependent, immature followers, rather than providing a model and inspiring support for self-actualizing followers (Musser, 1987), early successes nourish unrealistic expectations on the part of both the leader and the followers. If the problems become too great, the group's expectations may eventually surpass the leader's presumed magical powers, causing the leader's downfall (Heifetz & Sinder, 1987).

According to McGill and Slocum (1998), many organizations now expect and encourage their managers to behave more like charismatic leaders, yet most managers do not have the personal requisites and will fail in this attempt. The authors suggest instead that the managers know their job, act in alignment with their

organization's vision and values, and encourage listening and choice.

## Empirical Studies of Charismatic Leadership

---

The earlier case studies, retrospective analyses, and commentaries about the impact of charismatic leaders on their followers have been augmented, beginning in the mid-1980s, by laboratory experiments and questionnaire and interview surveys of the military, health organizations, business firms, NGOs (nongovernmental organizations), and educational organizations. Trice and Beyer (1986) were able to list nine sociological and anthropological field studies of charisma as of 1977 that they regarded as relevant, but House (1977) was unable to unearth any controlled empirical efforts to investigate the phenomenon at that time. The paucity of studies may explain why charisma was not indexed in *Psychological Abstracts* as of 1969 (Stark, 1970). At least two reasons may underlie the paucity of such laboratory and field experiments and surveys until recently. First, many if not most scholars, such as Beyer (1998), assumed charisma to be a rare attribute, limited to a few extraordinary leaders. Second, they thought it was impossible to bring charisma into the laboratory or to measure it with adequate validity. Both assumptions proved to be unwarranted.

### ***Laboratory Experiments on Charisma***

Brown and Lord (1999) pointed out the advantages of using experiments to study charisma. Experiments can avoid the effects of perceptual and cognitive errors in memory, nonverbal leadership, and unconscious influences that distort perceptions and beliefs in surveys and interviews. Howell (1985) succeeded in bringing the phenomenon of charisma into the laboratory. In the first such laboratory experiment, she compared the effects on subordinates of three types of leaders: charismatic, structuring, and considerate. The leaders' roles were played by two actresses, both of whom were trained for 30 hours. The actresses' training consisted of in-depth descriptions of their roles and a demonstration of the behaviors, emotional states, body language, facial expressions, and para-linguistic cues that they were to use in the experiment. The actresses viewed videotapes of actual managers who portrayed the different styles of leadership, and they rehearsed extensively. Videotapes of the actresses enacting the three styles after training were rated by 203 judges; this manipulation check attested to the validity of the actresses' performance. When playing the charismatic, structuring, and considerate roles:

The [charismatic] leader articulated an overarching goal, communicated high performance expectations, exhibited confidence in participants' ability to meet these expectations, and empathized with the needs of participants. ... The highly charismatic leader also projected a powerful, confident, and dynamic presence and had a captivating, engaging voice tone. ... Nonverbally, the charismatic leader alternated between pacing and sitting on the edge of her desk, leaned toward the participant, maintained direct eye contact, and had a relaxed posture and animated facial expressions. ...

The structuring leader ... explained the nature of the task, provided detailed directions, emphasized the quantity of work to be accomplished within the specified time period, maintained definite standards of work performance, and answered any task related questions. ... Nonverbally, the structuring leader sat on the edge of her desk, maintained intermittent eye contact, and had neutral facial expressions and a moderate level of speech intonation. ...

The considerate ... leader engaged in participative two-way conversations, emphasized the comfort, well-being, and satisfaction of participants, and reassured and relaxed participants. The highly considerate leader was also friendly and approachable and had a warm voice tone. Nonverbally, the considerate leader sat on the edge of her desk, leaned toward participants, maintained direct eye contact and had a relaxed posture and friendly facial expressions. (Howell, 1985, p. 8)

The laboratory task was an in-basket exercise requiring the completion of 15 memos in 45 minutes, followed by an optional task of five memos to be completed in an additional 15 minutes; most participants actually completed the optional task. Two coworkers who were confederates of the experimenter, plus a participant subject, made up the task group. The confederate coworkers (also trained) either encouraged the participant (high-productivity norming) or discouraged the participant (low-productivity norming). A total of 144 undergraduates were allocated to the six experimental treatments, 24 participants per treatment, so that each type of leadership was combined with the contrived high-or low-productivity norm. The most important finding was that only the charismatic leader was able to generate high productivity when confederate coworkers tried to discourage the participant. The leader who initiated structure did almost as well, but only if the coworkers encouraged high productivity. The structuring leader generated even less productivity than the considerate leader when coworkers were discouraging and set a low-productivity norm. In addition, in contrast to participants who worked under the leaders who initiated structure or were considerate, participants who worked under a charismatic leader had higher task performance, suggested more courses of action, had greater satisfaction with the task, felt less role conflict, and were more satisfied with the leader. Also, the qualitative task performance of individuals with a charismatic leader was better than that of individuals with a considerate leader.

Bramwell (undated) arranged for female participants to receive instructions from a female leader about completing an essay, to see how people reacted physiologically to the task. The leader acted like a charismatic for 32 of the participants and noncharismatic for 30. The subjects wore a blood pressure cuff and completed questionnaires during the course of the experiment. Systolic blood pressure rose from means of 107 to 110 for those with the charismatic leader but remained almost unchanged for those instructed by the noncharismatic leader. Those experiencing the charismatic leader thought their performance was higher (although it was not) and reported a more positive mood than those instructed by the non-charismatic leader.

Shea and Howell (1999) conducted an experiment with a 2 3 3 design. The situation involved confederates acting as charismatic leaders on noncharismatic leaders, and internal, external, or no feedback. There were four trials of the task for the 99 participating graduate students, which was to manufacture real electrical wiring harnesses as directed by the leader. The performance of the participants instructed by the noncharismatic leader without feedback deteriorated substantially, but those working under the charismatic leadership did as well with or without feedback, perhaps sustained by their heightened motivation. Results indicated that the presence of feedback reduced the self-efficacy effects of charismatic leadership on performance.

Hunt, Boal, and Dodge (1999) conducted an experiment to compare the effects of charismatic visionary leadership and charismatic leadership brought on by a crisis and after the crisis disappeared. Awamleh and Gardner (1999) compared the impact of charismatic leadership on perceptions of the contents of a message and its delivery with nonverbal gesturing and facial expression. The delivery accounted for 58% of the variance in attributed charisma.

## ***Surveys and Interviews***

Based on House's (1977) theory of charismatic leadership, Smith (1982) identified, by nominations, a sample of 30 charismatic and 30 noncharismatic leaders, who represented a broad sample of formal work organizations in the business, industrial, and governmental sectors. Smith administered 38 scales to subordinates to describe their superiors' attitudes and behavior. A discriminant analysis and cross-validation revealed that 7 of 18 emergent dimensions formed from the 38 scales significantly differentiated the charismatic from the noncharismatic leaders. The charismatic leaders were seen to be dynamic (emphatic, active, fast, aggressive, bold, extroverted, energetic, and frank). Subordinates who worked for charismatic

leaders developed more self-assurance than did those who worked for noncharismatic leaders. They said they experienced more meaningfulness if their leader had been nominated earlier as charismatic. In addition, they worked longer hours per week, which suggests that their motivation was heightened. Compared with subordinates of the noncharismatic leaders, they revealed a higher level of trust and acceptance of the charismatic leader in their ratings of “self-disclosure” to the leader.

O'Reilly (1984) found, in a survey of employees of Silicon Valley electronic firms that the credibility of top managers, as judged by their dynamism, trustworthiness, and expertise, was significantly enhanced if the CEOs were regarded as charismatic. The employees' commitment was similarly elevated.

Applying a revised scale of charisma developed by Podsakoff, MacKensie, Moorman, et al. (1990), Agle (1994) showed that 250 CEOs rated as more charismatic (dynamic, exemplary, etc.) by their top management team were more effective in terms of their organization's independently obtained performance record. Deluga (1995) found that 63 subordinates in an engineering division of a manufacturing firm who attributed more charismatic leadership on the Conger-Kanungo (CK) questionnaire to their 29 supervisors were also more likely to display organizational citizen behaviors (OCBs): conscientiousness, sportsmanship, civic virtue, courtesy, and altruism. Pitman (1993) obtained correlations between overall commitment of 245 white-collar workers in six firms of .24 and .23, respectively, with their MLQ charisma and CK ratings of their supervisors.

Shamir, Zakay, Breinen, et al. (1998) derived and tested several hypotheses about the effects of charisma. The hypotheses were derived from Shamir, House, and Arthur's (1993) Theory of Charismatic Leadership and its extension. The leadership of each of 50 company officers from the Israeli Defense Forces (infantry, tank, and engineering) were rated by superiors, peers, and subordinates. A total of 135 officers, 218 noncoms, and 1,197 soldiers participated. Respondents (11 or 12 per company) answered questions about either the company commanders or the companies. Four factors were extracted from the data about the company commanders: (1) Supportive behaviors (e.g., talks to soldiers like a friend of theirs); (2) Exemplary (e.g., full of energy and very active), (3) Ideological emphasis (e.g., often refers to national history); (4) Emphasizes collective identity (e.g., emphasizes the differences between the company and other companies). Stepwise analyses of the leaders' support regressed on the subordinates' attitudes toward their companies indicated that leader support was more important than the leaders' emphasis on collective identity. The leaders' exemplary behaviors were unrelated to any of the unit appraisals. An unanticipated finding was that the leaders' emphasis on ideology was *negatively* related to predicting soldiers' self-efficacy, identification with their unit, and attachment to their unit. The investigators concluded that the soldiers had become somewhat alienated from the mandatory military service—they viewed the highly dedicated company leaders as representatives of the interests of the larger system rather than their own interests. The leaders' ideological comments were seen as an effort to pressure them to perform.

*Meta-Analytical Findings.* DeGroot, Kiker, and Cross (2000) conducted 16 meta-analyses of studies of the correlations between leader charisma and effectiveness, as well as between leader charisma and subordinate effectiveness, effort, and satisfaction. For 23 analyses involving 5,577 respondents, charismatic leadership correlated on the average .74 (when corrected) with leadership effectiveness. But the mean correlation dropped to .50 for five studies when same-source variance was controlled. When 467 groups were used as the basis for analysis, the corrected mean correlation was .49, compared with .76 when the analysis was at the level of 5,110 individuals for 18 studies. The corrected mean correlation between the leaders' charisma and their subordinates' effectiveness was .31.

*Multifactor Leadership Questionnaire (MLQ) Scale of Charismatic Leadership.* Bass (1985c) developed a charismatic leadership scale of 10 items of the MLQ (Bass & Avolio, 1988) dealing with both the leader's behavior and the follower's reactions. He began with Burns's (1978) definition of a transformational leader who raises the followers' level of consciousness about the importance and value of designated outcomes and ways of reaching them; gets the followers to transcend their own self-interests for the sake of the team,

organization, or larger polity; and raises their level of need on Maslow's (1954) hierarchy from lower-level concerns for safety and security to higher-level needs for achievement and self-actualization.

Seventy senior South African executives (all male) were able to describe at least one such transformational leader they had known during their careers. Their descriptive statements, along with others about transactional leadership that featured an exchange of rewards for the follower's compliance with the leader, were sorted by 11 graduate students into transformational and transactional. The 73 statements on which the judges could agree were administered to 177 senior U.S. Army officers who were asked to describe their most recent superior, using a 5-point scale of frequency, from 0 = the behavior is displayed not at all to 4 = the behavior is displayed frequently, if not always. The first factor that emerged was labeled charismatic leadership because it seemed to contain most of the components of such leadership. Highest item factor loadings on the first factor were:

.87, I have complete faith in him.

.86, Is a model for me to follow.

.85; Makes me proud to be associated with him.

Sixty-six percent of the variances of the 73 items could be accounted for by this first factor of charismatic leadership (Bass, 1985a). An even larger percentage was accounted for in a comparable sample of U.S. Air Force officers (Colby & Zak, 1988). Hater and Bass (1988) achieved similar results when they refactored the 70-item questionnaire that subordinates completed to describe their immediate management superiors. Onnen (1987) obtained similar findings from 454 parishioners who described their Methodist ministers. A 10-item scale of these charisma items was included in the Revised MLQ-5X. Reliabilities of .85 and above were routinely reported for descriptions of superiors by large samples of subordinates in military and industrial settings (Bass & Avolio, 1991). Hater and Bass found that 28 managers in an express package shipping firm who were identified by their superiors as "top performers" earned a significantly higher charismatic leadership score from their subordinates than did a random sample of 26 ordinary performers.

*Relationship to Effective Leadership.* For the samples of officers in the U.S. Army and U.S. Air Force, the MLQ charisma scale correlated .85 and .90 with the rated effectiveness of the officers and .91 and .95 with satisfaction with their performance as leaders. For a sample of Indian managers in an engineering firm and an American sample from high-tech companies, Waldman, Bass, and Einstein (1985) reported correlations of .72 and .81 between subordinates' ratings of the charisma of their leaders and the effectiveness of their leadership. This finding was in contrast to the correlations between rated effectiveness and how much contingent rewarding and management by exception the managers practiced. The average correlation between contingent reward and effectiveness was only .48. The correlation between ratings of the leaders' activity in practicing management by exception and the leaders' effectiveness was .06.

Gibbons (1986) obtained similar results in a computer firm; Bass (1985a) for New Zealand educational administrators and professional personnel. Yokochi Bryce (1989) for managers from 14 Japanese firms, and Boyd (1989b) for U.S., Canadian, and German NATO field grade officers. Similarly, Hoover (1987) reported correlations of .69 and .66 between the charisma on the MLQ of headmasters of private schools and their effectiveness and satisfied subordinates.

Seltzer and Bass (1987) obtained a correlation of .81 between charismatic leadership and effectiveness, according to 875 part-time MBA students who described their current boss, and according to the subordinates of 98 currently enrolled part-time MBA students. The correlation with satisfaction with the leader was .86. This correlation was considerably higher than the correlations of effectiveness and satisfaction with other measures of leadership behavior, such as consideration and the initiation of structure. A similar pattern emerged in determining how much stress and burnout was avoided in the subordinates of charismatic leaders (Seltzer, Numerof, & Bass, 1989). Among 264 retail chain-store employees, Peterson, Phillips, and Duran (1989) found that the MLQ charismatic leadership ratings they gave their supervisors contributed more to the

predictions of organizational commitment of the employees and their perceptions of the store's effectiveness than did any of the other leadership measures employed in the study—which included performance (P) and maintenance (M) leadership and initiation and consideration. Leaders with high charisma scores on the MLQ encouraged self-actualization among subordinates. Correlations between charisma and measures of subordinate self-actualization ranged from .43 to .65 (Seltzer & Bass, 1987).

*Caveat.* Much of the foregoing correlational evidence was from the same source, the leaders' subordinates. Avolio, Bass, and Yammarino (1988) showed that although the charisma-effectiveness connection was inflated, coming as it did from the same source, when one subordinate of the same leader provided the assessment of leadership and another the assessment of effectiveness, the connection remained, but to a lesser extent. Nor was the connection affected by a generalized feeling of satisfaction. Only about 10% of the measure of charisma could be accounted for by the bias of leniency (Bass & Avolio, 1988). In addition, superiors agreed that charismatics, as described by subordinates, were more effective (Hater & Bass, 1988). As was seen in [Table 21.1](#), superiors gave higher ratings of performance to managers whom subordinates had described as charismatic on MLQ-R, Form 5. As is shown in [Table 21.2](#), Yammarino and Bass (1989) found that better fitness reports and recommendations for early promotion from their superiors were earned by 186 naval officers whose subordinates had described the officers on MLQ, Form II as charismatic leaders. The subordinates' descriptions of the charismatic leadership of these officers, all graduates of the U.S. Naval Academy, were also predicted by the grades for overall military performance that the officers had earned at the academy.

In addition, subordinates' identification of charismatic leaders on the MLQ predicted independent objective criteria of the leaders' effectiveness. Onnen (1987) reported a substantial correlation between the parishioners' descriptions of charismatic Methodist ministers on the MLQ and the parishioners' Sunday church attendance. The charismatic leadership scores also correlated with the growth in church membership.<sup>5</sup>

*Simulated Business Competition.* The pattern of correlations was the same when the MLQ, Form 5 questionnaire was used by MBA students in a simulation to rate the presidents of 27 fictional companies. Each firm was composed of nine MBA students who were competing in a semester-long complex business game with students representing two other such firms. Although the business game ran for 12 weeks, it simulated eight quarters of business performance. Leadership ratings of each team's president were collected at the end of the eighth quarter. The success of the presidents and their firms was announced at the end of each of the first eight quarters. Although each company began with equivalent assets, companies led by presidents rated highly in charismatic leadership also performed significantly better on objective indexes of success such as returns on investment, stock prices, and share of the market. The results were the same when independent raters viewed videotapes of the company meetings to complete the MLQ to describe the presidents. The judgments of the raters of the videotapes were in agreement with those of the students who acted as colleagues of the company presidents (Avolio, Waldman, & Einstein, 1988).

*Conger-Kanungo Charismatic Leadership Questionnaire (CK).* To examine the behavioral and attributional components of their model of charismatic leadership to describe a leader, Conger and Kanungo (1994) distributed a refined questionnaire to 488 U.S. and Canadian managers in four organizations. Examples of the 25 items (Conger & Kanungo, 1988) with responses ranging from 6 = Very characteristic to 1 = Very uncharacteristic were: "Often incurs high personal costs for the good of the organization;" "Exciting public speaker;" "Uses untraditional means to achieve organizational goals." The researchers demonstrated their scale's convergent and divergent validities. Factor analysis exposed their elements of charisma: vision and articulation, sensitivity to environment and member needs, personal risk, unconventional behavior, and avoiding the status quo. The CK overall charisma scale has been found to be correlated 0.85 with the attributed charisma scale of the MLQ.

*Some Other Charismatic Leadership Scales.* Kouzes and Posner (1987) organized scales labeled

challenging the process; inspiring a shared vision; enabling others to act; modeling the way; and encouraging the heart. House (1997a) substituted *value-based* for charisma scales: articulation of a vision; communication of high performance expectation; displaying self-confidence; role modeling; showing confidence in and challenging followers; integrity; and intellectual stimulation. Behling and McFillen (1996) developed charismalike scales for displaying empathy, dramatizing the mission, projecting self-assurance to enhance image, assuring competency, and providing opportunities to experience success.

## A Dynamic Model of the Charismatic Process of the Leader, the Followers, and Their Social Interaction

---

Jacobsen and House selected six highly documented charismatic leaders (J. F. Kennedy, Theodore Herzl, O. C. Wingate, Lee Iacocca, Adolf Hitler, and Mary Baker Eddy) to develop a dynamic model (Forrester, 1961) to reproduce a time series of data for each of them so as to determine how well the data matched a theoretical integration of the charismatic process. The process involved integrating the leader, the led, and their interaction. The computer simulation began with the percentage of the followers who accepted the status quo, identified with the leader, were active, or were dedicated. Next to be entered were the time and the percentage who recognized the leader. This was followed by times and percentages of people aroused, then committed, disen-chanted, and defected. Finally entered were the times and percentages of followers who developed resentment and alienation as a consequence of bureaucratic regimentation. After the necessary estimates of parameters were included, 16 sets of data were successfully reproduced from the theoretical integration. The theoretical numbers accounted for 76.7% of the empirical data.

## Criticisms of Charismatic theory

---

As a religious concept that was adopted by Weber, charismatic leadership was explained by divine inspiration. Turner (1993) argued that the secularization of charisma by Weber (1922/1947) failed to explain the secular power of charismatics on the followers' expectations and internalization of changes in attitudes and behavior. Turner suggested that the charismatic offers a new vision of opportunities with risks and "provides through his or her own conduct evidence of the realizability of this vision through submission" (p. 235). Beyer (1999) argued that the neo-Weberian theories downgraded the power of the truly Weberian charismatic leader. She felt that the concept was a tamed version of charisma "diluted in its richness and distinctiveness" (p. 308). As noted earlier, she reiterated that five elements must be present for charismatic leadership to be seen: an extraordinary gifted person, a social crisis, a radical solution, transcendent powers, and repeated success. House (1999) agreed with Beyer that too much emphasis is placed on the effects of charismatic leaders on individual followers, compared with their effects on collectives or organizational performance. More attention needs to be paid to charismatic effects on radical change, specific follower behaviors, and different follower preferences in different situations. According to DiTomaso (1993), the post-1990 theories of charismatic leadership have "insufficiently used" the insights of Weber and Etzioni, for whom charisma is about wisdom. Furthermore, insufficient attention has been paid to the tension in the emergence and development of charisma. Calas (1993) faulted neo-Weberian theorists for omitting Weber's text on routinization of charisma and for upholding the wildest aspects of charisma. Hummel (1975) argued that charismatic leadership was not applicable to East Asian cultures. Shamir and Howell (1999) agreed with Bass (1997) and House, Wright, and Aditya (1997) that charismatic leadership can be found universally, to some degree, across cultures and countries. However, in many situations, the context may be particularly important to its emergence and

continuance.

Yukl (1999) saw ambiguity in the concept because of the differences in how charisma is defined and measured. Conger and Kanungo (1998) regard charisma as an attribution; Shamir, House, and Arthur (1993) viewed charisma in terms of the behavior of the charismatic leader and how the leader profoundly influences the followers. Bass and Avolio (1991) conceived of charisma as behavior and as an attribution in the MLQ scales of idealized influence (charisma). Charismatic theory placed too much emphasis on the dyadic leader-follower relationship and not enough on the leader-group relationship. Theorists of charisma looked more often at socially acceptable behaviors and avoided manipulative and political behaviors such as staging events and indoctrinating new members. They did not pay enough attention to how charisma is lost. Although the dark side of charismatic leadership is acknowledged (Howell, 1988), Yukl (1999) suggests there is a need for further clarification of conditions in which a charismatic leader is not desirable. For instance, the need for a charismatic leader may be contraindicated in a self-managed team. Moreover, due to insufficient research, we don't know how charisma is lost. How is charisma affected by the end of a crisis, or by the leaders' obvious failures and betrayals? What leads to hate, resentment, and alienation in the love-hate relation of followers with charismatic leaders?

## Inspirational Leadership

---

*Differences from Charismatic Leadership.* Although inspirational leadership is highly correlated with charismatic leadership, inspirational leadership does not necessarily imply that inspired followers resolve their intrapsychic tensions by identifying with the leader, forming a strong commitment to the leader with uncritical and unquestioning obedience, or attributing supernatural powers to the leader. The inspirational leader can symbolize or represent the follower's ego; the charismatic leader can substitute for the follower's ego ideal (Bass, 1988).

Followers perceive an inspiring leader to be knowledgeable, enlightened, and sensitive to the problems at hand, and from these perceptions, their confidence in the leader grows. Their trust in the inspiring leader arises from the meaning the leader can give to their needs and actions. Followers share with the leader common beliefs about what is wrong, beliefs the leader articulates publicly for them. Unlike the charismatic leader, who substitutes for the followers' ego ideal, the inspirational leader provides symbols for it. Inspirational leaders help followers feel more powerful by setting forth desirable goals and providing the means to achieve them (McClelland, 1975). Also, inspiring leaders may serve well as spokes-persons or representatives of their group. Winter (1967) showed business students a film of President John F. Kennedy presenting his inaugural address. The stories that the students were asked to write after seeing the film were contrasted with those written by other students who saw a film about modern architecture. Kennedy inspired an uplifting of spirit and an elevation in the students' sense of power, not the usual responses to charisma—obedience, loyalty, and submission.

Charismatic leaders are more likely than inspirational leaders to be regarded with awe and a sense of mystery, and to be considered infallible. But Tepper and Percy (1994) factored a 24-item version of the MLQ and concluded along with Bass (1985a) that charisma and inspirational leadership form a single construct. A serious problem in meaning for the followers creates the possibility that an inspirational leader will emerge.

Although conceptual distinctions between charismatic and inspirational leadership can be made, they may be difficult to establish empirically. In military and industrial surveys of subordinates' descriptions of their superiors on questionnaires, Bass (1985a) was unable to obtain a consistent inspirational factor that was separate from a factor of charismatic leadership. According to Fromm (1941, p. 65), the charismatic leader not only embodies a more extreme and clearly defined personality for those who identify with him but is able to

“arrive at a clearer ... outspoken formulation of ... ideas for which his followers are already prepared psychologically.”

In reality, charismatic leaders tend to be highly inspirational, although inspirational leaders may not be charismatic. Inspirational leaders who are effective would be *outstanding* leaders as defined by House (1999) and Fromm (1941, p. 65). In contrast to typical leaders, outstanding leaders can articulate the mission of their followers, have the capacity to act efficiently, have conceptual and analytic skills, and are self-confident (Nygren & Ukeritis, 1993).

### ***Behavior of Inspirational Leaders***

As with charismatic leaders, the behavior of an inspirational leader may be perceived as inspirational by one person and as hokum by another. What is challenging for one follower is easy and dull for another. The inspirational leader needs to have insight into what will be challenging to followers, and why. Inspirational leaders set challenging objectives; align followers with a sense of mission; use symbols and images cleverly to get ideas across; mold followers' expectations; provide meaning for proposed actions; point out reasons why followers will succeed; remain calm in crises; appeal to feelings; call for meaningful action; emphasize beating the competition and cooperating with collaborators; envision an attractive, attainable future; and articulate how to achieve that future. They provide and manage meanings, build confidence in followers, encourage sharing of goals, instill pride, take calculated risks, and are positive. They focus on “the bright side of things” (Avolio & Bass, 1991). Inspirational leaders in a situation requiring teamwork and cohesion selectively try to arouse followers' need for affiliation; in a situation requiring followers to persuade others, the leaders try to arouse the power motive in their followers (House & Podsakoff, 1994).

Inspirational leader express goals that their followers want to attain (McClelland, 1975). But the leaders need to express vivid goals that strengthen and uplift the followers (DeCharms, 1968). Such leaders “conceive and articulate goals that lift people out of their petty preoccupations, carry them above the conflicts that tear a society apart, and unite them in the pursuit of objectives worthy of their best efforts” (Gardner, 1965b, p. 98). According to Yukl and Van Fleet (1982, p. 90), inspirational leadership “stimulates enthusiasm among subordinates for the work of the group and says things to build their confidence in their ability to successfully perform assignments and attain group objectives.” Inspirational leaders encourage followers' self-expression and enhance their self-efficacy with positive feedback and expressed expectations about their performance. Group efficacy is also encouraged in the same way.

Inspirational leadership was mentioned frequently in 1,511 critical incidents collected by Yukl and Van Fleet about the behavior of effective leaders in the ROTC, and in 129 such incidents about U.S. Air Force officers during the Korean War. The inspirational behavior of leaders included instilling pride in individuals and units, using pep talks, setting examples of what is expected with their own behavior, and building confidence and enthusiasm. In these critical incidents, inspirational leadership behavior correlated with objective measures of effectiveness as a leader.

High levels of activity, coupled with strong self-confidence, determination, ego ideals and a sense of mission, were seen to lie behind the inspiring success of CEOs in turning around their organizations. Peters (1980) reported on 20 companies that had “executed major shifts in directions with notable skill and efficiency. Their CEOs chose a single theme and almost unfailingly ... never miss[ed] an opportunity to hammer it home.” They consistently supported the theme, usually over a period of years. In this way, they orchestrated a shift of attention throughout management. According to 413 management students, a good president of the United States exhibits the same kinds of inspirational qualities as a good CEO. Such good leaders share high levels of energy, active involvement, and articulateness (Butterfield & Powell, 1985).

Similarly, Fahey and Harris (1987) reported on the inspirational aspects of effective leadership in the U.S. Navy. Nearly 30 naval commands were nominated for their excellence by 300 naval officers. A total of 600 interviews were then held with the officers and enlisted personnel. Among other things, the leaders of these excellent commands were described as “passionate about their mission,” and the message they gave to their commands was that everyone could be a winner. High standards were to be maintained. Like the CEOs, they had points of focus such as safety and cleanliness when they made face-to-face contact throughout their commands.

Vaill (1978, p.110) found that members in high-performing systems could relate “peak experiences in connection with their participation. They were enthused and communicated joy and exultation.” When elated by inspiring leaders, euphoric subordinates would accept increased risks.

[Familiar are] ... the stirring preachers of evangelism, the lectern-pounding political orators, and the rousing after-dinner speakers. ... Much of this arousal has been institutionalized in anonymous media messages. Social and political movements ... depend heavily on transforming a passive, inactive constituency into an aroused, excited, active one. (Bass, 1985a, p. 66)

Listening to audiotaped inspirational speeches, such as Winston Churchill’s speech about Dunkirk, Thomas Jefferson’s first inaugural address, and Henry V’s St. Crispin’s Day speech at Agincourt in Shakespeare’s play, generated more activation among subjects (according to their responses to an adjective checklist and their urinary epinephrine level—a physiological indicator of activation) than did listening to audiotaped travel lectures. However, the inspirational speeches also increased the subjects’ need for power, which was reflected subsequently in their stories on the Thematic Apperception Test, or TAT (Steele, 1973, 1977; Stewart & Winter, 1976).

Inspiring leaders have the ability to influence subordinates to exert themselves beyond their own expectations and self-interests. That extra effort is inspired by the persuasive appeal of the leaders’ language, symbols, images, and vision of a better state of affairs. It is stimulated by the subordinates’ perceptions that they and the leader have common purposes. It is reinforced by various ritualistic institutional practices and by peer pressure.

As Conger (1991) noted, the vision has to be framed in words that amplify values, beliefs, and the importance of the mission. Would-be inspiring leaders have to communicate the vision powerfully. They must use rhetoric that can energize through the words chosen. They use metaphors, analogies, and stories to convey the message. Alliteration, cadence, and repetition strengthen what is sensed. The main overlapping components of inspirational leadership behavior can be seen to include managing meaning, molding followers’ expectations, envisioning, and intellectually stimulating followers.

### ***The Management of Meaning***

Den Hartog (1997) suggested that inspirational leadership infuses work with values and increases the enthusiasm and commitment of followers by making the work more meaningful. Thus goals are presented in terms of their values. This makes accomplishment of the goals more meaningful to followers. Increased meaningfulness increases their willingness to expend effort to achieve those goals.

Heifetz and Sinder (1987) found a high degree of agreement among several hundred elected, appointed, and career officials at the local, state, and federal levels of the U.S. government, foreign government officials, military officers, and managers in the private sector when these respondents were asked what their constituents expected of them. Many answered that their constituents expected inspiration, hope, consistency, direction, and order. What the leaders felt was most often expected of them was that they would provide their constituents with meaning, security, and solutions to problems. This ability to manage meaning was seen by

Smircich and Morgan (1982, p. 261) to be particularly important to a leader:

Leadership works by influencing the relationship between figure and ground, and hence the meaning and definition of the context as a whole. The actions and utterances of leaders guide the attention of those involved in a situation in ways that are consciously or unconsciously designed to shape the meaning of the situation. They ... draw attention to particular aspects of the overall flow of experience, transforming what may be complex and ambiguous into something more discrete and vested with a specific pattern of meaning. ... They ... frame and shape [and “punctuate”] the context of action in such a way that the members of that context are able to use the meaning thus created as a point of reference for their own action and understanding of the situation.

The leader must be able to deal with the equivocalities of many interactive situations and the interpretive schemes of those involved. The leader must then “embody through use of appropriate language, rituals, and other forms of symbolic discourse, the meanings and values conducive to desired modes of organized action” (Smircich & Morgan, 1982, p. 269). Levinson and Rosenthal (1984, p. 284) agreed: “The fundamental communication [by leaders] is that of the meaning of the organization.” The meaning is found in the image of the organization, its place in the environment, and its collective purpose.

Inspirational leaders compare their groups with various referents such as: (1) competitors—“we can do better than all of our competitors;” (2) ideals—“we can achieve our best performance;” (3) goals—“we can attain whatever we set our minds to do;” (4) the past—“we can do better than we’ve done before;” (5) traits—“this is what we should look like;” and (6) stakeholders—“we can make our employees our strongest advocates.” New meaning can be provided by unfreezing old interpretations and creating new ones. New languages, new jargons, new lexicons, and new arrangements can be introduced to provide the new meanings (Cameron & Ulrich, 1986). All these efforts of the inspirational leader serve to increase the *frame alignment* of followers and leaders, linking their interpretive orientations (House & Podsakoff, 1994).

Inspirational leadership has also been equated with demagoguery, manipulation, exploitation, and mob psychology, for it tends to involve an emphasis on persuasive appeals and emotional acceptance. Riker’s (1986) switching tactics may come into play. Meaning may become convoluted in the leader’s efforts to resolve the rhetorical problems facing his or her followers. Simons (1970) listed the ways in which leaders of social movements may resolve rhetorically the problems a social movement has in attracting and maintaining followers, securing the adoption of its program by the larger society, and dealing with resistance from the larger entity. The radical goal images the leaders depict may be crossed with the conservative ways they propose to attain them. Or the leaders may disavow the radical program they seek to achieve to gain a more widespread, diverse following. Insistence on maintaining the movement’s values may require abandoning the tactics that would implement its program. Ethics give way to rationalized expediency.

Ideology built on logic gains intellectual respectability, but mass followings may find more meaning in oversimplified, magical beliefs about solutions to problems. Folk arguments, myths, and deceptions replace logical exposition.

### ***Use of Symbols***

Inspirational leaders make extensive use of symbols—representations of chunks of information. Symbols are signs that represent sets of cognitions. The cognitions are linked by overlapping functional associations (Eoyang, 1983). But as Tierney (1987) noted, symbols are more than objectifications of meaning. They are strategies for understanding, for making sense, consciously or unconsciously, of the organization or the environment. Leaders justify their existence and actions by their insignia, formalities, stories, ceremonies, conferences, and appurtenances. The symbols mark them as the center of attention and influence (Geertz,

1983). Inspiring leaders select relevant gestures and symbols to convey their message. They also use paradoxical and counterintuitive symbols to communicate their vision for the future (Lipman-Blumen, 1996).

Tierney (1987) collected interview data from 32 college presidents to focus attention on their symbolic purposes and performance. The presidents talked about themselves as metaphors. For example, they said that they provided “the glue so that their organization stuck together.” They would give a personal computer to every faculty member as a physical symbol that teaching was going to be changed at the institution. The personal computer could become as much of a physical symbol as the school tie. Presidential concern was symbolized by the practice of walking-around management, knowing every faculty member by his or her first name, or meeting students “on their own turf.” Structural innovations, such as the creation of task forces, symbolized the prospect of a new broom for sweeping the organization clean. The president was a personal symbol of the campus when speaking to the community. He or she converted ideas about the institution’s values into images that could be symbolized; thus, the diploma mill was changed to the seat of learning.

Symbols provide a greatly simplified message that can have inspirational meaning. For instance, the cross symbolizes Christianity, as well as its emphasis on suffering, sacrifice, and redemption. Gandhi’s spinning wheel symbolized Indian self-reliance, the value of cottage industries, the rejection of the British raj, and the demand for India’s independence. Confusing, contradictory, or ill-understood ideas can be made into a coherent whole through symbols. Inspirational leaders substitute symbols, as well as slogans and simple images, for complex ideas. The metaphor of a row of falling dominoes substituted for the complexities of the Cold War. The slogan “Never again!” conveys 2,000 years of Jewish history, the Holocaust, and the rebirth of Israel. “Inshallah” conveys the Muslim’s fatalistic submission to God’s will. The conservative dress code for IBM employees, instituted by Thomas J. Watson, Sr., was intended to impress customers and employees alike. The code symbolized dedication to service, uniformly high quality, and seriousness of purpose. Social and organizational realities are created from such codes and symbols (Stech, 1983).

The replacement of old symbols by new ones helps people recall new ideas and beliefs with new emotional values. For example, the Iranian revolutionaries who marched with flowers sticking out of their rifle barrels to signify a new era of peace and brotherhood marched again against Iraq with headbands to signify their readiness for martyrdom and war to the death. Symbols can stand for inspirational solutions to problems. In communist societies, the hammer and sickle signify the worker and peasant. The 50 stars and 13 stripes in the American flag signal the federation of the original 13 sovereign states and the current 50 states. Inspirational leaders use symbols to draw attention to their leadership. The “crowns and coronations, limousines and ideas come together with leading institutions. The important events within the arena are seen by followers as what “translates intentions into reality” (Bennis, 1982, p. 56).

## ***Management of Information***

Impression management is aided by the fact that people are willing to draw inferences about the personal characteristics of others with only limited information (Schneider, Hastorf, & Ellsworth, 1979) about their physical appearance, expectations from the role or status, or expressive behavior, such as facial expressions (Goffman, 1959) and vocal intensity (Allport & Vernon, 1933).

Television has both helped and complicated the building and maintenance of images. Thus a short presidential candidate may have to avoid being seen with a tall opponent in a television debate, and may arrange to stand on a higher platform to make his height equal to that of taller candidates. The brevity and selective editing capabilities of television can be used to protect the leader’s image, but the live camera is also a force for bringing reality into the living room. Events that are favorable to the person’s image can be staged, but events that are unfavorable to the image can also dramatically show up, as if the leader were face-to-face

with supporters. Impression management is effective up to a point; it then can backfire or have a boomerang effect (Jones & Wortman, 1973). According to a field survey of direct observations by Gardner and Martinko (1988), high school principals who flattered people more often were less adequate in their performance than were those who talked more about the organization.

Gardner and Martinko agreed with Schneider (1981) that the management of impressions is achieved through “the manipulation of information about the self by the actor,” but it also can be achieved by manipulating information about the organization that the impression manager leads. The presentation can be verbal, nonverbal, or in the form of artifactual displays such as dress and office decor. The preferred targets of the principals’ verbal presentations about themselves were their superiors. The principals were more apologetic to familiar than to unfamiliar listeners, and used descriptions of their organizations and of themselves more frequently in dyadic than in group settings and in interactions with those outside their organization than those inside it.

The annual reports of CEOs to stockholders are often efforts to impress the stockholders with the quality of the firms’ performance and future. Salancik and Meindl (1984) examined the annual reports of 18 U.S. corporations over an 18-year period and concluded that those CEOs whose firms operated in unstable environments and who therefore lacked real control over the organization’s annual focus emphasized how much they were in control over organizational outcomes. For instance, they announced executive changes to imply that management was dealing with the organization’s unstable environment. But these impressional explanations had a positive impact on the future performance of the firms that used these tactics. A similar effect was achieved by a bogus professor who delivered a nonsensical lecture on the application of mathematical game theory to the education of physicians. The bogus professor (a trained actor) was introduced to his audience as having degrees and publications (all of which were phony). The lecture consisted of double-talk, contradictory statements, seductive gestures, humor, and meaningless references to unrelated topics. The “professor” earned high ratings from the 55 students, none of whom detected the hoax. However, when videotapes of a similarly seductive lecture included valid content, students actually learned more of the content from the seductive lecturer (Scully, 1973).

Kerman and Hadley (1986) described in detail how the images of political candidates are created by media consultants. The consultants begin with analyses of the current image. For example, Jay Rockefeller, a West Virginia gubernatorial candidate in 1980, began as an individual whom the public saw as unforceful, ineffective, and a stranger—neither as a leader nor a friend. As a member of the Rockefeller family, he was judged to be cold, elitist, uncaring, and manipulative. The media consultants carefully planned what Rockefeller would say, how he would say it, and when. They determined the exact language and terminology he would use in his speeches, press releases, and television commercials; the specific issues and subject matter that he would communicate to the voters; and his physical appearance, including his haircut and style of clothing. At the end of the campaign, the image of Jay Rockefeller was that of a casual, down-to-earth, warm, open, and friendly person. Even as a member of the Rockefeller family, he was not seen as powerful, forceful, effective, or influential. A Democrat, he won the election decisively, despite the Republican landslide everywhere else, in the wake of President Reagan’s election in 1980.

Much of the successful political career of George W. Bush, twice elected governor of Texas and twice elected U.S. president, was attributable to the astute media manipulations directed by his advisor Karl Rove.

### ***Molding Followers’ Expectations***

Livingston (1969) called attention to the effects in management of interpersonal expectancies. According to Edwards (1973), the most effective supervisors are those who can create high expectations for performance for

subordinates to fulfill. Less effective supervisors fail to develop such expectations. And the more ambiguous the criteria for evaluating the group's performance, the greater is the leader's influence in defining expectations about the situation. Arvey and Neel (1974) showed that the performance level of 130 engineers was a function of their expectation that their effective performance of their jobs would be rewarded and that their supervisor was concerned about their performance. Likert (1961a) also emphasized the importance for superiors to communicate their high expectations to their subordinates.

As molders of expectations, inspirational leaders can redirect their organizations with clear agendas of what needs to be done. They know enough not to be satisfied with easy cures or apparent panaceas. They also are able to avoid letting their enthusiasm trap them into creating unreasonable expectations in their subordinates and un-invited acceptance of their ideas (Tichy & Devanna, 1986). Harold Geneen, the former CEO who built IT&T, saw himself as setting high expectations in a number of ways. He considered himself a leader who established hard, challenging goals for the organization and who served as a model of hard work and long working hours for his subordinates (Geneen & Moscow, 1984). Kanter (1983) reported on 200 "change-masters" (leaders who successfully changed their groups). They led their teams to expect to share in the credit for the results of the changes. After the changes, they continued to inspire, encourage, and stimulate the teams who worked with them.

Closely allied to the preceding expectation setting is Vaill's (1982) concept of *purposing*, a continuous stream of actions by inspiring leaders in complex organizations that induces clarity, consensus, and commitment regarding the organization's basic purposes. Leaders of a high-performing system define and maintain a sense of purpose among all members of the system. Purposing is seen when the members can develop and express deep feelings about the system, its aims, its people, its history, and its future, and therefore can focus on the issues and variables in the system that make a difference in its performance.

*Enabling and Empowering.* Followers' expectations about what they may accomplish can be increased if their leader obtains or shows them how to obtain the resources that will enable them to reach their higher goals. Or the leader may reduce or remove constraints or show the followers how to do so. For instance, the leader can focus attention on the technical, political, and cultural resistance to change and can work with followers to overcome such resistance. Threats can be turned into opportunities. The expectations of followers can also be raised by the leader's nonverbal behavior toward them. When in discussion with followers, leaders can avoid keeping the followers waiting, avoid using furniture as a barrier, make frequent direct eye contact, sit or stand close, nod their head rather than tilt it backward when the follower is speaking, smile frequently, and avoid sounding bored and uninterested (Baird & Weiting, 1979).

Followers can be empowered by increasing their autonomy and discretionary opportunities and getting support from higher authority for their efforts. Leaders can arrange for key employees and higher authorities to signal their public commitment to new goals. Encouragement and involvement can be stressed at all levels. Structure and systems can be modified to enable and empower subordinates to stretch to achieve greater accomplishments (Cameron & Ulrich, 1986).

Leaders can promote enabling by stressing that everyone can be a winner through constant learning and improvement. Risks can be taken, and mistakes can be tolerated. Performance can be steadily improved by incremental demands on subordinates. For starters, a half-mile run can be achieved by everyone. Then a mile run can be accomplished. Ultimately, everyone can run seven or eight miles (Harris, 1987). Enabling and encouraging others to act, and showing the way, requires inspiring a shared vision (Kouzes & Posner, 1987).

*The Pygmalion and Galatea Effects.* The Cyprian king Pygmalion fell in love with the beautiful statue he had carved. Aphrodite turned the statue into a real woman, Galatea. Pygmalion's fantasy about Galatea became a living reality.

The Pygmalion and Galatea effects have been seen at school and work. What teachers expect of their pupils and what managers expect of their subordinates influences the pupils' and subordinates' performance and

progress. In turn, pupils and subordinates tend to do what they believe is expected of them (Livingstone, 1969). These effects were first demonstrated in experiments by Rosenthal and Jacobson (1968) in relation to school-teachers' expectations about their pupils and their pupils' intellectual gain in test scores over a period of eight months. King (1971) showed that, compared with controls, employees fictitiously identified to their supervisors as of high aptitude achieved higher appraisals, higher retention and peer ratings, and lower absenteeism. Chapman and McCaulley (1993) looked for the Pygmalion and Galatea effects in a large-scale study with unobtrusive measures and without needing any interventions or manipulation. For 3,234 students, they found that those who received National Science Foundation fellowships, compared with those who did not receive them, were much more likely to graduate four or more years later. Both their own and their professors' expectations were raised. An uncontrolled factor was how the NSF award provided financial freedom and greater access to departmental support.

McNatt (1997) conducted a meta-analysis of 19 studies with 7,542 subjects in management or organizational settings supporting Pygmalion effects, which accounted for 2% to 6% of the differences in outcomes. In 11 military studies, the Pygmalion effect accounted for 5% of the differences between experimental and control groups. In eight nonmilitary studies, the comparable figure was 2%. Eden (1988b) suggested that the mediating variable is self-efficacy. Positive expectations increase self-efficacy, which leads to improvement.

Rosenthal (1994) noted that by 1994, 464 experiments had been completed examining Pygmalion effects. The interpersonal expectancy effects have been found influential when experimental treatments have been compared with controls in many other diverse settings. Subjects included judges who believed the defendant was guilty when they instructed juries, and for nursing home caregivers ameliorating depression in patients.

Groups can increase their effectiveness by harnessing the Pygmalion and Galatea effects (Eden, 1984). Leaders who have confidence in their subordinates set difficult goals and arouse the subordinates' expectations about achieving these goals (Eden, 1988). Doing so encourages the self-fulfilling prophecy among the subordinates that they will succeed and, as a consequence, actually increases the likelihood that they will attain the goals (Livingstone, 1969). Eden and Shani (1982) found that the performance of leadership trainees in a field experiment in the Israeli Defense Forces was improved by building up their instructors' positive expectations about them. The 105 trainees were assigned at random to one of three conditions: high, regular, or unknown "command potential." The instructors and assistants were led to believe that each trainee had one of the three levels of command potential. The *expectancy induction* accounted for 73% of the variance in the trainees' objective achievement scores. Similar effects occurred for the trainees' attitudes. Those in the "high-potential" condition reported greater satisfaction with the course and more motivation to go on to the next course. The instructors' expectations about the performance of the trainees appeared to transfer to the trainees' self-expectations. This is the Galatea effect. When 20 sales supervisors of 259 salaried sales employees were told which of their employees were supposedly "exceptional" (actually a random designation), the Pygmalion effect emerged in the employees' sales performance over the next three months as well as in higher evaluations of their performance and in higher self-expectations (Sutton & Woodman, 1989). Atwater (1988) showed that supervisors' social and supportive leadership behaviors were correlated .48 and .38, respectively, with what the supervisors felt their bosses expected of them. Eden (1988a) suggested that Pygmalion induction can be used with supervisors of new hires, as was done for an assembling and packaging unit in an Israeli production plant. The plant manager told the production manager that he had personally selected the new hires, and that they were all excellent workers who should give the supervisor no problems and should attain standard production levels quickly. Actually, these workers were chosen at random, as were the workers in the control group. The experimental group reached standard production before the controls and went on to exceed it.

To test the Galatea effect, Eden and Ravid (1982) had a psychologist inform trainees in advance that they had "high, regular, or unknown" command potential. Then the psychologist withdrew. Instructors were not

preconditioned. Trainees who were given the most positive messages about their “command potential” did better. Ignoring the sex differences, Eden (1984) concluded, as had Locke, Latham, Saari, et al. (1981), that managers need to be shown the utility of encouraging their subordinates with hard goals and high expectations.

Findings were only modest for seven field training experiments by Eden, Geller, Gerwitz, et al. (2000). Managers were trained in the “Pygmalion leadership style” to convey high performance expectations to subordinates, create a supportive climate, and attribute subordinate success to stable internal causes. The mean effect size with 61 effects of the training for leaders and followers was only .13.

Some of the earlier Pygmalion results were questioned because of inadequate methods. For instance, expectancy manipulations were weak and unchecked. Other results were found to be due mainly to moderator variables, as when only those of low achievement were influenced and nonverbal effects were uncontrolled (McNatt, 1997). Rosenthal (1974) observed that teachers of high-expectancy children provided a more supportive climate, harder materials to be learned, verbal and nonverbal cues, more time, and more feedback.

*Metharme Effect.* Metharme was Pygmalion and Galatea’s daughter, the result of a self-fulfilling prophesy. Field (1989) proposed that leaders’ prophesies could be self-fulfilling or self-defeating, depending upon the leader’s optimism or pessimism about the follower and the follower’s positive or negative reactions to the leader. If the leader’s prophesy was optimistic and the follower reacted positively, the Pygmalion effect would emerge. But if the leader was pessimistic and the follower was *counter-dependent*, a positive outcome was also possible. The prophesy could also be self-defeating despite the leader’s optimism if the follower reacted negatively and the anticipated outcome was suppressed. If the leader was pessimistic and the follower negative, outcome failure would be confirmed by the prophecy.

*Golem Effect.* The golem was a legendary automaton—an inadequate person created by a cabalist rabbi. The leaders of inadequate persons, known underachievers, expect less of them, and the underachievers perform accordingly. However, greater effects for improvement can occur with underachievers than others if there are upper limits of performance and if the leaders’ and underachievers’ expectations are raised. This golem effect was demonstrated by Babad, Inbar, and Rosenthal (1982). In McNatt’s (2000) meta-analysis for 1106 cases from eight studies, the golem effect accounted for 15% of the differences between experimental treatments and controls.

Female trainers of 20 squads totaling 225 soldiers in a special program for disadvantaged 18-year-old women (with limited schooling and substandard or borderline qualifications, from disadvantaged families, and of low socioeconomic status) who enlisted in the Israeli Defense Force were divided into an experimental group and a control group. Davidson and Eden (1997) observed the golem effect in the 10 squads who served as the control group. The low outcomes achieved by the controls were explained by the trainers’ low expectations of the special program recruits. But the squad trainers who were led to believe that the underprivileged women had high potential avoided the golem effect. The trainers’ expectations were much higher and the trainees’ expectations, motivation, and performance were significantly higher than those of the controls.

## ***Impression Management***

Self-presentation is a natural part of social interaction (Goffman, 1959). Impression management involves what we do in social interactions to create and maintain desired impressions of ourselves in others (Schlenker, 1980). It is the attempt to control the image others have of us (Rosenfeld, Giacalone, & Riordan, 1995). It may be an honest self-presentation or it may be deceptive (Gardner & Avolio, 1997). Such impressions will affect how much we are esteemed by others and, therefore, how much we can be successful in influencing them.

Wayne and Ferris (1988) arranged for 96 undergraduates to serve, in turn, as the supervisor of a confederate of the experimenters. The confederate acted as a subordinate in a simulated work setting in which mail orders were processed for a catalog firm. Compared with a control, the supposed subordinate impressed each of the 96 student subjects with self-enhancing communications, flattery, conformity, and doing favors for the supervisor. The subordinate's use of impression management substantially increased the supervisor's liking and appraised performance of the subordinate, as well as satisfaction with the exchange relationship. The same kind of impression management by bank employees was reported in a survey of how much these subordinates reported they praised their supervisor and did personal favors for him or her. According to the 23 supervisors of the 84 bank employees, those employees who practiced impression management were better liked by the supervisors. Being better liked, in turn, resulted in higher performance appraisals for the subordinates and more satisfying exchange relations. Impression management may also involve creating and maintaining desired impressions about organizations to promote the loyalty and commitment of others to the organizations.

The ability to impress others is affected by physical distance, demographic dissimilarity, and reduced network centrality. Barness, Diekmann, and Seidel (2002) obtained results indicating that—contrary to their expectations—among 98 subordinates and their 29 supervisors, the more the pairs of subordinates and supervisors worked in different physical locations as members of an Internet firm, the more the subordinates used impression management in their communications. If subordinates differed in age, they were less likely to try to ingratiate themselves with their supervisors; but if subordinates differed in sex, they were more likely to try to impress their supervisors. These relationships were affected by the familiarity of the subordinates with the other members of the firm.

Although some of the political leaders Willner (1968) studied were primarily men of action and not of a scholarly bent, Willner wrote of “their capacity to project the image of unusual mental attainments.” These leaders could seize on information and ideas from many sources and, with their excellent memory, they would convey the impression of possessing a powerful mind and a wide range of knowledge. Franklin Delano Roosevelt and Benito Mussolini, for instance, used their prodigious memories to impress listeners. Horatio Nelson was a master of impression management and “took care to foster his own legend.” He arranged for his after-action dispatches to be leaked immediately to the press and for his image to appear on souvenirs. At the same time, Nelson was extremely competent, and developed new strategies that were employed by the British Navy for a hundred years following his death at the Battle of Trafalgar in 1805. He reinforced the confidence of the fleet's personnel when he signaled his fleet that “En gland expects every man to do his duty” (Adair, 1989).

It is a leader's *perceived* competence that determines whether his or her attempts to influence will be accepted by followers. Impression management is an important requirement for building followers' confidence in leaders (Adams & Yoder, 1985). To some degree, one's success as an inspiring (as well as charismatic) leader may be due to how one presents oneself to the other members of the group (Goffman, 1959). For example, if would-be leaders give the impression that they have had previous experience (even if they have not) with the group's task, their views are more likely to be accepted. Of course, they have to be credible. In the same way, by paying attention to their own dress and speech, by an appropriate amount of name-dropping, by being seen with the “right” people, and so on, leaders can raise their esteem in the eyes of their fellow members, which will contribute to their followers' confidence in them. Political leaders, in contrast to statesmen, stand or fall at election time on how well they and their staffs manage the public's impressions of them. For example, President Gerald Ford actually was successful in bringing inflation down and reducing unemployment. However, he failed to win a full term in office after his appointment to a first term following Nixon's resignation. This was partly because he lacked communication skills, and the voting majority in 1976 perceived him to be the cause of a recession he actually had inherited (Sloan, 1984).

The president's wife is another illustration of the management of impressions. Her loyalty, discipline, and

circumspection are all dramatically, and continually, presented to the public. (Caesar's wife must be above reproach.) The wife's visible presence alongside the president in rituals of public leadership assures the viewer symbolically of the morality and trustworthiness of the president (J. B. Gillespie, 1980). The damage done to Bill Clinton's popularity by his sexual peccadilloes was offset to a considerable degree by his wife, Hillary Rodham Clinton, who continued to stand by him. Such damage control to protect the public impression of political leaders is often the work of "spinmasters" who quickly offer alternative explanations for the leader's misbehaviors.

Gardner and Avolio (1997) note that just as leaders may want to impress followers, so followers may want to impress their leaders. Leaders more often use tactics such as exemplification and self-promotion; followers use ingratiation and supplication more often (Jones & Pittman, 1982). Exemplification was most frequently used by charismatic world leaders, according to a biographical study of them (Gardner & Cleavenger, 1996). Gardiner and Martinko (1988) suggested that followers were most likely to use ingratiation. Ronald Reagan exemplified traditional American values; Nelson Mandela exemplified the victim of oppression who could forgive and forget.

Leaders often engage in self-promotion so that followers can attribute to them expertise, esteem, and power. In turn, leaders seek to project their power as well as to be seen by followers as influential, innovative, and unconventional. Followers may cue leaders about their uncomfortable uncertainty about a situation; leaders may respond by impressing followers with their knowledge about how to handle the situation and their self-confidence in doing so. But such self-promotion may be overdone, and the leaders' attributed good qualities may be diminished. Charismatic leaders are particularly skillful in deflecting threats to their reputation. Ronald Reagan was labeled the Teflon president because numerous scandals in his administration could not stick to him (Gardner & Avolio, 1997).

Leary and Kowalski (1990) conceived of two separate processes to describe impression management: the motivation to impress others and the impression the leader (or follower) tries to construct. The motivation depends on the goals sought by impressing others, the value of the outcomes sought, and the discrepancy between current and desired impressions held by others. The construction of the image depends on the leader's (or follower's) self-concept, the desired images of their identity, role constraints, the others' values, and their current social image. Indirect managing of impressions was connected by Andrews and Kacmar (2001) with factored scales of boasting, blurring, blaring, and burying. Bratton, Carlson, Witt, et al. (2003) reported that impression management influenced performance appraisals in highly political environments, but not in nonpolitical environments.

Nguyen and McDaniel (2001) conducted a meta-analysis of the impact of various tactics used to impress others. They accumulated 20 studies in work settings in which they found, for 220 to 3,870 employees, mean correlations between the effects of impressing others and various outcomes. Interviewers were most affected by job applicants' impression management ( $r = .50$ ). The use of ingratiation by applicants correlated .43 and the use of self-promotion correlated .59, on average with interviewer ratings. Being liked by peers and appraisals of promotability were unaffected. Modest effects were found for employees being liked by supervisors ( $r = .29$ ) and performance appraisals from their supervisors ( $r = .22$ ). When various tactics used to impress others were combined for 19 correlations and 2,072 employees, a mean corrected effect of .22 was obtained. With 18 available correlations for 918 employees, a mean corrected effect of the use by subordinates of ingratiation on their supervisors' performance appraisals of them was .27.

*Image Building.* Impression management reaches its peak in image building. This was seen by House (1997) as an important behavior of the charismatic leader. Gardner and Avolio (1997) also regarded image building as critical to charismatic leaders to build and maintain their reputation in the eyes of their followers. When contact with political leaders is mainly through interviews on television and the leader's image is systematically modified to suit the feedback obtained from public opinion polls, the voting public responds to

the image created for that purpose. The 1988 Bush-Dukakis presidential election campaign clearly showed the manufacturing of images of leadership that were unrelated to reality. George H. W. Bush, the conservative “wimp,” was converted overnight into the strong, decisive, patriotic, religious, forceful law-and-order candidate, who stood for mainstream American values of family, patriotism, and support of education and the environment. Michael Dukakis, the low-key pragmatist, was converted into a liberal ideologue by the same myth makers. Dukakis was pictured as a “card-carrying” member of the American Civil Liberties Union who furloughed murderers to repeat their crimes, would take away citizens’ rights to own guns, and opposed the recital of the Pledge of Allegiance in public schools. Continued polling and the election itself reflected the extent to which voters chose one image over the other, rather than one person over the other.

## ***Envisioning***

Envisioning a desired future state and showing followers how to get to it are basic components of the inspirational process. They require not only technical competence but artistry and creativity. Despite the thoroughness of the data and the complexities of the problem, the capable inspiring leader can reduce matters to a few key issues before asking others to consider what is to be done. Doing so does not necessarily mean advocating simple solutions; rather, it means that complex problems are organized into a few central themes for examination (Tichy & Devanna, 1986). Envisioning is particularly important when the group or organization is facing illstructured problems (Mitroff, 1978). Planful opportunism in leaders “can turn unpredictable events into building blocks of change” (Tichy & Devanna, 1986, p. 94). Inspiring leaders look ahead optimistically despite the current uncertainties of internal and external threats to, and opportunities for, the organizations. Yet Bruce (1986, p. 20) noted:

In the minds of CEOs ... the vision is never clear, only a foggy haze and a multitude of conflicting signals. We see the future darkly, while ignorant armies of experts shout across a smoky field at one another.

Envisioning is the creating of an image of a desired future organizational state that can serve as a guide for interim strategies, decisions, and behavior. It is an important function in the public as well as private sectors (Berger, 1997). It is fundamental to effective executive leadership. Without the ability to define a desired future state, the executive would be “rudderless in a sea of conflicting demands, contradictory data, and environmental uncertainty” (Sashkin, 1986, p. 2). Envisioning integrates what is possible and what can be realized. It provides goals for others to pursue and drives and guides an organization’s development (Srivastva, 1983). Bennis and Nanus (1985) concluded, from in-depth interviews with 90 top directors and executives, that envisioning requires translating intentions into realities by communicating the vision to others to gain their support. Envisioning is the basis for empowering others, for providing them with the “social architecture” that will move them toward the envisioned state. It involves paying close attention to those with whom one is communicating, zooming in on the key issues with clarity and a sense of priorities. Risks are accepted, but only after a careful analysis of success or failure. However, it should be noted that envisioning focuses more on success than failure and more on action than on procrastination. Baum, Locke, and Kirkpatrick (1998) used a longitudinal design to collect data from 183 CEO entrepreneurs and selected employees. Structural modeling confirmed that the attributes and contents of visions expressed orally or in writing led directly to future growth in ventures.

*Counterintuitive Initiatives.* Some leaders, such as Mahatma Gandhi and Mikhail Gorbachev, introduced inspiring ideologies and actions that are the opposite of what was expected. In return for violence against their supporters, Gandhi and Martin Luther King Jr. preached nonviolence. For the 70-year-old, closed, highly structured, authoritarian Soviet society, Mikhail Gorbachev introduced perestroika and glasnost

—restructuring and openness—in an effort to reform the system (Lipman-Blumen, 1996). After four decades of continued belligerency between Israel and Egypt, President Anwar Sadat went to Jerusalem to address the Israeli Knesset. The peace treaty that was eventually signed has lasted for almost 30 years. When Nelson Mandela visited the United States and was strongly criticized for his support for opponents of U.S. policy—Yasir Arafat, Fidel Castro, and Muammar al-Qaddafi—he said he welcomed their endorsement of his antiapartheid movement but declined to comment further about them (Greenfield, 1990).

### ***Intellectual Stimulation***

I was unable to consistently separate an inspirational from a charismatic leadership factor in factor analyses of U.S. Army officers' MLQ descriptions of their superiors. But I did obtain a separate factor of intellectual stimulation (Bass, 1985a). Hater and Bass (1988) replicated this finding with a sample of industrial managers. Items of this factor included such statements as "Provides reasons to change my way of thinking about problems," "Stresses the use of intelligence to overcome obstacles," and "Makes me think through what is involved before taking actions."

Subordinates in military, industrial, and educational organizations who described their superiors as frequently engaging in intellectual stimulation tended to view the superiors as highly effective and satisfying. Avolio, Bass, and Yammarino (1988) found correlations of .54 and .73 between intellectual stimulation and effectiveness for two samples of managers. Comparable correlations of the relation of the leadership to subordinate satisfaction were .48 and .67. Bass (1985a) and Seltzer and Bass (1987) reported correlations in the same range. As was seen earlier in [Table 21.1](#), Hater and Bass (1988) found positive correlations between superior's evaluations of managers and the extent to which the managers were described as intellectually stimulating. Avolio, Waldman, and Einstein (1988) obtained correlations between the extent to which the supposed presidents of 27 complex business-gaming teams were intellectually stimulating and the teams' market share (.56), debt-to-equity ratio (2.56), returns on assets (.46), stock prices (.47), and earnings per share (.37).

Keller (1989) correlated the MLQ intellectual stimulation of 66 R & D project team leaders according to the team members with superiors' evaluations of the teams' effectiveness and the number of patents produced by the teams. Intellectual stimulation of the team leaders correlated .36 with the supervisors' evaluations of the team performance and .25 with patents produced by the teams. The effect was more specifically pinpointed in the case of patents produced when the results were subdivided for the 30 teams engaged in research projects and the 36 teams engaged in developmental projects. Intellectual stimulation of the leaders correlated .57 with patents produced by the research teams but only .01 for those engaged in more routine developmental activities. However, along with the benefits to teams and organizations of intellectually stimulating leadership, elsewhere a cost of intellectual stimulation may have been revealed as well.

## **Summary and Conclusions**

---

Since its conception by Weber in the early twentieth century, charismatic leadership has undergone considerable development, although until the 1980s there was much commentary but little empirical research about it. Charismatic leaders may be personalized or socialized, due to their positions or personalities, and close or distant. By 2006, charisma had become a frequent topic of empirical research. Two attributes are seen to be essential for the charismatic relationship: charismatic leaders must be persons of strong convictions, determined, self-confident, and emotionally expressive; and their followers must want to identify with the leaders as persons, whether they are or are not in a crisis. Whether charismatic leaders are self-aggrandizing or

prosocial, they generate extraordinary performance in the followers. Followers are more susceptible to charismatic leadership in their readiness to identify with it and accept its mystique.

Crises may or may not be the underlying cause for the emergence of charismatic leaders. Generally, charismatic leaders are more effective than noncharismatic leaders, but effectiveness and routinization may or may not automatically follow in their successors.

Inspirational leadership does not necessarily depend on charismatic personal identification processes. Rather, the mutual goals of leaders and followers are identified and encouraged by the leader. Inspirational leadership stems from the management of meaning and impression management. Inspirational leaders build their followers' expectations by envisioning describable futures and articulating how to attain them. Charismatic leadership and inspirational leadership are major components of transformational leadership, discussed in [Chapter 22](#).

<sup>1</sup> See, for example, Schiffer (1973), Schweitzer (1984), and Willner (1968).

<sup>2</sup> Blau and Scott (1962), Etzioni (1961), and Friedland (1964).

<sup>3</sup> Descriptions of the communes could be Guttman-scaled with a reproducibility of the hierarchy of 93. (A Guttman scale is a set of statements that can be ordered so that endorsement of a particular statement will predict endorsement of all those higher in the ordering of the statements and rejection of all those lower in the ordering. A perfect ordering has a reproducibility of 1.00.)

<sup>4</sup> This questionnaire was developed to measure the factors in transformational and transactional leadership, one of which was charismatic leadership. The scale of charismatic leadership is described later in this chapter.

<sup>5</sup> Further evidence about the predictions of objective leader effectiveness from MLQ charisma scores will be presented in [Chapter 22](#) on transformational leadership.

---

# Transformational Leadership

A leader is *transactional* when the follower is rewarded with a carrot for meeting agreements and standards or beaten with a stick for failing in what was supposed to be done. If the leader is limited to such behavior, the follower will feel like a jackass (Levinson, 1980b). Leaders must also address the follower's sense of self-worth, one of the things that *transformational* leaders do. Transformational leaders motivate their followers to do more than the followers originally intended and thought possible. The leader sets challenging expectations and achieves higher standards of performance. Transformational leadership looks to higher purposes. Transformational leaders are expected to cope better with adversity (Parry, 2005). Parameshwar (2003) noted that 10 global leaders of social change developed transcendental higher purposes and went beyond the ordinary by: (1) exposing unresolved, disturbing human rights problems; (2) untangling false interpretations of the world; (3) breaking out of conventional solutions; and (4) making use of transcendental metaphors. Many leaders of world religions, such as Jesus, Mohammed, and Buddha, were transforming. They created visions, shaped values, and empowered change (Leighton Ford, 1981). Both transactional and transformational leadership were demonstrated by the Greek leaders of the *Anabasis* (Xenophon, c. 400 b.c.e.) marching the mercenary Greek army safely through 1,000 miles of hostile Persian territory (Humphries, 2002).

Transactional leadership emphasizes the exchange that occurs between a leader and followers. This exchange involves direction from the leader or mutual discussion with the followers about requirements to reach desired objectives. Reaching objectives will appear psychologically or materially rewarding. If not overlooked or forgiven, failure will bring disappointment, excuses, dissatisfaction, and psychological or material punishment. If the transaction occurs and needs of leader and follower are met, and if the leader has the formal or informal power to do so, he or she reinforces the successful performance.

Up to the late 1970s, leadership theory and empirical work were concentrated almost exclusively on the equivalent of transactional leadership. The exceptions were political, sociological, and psychoanalytical discussions of charisma. Today both transformational and transactional leadership have a wide range of applications, ranging from teaching and nursing to police work and personal selling (Jolson, Dubinsky, & Yammarino et al. 1993).

Freud (1922) recognized that leadership was more than a transactional exchange. The leader embodied ideals with which the follower could identify. Bernard (1938) noted in his examination of corporate executives that tangible inducements were less powerful than personal loyalties. Hook's (1943) heroes in history made events as well as waiting for them to happen. Political leaders could be reactionary, conservative, reforming, radical, or revolutionary agents of change (Dvir, 1998).

Transformational leadership was first mentioned, as such, by Downton (1973) as different from transactional leadership. Soon after, House (1977) presented a theory of charismatic leadership with testable hypotheses. But with perspectives from Maslow's needs hierarchy and from writing biographical studies of Presidents Roosevelt and John F. Kennedy, in a book entitled *Leadership*, James MacGregor Burns (1978) opened wide the impetus for research to contrast transformational leadership to transactional leadership as its opposite. This was followed by Bass (1985a), who demonstrated that empirically transformational and transactional leadership were two positively correlated dimensions. Furthermore, transformational added to transactional leadership effects.

Empirical leadership research up to the late 1970s attended mainly to observable, short-term, leader-follower relations in small groups on the micro level of organizations. There was much less empirical research about senior executives and heads of organizations at the macro level or leaders of societies at the meta-level, although much had been written about leadership at the higher levels. In the mid-1970s, the survival of the field of leadership study was seriously questioned. In 1975, a commentator was reported to have quipped, "Once I was active in the leadership field, Then I left it for about 10 years. When I returned, it was if I had been gone only 10 minutes" (Hunt, 1999, p. 130). In 1975, John Miner argued that "the concept of leadership itself has outlived its usefulness" (Hunt & Larson, 1975, p. 200). Some theorists and practitioners thought the concept of leadership might wither away. They suggested that what was attributed to effective leadership could better be explained by social, organizational, and environmental effects (Pfeffer, 1977). Leadership was thought to be a fiction of the imagination, overemphasized in the highly individualistic United States (Hosking & Hunt, 1982). According to Hunt (1999, p. 130),

the study of charismatic and transformational leadership came in to save the day. ... [A] major contribution, if not *the* major contribution of transformational and charismatic leadership has been its transformation of the field. This transformation involves a field that had been rigorous, boring and static ... examining more and more inconsequential questions and providing little added [by] the plethora of published studies.

Transformational leadership represented a seminal shift in the field of leadership (Bass, 1993).

*The New Leadership.* Bryman (1992) labeled as the "new leadership" the introduction of transformational leadership and related concepts such as charismatic, visionary, inspirational, values-oriented, and change-oriented leadership. House and Aditya (1997) referred to these concepts as *neocharismatic*. The new leadership represents a paradigm shift that moved the field out of its doldrums (Hunt, 1999). Along with reinforcing the importance of transformational leadership, Burns (2003) agreed with Thomas Jefferson about the importance of leadership in the pursuit of happiness. Evidence of the transactional and transformational behavior of leaders in a wide variety of circumstances, political, business, education, family, sports, and law enforcement (Bass & Riggio, 2006) is well documented. Less well known is street-level transformational leadership of social caseworkers with their disabled or welfare clients (Dicke, 2004)

## Components of Transformational Leadership

---

Burns (1978) defined a *transforming* leader as one who: (1) raises the followers' level of consciousness about the importance and value of designated outcomes and ways of reaching them; (2) gets the followers to transcend their own self-interests for the sake of the team, organization, or larger polity; and (3) raises the followers' level of need on Maslow's (1954) hierarchy from lower-level concerns for safety and security to higher-level needs for achievement and self-actualization. Transforming leadership elevates the follower's level of maturity, ideals, and concerns for the well-being of others, the organization, and society. The content of transformational leaders tends to be optimistic (Berson, Shamir, Avolio, et al. (1998). Transforming leaders point to mutual interests with followers. They engage followers closely without using power, using moral leadership. They transform individuals, groups, organizations, and societies. Between 1980 and 1985, Bass (1985a) formulated a multidimensional theory of transformational and transactional leadership and verified it with military and civilians describing their respective leaders. Burns agreed that transformational and transactional leadership were not opposite ends of a single dimension but multidimensional.

*Measurement.* Seventy senior South African executives (all male, one black) described how one such leader they had known in their careers had influenced them. Their descriptive statements were sorted by 11 graduate students into transformational and transactional. Seventy-three of the 143 statements on which the

judges could agree were administered to 104 senior U.S. Army officers (almost all male). The officers were asked to describe their most recent superior, using a five-point scale of frequency, from 0 = the behavior is displayed not at all to 4 = the behavior is displayed frequently, if not always.

A first factor analysis of the 73 items was completed (Bass, 1985c). The factors described the behavior and attitudes of transformational and transactional leaders in three correlated transformational leadership factors: (1) charisma, (2) intellectual stimulation, and (3) individualized consideration. Later a cluster of three items was identified as inspirational motivation. Also, two transactional factors emerged that reflected positive and negative reinforcement, respectively: (4) contingent reward and (5) management by exception. They were uncorrelated with each other. Subsequently, Bass and Avolio (1990) relabeled the charismatic factor idealized influence because of the popular meaning of charisma in the public mind as being celebrated, flamboyant, exciting, and arousing. It was often a highly publicized creation of media hype. It was also associated pejoratively with Hitler's effects on the German people.

### ***Charismatic Leadership (CH) or Idealized Influence (II)***

Charisma was the subject of [Chapter 21](#). As Bass (1985a) and others noted, it could not be separated factorially from inspirational leadership (Hinken & Tracey, 1999). Nevertheless, the charismatic leader is likely to be transformational, but it is possible—although unlikely—to be transformational without being charismatic. A highly intellectually stimulating teacher, for instance, may transform students without their regarding the teacher as charismatic.

### ***Inspirational Motivation (IM)***

Although inspirational motivation could not be separated factorially from charisma because of the conceptual differences between charisma and inspiration discussed in the previous chapter, a 10-item scale of inspirational motivation was maintained in the Multifactor Leadership Questionnaire-Form 5X along with the other factor scales (Bass, 1985c).

### ***Intellectual Stimulation (IS)***

This is probably the least recognized of the transformational factors. Avolio (1999) pointed out that a majority of managers and employees believe that their intellect is underutilized, yet in the postindustrial world an organization's intellectual capital may be more important than its physical capital. Worldwide, at least 40 idea generation methods are known, but often they remain misunderstood and mistrusted by skeptics. Some, using intuitive association, such as brainstorming, are well known; others, involving systematic variation and idea structuring, less so (Geschka, von Reibnitz, & Storvik, undated). It is an intellectually stimulating challenge to persuade a group to use any one of these methods and to teach it how to do so.

Bass (1985a) obtained a factor of intellectual stimulation in U.S. Army officers' MLQ descriptions of their superiors. Many subsequent factor analyses replicated this finding with a variety of samples of military, industrial, and educational managers and leaders (Avolio, Bass, & Dong, 1999; Antonakis, 2000). Items of this factor included such statements as "Provides reasons to change my way of thinking about problems," "Stresses the use of intelligence to overcome obstacles," and "Makes me think through what is involved before taking actions."

*Personal Creativity versus the Intellectual Stimulation of Others.* There is a difference between

possessing competence, knowledge, skill, ability, aptitude, and intelligence and being able to translate these qualities into action as intellectual inspiration and the stimulation of others. Presidents Jimmy Carter and Herbert Hoover exemplified technically competent leaders who failed to inspire. John F. Kennedy and Franklin Delano Roosevelt are illustrations of presidents who were not as intellectually astute as Carter and Hoover but were far superior in their ability to stimulate others intellectually, to imagine, to articulate, and to gain acceptance of and commitment to their ideas. The proposals and ideas of Daniel Patrick Moynihan, the liberal Democratic senator from New York, were repeatedly ahead of his time. He introduced original and provocative ideas that often stimulated liberal opposition rather than support. His 1965 report suggested that the black family was falling apart and social legislation was needed. He was roundly attacked by blacks and liberals. It was only in the 1980s that adverse black family statistics revealed Moynihan as a visionary. In 1970, he supported a guaranteed annual income for the impoverished. It was shot down by the Welfare Rights Organization with rightwing assistance. Welfare reform had to wait until 1988, when he supported the beginnings of workfare legislation. "No politician is as good as Moynihan at generating good ideas ... (but not) getting things done" (Lemann, 1990, p. 4).

Intellectual stimulation is much more than a matter of broadcasting good ideas. For instance, in the public sector, Roberts (1988) demonstrated that the intellectual generation of ideas and framing of problems were not enough. Makers of politically innovative policies have to serve as catalysts by: (1) mobilizing and building support for their ideas; (2) circulating their ideas through various media available to them; (3) collaborating with other highly visible and reputable groups and organizations; (4) creating demonstration projects; (5) sponsoring reforms in the legislature; (6) positioning and developing supporters in the government; (7) enlisting champions to introduce their proposed legislation; (8) influencing and creating public interest groups and associations; and (9) monitoring and evaluating the extent to which the legislation that is passed conforms to the policies that were promoted.

*What Leaders Do To Be Intellectually Stimulating.* Intellectually stimulating leaders help to make their followers more innovative and creative. They question assumptions, reframe problems, and look at old problems in new ways. Public criticism of followers and their mistakes is avoided. New ideas are sought from followers. They are encouraged to "think out of the box," to address problems, and to consider alternative solutions (Bass, 1998). Intellectually stimulating leaders see themselves as part of an interactive creative process (Brown, 1987). Not bound by current solutions, they create images of other possibilities. Orientations are shifted and awareness of the tensions between visions and realities is increased.

Intellectually stimulating leaders are often empowering (Spreitzer & Janasz, 1998). They move subordinates to focus on some things and ignore others. A pattern is imposed on a flow of events to simplify their complexity and diversity. The real world is made easier to understand (Bailey, 1983). Intellectual stimulation can move subordinates out of their conceptual ruts by reformulating the problem that needs to be solved. Wicker (1985) provided numerous examples of what can be done to move followers to "think out of the box." Ideas can be played with by applying metaphors and similes (e.g., interpersonal attractiveness is like a magnetic field). The scale can be changed (e.g., a sandbar can be likened to a galaxy of stars). The absurd or fantasy can be considered (e.g., suppose water floated on oil). Alternative states can be imagined, such as particles becoming a wave. Nouns can be changed into verbs. The figure and ground can be transposed (e.g., to concentrate on the space around the object instead of the object). Contexts can be enlarged or subdivided. Hidden assumptions can be uncovered (e.g., failures may be due to poor planning, not to lack of ability). Infante and Gordon (1985) noted that it was more satisfying to subordinates if their supervisors argued for their own formulations and refuted other points of view, but it was more dissatisfying if the supervisors attacked subordinates' self-concepts. Unfortunately, some people mistake argumentation for hostility. The former is favored in leaders; the latter is not.

Quinn and Hall (1983) proposed that leaders intellectually stimulate followers in one of four ways: rational,

existential, empirical, and ideological. *Rationally oriented leaders* emphasize ability, independence, and hard work. They try to convince colleagues to use logic and reason to deal with the group's or organization's problems. *Existentially oriented leaders* try to move others toward a creative synthesis by first generating various possible solutions in informal interactions with others and their common problems. *Empirically oriented leaders* promote attention to externally generated data and the search for one best answer from a great deal of information. *Idealists* encourage speedy decisions; they foster the use of internally generated intuition. They gather only a minimum amount of data before reaching a conclusion (Quinn & Hall, 1983).

Intellectually stimulating leaders see themselves as part of an interactive creative process (Brown, 1987). Not bound by current solutions, they create images of other possibilities. Orientations are shifted, awareness is increased of the tensions between visions and realities, and experiments are encouraged (Fritz, 1986). Intellectual stimulation contributes to the independence and autonomy of subordinates and prevents *habituated followership*, characterized by the unquestioning trust and obedience of charismatic leader-follower relations (Graham, 1987). Intellectual stimulation is much more than a matter of broadcasting good ideas.

Chaffee (1985) suggested that three strategies are pursued in finding solutions to the organization's problems: linear, adaptive, and interpretive. If *linear* data are gathered and analyzed, alternative actions are formulated with expected outcomes if a particular action is taken. If an *adaptive* strategy is pursued, the effort will be to adjust the organization to environmental threats and opportunities by being particularly cognizant of the revenues and resources needed from the environment. If an *interpretive* strategy is pursued, reality is less important than are perceptions and feelings about it. Values, symbols, emotions, and meanings need to be addressed. Neumann's (1987) interview study of 32 college presidents found that with experience, the presidents tended to move toward more interpretive strategies if they had not initially emphasized them. The shift of experienced presidents away from purely adaptive strategies was most evident.

Military and political planners need to be encouraged to engage in *second-curve thinking*. They need to develop alternative possible scenarios of what is likely to happen after the victory they have planned for. In the same way, planners for organizations need to consider looking at alternative scenarios of how the organization and its environment is likely to be affected by the success of their *first-curve* plans. Royal Dutch Shell executives draw up such possibilities and distribute them widely to keep its executives thinking ahead to avoid being surprised (Handy, 1994). There was insufficient and inadequate second-curve thinking by the U.S. administration about what would happen in Iraq after the initial success of its first-curve plan to bring down Saddam Hussein's regime (Woodward, 2004).

*Central versus Peripheral Routing.* Intellectual stimulation takes people on what Petty and Cacioppo (1980) conceived of as the *central* route to being persuaded, which occurs when people are ready and able to think about an issue. It may be contrasted to persuasion via the *peripheral* route, which occurs when people lack either motivation or ability. Persuasion through the central route produces enduring effects; persuasion via the peripheral route lasts only if it is bolstered by supportive cognitive arguments. If persuasion is by the peripheral route, it is necessary only for the source of the persuasion to be liked. The distinction between central and peripheral processing has much in common with the distinctions between deep versus shallow processing, controlled versus automatic processing, systematic versus heuristic processing, and thoughtful versus mindless or scripted processing (Cialdini, Petty, & Cacioppo, 1981).

### ***Individualized Consideration (IC)***

Individually considerate leaders pay special attention to each follower's needs for achievement and growth. New learning opportunities are created, along with a supportive climate. Individual differences in needs are

recognized. The leaders serve as coaches and mentors for their followers. They attend to the individual followers' differential needs for growth and achievement. Followers are helped to reach successively higher levels of development. New learning opportunities are created in a supportive environment. "Walking-around management" is practiced. The individually considerate leader personalizes relations, remembering names and previous conversations. Two-way communication is encouraged. Tasks are delegated to provide experience and to develop followers. The individually considerate leader is an effective listener (Bass, 1998) and more delegative in management style (Gill, 1997).

Bracey, Rosenbaum, Sanford, et al. (1990) stated that leaders need to be caring by telling the truth with compassion, looking for others' loving intentions, disagreeing with others without making them feel wrong, avoiding suspiciousness, and recognizing the qualities in each individual regardless of cultural differences. Greenleaf's (1979) servant leadership heavily emphasizes individualized consideration.

When faced with changed processes making employees redundant or the need to cut costs, individually considerate management restructures the organization responsibly (Cascio, 1995). Whenever possible, employees are retrained and redeployed to avoid layoffs. Merck even arranged for temporary transfers of employees to other firms. Actually, it may be less profitable for firms to downsize to cut costs because of the expense of separations and rehiring when business turns around (McKinley, Sanchez, & Scheck, 1995).

### ***A Combining of Transformational Factors***

Although they are conceptually different and form independent clusters of items, the component factors of transformational leadership uncovered by Bass (1985a) are intercorrelated. Sixty-six percent of the covariance of all the items in transformational leadership could be accounted for by the first factor of charismatic leadership (Bass, 1985c). An even larger amount was accounted for in a comparable sample of U.S. Air Force officers (Colby & Zak, 1988). Hater and Bass (1988) achieved similar results when they refactored the 70-item questionnaire that subordinates completed to describe their immediate management superiors. Onnen (1987) obtained similar findings from 454 parishioners who described their Methodist ministers. A single transformational leadership score can be meaningfully calculated for selected studies and analyses. The antecedents and effects of this transformational score have been compared with the effects of transactional leadership that is composed of the factors of contingent reward and management by exception. The results of extensive surveys of more than 1,500 general managers, leaders of technical teams, government and educational administrators, upper middle managers, and senior U.S. Army officers that were discussed earlier for charismatic leadership are also relevant for transformational leadership. Subordinates of these leaders, who described their managers on the MLQ-Form 5 as being more transformational, were also more likely to say that the organizations they led were highly effective. Such transformational leaders were judged to have better relations with higher-ups and to make more of a contribution to the organization than were those who were described only as transactional. Subordinates said they also exerted a lot of extra effort for such transformational leaders. If leaders were only transactional, the organizations were seen as less effective, particularly if most of the leaders practiced passive, reactive management by exception intervening only when standards were not met.

## **Components of transactional Leadership**

---

According to Burns (1978), transactional leadership is the exchange relationship between leader and followers aimed at satisfying their own self-interests. Its factors in Bass (1985c) were contingent reward and management by exception. The latter factor was subsequently divided into active management by exception and part of

passive leadership and laissez-faire, the avoidance of leadership, delineated in [Chapter 6](#). Contingent reward and management by exception are ways of looking at *reinforcement leadership*, discussed in [Chapter 15](#). With active management by exception, the leader attends to each follower's performance and takes corrective action if the follower fails to meet standards. With passive management by exception, the leader waits for problems to arise in the follower's performance before taking corrective action in the belief that "If it ain't broke, don't fix it" (Bass & Avolio, 1990). "The transactional leader closely resembles the traditional definition of the manager" (Kouzes & Posner, 1995, p. 321).

Ten-item scales of transactional leadership were included with MLQ 5-R. High reliabilities (.85 and above) were routinely reported for descriptions of superiors by large samples of subordinates in military and industrial settings (Bass & Avolio, 1989). The 10 items of each scale were reduced to four in a short form (MLQ-5X) with some loss of reliabilities, as expected (Bass & Avolio, 1990).

### ***Contingent Reward (CR)***

This is a *constructive* transaction. The leader assigns a task or obtains agreement from the follower on what needs to be done and arranges for psychological or material rewards of followers in exchange for satisfactorily carrying out the assignment (Bass, 1998). For 207 British managers, Gill (1997) found that the managers who were *directive* practiced more contingent rewarding ( $r = .24$ ). The psychological rewards may include positive feedback, praise, and approval. The material rewards may include a raise in salary, an award, or citation for merit.

Originally conceived as a transactional reinforcement, contingent reward correlates more with transformational than with transactional leadership. Explanations were found by Silins (1994) and by Goodwin, Wofford, and Whittington (2001). Contingent reward has two aspects. Silins found that contingent rewarding with external material rewards such as a raise in pay was transactional; contingent rewarding involving internal psychological processes such as praise was transformational. For Goodwin et al., the transactional factor was explicit reward, such as a commendation for good performance; the transformational factor was implicit, such as expressing admiration of the follower for good performance. Goodwin, Wofford, and Whittington (2001) completed a factor analysis of 154 employees describing their supervisors with the MLQ and a confirmation with MLQ data from an additional 209 employees describing their supervisors. Two CR factors were found and confirmed: explicit contingent rewarding and implicit psychological contracting. Consistent with these findings, higher-order factors unearthed in large sample factor analyses by Avolio & Bass (1999), Antonakis (2001), and others also showed that contingent reward could be both transformational and transactional. CR was transformational when the rewards were psychological, like supervisory recognition and praise for a follower's good work. CR was transactional when the rewards were material, like increased pay.

### ***Management by Exception (MBE)***

This is a corrective transaction. If active, the leader monitors the deviances, mistakes, and errors in the performance of the followers and takes corrective action accordingly. If passive, the leader takes no corrective action before a problem comes to his or her attention that indicates unsatisfactory follower performance (Bass, 1998). The corrective action may be negative feedback, reproof, disapproval, or disciplinary action. Denston and Gray (1998) completed both qualitative and quantitative studies of MBE showing that MBE behavior fell into three categories: autocratic (directive), maintaining the status quo, and overregulation. As noted above, Gill also found that the more directive the leaders, the more they practiced MBE. Generally, MBE is lower in

reliability than the other MLQ factors.

## The Model of the Full range of Leadership

---

Transformational and transactional factors were conceived by Avolio and Bass (1991) as continua in leadership activity and effectiveness. Added was laissez-faire or nonleadership to the bottom of the continua in activity and effectiveness. By definition, transformational leadership was more active than transactional leadership, which was more active than laissez-faire leadership. Empirically, transformational leadership was more effective than transactional leadership, which was more effective than nonleadership. Avolio and Bass (1999) used 14 samples involving 3,786 MLQ survey participants describing their leaders to test nine factorial structures to determine the best fitting models. The best fitting models contained six lower-order factors: charisma (CH 1 IN), intellectual stimulation (IS), individualized consideration (IC), contingent reward (CR), active management by exception (MBEA), and passive avoidance (PA). Three higher-order factors emerged: transformational leadership and contingent reward, developmental exchange (IC 1 CR), and corrective avoidance (PA 1 MBEA). Antonakis (2001) and Antonakis and House (2002) found that the model of the full range of leadership remained valid, although they could point to a variety of moderators that affected results. These included the sex of leaders and followers, the risk and stability of conditions, and the leaders' hierarchical level.

## Other Concepts and Methods Relevant to Transformational and Transactional Leadership

---

### *Qualitative Approaches*

The pattern of factors that Bass (1985c) extracted provided a portrait of the transformational leader that Zaleznik (1977) had independently drawn from clinical evidence. Zaleznik's leaders attracted strong feelings of identity and intense feelings about the leader (charisma). They sent clear messages of purpose and mission (inspi-rational leadership), generated excitement at work, and heightened expectations through images and meanings (inspirational leadership). They cultivated intensive one-on-one relationships and empathy for individuals (individualized consideration) and were more interested in ideas than in processes (intellectual stimulation). Tichy and Devanna (1986) concluded from interviews with 12 executives that transformational leadership is broader than charisma. They reported that transformational leaders were intuitive, cautious to avoid unrealistic expectations, empowering, and envisioning with clarity. Bennis and Nanus (1985, 1988) interviewed 90 public and private CEOs who said they made special efforts to inspire followers to greater productivity. Their followers said the executives raised their consciousness and provided a radiant but realistic vision of the future.

Marion and Uhl-Bien (2001) introduced *complexity leadership*, that enlarges transformational leadership to include catalyzing organizations from the bottom up through fostering the microdynamics of interaction among ensembles, coordinates the behavior among the ensembles. It allows for random effects and futures dependent on networks, structure, and relationships. It is based on complexity theory, borrowed by the social sciences from the physical sciences (Marion, 1999). Anderson (2000) suggested five leadership skills of increasing complexity needed by leaders to be transformational: (1) personal mastery to provide for clarity of beliefs and purpose of life; (2) interpersonal communications to build interpersonal relationships; (3)

counseling on how to manage problems; (4) consulting about team and organizational development; and (5) versatility in styles, roles, and skills.

### ***Quantitative Approaches***

Podsakoff, MacKenzie, Moorman, et al. (1990) validated six transformational factors for the Transformational Leadership Inventory (TLI): (1) articulating a vision, (2) providing an appropriate model, (3) fostering the acceptance of group goals, (4) high performance expectations, (5) providing individualized support, and (6) individualized consideration. Podsakoff, MacKenzie, and Bommer (1996) showed that transformational leadership was generally independent of most contextual substitutes for leadership. Alimo-Metcalfe and Alban-Metcalfe (2000) used Kelly's Repertory Grid Technique to elicit constructs from 48 female and 44 male middle, senior, and top managers about the similarities and differences of managers with whom they had worked in the British Health Service or local government. To form constructs, the managers were asked to choose the most and least alike leaders who had "had a powerful effect on their motivation, self-confidence, self-efficacy and performance." The 1,464 responses were factor analyzed to yield reliable factors that generally appeared close to the transformational components of leadership described above: (1) inspirational networker and promoter; (2) encourages critical and strategic thinking; (3) empowers, develops potential; (4) genuine concern for others; (5) accessible, approachable. Other factors described the personality of the transformational leader: (6) decisiveness determination and self-confidence and (7) integrity (trustworthiness, honesty, and openness). Two transactional factors surfaced, one concerned with (8) political sensitivity and skills (in local government) and (9) clarifying boundaries. This last factor also included involving others in decisions. The nine factors were formed into the Transformational Leadership Questionnaire (TLQ).

Kouzes and Posner (1987) extracted a profile of transformational leadership from interviews asking leaders to describe their personal best leadership experience. Subsequently, they used the interview information to develop the Leadership Practices Inventory (LPI) for followers to complete. They noted that transformational leaders (1) challenge the process, constantly searching for new opportunities, ready to experiment and take risks, and remaining open to new ideas; (2) inspire a shared vision, articulating direction, ideals, and the special nature of the organization; (3) enable others to act by promoting collaboration and cooperative goals and establishing trust and empowerment; (4) model the way by behavior that is consistent with the vision and instills values supporting the vision; and (5) encourage the heart with high expectations, supporting persistence, rewarding others for success, and celebrating achievements. Carless (1999) administered the LPI and MLQ to 777 subordinates of 695 branch managers in an international bank in Australia. The LPI scales and the MLQ transformational scales were highly correlated.

Yukl (1987) initiated the Managerial Practices Survey (MPS) (Yukl, Wall, & Lepsinger, 1990) by first organizing a taxonomy of leadership and management practices based on factor analyses, expert groups, and prior theory. In the MPS scales that resulted, transformational leadership could be seen conceptually in motivating and inspiring, intellectually stimulating, problem solving, coaching, and supporting and mentoring. Transactional leadership could be seen in recognition, rewards, informing, clarifying roles, and monitoring operations. Tracy and Hinken (1998) found correlations ranging from .67 to .82 between the MLQ components and four selected MPS scales: clarifying roles, inspiring, supporting and team building. House (1997a) substituted value-based for charisma scales. Included were articulation of a vision, communication of high performance expectation, displaying self-confidence, role modeling, showing confidence in and challenging followers, integrity, and intellectual stimulation. Behling and McFillen (1996) developed scales for rating leaders on displaying empathy, dramatizing the mission, and projecting self-assurance to enhance image,

to ensure competency and to provide opportunities to experience success. Jackson, Duehr, and Bono (2005) reported on the utility of using a questionnaire to measure empowerment along with a questionnaire to measure transformational leadership to predict performance, job satisfaction, and commitment. Jaussi and Dionne (2004) showed that an assessment of a leader's unconventional behavior (e.g., standing on furniture or hanging ideas on clotheslines) added in regression analysis beyond transformational leadership to the prediction of followers' satisfaction and perceived leader's effectiveness.

### ***The Neocharismatic Leadership Paradigm (NLP)***

According to House and Aditya (1997), the theories of NLP include various theories of charismatic leadership (House, 1977; Conger & Kanungo, 1987; Shamir, House, & Arthur, 1993), theories of transformational leadership (Burns, 1978; Bass, 1985a), and visionary theories (Bennis & Nanus, 1985; Sashkin, 1988; Nanus, 1992). House, and Shamir (1993) provided a chart of the behaviors to be found in these theories cited by their authors ([Table 22.1](#))

As currently defined by theorists and empiricists such as House (1999) and House and Shamir (1993), no distinction is made between charismatic and transformational leadership. They prefer to merge the two concepts as charismatic/transformational leadership. They see the same common motivational elements in charisma and transformational leadership (excluding individualized consideration). They connect the merged concept to followers' self-concepts, internalized values, and cherished identities. The concept correlates with increasing collective efficacy and high expectations. Goals and values are linked to a sense of mission and to an ideal vision of a better future. But Bass (1998) argues that although the same leaders tend to be inspirational, intellectually stimulating, and individually considerate as charismatics, it is useful to keep the concepts separate, for they involve different behaviors and development. Although inspirational motivation and charismatic leadership are highly correlated and charismatic leaders are inspirational, inspirational leaders may not necessarily be charismatic: General Omar Bradley is an example. Napoleon and Alexander the Great were charismatic, inspirational, and intellectually stimulating but not particularly individually considerate as they grew in power and success. Horatio Nelson, the British admiral, was a transformational leader in the truest sense. He was charismatic and idealized by the English, he inspired his seamen and officers, and he revolutionized war at sea. He was also individually considerate and tried to meet the needs of his officers and seamen (Adair, 1989).

More rather than less differentiation is needed between charisma and transformational leadership, according to Hunt and Conger (1999). Conger (1999) and Yukl (1999) further discussed the need to maintain the distinction. Beyer (1999) asked how a charismatic leader transformed an organization.

### ***Leader-Member Exchange (LMX)***

LMX focuses on the rated quality of the dyadic relationship between superior and subordinate (Graen & Scandura, 1986). Since it can be a motivating exchange between two parties, it was assumed to be transactional (1989). Nevertheless, Graen and Uhl-Bien (1991) examined how quality LMX develops over time. LMX is a transactional exchange early in the process and later may correlate positively with transformational leadership. Tejeda and Scandura (1994) found a positive common correlation between supervisors' transformational leadership and the quality of LMX between supervisors and subordinates in a health care organization. Furthermore, Dansereau (1995) argued that the quality of LMX depended on the leader supporting subordinates' self-worth and showing confidence in the subordinate's integrity, motivation, and ability, as well as being concerned for subordinates' needs. Greenleaf's (1977) servant leadership and Block's (1993) leader as

steward come to mind.

## Servant Leadership

Smith, Montagno, and Kuzmenko (2004) compared transformational leadership with servant leadership. While transformational leaders share and align their followers' interests, servant leaders put the interests of their followers before their own. Both emphasize personal development and empowerment of the followers. Both facilitate the achievement of followers.

Transformational leadership may be more relevant in a dynamic, changing environment; servant leadership may be more applicable in a stable environment.

Table 22.1 Behaviors Specified in Charismatic, Transformational, and Visionary Theories of Leadership

	Weber, 1947	House, 1977	Burns, 1978	Bass, 1985	Bennis and Nanus, 1985	Conger and Kanungo, 1987	Sashkin, 1988	Shamir et al., 1991
Visionary	X	X	X	X	X	X	X	X
Frame alignment								X

## Deming's Quality Improvement

Leadership was an important aspect of W. Edwards Deming's 14 points for Total Quality Management. Sosik and Dionne (1994) selected five of Deming's points for improving quality—change agency, teamwork, trust building, short-term goal eradication, and continuous improvement—and their likely linkage to the Full Range of Leadership. They proposed that in line with Deming, transformational leaders are agents of change, encourage teamwork, promote continuous improvement, build trust, and eradicate short-term goals.

## Directive and Participative Leadership

Transformational leaders can be *directive* or *participative*. Charismatic leaders may direct their dependents out of crises; inspirational leaders direct their followers with slogans like "Never again." Intellectually stimulating leaders direct their followers how to think through problems. Individually considerate leaders decide that only some followers need help. Critics see transformational leaders as elitist and autocratic. Nonetheless, charismatic leaders can be participative, for instance, by sharing in the building of visions. Inspirational leaders may listen to their followers before asking for a consensus about simplifying their ideas.

Intellectually stimulating leaders may help followers to reexamine their assumptions. Individually considerate leaders may encourage followers to give one another support when they need it (Bass, 1998). After spending 27 years imprisoned by the white South African government, Nelson Mandela was directive and transformational when he declared, "Forget the past," and showed his strong support for reconciliation. Gill (1995) reported a correlation of .29 between inspirational and participative leadership.

In the same way, the transactional leader can be *directive* or *participative*. The directive leader, practicing contingent reward, may decide to reward followers for their good performance. The *directive* leader can practice management by exception by taking disciplinary action for an observed violation of the rules by followers. Gill (1995) found correlations with *directive* leadership of .25 with contingent reward and .20 with management by exception. The *participative* leader may practice contingent reward by asking followers what needs to be done to achieve common goals. The participative leader can practice management by exception by asking how observed mistakes could be corrected. Nelson Mandela was *participative* and transactional when he campaigned for his successor as president and promised voters better housing. Gill (1995) reported a correlation of .35 between *participative* leadership and contingent reward but  $-.18$  with management by exception.

### ***LBDQ Consideration***

Individualized consideration, as measured by the MLQ, is empirically correlated .69 with consideration of the Leader Behavior Description Questionnaire, yet they are somewhat distinct in concept (Seltzer & Bass, 1990). Consideration involves the leader's friendliness, approachability, and participative decision making. Individualized consideration involves the leader's concerns for each follower as an individual and with the follower's development. It includes knowing the individual follower's needs, raising followers to higher levels of maturity, delegating opportunities for follower self-actualization, and helping followers to attain higher moral standards. Individually considerate leadership is closely associated with quality orientation and good behavioral relations with individual subordinates, less so with relations with all the subordinates as a group. Leaders high on both scores may be either directive or participative (Bass & Avolio, 1993a).

### ***Connective Leadership and Social Processes of Leadership***

Lipman-Blumen (1996) conceived of *connective* leadership as a contrast to *instrumental* leadership. Connective leaders intuitively focus on the interconnections among people, processes, and institutions. They make use of ethical social and political strategies to join their vision with the dreams of others. They strive to overcome mutual problems. They create a sense of community in which diverse groups can be valued members and enjoy a sense of belonging. They bring together others to encourage the assumption of responsibilities by active participants. They nurture potential leaders and successors. They build democratic institutions instead of creating dynasties and oligarchies. They dedicate themselves to goals beyond their own and demand sacrifices from others only after they have made sacrifices themselves. Connective leaders can also be instrumental. They will try to use others as well as themselves as instruments to achieve their common goals. Readers will recognize similar elements in connective leadership and transformational, charismatic, and servant leadership. Examples of connective leaders are leaders of voluntary organizations who attract dedicated workers by providing opportunities for ennobling action. They combine collaboration, nurturance, and altruism with the use of power and instrumental action. They assemble temporary creative teams of professionals for each new organizational project. They rally multiple short-term political coalitions to address diverse problems. They are dedicated activists, sacrificing careers, well-being, or even their lives for their

community (Lipman-Blumen, 1996). Akin to constructive leadership, Parry (2002) validated a scale, Social Processes of Leadership (SPL). SPL was about influence, processes, relationships, interactions, and position in organized society. Parry found the scale highly correlated with various measures of transformational leadership.

*A Hierarchy of Leader Effectiveness.* Ordinarily, a hierarchy of effectiveness was found. Transformational leadership was more effective than contingent reward; contingent reward was more effective than active management by exception; and active management by exception might be positive or negative in effect on subordinates' performance but was more effective than passive management by exception. Laissez-faire leadership was correlated moderately to highly negatively in effectiveness. Similar results were found for managers, project leaders, and staff professionals in a wide variety of firms and agencies (Bass, 1998) and in many developed and developing countries on five continents (Bass, 1997).

## ***Envisioning***

*Vision* arose as a leadership concept in the 1980s as a response to the need for firms to adapt rapidly to advancing technology and domestic and global competition (Conger, 2000). The concept of vision spread rapidly to nonprofit agencies and had always been of consequence to politicians and statesmen. Sashkin (1986, 1988) detailed and assessed the visionary leader. Vision is a notable correlate of the transformational process (Brown, 1993) and the transformational components of charismatic, inspirational, and intellectually stimulating leadership. As noted in [Table 22.1](#), envisioning is included in most theories of charismatic and transformational leadership. The vision of the charismatic leader has both a stimulating and unifying effect on the follower (Berlew, 1992). Visionary leaders have a sense of identity, direction, and strategy for implementation (Nygren & Ukeritis, 1993). The vision is often a collaborative effort of a leader and colleagues and ties together a variety of issues and problems. To maintain their emotional appeal, it is better for a vision to be presented visually rather than only be posted or in writing (Hughes et al. 1993).

*Purposes.* Visions are goals that are forward-looking and meaningful to followers. They involve accurately interpreting trends or articulating future-oriented organizational goals. They provide a road map to the future with emotional appeal to followers. They help followers know how they fit into the organization (Bryman, 1992). They evolve in one or more of four ways from: (1) a leader with foresight who is sensitive to emerging opportunities; (2) networks of insightful organizational members; (3) the accidental stumbling onto opportunities and recognizing them; and (4) a process of trial and error with many experiences. They may be value and mission statements. According to Sashkin (1988), the cognitive skills required for envisioning are: expressing and sharing the vision with managers and employees in order to detail, revise, and review policies and programs, and to monitor their effects. Most people can envisage near futures up to one year, but few can think 10 to 20 years ahead, as might be required in a vision of the head of a large firm, political movement, or military organization.

A vision serves as a guide for interim strategies, decisions, and behavior. "Vision provides the direction and sustenance for change ... and help us navigate through crises" (M. Hunt, 1999, p. 12). It is an important function in the public as well as private sectors (Berger, 1997). It is fundamental to effective executive leadership. Without the ability to define a desired future state, the executive would be "rudderless in a sea of conflicting demands, contradictory data, and environmental uncertainty" (Sashkin, 1986, p. 2). A vision integrates what is possible and what can be realized. It provides goals for others to pursue and drives and guides an organization's development (Srivastva, 1983). Vision is a mental model of a future state of the organization (Nanus, 1992), an ideal image of the future (Kouzes & Posner, 1995). It connects beliefs about what can be done in the future (Thoms & Greenberger, 1995). Mikhail Gorbachev, in the 1980s, envisioned a unified Europe stretching to the Urals. By 2002, a step in this direction had been taken by Russia in accepting a seat as

a limited partner in NATO.

Bennis (1982) called attention to the importance of vision to leaders. It was a major contributor to the success of 90 executives interviewed by Bennis and Nanus (1985). Likewise, Martin (1996) found that visionary leadership contributed to followers' supportive attitudes. Envisioning is particularly important when the organization is facing illstructured problems (Mitroff, 1978). Conger (1999) viewed what distinguished charismatic leaders at higher organizational levels from others as the strategic decisions they formulated and articulated. The more the vision was out of the ordinary, the more it became challenging and a force for change (Conger, 1999). But for Harari (1997), "Vision must be pragmatically bifocal," i.e., expected to encompass both current and future best opportunities. And Bruce (1986, p. 20) noted, "In the minds of CEOs ... the vision is never clear, only a foggy haze and a multitude of conflicting signals. We see the future darkly, while ignorant armies of experts shout across a smoky field at one another."

*Example: J. Robert Oppenheimer.* The primary source of the attractiveness of a vision to followers is their perception of the qualities of the leadership (Conger, 2000). This was illustrated by the case of J. Robert Oppenheimer, who in 1943 was appointed director of the newly founded Los Alamos National Laboratory to develop the atom bomb. I. I. Rabi (1969) said that based on his experience and personality, it was difficult to imagine a *less* likely choice. Oppenheimer had no administrative experience other than building the theoretical physics department at Berkeley. He was unknown to the government leaders who initiated and championed the project. He was seen as arrogant and nasty and at times made others feel foolish and inferior. It was expected that the director would be an expert in experimental, not theoretical, physics. Nonetheless, Oppenheimer succeeded brilliantly, first because he had a clear vision of the mission of the laboratory and was able to communicate that vision to organization members at every level, and second, because he was technically brilliant and outstanding in his intellectual stimulation, which helped colleagues think through problems. According to such scientists as Hans Bethe, Joseph Hirschfelder, Emilio Segre, and Edward Teller, he was "a genius in finding other people's mistakes," was a remarkably fast thinker, had an "iron memory," and understood everything that was done in the lab, whether it was chemistry, physics, or machining, and then could coordinate the activities. He supported the vision by creating a laboratory environment of commitment and involvement of several thousand members, making each of them feel that he could contribute to the project. He overcame demands from higher authority for secrecy between laboratory divisions by organizing in terdivisional meetings and sharing of problems and progress. Trust in him was high because of his integrity (Ringer, 2002).

*Vision Statements.* An organization's *mission* statement describes the activities to be performed for its clients, constituents, or customers (Yukl, 1998). It is not the same as vision. The core of a vision for the organization is its mission, but it adds meaning and purpose for the activities, arouses emotions, and is inspirational and intellectually stimulating. The vision should present an optimistic view of the future. It should express complex ideas in simple words and be a clear and credible statement of the future (Bass & Avolio, 1990). The vision should convey an image of what can be achieved, why it is worthwhile, and how it can be done (Yukl, 1998, p. 443). In a workshop for various sectors of a community, Berson, Shamir, Avolio, et al. (2001) sorted the vision statements of 141 participating leaders into 12 categories. They rated the "inspirational strength" of each vision and obtained four orthogonal factors. The first factor, optimism and confidence of the vision, accounted for 53.7% of the variance among the 12 categories. The factors were correlated with the MLQ assessments obtained prior to the workshop from the participants' subordinates back at work. The factor of optimism and confidence correlated significantly .28, with charisma; .20 with inspirational motivation; .21 with intellectual stimulation; .15 with individualized consideration; and .15 with contingent reward. Specificity and direction of the vision correlated .15 with intellectual stimulation. McClelland and Winter's motive imagery provided reliable and relevant measures of visionary statements. The effects of the statements were related to the expectations of government agency managers and managers in

entrepreneurial businesses. Their individual and unit performance in the government agencies were significantly affected by affiliative motive imagery. Power motive imagery in the vision statements correlated significantly with venture business growth in sales and profits in entrepreneurial firms (Kirkpatrick, Wofford, & Baum, 2002). Different factors emerged when a total of 672 vision statements were factored for 194 Singaporean respondents into (1) expertise, (2) strategic thinking, and (3) unconventionality (Khatri, Ng, & Lee, 2001).

The organizational culture plays a significant role. Visionary leaders turn their cultural ideals into organizational realities. In the process, they promote a philosophy that will be enacted by the vision's policies and programs (Sashkin, 1988). Followers react positively when the vision reflects their values and provides information to direct their future behavior. The vision serves as a metagoal for the leader to pursue (Thoms & Govekar, 1997).

*Vision Requirements.* A new vision guides the leader in maintaining or changing the organization's culture to redirect it into different missions (Bryman, 1992). For this, the vision needs to be properly communicated.

This can be achieved through leaders themselves acting as personifications of their visions and by proper attention to the rhetorical strategies by which the vision is communicated. ... Equally, the leaders need to establish an organizational framework which will facilitate the accomplishment of the vision. ... Leaders must constantly reiterate the vision and its desirability. (Bryman, 1992, pp. 137, 175)

The propagation of a vision is an important requirement of the CEO and top management. The CEO needs to align the TMT around the vision to effectively transmit it to the organization. The CEO needs to be the chief sense maker and sense giver. Although there may be negotiation, reformulation, and realignment, as the vision moves through the organization, the CEO remains responsible for its maintenance (Williams & Zukin, 1997).

Bennis and Nanus (1985) concluded, from in-depth interviews with 90 top directors and executives, that envisioning requires translating intentions into realities by communicating that vision to others to gain their support. Envisioning is the basis for empowering others, for providing them with the social architecture that will move them toward the envisioned state. It involves paying close attention to those with whom one is communicating, zooming in on the key issues with clarity and a sense of priorities. Risks are accepted, but only after a careful analysis of success or failure. Judge and Bono (2002) confirmed in surveys of 115 supervisors rated by 319 direct reports that transformational leadership was associated with vision content of higher-than-average quality.

*Measurement and Correlates.* Envisioning focuses more on success than on failure and more on action than on procrastination (Brown, 1993). Sashkin (1986, 1988) detailed the requirements to assess the visionary leader. The Leader Behavior Questionnaire (LBQ), developed by Sashkin and Fulmer (1985), a self-report of visionary leadership, included scales of focused attention, long-term goals, clarity of expression, caring, propensity to take risks, and empowerment. Stoner-Zemel (1988) found that visionary leadership, as measured by the LBQ, correlated with employees' perceptions of the quality of their work lives. Ray (1989) showed that LBQ-assessed visionary leadership was related to a factory culture of organizational excellence. And Major (1988) obtained LBQ assessments in 60 high schools that linked the visionary leadership behavior of their principals with whether the schools performed high or low on various objective criteria.

Visionary leaders have a sense of identity, direction, and strategy for implementation (Nygren & Ukeritis, 1993). A 12-item Vision Ability Scale was validated by Thoms and Blasko (1999). For samples of a total of 891 college leaders attending the same national program in various locations, the scale correlated significantly .37, with self-rated MLQ inspirational motivation and .42 with the combined MLQ transformational leadership scores. Likewise, vision ability correlated .38 with LPI inspiring a shared vision. Significant positive correlations were also found with measures of optimism, positive outlook, and future time perspective. Baum, Locke, and Kirkpatrick (1998) used a longitudinal design to collect data from 183 CEO entrepreneurs and

selected employees. Structural modeling confirmed that the attributes and contents of visions expressed verbally or in writing directly led to future venture growth.

*Vision and the Transformation of Followers.* The transformational leader concretizes a vision that the followers view as worthy of their effort, thereby raising their arousal and effort levels. However, people who seek to identify with the leader but who are distant from him or her may become only partially aroused and committed and may not take action to conform to the leader's initiatives. Nevertheless, if they are free to act and are not constrained by other commitments or the lack of opportunity, they will actually become committed to leaders even at a distance. This was confirmed by Judge and Bono (2002) in surveys of 130 leaders' visions, each described by their supervisor and three direct reports, that transformational leaders articulate and use visions more than do transactional leaders. Followers are more confident in the visions of transformational leaders and more committed to the visions. Downton (1973, p. 230) described this process as *transformational* rather than *transactional*, noting its greater likelihood of taking effect:

The opportunity for action is apt to be greater than strictly transactional relationships because the follower who identifies with a leader can transform his behavioral pattern without necessarily exchanging tangible goods with the leader ... a new moral code ... can be put immediately into practice, no matter how distant the leader and the opportunities for organizational activity.

*Visions of Reformers, Revolutionaries, and Radicals.* *Reformers* of political movements and governments such as Vicente Fox of Mexico, are able to convey to others a vision of what the society would be like, how it would look, if its ideals were supported. They espouse myths that sustain the political community and its professed ideal cultural patterns. Practices that depart from the ideals must be changed or eliminated in the desired future state. *Revolutionary leaders* such as Fidel Castro, on the other hand, envisage a future in which the sustaining myths and current cultural patterns have been rejected and society has been fundamentally reconstituted (Paige, 1977). The future the revolutionaries envisage in their rhetoric of the new regime is surprisingly devoid of details or mentions of justice, despite their focus on the injustices of the regime they intend to overthrow by force (Martin, Scully, & Levitt, 1988). *Radicals* of both the political Right and the political Left are likely to be ideologues, inflexible in their vision with everything black or white, never gray, extreme in their views, and intolerant of those who don't share their vision (Mumford & Strange, 2002). Nevertheless, radical dissenters may contribute to transformations by disrupting fundamental assumptions and beliefs of the mainstream majority (Elmes & Smith, 1991).

*Rational and Emotional Elements.* Cameron and Ulrich (1986) pointed to the rational and emotional elements of envisioning. The rational element articulates a vision in which questions about purpose, problems, missing information, and available resources are answered. The emotional element articulates a vision of a holistic picture that is intuitive, imaginative, and insightful. It uses symbols and language that evoke meaning and commitment.

*Strategic Planning.* Other aspects of envisioning that are relevant in different ways at different levels of management in the complex organization include the formulation of strategies based on the contingencies of the threats and opportunities of the organization, its resources, and the interests of its constituencies. Leaders must be able to formulate and evaluate appropriate organizational responses and arrange for their implementation in operations and policies (Wortman, 1982). Leaders will be more effective in doing so if they are proficient in gathering and evaluating ideas, storing information, thinking logically, and learning from their mistakes (Srivastva, 1983). As they rise in their organizations, the abilities that are required of them will shift from dealing with concrete matters that have short-term consequences and for which all the parameters are known to more abstract issues with greater amounts of uncertainty and longer-term consequences (Jacobs & Jaques, 1987).

*Vision and Consciousness Raising.* Long-range visions need to be detailed. The leader must understand the key elements of the vision and consider the "spill-over" effects of their future development. Furthermore,

the leader must be able to communicate his or her vision in ways that are compelling, make people committed to it, and help make it happen. As Bennis (1982, 1983) concluded after his interviews with 90 innovative organizational leaders, the leaders could communicate their vision to clarify it and induce the commitment of their multiple constituencies to maintaining the organization's course. These leaders also revealed the self-determination and persistence of charismatic leaders, especially when the going got rough. Yet they emphasized their and their organizations' adaptability to new conditions and to new problems. They concentrated on the purposes of their organizations and on "paradigms of action." They made extensive use of metaphors, symbolism, ceremonials, and insignias as ways of concretizing and transmitting their visions of what could be. They pictured what was right, good, and important for their organization and thus contributed considerably to their organization's culture of shared norms and values.

This arousal of consciousness and awareness in followers of what is right, good, and important, which new directions must be taken, and why, is the most important aspects of intellectual stimulation. The "mass line" leadership of Mao Zedong illustrated its application to social and political movements. The scattered and unsystematic ideas of the Chinese masses about marriage, land, and the written language were converted by the Communist Party leadership into a set of coherent, concentrated, and systematic ideas for reform, which were fed back to the masses until they embraced them as their own. Mao even seemed to practice this strategy in his one-on-one discussions with others (Barlow, 1981).

*Intuitive Aspects.* For Pondy (1983), envisioning begins with intuitive interpretations of events and data that give meaning to new images of the world that ultimately can be clarified into strategies for an organization. Symbols and phrases are invented to focus attention on the strategic questions that are needed to get others involved in the process. As Jim Renier, the CEO of Honeywell, suggested, although the vision that emerges may be that of the single-minded chief, it often evolves, in larger organizations in particular, out of the chief's give-and-take with many others during repeated reviews of the possibilities of the desired future state. Renier (as quoted in Tichy & Devanna, 1986, p. 128) put it this way: "What you've got to do is constantly engage in iterating what you say [about the vision] and what they say is possible. And over a couple of years the different visions come together."

With their ability to provide images of the future state, inspiring leaders provide direction. A commonly used metaphoric vision, a cliché favored by political leaders, is the path, road, or journey that must be taken that gives direction to the followers (Tucker, 1981). But metaphoric visions can boomerang into apocryphal anecdotes and reverse in meaning. For example, King Canute wanted to convey his limitations to his courtiers and used his lack of control over the ocean tides to illustrate his point. History converted the metaphor into an illustration of the king's foolish pomposity in trying to command the sea not to roll up the beach.

*Can Envisioning Be Developed?* Mendell and Gerjuoy (1984) accepted the conventional wisdom that visionary leadership cannot be effectively taught. Unless the talent is there already, managers can only be prepared to anticipate possibilities. If this were true, then only recruiting and selection would ensure an adequate number of capable inspiring leaders with vision. But is it possible for managers to develop their ability to envision and to be more inspirational leaders, in general?

Exercises provide practice that engages trainees in envisioning their organization's future. In such exercises, executives are asked to talk about how they expect to spend their day at some future date—say, three years hence—or what they expect their organization to look like. Or they may be asked to write a business article about their organization's future. These comments are then evaluated with feedback. From these visions, leaders and managers can draw up mission statements and the specifications that must be met by such an organization (Tichy & Devanna, 1986).<sup>1</sup>

*Caveat.* Visions may be too abstract, too complex, unrealistic, unreachable, or impractical. They may also be too inspirational. Fulfilling a vision may become an end in itself or a distraction rather than paving the way to a valued goal (Langeleler, 1992). Meindl (1998) regarded visionary leadership as a "vague and mysterious

concept.” He cited Collins and Porras (1994), who declared that the best companies have not relied on visionary leadership to sustain their competitive advantage. Additionally, Meindl (1998) argued that much of the salutary reporting about the positive effects of visionary leadership on organizational performance may be a myth, a product of the “Romance of Leadership” (Meindl, 1995). Successful organizations often attribute the outcome, incorrectly, to effective leadership. Meindl (1998) suggested that there may be more significant leadership tasks than envisioning: “We too often rely on overblown, highly romanticized images of great visionary leaders with special cognitions of the future” (p. 22). Nevertheless, at the same time, Meindl agreed that organizational members could be guided by a shared vision of a desired future state and that a leader with the necessary skills can shape and foster that vision.

## Antecedents of Transformational and Transactional Leadership

---

What predisposes individual leaders to transformational or transactional leadership? The answers include individual differences in personality and differences in cognitive, social, and emotional competencies. Much evidence has accumulated that age, education, and experience are likely to correlate with the transformational leadership and transactional leadership of both the rated leaders and the followers. Additionally, leaders’ inventoried or tested traits and beliefs have been found to be correlated with their leadership ratings by their followers, peers, and/or superiors. In turn, these ratings have been found to be dependent on the traits of the followers.<sup>2</sup>

### ***Personality***

Personality predictors of transformational leadership have been found in a wide variety of sites, ranging from business and industry to community leaders’ programs. According to Popper and Mayseless (2002), the internal world of the transformational leader is characterized by the motivation to lead, self-efficacy, and the capacity to relate to others in a prosocial way. The transformational leader is optimistic and open to new experiences and others’ points of view. There is a disposition for social dominance, the capacity to serve as a role model, and a belief in the ability to influence others. As noted in [Chapter 5](#), the Big 5 structure of personality with its five factors, each with several facets, has provided a widely accepted way to structure the study of personality as a predictor of performance. For example, Judge and Bono (2001) collected 14 samples of community leaders’ Big 5 NEOAC scores and their facets using the Costa and McCrae (1992) 240-item NEO Personality Inventory. Also, the 261 leaders were each MLQ-rated by one or two subordinates. The simple correlations of charisma, inspirational leadership, intellectual stimulation, and individualized consideration correlated with extraversion, openness, and agreeableness, respectively, as follows: extraversion, .22, .24, .14, and .23; openness, .18, .22, .10, and .21; and agreeableness, .28, .21, .24, and .23. Neuroticism and conscientiousness did not correlate with any of the transformational leadership factors. The MLQ transactional factor of contingent reward was negatively correlated  $-.20$  with agreeableness. Passive management by exception correlated  $-.15$  with agreeableness and  $-.18$  with conscientiousness.

Lim and Ployhart (2000) correlated the five NEOAC factors with the transformational leadership scores of the leaders of 39 Singaporean combat teams. The 202 team followers used the MLQ to rate their respective team leaders. Correlations of transformational leadership of the leaders with the five personality factors NEOAC, measured by the International Personality Item Pool (IPIP) were as follows: neuroticism,  $-.39$ ; extraversion, .31, openness,  $-.08$ ; agreeableness,  $-.29$ ; and conscientiousness,  $-.09$ . Among the 79 studies classified in terms of the Big-Five factors in the meta-analysis by Judge, Bono, Iles, et al. (2000), reviewed in

[Chapter 5](#), 11 to 15 correlations between each of the NEOAC categories and judgments of transformational leadership were significant, as follows: neuroticism,  $-.21$ ; extraversion,  $.25$ ; openness,  $.30$ ; agreeableness,  $.27$ ; and conscientiousness,  $.19$ . In line with predictions, Bommer, Rubin, and Baldwin (2004) found that cynicism about change among 2,247 subordinates correlated  $-.29$  with the transformational leadership of their focal leaders. This was offset by the correlation of  $.45$  when transformational peer leadership of the 227 managers was present. Van Eron and Burke (1992) completed a survey of 128 senior executives and their 615 subordinates from a global firm and showed that the executives who described themselves as sensing rather than intuitive on the MBTI were more inspirational on the MLQ. Also, they were more judging than perceiving, according to their subordinates ( $r = .44$ ;  $.30$ ). They also were more likely to regard work as a strong sense of mission ( $r = .34$ ;  $.23$ ).

*Military Studies.* Clover (1988) compared on selected personality traits U.S. Air Force Academy commissioned officers who scored higher in charisma, intellectual stimulation, and individualized consideration on the MLQ with those who scored lower. Clover concluded that the transformational leaders were more likely to be more flexible, more compassionate, more pragmatic, and less tough. Ross and Offerman (1997) replicated the study with 40 Air Force Academy officers who completed the Adjective Checklist (ACL) (Gough & Heilbrun, 1983) and 4,400 cadets who completed a shortened form of the MLQ on the officer who commanded their squadron. Four cadets also completed the ACL on their squadron commander. The officers' self-ratings on the ACL were combined with the four cadets' ACL ratings to provide the personality trait measures. Transformational officers were more self-confident, more pragmatic, more nurturant, less critical, and less aggressive.

Avolio, Bass, Atwater, et al. (1994) examined the tested personality traits of junior-year cadet officers at Virginia Military Institute (VMI). MLQ ratings were provided by their subordinates. Hardiness (Kobasi, Maddi, & Puccelli, 1982) and physical fitness correlated with the cadet officers' transformational leadership. Atwater and Yammarino (1993) correlated Cattell's (1950) 16 PF Inventory personality assessments with MLQ ratings of 107 Annapolis midshipmen who served as summer squad leaders of 1,235 plebes. MLQ-rated transformational leadership, as appraised by the plebes' superiors, correlated  $.24$  with 16 PF self-discipline and  $.26$  with 16 PF conformity. Additionally, Atwater and Yammarino (1989) found that the Annapolis midshipmen squad leaders appraised by their plebe subordinates as transformational described themselves as more likely to react emotionally and with feeling.

*Community Leaders.* Avolio and Bass (1994) correlated the Gordon (1963) Personal Profile (GPP), a forced-choice inventory, with MLQ ratings by subordinates of 118 leaders in their various public and private agencies and business firms in one middle-sized city in the United States. GPP ascendancy and sociability scores correlated  $.21$  and  $.23$  with charisma and inspirational motivation, respectively. Bass and Avolio also administered a sense of humor scale, which correlated positively but not significantly with all four components of transformational leadership. The MLQ component scores of the community leaders were also correlated with the Myers-Briggs Type Indicator (MBTI). Charisma and individualized consideration were predicted, respectively, by more MBTI feeling and less thinking ( $r = .25$ ,  $.22$ ). Inspirational motivation was predicted by intuition ( $r = .20$ ) and not sensing ( $r = .19$ ). The transactional factor of passive management by exception correlated with more sensing ( $r = .23$ ) and less intuition ( $r = .28$ ).

A meta-analysis by Lowe, Kroek, and Sivasubrahmanian (1996) compared public with private organizations and showed that leaders from public organizations were higher in mean factor scores than leaders from private ones in transformational leadership: charisma,  $-.61$  versus  $-.33$ ; individualized consideration,  $-.58$  versus  $-.33$ ; and intellectual stimulation,  $-.52$  versus  $-.40$ . They also differed in transactional management by exception,  $-.41$  versus  $-.16$ , and contingent reward,  $1.85$  versus  $1.75$ . The meta-analysis also compared military with civilian organizations. Military leaders were higher than civilians in the factor mean scores for transformational leadership and for management by exception.

## Competence

Cognitive, social, emotional, and other competencies have been found to be significant antecedents of transformational and transactional leadership, especially social and emotional competence (Bass, 2002). Older and more experienced Dutch managers, usually at higher organizational levels, saw a greater need for inspirational leadership, cognitive, and social competence. Younger Dutch respondents viewed their leaders as more transactional, especially if they were in sales or marketing (Tail-lieu, Schruijer, & van Dijck, undated).

*Cognitive Competence.* According to Wofford and Goodwin (1994), cognitive ability is what distinguishes transformational from transactional leaders. Subordinates' MLQ ratings of the charisma and inspirational motivation of 782 managers correlated .13 and .16, respectively, with the Owens Biographical Questionnaire scale of intelligence (Southwick, 1998). Subordinate ratings of charisma, inspirational motivation, and intellectual stimulation correlated .33, .33, and .23 respectively, with management committee evaluations of middle managers' good judgment (Hater & Bass, 1988). Cattell's (1950) 16 PF Inventory intelligence score correlated .20 with midshipmen's transformational leadership. However, the Scholastic Aptitude Test (SAT) failed as a significant predictor of transformational leadership among midshipmen (Atwater & Yammarino, 1993) and military cadets (Avolio, Bass, Lau, et al., 1994).

*Social Competence.* The use of humor was found by Avolio, Howell, and Sosik (1999) to correlate .56 with the transformational leadership behavior of 115 Canadian managers and executives and .45 with their practice of contingent reward.

Eloquence is one of the most important competencies for transformational leaders. Persuasiveness and social sensitivity, as obtained from Owens's biodata, correlated between .14 and .22 with charisma and inspiration (Southwick, 1998). For Hater and Bass, the correlations with the transformational leadership factors were .32, .33, and .33 with the quality of the managers' communications. According to their 968 subordinates, Israeli industrial managers who were more transformational leaders were more open, informal, frank, careful listeners and careful transmitters on the Klaus & Bass Communications Style Inventory (1982). Correlations ranged from .30 to .64 (Berson, 1999). Social sensitivity in biodata correlated .14 and .18 with charisma and inspirational motivation and .15 with individualized consideration (Southwick, 1998). Sociability and ascendance on the Gordon Personal Profile correlated between .21 and .25 with the charisma and inspirational motivation of community leaders (Avolio & Bass, 1994).

*Emotional Competence.* Transformational leaders were higher in their internal locus of control (Rotter, 1966). Internal locus of control, as measured by the Personality Orientation Inventory (Shostrom, 1974), correlated higher (between .33 and .46) with the four transformational components as obtained from the subordinates of Digital Equipment executives (Gibbons, 1986). Internal locus of control of 78 senior executives in a Canadian financial institution correlated significantly with a short version of the MLQ rated by an average of four followers, as follows: charisma, .18, .25, and individualized consideration, .33. (Howell & Avolio, 1993). Similarly, inner direction on the Personal Orientation Inventory (Shostrom, 1974) of 20 Digital Equipment executives correlated .37, .33, and .44 respectively, with the three transformational factors of charisma, inspirational motivation, and individualized consideration, as MLQ-rated by their subordinates.

Other emotional competency (or emotional intelligence) assessments that were antecedents of transformational leaders included self-acceptance, .43 to .46 (Gibbons, 1986) and significant biodata antecedents such as self-esteem, self confidence, being energetic, having a strong work ethic and sense of responsibility, setting difficult self-goals, and being comfortable in new situations (Southwick, 1998). In an experiment by Newcombe and Ashkanasy (2002), when 537 participants evaluated videotaped leaders, they rated leaders more favorably if the leader's positive or negative emotional facial expressions were congruent with the emotional content of their verbal messages. According to a study by McColl-Kennedy and Anderson

(2002), frustration had a negative mediating effect on the impact of transformational leadership. The emotion of optimism had a bolstering effect.

Emotional competencies that significantly predicted transformational leadership were hardiness (Kobasa, Maddi, & Kahn, 1982), optimism, positive thinking, behavioral coping, feeling over thinking (Atwater & Yam-marino, 1993); risk taking (Hater & Bass, 1988); personal adjustment and nurturance (Ross & Offerman, 1997). The optimism and positive thinking of transformational leaders was confirmed by Speitzer and Quinn (1996). Ashkanasy and Tse (2000) inferred that transformational leaders have a positively biased schema for processing information. They constructed a model that, among other things, showed that transformational leaders were in touch with their own emotions, could regulate their own emotions, and were emotionally stable and less stressed. Transformational leaders could control their own and others' emotions. They had emotional intelligence (Das-borough, 2002). Pastor and Nebeker (2002) reported that among 170 executives, managers, and supervisors and 380 to 450 subordinates, emotional reasoning correlated .33 with contingent reward but understanding emotions was negatively correlated with active and passive management by exception ( $r = -.29; -.28$ ).

### ***Organizational Levels***

A study of how the organizational level of leaders' positions affects their transformational and transactional performance was completed by Bullis, Kane, and Tremble (1997). They reported on three levels of U.S. Army officers. At the highest level studied were approximately 295 battalion commanders (lieutenant colonels); at the second level were approximately 440 company commanders (captains); and lowest were approximately 3,170 platoon leaders (lieutenants). Officers at each level were MLQ-rated by members one level below them. [Table 22.2](#) shows the generally increasing scores at each level. Gottlieb (1990) found the same trend when she compared each of the transformational factor scores of 76 Veterans Administration hospital chief nurses and 545 associate chief nurses, except that management by exception was the same at both organizational levels she studied. The chief nurses were MLQ-rated by their immediate subordinates, the associate chief nurses, who, in turn, were MLQ-rated by their 1,532 immediate subordinates.

### ***Organizational Characteristics***

Bass (1985c) proposed that transformational leadership would be more likely to appear in *organic* organizations, as described by Burns & Stalker (1961), and transactional leaders would be more common in *mechanistic* organizations. In a comparison of 511 employees in a manufacturing environment with 539 employees in an R & D environment, Berson and Linton (undated) found that transformational leadership related more to quality climate perceptions and satisfaction with projects than with processes or manufacturing settings. Koopman (1991) expected that transformational leadership was more effective in innovative organizations and transactional leadership in bureaucratic organizations. For Quinn (1988), the orientation of organic organizations was supportive, innovative, and flexible (i.e., transformational). The orientation of mechanical organizations was toward rules, goals, and control (i.e., transactional). Den Hartog, Van Muijen, and Koopman (1996) randomly split the 330 employees in 28 departments in different Dutch organizations in business, social service, health care, and local government. One of the subsamples used the MLQ (8Y) to rate the transformational and transactional leadership of its supervisors; the other subsample completed the Focus-Culture Questionnaire about its departmental culture. The results were as predicted: transformational leadership correlated .72 with cultural support and .69 with innovativeness; transactional leadership correlated .52 with cultural support and .48 with innovativeness. On the other hand, transactional leadership was more

prevalent than transformational leadership in departments with more rules and goals orientation. Transactional leadership correlated .54 with rules and goals in departmental cultures.

Both similarities and differences were present in the occurrence and effects of transformational leadership from one country culture to another (Bass, 1997). This was subsequently documented in the Globe Study (House, Hanges, & Javidan, 2004) involving more than 15,000 managers in the same three industries in 62 countries. Considerable amounts of both universality and specificity were found in the data from the different organizations and countries (see [Chapter 33](#)).

### ***Follower Characteristics***

The findings were mixed. The followers' locus of control made a difference. A thesis by Pastor and Mayo (1996) showed that for 180 college students MLQ-rating their classroom professors, internal locus of control correlated significantly with inspirational, individually considerate, and contingent rewarding teachers. Among 54 Israeli military groups, the followers' level of development predicted their leaders' transformational leadership (Dvir & Shamir, 2003). In the 1996 presidential election, those affiliated with the Democratic Party saw Bill Clinton, the Democratic candidate, as more transformational ( $r = .31$ ) and the Republican candidate, Bob Dole, as less transformational ( $r = -.36$ ). (Pillai & Williams, un-dated).

Table 22.2 U.S. Army Organizational Levels as Antecedents of the Mean Multifactor Leadership (MLQ) Means of Platoon Leaders (Lieutenants), Company Commanders (Captains), and Battalion Commanders (Lt. Colonels)

	Platoon Leaders Lieutenants	Company Commanders Captains	Battalion Commanders Lt. Colonels
Attributed Charisma	3.08	3.83	4.02
Behavioral Charisma	2.99	3.77	4.03
Inspirational Leadership	3.10	3.79	3.99
Intellectual Stimulation	2.83	3.45	3.56
Individualized Consideration	2.82	3.66	3.57
Contingent Reward	2.59	2.86	2.87
Active Mgmt by Exception	2.92	3.01	2.90
Passive Mgmt by Exception	2.61	2.20	2.14
Number of Leaders Rated	442	213	53
Number of Subordinate Raters	3170	440	295

SOURCE: Bullis, Kane, and Tremble (1997).

Ehrlhart and Klein (2001) created a scenario of a transformational district manager who communicates high performance expectations, exhibits confidence in followers' abilities, takes calculated risks against the status quo, and articulates a value-based vision and collective identity. Scenarios of relations-oriented and task-oriented district managers were also created. A total of 267 University of Maryland students (62% female) of diverse ethnicities, almost all with work experience, were asked to rate their preferences to work for each of the three district managers. The students chose to work with the transformational manager if the students had participative work values ( $r = .23$ ) and high self-esteem ( $r = .16$ ). In addition to showing the expected positive effect on 502 service employees on their identification with the organization when their leaders were transformational, Epitropaki and Martin (2005) also found that the effect was greater when the employees were low in positive emotionality and high in negative emotionality. Harland, Harrison, Jones, et al.

demonstrated that resilience was stronger among subordinates of transformational leaders (2005). But Bono and Judge (2000) found few significant effects on transformational leadership of various follower personality characteristics for more than 1,200 followers rating their more than 300 leaders. And contrary to expectations, Dockery (1993) failed to find that subordinates who were low in independence would respond more favorably to transformational leaders.

## Effects of Transformational and Transactional Leadership

---

Numerous scholars expected that transformational leadership was a key to organizational and follower success. Bryant (2003) proposed that transformational leaders may be more effective in creating and sharing knowledge individually and in small groups but transactional leaders may be more effective in exploiting knowledge at the organizational level. Underlying the effects of the transformational leader on follower performance is its enhancing personal identification with the leader through bolstering the self-worth of the follower in contributing to what needs to be done and the social identification of the follower with the organization (Kark & Shamir, 2002). These scholarly expectations were supported by biographies of world-class industrial, military, and political leaders (Bass, Avolio, & Goodheim, 1987). The results of the extensive surveys of over 1,500 managers, leaders of technical teams, government and educational administrators, upper middle managers, and senior U.S. Army officers that were discussed in [Chapter 21](#) for charismatic leadership are also relevant for transformational leadership. Subordinates of these leaders who described their managers on the MLQ—Form 5 as more transformational were also more likely to say that the leaders and the organizations they led were highly effective. Such transformational leaders were judged to have better relations with higher-ups and to make more of a contribution to the organization than were those who were described only as transactional. Subordinates said they also exerted a lot of extra effort for the transformational leaders. If leaders were only transactional, the organizations were seen as less effective, particularly if most of the leaders practiced reactive passive management by exception (intervening only when standards were not being met). Subordinates said they exerted much less effort for such leaders (Bass & Avolio, 1989). Subordinates and followers set higher purposes in their work for transformational leaders (Sparks & Schenk, 2001); performed beyond social expectations (Berson, undated); expended more effort and were more committed and involved (Harvey, Royal, & Stout, undated).

However, Vera and Crossan (2004) noted that strategic leaders can promote using both transactional and transformational leadership. Bono and Judge (2003) showed in two studies with diverse samples that followers of transformational leaders felt their work was more important and more in accord with their motives, values, and self-concepts. Dumdum, Lowe, and Avolio (2002) extended the meta-analysis of Lowe, Kroeck, and Sivasubramaniam (1996), validating the effects on followers' effort, performance, and job satisfaction.

The commentary and empirical results of political leaders, educators, military leaders, and business leaders indicated that transformational leadership was more effective in military than civilian studies. Also, management by exception was less effective in civilian than military studies (Coleman, Patterson, Fuller, et al., 1995; Lowe, Kroeck, & Sivasubramaniam, 1996).

### ***Political Leaders, Public Service, and Other Nonprofit Leaders***

When faced with political chaos and an angry public, with policy making taken over by radical minorities and legislatures elected on the basis of single negative issues, Abels (1996) suggested that political leaders must compete by being more transformational. Rosenbach and Mueller (1988) used an abbreviated version of the MLQ to survey the descriptions of 110 fire chiefs by their 732 subordinates and again showed that the

transformational leader components were more highly correlated with the subordinates' perceptions of effectiveness and satisfaction than were the components of transactional leadership.

Police officers of various ranks were asked to take the role of subordinates negotiating with transformational or transactional superiors described to them in scenarios. Officers whose "superiors" were described as transformational were significantly more likely to attempt to influence their superiors upwardly than were those officers whose superiors were supposedly transactional. Officers with transformational superiors were significantly more likely to employ rational tactics of upward influence rather than try to be ingratiating or use direct requests and strong emotion (Deluga & Sousa, 1990). South African cricket union chief executive officers rated their teams as more effective on the Effectiveness Survey for Cricket Administration if the executives were more transformational in their MLQ scores, according to ratings by their subordinates (Ristow, Amos, & Staude, 1999). Onnen (1986) demonstrated that Methodist ministers who were transformational generated more growth in their church membership, budgets, and attendance at Sunday services.

Many historical examples can be cited about the effects of transformational and transactional leaders on international relations. Henry Kissinger's (1994) description of U.S. diplomacy was transformational when it emphasized ideals of democracy, freedom, and individualism and the United States was a haven for the oppressed of Europe. Vision drove the American dream of a continentwide country. The purchases of the Louisiana Territory and of Alaska were due to the visionary leadership of President Thomas Jefferson in 1803 and Secretary of State John Seward in 1867. On the other hand, diplomats negotiate deals between countries in which much transactional leadership is exerted to exchange resources for agreements and promises. Threats and counterthreats are used to try to forestall actions of competing parties.

## ***Educators***

C. Patterson (1995) suggested that college faculty needed to be transformational leaders in order to inspire their students to become more active, enthusiastic learners. Sergiovanni (1990) posited that when transformative leadership results in moral authority that goes beyond bureaucratic direction and unites followers in pursuit of higher-level goals, commitment and performance far exceed expectations. Leaders' vision, individualized consideration, and intellectual stimulation lie behind improved teachers' practices, according to a large-scale qualitative study of innovation in the Netherlands (Geijsel, Sleegers, & van den Berg, 1999). Similar conclusions were reached about the positive correlations obtained between effectiveness and the factors of transformational leadership for vocational education administrators (Daughtry, 1997), chairpersons of university academic departments (Brown & Moshavi, 2002), public school principals (Kirby, Paradise, & King, 1992; Leithwood, 1994), private school principals, and principals of private schools (Hoover, 1987) and similarly for chairpersons of academic university departments. Among 440 university faculty in 70 departments, faculty satisfaction was positively correlated with the transformational leadership of their department heads (Brown & Moshavi, 2002). When 120 liberal arts undergraduates rated each one of their instructors in the arts and sciences as higher in transformational leadership, they also indicated that the instructor was more respected, trusted, and involving, as well as more satisfying and effective (Harvey, Royal, & Stout, 2003).

Using enrollment growth as an indicator of institutional effectiveness, Cowen (1990) found it to be correlated with transformational leadership on the part of 153 university presidents. Vistro (1999) obtained a positive relationship between the performance of Filipino Teacher Licensure exams and the transformational leadership of the deans and chairpersons of the private teacher education institutions the teachers had attended. Again in the Philippines, if schoolteachers rated their principal as transformational leaders, student learning was

better (Catanyag, 1995). Philbin (1997) found that teacher satisfaction, perceived school effectiveness, and effort were higher if the high school principal was transformational. Students' learning, as measured by Indiana's annual achievement test, was greater, but only if the students were higher in cognitive ability and socioeconomic status. Students lower in cognitive ability and socioeconomic status did not benefit from the principal's style of leadership. Major (1988) reported that pupils demonstrated better performance in schools led by principals who were high rather than low in transformational leadership. Following a review of six qualitative and 15 quantitative studies of the effects of transformational leadership in schools by Leithwood, Tomlinson, and Genge (1995), Leithwood (1995) concluded that the effects of transformational leadership included: (1) identification of goals, development of a schoolwide vision, and its inspirational dissemination, along with high expectations for the functioning of teachers and students; (2) involvement of staff, teachers, parents, and students; (3) development of structures from the bottom up; and (4) development of a collaborative culture. Effectiveness was seen in the professional development of the teachers and the expansion of their problem-solving capacity. Leithwood and Stein-bach (1991) noted that the transformational leadership of effective school principals would show up in their expert everyday problem solving. They can articulate interpretations of problems for others and share with others their strong concerns about problems. They demonstrate respect for others and strong appreciation of professional and human values. Major (1988) obtained LBQ assessments in 60 high schools that linked the visionary leadership behavior of school principals with how well the schools performed on various objective criteria.

### ***Military and Naval Leaders***

As noted in the preceding chapter, Yammarino and Bass (1988, 1989) collected subordinates' MLQ ratings of a 5% representative sample of the junior commissioned officers serving in the U.S. surface fleet. Also obtained from the superiors for the 186 officers were their cumulative fitness reports and recommendations for early promotion. The component factors of transformational leadership correlated as follows with fitness and promotion recommendations, respectively: (1) charisma, .38, .37; (2) inspirational motivation, .25, .28; (3) intellectual stimulation, .31, .34; and (4) individualized consideration, .21, .24. The transactional factors describing the subordinates correlated with their superiors' appraisals as follows: (5) contingent reward, .20, .24; (6) active management by exception, .22, .28; (7) passive management by exception, -.05, -.04; and (8) laissez-faire leadership, -.31, -.31. Similarly, transformational leadership of focal officers in Marine Corps transport squadrons in terms of MLQ ratings from their supervisor, peers, and subordinates had a strong relationship with the effectiveness of the focal officers and unit cohesion and morale (Salter, 1989). Findings were the same for correlations obtained in ratings by subordinates of U.S., Canadian, and German field-grade officers serving in NATO (Boyd, 1988). Masi and Cooke (2000) found that the MLQ transformational leadership of 78 company commanders accounted for 36% of the variance in motivation of their 145 army recruiting station managers. Positive correlations were routinely found between transformational leadership and satisfaction with military leaders and with the unit led by the leader (Lowe, Kroeck, and Sivasubramanian, 1996). For instance, the 4,400 Air Force Academy cadets who MLQ-rated the commissioned officers in charge of their squadron yielded significant MLQ correlations with satisfaction with their squadrons as follows: charisma, .43; individualized consideration, .38; and intellectual stimulation, .23.

Clover (1989) used an abbreviated version of the MLQ to correlate the descriptions of 3,500 subordinates at the U.S. Air Force Academy of their commissioned officer squadron commanders and various measures of their squadrons' performance. Commanders who received higher ratings in transformational leadership led better-performing squadrons and were more likely to be seen as preferred role models by the cadets. On the other hand, open-ended questions in interviews with cadets revealed that *transactional* squadron leaders were

perceived as selfish, lacking in empathy, social skills, and trust. They made rash decisions and caused frustration, reduced morale, and created disunity in the group (Clover, 1990). At the U.S. Military Academy (West Point), 437 junior year cadets MLQ-rated their 250 senior-year cadet leaders. The transformational leadership scores of the cadet leaders significantly correlated .20 with their military performance grades as seniors. Their corresponding transactional scores correlated .01 with their military performance grades (Bartone & Dardis, 2001). On the other hand, Ross and Offerman (1994) failed to find that the academic, athletic, or military performance of Air Force Academy cadets was predicted by the transformational leadership of their commissioned officers. They did find that contingent reward correlated .34 with satisfaction.

### ***Business and Industrial Managers***

If widely practiced in a firm, transformational leadership ought to earn the firm a corporate image as a good company to work for and to do business with (Bass, 1990). It should help recruiting and improve organizational and individual development. Many studies have found positive correlations between subordinate ratings of the transformational leadership of managers and professionals and their effectiveness as leaders. Posner and Kouzes (1990) found that scores based on their five transformational leadership practices as a whole accounted for 55% of the variance in subordinates' appraisals of the effectiveness of their leaders. Shea and Howell (1998) proposed that transformational leadership enhanced followers' self-efficacy and outcome expectancies.

*National Findings.* Williams, Turner, and Parker (2000) reported that those of 211 Australian manufacturing technicians who rated their team supervisors as transformational were more likely to comply with safety regulations and were more likely to take safety initiatives. Zhu, Chew, and Spangler (2005) demonstrated that CEOs' transformational leadership, mediated with a committed and capable workforce, produced superior organizational outcomes. Singer (1985) showed that employees in New Zealand preferred working with leaders who were more transformational than transactional. In the United States, at Federal Express, transformational leaders were found to assume a focal role in innovation by creating a learning orientation that promoted organizational learning (Hult, 1995). In Canada, Howell and Avolio (1993) obtained strong positive results showing that the consolidated business units of a Canadian insurance company were significantly more likely to reach targeted quotas a year later if the 78 senior managers had been MLQ-rated as transformational a year before. (The reverse was true for transactional managers.) In a study of 267 employees in three Dutch organizations, Den Hartog (2000) found that if 267 employees in three Dutch organizations rated their supervisors as more inspirational, the employees were more emotionally committed to their line of work, but Den Hartog failed to find that the rated inspirational leadership of the supervisors predicted employee self-efficacy. In 24 German firms, positive and significant regressions were found between the transformational leader behavior of supervisors and innovation among 161 R & D, marketing, and HR employees. Task performance was predicted to the same extent, but active management by exception by the supervisors was contraindicated (Rank, Nelson, & Xu, 2003). In Austria, the MLQ transformational leadership scores of 120 branch bank managers predicted long-term market share and customer satisfaction (Geyer & Steyner, 1998). On North Sea oil rig platforms off the coast of Scotland, supervisors rated more transformational by their subordinates were more effective (Carnegie, 1995). Transformational middle and top managers in a large Israeli telecommunications firm were more effective communicators, according to their immediate subordinates. They conveyed strategic organization goals better. Their subordinates were more familiar with the goals of the organization (Berson & Avolio, 2004). In a Chinese state enterprise, transformational managers, as rated by their subordinates, were judged to be more effective (Davis, 1997). Shin and Zhou (2003) demonstrated that creativity was greater among 290 employees in 46 Korean

companies if their supervision was transformational. At three Japanese nuclear power stations, both transformational supervisors and their subordinates received better performance ratings by 566 maintenance employees than did their transactional counterparts (Bettin, Hunt, Macauley, et al., 1992).

*Labor Leadership.* The transformational leadership of union stewards predicted greater participation of members in union activities and loyalty to the union (Kelloway & Barling, 1993). Many labor union presidents transformed the everyday lives of working men and women. They were shapers of a new order and movers, shakers, and servants of the labor movement (Dubinsky & Van Tine, 1992).

*Other Findings.* Zorn (1988) observed that the transformational leaders among 73 pairs of small-business owners and their employees were more person-centered and more complex interpersonally. Sridhar, Valecha, and Sridhar (1994) obtained positive relations between transformational leadership and follower empowerment: Bass (1990, 1998, 1999) reported that subordinates indicated that they exerted extra effort and were more satisfied with supervisors whom they rated highly in transformational leadership. In a medical technology firm, the frequency and quality of the content of information sought from their supervisor depended on how much 75 employees rated their supervisor as transformational (Madzar, 2001). Salespersons assessed as more transformational also performed better in sales (Garcia, 1995).

In six organizations, transformational leadership of supervisors correlated with commitment to their organizations of white-collar employees (Pitman, 1993). The commitment of 862 insurance employees was enhanced by the inspirational leadership of senior management (Niehoff, Eng, & Grover, 1990). In an experiment with 194 business students, Waldman, Bass, and Einstein (1987) showed that the performance appraisals of subordinates were higher if their leaders were described as transformational on the MLQ. Federal Express superiors of 54 managers rated the managers significantly higher in judgment, quality of decision making, financial management, communication, persuasion, and risk taking if the managers were described by their 306 subordinates as more charismatic or intellectually stimulating. No such significant correlations were found when the managers were described by their subordinates as practicing transactional leadership (Hater & Bass, 1988). Tepper (1993) reported finding that among 95 lower-level managers from a large financial institution, transformational managers were more likely to use legitimating tactics and to foster more identification and internalization in their subordinates, but transactional managers (as would be expected) were more likely to use exchange and pressure tactics.

*Findings in Simulations.* Similar results were obtained in simulations. Avolio, Waldman, and Einstein (1988) found that transformational “presidents” of simulated business firms generated more profitability, a greater share of the market, and better debt-to-equity ratios (Avolio, Waldman, & Einstein, 1988) than did the transactional “presidents.” Ahead of their time, Litwin and Stringer (1966) demonstrated that transformation-like leadership resulted in more productivity at lower costs than did authoritarian or democratic styles imposed on simulated business firms. Jung (2000–2001) found that the fluency and flexibility of divergent thinking in brainstorming in simulated business exercises was greater under transformational than transactional leadership.

*Stress and Burnout.* Selzer, Numeroff, and Bass (1989) found, as expected, for 875 part-time MBAs MLQ-rating their work supervisors that charisma, intellectual stimulation, and individualized consideration correlated  $-.52$ ,  $-.36$ , and  $-.46$ , respectively, with the Gillespie and Numeroff Burnout Inventory (sample item: “I’m fed up with my job.”) (Gillespie & Numeroff, 1984). Management by exception correlated  $.22$  with burnout. Leadership style and symptoms of stress correlated significantly but to a lesser extent. However, the part of intellectual stimulation that required backing opinions with reason correlated *positively* with burnout and symptoms of stress when charisma and individualized consideration were held constant.

### ***Health Care Directors and Personnel***

Among Pennsylvania hospital nurse executives, 37% of the variance in effectiveness, 63% of the variance in the job satisfaction, and 89% of the extra effort their staff nurses made were accounted for by the transformational leadership model (Altieri, 1995). Gottlieb (1990) found that older Veterans Administration chief nurses and associate chief nurses were rated by their immediate subordinates higher in all MLQ factors of transformational but not transactional leadership. In 87 Spanish health care centers and 88 drug treatment centers, the family doctors, pediatricians, nurses, and clerks MLQ-rated the center coordinators. If they rated the coordinators as more transformational, they were more likely to regard them as legitimate in organizing, managing, controlling, and evaluating each team member. There were fewer role conflicts better interpersonal relations, and a greater sense of autonomy if the coordinators were rated as more transformational (Morales & Molero, 1994, 1995).

### ***Caveat***

Some of the preceding findings on effectiveness of leadership behavior were based on ratings by the same person of *both* the leadership and the outcomes. Nonetheless, there is considerable evidence from meta-analyses that factors of transformational leadership correlate moderately positive or higher with effectiveness even when such results are eliminated from consideration. At least two meta-analyses of the correlations of *subjective* percept-percept ratings where the same rater provided both leadership ratings and outcomes were compared with correlations of transformational leadership ratings with *objective* measures of effectiveness free of same-source bias. The subjective mean correlations results were higher with same-source outcomes and lower with objective outcomes. For example, Coleman, Patterson, Fuller, et al. (1995) analyzing 16 studies involving 4,034 cases using rated subjective effectiveness and 11 studies totaling 577 cases using objective effectiveness, found that the factors of transformational leadership varied in mean correlation with subjective effectiveness from .45 to .48. The comparable figures for objective effectiveness varied from .28 to .36.

The possibilities of same-source bias were eliminated in a study of 90 U.S. Army light infantry platoons. On their home base, half the 30-odd riflemen in each platoon MLQ-rated the leaders of their platoon. The other half provided measurements, using a Team MLQ, of platoon or company effectiveness (potency, cohesiveness, etc.). Peers and company commanders also MLQ-rated the platoons' leaders. The platoons then underwent 11 near-combat missions in a Joint Readiness Training Center (JRTC) accompanied by 2 of 38 trained observer-controllers (O/Cs) who evaluated the effectiveness of each of the leaders and the platoons after the first and last missions and 1 in between. There were significant positive correlations among the home base MLQ leadership ratings and the independently obtained measurements of home base platoon potency, cohesiveness, and effectiveness. The home base MLQ data significantly predicted the performance of the leaders and the platoons in the JRTC near-combat missions as evaluated by the O/Cs.

A structural model showed that direct and indirect home base MLQ and Team MLQ scores assessing the platoons, lieutenants, and platoon sergeants had significant path correlations with MLQ predictions from home base that could account for 14% of the variance in platoon effective performance at the JRTC. The indirect effects were mediated by potency and cohesion. The home base transformational leadership of the lieutenants and sergeants correlated .33 and .35 with potency and .27 and .46 with cohesion, respectively, which in turn correlated .17 and .26 with JRTC performance. Transactional leadership was negatively correlated with the mediators and often not significantly.

Another of the examples validating the effectiveness of transformational leadership free of same-source bias was obtained for Singaporean combat team leaders. They were rated in efficiency and quality at the end of their training by five supervisors each. They were also appraised in military combat efficiency and quality by an independent assessor following a one-day assessment as the trained teams dealt with six military tasks. The 202

team followers completed the MLQ on their leaders. Transformational leadership, as rated by the followers, correlated .41 with efficiency plus quality as rated by the supervisors and .43 as rated by the assessor (Bass, Avolio, Jung, & Berson, 2003).

## Other related Concepts and Propositions

---

### *Champions of Innovation*

Radical military innovations require champions, committed, persistent, and courageous, in advocating the innovation (Schon, 1963). Brigadier General Billy Mitchell, the commander of the Allied Expeditionary Forces' air force in World War I, championed airpower over battleships, and Admiral Hyman Rickover championed nuclear over conventional submarines. The same entrepreneurial supporters are required for the success of new business ventures, according to Collins, Moore, and Unwalla's (1970) psychological profile of 150 entrepreneurs. Champions keep product innovations alive (Dougherty & Hardy, 1996). The same is true for the success of environmental issues. According to L. R. Anderson's (1996) dissertation on 132 environmental champions, success depended on selling behaviors opportunistically, framing dimensions distinctive to the issue, packaging the matter as a business issue, and avoiding drama, emotion, and proenvironmental rhetoric. Action was inspired by an educational and intellectually stimulating approach. Howell, Shea, and Higgins (1998) completed a factor analysis of the acts of champions. Three factors were extracted: (1) demonstrating confidence in the innovation, (2) gathering support and involvement, and (3) persisting under adversity.

In comparison to matched leaders of established businesses, organizational champions were found by Ippoliti (1989) to score significantly higher on the combined four transformational MLQ scale scores provided by their subordinates. Champions also scored higher than average on the scales of charisma (3.15 versus 2.48), individualized consideration (2.83 versus 2.35), intellectual stimulation (2.75 versus 2.44), and inspirational motivation (2.49 versus 1.87).

*Comparisons of Champions and Nonchampions.* Twenty-five champions of innovation in information technology in 25 different companies and 25 nonchampions were matched by Howell and Higgins (1990) by company, age, salary, job, function, and education. They were identified from 153 interviews with colleagues and peer nominations. Themes drawn from content analysis of interviews with the champions and nonchampions were accurately classified 82% by discriminant analysis as champions or nonchampions. Champions were more likely to reveal ideological goals, confidence in self and others, and unconventional and environmentally sensitive behaviors. A factor of champion leadership behavior discriminated champions from nonchampions with 84% accuracy. Factor loadings on this factor were high for charisma .48; inspirational leadership, .77; intellectual stimulation, .36; and individualized consideration, .27. Other discriminating behaviors were risk taking, achievement, innovativeness, social adroitness, and endurance. Still another comparison of interviews of 19 pairs of matched champions and nonchampions of innovations by Howell and Boies (2004) revealed that the champions showed more enthusiastic support for new ideas, connected the innovation to positive organizational outcomes, and made use of more informal selling.

### *Transformational Leadership Augments Transactional Leadership*

Burns (1978) originally argued that transformational leadership and transactional leadership are at opposite

ends of a continuum. However, Bass (1985a) suggested that transformational leadership augmented the effects of transactional leadership. To specify the effects more clearly, Waldman, Bass, and Einstein (1985) computed a hierarchical regression analysis of transactional and transformational leadership on self-reported measures of effort and performance for two samples of U.S. Army officers and one sample of industrial managers. They first entered the two transactional leadership scores for contingent reward and management by exception into the regression equation. When they followed with the entry of the interrelated transformational leadership scales of charisma (containing inspirational elements), intellectual stimulation, and individualized consideration, they demonstrated that transformational leadership had an incremental effect over and above transactional leadership. The incremental increases ranged from 9% to 48% for the different samples and outcomes predicted. For both outcomes and in all three samples, transformational leadership had a highly significant incremental effect, over and above transactional leadership. Seltzer and Bass (1987) obtained similar results for part-time MBA students' descriptions of their full-time superiors on the transactional scales of initiation and consideration and the augmenting transformational scales. Waldman and Bass (1989) found the augmentation effect of transformational charisma on transactional contingent reward when predicting the fitness reports obtained by U.S. Navy officers. The same augmentation in leaders' effectiveness was obtained when the transformational MLQ scale ratings of U.S. Army platoon lieutenants, company commanders, and battalion commanders of 3,216 soldiers were added in regression to transactional LBDQ initiation of structure.

The augmentation effects of transformational leadership on effectiveness and satisfaction were reported by King (1989) for high school and higher educational administrators and by Koh, Terborg, and Steers (1991) and Terborg (1995) for Singapore high school principals. Kessler (1993) reported an augmentation effect of transformational leadership on transactional leadership on employee job satisfaction in a research work environment. Howell and Avolio (1989) obtained results of an even more complex model of the role of transformational leadership among 76 Canadian insurance managers in their contributing to their organizations' effectiveness. They combined the managers' inner directiveness, their transactional and transformational leadership (MLQ-10), and their managers' perceptions of the organizational culture. Accounted for was 36% of the variance in the sales targets that units met a year later, according to a hierarchical regression analysis. Transformational leadership alone accounted for one third of the accuracy of the multiple predictions from augmented transactional leadership in predicting sales performance.

### ***Integration of Transformational, Charismatic, Visionary, and Related Theories***

Based on Shamir's (1992) ideas about the importance of the followers' self-concept, House and Shamir (1993) integrated theories of the new leadership. They centered the theories around how the charismatic leader increases the value and salience of followers' efforts by connecting them to valued aspects of the followers' self-concept. In this way, the new leadership theories "harness the motivational forces of self-expression, self-consistency, self-esteem, and self-worth" (p. 90). Charismatics have, in common with transformational, visionary, and other new-style leaders, role modeling, risk taking, image building, trust building and establishing competence. The leaders are intellectually stimulating but not necessarily individually considerate or adaptive. In their Neocharismatic Leadership Theory, House and Aditya (1997) emphasized four common characteristics of the various new-style leadership theories. They all attempt to explain: (1) how followers are led into attaining outstanding accomplishments; (2) how leaders achieve high degrees of motivation, commitment, loyalty, admiration, respect, and trust; (3) the importance of leaders' symbolic, emotionally appealing, supportive, and intellectually stimulating behaviors; and (4) the leader's effects on follower satisfaction, performance, self-esteem, and identification with the leader's vision and values and the collective.

*A Syncretic Model of Charismatic/Transformational Leadership.* Behling and McFillen (1996) applied what they regarded as six attributes of leader behavior drawn from the literature on charismatic and transformational leadership. They developed an inventory of internally consistent and leader behavior scales: (1) displays empathy, dramatizes the mission; (2) projects self-assurance; (3) enhances the leader's image, assures followers of the followers' competency; and (4) provides followers with opportunities for success. Another section of the inventory of ratings dealt with followers' beliefs in their leaders. The beliefs formed three distinct factors: (1) inspirational leadership, (2) awe of the leader, and (3) sense of empowerment. Additionally, the three belief factors correlated .63, .28, and .38, respectively, with ratings of how much the meaningfulness of work was experienced. The leader's empathy and dramatization of the mission were inspiring. The leader's self-confidence and image enhancement generated awe. Finally, the leader assured followers of their competency to provide them with a sense of empowerment and opportunities for success.

## Criticisms and Problems

---

Northouse (1995) believed that transformational leadership had a strong intuitive appeal, emphasized the importance of followers in the leadership process, went beyond the traditional exchange models of leadership, broadened the concept of leadership to include the growth of followers, and placed emphasis on morals and values. However, he saw, as weaknesses, lack of conceptual clarity and implications that transformational leadership is a personal trait. Furthermore, he felt, it was elitist and undemocratic. Hoffman, Blair, and Helland (2005) could not find the expected agreement between subordinates' ratings of transformational leaders and observers' ratings. Gronn (1997) viewed transformational leadership as of little use in fostering organizational learning in the Anglo-American world.

Yammarino, Spangler, and Dubinsky (1998) completed a WABA analysis for the MLQ-rated transformational, contingent reward, and satisfaction of 111 salespeople and their 34 superiors embedded in 34 work groups. Only individuals made a difference. Dyadic and group relations were of no consequence.

*The Taming of Charisma.* Beyer (1999) argued that the current concept of charismatic/transformational leadership was a watered-down version dealing with ordinary rather than exceptional leadership, but Beyer contradicted herself by arguing that charismatic/transformational leadership presented a heroic portrayal of leadership. House (1999) agreed with her that too much emphasis was being placed on the effects of leaders on individual followers instead of group and organizational performance. There was a failure to relate specific follower behaviors to leader visions. Charisma was tamed by its dilution. Beyer added that Weber's (1924/1947) concept of *radical* change by the charismatic/transformational leader was ignored. Ignored also was the importance of contextual and cross-cultural differences. But House faulted Beyer for ignoring the evidence, and refused to accept her other criticisms: confusing behavior and outcomes, recognizing charisma as transient, failing to account for powerful charismatic attraction, and failing to focus exclusively on truly exceptional and extraordinary leaders and leadership.

### ***Change in Concept***

Couto (1993) decried the falling away in Bass (1985c) from the humanistic concept of transforming leadership that Burns (1978) had introduced. *Transforming* leadership was focused on leadership of political and social movements and social change; Bass's *transformational* leadership emphasized its precursors and effects in formal organizations and agencies but did not exclude political leaders. Couto explained that, for Burns, the transforming leader changes followers into disciples whom, in time, others may follow. The leader is a moral agent who moves followers to be aware of how strongly they feel about their needs and to define their values

so meaningfully that they can proceed with purpose. Transforming leaders are invested with power to use their principles to move followers to change others and themselves into persons who share both modal and end values.

The concept of heroic leadership is substituted for charismatic leadership. Followers place their confidence in heroes because of their reputation. Heroes are idealized, but they are not transforming since they lack the deeply held motives and goals shared by transforming leaders and followers. Nor are executives in formal organizations and institutions transforming leaders, since they do not ordinarily achieve social change. Couto concluded with the reasons for maintaining the differences between transforming and transformational leadership and their relevance to different contexts with an analogy:

Bass has done for transforming leadership what David Lilienthal did for the concept of “grassroots democracy” within the Tennessee Valley Authority (TVA). He has placed a radically transforming concept in the service of institutional practice. Bass, like Lilienthal, changed ... radical transformation from social change to ... achievement of institutional goals. (Couto, 1993, p. 6)

### ***Psychometric Problems***

There are several problems with the Multifactor Leadership Questionnaire. Management by exception is lower in internal consistency than the other factored scales. Different factor structures emerge in some studies. A single factor could account for transformational leadership based respectively on a Dutch version of inspirational leadership (Den Hartog, Van Muijen, & Koopman, 1997), the transformational components of the MLQ (Tepper & Percy, 1994), or the five transformational components of the LPI (Fields & Herold, 1997). Carless (1999) reported the same results for MLQ data and suggested that the underlying common element might be a general impression of liking the leader. Vandenberghe, Stordeur, D'hoore, et al. (2001) proposed in a factor study of 1,059 nurses in Belgium that the single factor of active leadership could encompass all of transformational leadership and contingent reward. On the other hand, Antonakis (2001) obtained results indicating that the MLQ components were structurally all distinctly different factors. Similarly, Bass (1985c), Antonakis (2001), Tejeda and Scandura (1997), and Avolio, Bass, and Jung (1999), among others, were able to discriminate three or four transformational factors from among scales of behavioral charisma, attributed charisma, inspirational motivation, intellectual stimulation, and individualized consideration. Second-order factors were extracted to facilitate the unbundling of the correlated transformational leadership scales.

*Level of Analysis.* Much transformational leadership research has examined the relation of the leadership to group and organizational outcomes. However, Yammarino and Dubinsky (1994) completed a WABA study for 105 drug firm salespersons (detail persons who call on physicians, dentists, and other health professionals). The analysis showed that the leader-subordinate relations could be accounted for by the individual differences among the raters of each supervisor of the detail persons. Each supervisor viewed each subordinate uniquely; each subordinate rated each supervisor uniquely. But it was also possible that each dyad of subordinate and supervisor was meaningfully different within the same group supervised. Some dyads might involve in-group members; others, out-group members. In any case, there was little or no explanatory variance left in the leader and whole group, as such (Dansereau, 1995; Yammarino, 2002; Yammarino, Dionne, & Chun, 2002). The relation of the leader to his or her entire group is usually the basis of leadership research, but these studies suggested that leaders did not differ from one another as much as a given leader differed in relation from one subordinate to another.

*Lack of Ethnographic Studies.* Gronn (1999) decried the lack of ethnographic studies of transformational leadership. These should be studies by trained observers over time of the dynamics of the

leaders in action. Instead, he noted, "The bulk of transformational leadership research is confined either to orthodox, tick-a-box or circle-a-number respondent surveys of superiors or structured interviews with diverse informant samples" (p. 16).

*Other Possible Biases.* Ratings of transformational leaders may be strongly affected by the leaders' celebrity status as well as by their popularity. How much salespersons were perceived as influential correlated .74 with their perceived ability, .68 with their perceived value, and .50 with their popularity, according to sociometric ratings of 202 salespersons (Bass, 1960). It is likely that the perceived ability, value, and popularity of leaders would correlate with the extent they exerted transformational leadership. In the same way, transformational behavior is usually seen as more desirable than transactional behavior and is reflected in MLQ items. When a forced choice version of the MLQ (Form 8X) was compared with a regular listing of items (Form 8Y), the transformational mean scores were deflated. Again, correction for social desirability of the items is needed.

*Contingent Reward: Both Transactional and Transformational.* Among the transactional factors, as noted earlier, contingent reward empirically forms two factors. It is partly transformational when it concerns psychological reward and is intrinsically valued by the follower. Contingent reward is transactional when it is material in nature and extrinsically valued. The pruning of management by exception by the shortening of its original 10 items to create active and passive factors (Hater & Bass, 1987) was psychometrically acceptable in the six-factor models of Tejeda and Scandura (1997) and Avolio, Bass, and Dong (1999). Nevertheless, the scales need enlarging for practical purposes.

*Need for More Experimentation.* Brown and Lord (1999) argue that the study of the new leadership has been too dependent on survey and field studies. There has not been a comparable amount of study invested in experimental studies. For instance, we are often not cognizant of nonverbal behaviors, as they are processed too quickly. Brown and Lord cited a study by Awamleh and Gardner (1999), noted before, in which it was concluded, on the basis of a controlled experiment, that only 3% of the perceived charisma of a visionary message was due to its content and 40% to 58% was due to its style of delivery. Brown and Lord also argued that since transformational leadership involves followers' strong emotional attachment, its antecedents may occur too rapidly and outside of conscious awareness to be reported in a survey. To reliably capture the effect requires controlled experiments.

## Summary and Conclusions

---

Transformational leadership builds on transactional leadership. Leaders have a profile of how frequently they are transformational and how frequently they are transactional. Many active leaders may be high in both. Others may be high in one and low in the other. Less active leaders may be low in both. Considerable evidence has accumulated on the greater effectiveness of transformational leadership of political leaders, public officials, nonprofit agency leaders, religious leaders, educators, military officers, business managers, and health care directors.

Inspirational leadership does not depend on personal identification processes. Rather, the mutual goals of leaders and followers are identified and encouraged by the leader. Inspirational leadership stems from the management of meaning and impression management. The inspirational leader builds followers' expectations by envisioning a mutually describable future and articulating how to attain it. Leaders can use many intellectually stimulating ways to move followers out of their conceptual ruts. Intellectual stimulation, charismatic leadership, and inspirational leadership are major components of transformational leadership, which adds to transactional leadership in generating positive outcomes in the groups and organizations led. But above and beyond this, understanding the effects of such leadership requires examining the situation further.

<sup>1</sup> Such educational activities will be discussed further in [Chapter 34](#).

<sup>2</sup> A trait may be an antecedent or predisposition that relates to the appraised leadership performance. Yet in many cases, the correlation between the trait and obtained leadership can be due to a third variable, such as likability. Same-source bias is present when the same raters provide the data for both the trait and the leader's performance. Some measures, such as age and experience, are clearly antecedents of the current leadership and can arguably be regarded as cause and effect if not accounted for by their mutual correlations with a third variable

## PART VI

---

# Management and Organizations

## CHAPTER 23

---

# Managerial Work

What roles in organizations do leaders and managers play? What organizational functions do they serve? How does the hierarchical level of the organizational leader and manager affect these activities? Are their roles changing? What makes their activities more or less effective?

From the top to the bottom echelons of the formal organization, except for the lowest level, all members report directly to a higher authority and lead followers at the levels below them. They are leaders *inside* organizations as well as leaders *of* organizations. The operating employee reports to a supervisor, the supervisor to a manager, the manager to an executive, the executive to the chief executive, and the chief executive to a board of directors, which is responsible to a constituency of shareholders or a public body.

## Functions of Management and Leadership in Formal Organizations

---

As was noted in [Chapter 2](#), for classical management theorists like R. C. Davis (1942), Urwick (1952), and Fayol (1916), orderly planning, organizing, and controlling were the functions of supervisors, managers, and executives in formal organizations of hierarchically arranged groups and individuals. Planning, organizing, and controlling were regarded as completely rational processes. For some, such as K. Davis (1951), the prescription for business leaders was the same as for managers—to plan, organize, and control an organization's activities. Little attention was paid to the human nature of the members constituting the organization. Although organizations strive for rationality, observation suggests that such rationality is limited (March & Simon, 1958). Nevertheless, understanding the purpose of the manager requires consideration of the planning, organizing, and controlling functions of the manager, for whom supervision and leadership may often be the most important but not the only aspect of his or her responsibilities. Thus an empirical factored survey, completed by Wofford (1967) (one among many), could reveal factors to describe managers' functions as setting objectives, planning, organizing, leading, and controlling. Managers in organizations do perform the functions of planning, organizing, and controlling. But limiting the analysis to such general functions inhibits a more searching type of inquiry into the nature of managerial performance—about what administrators, managers, and executives actually do. Leadership remains an important component to the degree that management means getting work done with and through others. The overlapping needs of the organization, task, team, and individual must be addressed. Thus Coffin (1944) modified the classical functions of management as follows: formulation (planning), execution (organizing), and supervision (persuading). Adair (1973) conceived the functions as planning, initiating, controlling, supporting, informing, and evaluating.

*Cognitive, Behavioral, and Socioemotional Components.* Organizational leadership has both interpersonal and strategic components (Lohmann, 1992). Barnard (1938) was most influential in introducing the need to include more behavioral, intuitive, social, and emotional components in the functional analyses of organizational leadership. Numerous other scholars incorporated behavioral, social, and political elements in their analyses of the functions of organizational leadership. Barnard (1946b) identified the functions of

organizational leadership as: (1) the determination of objectives; (2) the manipulation of means; (3) the instrumentation of action; (4) the stimulation of coordinated effort. In this light, E. Gross (1961) elaborated on the functions of organizational leadership to define goals, clarify and administer them, choose appropriate means, assign and coordinate tasks, motivate, create loyalty, represent the group, and spark the membership to action. Similarly, Selznick (1957) suggested the following functions of organizational leadership: (1) definition of the institution's mission and goals; (2) creation of a structure for accomplishing the purpose; (3) defense of institutional integrity; (4) reevaluation of internal conflict. In a study of leadership in Samoa, Kessing and Kessing (1956) identified as leadership functions consultation, deliberation, negotiation, formation of public opinion, and decision making. Katz and Kahn (1966) proposed three functions of leadership in terms of the organization's actual formal structure: (1) the introduction of structural change (policy formation); (2) the interpretation of structure (piercing out the incompleteness of the existing formal structure); (3) the use of structure that is formally provided to keep the organization in effective motion, operation, and administration. Organizational leaders and leaders within organizations need to deal with both *intellectual* and *social* complexity. Intellectually, they must be able to assimilate complex information, work with cognitive complexities and conflicting points of view, and integrate diverse organizational stimuli. Social complexity arises, as leaders must deal with diverse individuals and units with conflicting demands, agendas, and goals. The complexity of roles increases with increasing organizational levels in both military and civilian hierarchies (Jacobs & Jaques, 1987). Self-monitoring, social intelligence, social perceptiveness, and behavioral flexibility become important with an increasing hierarchical level (Zaccaro, Gilbert, Janelle, et al., 1991). Zaccaro, Marks, O'Connor-Boes, et al. (1995) found that skills in solving complex problems increased with rank when 101 lieutenants, majors, and colonels were compared. Dean and Sharfman (1996) analyzed 52 decisions made by the top executives of 24 firms. The decisions were more effective when the executives collected relevant information and used analytical techniques. On the other hand, decisions were less effective when the executives made use of power or hidden agendas. Drucker (2000) suggested that organizational leaders need to self-assess their ethics, engage in constant self-development, be flexible in mentality, and know when to lead and when to follow. A 1992 manual of functions for operations manager, team leader, and supervisor (Anonymous, 1992) included planning, controlling, problem solving, continuous improvement, providing performance feedback, coaching, counseling, and training, creating and maintaining a motivated work environment, and representing the organization.

*Overlap between Managing and Leading.* This overlap is seen most clearly when one considers the human factor and the interpersonal activities involved in managing and leading. Skill as a leader and in relating to others is a most important requirement at all levels of management. It is clearly recognized at the first level of supervision; it is not as well recognized at the top of the organization. Nonetheless, interviews with 71 corporate executives by Glickman, Hahn, Fleishman, and Baxter (1969) revealed that at the top of a corporation, the group of consequence is relatively small. The group's members have highly personal relationships. They interact with one another as in a small group. A high proportion of group involvement is usual. Informal procedures supplant formal ones. Consistent with these findings, when Richards and Inskeep (1974) questioned 87 business school deans, 58 business executives, and 40 executives in trade associations about what kind of continuing education middle managers need most, these executives gave top priority to improving human relations skills. They considered improving quantitative and technical skills to be of secondary importance. Similarly, Mahoney, Jerdee, and Carroll (1965) found that the single most important function of first-level managers is to supervise others. The authors recognized eight important managerial functions: planning, investigating, coordinating, evaluating, supervising, staffing, negotiating, and representing. Their questionnaire survey of 452 managers from 13 companies in a variety of industries varying in size from 100 to over 400 employees revealed that more time was spent on supervision than on any other function (28.4%). Supervising, along with the four other functions of planning, investigating, coordinating, and

evaluating, accounted for almost 90% of the time that the 452 managers spent at work.

Solem, Onachilla, and Heller (1961) lent further weight to the importance of the human factor by asking 211 supervisors in 26 discussion groups to post and select problems for discussion. In all, 58.8% of the first-level supervisors and 35.3% of the middle managers wanted to talk about subordinates' motivation to follow instructions, meet deadlines, or maintain the quality of production. Over 40% of the staff supervisors were concerned about dealing with resistance to change, as were 36.4% of the middle managers and 22.7% of the first-line supervisors. The first-line supervisors were most concerned about disciplinary problems and problems of promoting, rating, and classifying employees, while the middle managers were most interested in talking about problems of selecting, orienting, and training employees.

## What Leaders and Managers Do

---

Gilmore (1982) saw leadership as being centrally concerned with the management of boundaries. Managing at the top organizational levels, the leader protects the organization from the risk of subversion by outsiders' values and practices. At the same time, the leader manages the importation into the organization of opportunities for learning. At the interpersonal level, the leader manages the boundary between maintaining the role requirements of self and others and making decisions based on personal considerations.

### *Managers as Linchpins*

Rensis Likert (1961a, 1967) emphasized the linchpin function of managers. As linchpin, the manager connects a group that is composed of the manager's superior and his or her peers with a group that is composed of the manager and his or her subordinates. For Dagirmanjian (1981), leaders serve as managers by linking the whole organization with their subordinates. The leadership function in nursing was seen by Bernhard and Walsh (1981) to involve coordinating similar activities in two groups: those who seek care and those who give it.

### *Leaders or Managers?*

There is a line of reasoning that draws a sharp distinction between leadership and management. It considers leadership to be the discretionary activities and processes that are beyond the manager's role requirements as mandated by rules, regulations, and procedures. Leadership is whatever discretionary actions are needed to solve the problems a group faces that are embedded in the large system (Osborn, Hunt, & Jauch, 1980). Leadership fits with an *organismic* view of organizations; management, with a *mechanistic* view (Terry, 1995). The environment of leaders is more hectic; the environment of managers is more static and stable (Bhatia, 1995). Leaders are more transformational; managers are more transactional. Leaders do the more correct things; managers do things correctly (Parry, 1996). However, Grove (1986) roundly rejected the distinction, stating that the effective manager must have the clarity of purpose and motivation of the effective leader. J. W. Gardner (1986b, p. 7) agreed: "Every time I encounter an utterly first-class manager, he turns out to have quite a lot of leader in him ... even the most visionary leader will be faced on occasion with decisions that every manager faces: when to take a short-term loss to achieve a long-term gain, how to allocate scarce resources among important goals, whom to trust with a delicate assignment." For Gardner (1993), the required distinction is between the *leader-manager* and the routine manager. Gardner's leader-manager, in contrast to the routine manager, thinks long-term, can look beyond the unit he or she heads to see its relation to the larger system, and can reach and influence others outside his or her unit. The leader-manager emphasizes vision,

values, motivation, and renewal and can cope with conflict. Gardner summed up leader-managers' tasks as: envisioning the group's goals; affirming the group's values, motivating its members; managing; achieving workable unity among the members; explaining what needs to be done; serving as a symbol; representing the group; and renewing the group. Leaders must be able to resolve conflicts, mediate, compromise, and build coalitions and trust. For this they need political skills as well as task and socioemotional competencies (J. W. Gardner, 1988).

Gardner (1990) also noted that senior leader-managers took advantage of the informal network to get information and used their centrality to set agendas, make strategic moves, and mobilize support from allies and from lower-level leaders. According to Zaccaro (2002), senior leader-managers also engage in goal setting, boundary spanning, planning, strategizing, and envisioning. At lower levels, they are responsible for operations and maintenance within their unit. At higher levels, they face more informational and social complexity. They need to search their environment for opportunities and threats. Nonetheless, Krantz and Gilmore (1990) suggested that management and leadership are completely different. Management is idealized as the technique for achieving an organization's objectives. Leadership is idealized as heroic, visionary, and mission-oriented. The modern leader-manager is more like a team coach who expects a 100% team effort, scouts for talent, and motivates individual initiative and imagination (Conway, 1993). Parry (1996) also listed additional differences between leaders and managers. He cited Australian Prime Minister Bob Hawke as an example of a person who was a transactional manager when meeting with his cabinet and a transformational leader when addressing the Australian public on television.

Leaders manage and managers lead, but the two activities are not synonymous. Leaders facilitate interpersonal interaction and positive working relations; they promote structuring of the task and the work to be accomplished. (E. C. Mann, 1965). All the management functions of planning, coordinating, staffing, and so on can potentially provide leadership; all the leadership activities can contribute to managing. But if trust is a key to leadership, and competence in making decisions is essential to building trust, trust and competence are important in managing resource allocations (Ulmer, 1996). Nevertheless, some managers do not lead, and some leaders do not manage (Zaleznik, 1977). Some leaders are authentic, others are not. In the past century, there has been a decided change in both leadership and management. The autocratic "bridge to engine room management" no longer works (Conway, 1993).

For the military, the leader-manager controversy continues about the importance of leading soldiers rather than managing bureaucratic technological systems. Advancement to senior levels may be due to technological proficiency instead of leadership potential, when the reverse may be needed. As Sarkesian (1985) noted, low-intensity warfare against terrorism and insurgencies calls for leadership and management of fewer large divisions and more smaller brigades and special operations units. Meyer (1983) saw the solution as the development and maintenance of unit-based organizations that make strong, continuing leader-follower relationships possible.

Leadership is path-finding; management is path-following. Leaders do the right things; managers do things right (Bennis & Nanus, 1985). Leaders develop; managers maintain. Leaders ask what and why; managers ask how and when. Leaders originate; managers imitate. Leaders challenge the status quo; managers accept it (Bennis, 1985, 1989). Leaders function in a higher domain of cognitive analysis, synthesis, and evaluation; managers function in a lower cognitive domain of knowledge, comprehension, and application (Capozzoli, 1995). Leadership is concerned with constructive or adaptive change, establishing and changing direction, aligning people, and inspiring and motivating people (Kotter, 1990). Leaders' behaviors arouse followers' motives. They are relations-oriented. They set the direction for organizations. They articulate a collective vision. They infuse values and set examples. They sacrifice and take risks to further the vision. They appeal to the self-concepts of their followers. They inspire followers by exhibiting self-confidence, persistence, and determination. They influence their followers through the esteem attributed to them by their followers. They show how much they value their group. They speak for their group. Followers internalize the leader's

expressed values, identify with the group, and can continue without the leader (House, 1995).

Managers plan, organize, and arrange systems of administration and control. They hold positions of formal authority. Their position provides them with reward, disciplinary, or coercive power to influence and obtain compliance from subordinates. The subordinates follow directions from the manager and accept the manager's authority as long as the manager has the legitimate power to maintain compliance—or the subordinates follow out of habit or deference to other powers of the leader (House, 1995). Management is concerned with consistency and order, details, timetables, and the marshaling of resources to achieve results. It plans, budgets, and allocates staffs to fulfill plans (Kotter, 1990).

The psychoanalyst Zaleznik (1977) stated that leaders and managers differ in how they relate to their roles and their subordinates. Leaders but not managers tend to be more charismalike. Leaders attract strong feelings of wanting to be identified with them. They maintain intense interpersonal relations. Leaders send out clear signals of their purpose and mission; managers tend to be more ambiguous or silent about their purpose. Leaders, but not managers, generate excitement at work. Managers are more likely to see themselves as playing a role; leaders behave as themselves. Leaders are more concerned about ideas to be articulated and projected into images; managers are more concerned about process. Leaders, for Zaleznik, are more likely to be transformational than are managers. On the other hand, managers more readily practice contingent-reward and management by exception; they want to maintain a controlled, rational, equitable system. While managers tolerate the mundane, leaders react to it “as to an affliction.” Managers who combine intuition with rationality as well as the personal characteristics of a leader make the most successful general managers (Kotter, 1982a), middle managers (Kotter, 1985), and senior and lowest-level managers (Kotter, 1988). Based on 900 questionnaires and interviews with executives from 150 organizations, Kotter (1988) concluded that successful managerial leadership requires sophisticated recruiting, early identification of development needs and planning for them, an attractive working environment, challenging opportunities, and support of line management without short-term pressure.

*A Leader-Management Model.* MacKenzie (1969) illustrated the great variety of activities that a typical manager may perform. Some of them, such as forecasting and budgeting, have relatively less to do with leadership as such (unless the latter is defined most broadly); and some have relatively less to do with management. People, ideas, and things are at the core of the different elements, tasks, functions, and activities that may be part of the manager's job. These are the basic components of every organization with which the manager must work. According to MacKenzie, ideas create the need for conceptual thinking; things, for administration; people, for leadership. Three functions—the analysis of problems, decision making, and communication—are important at all times and in all aspects of the jobs held by managers. These three functions permeate the entire work process. Also, at all times, managers must sense the pulse of their organization. Other functions occur ideally (but not necessarily in actual practice) in a predictable sequence of planning, organizing, staffing, directing, and controlling. How much managers are involved in these sequential functions depends on their position and the stage of completion of the projects with which they are most concerned. We may quarrel with the idea of limiting leadership to the people element; but, as will be noted later, the administrative and conceptual thinking required are so interlocked with the influence processes that the distinction is of academic rather than practical consequence. However, the sheer diversity of activities and their linkages to the functions and tasks of management are important. This diversity shows the inadequacy of any simple approach to capture what is involved in the managerial and leadership processes. The diversity in how managers and organizational leaders spend their time, with whom they spend it, and what they do has been corroborated by numerous investigators. For example, Stewart (1967) confirmed the diversity of managerial activities when she asked 160 managers to record all job behavior incidents longer than five minutes in duration that occurred for them.

*Alignment.* Leaders and managers align the objectives of their subordinates and themselves with the goals

of the organization to manage innovations, manage resources, lead change, lead learning, and manage the diverse interests of stakeholders. Both leaders and managers make mistakes, but the good ones learn from their mistakes, accept responsibility for them, and try not to make the same mistake twice. They ask the right questions, anticipate crises, and do not allow short-term objectives to interfere with longer-term goals (J. Reynolds, 1994). Gustafson (1999) suggests that an individual-organizational “balanced scorecard” needs to be used by leaders and managers in evaluations. Individual performance appraisals need to reflect what the organization wants to accomplish. Outcome measures can help align operations with strategic goals. Three to five cycles of application are needed for adequate testing and revision of the appraisal framework.

*Innovation.* Innovations are stimulated by unexpected occurrences, incongruities, process needs, and changes in industries and markets (Drucker, 1991). Leaders need to be alert to these occurrences (Kotter, 1991). Bennis (1991) listed six ways for leaders and managers to foster and support innovation: (1) create a compelling vision; (2) create a climate of trust; (3) create an environment that reminds people about what is important; (4) encourage learning from mistakes; (5) create an empowering environment; (6) create a flat, flexible, adaptive, decentralized organization. Organizational leaders need constancy. They need to practice empowerment and to encourage flatter, adaptive, flexible, decentralized organizations.

*Resources.* The benefits and costs of resources need to be weighed. Equitable distribution of resources needs to be maintained. Knowledge is an essential resource for leaders and managers. Where technology is important, engineering and science may be necessary. Likewise, in health care administration, medicine or nursing is of consequence. In financial services, accounting, finance, and business law are of equal consequence. Knowledge of marketing, salesmanship, and consumer behavior is needed in the mass retailing and consumer service industries.

*Change.* Leadership is central to the organizational change process. Sometimes it is managed from the top with little feedback from followers. Other times it may begin with suggestions from supervisors or middle management and their subordinates and work its way up. Envisioning, energizing, and enabling characterize leaders of the change process (Dodge, 1998). An action learning procedure, Organizational Fitness Profiling, can be introduced to provide a guided process for organizational change (Beer, 1997). Changing corporate culture and members’ behavior takes three to ten years. Changes in the culture’s values may enhance the behavior. Change usually begins with corporate strategy set by top management. To implement change, the vision, strategies, and values to be changed are communicated downward. Upward initiatives, feedback modifications, and other inputs are sought from below, from the board of directors, and from relevant outsiders. Needs, required learning, and learning opportunities are assessed, modeled, and rewarded to fit the strategies. The changes are constantly reinforced (Wilhelm, 1992). Beer, Eisenstat, and Spector (1990) proposed a six-step change process: (1) Mobilize commitment to change through joint diagnosis of problems; (2) Develop a shared vision of how to organize and manage; (3) Foster consensus for the new vision and competence in how to begin and continue the change; (4) Begin with the units most ready for change; (5) Spread the change to the other units; (6) Monitor and adjust the process to handle problems that arise in the change effort. Top management must practice what it preaches. Attention to needed change can both create economic value for shareholders in the short term as well as develop an open, trusting culture in the long term (Beer & Nohria, 2000).

To illustrate Weick’s (1988, 1995) theory of how leaders make change meaningful to others and bring about change, Kurke and Brindle (1999) used what Alexander the Great did to enact change in his brief but highly successful conquest of much of the known world. Alexander *reframed the problems he faced*. For instance, at the time, Tyre was on an island with a strong fleet. Alexander took nine months to build a causeway from the mainland to the island so his soldiers could walk to the island. He used *symbolism*. It was predicted that whoever untied the Gordian Knot would conquer the world. Alexander cut the knot with his sword. Wherever possible, he made *strategic alliances*. When he crossed into India and defeated Porus, instead

of killing him he made him an ally. He strengthened his identity as ruler of the former Persian Empire rather than the conquering Greek general by adopting Persian garb and ritual and marrying his Macedonian soldiers (and himself) to Persian women. Kirke and Stein (1986) made the case that Alexander's successful strategies made him great.

*Learning.* Leading and managing learning include mentoring, modeling, and monitoring the learning of followers. Leaders take a personal interest in the learning of others. They reflect on their experiences, and, where applicable, they define problems using solutions they have already learned. They find time for self-renewal and for serving as catalysts. In learning organizations, leaders continually attend to the learning agenda and institutionalize the commitment to the learning process. They establish routines to receive undistorted feedback. They learn from mistakes and encourage others to do the same (McGill & Slocum, 1994).

*Stakeholders.* Stakeholders include all those who have an interest in the actions of the organization and the ability to influence it. Stakeholders benefit from leaders and managers who can balance the relative satisfaction of stakeholders' interests in the corporation: owners, shareholders, management, employees, suppliers, customers, families, community, state, and nation. Leaders and managers need to achieve a consensus from their stakeholders about what and how to do so (Savage, Nix, Whitehead, et al., 1991). Charismatic-transformational leaders and managers can induce change among immediate followers and those at a distance. But transactional leaders can use contingent reward to do the same.

### ***Public Service and Nonprofit Leaders and Managers***

*Law Enforcement and Police Officers.* These leaders are faced with problems equivalent to those of other public service and not-for-profit managers of the same hierarchical rank. According to Ceballos (1999), they have to deal, in order, with five issues: budgets and funding, developing leaders and managers, advances in technology, community policing, and ethics. Finances depend on how much federal, state, and local governments are involved and how much support can be obtained for developing police managers and executives. New technology, such as DNA testing, is helping investigative police work. Changes in community policies on policing can have dramatic effects on local crime rates. The use of force, accountability, and responsibility are affected by ethical conduct. These same characteristics are relevant to the role of prison warden. The warden is likened to a military commander with lieutenants and sergeants. Wardens learn their roles for this "most arduous occupation" (Bryans & Wilson, p. 191) by word of mouth and by copying role models. They receive little training for the role. There has been little research on their behavior and the relation of their behavior to success and effectiveness in prisons in the United States, and even less in Britain. The Federal Bureau of Prisons' Institutional Character Profiling, available since 1990, provides a way of assessing institutional stability, the staff's quality of work life, inmates' working and living conditions, and relations among the correctional officers. Written tests and simulations are also available for candidate selection (Bryans & Wilson, 2000). In his review of *A View from the Trenches: A Manual for Wardens and by Wardens* (NAAWS, 1999), Morganbesser (1999) quotes a former warden (Bronson, 1997), who called the warden's job impossible. The warden's discretionary authority was likely to be challenged and the warden suffer from burnout. Nevertheless, Cullen et al. (1993) found that wardens had a high level of job satisfaction. According to Morganbesser, considerable efforts are beginning to occur in training for wardens and correctional officers at the National Academy of Corrections and the Federal Bureau of Prisons. These include peer-oriented training, mentoring, and other management development programs. As would be expected of free workers, Gillis, Getkate, Robinson, et al. (1995) found that inmates of a correctional institution who rated their supervisors as transformational had more motivation to work; supervisors rated as laissez-faire leaders correlated with less motivation by inmates to work.

*College Presidents.* These executives have to engage in many of the same activities as leader-administrators and CEOs. Nonetheless, few are like Father Theodore Hesburgh of Notre Dame in performance and strategy. Over a 35-year period in office, Father Hesburgh's actions raised Notre Dame's endowment fund from less than \$10 million to more than \$300 million. At the same time, he greatly increased Notre Dame's scholarly mission at the expense of moving football (ordinarily a prime reason for alumni giving) from its preeminent niche to a more appropriate place in the university (Anonymous, 1987).

Finances are seen to be the main issue confronting college presidents (*The New York Times*, 2005). For Cohen and March (1974), college presidents face a great deal of ambiguity. Their organizations have problematic goals and operate with inconsistent and ill-defined preferences. Their technology is unclear. They use trial and error to operate. The participation of its members varies. The organizational boundaries are uncertain. The presidents must exert leadership on issues of high inertia and low salience for most members in an "organized anarchy." Bensimon (1988, pp. 3–7) obtained suggestions from interviews with 35 new and experienced presidents about what new presidents should do. They need to: (1) make several visits to their new campus before taking office; (2) get to know and become known to the significant players; (3) read as much as possible about the institution's operations, procedures, and history and pay attention to them; (4) listen to constituents and observe processes before launching a search for problems; (5) get involved in the budgetary process; (6) accumulate credit for consulting others and being willing to listen before launching change efforts. In a study of 32 institutions of higher education, Birnbaum (1990) found that 75% of newly appointed presidents had faculty support that fell to 25% for presidents who had been in office for a longer time. Those who were able to maintain faculty support throughout their tenure were more likely to seek faculty input. They supported governance structures and an action orientation. They remained totally involved but did not micromanage. Long-term presidents who lost faculty support as well as support from other constituencies, such as the students, the board, and the community, were authoritarian and saw leadership as top down. They outraged the faculty when they took precipitous action without consultation. In evaluating a president, board members and administrators are more favorable in their evaluation compared to other campus leaders; faculty leaders are least favorable (Fujita, 1990).

Nine effective state university presidents and their institutions of higher learning were nominated by experts and compared to 16 representative state university presidents and institutions. The 25 universities had undergone the stress of five successive annual budget cuts. The presidents displayed more transformational leadership based on the Fisher-Tack Effective Leadership Inventory and were more likely to survive (Fisher, Tack, & Wheeler, 1988). Cowen (1990) failed to find that the style of leadership displayed by 153 presidents of four-year public colleges and universities improved student enrollments over a five-year period. However, enrollments did show improvement when the presidents were rated more favorably by their constituents and had been on campus longer.

*School Principals.* Repeatedly, studies of school effectiveness have shown that the principal's leadership and management are the keys to a school's effectiveness (Austin & Reynolds, 1990) and the initiation of improvement and change (Fullan, 1991). Effective school principals must contend with multiple demands placed on them daily. They must be instructional leaders, administrators, head teachers, moral leaders, role models, community workers, social service providers, and even fund-raisers. Time for reflection on needed systematic changes in the school is hard to find (Tewel, 1986). As instructional leader, the principal must be knowledgeable about effective instruction and able to evaluate it (Schlechty, 1990). Allen (1981) formulated a model for the school principal's performance that showed how successful outcomes for a school depend on the principal's selection of appropriate roles to enact for a given situation. Support for the model was obtained from panels of experts. The roles played by principals are similar to those of middle managers. They encompass managing resources, ensuring a safe school environment, and maintaining good relations with parents and community (Austin & Reynolds, 1990). Like most managers, they are subject to constant

interruptions, lack of time to plan, fragmentation of activities, and the need to comply with rules and regulations that are often statutory (Richardson, Short, Prickett, et al., 1991). In Ontario, principals at all levels of effectiveness cited difficulties with their boards and students. But only the ineffective principals added difficulties with their role and with their community (Leithwood & Montgomery, 1984).

By 1990, principals' roles were changing, according to 76% to 91% of a survey of 840 mostly principals or assistant principals in Washington State. Increasing were decentralization, diversity requirements, interaction with parents, special education, school community relations, and efforts to monitor truancy (Austin & Reynolds, 1990). According to Lake and Martinko (1982) and Martinko and Gardner (1984a, 1984b), who observed and coded the activities of highly effective and moderately effective school principals, the moderately effective principals spent more time with students and parents but less time with other outsiders than did the highly effective principals. The highly effective principals initiated 64% of the contacts; the moderates, 54%. While 47% of the moderates' contacts were judged to be human relations-oriented, only 30% of the highly effective principals' contacts were so judged. Conversely, 66% of the highly effective principals' contacts were task-oriented; 51% of the moderately effective principals' contacts were so designated.

*Assistant principals* serve schools in several ways. According to a study of the work of eight assistant principals in three large comprehensive public secondary schools in Southern California, they: (1) implement state requirements for the curriculum, its master schedule, and the schools' organizational regularity; (2) prepare the annual extracurricular activity calendar, which involves the values of the local community and the school. In completing this work, their supervisory duties require monitoring, supporting, and remediating (Reed & Himmler, 1985).

*"Grassroots" Community Leaders.* "Grassroots" leaders are ordinarily involved in a community issue but are less often in the mainstream of institutional leadership. They tend to use unconventional techniques and are motivated more by passion than money, by personal commitment to service, social change, and social justice. Their leadership efforts are often initiated by a struggle. They may be involved because of religious or spiritual beliefs. They are more enthusiastic about shared leadership than about hierarchical leadership (Anonymous, 1999). "Grass roots" leaders can now be mobilized very quickly through the Internet and have become a political force as lobbyists in local, state, and national affairs.

## Methods and Dimensions for Studying What Managers Do

---

Chapters 4 and 5 described many of the methods that are available for studying leaders as persons. Most of these methods are paralleled by procedures for studying the positions of managers and executives. They include checklists, logs, diaries, and retrospective accounts from interviews, panel discussions, observations, and questionnaire surveys of focal managers and their colleagues. Positions are analyzed, as well as functions, activities, and completed work. The characteristics of the process in which the manager works are another way of analyzing what the manager does. Stewart (1967, 1982b) analyzed the duration of specific activities, the mode of communications used, and the particular persons contacted to detail the characteristics that distinguish among managers' positions.

### ***Recording of Activities***

Managers' behaviors may be recorded by observers in a log or by the managers themselves in a diary or rated in response by interviewers. Based on diaries, observations, and interviews, Stewart (1982) proposed that three dimensions could describe any manager's job: (1) *demands*—the role expectations set by superiors, rules, policies, deadlines, and situational conditions requiring conformity for survival in the role; (2) *constraints*—

organizational, technological, or environmental conditions limiting the manager's role and choices; (3) opportunities and activities the manager can freely choose and prioritize. Managers need to reduce the demands and constraints in order to be freer to determine strategies. This may call for interpersonal skills and cognitive competencies. Economic downturns, increased competition, government regulations, and labor unions are some of the sources of external constraints on top management. Their discretion may also be restricted by internal sources such as the legacy of the organization's founder, the influence of the dominant owner, lack of membership in a family-owned corporation, and the strength of the board of directors (Hambrick & Finkelstein, 1987).

S. Carlson (1951) analyzed self-and assistants' recordings of the activities of 10 mainly Swedish executives for four weeks. For each action, the recordings noted the site, the person who was contacted, how the communications were conducted (face-to-face or otherwise), the issues involved, and the actions taken. Employing similar records, T. Burns (1957) collected three to five weeks of the diary entries of 76 British top managers. Dubin and Spray (1964) depended on the self-descriptions by eight executives of all "job behavior episodes" over a two-week period. For each episode, they indicated its behavioral content, when it began and ended, who initiated it, with whom the interaction occurred, and how it was conducted. Home and Lupton (1965) made use of checklist records of the activities of 66 managers for a one-week period.

Carlson and James (1971) asked 88 insurance agency managers and 252 supervisors to record their work activities over five weeks and again six months later. Correlations between the first and second measures ranged from .78 to .96, indicating a rather high degree of stability in reported work performance over time. Kelly (1964) used activity sampling in a study of manufacturing executives. His results showed that managers who performed identical functions exhibited similar activity profiles. Likewise, Stogdill and Shartle (1955) asked U.S. Navy officers to keep a minute-by-minute log of their activities for a period of three days. After the logs were collected, the officers were asked to estimate the percentage of time they had spent in different activities during the period. The correlations between logged time and estimated time were computed. The results indicated a fairly high correspondence between logged time and estimated time for objectively observable performances such as talking with other persons, reading and answering mail, reading and writing reports, and operating machines. Less objective, less readily observable forms of behavior, such as planning and reflection, failed to yield estimates that corresponded highly with logged time. Nor was there a high correlation between logged and estimated behavior for infrequent activities such as teaching and research. Carroll and Taylor (1968, 1969) collected brief self-reports from 21 managers on what they were doing at a randomly selected minute during each half hour of a period of investigation. The same information for the 21 managers was provided as the time estimates and other observational methods used by an outside observer. Komaki, Zlotnick, and Jensen (1986) introduced further sophistication into observational procedures by using micro analytical coding procedures that were again based on careful time sampling.

*Content Analysis of Biographies of Organizational Leaders.* Van Fleet and Peterson (1995) created the Career Description Analysis, a procedure for content analysis of biographies and autobiographies of organizational leaders. For instance, of 10 military leaders, Generals Omar Bradley (14%) and Dwight Eisenhower (11%) were considerably higher in their percentages of frequency of clarifying work roles and objectives than were Marine General Alexander Vandergrift (5%) and General George Patton (4%). Most frequently *inspiring* of 14 business leaders were Mary Kay Ash (12%) and Thomas Watson, Sr. (11%), compared to John DeLorean (3%) and Alfred P. Sloan (2%).

*Case Studies.* Qualitative studies of individual or multiple cases that might include quantitative data were popularized as the method of choice for professional education by the Harvard Business School. It was influenced by the use of legal cases for setting precedents and educating lawyers and judges. Hunt and Ropo (1995) demonstrated that with a suitable conceptual framework, a case could generate testable propositions. For example, in the case of Roger Smith's tenure as CEO from 1981 to 1990 at General Motors, they

proposed that the availability of vast amounts of resources tends to encourage bold but not necessarily wise decisions. Other propositions concerned Smith's limited behavioral complexity, critical tasks, and organizational culture.

*Critique.* Despite the face validity of observational approaches, Martinko and Gardner (1985) found a number of shortcomings in them. First, because sample sizes are usually small, the result is the questionable generalizability of conclusions. Second, such approaches often lack adequate reliability checks. Observers need to take account of the multiple purposes of a single action, whose coding is often unreliable. Third, observational reporting is usually simplistic, mechanistic, and narrow in perspective and tends to ignore variations among positions and their situational circumstances. Fourth, such approaches fail to remain consistent in using an ideographic, longitudinal, or case-by-case orientation or a nomothetic approach that aggregates and averages observations across individual positions and situations.

Self-reporters and observers are likely to miss many fleeting, transient actions. Usually, observers can only infer the manager's purposes and the intentions of a manager's observable action. Moreover, much of a manager's behavior is cognitive and unobservable (Stewart, 1965). Observational studies need to be buttressed by interviews and questionnaires using larger samples.

### ***Questionnaires, Interviews, and Panel Discussions***

Extensive interviews precede the development of custom-made questionnaires if suitable questionnaires are not already available. A sample of senior managers might be interviewed for developing questionnaires about work done. A cross-sectional sample of the hierarchical levels and functional areas would be needed for developing a questionnaire about the work done by supervisors, managers, and executives. The questions may be structured, with alternative possible answers provided, or with an open-ended section, with respondents free to answer in their own words. Then managers or their associates can be asked to complete the structured questionnaires organized by clusters, factors, or dimensions of activities in which ratings are made of how much time the managers spend on the different functions, tasks, and activities; with whom they spend their time; and in what ways. Illustrative are investigations by Allen (1981), Korotkin and Yarkin-Levin (1985), and Sperry (1985). Allen collected self-rated questionnaire descriptions from 1,476 New York City government managers about their tasks. Korotkin and Yarkin-Levin used both interviews and questionnaires to generate lists of tasks describing the required activities of U.S. Army commissioned and non-commissioned officers. Sperry held a series of discussions with senior federal career managers to obtain information about their role orientation and job problems.

Questionnaires for describing positions have been used extensively. Hemphill (1960) used the Executive Position Description Questionnaire (EPDQ) to examine the positions of 93 business executives located in five companies. The positions represented three levels of organization and five specialties (research and development, sales, manufacturing, general administration, and industrial relations). Data were obtained on 575 items that were classified as: (1) position activities, (2) position responsibilities, (3) position demands and restrictions, (4) position characteristics. Correlations were computed between positions: (1) within each organization, (2) within each level of the organization, and (3) within each specialty. Again, systematic differences were associated with differences in the hierarchical levels in which the positions were located. The results indicated a greater degree of similarity between positions in the same specialty but were different at different levels. Hemphill also factor-analyzed the correlations among the 575 items. Ten factors emerged: (1) providing a staff service for a nonoperational area; (2) supervising work; (3) business control; (4) technical (markets and product); (5) human, community, and social affairs; (6) long-range planning; (7) exercise of broad power and authority; (8) business reputation; (9) personal demands; and (10) preservation of assets.

With a heavier emphasis on the functional responsibilities of different managerial positions, Tornow and Pinto (1976) developed the Management Position Description Questionnaire (MPDQ) to provide a similar analysis for higher-level managers. Thirteen functions and associated work done for executives could be differentiated and evaluated. These were (1) product, marketing, and financial strategy planning—long-range thinking and planning; (2) coordination of other organization units and personnel—coordinating the efforts of others over whom one exercises no direct control; (3) internal business control—reviewing and controlling the allocation of personnel and other resources, cost reduction, performance goals, budgets, and employee relations practices; (4) products and services responsibility—planning, scheduling, and monitoring products and the delivery of services; (5) public and customer relations—promoting the company's products and services, the goodwill of the company, and general public relations; (6) advanced consulting—application of technical expertise to special problems, issues, questions, or policies; (7) autonomy of action—discretion in the handling of the job, making decisions that are most often not subject to review; (8) approval of financial commitments—authority to obligate the company; (9) staff service fact gathering—the acquisition and compilation of data and record keeping for a higher authority; (10) supervision—getting work done efficiently through the effective use of people; (11) complexity and stress—handling information under time pressure to meet deadlines, frequently taking risks, interfering with personal or family life; (12) advanced financial responsibility—preservation of assets, making investment decisions and large-scale financial decisions that affect the company's performance; (13) broad personnel responsibility—management of human resources and the policies affecting it. Tornow and his colleagues continued this line of investigation for 11 years in different industries, for different organizational levels, and in upward of 20 countries involving more than 10,000 managers. The instrument they validated, the MPDQ, contains about 250 items of required activities, contacts, skills, knowledge, and abilities. In rating each item to describe the management position, the job analyst weighed the importance, the criticality, and the frequency of occurrence of the item. Managers indicated that 85% of their jobs were adequately described by the items of the MPDQ, according to managers in both the United States and foreign countries (Page, 1985, 1987).

*Profiles of Managerial Positions.* Managerial positions can be usefully profiled on factors and compared with norms for the different levels of management. Seven large-scale studies that searched for factor analytic solutions were carried out in a variety of industries, including banking, manufacturing, and retailing. Seven types of these factors consistently emerged across these studies: (1) planning, (2) controlling, (3) monitoring business indicators, (4) supervising, (5) coordinating, (6) sales/marketing, and (7) public relations and consulting (Page & Tornow, 1987). In the profiles of the factor scores for the positions of 108 executives, 125 managers, and 196 supervisors, executive positions stood out in their planning, controlling, and monitoring business indicators and in their public relations activities. Supervisors' positions differed the most from those of the managers and executives in supervisory activities and their relatively low scores in comparison to the others on most of the other factors. The managers' position tended to come closer to those of the executives in planning, controlling, coordinating, and consulting and closer to the supervisors in public relations.

Consistent with these findings, a factor analysis reported by Dunnette (1986) of 65 managerial tasks yielded factors, including: (1) monitoring the business environment; (2) planning and allocating resources; (3) managing individuals' performance; (4) instructing subordinates; (5) managing the performance of groups; (6) representing the groups. Comparisons among 574 first-level, 466 middle-level, and 165 executive-level managers indicated that as the hierarchical level increased, so did the managers' functions of monitoring the business environment and coordinating groups. At the same time, the instruction of subordinates and the management of individual performance decreased.

Yukl, Wall, and Lepsinger (1988) reported on the development and validation of the Managerial Practices Survey (MPS). The survey focused on managerial behavior, i.e., "answers requests, invites participation, determines how to reach objectives, assigns tasks, praises, facilitates the resolution of conflicts, and develops

contacts.” Colleagues and job incumbents rated the importance and relevance of each behavior to carrying out the manager’s responsibilities effectively. The 1988 version (Yukl, 1988, 1989, 2002) was grouped into 11 scales. The scales were developed using factor analysis and judges’ categorizations of the items. The 11 scales assessed the following behavioral dimensions: informing, clarifying, monitoring, problem solving, planning and organizing, consulting/ delegating, motivating, recognizing/rewarding, supporting, networking/interfaces, and conflict management/ team building.

*Managerial Role Activities.* Empirically obtained managerial roles by Hales (1986) and Page and Tornow (1987) included disturbance handling, innovating, sales/ marketing, public relations, and labor relations. Morse and Wagner (1978) used a modified list of nine of Mintzberg’s (1973)<sup>1</sup> managerial roles (see below) to classify managerial activities in a descriptive questionnaire. After several refinements by means of factor analysis, they constructed a list of 51 activities that could be used by managers to evaluate the effectiveness of another manager with whom they worked closely. By rating a manager on each activity, a colleague could evaluate the manager’s behavior. Six extracted factors covered the original nine role activities: (1) managing the organization’s environment and its resources (effective managers are proactive and stay ahead of changes in their environment; basing plans and actions pertaining to the organization’s resources on clear, up-to-date, accurate knowledge of the objectives of the company), (2) organizing and coordinating (effective managers fit the amount of formal rules and regulations in their organizations to the tasks to be done and to the abilities and personalities of the people doing them; these managers are not difficult to get along with or to coordinate with), (3) information handling (effective managers make sure that information entering the organization is processed by formal reports, memos, and word of mouth on a timely basis so it is usable and current and provides rapid feedback; they make sure that the person who has to use the information clearly understands it), (4) providing for growth and development (effective managers ensure, through career counseling and careful observation and recording, that their subordinates grow and develop in their ability to perform their work; they guide subordinates by commending the subordinates’ good performance); (5) motivating and conflict handling (effective managers transmit their own enthusiasm for attaining organizational goals to others; they are not plagued by recurring conflicts of a similar nature that get in the way of associates’ efforts to perform their jobs), (6) strategic problem solving (effective managers periodically schedule strategy and review sessions involving the design of projects to improve organizational performance and to solve organizational problems; they spend considerable amounts of time looking at their organization for problem situations and for opportunities to improve their subordinates’ performance).

Managers are often required to allocate or recover resources. They need to understand the rules involved. Allocators generally favor giving and taking back resources based on needs. Equality is favored particularly when resources are to be recovered. Generally, recovery decisions are harder to make than allocations. Monetary and facilitative resources tend to be most difficult to allocate (Parks, Conlon, Ang, et al., 1999). Evaluations of 231 managers by colleagues were higher for better-performing managers on all six dimensions in three of six offices, according to objective criteria such as net profit, data budgeting, and the volume of customer billing. The evaluations were correlated between .41 and .65 with superiors’ rankings of how well the managers were performing. Multiple regression analyses indicated that the managerial activities that were of most consequence to the end results were, first, managing the organization’s environment and resources; and, second, motivation and conflict handling. But the consequences depended on the organization’s objectives. Thus, according to multiple regressions, in contrast to other kinds of firms, in a data processing firm, accounting and handling financial records for clients, information handling, and strategic problem solving by the managers contributed the most to the appraised performance of the managers by their superiors. A similar line of investigation was completed using the Management Practices Survey (MPS). Yukl and Kanuk (1979) showed that for 151 employees of beauty salons who described their salon managers, the average monthly profit margins of the salons correlated .47 and .49, respectively, with the extent to which managers were seen to engage in clarifying

and motivating activities.

Numerous other examples can be provided. Thus cadet sergeants' clarifying and motivating correlated .26 and .30, respectively, with the performance of the ROTC units for which they were responsible (Yukl & Van Fleet, 1982). Problem solving and recognizing/rewarding correlated .39 and .42, respectively, with the behavior of managers when the managers were responsible for the performance of insurance salespersons in retail department store outlets (Yukl & Carrier, 1986). For 24 school principals studied by Martinko and Gardner (1984b), whose managerial behavior was described by their school-teachers, again problem solving, clarifying, monitoring, and motivating correlated with effectiveness (between .36 and .49), as did networking/interfaces (.47). Miles (1985) found that these and the other 13 scales of activities of the MPS by 48 directors of home economics programs correlated between .21 and .42 with the quality of the county programs they administered. Similar results were found for department heads.

*A Behavioral Checklist Analysis.* Tsui (1984) pointed out that a manager's reputation for effectiveness depends on satisfying at least three constituencies: superiors, peers, and subordinates. The performance appraisals earned by a manager, merit pay increases, rate of promotion, and career advancement were highest when the manager's reputation for effectiveness was high among all three constituencies. Such threefold reputational effectiveness correlated with behavioral checklists of roles taken by a sample of managers. Mean correlations for the threefold reputational effectiveness of managers and the extent to which the managers engaged in each of six Mintzberg roles were as follows: leader (.45), liaison (.23), entrepreneur (.37), environmental monitor (.34), resource allocator (.37), and spokesperson (.35). Multiple regression analyses indicated that almost 30% of the reputational effectiveness could be accounted for alone by the extent to which managers engaged in the roles of leader and entrepreneur. Expected differences emerged, however, among the constituencies in what role activities were important for reputational effectiveness. In a subsequent study, Tsui and Ohlott (1986) found that the various constituencies had similar models of the elements of managerial effectiveness but differed on the relative importance to attach to each. The roles of leader and entrepreneur (planner, controller, implementer of change) were most salient for managerial effectiveness in their models of what was important in the role repertoire of the focal manager they described.

*A Three-Stage Model of Effective Leader-Managers.* Neider and Schriesheim (1988) developed a three-stage model that is presented in [Figure 23.1](#). The three stages deal with precursor conditions, maintenance functions, and reassessment and monitoring. Precursor conditions are the organizational functions and tasks that take place to set the stage for effective leadership and management. They include a thorough job analysis, detailed compensation analysis, good selection strategies, and sound orientation training of the subordinates. In the first stage, effective leaders pay attention to the data necessary to clarify fully for subordinates how their efforts will result in the attainment of the objectives of the job. Equity and desired rewards that are contingent on performance are key considerations. Effective leaders ensure that the subordinate's knowledge, skills, and abilities match the requirements of the job. The second stage involves career pathing for the subordinate, goal setting, and performance-contingent and individualized consideration focused on the development of the subordinate through suitable delegation. Both the subordinate's self-esteem and the organization's attractiveness to the subordinate are thus enhanced. In the third stage, the effective leader provides feedback and meetings at which the alignment of the subordinate's needs and performance with the organization are reassessed and misperceptions are corrected. Here, intellectually stimulating leadership helps solve the subordinate's problems.

**Critical Incidents.** Flanagan (1951) originated the *critical incidents* technique. Respondents describe incidents of effective and ineffective job performance they have observed or in which they have been involved. The technique was applied to a study of the jobs of U.S. Air Force officers and research executives. It was possible to classify the incidents under the following major headings: supervision, planning and direction, handling of administrative details, exercise of responsibility, exercise of personal responsibility, and proficiency in a given specialty. In the same way, Wallace and Gallagher (1952) analyzed the job activities and behaviors of 171 production supervisors in five plants. They collected and classified 3,765 behavioral incidents by the topic involved, location of the incident, person contacted, and nature of the foreman's behavior during the incident. Along similar lines, Williams (1956) and Kay (1959), among others, were able to describe managerial jobs in terms of critical requirements. Williams collected more than 3,500 incidents from a representative sample of 742 executives who were distributed proportionally by industry, company size, and geographic location. Kay collected 691 critical incidents of foremen's behavior from managers and rank-and-file employees.

### ***Biases in Time and Work Methods of Study***

According to a review by Carlson and James (1971) of the various methods employed to study what managers do, how they spend their time, and what functions they perform, adequate reliabilities and validities have been obtained.<sup>2</sup> Nonetheless, systematic biases can be seen.

**Substantive Problems.** An obvious error occurs if the description is more about a particular job incumbent than about the position as it is and should be performed by the average or typical incumbent. Another bias is due to the fact that managers in a hierarchy think they have a bigger job than their immediate superiors think they have. At the same time, managers think their subordinates have smaller jobs than the subordinates think they have (Haas, Porat, & Vaughan, 1969). The importance of the position and its duties depends on who is describing them. Several investigations corroborated this fact.

Brooks (1955) asked 96 executives, their superiors, and their subordinates to rate the work performed by the executives as indicated by 150 functional items. The executives rated themselves higher than they were rated by their subordinates in such activities as defining authority, delegating, planning, and showing how jobs related to the whole picture. Again, supervisors and subordinates differed in the requirements they saw for other aspects of the supervisor's job. According to Sequeira (1964), supervisors perceived that they were required to perform duties that did not legitimately belong to their jobs. Among these duties were: training new workers on the job, arranging wage agreements, and checking supplies. Workers expected their supervisors to do more than the supervisors required of themselves in settling personnel problems and grievances, clarifying work difficulties, and improving work methods and conditions. A study by Yoga (1964) of 11 plants in India in three industries (textiles, processing, and engineering) yielded similar results.

**Methodological Problems.** According to McCall, Morrison, and Hanman (1978), managers' behavior is usually described in global dimensions, such as planning and controlling, instead of actual observable behaviors because so many studies depend on interviews or questionnaires of the managers themselves. The results are then summarized with factor analyses. The responses of the managers provide only indirect information about

what the managers do. This is in contrast to observations of what they actually do. The self-reports deviate considerably from observations and records of their behavior (Horne & Lupton, 1965; Kelly, 1964)—although as noted before, Navy officers could accurately estimate the logged time they spent on observable activities. Diaries, as self-reports, are also likely to deviate from summary estimates as well as from independent observers' descriptions (T. Burns, 1954). "Managers are poor estimators of their own activities" (Mintzberg, 1973, p. 222). Thus, as Lewis and Dahl (1976) point out, although 12 university administrators estimated in a summary judgment that they had spent 47% of their time in meetings, their diaries for five weeks indicated that they had spent 69% of their time in such meetings (Lewis & Dahl, 1976).

The discrepancy between what managers say they do in response to questionnaires and what they actually do is to be expected. Managers do not consciously plan ahead to summarize all their activities in a retrospective survey. "Managerial work activities are fragmented, brief, diverse, fast-paced and primarily oral, [and] the sheer volume and nature of activities seriously hinder a manager's efforts to conscientiously observe and purposively memorize activities for accurate reporting on a future survey" (McCall, Morrison, & Hanman, 1978, p. 27). Furthermore, regardless of the self-reporting method used, social desirability is likely to inflate results (Weiss, Davis, England, & Lofquist, 1961). As with many other methodological problems, for confidence in the conclusions reached, the solution usually lies in using multiple methods that combine self-colleagues', and observers' reports with a mix of logs or diaries and interviews or questionnaires.

*Personal Preferences.* Different managers can occupy a position with the same requirements yet display considerable differences in how they fulfill their responsibilities. Stewart (1976b) observed that the activities of incumbents in management positions with the same function and at the same level varied considerably because managerial jobs have a certain amount of choice beyond the basic demands of the job. To a considerable degree, managers can work on tasks of their choosing and when they want to. Stogdill and Shartle (1955) pointed out that regardless of the different requirements of the new position to which they were transferred, naval officers spent the same amount of time on some activities in both positions. In the same way, Castaldi (1982) found that seven of ten CEOs who headed companies of the same size in the same industry (small furniture manufacturing) agreed about the importance they attached to operational activities. The seven attached more importance to strategic activities only. The majority's emphasis on strategic activities was seen to be a consequence of the static technology of the furniture industry, the strong competitiveness among firms, and the long tenure of the CEOs.

## Time Spent and Work Done by Managers

---

### *Use of Time*

Most studies have focused on how managers spend their time, what work they do, and what roles they play. The frequency, importance, and criticality of these factors have been the usual gauges of consequence. Clearly, according to diaries and observational studies, managers work long hours, ranging from 50 to 90 hours per week, some of which may be carried on outside the office. Senior managers work longer than do lower-level managers but on fewer activities. Those with well-defined functions, such as accounting managers, can work fewer hours (McCall, Morrison, & Hanman, 1978). Shipping supervisors differ systematically from production supervisors in the time they spend in planning and scheduling work and in maintaining equipment and machinery (Dowell & Wexley, 1978).

With his background as a former director of research on job and occupational information, Shartle (1934, 1949b) suggested that executive work could most meaningfully be quantified in terms of the amount of time

devoted to various activities. Stogdill and Shartle (1955) compared the time use profiles of 470 U.S. Navy officers and 66 business executives. They found that both groups spent more time (about 34%) with subordinates than with superiors or peers. Furthermore, both groups devoted about 15% to 20% of their time to inspections, examining reports, and writing reports, and spent somewhat more time in planning than in other major administrative functions. The profiles suggested a high degree of similarity in administrative work between military and business organizations. Similarly, Jaynes (1956) analyzed variations in the performance of 24 officers in four submarines and 24 officers who occupied identical positions in four landing ships. He reported that variance in performance was more closely related to the type of position than to the type of organization in which the position was located.

In the previously cited study of executives in Sweden, S. Carlson (1951) found that they spent about 20% of their time in internal and external inspections and almost 40% of their time acquiring information. The remainder of their time was divided about equally among advising and explaining, making decisions, and giving orders. Most of the executives felt overworked, complaining that they had little time for family or friends. According to Horne and Lupton's (1965) study of 66 managers, a large percentage of a manager's time is spent in discussions with others—44% informally, 10% in formal meetings, and 9% on the telephone. In contrast, only 2% is spent in reflecting, 10% in reading, and 14% on paperwork. At least half these activities occur in the manager's own office. The most frequent purposes are to transmit information (42%), discuss explanations (15%), review plans (11%), discuss instructions (9%), review decisions (8%), or give and receive advice (6%). Mowll (1989) found in a study of more than 1,200 health care patient account managers that they spent more than 30% of their typical day supervising their departmental staff. Their effectiveness depended on how well they allocated their time and motivated their staff. As will be discussed in [Chapter 29](#), by the 1990s, these percentages had to be adjusted due to the fact that managers were spending an increasing amount of their time on e-mail, the Internet, and their organizations' intranet.

*Time Spent on Activity by Position.* Stogdill, Shartle, Wherry, and Jaynes (1955) studied 470 U.S. Navy officers in 45 different positions or job categories. The officers were located in 47 different organizations. Data were obtained from all officers on the percentage of their working time that was devoted to the performance of 35 tasks, including personal contacts, individual efforts, and handling other major responsibilities. The results were related to the officers' level in the organization, military rank, scope or responsibility, scope of authority, and leadership behavior. Stogdill, Wherry, and Jaynes (1953) factor-analyzed these naval officers' profiles to cluster the positions of officers doing similar work, such as public relations directors, coordinators, and consultants. Then, they correlated the scores for the specialties with how occupants spent their time. Eight factors emerged from the analysis: (1) high-level policy making, (2) administrative coordination, (3) methods planning, (4) representation of members' interests, (5) personnel service, (6) professional consultation, (7) maintenance services, and (8) inspection. The officers clustered in terms of how their assignments and activities made use of their time. The clusters were (1) technical supervisors (teaching, supervising, using machines, and computing); (2) planners such as operations officers (scheduling, preparing, procedures, reading technical publications, interviewing personnel, and consulting peers); (3) maintenance administrators (interpreting, consulting, attending meetings, and engaging in technical performances); (4) commanders and directors (representing, inspecting, and preparing reports); (5) coordinators, such as executive or staff officers (consulting juniors, supervising, scheduling, examining reports, and interviewing personnel); (6) public relations officers (writing for publication, consulting outsiders, reflecting, and representing); (7) legal or accounting officers (consulting juniors, professional consulting, interpreting); and (8) personnel administration officers (attending meetings, planning, and interviewing personnel).

T. A. Mahoney (1955) plotted the time usage profiles of 50 company presidents against those of 66 business executives reported by Stogdill and Shartle (1956). The two profiles were almost identical. T. A. Mahoney (1961) next analyzed the performance of 348 business executives in terms of eight functions. The

performances with the percentage of time devoted to them were as follows: supervision (39%), planning (18%), generalist (14%), investigation (8%), coordination (6%), negotiation (5%), evaluation (4%), and miscellaneous (7%). Similar patterns of time usage were reported by Mahoney, Jerdee, and Carroll (1965) for a sample of 452 managers drawn from all organizational levels. A minimum amount of time was spent on each of these functions, although the percentage varied as a function of hierarchical level. For example, at lower hierarchical levels, more time was spent in supervision. At higher levels, more time was spent in planning. Replicated by Penfield (1975), these results were consistent with Stogdill, Shartle, Wherry, and Jaynes's (1955) findings for naval officers, and Haas, Porat, and Vaughan's (1969) findings for bank officials. Fleishman (1956) used the same kinds of data to analyze the differences between administrators in military and industrial organizations. He observed that differences *between* the patterns of administrative performance in industrial and naval organizations were generally no greater than differences *within* the two types of organizations. Taken together, all these studies indicated that time profiles of managerial positions tend to shift systematically with the hierarchical level of positions and the functional role of the positions in the organization. The patterns of time spent tend to be similar for positions that are comparable in level and function in different types of organizations.

Yukl (1998) concluded that managers need to understand the demands and constraints on their time. They need to know what others expect of their time. They need to appreciate what priorities in the use of their time are expected of them by subordinates, colleagues, and their superior. But they also need to be proactive in taking a broader perspective on how to spend their time aligned with organizational strategies. They need to make time for reflection, planning, daily and weekly activities, and avoiding procrastination.

## ***Work Done***

Contrary to both popular and classical images of management, much more managerial work involves handling information than making decisions. McCall, Morrison, and Hanman (1978) reached this conclusion from diaries and observational studies by Brewer and Tomlinson (1964) and Horne and Lupton (1965). As Carroll and Gillen (1987) noted, the simple classical view of the manager as one who gets work done through prescribed and orderly planning, organizing, and controlling has given way to a more complex romantic view, stimulated by the work of Mintzberg (1973), which is detailed below. Instead of the prescribed best ways to fulfill the managerial role, what we now have is a picture of harried executives putting out fires on demand, rather than systematically carrying out their prescribed functions in an orderly fashion. Both Guest (1956) and Ponder (1958) reached similar conclusions earlier from observational studies of production supervisors who had to handle a variety of problems quickly. One problem followed another with less than a minute for each on the average. More than 50% of the supervisor's time was spent in face-to-face interactions, more often with subordinates than with outsiders, although the supervisors had more total contacts with the latter. Landsberger (1961) also noted at the middle-management level the same pattern of brief, varied, and fragmented activities with much lateral interpersonal interaction.

Numerous other empirical investigations revealed a great variety in the functions describing what managers actually did. Managers do not behave according to textbook requirements for orderliness, planning, optimum decisions, and maximum efficiency. Rather, managerial processes, according to Mintzberg's (1973) in-depth study of five executives, are characterized by brevity, variety, and discontinuity. Managers rely on judgment and intuition, rather than on formal analysis, which makes it difficult to observe clearly their decision making processes. Kurke and Aldrich (1983) supported Mintzberg's conclusions in a complete replication with four CEOs for one week. Yet Snyder and Glueck (1977), in a replication of Mintzberg's (1973) study, found managers to be more careful planners. But brevity in any one activity, interruptions of that activity, and

discontinuity from one activity to the next were characteristic of what was gleaned from managers' diaries, recordings, and observations (Mintzberg, 1973). Although planning was regarded as a key element in the classical view of management, managers at all levels, according to diaries and observation, actually spent less time at it because of interruptions and demands on their time for other activities (McCall, Morrison, & Hanman, 1978). Mintzberg concluded that managers were oriented toward action, not reflection.

There is a certain amount of ritualistic and regular duties in managerial work. Since personal communication is favored over written documents, managers spent a good deal of time on the telephone or in meetings. Klaus and Bass (1981) found that this tendency increased when managers dealt with peers. If the peers are at a distance, contact was by telephone; if they were close, the contact was face-to-face. But if the communication was with persons who were higher or lower in the organizational hierarchy, it was usually done through memos. E-mail now substitutes considerably for memos, telephone, and meetings, as will be discussed in [Chapter 29](#).

*Effects of Hierarchical Level.* Barnard (1938) considered how the functions of the executive varied according to the location of the executive's position in the organizational hierarchy. Political considerations also affected what could be done at different levels of the hierarchy. Nicholls (1990) noted that managers at lower levels engaged in *micro* managerial leadership with jobs and tasks and short-term performance goals. At upper levels of management—*macro* managerial leadership was concerned about organizations and long-term performance goals. T. V. Mumford (2003) agreed that the skill requirements for managerial leadership were different at different organizational levels, although some basic management skills were needed at all levels. This model was supported by evidence from close to a thousand lower-level military officers. The scope of activities, the need for more conceptualization, and complexity of relations increased with increases in hierarchical level. For Zaccaro (1996), managerial leadership of single units is direct; problems are concrete and have a short time frame. At higher levels, multiple units are managed, and managerial leadership is more indirect.

In the U.S. Army, majors, captains, and lieutenants are like middle managers; sergeants and corporals are the equivalent of civilian supervisors and technical specialists. Job analytic studies were completed by Stogdill, Scott, and Jaynes (1956), who asked U.S. Navy officers to use Work Analysis Forms (Stogdill & Shartle, 1958) to indicate "what I do" and "what I ought to do." Junior officers also indicated their perception of what their senior officer did and ought to do. Senior officers expected and were expected by the junior officers to engage more often than junior officers in such activities as attending conferences, consulting superiors, examining reports, planning, and coordination. Seniors expected and were expected by juniors to do less than junior officers in writing reports, reading technical publications, scheduling and routing, research, and engaging in technical and professional operations. Both junior and senior military officers reported that, compared with what they *actually* did, they *should* do more inspecting, research, planning, public relations, reflection, reading of technical periodicals, and writing for publication. Both senior and junior officers reported that they should do less consulting with assistants and superiors, interviewing personnel, reading and answering mail, preparing charts, supervising, interpreting, and scheduling. Sherif (1969) used the Work Analysis Forms in a comparative study of three levels of managers in six diverse organizations. As would be expected, top managers consulted more with subordinates, while managers at the bottom consulted more with superiors and peers. Middle managers fell between the other two groups in contacts with superiors, peers, and subordinates. In regard to individual effort, examining reports and thinking increased with the level of the position, while writing reports, computation, and use of machines decreased. With respect to major functions, preparing procedures, coordinating, and evaluating increased with the level of the position, and supervision and personnel activities decreased. Haas, Porat, and Vaughan (1969) also used an adaptation of the Work Analysis Forms in a comparative study of three levels of organization. Planning and coordination were done most in top-level positions; negotiating, in middle-level positions; and supervising, at lower levels. All levels combined did more

investigating but less planning than they thought ideal.

*The First-Level Supervisor.* In a survey of 10,392 supervisors, Richardson, Bellows, and Henry (RBH) noted the five most important of supervisory role requirements of 25 listed. These were: (1) to work with others; (2) to get others to do what needs to be done; (3) to adapt quickly in emergency or problem situations; (4) to pass on and explain instructions to others; (5) to plan ahead. No contribution to strategic thinking was included among the 25. Observational studies of the work done compared effective and ineffective production supervisors. The better supervisors were compared with the poorer ones by performance appraisals and the productivity of their groups. The better supervisors spent less time on purely production matters, gave more general work orders, initiated interpersonal contacts more frequently, and spent more time with staff and service personnel outside their work group (Pondevy, 1958).

Specialized questionnaires were developed for the study of the position of first-level supervisor. Following Hemphill's (1960) work on the dimensions of managerial jobs, Prien (1963) constructed the Supervisor Position Description Questionnaire with items written by job analysts who were guided by an outline of general supervisory functions. Thirty supervisors indicated the extent to which each of the items was descriptive of their work. Prien extracted seven factors: (1) employee supervision; (2) employee contact and communication; (3) union-management relations; (4) manpower coordination and administration; (5) work organization, planning, and preparation; (6) manufacturing process supervision; (7) manufacturing process administration. Using a similar methodology, Dowell and Wexley (1978) factor-analyzed the responses of 251 supervisors regarding the importance of 89 work activities of first-line supervisors. The factor structure obtained from the intercorrelations among ratings of importance was highly congruent with the factor structure obtained from the intercorrelations among the ratings of the amount of time spent in an activity. The seven dimensions along which the positions of first-level supervisors could be ordered were: (1) working with subordinates (informing them of the performance expected, instructing them in safe working habits, seeing that safety equipment is used, instructing them in the proper use of materials and equipment, observing their work activities, listening to their ideals and problems, and settling disciplinary problems or potential grievances); (2) organizing the work of subordinates (talking with supervisors in other departments about production, scheduling overtime, shifting people to other jobs, establishing priorities on "down" equipment, and assigning employees to specific jobs); (3) work planning and scheduling (consulting with the departing supervisor about conditions on the shift, reading records of previous shifts' activities, planning production for the shift, and completing reports on conditions at the end of the shift); (4) maintaining efficient and high-quality production (checking the quality of production; finding the causes of low production or poor quality; determining production levels, the quality of the production, and the kinds and causes of waste; and soliciting suggestions from subordinates regarding improvements in work methods); (5) maintaining safe, clean work areas (communicating Occupational Safety and Health Act regulations to workers, checking that walkways and fire exits are clear, completing maintenance records, and inspecting work areas for cleanliness); (6) maintaining equipment and machinery (diagnosing problems with machines, adjusting machines, checking maintenance work when completed, inspecting machines for proper working order, and setting up machines); (7) compiling records and reports (compiling miscellaneous reports, distributing tools or equipment, keeping personal records of job incidents, performing routine checks of safety devices, and notifying people of changes in schedules).

*Dynamic Models.* Wofford (1967, 1970, 1971) reached a somewhat simpler set of more psychologically defined dynamic factors to describe a manager's behavior: (1) neatness and accuracy in planning, organizing, and controlling; (2) use of power and pressure to achieve employees' compliance; (3) maintenance of interpersonal relationships (personal interaction as a leader); (4) security and maintenance (reactions to or the avoidance of feelings of insecurity); and (5) dynamic and achievement orientation (setting specific goals). Mumford, Fleishman, et al. (1988) started with a list of 156 tasks and 69 possible job performance

dimensions to describe the positions of U.S. Army officers. A total of 96 officers judged the importance, time spent, and freedom to decide on how, when, and where each of 13 job performance dimensions was relevant. The most important dimension was setting an example for others to follow. The dynamic model the authors were able to organize linked the job performance dimensions into a coherent design.

*Networking and Boundary Management.* Mumford, Fleishman, et al. (1988) modeled the leader-subordinate relation without much reference to persons outside the group except as imported information. However, McCall, Morrison, and Hanman (1978) concluded, from diary and observational studies,<sup>3</sup> that although lower-level managers spend most of their time within their own departments and organizations, senior managers have much more contact with those outside the organization. Luthans (1986), among others, paid special attention to the relations of the managers to others, outside their immediate subordinates or immediate superior. He concluded from observing more than 300 managers that although three clusters<sup>4</sup> of inside activities could be described, the most important was the fourth cluster of “networking,” socializing, and “politicking” with those other than one’s immediate colleagues. Such networking appeared to be most important among the four clusters of activities. Luthans, Rosenkrantz, and Hennessey (1985) inferred, from participant observers’ records of 52 managers in a state department of revenue, a manufacturing plant, and a campus police department, that success in the organization was enhanced by networking with such outsiders, socializing, and playing politics. Gardner (1988) noted that “politics” can make a positive contribution within organizations or can be regarded pejoratively. As a positive contribution, the leader-manager may reconcile conflicting parties by intervening in a dispute or mobilizing the group to agree to common goals. Or playing politics may mean manipulation, mistrust, self-promotion, favoritism, and hidden alliances.

Successful managers engaged more than did the less successful managers in conflict management, planning, coordinating, and decision making. An in-depth study of 15 successful general managers by Kotter (1982a) again emphasized the importance of time spent with outsiders as well as with others in their own organization. Kotter considered many of these contacts to be network building. A manager’s agenda could be more readily implemented if he or she had developed a high-quality network. Sayles (1964) also focused particular attention on the manager’s lateral networking. The networks included relationships dealing with: the work flow, trading, service, giving or receiving advice, evaluating other groups or responding to the requests of those evaluating one’s group, limiting or controlling decisions made by other managers, and engaging in innovations. McHenry (1986) generated two factors involving the importance attached to a manager’s lateral activities for a sample of 400 managers: (1) coordinating interdependent groups and (2) representing one’s work group. In the same way, after general managers set agendas to establish loosely connected goals and plans for short-, medium-, and long-term responsibilities, they develop a cooperative relationship networking with those individuals needed to satisfy the agendas. They get the networks to implement the agendas (Kotter, 1982a).

## Mintzberg’s Managerial Roles

---

Mintzberg (1973) presented a model of 10 management roles that was dynamic and included activities both inside and outside the organization. It generated a great deal of interest and subsequent use. A former journalist, he intensively studied five CEOs and their organizations, along with a calendar of their scheduled appointments for a month. Additional data collected during a week of structured observations included anecdotal data about specific activities, chronological records of activity patterns, a record of incoming and outgoing mail, and a record of the executive’s verbal contacts with others. The CEOs were found to work at an unrelenting pace on a wide variety of tasks. They were subject to frequent interruptions. They preferred specific, well-defined activities of current importance over work on general functions of less certainty and less immediate relevance. In addition, they preferred verbal contact with others to written contact.<sup>5</sup>

## Ten Integrated Roles

On the basis of these data, Mintzberg divided managerial activities into interpersonal, informational, and decisional roles. The interpersonal category contained three specific roles: (1) the *figurehead* role, (2) the *leader* role, and (3) the *liaison* role. In the figurehead role, managers perform symbolic duties as heads of the organization. In the leader role, managers establish the work atmosphere and motivate subordinates to achieve organizational goals. In the liaison role, managers develop and maintain webs of contacts outside the organization to obtain favors and information. The informational category also included three roles: (1) the *monitor* role, (2) the *disseminator* role, and (3) the *spokesman* role. In the monitor role, managers act as collectors of all information that is relevant to the organization. In the disseminator role, managers transmit information from the outside to members in the organization. In the spokesman role, managers transmit information from inside the organization to outsiders. Last, there were four specific decisional roles: (1) *entrepreneur*, (2) *disturbance handler*, (3) *resource allocator*, and (4) *negotiator*. Managers adopt the entrepreneurial role when they initiate controlled change in their organization to adapt to the changing conditions in the environment. In the disturbance handler role, they are forced to deal with unexpected changes. In the resource allocator role, they make decisions concerning the use of organizational resources. In the negotiator role, they deal with other organizations or individuals. The 10 roles are an integrated set. Formal authority supports the three interpersonal roles, which in turn result in three informational roles. The authority and informational roles enable the CEO and senior executive to play the four decisional roles. Fewer of the roles are relevant at the middle-management and supervisory levels.

To measure the extent to which managers had to be engaged in Mintzberg's roles, Pavett and Lau (1983) asked 48 manufacturing managers to indicate the importance of 69 activities in carrying out their duties and the approximate amount of time they spent on each activity. The roles of leader and entrepreneur were deemed most important and were those on which the most time was spent. Time spent on a role correlated with its importance between .63 and .85.

Although McCall and Segrist (1980) found that managers' performance in six of the roles correlated with the managers' rate of promotion, they obtained too much overlap in the activities among the roles that were supposed to be distinct. Snyder and Wheelen (1981) reported difficulty in assigning specific activities to specific roles. One activity appeared relevant to several roles, and the roles were not mutually exclusive. For instance, when one of the subordinates of a school superintendent attended a United Way campaign fund-raising meeting, she did so as the formal representative of the school system. The superintendent, if present at the meeting, attended as a figurehead. The superintendent took the opportunity to chat with an influential outsider about a problem to obtain advice. In this case, he was acting as liaison, monitor, and spokesperson. As many others found, particularly at executive levels, as Mintzberg had emphasized, relatively little time was spent on any one role. There was much shifting from one role to another (Aldrich, 1983).

*Role Clusters.* Shapira and Dunbar (1978) simulated the CEO's job as head of a firm of 6,000 employees with an in-basket test completed by 54 MBA students at Hebrew University in Jerusalem, Israel. Each "CEO" could exercise each of the 10 managerial roles in dealing with the 16 memos in the in-basket and with the agenda he or she had prepared. A small space analysis indicated that the 10 roles could be described meaningfully with two clusters. The first cluster was made up of the liaison, disseminator, spokesman, and figurehead roles. These roles were concerned primarily with the generation and transmission of information. The cluster corresponded with Mintzberg's (1975) notion of the executive as the general nerve center of the organizational unit. The second cluster of roles—entrepreneur, negotiator, leader, disturbance handler, monitor, and resource allocator—was concerned primarily with the active formulation and execution of decisions.

*Role Factors.* A number of investigators, such as Morse and Wagner (1978), Lau, Newman, and Broedling (1980), and Tsui (1984), used Mintzberg's set of roles to generate and factor specific leadership and management role activities that could then be used for checklists of observed behaviors and questionnaire surveys. These could then be self-rated or completed by superiors, peers, or subordinates. Lau, Newman, and Broedling (1980) extracted four factors from a questionnaire survey of the behavior of 210 governmental managers: (1) leadership and supervision, (2) information gathering and dissemination, (3) technical problem solving and executive decision making, (4) allocating resources. On the basis of ratings by 1,080 personnel in the division of a large corporation of self, superiors, peers, or subordinates using survey questionnaires, Tsui (1984) extracted six factors: (1) leader (evaluates subordinates, resolves conflicts, facilitates development, and alerts subordinates to problems); (2) spokesperson (serves as expert, represents unit); (3) resource allocator (distributes resources, decides on programs to be supported); (4) entrepreneur (plans, implements, controls change); (5) environmental monitor (gathers information about market, customers, and competition); (6) liaison (attends meetings in other units and social functions).

## Managerial Activities

---

Managers in the same positions may be required to engage in somewhat different activities, or they may do so as a matter of personal competence or preference. They may be more effective or less effective depending on the extent to which they emphasize certain activities and processes at the expense of other work they might do. Campbell, Dunnette, Lawler, and Weick (1970) proposed a *person-process-product model* of managerial effectiveness. The *person* in the model refers to the managers' competencies, such as those discussed in [Chapter 5](#). The *product* is an organizational result, such as productivity. The *process* is the manager's on-the-job activities. All three components—person, process, and product—need to be understood in evaluating the manager's effectiveness in identifying and judging the observable actions and roles resulting in the accomplishment of organizational objectives (Porter, Lawler, & Hackman, 1975).

### *Differences in Activity*

Effective leaders tend to be more active than ineffective leaders, although the contrary was found for first-level supervisors dealing with production in less well conducted investigations in the 1950s. These supervisors of well-run work groups may have had more free time to plan and think ahead. They may have been more efficient in getting done what needed to be done or they were better at delegating. Or they may have had more competent subordinates. Martinko and Gardner (1985) suggested that the earlier findings about supervisors' activity rates were too fraught with statistical problems to be accepted with any confidence. A much stricter study by Komaki, Zlotnick, and Jensen (1986) supported the more general conclusions that effective leaders are more active than ineffective ones are. They observed 24 managers in a medical insurance firm up to 20 times over the interval of the study, using a rigorous set of observational procedures. They classified observations and activities according to operant theory: performance antecedents, performance monitoring, performance consequences, own performance, work-related, non-work-related, and solitary. Sets of observers were trained to achieve high interobserver agreement of 90% or better. Of the 24 managers, 12 were identified by their superiors as effective, and 12 as marginal. Significantly more time was spent by the effective than the marginal managers in collecting information on employees' performance. The effective managers were more likely to observe employees in action than to depend on self-reports or secondary sources. They more often sampled the employees' work, but they did not provide any more positive, neutral, or negative consequences. Komaki inferred that given their greater monitoring behavior, the effective managers were more likely to

provide contingent reinforcement of the subordinates. Similar observational analyses were completed on the behavior of 19 sailboat racing captains by Komaki, Desselles, and Bowman (1989). The correlation of the order in which the boats finished the race (from first to last) was  $-.53$  with the amount of monitoring by their captains and  $-.59$  with the amount they fed back consequences. Their coaches' ratings of the captains' effective handling of their crews were related in the same way to their observed monitoring and consequences.

### ***Amount and Quality of Planning***

The activities of managers are supposed to be organized and orderly, but, as Mintzberg (1973) noted, they may be just the opposite. An executive commented, "My day consists in running from one meeting to the next, fielding questions from my internal staff and outsiders, trying to respond to telephone messages, trying to smooth over an argument between a couple of people, and keeping my ever-higher in-basket from toppling down on me" (p. 26). Setting a daily, weekly, and longer-term work agenda with intentions and priorities about time, tasks, and goals can help to increase the organization and order in the activities (Barry, Cramton, & Carroll, 1997). Many managers do find time for short-term and long-term planning. Despite the lack of time for reflection and planning, how much time is spent on planning seems to differentiate effective from ineffective managers at the top as well as the bottom of the hierarchy. Stagner (1969) found that the time that 109 CEOs spent in organizational planning was related to the firm's profitability. Similarly, General Electric (1957) supervisors with better production records were seen to spend more time in long-range planning and organizing than were supervisors with poorer production records. E. Williams (1968) compared the activity patterns and preferences of 30 effective and 30 ineffective executives. The effective executives scored significantly higher in planning as well as in responsibility, human relations, decision making, and problem solving. Although the two samples differed in the time devoted to organizing and controlling, the ineffective executives spent less time in planning and rated organizing and controlling significantly higher in importance than did the effective executives. Apparently, the comparative deficiency in planning among the ineffective executives was accompanied by a perceived need for higher degrees of control.

The quality of planning has been assessed based on the demonstrated skills of the planners. Bray, Campbell, and Grant (1974) showed that skill in planning, as measured in AT&T assessment center exercises, was one of the best predictors of subsequent managerial success. Boyatzis (1982) also found competence in planning to be related to managerial effectiveness. Gillen and Carroll (1985) reported a correlation between planning skill and unit production of  $.34$  in manufacturing firms and  $.43$  in aerospace firms for a total sample of 103 unit managers in 10 firms.

*Functional Differences Related to Managerial Effectiveness.* In addition to differences in planning, other functional differences were found by Heizer (1969) in managers assigned to the same line and staff positions. The differences correlated with their effectiveness. Heizer asked 200 managers to write about incidents of effective and ineffective managerial behavior. Effective managers differed significantly from ineffective managers in planning, coordination, delegation, and staffing. In the same way, Kavanagh, MacKinney, and Wolins (1970) reported that the extent to which the department head fulfilled the functions of planning, investigating, coordinating, evaluating, supervising, and representing was related to the job satisfaction of the supervisors below the department head. Effective managers differed from ineffective ones in what they did to contribute to the surrounding organization. In a study of 345 R & D employees in a large chemical laboratory, Allen, Lee, and Tushman (1980) discovered that the overall performance of technical service projects was better if the project manager planned to link the project with other parts of the organization. Ghiselli and Barthol (1956) found that successful supervisors differed from unsuccessful ones in perceiving themselves as full of plans, loyal to the company and to subordinates, and as having the

responsibility of working with people to achieve organizational goals. Unsuccessful supervisors saw themselves as good fellows, well liked, and responsible for production. The unsuccessful managers relied on their ingenuity and resourcefulness to get the job done, rather than on their planning. Successful supervisors identified with their work group and its members, whereas unsuccessful supervisors were more interested in making a living. Levi and Mainstone (1992) examined the effects of the breadth and focus of priorities planned for by 165 business students participating in 20 top management positions for a day in the Looking-Glass, a high-fidelity simulation of the organization of a glass company. The participants concentrated more on crises than on problems and opportunities. The quality of their decisions was greater if they kept a broader focus.

*Same Role Requirements but Different Processes.* The same role requirements may be met by managers in different ways with different processes. For instance, Strauss (1962) found considerable differences in interpersonal patterns of contact and in oral versus written communications among purchasing agents with similar job descriptions. Similarly, Whitely (1985) demonstrated, with 70 managers studied for seven consecutive days during two weeks, that managerial positions with similar behavioral content still allow incumbents considerable latitude in how they choose to enact their roles. For instance, managers in accounting, management analysis, and reimbursements, engaged in the function of internal business control, differed significantly in the frequency of their scheduled activities, activities lasting 60 minutes or more, and contacts with their boss and peers. As Stewart (1982a) emphasized, there is a need to distinguish between the demands placed on an incumbent to a job, the constraints within functions that must be carried out, and the choices that can be made in carrying them out.

The characteristics of the process in which the manager engages are another way of analyzing what the manager does. R. Stewart (1967, 1982b) analyzed the duration of specific activities, the mode of communications used, and the particular persons contacted to detail the characteristics that distinguish among managers' positions. Thirteen reliably discriminable categories of characteristics of the managerial process were obtained by Whitely in his study of 70 managers: (1) scheduled activities, (2) activities of fewer than five minutes' duration, (3) activities of more than 60 minutes' duration, (4) face-to-face contacts, (5) self-initiated activities, (6) activities carried out alone, (7) contacts with two or more persons, (8) percentage of contacts with the boss, (9) contacts with peers, (10) contacts with subordinates, (11) contacts with external persons, (12) information-seeking activities, (13) decision-making activities.

## Moderators of the Manager's Work, Function, and Roles

---

Considerable evidence has been amassed to show how management positions differ depending on their area of responsibility in the organization, their hierarchical level in the organization, changes within organizations, and differences among organizations.

### ***Function of the Manager's Position***

Managers' areas of responsibility make a considerable difference in how they spend their time, on what activities they work on, and which are most critical and important to their success. For instance, supervising is more significant to merchandising managers than to data processing or finance managers. Thus, Alexander (1979b) found that informational roles, as expected, were much more salient in staff positions while interpersonal roles were more important in sales positions. Among the 225 managers studied in production, marketing, and accounting, Alexander noted, that compared to production managers, marketing and accounting managers reported themselves as facing more requirements to enact the informational roles of

monitor, disseminator, and spokes-person. Fewer differences were seen in the requirements of other roles. Pavett and Lau (1983) reported on the self-ratings of 180 top, middle, and lower managers in Southern California, on 54 items concerning the importance to their success of enacting Mintzberg's 10 roles plus an eleventh role of technical expert. The roles of leader and monitor were perceived to be highest in importance to sales and marketing; spokesperson and resource allocator to accounting and finance; and technical expert to research and development. For general managers, human and conceptual skills were seen as most important. In accounting and finance, the greatest importance was attached to technical skills, and in sales and marketing it was apportioned most to political skills.

In an in-depth report on 20 project managers, Spitz (1982) pointed out that the pattern of demands on a project manager may change over time as the project develops. That is, the particular skills required for the project manager's integrative efforts will shift with the changing project. Vaughan (1981) concurred. Using structured interviews, she found that for expatriate matrix project managers in a large multinational firm, there were important shifts in roles owing to the matrix in which they worked and as a consequence of changes in the phases of the project. The project managers could best be described as boundary-spanning experts and focal managers of a developmental process.

### ***The Importance of Functional Area of Experience***

In a survey of 700 managers, Shapira (2000) found that each manager's personal experience and perceptions had a strong influence on the willingness to make risky decisions. In the same way, Waller, Huber, and Glick's (1995) interviews with executives—31 in manufacturing, 17 in health care service, and 15 in other kinds of service—revealed that their different functional area experience resulted in their differing perceptions about their own organizations' effectiveness. However, unexpectedly, their perceptions of their organizational environments did not differ.

### ***The Importance of Hierarchical Level on Role Requirements***

For Hunt (1991), leaders perform the functions appropriate to their task requirements. To develop leaders for higher levels requires developing their ability to handle complexity. Barnard (1938) noted that top management is concerned with broad policies, objectives, and plans. These purposes and objectives become more specific as they filter down to lower levels, where the work is actually done. In addition, according to W. A. Scott (1967), unlike middle and lower managers, top managers are both the ultimate teachers and the judges of subordinates. They must be sensitive to the interactions among people below them and to their material resources. They must be more than just subject matter experts in their thinking. They need to look at a broad scope of information, while the expert analyzes a narrow scope in depth. They need to adopt multiple perspectives, while the expert fixes on a single perspective. They need to consider long-range consequences, while the expert deals with short-term problems. They manage group interactions, while experts participate as members of the group. They need to integrate multiple inputs, while the expert provides the inputs of knowledge. They focus on process, while the expert attends to content (Laskey, Leddo, & Bresnick, 1990). At lower levels in the organizational hierarchy, Whyte (1956) observed that the primary function is to perceive one's task accurately and to conform to it. Technology and controls are most important. Nevertheless, if the broad objectives and policies set at the top are to be operationalized and successfully carried out, managers at lower levels must exhibit considerable initiative (Fiedler & Nealey, 1966). Innovative breakthroughs or discontinuous innovation require continuing senior management support of R & D efforts (Morone, 1997). Senior management must provide a safe place where incubation of innovations can occur, old practices can be

questioned, and new ideas can be encouraged and communicated upward for a fair evaluation. Control can be relaxed by using self-managed teams of creative people who can think “outside the box” (Nutt, 1999).

On the one hand, Argyris (1964a) observed that the objectives of the job and interpersonal factors play more important roles in influencing the effectiveness of managers higher in the hierarchy. On the other hand, Pfiffner and Sherwood (1960) noted that, in particular, first-level supervisors work under considerable time pressure and have frequent and direct personal contact with the work. Nealey and Fiedler (1968) added more specifically that the typical functions of first-line supervisors are production, maintenance, on-the-job training, and control of materials and supplies. Second-level managers deal with cost control, setting standards, selection and placement, coordination of work units, and formal training. The second-level manager needs less technical expertise about specific production processes than does the first-level supervisor, for the second-level manager may supervise several departments involving different technical processes.

A survey of 1,476 New York City managers revealed that those at higher levels reported having a considerably greater variety of activities to perform than did those at lower levels (Allen, 1981). Dubin and Spray (1964) analyzed the logs kept by executives over a two-week period. Lower-level managers were more likely than those at higher levels to concentrate their time on a single activity. At the same time, the sheer number of incidents per day in which a manager is involved is highest for first-line supervisors and declines with increasing levels of management. For example, Thomason (1967) reported the average number of activities for different levels of management as follows: first-level supervisor, 413; superintendent, 309; area superintendent, 274; general manager, 91.

Pfiffner and Sherwood (1960) noted other differences in activity and function between first-level and middle managers. First-level supervisors work under more time pressure and have more direct and frequent contact with subordinates with the work. T. Burns (1954) found that middle managers spend more time with their superiors than first-level supervisors do and use formal communications in their work to a greater extent than do first-level supervisors.

*Effect on Roles Enacted.* Paolillo (1981b) found that among 352 managers, the importance and time spent on 7 of the 10 roles identified by Mintzberg depended on the managers’ level in the organizational hierarchy. Similarly, Klauss, Flanders, Fisher, and Carlson (1981b) asked 753 senior and 847 midlevel federal managers to indicate how important Mintzberg’s roles were and how much time was spent on each of them. Seniors attached more importance than did midlevel managers to all the roles except leader, disseminator, and negotiator. Senior managers were particularly likely to spend more time acting as figureheads and spokespersons than were the midlevel managers.

In agreement with L. D. Alexander (1979a) and Paolillo (1981b), Pavett and Lau (1983) reported that hierarchical levels made a difference in the importance attached to the different roles. All three studies found that the roles of disseminator, figurehead, negotiator, liaison, and spokesperson were deemed more important at the higher managerial levels than at the lower levels. Consistent with these results, Hall, Bowen, Lewicki, and Hall (1975) reported that among the 10 roles carried out by 103 middle managers in manufacturing, the role of leader was most important and consumed the most time. Being a figurehead was least important and least time-consuming. The amount of time spent in leading declined with increasing echelons in the hierarchy (Pavett & Lau, 1983).

P. Allen (1981) examined the task dimensions of 1,476 managers working for New York City. The *analytical-evaluative task* dimension required managers to analyze and evaluate laws, problems, programs, work procedures, processes, and reports. The task was more important for senior-level managers than for managers at either the entry or the middle level. However, *monitoring* required managers to develop and use mechanisms to ensure adequate progress toward goals, to maintain appropriate records, and to inspect ongoing activities. This task was less important for the senior level than for the middle or lower level. In L. D. Alexander’s (1979a) previously cited study, hierarchical level made a considerable difference in 7 of Mintzberg’s

10 role requirements. With increasing hierarchical level, there were increasing requirements for the roles of figurehead, liaison, monitor, disseminator, spokesperson, and entrepreneur. The negotiator role was seen as being required most by middle managers.

*Level and Time Spent.* T. A. Mahoney (1961) concluded from several studies (e.g., L. Strong, 1956; *Fortune*, 1946), that the higher the level of managers' positions, the more hours per week they devoted to their job and the more time they spent in planning and organizing, rather than in the technical work of the organization. This finding was corroborated by Mahoney, Jerdee, and Carroll (1965). Whereas supervising was the main activity of 51% of the lower-level supervisors, it was the main function of only 36% of the middle managers and 22% of the senior managers. On the other hand, executives were more likely to be generalists and planners than lower-level managers were.

Second-level managers appear to be more oriented toward their superiors, and first-level managers toward their subordinates (Pfiffner & Sherwood, 1960). Berkowitz and Bennis (1961), Guest (1956), and Piersol (1958) concluded that first-level supervisors spent more time interacting with their subordinates than with their superiors. Although face-to-face communication was the most frequent form of interaction for managers at all levels, senior executives more often initiate than receive contacts, according to the logs they kept for two weeks (Dubin & Spray, 1964).

*Time Lag between Decisions and Consequences.* Jaques (1956) advanced the hypothesis that high-level administrative work is characterized by long time lags between the time a decision is made and the impact of the decision on the organization. If so, high-level managers would personally exhibit comparatively high degrees of future orientation and tolerance for delayed outcomes in their time perspectives. Jaques's proposition was supported by an investigation of four levels of supervisors and managers from the shift supervisor at the bottom to works managers at the top in the same British factory. Almost all decisions of a shift supervisor were about matters that occurred within a two-week period. On the other hand, only 3.3% of the decisions of the works manager involved questions of short duration; 50% of the decisions of the works manager involved policies with time perspectives of a year or longer. No one at lower levels was involved in decisions involving such periods of time (Martin, 1959). However, in a study of 141 managers at six levels of a plant, Goodman (1967) failed to find that future orientation and preference for delayed gratification were highly related to the level of an executive's position.

Despite Goodman's (1961) negative results, most other observers agreed with Jaques. The time perspective of managers at higher levels requires them to live with more uncertainty and lack of feedback. They need to consider longer-range goals. They need to go without evaluating the effects of their decisions for long periods. Decisions at the highest levels involve especially high uncertainty and risk. Thus W. A. Scott (1967) observed that "top management must have the ability to detach itself from the internal imperatives of coordination and to reflect on the general purposes and objectives of the company in its industry and society." Because of the nature of their role, top managers are often detached from outside judgment or objective criteria against which they can appraise their approach to problems to their decisions, and to their philosophy. The lower-level manager can be appraised against the tangible output and the department's performance. The long time span of the decision and the subjectivity of the job of the top manager make appraisals more difficult.

According to detailed interviews with 31 senior federal executives in six different government agencies, Klauss (1981) concluded that senior federal executives need a systems view, a strategic focus, and a proactive stance. They need the ability and willingness to: (1) maintain a network of formal and informal contacts; (2) support and encourage staff personnel; (3) manage diverse interests; (4) market and persuade; (5) take risks; (6) maintain integrity and credibility. They must be concerned for broad-based sources of information. Persistence, persuasiveness, flexibility, open-mindedness, and self-confidence are also important.

Jacobs and Jaques (1987) argued that different critical tasks with different time lags between decisions and their consequences are required of leaders at different organizational levels. As leaders rise in the hierarchical

level, the nature of their tasks changes systematically in the direction of requiring greater conceptual effort and the capacity to deal with more uncertain and more abstract constructs. Effectiveness at any given level thus depends on the capacity to learn the role behaviors demanded by the tasks at that level. As Rusmore (1984) demonstrated, *fluid intelligence* or creativity becomes more predictive of success at higher organizational levels; *crystallized intelligence* is more predictive of success at lower levels. Jacobs and Jaques (1987) spelled out the different types of activities performed by leaders in the lower, middle, and top echelons of a large corporation. Leadership at each level has discrete tasks to perform that add value to each other level. The time spans of the tasks increase with increasing levels.

*Effect on Implicit Requirements.* Den Hartog, Koopman, and Van Muijen (1997) used the Internet to query a Dutch telepanel of 2,161 respondents (1,198 men, 963 women) about 22 characteristics for being a good or outstanding top manager, and again for being a good or outstanding department manager or supervisor. As might be expected, traits identified as more important for top managers were “charismatic,” “inspirational,” “visionary,” “innovative,” and “persuasive.” Characteristics seen as more important for lower level managers were “supportive,” “compassionate,” “people-oriented,” “participative,” “leading,” and “concerned for subordinates’ interests.” Women raters considered dominance as less desirable for leaders and attached more importance to people orientation, long-term orientation, and diplomacy; men placed more importance on being inspirational, rational, and persuasive.

Peters (1979) noted the peculiar difficulties involved in carrying out the role of CEO or senior executive and the remedies for each of these difficulties. For example, according to Peters, senior managers are given only one option, usually in accord with their preferences. However, over time, they can shape each option presented by subordinates in their review and contextual evaluation. Time is fragmented, but the senior manager can use the fragments as a succession of opportunities “to tackle bits of the issue stream.” The fragments also provide a rich variety of information. Although major choices take months or years to emerge, the time provides opportunities to build a strong consensus and requirements for implementation. Peters concluded that top management’s most important role is that of shaping the organization’s values to provide coherence “in an untidy world, where goal setting, option selection, and policy implementation hopelessly fuzz together.” Although CEOs are supposed to formulate strategy for subordinate executives and middle managers to implement, the CEOs actually spend more of their time on implementation than formulation. They are more action-oriented than reflective (Zaccaro, 1996). This conclusion was illustrated in Kotter and Lawrence’s (1974) study of the activities of city mayors. Effective mayors built consensus among key stakeholders in favor of a few new directions. Ineffective mayors tended to make major commitments before they had developed the support for them.

*Effects of Level by Function.* Using Hemphill’s (1959) EPDQ, other investigators have generally corroborated the influence of hierarchical level and function on a manager’s activities.<sup>6</sup> For positions within the functional areas of data processing, finance, and merchandising, McHenry (1986) reported mainly positive correlations between the pay grade of 343 first-level and middle-level managers in a large retail organization and their activities, but pay also depended on their functions. For instance, the activity of supervising appears much more strongly linked with the hierarchical level of a position in merchandising than with positions in data processing and finance. On the other hand, long-range planning is related more to the hierarchical level of a position in finance and merchandising. Generally, the effect of hierarchical level is less strong in data processing. At each level, the manager’s constituents and interests are different. At the top, managers are concerned with sponsors, clients, and the community, as well as with their own subordinates. At the bottom, the first-level supervisors are concerned with the interests of their superiors, their peers, and their subordinates, as well as with the interests of others, such as union stewards and outside inspectors. In all, managers spend relatively little of their time with their superiors, according to Brewer and Tomlinson (1963–1964), and, as was noted, much time may be spent with a wide variety of other parties, not just subordinates (M. W.

### ***Importance of Differences among Organizations***

Earlier, it was noted that, generally speaking, a manager in one organization will exhibit the same time profile and pattern of work as counterparts in other organizations with the same type of job. Nevertheless, the characteristics of an organization can make an obvious difference in the manager's activities. For instance, executives in public utilities must spend more time dealing with community relations than do their counterparts in manufacturing. Katzell, Barrett, Vann, and Hogan (1968) studied the relationship between nine executive role patterns and their organizations' characteristics. The data were provided by 194 middle-management personnel working for the U.S. Army. The organizational dimensions that were most highly related to the roles performed depended on the level and mission of the organization within the army. The roles most affected were controlling, staffing, and time spent with other persons. Schneider and Mitchel (1980) used a mailed questionnaire to survey 1,282 field agency managers working in one of 40 different life insurance companies. The investigators were able to identify six factors that could be used to describe the activities of the agency managers: (1) general management, (2) training and evaluation, (3) supervising, (4) goal setting, (5) serving clients' needs, and (6) enhancing agency visibility and capability. Schneider and Mitchel obtained modest correlations between the frequency at which the agency managers engaged in the six factored activities and the characteristics of the agencies studied. General management activity and the enhancement of visibility were more frequent in agencies with a larger number of agents and supervisors. The managers' client service activities depended on whether the agency was a branch or was independent. Differences in company policies and practices also made a difference in the managers' activities.

*Effects on the General Manager.* Interviews with senior executives of 24 Canadian companies and the executives' responses to questionnaires showed that general managers engaged in different activities, depending on their companies' particular strategies. If the companies were trying to develop themselves by expanding their markets, personnel, and investments, the functions and activities that were most important to their general managers were marketing, finance, and research and development (R & D). If the companies were trying to stabilize themselves by lowering costs and improving products, productivity, and investments, the functions of consequence to their general managers were production engineering, finance, and R & D. If the companies were trying to reverse their declining markets and cash flows, along with paying special attention to finance and production, general managers needed to be flexible and able to deal with uncertainties and crises. Yet, regardless of the company's strategy, the general manager had to be an effective leader. Leadership played an important integrative role in whatever other roles were assigned to the manager (Herbert & Deresky, 1987).

### ***Promoting Individual Relationships in the Large Organization***

Although interpersonal skills are important at every level of management in an organization, Jacobs and Jaques (1987) deduced different components of such skills that are required at different levels. At the lower production levels of the organization, managers must provide interpersonal feedback, try to create a supportive work atmosphere, "map" the interpersonal relations within the small work group and among work groups, and maintain equity within the workforce. They must also counsel and evaluate individuals and orient new personnel. At the upper middle-management levels, interpersonal skills are required to build and maintain a consensus on objectives within the organization, develop the capabilities of subordinates, and begin the development of information networks that are essential for effectiveness. Organizational communication must be facilitated, along with a supportive environment. Personal problems of colleagues may need to be handled.

At the top of the organization, systems managers need to be competent in their relations with outside agents, agencies, and the community. Again, they need to foster a climate that is supportive and motivating. Many top executives are able and willing to open and maintain interpersonal contacts all through their system. They practice management by “walking around” to meet employees—whatever their level in the organization—as they perform their tasks. Such one-on-one communications contribute substantially to the effectiveness of the organization and the satisfaction of employees (Peters & Austin, 1985).

Another tactic of top executives is to communicate directly with every employee in brief, attention-grabbing notes. Admiral Elmo Zumwalt did so with his famous Z-grams to the various units under his command. Electronic mail, which instantly links every member of the organization with every other member, provides a ready opportunity for such contact between the top and the bottom levels of an organization. However, whether such one-on-one contact enhances relationships depends on whether overloading is avoided and the quality and interest of the messages remain high.

Klauss's (1981) study of 31 senior executives in government service found that a cluster of competencies, which involved sensitivity to individual and interpersonal dynamics, contributed to their effectiveness. When the effective executives spoke of critical incidents, they added to the technical or political aspects by clarifying information about the personalities involved and the human dynamics that influenced the situation. What was important to them was an understanding of the key actors involved—their general predispositions, biases, and orientations to given issues. The executives conveyed a sensitivity to the personal reactions and feelings of key officials who could be affected by or who could influence a course of action. Not only were they acutely aware of the personal and interpersonal factors that were important to each situation, they maintained informal networks to obtain insights into the predispositions and views of key higher-level officials.

*Effects of Changes in Organization, Technology, and Society.* Changes in the managers' organization will result in considerable changes in their activities. In a study of first-level production supervisors in four plants, Wikstrom (1967) initially found that the supervisors tended to make decisions the way individual workers do, without reference to larger organizational considerations. Then numerous specialists were introduced into the organization who influenced production in various ways. After the specialists were introduced, the supervisors were required to coordinate and sequence the manufacturing processes. Since the supervisors had to coordinate the impact of the various specialists, they had to assume managerial functions and decision making responsibilities. K. W. Harris (1968) surveyed 23 school superintendents, each with more than 25 years of tenure in the same position. The superintendents reported spending much less time on curriculum and pupil personnel problems than they had done a quarter century earlier and much more time on problems involving buildings, finance, and school-community relations. Clearly, the activities of the superintendents had changed within the same school districts with the changes in societal requirements.

Baliga and Hunt (1988) detailed the finer tuning of requirements for leadership as the organization goes through its life cycle of gestation, birth, growth, maturity, and revitalization or death. For gestation and birth, effective leadership at the top calls for developing a viable strategy and acquiring the resources to translate the strategy into an organizational reality. The representation of ideas and transformational leadership among external stakeholders are most salient here. Likewise, recruitment and commitment from key personnel are critical. For lower-level managers, the socialization of subordinates is of primary importance, along with the selection of appropriate technologies and the design of information, control, and evaluation systems. During the growth stage, Baliga and Hunt noted that although senior managers need to maintain transformational leadership with external stockholders, their transactional activities are of more consequence with subordinates. For lower-level managers, initiation, consideration, and task-and relations-oriented leadership become most important. At maturity, senior managers are required to pay more attention to subordinates, compared to their earlier emphasis on relations with external stakeholders. Ideally, junior managers should be able to handle all problems that occur at levels below them. With decline and revitalization, more transformational attention by

senior management is again needed with external stakeholders as well as with subordinates. Lower-level managers have to assist the seniors in this regard.

*Computerization.* Much of the research discussed in this chapter predated the computer and electronic revolutions. As will be detailed in [Chapter 29](#), much of the management decision making in firms is computer-assisted or even fully programmed. The computer at the manager's desk may provide instant electronic contact with every other manager or professional in the firm, as well as with voluminous information banks. Clearly, new descriptions of the way managers spend their time and the activities in which they engage are essential. Leavitt and Whisler (1958) and Uris (1958) anticipated that in the 1980s changes in the content and scope of the manager's role would occur because of the computer. They noted that the ranks of middle managers would be reduced and that top managers would communicate directly with lower-level managers through their computers. The "downsizing" of management in many U.S. firms in the 1980s through layoffs, "outplacements," and early retirement (McCormick & Powell, 1988) are a validation of these earlier prophecies about the decline of middle management. And the activities as well as the number of first-level supervisors have changed. Kerr, Hill, and Broedling (1986) called for using self-managed, autonomous work groups in which leadership is shared or informally provided by a team leader. Managers of such groups remain external to the groups. Leadership facilitates self-observation, self-evaluation, and self-reinforcement (Manz & Sims, 1987). Vander-slice (1988) went further to propose flat, "leaderless organizational structures." Self-managed teams have become prominent in the twenty-first century, as has teamwork in general (see [Chapter 26](#)).

Computer-driven automation and information management continue to increase at the workplace of first-level supervisors and their work groups; likewise, technology and required technical knowledge advances for the supervisor have increased. Specialized staff units continue to grow in size and importance, adding to the prospects of increasing conflicts between supervisors and staff experts. The particular activities and characteristics of the management process of first-level supervisors continue to change. First-level supervisors now spend more time with outside staff consultants who are involved with management information systems, new technologies, retraining workers, equal employment opportunities, and legal issues. They also spend more time serving as participative leaders of their work groups.

Pedigo (1986) completed a survey of the impact of the computer on the manager's role. First-level managers were the heaviest computer users. However, over time, as these first-level supervisors are promoted, usage increases at higher levels. Pedigo may be underestimating upper management's usage in that even though such managers may not use computers directly, they may be dependent on computer-generated information obtained from staff assistants. Again, as high school and college graduates of the 1980s and 1990s, who have had "hands-on" experience with personal computers, move into middle-and senior-management ranks, they are likely to replace pencils, written memos, and telephone with online personal computers and pocket PCs. The typical executive now travels with a wireless cell phone and a laptop or pocket computer.

## Summary and Conclusions

---

Managers must both lead and manage (Hosmer, 1982). Leaders manage and managers lead, but there is considerable correlation in what both do. Much depends on the level and function of the manager. Diaries and observational studies compete with interviews and questionnaire surveys in helping us understand how leaders and managers spend their time and the work they do. Attention was directed toward the frequency, importance, and criticality to the organization of the manager's various activities, functions, and roles, as well as to the knowledge, skills, and ability required for the position. The informants could be observers, colleagues, or managers themselves, who responded in structured interviews or surveys. These descriptions

could be augmented by prescriptions about what managers ought to do. What managers ought to do could be sought empirically by comparing the work done by effective and ineffective managers. There is much more to management than planning, directing, controlling, and supervising subordinates. However, the manager's effectiveness depends, to a considerable degree, on getting work done through others and networks of others. Activities are brief, fragmented, and discontinuous, rather than deliberate and reflective. Key activities include monitoring the environment, coordinating and representing others, and handling information and its sources. Interpersonal skills are needed at all hierarchical levels.

A manager's hierarchical level affects the time during which decisions are to be made and the lag in feedback about the effects. Work overload is a common experience at all organizational levels, as are systematic differences in the effective and ineffective performance of managers.

Earlier chapters delineated how leaders and managers differ in competencies, attitudes, values, and styles of behavior. This chapter showed how their activities and roles have been described and prescribed and how organizational leaders and managers in the same position may differ in their models of what is required and how they will actually perform in the position. Senior managers also need to be adept at strategic thinking.

<sup>1</sup> See, e.g., Kmetz and Willower (1982), Kurke and Aldrich (1979), Martin and Willower (1981), O'Dempsey (1976), Snyder and Clue (1980), and Sproull (1981).

A. Stewart (1967).

<sup>3</sup> See also T. Burns (1954), Horne and Lupton (1965), Mintzberg (1970), and Stewart (1967).

<sup>4</sup> The three clusters were: (1) routine communication associated with processing paperwork and exchanging routine information; (2) planning, decision making, and controlling; (3) human resource management activities, such as motivating, positively reinforcing, disciplining, punishing, managing conflict, staffing, and training and developing.

<sup>5</sup> Many previously cited, large-scale management surveys of communication patterns, time spent, and work done corroborated the tendency for interpersonal interaction among managers in large organizations to be primarily verbal rather than written. This was changed by the advent of e-communications.

---

# Strategic and Executive Leadership

Executive strategic thinking may be premised on a serious flaw. Michael Porter (1980) convinced academia and management alike that the most important criterion for success of a business in the global marketplace was getting and staying ahead of its competitors. Market share was logically expected to correlate with profitability. This placed the emphasis of strategic leadership on beating the competition. Beliefs remain strong that a firm should do better than its competition. Just doing the best it can is not enough (Armstrong & Collopy, 1996). But empirical evidence suggests otherwise. Armstrong and Collopy (1996) showed that 40% of 1,016 participants in a laboratory experiment were willing to sacrifice profits in their pricing decisions in order to beat or harm their competition. Additionally, in a field study, they found that firms with competition-oriented strategy of enlarging market share were less profitable than those that were directly oriented to profits. Again, using the results of 48 studies and 276 effects, Szymanski, Bharadwaj, and Varadarajan (1993) completed a meta-analysis of the relationship between market share and lagged return on investment (ROI). They discovered that the relationship disappeared when other variables were controlled. Armstrong and Green (2005) reported that over five successive seven-year periods between 1938 and 1983, for 20 of the largest U.S. corporations, correlations between competitive orientation and ROI ranged from .37 to .54. Pursuing market share for its own sake was actually harmful to ROI! A replication with additional criteria of profitability from 1955 to 1997 of real return on equity and percentage of after-tax returns on sales again revealed that all correlations were negative, ranging from  $-.28$  to  $-.73$ . Furthermore, the objectives of strategic thinking of leaders in for-profit firms must encompass more than profitability alone. The leaders of nonprofit organizations and government agencies must also look at the benefits generated by their expenditures.

## Upper-Level Management theory

---

Increasingly referred to as *upper-level management theory*, strategies are a product of the interaction of the individual leader and the organization's internal and external environment. Systems thinking is required that aims to produce the synergies that are more than the sum of the individual parts of the organization. Complexity is the rule rather than the exception. The complexity is illustrated by two organizations jointly supporting basic research but competing in the same market.

## Agency Theory

---

This theory builds on the delegation by the sponsors, owners, and shareholders of for-profit organizations to managers as agents of authority and responsibility. It assumes that corporate owners and their agents are individualistic, self-serving, and opportunistic and that chief and senior executives, as agents of the owners and shareholders, are motivated primarily to increase their own rewards and secondarily to please the owners, shareholders, and boards of directors. For profit-making organizations, financial success is the criterion of organizational success (Jensen & Meckling, 1976). For Porter (2001), it is the single goal for business strategizing. Satisfaction of employees, customers, and other constituents is relegated to being the *means* to the

objective of financial success. Clearly, to stay in business, firms have to make money or be continually subsidized by parent companies or government. Inside the organization, Williamson (1975) conceived the business organization as a marketplace for resources and rewards among competing departments, managers, and employees. But for those concerned with the human side of enterprise, along with achieving financial goals, chief and senior executives need to balance the needs and interests of their various stakeholders in the corporation—the owners, shareholders, managers, employees, customers, and community. This has to occur in the framework of local, state, national, and international agency regulations, as well as be reflected in the satisfactory treatment of the corporation's physical and social environment (Bass, 1952; Davis, Schoorman, & Donaldson, 1997). As Simon (1979) argued, to improve the performance of organizations, optimal decision making requires considering *both* economic and better utilization of human resources (Franke & Miller 2005).

## Interplay between Strategy and executive Leadership

---

Eddie Rickenbacker was president of Eastern Airlines from 1934 to 1959 and then CEO until 1963. His strategy and leadership style, which made Eastern the largest and most profitable U.S. airline, also led to its bankruptcy. A World War I hero, he was personally adventurous, but when it came to business, he was extremely cost-conscious and was last to invest in new models of planes and equipment. He let other airlines learn how to deal with the problems of the new aircraft. Maintenance costs were kept low. Before 1978, the federal government highly regulated the airline industry and allowed no competition on Eastern's lucrative New York–Miami route. Eastern had a monopoly on flights from the Northeast to Florida and promoted summer vacations in Florida to provide year-round business. But then the external environment changed in three ways: (1) Instead of carriers being limited to one for each route, another one or more were added to Eastern's routes; (2) Piston engine planes with propellers were replaced by jets; (3) The federal regulators did not allow Eastern to fly to the Pacific coast as all of its competitors did. Rickenbacker's strategies subsequently resulted in his continuing to purchase propeller planes such as the Lockheed Electra while his competitors purchased jets. In 1955, he ordered 26 jets but cut back orders to 16, foreseeing an oversupply of jet seats. This allowed Delta to obtain a competitive advantage by purchasing the planes. To minimizing costs with tight scheduling, Rickenbacker approved heavy use of his fleet, the arrangement of first-class seats five to a row (instead of four), overbooking, and reduced attention to passenger services—and lost many customers. When he tried to attract more passengers by scheduling more flights on the same routes, the result was a lot of empty seats. Eastern never recovered its preeminence in the industry and finally went bankrupt.

Personally, "Captain Eddie" dominated the company. He was a stickler for detail. When he found problems or inconsistencies, he was immediately on the phone to the offending unit head. He challenged, heckled, and threatened his managers and executives when they presented performance appraisals of their units to him. But instead of hurting morale, his actions built a sense of camaraderie. Though he was feared, he was also respected. He knew all his pilots by name. He was a benevolent autocrat in that he saw that employees who originated good ideas were rewarded, and he gave many managers a lot of responsibility. Eastern employees felt like members of one big family with a patriarch at its head. Unfortunately for Eastern, Captain Eddie couldn't change his ways (Spencer & Carte, 1991).

Since Eastern folded, other airlines such as Pan Am have also terminated or changed. In spite of mismatched airline fleets, problems with pilots' seniority, and unions, as of April 2008 Delta Airlines and Northwest Airlines were moving toward a merger to create the world's largest airline. Only short-term benefits are expected for stockholders and executives; smaller airports may suffer and more efficient management may not materialize. Information about the merger has appeared in major newspapers.

## ***Professionalization of the CEO***

Keiser (2004) found, among 70 CEOs from 247 firms, systematic increases in the criteria of professionalization for some but not all between 1960 and 1990. By 2000, most organizations had adopted the title CEO; none had used it in 1960. During the same period, the CEOs' intellectual capital increased. In the early 1960s, about 40% had graduate degrees; by the late 1980s, the same was true for 80%. MBAs increased from 7% in 1960–1964 to 34% in 1985–1989. Only 3% were selected from the outside in 1960–1964; 28% were outsiders in 1985–1989. Many more entered the firm at higher echelons in 1985–1990 than in prior years. But they lacked other aspects of professionals that physicians, lawyers, engineers, and accountants had, such as licensing and a code of ethics. When CEOs subscribe to agency theory and attempt to maximize satisfaction of their own interests, they are unlike professionals, who are more likely to have a service orientation.

## ***The Top-Management Team (TMT)***

The senior executives in the upper echelons of an organization may be a loose collection, each running a different unit and seldom meeting or working with their counterparts. They lack the behavioral integration of a team. The members of a top-management team (TMT) synthesize their knowledge and expertise. They interact to discuss and make decisions and recommendations based on their varying expertise and knowledge (Hambrick, 1994). Thirty-eight top-management Australian teams were more likely to share tacit knowledge when they felt they had supportive leadership (Rowe, Christie, & Martin, 2003). Mooney (2003) studied 42 groups of senior executives and found that whether or not they formed real teams depended on the size of the firm, its strategy, the amount of organizational slack, and the executives' homogeneity. According to Quinn (1996), TMTs need to overcome the divisiveness of individual self-interest, insecurity, distrust, and political posturing. High-level cooperation and enthusiasm can come about only among competent people with clearly defined roles who work cohesively in trusting relationships, exercise personal discipline, and are willing to work for the good of the team.

Long-tenured top-management teams' strategic decisions about investing in R & D are tempered by the oversight of the board of directors and individual investors. This is especially so when the outside directors are prominent members of the board and the senior executives are long-tenured and diverse in their functions in the organization (Kor, 2002). The tenure of senior executive teams in 100 chemical, computer, and natural gas distribution firms affected their strategies and performance, according to a study by Finkelstein and Hambrick (1990). If they long had had tenure, they followed more persistent strategies and conformed closer to the average in their industry in strategy and performance. The more discretion they had, the more successful their strategies were.

*Diversity within TMTs.* Results on the effects of diversity of backgrounds of TMT members on outcomes have been mixed. Fishman (2003) reported that pharmaceutical patent citations and technological boundary spanning of TMT members in 52 firms were predicted by heterogeneity in their functional backgrounds. Roure and Keeley (1990) found that functional heterogeneity of the backgrounds of TMT members had positive effects on financial performance of their firms, but West and Schwenk (1996) did not. Barsade, Ward, Turner, et al. (2000) obtained evidence that if the 36 TMTs of profit and nonprofit

organizations, named by their CEOs as members of the CEO's TMT, were diverse in their functional backgrounds, the organizations exhibited significantly greater market-adjusted returns on investment for the years the TMTs worked together. However, diversity of affect of the team members failed to significantly relate to TMT performance.

Knight, Pearce, Smith, Smith, Olian, et al. (1999) found that educational diversity contributed to financial success, but diversity of experience did the reverse. Certo, Lester, Daily, et al. (2003) presented a meta-analysis of the financial performance of firms and their TMTs' demographic characteristics. The functional heterogeneity of the TMT members accounted for 16.5% of the variance in sales growth and 7.5% of the rate of return on investment. Sales growth was also significantly greater when TMTs were larger ( $R^2 = .079$ ). But diversity of organizational tenure, executive tenure, and education had little or no effect. The functional heterogeneity of a 20% survey sample of 450 hospital TMTs by Michie, Dooley, and Fryxell (2003) found that greater functional heterogeneity contributed to greater cooperation and greater decision quality mainly when there was greater consensus about goals. Where goals consensus was low, functional heterogeneity was contraindicated. But for the effect to occur, the diversity of backgrounds had to be related to the tasks that needed to be done (Simons, Pelled, & Smith, 1999).

Consistent with the above findings about the impact of TMTs' diversity on organizational strategic effectiveness, the same results appeared for diversity of power and for cognitive conflict in attitudes, beliefs, and opinions in interaction about strategy. For example, greater *distribution of power* among the most important members of their TMTs contributed to the effective performance of 51 hospitals. Power was defined for the peer raters as the ability to influence strategic agendas (A. Smith, Pitcher, Houghton, et al. 2003). Similar results were obtained in computer firms by Halebian and Finkelstein (1993). Again, Ensley and Pearce (2001) used structural equation modeling to predict the performance of 158 new venture firms in 1994 and 1995. The path coefficient between diversity of opinions—cognitive conflict—and new venture growth in 1994 was .32. In 1995, the path coefficients of cognitive conflict were -.63 with new venture revenues and 0.77 with new venture profit. In both years, *emotional* conflict was negatively related to profit and revenues (-.34, -.38).

*Variety of Executives' Roles.* The roles of CEOs and senior organizational leaders vary to some extent depending on the nature of the organization. Providing strategic leadership is an important role for the CEO and may be the most important role for many (Farkus & De Backer, 1996; Korn-Ferry, 1988). However, CEOs and senior executives are likely to spend more time on implementing strategies than formulating them. But over time, successive organizational leaders play an important role in strategy formulation (Leavey, 1996).

The knowledge requirements of an ad agency business director, for example, differ from those of the head of an automobile manufacturing business. But they also have much in common (Levinson, 1981; Jaques & Clement, 1991). They need to understand balance sheets, the health of their markets, the products and services that can serve those markets advantageously, and the availability of capital. They need to know how to optimize the interests of the organization's various constituencies, how to manage change in good times and bad times, how to use authority and accountability, and how to assemble an effective management team of diverse competencies and interests (Ball, 1999). Not to be ignored is the less visible role of supporting or failing to support an organizational project. For instance, an organizational development project was run for two years without the cooperation or interest of the CEO of a hospital. The CEO was pressured into accepting the project. A new CEO in the next two years was enthusiastic about the project. Interviews with 150 employees and questionnaires with 650 employees found negative results for the project conducted for the first two years with the uncooperative CEO and positive results during the second two years with the cooperative CEO (Boss & Golembiewski, 1995).

*Roles Differ from Those of Lower-Level Managers.* Zaccaro (1996) distinguished executives from lower-level leaders in their (1) planning and creating policy within a larger time horizon; (2) interacting more

frequently with external organizational constituencies; (3) engaging in more network development and consensus building; (4) developing a more comprehensive cognitive map of the organization and its environment. Executives contribute to organizational effectiveness by their long-term planning, boundary-spanning activities, network development, consensus building, and high-quality cognitive map of the organization and its environment. Although the myth continues that executives spend most of their time in *formulating* strategies, the facts are otherwise: they spend much more of their time in *implementing* strategies. Executives are action-oriented rather than reflective (Zaccaro, 1996). According to a job analysis by Baehr (1992) involving 1,358 managers, executives concentrate on setting objectives, making decisions, developing the workforce, and dealing with outside contacts and the community. Previous successful financial performance of the CEO's firm increases the CEO's power to influence the board of directors, the shareholders, and the employees. In turn, powerful CEOs induce better financial performance in the future (Daily & Johnson, 1997).

*Relationship of the CEO to the Board of Directors.* Rational economic models such as agency theory assume that the CEO will try to maximize his or her own preferences at the expense of the shareholders. Board governance should protect the shareholders against the self-aggrandizement of the CEO. Shareholders prefer to make CEO compensation dependent on corporate performance. The effective performance of 504 Fortune 500 firms related more highly to specific, guaranteed CEO salaries than to uncertain stock options whose value depended on stock performance. Sanders (1995, p. 268) concluded that "Agency theory has little explanatory power regarding the structure of CEO compensation." More helpful in explaining results were behavioral models, as with whom the CEO was being compared and the distribution of power. A behavioral model assumes that ideal CEOs are selected and rewarded by boards as stewards who have satisfied the interests of diverse stakeholders. A political model assumes that the selection and evaluation of the CEO by the board may depend on whether family members, friends, insiders, social acquaintances or prominent politicians are on the board. Xie, O'Neill, and Cardinal (2003) looked at how the composition of 41 boards affected the R & D performance of their respective firms. The intensity of R & D was lower if the board contained more directors from outside who were more diverse in functional backgrounds. Also, R & D performance was lower if the board members had more outside commitments.

The application of the board's controls will diminish as the CEO learns the role, increases in decision-making competence, learns how to work with the board and top management, and learns who are the most important stakeholders (Shen, 2003). CEOs can exert influence on boards when selecting new members and serving as outside board members of other organizations. They can help or hinder work in the boardroom (Rankin & Golden, 2002). Until recently, boards have been reluctant to exert their power to force the resignation of the chief executive, but increasingly they have ousted CEOs for the poor performance of their organizations, for failure to meet expectations, for scandalous behavior, for causing too much internal friction by being too autocratic, or for failure to keep up with the competition. In one month alone in 2005, a record number of company heads (103) were changed (Barrionuevo, 2005).

*Relationship of the CEO to Stakeholders and Shareholders.* Ackermann and Eden (2003) noted the importance of the CEO and top management to identifying the most powerful stakeholders inside and outside their organization, particularly how they notice and react to intended strategies and whether or not they are supportive. During times of change there is an increase in communications, usually letters, from the CEO to the shareholders to supplement quarterly reports and annual meetings. Between 1980 and 1999, General Electric sent out letters to try to reassure shareholders of the value of its radical reorganization and to reduce their uncertainties about its effects. The letters were more supportive than operational. They included warnings, actions, explanations, achievements, and predictions (Palmer & King, 2003).

CEOs differ in the priorities they set for paying attention to the different stakeholders. Agle, Mitchell, and Sonnenfeld (1999) examined, for 80 CEOs, how important to them were the various stakeholders of their

corporation and the extent to which the various stakeholders had power, legitimacy, urgency, and salience for the CEOs, and high priority from top management. According to regression analyses, the percentage of the combined covariance of stakeholder power plus legitimacy plus urgency plus salience in the eyes of the 80 CEOs was 52% for customers, 48% for community, 30% for shareholders, 23% for government, and 17% for employees. When top management had values more oriented to others than to self, it gave higher priority to employees, government, and community. Top management also paid more attention to ethical and corporate social responsibility and was attentive to all the stakeholders. But according to Cannella and Monroe (1997), the economic and social models are limited. A more realistic view of how top managers strategize needs to include technology, markets, personality, transformational leadership, and executive envisioning. For instance, high-technology companies need to rapidly develop and implement strategies for short product life cycles that make it possible to integrate technology with market opportunity (Hughes, 1990).

*Requisites for Executive Effectiveness.* By 1840, the need of the emerging railroad industry to deal with organizing personnel and equipment over a broad geographic area sparked the growth of traditional rational organizational theory (Fox, 1994). Many theories of organization became prominent in the years that followed in the industrialized world, like those of Taylor (1911), Fayol (1916), Diemer (1925), and Cornell (1928). R. C. Davis (1951) built his functions of the executive around planning, direction, and control, a strategy that today is regarded as the traditional approach to executive management. But according to Fox (1994), Davis also took into account behavioral considerations, such as the motivating value of goals and their multiplicity and modification over time. Also included by Davis was the importance of coordination, status, evaluation apprehension, the utility of participation, pattern recognition, and feedback.

A corporation's *reputational capital* is another intangible value that contributes to its effectiveness and gives it greater competitive advantage. Reputation is enhanced by executive leadership, oversight, a reputational audit, and publicized awards and rankings for excellence (Petrick, Scherer, Brodzinski, et al., 1999).

In *systems theory*, the functions of executives are divided into exploratory functions and decisions about *inputs* of personnel, equipment, materials, accounting, and information; *throughputs* of production and processing; and *outputs* such as sales, marketing, growth opportunities, and again information (Hambrick & Mason, 1984). Rather than maintaining a compartmentalized silo mentality, executives need to draw their expertise from a wide range of experiences to contribute to innovative decision making (Hoffman & Hegarty, 1993). Zaccaro (1996) listed traits that were likely to assist executives in carrying out their functions. Some of them included career experience, relevant education, and functional background. Effective executives are able to deal with cognitive complexity, ready to take risks, and self-efficacious, and want to achieve. From a study of 27 government executives, Markessini, Lucas, Chandler, et al. (1994) added that effective executives required envisioning, multinational knowledge, consensus building, and an understanding of their whole organizational system. From a review of studies, Zaccaro (1996) concluded that organizations were more effective when their executives engaged in long-range planning and boundary spanning along with consensus building and network development. Javidan (1992) described a survey of the effectiveness of more than 500 middle, upper-middle, and senior executives by their immediate subordinates. Effective senior executives were viewed as dedicated and tenacious visionaries who could mobilize their subordinates. They were concerned coaches and remained in touch with their employees. They recognized accomplishments and served as good representatives outside the organization. According to Kennedy (1995), they avoided making political mistakes when newly promoted into senior management. They took care to understand top management's agenda and did not try to micromanage the successors to their previous positions.

Agency theory accounts for the behavior of self-interested CEOs. They are agents of the owners and shareholders. As their compensation often tends to depend more on the size rather than their organization's profitability, they need to have bonuses and other incentives to share their stockholders' interests in returns on investments (Jensen & Meckling, 1976). However, a more effective, mature, transformational CEO goes

beyond self-interest and balances the competing demands of the marketplace with the demands of the organization's managers, employees, and other stakeholders. The opposing demands on senior executives are for flexibility versus stability, process versus outcome, and focus inside versus outside the organization (Hart & Quinn, 1993). The effective executive can deal with these competing requirements (Quinn, 1988). The less self-oriented, narcissistic CEO becomes a steward or custodian of the organization and its constituencies and takes satisfaction from building and maintaining a healthy organization. The steward may actually generate better returns on investment. Such a CEO may gain more support from the organization's stakeholders and enhance their motivation to excel.

*Executive Effectiveness in the Nonprofit Organization.* From a review of the literature, Mary S. Hall (1994) extracted 70 requirements for executive effectiveness in nonprofit organizations. Many requirements that she found were the same for executives in the nonprofit sector as for those in for-profit organizations. But particularly essential for the nonprofit executive are: (1) a deep commitment to the organization and projection of devotion to achieving its goals; (2) understanding and communicating the unique tradition and role of the nonprofit sector; (3) commitment to the common good and practicing what is preached; (4) knowing what and how to make quantitative and qualitative evaluations of the organization's performance; (5) building an organization that cares about the people and the clients it serves; (6) understanding clients' needs and serving as an advocate for them; (7) building the knowledge, commitment, and skills of the board; (8) recruiting, managing, and developing dedicated volunteers with recognition and rewards; (9) understanding public policy-making processes; (10) building community relations to facilitate cooperation with other public and private organizations; (11) mastering the use of media and practicing good public relations; (12) knowing the fund-raising process and negotiating effectively with funding sources.

*Military Executive Effectiveness.* U.S. Army lieutenant generals and full four-star generals are the equivalent of civilian CEOs in terms of the size of the organizations they lead and their level in the hierarchy. The brigadiers, major generals, and colonels below them also have executive functions. Leadership is seen as an important function of military service. Four-star generals report more boundary spanning and longer time spans of work than do lieutenant generals (Harris & Lucas, 1991). Both ranks of top generals engage in development of networks and more spanning of boundaries than do major and brigadier generals, but the lower-level generals need to know more details about the Army system (Lucas & Markessini, 1993). Colonels are more involved in setting goals and policies planning, and other executive functions than are officers below them (Steinberg & Leaman, 1990).

### ***Competencies of Effective CEOs and Senior Executives***

Zaccaro (1996) summarized studies that had compared the abilities of executives with those of lower-level managers and supervisors. Executives exceeded those lower in the organization in intelligence, creative potential, creative thinking, intuition, intuitive thinking, problem-management skills, toleration of ambiguity, and dealing with anxiety. Hurley and Sonnenfeld (1995) compared 683 top managers with a matched sample of middle managers, finding that the breadth, length, and nature of experience were significantly higher in the top-management sample. Jacobs and Jaques (1987) pointed out that executives develop a framework of understanding that provides meaning for organizational members' efforts toward collective action. According to Zaccaro (1996) *conceptual capacity* is required in executives as they deal with issues of *cognitive complexity*, that is, novel, unstructured, and ill-defined problems (Davidson, Deuser, & Sternberg, 1994). Executives must be able to display *behavioral complexity*—the ability to enact different and sometimes opposing roles. They must attend to *social complexities* when proposing actions. Senior executives are likely to be boundary spanners and need to deal with subordinates from different cooperating and competing groups,

managers, employees, and functions (Zaccaro, 1996). In-depth interviews with 18 business leaders by Tait (1996) revealed that requisite qualities for their success included the ability to make sense of complicated patterns of events and extract clear goals for the organization. They also needed to be able to take independent and unpopular courses of action when necessary. As strategic leaders, CEOs and senior executives must know how to harness the brainpower within their organizations, according to Percy Barnevik of ABB. In a similar vein, Jack Welch at General Electric would ask GE managers what their ideas were, with whom they had shared; and who had adopted them (Bennis, 1999). A high level of conceptual development is needed by senior executives. Their cognitive capacity should enable them to construct a perspective on a broad, complex understanding of events both inside and outside the organization and to handle highly complex managerial work (Lewis & Jacobs, 1992). They must deal with cognitive complexity (Hunt, 1991). Sash-kin (1990) added to the need for cognitive capacity, self-efficacy, and the power motive as personal requirements for competence in strategic leadership.

*Foresight.* Farkas and De Backer (1996) also noted that entrepreneurial leaders should be as intuitive about what customers want next as the next maneuver of a competitor. Nevertheless, cognitive capacity is involved in the goal of adding value to the organization, with systematic and structured analysis of the state of the organization now and in the future. Strategically oriented CEOs focus on what comes next and try to make it happen. In 1995, Coca-Cola's senior management concentrated on reinventing the brand to make it new and relevant. Dell Computer CEO Michael Dell aimed to position the Dell personal computer for the future. Bob Galvin of Motorola (1991) argued that organizational leaders must be better anticipators and committers. Tom Sternberg, the CEO of Staples, carefully studied purchasing patterns and competitors. He questioned customers about what his chain of stores could do better. Jack Welch reinvented General Electric by selling the companies that were not profitable and keeping only those that dominated their markets and fit with a strategy to move into high technology and services.

*Social Skills and Self-Monitoring.* Connelly, Gilbert, and Zaccaro (2000) found that executives' social skills and knowledge contributed to quality solutions and achievement. For Mumford, Zaccaro, Harding, et al. (2000), executives' effectiveness depended on their ability to solve the complex social problems of organizations. K. L. Scott (2003) argued that self-monitoring would affect CEOs' strategic leadership practices. She hypothesized that high self-monitoring CEOs would be more effective at exploiting and maintaining the organization's core competencies, developing human capital, sustaining the organizational culture, and balancing organizational controls. Low self-monitors would be more effective at emphasizing ethical practices and communicating visions and plans. For new product ventures, S. M. Jensen (2003) proposed that entrepreneurs must have sufficient influence and confidence, involving self-efficacy, optimism, resiliency, and hope, to exert leadership in order to collaborate with others.

Korn/Ferry International (1988) and Columbia University conducted a survey in 1988 and then again in 2000 of 1,500 chief executives in the United States, Western Europe, Latin America, and Japan about the requirements of their positions. Strategy formulation was ranked first among the 10 most important areas of competence required both times by 75% to 80% of the respondents. There was general agreement about the importance of the required expertise, although strategic formulation was rated slightly lower in Latin America. Seen as important by 45% to 50%, competence in marketing and sales ranked second in 1988 and third in 2000. Human resource management changed places with marketing and sales, ranking third in 1988 and second in 2000, with the percentage of endorsement ranging from 40% to 50% (with western Europe lower than the other regions). Negotiation and conflict resolution ranked fourth and accounting and finance fifth in both years, with lower percentages of endorsement (under 30% with Japan being much lower than the other regions). Lower still in ranking were media skills, international economics and politics, production and operations, science, technology, and R & D. In 2000, computer literacy replaced foreign languages in tenth place. Implementation of strategies was probably included in strategic formulation or left to subordinate senior

executives to do.

*Charismatic Leaders.* Charismatic leaders are expected to increase the effectiveness of those they lead both closely and at a distance (Waldman & Yammarino, 1999). They earn premium compensation for their charismatic personalities. Nevertheless, sometimes they may do more harm than good for their organizations (Vara, 2002). Khurana (2002) discovered that charisma was one of the criteria used by boards of directors in their search for and selection of 40 CEOs. For 59 very large firms, CEOs' charisma contributed to shareholder returns only during perceived uncertainties in the firms' markets. In these same firms, charismatic CEOs were paid a premium when there was high uncertainty or crisis in the market, such as instability in countries where business was conducted. However, their salaries and bonuses were lower than average when there was perceived high political uncertainty, such as unpredictability of government agencies (Tosi, Misangyi, Fanelli, et al. 2004).

Agle (1993) factor-analyzed a survey of 1,540 members of 258 top management teams who rated the charismatic leadership of their 250 CEOs using scales adapted from Podsakoff, Mackenzie, Moorman, et al. (1990). In the best regression model, five factors emerged. Three correlated significantly with CEO accomplishment, organizational effectiveness, and better stock performance. The correlations were as follows: (1) dynamic leadership (-.39, -.33, -.29), (2) exemplary leadership (-.52, -.36, -.19), (3) leader high performance expectations (-.21, -.23, -.04). For an analysis reported by Wolfe, Lucius, and Sonnenfeld (1998), 66 of these top-management teams also reported that their influence over their organizations was greater and the teams experienced less conflict if they and their own CEO served as trusted examples and exhibited personal dynamism.

*When CEOs and Senior Executives Fail.* The turnover of CEOs increased by 53% between 1995 and 2001. Average tenure declined from 9.5 to 7.3 years and has continued to decline since then. Poor financial performance of the firms led by a CEO increased 130% and was the reason for the CEOs' discharge or resignation (Pasternak, 2002). Based on a survey of 91 chief executives and seven interviews, Judge (1999) concluded that executives failed for several reasons: they did not provide a vision of the needed strategic path, did not understand the different interests of their important constituencies, did not prioritize goals, and failed to exemplify trust and integrity for their organization. Charan, Rosen, and Abarbanel (1991) described cases where the easier-to-do top management's strategic formulation failed in the harder-to-do strategic implementation. One CEO discovered that top-management team members delayed high-priority strategic divestitures with which they disagreed. A critical computer system conversion had not started when its expected time for implementation was already half over. Internal pricing disagreements were holding back sales efforts and reaching strategic goals.

Levinson (1988) argued that many executives fail because they have focused on short-term results and are insensitive to the feelings of employees and customers. They run a tight, highly controlled organization that is inflexible and unadaptive when faced with the need to change. Nutt (1999, 2002) pointed out that the self-interest that causes executives to fail can take many forms: they keep secret their plans of action for fear that openness will reduce the success of the plan; they pursue a plan and want to keep secret their self-interest in the plan; they make quick decisions without considering alternatives; they ignore ethical considerations and carry out deceptions to protect themselves; they skip or limit search; they make premature commitments and misuse resources; they blunder by making poor decisions, premature commitments, and misusing resources. Examples include the decisions by Quaker Oats' executives to acquire Snapple and Disney's executives to open Euro Disney.

Executives fail when they become too involved in their personal interests and not enough in their constituent's and organization's interests. Senior executives fail when their strategic vision of the future direction blocks out important opportunities, distorts market realities; fails to recognize a changed environment (Conger, 1990). Executives fail when they stretch the organization's resources beyond limits

(Ulmer, 1998). They fail when they confuse a good, well-communicated strategy to their organizational implementation of the strategy. They fail when their strategy for change is “narrow, unsystematic, and programmatic [and] does not address root causes” (Beer & Eisenstat, 2000). They fail when they allow narcissism to dominate strategic thinking. They fail when they create illogical organizational structures and compensation plans (Levinson, 1994). Like Levinson, Kets De Vries (1989) attributes executives’ failure to internal personal considerations. Executives who isolate themselves from reality self-destruct by becoming divorced from it, as do those who fear success. According to Hitt, Hoskisson, and Harrison (1991), misdirected attention and effort cause executives’ failure; they put too much emphasis on mergers and acquisitions, diversify too much, and ignore their human capital. They fail because of lack of attention to productivity, quality, innovation, and the need for a global strategy. Bennis (1999) attributes the failure of chief executives of public institutions to institutional and societal forces: (1) public institutions and agencies are easily politicized, (2) Politicized institutions are pulled in many directions at the same time and lose sight of their reason for existing, (3) Society overloads the institution with problems.

*Executive Derailment.* Lombardo and Eichinger (1989) followed up McCall and Lombardo’s (1983) analysis of managerial derailment with an examination of why senior executives are derailed. Derailed executives are those who have been plateaued, demoted or fired, accepted early retirement, or have seen their responsibilities reduced. In comparison to those who made it to the top, those who were derailed treated others poorly due to overambition, overindependence, isolation, abrasiveness, lack of caring, and/or volatility under pressure. They had difficulty in building a team due to poor selection, and/or they were dictatorial, overcontrolling, unable to resolve conflicts, and delegated poorly. They were unable to deal with complexity and ambiguity and collapsed under the pressure of a new situation. They were disorganized and attended to detail poorly. They failed to follow through and/or were untrustworthy. Or they were overly dependent on one strength, relied on others to shield their weaknesses, and/or were sheltered too long under the same boss or mentor. They had poor relations with senior management, in their inability to persuade or adapt to a boss with a different style. They had disagreements about strategy and/or were unable to influence across functions. They were insensitive to others, were arrogant, and ignored advice. Although such insensitivity was tolerated at lower levels of management, particularly if the managers were technical experts, it was the most common reason for derailment (Lombardo & Eichinger, 1989). The pattern of derailment was somewhat different in Britain. Compared on the 16 PF personality questionnaire with employed managers, 204 *redundant* executives were more socially bold, forthright, uninhibited, imaginative, and unconventional but less self-critical and politically skilled (Tyson et al., 1986). Again in Britain, 676 managers who had been derailed were extroverted, innovative, change-oriented, and independent. These traits might have resulted in more success in the United States. However, like derailed executives in the United States, the British managers, were less warm (Brindle, 1992).

Van Velsor and Leslie (1995) extracted four themes in a review of research reports between 1983 and 1994 of derailed executives and managers: (1) problems with interpersonal relationships, (2) failure to meet business objectives, (3) inability to build and lead a team, and (4) inability to develop and adapt. They also found increasing sources of failure in lack of business experience, preparation for promotion, and broad functional orientation. Of less importance was overdependency on an advocate or mentor. Sometimes the competent CEO was dismissed as a scapegoat for trusting the wrong people on the board or in the organization or for similar reasons (Boeker, 1992). This may be one of the reasons that for 400 firms in 21 industries between 1987 and 1996, CEOs who had chief operating officers (COO) under them as second-in-command generated \$10 million less in returns on assets (1%) than did those without such subordinates (Hambrick, 1989).

Brockman, Hoffman, and Fornaciari (2003) analyzed 194 large organizations that had filed for [Chapter 11](#) bankruptcy protection from their creditors. If their CEOs had more formal power, the businesses were more likely to survive and return to normality in a shorter time than those with less formally powerful CEOs.

Recovery took longer and survival was more problematic for organizations led by CEOs with more informal power or prestige.

*Examples of CEOs Who Failed.* Don Burr founded PEOPLExpress in the early 1980s with an emphasis on good working relationships among the employees. Leadership was shared, and employees had multiple job assignments. For instance, pilots might help at the ticket counter. The commitment, cohesion, satisfaction, and motivation of employees were high. The airline grew rapidly by offering no-frills, low-cost service that competed favorably with the industry giants like United, American, and TWA. High-performing teams were developed. But Burr failed to pay attention to what his competitors were doing. They were modernizing their information, scheduling, ticketing, and pricing systems in the newly deregulated airline industry. With much better financial and information resources, they could immediately undercut PEOPLExpress's prices. Scanning for competitive threats was missing, as was keeping up with available technology.

In comparison, Braniff Airways self-destructed rather than succumbed to more aggressive competition. Its management failed to train and reward its employees in order to compete effectively. It developed a reputation for disgruntled employees, delays, and poor relationships with passengers, particularly in Dallas, its home airport. Shortsighted and uninformed top management had poor relations with the federal agencies, creating angry regulators. CEO Harding Lawrence, among other Braniff senior executives, was seen as pushy, arrogant, and domineering. When Braniff got into financial trouble, the regulators went out of their way to aggravate conditions for the airline. Safety and maintenance problems were usually handled quietly by the Federal Aviation Agency. News about Braniff was spread to the metropolitan media and resulted in a major loss of customers. In dealing with its financial difficulties, top management got its employees to accept a 10% pay cut, but the news made travel agents wary about using Braniff for future bookings. Reducing unprofitable routes to reduce costs resulted in continuous schedule changes, which confused travel agents, the airline's own reservation agents, and travelers, particularly business travelers. The self-destruction was further mismanaged by poor communications. The last CEO, Howard Putnam, further exacerbated the loss of travelers by guaranteeing only one day at a time that Braniff would stay in business (Nance, 1984).

Dale Sundby, founder of PowerAgent was a good salesman but an ineffective CEO. He sold his investors on his business plan to revolutionize online advertising. Customers were to register online to receive ads in exchange for points to discount the cost of purchases. The highly persuasive CEO organized a board of directors, backers for the necessary capital, and 60 employees. But he was highly self-oriented and could not see beyond his own vision, which dominated his thinking, and his expectation that everyone would agree with him. He ignored market research. He spent lavishly on himself and associates. Without a product or production staff, he budgeted over half his capital on advertising. He expected to outsource software coding. This delayed the Internet process. He invested heavily in a marketing management team. He didn't listen when told that many prospects were being lost because registration was too long. Also, prospects wanted daily tips, not daily ads. Because he did not tell anyone else in the organization what was happening, morale and support disappeared. The board split on his spending and business plan. Refinancing that he expected because of his persuasiveness did not materialize. In 20 months, he burned through \$20 million and 60 employees (*New Business*, 1998).

### ***Executive Compensation***

Barkema and Gomez-Mejia (1998) presented a general framework for variables that determined executive compensation; these variables included market, organization size, executives' roles, and peers' compensation. Compensation was also determined by the governance structure, such as ownership, and the board of directors,

and by contingencies such as strategy, national culture, and tax system. Effects on compensation depended on whether compensation was linked to performance, short-or long-term. A meta-analysis by Tosi, Werner, Katz et al. (2000) of 187 CEO compensation studies found that firm size in assets, market value, and revenues accounted for half the variance in CEOs' compensation. Khan, Dharwadkar, Brandes, et al. showed that CEOs' salaries alone correlated negatively with the rate of return on investment (ROI) of 106 firms in 71 industries but positively in 45 with the number of institutional owners of the firms (banks, insurance companies, investment advisors, and investment companies). Although 570 CEOs' contracts in the largest corporations called for incentive plans to compensate CEOs for increasing the value of the firm, the plans tended to be ignored and were more symbolic than substantive, especially in firms with poor prior performance and strong CEOs (Westphal & Zajac, 1994). The relationship between stock returns and CEO tenure weakened, according to analyses by Hill and Phan (1991), as the longer-tenured CEO increased influence over the board. However, compensation based on performance correlated positively when the CEO faced moderate risks and had greater control of performance outcomes (Miller, Wiseman, & Gomez-Mejia, 2002). In the same way, pay contingent on performance was more likely in firms that were owner-controlled (an owner or institution owned more than 5% of the shares of the firm) than where the managers were in control. In the latter firms, size was more important (Tosi & Werner, 1995). Salaries tended to be linked to sales in highly regulated industries such as railroads and banks and tended to be linked to total profits in less regulated industries, according to a survey of 1,200 corporations by Kokkelenberg (1988).

CEOs' compensation increased by 600% between 1990 and 1999, far more than increases in inflation and employee wages (Reingold & Jespersen, 2000). CEOs may exit a firm with 20% or more of the recent annual profit of a firm, leaving 80% or less for all the other shareholders. After 18 months of service, a recent Disney CEO departed legally with a termination package of \$140 million! Halock (2004) compared for-profit firms with nonprofits in the same deciles of their respective distributions of CEO compensation. For managing the same relative level of assets, the for-profit executives earned more than as much annually as the nonprofit executives. Only under conditions of uncertainty was there a correlation between executive compensation and financial effectiveness in 48 Fortune 500 firms (Waldman, Ramirez, House, et al., 2001). Compensation was higher in times of crisis but lower in times of political uncertainty (Tosi, Misangyi, Fanelli, et al., 2004). However, under conditions of uncertainty, a correlation was found with financial effectiveness in 48 Fortune 500 firms (Waldman, Ramirez, House, et al., 2001). For a sample of 848 Fortune 1000 firms, CEOs' compensation was more accurately predicted by comparisons with CEOs in other firms by institutional and social comparison theory than by agency theory (Gilley, Coombs, Parayitam, et al., 2003). CEOs' compensation in 112 of Fortune 1000 firms was also found to be contingent on the percentage of outsiders on the board of directors (Olson, 2003). But in 90 high-technology firms agency theory did help account for the relationships between short-term compensation of CEOs and innovations as assessed by the number of patents obtained and the amount spent on R & D (Balkin, Markin, & Gomez-Mejia, 2000). The form of compensation—stock or stock options—had different motivating effects on the executives' tendencies to make acquisitions or divestitures. The form of compensation also influenced whether CEOs preferred taking risks with options or avoiding risks with stock (Sanders, 2001). Jaques (2001) noted that the compensation at the highest level of the managerial hierarchy (responsible for a time span of 20 years of control) was felt to be fair by the job occupant at 51 times the lowest management level (responsible for a time span of one day). Felt-fair compensation correlated .86 with time span of control. The same average ratios for these levels and all those in between have been universally endorsed for the past 50 years. However, there is much variation in CEOs' compensation among firms skewed to overpayment from the mean. The compensation and severance packages in excess of industry norms that CEOs and key executives, supported by their boards, have been awarded have raise questions about whether they are justified. While 50 years ago CEOs averaged 40 times the annual compensation of the average worker, by 2005 the figure had increased to more than 400 times. Combs and

Skill (2003) found that for 77 firms whose founders had just died, the successors' compensation was higher than expected when the support of the executive, the board, and the nominating committee for a successor was stronger. Other variables, such as firm size, were controlled. Executives' performance was less important than their executive entrenchment.

*Executives' Accountability.* To link executives' accountability and discretion to their compensation, Grossman and Hoskisson (1998) suggested a need to identify the organization's strategies and what can provide it with competitive advantages. If cash flow and operating efficiency are keys to corporate success, accounting measures should be used to link executives' competence to their compensation. If innovation is a key factor, compensation should be tied to measures of marketing success. If short-term success is emphasized, annual bonuses can be awarded. If long-term success is more important, restricted shares, stock options, or other forms of delayed compensation should be linked to performance.

The strategy of voluntary disclosures in 28 different firms appeared dependent on whether their CEOs were compensated by long-term incentives, owned a smaller percentage of shares in the company, and were in later stages of their careers (Natarajan & Rasheed, 2003). For Streufort and Swezey (1986), executives of firms in stable environments needed to be ready, willing, and able to engage in long-term planning. Conversely, Miller and Friesen (1980) suggested that CEOs in office for a long time are resistant to change and this rigidity is often a cause for strategic failure (see also Kets de Vries & Miller, 1984.) In 97 randomly selected small, mainly Franco-phone firms in a variety of industries in Quebec, Miller and Toulouse (1986) found that the CEOs' years in office correlated  $-.33$  with return on investment (ROI). On the other hand, net income growth correlated  $.36$  with the strategy to spend on R & D and commercialization of products. Net income growth correlated  $.47$  with a strategy of delegating authority.

## Setting Policies and Strategies

---

Masoud Ardekani-Yasai (in press) obtained evidence from 101 small manufacturing firms that the firms exhibited superior performance when their management's functional experience was congruent with the requirements of their strategies. CEOs and top management set policies and strategies for acquiring and integrating resources for the organization. Among their goals are to reduce uncertainty, increase stability, increase resources, and reduce competition. They strive to create favorable public images and opinions of the organization and its products and services. They oversee conformance with government policies, regulations, taxes, and trade. Indirectly, they influence government through personal influence, support of lobbyists, trade associations, and political campaigns. Ideally, top-level business leaders choose markets based on strategic planning and location of their facilities. They manage the management, production, and services systems. Their evaluations, coordination, and policies influence the organization's subsystems of finance, capital, and personnel (Day & Lord, 1988). James Webb, long-term director of the National Aeronautics and Space Administration, exemplified the effective chief administrator of a federal agency. According to Sayles (1979), NASA was superbly managed. In less than 10 years, the agency went from no knowledge of man in space to an operational space program. It was a tremendous accomplishment in organizational leadership. The required strategic thinking and implementation occurred in the face of many risks, uncertainties, and unknowns.

There is an interplay between the corporate strategy formulated by CEOs and what is required of the organization. If a CEO pursues a human assets strategy for the organization instead of one based on a bureaucratic box of rules, management will need to be ready to be more participative, consultative, and considerate in its leadership. Interpersonal skills will be seen as the sine qua non of the effective top executive (Sessa, 1999). The more the strategy is to take account of uncertainty and ambiguity in the organizational environment, the more top management will need to be adaptable, flexible, and open (Zaccaro, Gilbert, Thor,

et al., 1991). They will need to determine *strategic inflection points* when major changes take place in their business, such as the introduction of a new technology, a change in the regulatory environment, or a change in what their customers want. The inflection point is a sudden drastic change from a steady state or gradual expansion or contraction of supplies, demands, or organizational performance. At such a point, a fundamental change in business strategy is called for (Grove, 1999).

For Toney (1996), a firm's profitability depends on the CEO's actions. CEOs whose firms are consistently profitable maintain their focus on the bottom line. They pursue a corporate strategy and structure with profitability as a goal, as do their subordinates. Accounting and finance are stressed in an analysis of their daily decisions. It is unclear whether this approach is optimal for the various stakeholders and the long-term health of the organization. The successful implementation of strategies formulated by the CEO and top management will depend on their leadership and the qualities of their relations with managers and employees (Cannella & Monroe, 1997).

Finkelstein (1992) completed several studies of the powers of the CEO and the dominant coalition of senior executives. Four factors were extracted and validated from a survey of 1,763 executives. The highest-loaded item on each factor was (1) structural power (compensation, .86); (2) ownership power (family shares, .86); (3) expert power (critical functional experience, .85); and (4) prestige power (membership on nonprofit boards, .75). Evidence was found that diversification strategies and acquisitions in 102 firms were influenced in particular by the financial backgrounds and powers of their dominant coalitions of executives. Finkelstein concluded that to understand the strategic decision making in an organization, one must include the distribution of power in the dominant coalition of senior executives as well as the CEO's power and functional background. Song (1982) also found that firms tended to diversify by acquisitions if their senior executives had backgrounds in law, accounting, and finance rather than production or marketing. Acquisitions could be beneficial to the degree that, as Bergh (2001) argued, the acquiring firm attempted to hold on to the managers from the acquisition who had the highest rank and longest longevity in that firm. Bergh examined the success of 104 acquisitions retained or resold in five years. He reasoned that long-tenured top executives possess specific knowledge about the firm and demonstrate long-term commitment to the firm and its stakeholders. They are a source of continuity during the turmoil that follows an acquisition.

## ***Strategic Challenges***

The challenges of globalization have been accompanied by climate change, nanotechnology, Internet piracy, new societal norms, terrorist disruptions, the aging population, alternative measures of performance, and man-made environmental degradation (Grant, 2005). At the personal level, newly installed CEOs and top managers may miss the close peers and counsel they had before. Along with the oft-cited "loneliness at the top" syndrome, there is tension between attention to the present and attention to the future: "If you do not satisfy the present, there will be no future" (Bruce, 1986, p. 19). A survey of executives reported by Hughes (1998) suggested that the most important challenges facing their organizations were dealing with change; thinking strategically; dealing with business issues; and achieving focus, consensus, and vision. Well known is the extent to which domestic firms increasingly face competitive challenges from abroad. Many products and services first produced in the advanced industrial countries are now produced in China, India, and the developing countries. A huge annual trade deficit has been created in the United States even though its consumers benefit from lower prices. But higher-paying manufacturing employment in the United States is being replaced by lower-paying employment in services industries. Competing firms are a challenge in the United States, connected to a number of strategic factors that senior executives may be able to control. But as foreign competitiveness increases for various reasons, such as lower labor costs, the challenge may be met with increased innovation and

productivity, greater investment in capital, and more attention to human resources, quality, productivity, and innovation. Also needed is a better long-term global strategy. Better use of capital investment and human resources can contribute more to corporate profitability and economic growth than increased capital investment alone, according to empirical analyses by Franke and Miller (2005).

How many people should be employed by an organization is a question that cannot be answered by expanding immediately when the demand for the organization's products or services increases, and contracting immediately when they decrease. Strategically planned *right-sizing* is needed, taking into account the costs of cutting the labor force, laying off employees, and early retirements. With downsizing, there is a loss of teamwork, long-term corporate identity, and core competencies. The better employees may retire early. There may be a costly lowering of morale, negative effects on families and community, and the need to rebuild the staff when there is a turnaround. The alternative strategy is right-sizing; restructuring; transferring and retraining redundant employees; sharing jobs; cutting average working hours; providing temporary reassignments; and protecting teamwork and core competencies (Cascio, 1995; Hitt, Keats, Harback, et al., 1994).

History judges a CEO on the strategic conceptualizations that contribute to future success, not on a maintenance of the present situation. But the present imposes strong demands on the CEO's time, with its numerous review committees, preparations for board meetings and annual meetings, critical regulatory responses to governmental requests, and exorbitantly time-consuming internal and external ceremonial duties. Top corporate managers have to free themselves from these day-to-day operations and short-term goal orientations to focus more attention on long-term threats and opportunities and to provide long-term leadership on strategic issues and their analysis, the formulation of implementation, interpretation, and evaluation (Wortman, 1982). The strategies reflect the CEO's inclination and leadership (Staw & Sutton, 1993). Large organizations establish a chief of organizational operations (COO) to relieve the CEO of day-to-day burdens. According to Hambrick (1991), in general, the CEO's tenure in office may undergo five phases that determine the CEO's attention, behavior, and organizational performance: (1) response to the mandate to lead, (2) experimentation, (3) selection of an enduring theme, (4) convergence, and (5) dysfunction. Larger strategic changes are made earlier in the chief executive's time in office (Gabarro, 1987). As might be expected, CEOs remain in office longer in stable rather than turbulent industries (Norburn & Burley, 1988).

Hambrick, Finklestein, and Mooney (2005) have proposed as hypotheses that executives challenged by greater demands of their jobs, compared to their less challenged counterparts, will tend to (1) imitate the strategic actions of other firms and (2) display more extreme strategic behavior and vacillation. Different organizational strategies are needed to meet the different challenges to a firm and its management, depending on the rate of technological change in their industry and the maturity of the firm. For instance, in a growing company in a fast-changing industry, a *pioneering* strategy is needed for development of new products, licensing of larger firms, fast innovations, movement into markets, and speed of expansion. In a mature firm in a slowly changing industry, a *consolidation* strategy is needed, with wide product lines for broad markets, long-term supplier relations, and standardized products (Lei & Slocum, 2005).

*Dual CEOs.* Occasionally when two giant corporations, such as Citicorp and Travelers Group, merge, instead of a single CEO taking charge, co-CEOs are appointed to work as partners. The strategy is based on it being impossible for one CEO to oversee the challenging diversity and geographic spread. Other examples of organizations whose size led to a strategy of dual CEOs include ABC, Capital Cities, Unilever, and Goldman Sachs (Troiano, 1999).

*Strategic Change.* To make strategic changes, the organization needs to rethink its current values and reorient itself (Fitzgerald, 1988). Struckman and Yammarino (2003, p. 234) noted that a key difficulty in handling strategic change is "keeping an organization focused on delivering quality and timely products and services while dealing with various change initiatives. ... Everywhere managers turn, another change activity

kicks off.” Furthermore, if leaders want to carry out a long-term strategic change, they will need to be inspirational so that the concurrence of constituent stakeholders is internalized. To obtain quicker support for a short-term strategic change, executives will find that transactional leadership may work as well.

For O’Toole (1995), effective strategic leaders promote organizational alignment and adaptability, which are “powerful predictors of long-term organizational excellence” (p. 82). “*Alignment* is observable when everyone down the line in the organization knows and understands corporate objectives, is motivated to pursue them, and knows what they must do to contribute to meeting overall corporate goals. ... *Adaptability* ... allows the organization to innovate, avoid threats, and seize new opportunities” (pp. 92, 94). Perceived awareness of the alignment of the strategy with its conception and what is being realized begins to fall off rapidly at the second level of managers from the top and declines further with movement down the line. There is a need to remind the organization about the actual strategy that has been formulated, its connection to behavior (Hambrick, 1981), and how the organization is going to become distinctive and continue to improve on its ability to deliver to its stakeholders. Continuity of strategy as well as continual improvement needs to be maintained. Continuity and change support each other. The more explicit the strategy and goals, the more new opportunities can be recognized. Choice, trade-off, and fit are required for strategic change (Porter, 2001). Strategic change is more likely to occur when a new CEO is brought into the firm with a mandate for change from the board of directors based on tentative agreements between the CEO and the board. If the mandate is for continuing the old policies, little change can be expected. According to a study of 40 cases by Tishman, Newman, and Romanelli (1986), less change in strategy may be expected with a long-tenured CEO or if the CEO retires and is replaced by an insider without the board’s mandate for change (Hambrick & Fukutomi, 1991). When first appointed, CEOs, even before they move into their offices, may visit plants and shops, ask questions of personnel at various levels, talk with key people, and examine reports and other information sources to develop an understanding of operations and needed improvements. Initial changes are usually made in functional areas in which the CEO has had previous experience to demonstrate and evaluate success early on (Gabarro, 1985). If the CEO is hired during a crisis, the change will be for immediate relief in the short term to find time for longer-term solutions. Over time, commitment to a chosen strategy will increase, barring new alternatives. The relatively brief tenure of CEOs, currently averaging five years or less, may be due to the tasks becoming more routine, the CEOs’ increasing power, and CEOs becoming less responsive to associates and the rapidly changing business environment. Dramatic leadership successions, particularly of new CEOs from the outside, can bring on a change in a familiar corporate name to reflect the new leadership, new strategies, and reorganizations (Glynn & Slepian, 1992).

Janson (undated) suggested an eight-step strategy for a new CEO wanting to make an organizationwide change: (1) Ask the most powerful people in the organization what they regard as the organization’s strengths and weaknesses and what they would change if they had the opportunity; (2) Complete a diagnosis with the help of many others on what needs changing and the receptivity and obstacles to the changes, and identify people who can lead the change efforts; (3) Envision the changed organization; (4) Identify the gaps between the current organization and the envisioned organization; (5) Encourage total involvement of significant others in the change effort; (6) Tailor the change effort to the nature of the organization; (7) Enlist the relevant department heads and a transition manager to provide needed network communication and recognition of project coordinators and team leaders about what has been happening; (8) Measure how well objectives of the change efforts have been met. The survival of Sears for well over a century may be attributed to the strategic changes initiated by its new incoming chairmen that fit Sears’ changing internal and external environment. Julius Rosenwald, as new CEO, overhauled Sears’ cost and control mail-order systems to achieve greater efficiency. As retail stores gradually supported and replaced the mail-order business, Robert Wood came along as CEO to radically alter the business to fit the changing environment, from rural to urban marketplace (Stryker, 1961). It’s still too early to tell how Sears’ institutionalized values of customer service and product

quality will be affected by its merger with Kmart, which has focused on competing with lower prices.

The financial services industry has gone through two strategic transitions guided by strategic considerations. At first, in the typical insurance office, a few people handled the business. The same person might sell, underwrite, and process claims. Jobs were whole, customer service was personalized, the organization was flat, there was little overhead, and costs were acceptable. As business expanded, the industrial office was created, adapting the then-prominent rules for the factory of “scientific management.” Work was fragmented, direct contact with customers was abandoned, production lines were created, and people were organized to fit the system. Costly tangential jobs and multiple levels of management were created, and errors increased. Growth and work simplification were accompanied by a loss of service orientation and eventually diminishing effectiveness. The successful service organization pursues a new strategy for quality service, including: (1) a vision of customer service that focuses the organization’s values, beliefs, and norms on customer service; (2) a structure that is designed around some aspect of the customer, such as market segment or geographical location, rather than around the work process; (3) assigning responsibility for satisfying a particular set of clients; (4) moving accountability and decision making to the lowest possible level in the organization; (5) creating systems of customer feedback; (6) using computer technology to provide instant access by the service employee to the complete customer file (Janson, 1989).

*Strategic Leadership.* The founder’s personality has an impact on the culture of the organization and its subsequent strategies. If the founder is autocratic and controlling, like Harold Geneen of ITT, the organization will pursue a top-down strategy of leadership. If the founder is, like Bill Gore, team-oriented and participative, the strategy of leadership will reflect these values, as happened at Gore-Tex (Nahavandi & Malekzadeh, 1993). Top management’s leadership is required if a total quality program is to succeed. For instance, Choi and Behling (1997) noted that the attitudes and commitment of top executives were critical to the success or failure of total quality management (TQM) programs. During the 1990s, many were tried and abandoned. Success, continuation of TQM programs, and annual introduction of new TQM practices were much more likely when top management had a *developmental* orientation than when they had a *defensive* orientation—preoccupation with past problems, customers being seen as threatening, and unrealistic expectations. Management’s commitment to programs is critical. A meta-analysis of 18 studies of the impact on organizations of management by objectives (MBO) found that the gain in job satisfaction from the installation of MBO occurred only in organizations with highly committed top management. There was little gain in employees’ job satisfaction in firms where top management was less committed to implementing the MBO program (Rodgers, Hunter, & Rogers, 1993).

A new CEO is often chosen to match the organization’s current strategy. (Nahavandi & Malekzadeh, 1993), resulting in better implementation of the strategy (Michel & Hambrick, 1992). Strategic requirements provide the CEO with a cognitive map of the organization and its environment (Calori, Johnson, & Sarnin, 1994). However, the typical strategically oriented leader looks forward to setting directions for the organization (Arnott, 1995). The executive’s power is increased when the critical sectors of the environment can be scanned and scoped (Hambrick, 1981). Strategic leaders make and communicate decisions for their organization’s future (Zaccaro, 1996). They: (1) formulate or modify the organization’s goals and strategies; (2) develop structures, processes, controls, and core competencies for the organization; (3) manage multiple constituencies; (4) choose key executives; (5) groom the next generation of executives and personnel; (6) provide direction with respect to organizational policies; (7) maintain an effective organizational culture; (8) sustain a system of ethical values; (9) serve as the representative of the organization to government and other organizations and constituencies as well as negotiate with them. Such strategic leadership must be able to deal with ambiguity, complexity, and information overload. Adaptability and a sense of timing are required (House & Aditya, 1997; Boal & Hooijberg, 2001).

The organization’s strategy reflects its top management and its internal and external environments.

According to Nutt (1986), managers with different styles of leadership are likely to see a different amount of risk in a situation and to choose different strategies. Those who are more judgmental will choose strategies oriented toward action and capital expansion. Those who are more systematic will choose strategies that avoid taking immediate action. Innovations are most likely to be pursued by managements classified according to their strategies as *prospectors* rather than as *defenders* of the status quo; *analyzers*, who try to maximize profits by minimizing risks; or *reactors*, who are inconsistent in dealing with their environment (Miles & Snow, 1978). Prospectors look to discover and work with innovative products even though risks are high. Their firms are flexible in administration and technology. Their organizations invest in human resources and favor decentralization, organicity, and decentralization (Heller, 1994). The top managements of prospectors are most likely to be former outsiders (Chaganti & Sambhara, 1987). They prospect for strategies that others have already proved successful and therefore enter second into a market. This appears more advantageous to them than pioneering an innovation and entering the market first (Schnaars, 1994).

Strategic leadership requires creating meaning and purpose for the organization, with a powerful vision and mission that create a future for the organization (Ireland & Hitt, 1999). Sosik, Jung, Berson, et al. (2001, 2004) agree and call envisioning the heart of strategic leadership. In many organizations, the CEO and top management formulate and implement their strategies. Inputs from lower levels of management and employee networks contribute in a collaborative effort (Senge, 1997), particularly in the implementation of strategies (Cogliser, 2002). *Strategic maneuvering* is required when a firm is challenged by hypercompetitiveness in price, service, and quality, timing and knowledge, and strongly held markets and products. Hypercompetitiveness is illustrated by the airline-pricing fare wars. By the beginning of 2005, two discount airlines, Southwest and JetBlue, with lower costs, simpler fare structures, and lower prices than the main carriers, had captured 30% of the U.S. market. A major carrier, Delta Air Lines, cut its prices and fare rules drastically to match those of Southwest and JetBlue. Then other main carriers, American Airlines, Northwest, and US Airways followed suit, even though they could not afford the potential loss of revenues, in their effort to meet the competition. US Airways did not have the necessary “deep pockets,” it was already bankrupt, as was another main carrier, United Airlines.

A firm's seizing the initiative with hypercompetitiveness disrupts the status quo and may create a series of temporary competitive advantages with speed, surprise, and accurate forecasting (D' Aveni, 1994). Structural equation modeling for 76 executives and 528 colleagues who rated them showed that positive interpersonal relations and confident speech were antecedents of strategic leadership. In turn, the executives' strategic leadership contributed to their rated effectiveness, potential, and the performance of the unit they supervised (Gist & Gerson, c. 1998?) As might be expected, in a survey of more than 100 small and medium-sized businesses in Britain, transformational leaders engaged in significantly more strategic planning than did transactional leaders to achieve financial results, avoid problem areas, innovate, and improve short-and long-term organizational performance (O'Regan & Ghobadian, 2003).

*Strategic Decisions.* Like most organizational decisions, strategic decisions should proceed in an orderly fashion, beginning with anticipation and scanning for information (Bass, 1982). Both U.S. and Indian entrepreneurs and managers increase their scanning when they perceive increases in environmental changes and the importance and accessibility of information (Stewart, May, & Arvind, 2003). Ordinarily, this leads to the discovery of problems; diagnosis; a search for solutions; innovation; evaluation of and choice among alternative solutions; authorization; and implementation. Each phase may call for a return to an earlier one before going forward. Some phases are ignored more than others for rational or emotional reasons. For instance, a favorite alternative is seized on without considering other possibilities. Most of the phases may be implicit when the decision is based on intuition (Bass, 1982).

Such decisions coordinate diverse divisions in the organization, analyze contradictory and ambiguous information, and interpret events. Sometimes they need a long-term perspective (as much as 20 years ahead in

the military or government and industries), requiring heavy capital investments. Weiner and Mahoney (1981) sampled the performance of 193 manufacturing corporations. They concluded that what the top leadership decided to do had a strong influence on the corporations' profitability. Niehoff, Enz, and Grover (1990) reached similar conclusions about the effects on the commitment and satisfaction of 862 employees if their top management teams encouraged innovation, supported employees' efforts, and shared a vision and participation in decisions. But Crosby (1990) argued that creating the vision and the organization's direction was to be accomplished by the chief executive and implemented by his subordinates.

Farkas and De Backer (1998) formulated five approaches that CEOs headquartered in the United States, western Europe, and Japan say they pursue. They can all be considered as based on different strategic decisions about the best way to manage: (1) *strategic*, envisioning the future and planning how to get there (e.g., Coca-Cola, Newmont Mining, Staples, and Deutsche Bank); (2) *human assets*: managing people, policies, programs, and principles (e.g., Southwest Airlines, PepsiCo, Philips, and Massachusetts General Hospital); (3) *expertise*: championing specific proprietary expertise and using it to focus the organization (e.g., AngloAmerican, Ogilvy & Mather, Motorola, and Saint-Gobain); (4) *box*: creating, rules, systems, procedures, and values to control behavior and outcomes within well-defined boundaries (e.g., British Airways, HSBC, and Nintendo); (5) *change agent*: CEO acts as an agent of radical change from bureaucracies to new and different organizations (e.g., Goldman Sachs, Tenneco, and Mitsui). Each of the approaches may fail. For instance, at ITT the box approach was too rigid; Digital Equipment focused on its expertise approach, when actually it needed to change. All the interviewees saw the strategic approach as one of their roles, but only 20% saw it as their *defining* role.

*Use of Intuition.* Sadler-Smith and Sheffy (2004) suggested that rational and intuitive decision making should be seen as reinforcing rather than opposing each other, since much cognition occurs automatically and is intuitive. Intuition is the interplay of knowing based on expertise and sensing based on feeling. Understanding can be gained directly from intuition without rational thought or logical inference. Executives make considerable use of intuition. It increases with seniority, since it depends on experience. It is likely to develop from implicit, incidental, and unplanned learning experience and feedback. Also important are emotional memories and a "library of expertise" built up over the years. Intuitive understanding is gained from gut feeling and by attending to experiences that seemed to work even when they were contraindicated (Simon, 1987). According to Miller (2002) and Miller and Ireland (2005), much prior learning has been stored in memory with less than complete awareness and rationale. Intuition is conceived of as *automated expertise* or as a *holistic hunch*. Automated expertise is brought to the surface of awareness. Years of experience and learning are packed together into an instantaneous insight. A holistic hunch is a subconscious synthesis of diverse experiences, novel combinations of information, and strong feelings of "being right." The error rate of decisions based on automated expertise and hunches is high and unpredictable compared to the slower decision-making process of scanning, generation, and consideration of alternatives. Nevertheless, sometimes going ahead on a hunch cautiously with scrutiny, checking, and the use of explicit decision tools may pay off.

For David Myers, intuition may involve subliminal priming, implicit memory, emotional processing, and nonverbal communication. He pointed out that, actually, rapid cognition is the basis for many frequent small decisions we make without much awareness. We need accurate feedback when we make good decisions. To avoid bad intuitive decisions, we need to recognize when our reactions are being controlled by our rapid cognitions and subconscious biases. Intuition, for Seymour Epstein, is what we have learned without realizing it. It can be useful or maladaptive (Hogarth, 2001; Winerman, 2003). Greer (2003) noted that intuition helps us to make connections between events. But sometimes the connections don't exist. Intuition may interfere with sound decision making.

*Strategic Formulation.* Based on interviews of 75 executives, Sosik, Jung, Berson, et al. (2004) conceived strategy formulation as a weaving by leaders of inputs from people, technology, ideas, and

opportunities into a system of social, technological, and intellectual resources, to produce organizational success. From an empirical analysis of 27 business cases, Shevastava and Nachman (1989) developed a fourfold taxonomy of how and by whom business strategies are formulated. Strategies were formulated by: (1) a confident, dominant, aggressive, strong-willed, knowledgeable entrepreneurial type of executive with direct control and influence. The executive makes roles for others and controls their efforts; (2) a bureaucracy bounded by rules and structure that is guided by standard operating rules, procedures, and policies in shaping the strategy. Members take preassigned roles. The bureaucracy specifies the kind of information analysis, the criteria for choosing alternatives, and the procedures for ratification and authorization in the decision making; (3) a dominant coalition of executives, each with authority over an area. They shape strategy through negotiations; and decisions reflect their differing interests; (4) a professional individual or small group of professionals with control over information. The professionals are open, expert, autonomous, committed, and collegial. New rules are devised when needed.

In the 1988 and 2000 Korn/Ferry International surveys of 1,500 interviews with executives in the United States, Latin America, western Europe, and Japan, almost all agreed that in strategy formulation, it was very important for the CEO to convey a vision of the organization's future and to link compensation to performance. Almost all the North and Latin American and at least 75% of the European and Japanese chief executives agreed that ethics, frequent communications from the CEO to the employees, and promoting training and development were very important. Still seen by a majority of respondents as very important for the CEO to do in implementing formulation were frequent visits by the CEO to plants and offices and participation in community affairs. Pluralities varying from one region to another saw it as very important for the CEO to reward loyalty and tenure and to use outside consultants. Few, except in Japan (where the leader announces a decision after full consultation), required the CEO to make all the decisions.

*Management Awareness and Contributions to Strategy.* As the organization's strategy is formulated from the top down, perceived awareness of the alignment of the strategy with its realized strategy and the chief executive's conception begins to fall off rapidly at the second level of executives from the top and declines further with movement down the line. The CEO needs to be consulted to define the actual strategy that was formulated to connect strategy and organizational behavior. Executives and managers need to be queried (Hambrick, 1981).

Corporations are made up of many business units. Watson and Wooldridge (2001) surveyed, by mail, 82 business unit managers and executives in Britain below the CEO; they indicated that there was also an upward influence in the formulation of their corporations' strategies. Upward influence was relatively greatest from those managers and executives (1) who reported directly to the CEO; (2) from each corporation's largest business units; (3) from business units related to each corporation's core business; (4) from the most effective business units in each corporation, measured objectively.

### ***Components of Effective Strategic Leadership***

Top management sets the strategic purpose and direction of the firm by articulating and communicating a desired vision of the organization's future. Effective strategy is needed for an organization to achieve optimum performance or comparative advantage. It is also needed to keep up with competition in changes in technology and markets (Rowe, 2001). According to Beer and Eisenstat (2000), required for formulating and implementing an effective strategy are: (1) top-down direction that accepts upward influence; (2) clear strategies and priorities; (3) an effective top-management team with a general management orientation; (4) open vertical communication; (5) effective coordination; (6) allocation of clear accountability and authority to middle management. According to Ireland and Hitt (1999), effective strategic leadership practices also include:

(1) focusing attention on outcomes and processes; (2) seeking to acquire and leverage knowledge; (3) fostering learning and creativity; (4) improving work flows by attention to relationships; (5) anticipating internal and external environmental changes; (6) maintaining a global mind-set; (7) meeting the diversity of the interests of the multiple stakeholders; (8) building for the long term while meeting short-term needs; (9) developing human capital. These and other effective practices can give the organization advantages in a competitive environment (Ireland & Hitt, 1999). Competitive advantages in a global economy can also be gained from a strategy that depends on the leaders' global leadership skills as well as the reputation of the organization (Petrick, 1999). Raising the cognitive limits of the CEO and top management can result in strategic decisions such as restructuring, becoming larger by making acquisitions, and entering new markets (Mowday & Sutton, 1993).

The involvement of executive management in strategic planning is furthered by the presence in the organization of a salient strategic vision, according to a sample of 226 upper level executives in a Fortune 100 corporation undertaking a major strategic change (Oswald, Moss-holder, & Harris, 1997). Additionally, CEOs and top management need to be able to channel and support the champions of innovation and adaptation and the incubation of new ideas in a safe space without higher-ups who prematurely criticize new, undeveloped ideas. Controls need to be minimized and innovators need to feel free to speculate (Nutt, 1999).

*Personal Predilections.* In their strategizing, executives are faced with many alternatives, conflicting demands by constituencies, and information overload. Their decisions depend on their values, experiences, knowledge, and preferences (Finkelstein & Hambrick, 1996; Hambrick & Mason, 1984) and sometimes on whimsy. W. R. Grace stopped for breakfast at Coco's, a coffee shop, and liked it so much, he bought the company that owned the chain. In the same way, Victor Kiam liked the Remington razor so much that as the ads said; he acquired the company (Hall, 1984). IBM President Thomas Watson, Jr., chose a small prairie town, Rochester, Minnesota, as a site for a new plant because of a World War II army air force buddy who came from there.

Elenkov and Judge (2002) collected MLQ—Form 6S questionnaires from 490 presidents, CEOs, managing directors, and 371 other top-management team members in the United States, United Kingdom, Germany, Austria, Russia, and Ukraine. These executives were all involved in strategic decisions. Their transformational leadership scores accounted for 52% of the variance in product market innovations and 55% of their administrative innovations.

*Effective Strategic Decision Making.* Effective strategies depend on effective decision making. While snap judgments based on intuition may sometimes work out well, effective decisions ordinarily require an order in the process. Opportunities, threats, variance from expectations, or disturbances are observed. The problem is diagnosed, usually calling for more information and a search for solutions; development of innovations occurs, evaluation and choice among alternatives takes place, and the selected alternative is authorized and implemented. Whenever a phase cannot be completed successfully, there is a return to an earlier phase (Bass, 1983). Murnighan and Mowen (2002) add more in the process to the importance of feeling and intuition. The search phase is for detecting signals of threats and opportunities, followed by finding the causes. Blind spots need to be eliminated. The risks and rewards of alternative solutions are estimated, with choice based on avoiding a missed opportunity or a needless blunder. Whether or not to implement the choice should be based on a calculation of the *risk ratio*, the maximum estimated risk, compared with the probability estimate—the probability of success. This rational approach must be balanced with intuition (wisdom based on many reinforced experiences), particularly at top-management levels, even though rationality outperforms intuition in experimental studies (Nutt, 2002).

*Ineffective Strategies.* Cognitive shortcomings explain poor strategic decisions, such as paying too much for an unneeded acquisition. This seems to occur more often than not. Irrational and overconfident bidders do not know they are bidding against other bidders who are similarly overconfident (Zajac & Bazerman, 1991).

Overall, as a consequence of the self-confidence and hubris of its CEO, a premium is paid by an acquiring firm beyond the worth of the acquisition. *Firms that acquire other firms tend to decline in long-term profitability* (Valle, 1998). A number of critics agree that CEOs take self-serving positions in their strategic thinking. They attribute good performance to their organization and poor performance to the external environment (Mowday & Sutton, 1993). However, D'Aveni and MacMillen (1990) found evidence to the contrary. They compared the letters written by the leaders of 57 banks that declared bankruptcy with a matched sample of letters by solvent bank leaders. The letters were written during the five years before the declaration of bankruptcy. The strategies of the future bankrupt firms tended to ignore or deny their external environment, such as the lack of demand for their products and services. They focused internally on their debt, their creditors' demands, and changing their organization.

Greenwald (1985) pointed to three cognitive biases in strategic decision making: (1) Strategists look at events primarily in relation to themselves, (2) They see themselves as responsible for desired but not undesired outcomes, (3) They stick to their initial and favorite alternatives even when the supporting evidence is disconfirming. Other cognitive sources of error are that attention is directed away from goal direction by frequent disruptions, erroneous causal attributions are made; and people hold implicit, readily available, and strong but erroneous beliefs (Peterson & Sorenson, 1990). To avoid failure, strategic leaders need to avoid being enticed by the reputed and popular strategies for success in the new economy. Greco, Caggiano, and Ballon (1999) provide examples of how false assumptions and failure to qualify good ideas result in pursuing strategies that die or fail to grow.

*Middle Management's Role in Organizational Strategies.* Often, middle managers are responsible for implementing strategic decisions made by senior executives. Separating planning from implementation creates special problems (Bass, 1970a). As noted by Floyd and Woolridge (1992), senior executives complain that middle managers fail to take the necessary steps to implement strategies. The commitment to and understanding of what needs to be done may be poor. Middle managers don't articulate the same goals as do senior executives. If middle managers disagree with the strategic initiatives, they frequently work against implementation. To promote commitment, rewards systems and structures need to be aligned to fit the intended strategy. Middle management and supervisors' understanding of the strategy will be fostered by increased discussions with senior managers about the strategy and their criteria for success. Consensus is needed on how to implement the strategy. Strategically useful ideas can come from anywhere in the organization.

*Supervisors' Role in Organizational Strategies.* At the lowest leadership levels of the organization are department heads, supervisors, and team leaders. They may make suggestions upward that have implications for company strategy but generally are responsible for maintaining the work flow, morale, equipment, and safety of their subordinates. Sales supervisors and salespersons can bring home to the organization important ideas about competing products and organizational practices. They can serve as early warning signals. Production supervisors and their employees can contribute significant ideas about needed changes in internal organizational processes.

## Political Leadership

---

The Scottish philosopher David Hume (1741–1742) presented the first modern concept of political leadership. Political leaders share the values of the people and in a democracy formulate policies that a majority favor. Successful leaders are responsible for appointing judges, passing legislation, and providing political stability. Leaders with less support from the electorate form a loyal opposition. But this is no guarantee that the leader chosen will be effective. In a stable a democratic system, leadership takes place in an environment of political trust, social tolerance, recognition of political liberties, and popular support for equality of the sexes.

This is in contrast to the pseudodemocratic system common to many developing countries, where political and civil rights are ignored, emotionality trumps rationality, and religious zealotry is pervasive.

Even in true democracies, voters are highly biased in favor of one candidate over another for irrational reasons. They attribute favorable personality traits to leaders who share their political beliefs. For example, right-wing Israeli voters evaluate right-wing leaders as more friendly and task-oriented than left-wing leaders. Left-wing voters attribute friendliness and task orientation more to left-wing leaders than right-wing leaders. Both groups see the leaders on their side of political issues as closer to their ideal leader (Ellis, Nadler, & Rabin, 1996). Shamir (1994) found that the perceived charisma of candidates combined with Israeli voters' ideological positions to predict their voting preferences.

"Political leadership is one of the most widely noted and reported and least understood phenomena in modern politics." This was a comment in the 1976 presidential address by James MacGregor Burns to the American Political Science Association. He argued that lacking a general theory of political leadership, of necessity research fell back on a more specific study of the numerous political leaders. For Adel Safty (2000), political leadership is needed globally to promote peace, democracy, and human development within and between states. World War II was a consequence of the collective failure of the League of Nations and its political leadership.

There is much revisionism in what may be written about a political figure after 50 years. When seeking and retaining office, the politician must usually face pluralistic pressures. "The actions that endear the leader to one constituency may anger another ... the leader must show different faces to different constituencies or one enigmatic face to all." (Leaders have to consider the needs of their constituencies, the demands of powerful lobbies, and hopefully use their own best judgment.) "But all too often their judgment, befuddled by conflicting pressures, or their character, eroded by sell-outs, fails the test" (Gardner, 1993, p. 151).

Mikhail Gorbachev was unusual as a world-class leader in an authoritarian society. He openly called attention to what he did not know and invited help. He was crucial in changing the Soviet system (Khoubesserian, 1987). Was his career a success or a failure? Although he proceeded with caution to try to modernize the system, he was ousted from power and the Soviet Union crumbled as Ukraine and other Soviet republics seceded from the USSR. Innovation is difficult for political leaders who attempt to democratize an authoritarian regime. The new way must be initiated, legitimated, and sustained (Edinger, 1993). The political innovators Mahatma Gandhi and Jawaharlal Nehru captured, sustained, and adapted the British structure of government for India (Sheffer, 1993). In 1986, the CIA was perplexed by photos of Mikhail Gorbachev's facial expressions during conversation, which mirrored the facial features of the other leader, Ronald Reagan, with whom he was talking. Was this a sign of intense concentration? Empathy?

Burns (1978) introduced his theory of transformational and transactional leadership, to be presented in the next chapter, which advances the understanding of political leaders. The importance of charisma to political leaders was discussed in [Chapter 22](#). In his address, Burns pointed out that political leaders are expected to inspire and elevate the public and to show moral leadership. In a democracy, political leaders are expected to focus on the public's authentic needs. They turn threats into opportunities. In 1940, France was completely defeated by the German blitzkrieg. Charles de Gaulle took on the role of hero, seized the opportunity to mobilize Free French forces outside France, and did not succumb to irrational fears. In 1945, at the end of World War II, when Winston Churchill was asked by a woman, "During this terrible war, what was your darkest hour?," he replied, "Frankly my dear, I enjoyed every minute of it!"

### ***Influence of Public Leaders***

The influence of public leaders is felt when they bring together important figures from industry, government,

education, health care, and community activist organizations to collaborate on issues of mutual interest. They provide visions, initiate structure, and clarify what needs to be done (Berger, 1997). The credibility of public managers is critical when they try to introduce reforms in public agencies for their improvement (Gabris & Ihrke, 2003).

Avant (1994) regards most politicians as inauthentic. They are self-interested strategists. They try to ensure that they remain in power. They pursue goals based on whether they will help them stay in power. They try to control the bureaucracy to maintain their political advantage.

## American Presidents as Leaders

---

The American presidents since George Washington's two terms in office have formed an important field of leadership study for political scientists, historians, biographers, psychologists, psychoanalysts, and sociologists. Each president redefines his role as national leader, chief executive of the government, and commander in chief of the military. The president has a "bully pulpit" from which he can exert strong influence on the public and Congress. His rhetoric is important in articulating the concerns and aspirations as he sees them. He tries to form a sense of national purpose and identification (Fields, 1994). This is especially true if his rhetoric is *image-based* rather than *concept-based*. Image-based words include sweat, hand, root, heart, explore, rock, grow, path, journey, sweet, dream, listen, and see. Concept words include work, help, source, commitment, inquire, dependable, produce, endeavor, limit, alternative, request, moderate, idea, think, consider, and understand (Martindale, 1975). Emrich, Brower, Feldman, et al. (2001) calculated the relative frequencies compared to the total length of image-based and concept-based words in presidential inaugural addresses from George Washington to Jimmy Carter. A correlation of .50 was found of image-based indices with Murray and Blessing's (1983) list of the charisma of the 32 presidents. The correlation with charisma for concept-based rhetoric was -.27. There were no significant comparable correlations of concept-based indices with the list of greatness.

If members of the president's own party in Congress who supported his election found themselves opposed to one of his proposals, they would often change to supporting it. Nonetheless, Zeidentstein (1983) could find no consistent pattern of the relationship between presidents' popularity, from Dwight Eisenhower to Jimmy Carter, and their legislative success, although it appeared that Reagan's popularity helped his success in passing legislation through Congress. Some found that most important for a president's popularity was his perceived effect on the national economy or the economic well-being of voters (Kinder, 1981). Barber (1977) found that a president's success depended on how active the president was and whether or not he enjoyed power. The speeches of some presidents, like John Kennedy's, tended to be *positive* rather than *disapproving*, like Richard Nixon's. Two-term president George W. Bush's addresses were *simplified* solutions to problems in black or white. He was not a *complexifier* like Jimmy Carter—defeated for reelection—for whom possible alternatives had various shades of gray (Mazlich & Diamond, 1979). A relatively *inactive* one-term president, William Howard Taft, sandwiched between the *active* Theodore Roosevelt and *active* Woodrow Wilson, served as a transition between them in the regulation of corporations. Unlike Roosevelt, who viewed the president as a steward of the country and its constituencies, Taft was a constitutional literalist who emphasized the separation of powers of president, Congress, and the courts. He was concerned with controlling radical majorities (Anderson, 1982).

### **Presidential Power**

With the tyranny of the British King George III in mind, the framers of the U.S. Constitution were wary of

placing much power in the executive branch. Yet they also saw the ineffectiveness of the Articles of Confederation, which lacked a strong executive. But they assumed that the first president would be George Washington, who had the unreserved trust of the people and had to be persuaded to take the office by Alexander Hamilton. The powers of the president have been expanded ever since by strong presidents such as Jefferson, Jackson, Polk, Lincoln, Wilson, and the two Roosevelts (McDonald, 1994). Between 2001 and 2006, George W. Bush wielded extraordinary powers by decree in the war against terrorism, through executive orders. Additionally, he wrote signing statements on whether or not his administration would enforce new legislation enacted by Congress. This presidential behavior was never envisioned by the framers of the Constitution. Bush's popularity dropped from 90% to 30%.

### ***Presidents' Management Style***

Presidents differ in their management styles. Franklin D. Roosevelt kept his subordinates in competition with one another over decisions. He did not give them sufficient authority to act on their own, so he could maintain his power over decisions. He could be tricky and tough, but his objective was the emancipation of humanity. John F. Kennedy and Bill Clinton also kept their subordinates guessing about decisions. This was a way of keeping administrators in charge of large bureaucracies from tying up actions that the presidents wanted to see implemented. The three also had trusted informal advisers: Eleanor Roosevelt and Harry Hopkins for FDR, Robert Kennedy for JFK, Hillary Clinton for Bill Clinton, and Karl Rove for George W. Bush. Dwight Eisenhower, Gerald Ford, Ronald Reagan, and George H. W. Bush took a very different tack: they pursued an orderly process in which decisions were delegated to their subordinates in charge of the agencies and departments of the federal government. Jimmy Carter was known for his inability to delegate and impose orderliness to stop the feuds among federal agencies. Richard Nixon was highly controlling and secretive and kept information close to his vest. Lyndon Johnson worked closely and directly with Congress (Haass, 1995). Kennedy was open to communication, took responsibility for his administration's mistakes, and arranged to be the center of a network that included his subordinates, advisers, and consultants. Modern presidents have differed in their regard for public opinion polls. Some, like Truman, disliked and ignored them; some, like Clinton, consulted them almost daily. Nonetheless, there was a strong association between the presidents' annual positive approval ratings in Gallup Polls for each year in office of Eisenhower, Kennedy, Johnson, Nixon, Ford, Carter, and Reagan, and their legislative success on issues where the president took a position Rockman (1984, p. 118). These presidents' leadership and management styles were classified by Rockman as *drivers* or *coasters*. Drivers, like Johnson and Nixon, were entrepreneurial chief operating officers; coasters, like Eisenhower and Ford, were chief executive officers. Drivers pushed expansive policies; coasters were more incremental. Drivers were centrists and interventionist, using informal channels and uncertain jurisdictions; coasters favored decentralization and used formal channels and jurisdictions. Drivers were hierarchical and delegative. Critics branded Johnson as a micromanager and Nixon as ruthless and isolated. Some critics branded Eisenhower as an inefficient manager but, in reality, in his two terms in office, he gave the government a sense of direction and purpose with the support of public opinion (McInerney, 1981).

Ronald Reagan (1986) and his recruiters put a lot of effort into choosing his political appointees so he could delegate authority to them with the expectation that his policies would be pursued without his involvement in details. He insisted on mutual loyalty, which resulted in a relatively large number of scandals. Most of his carefully vetted aides were self-made millionaires and shared his probusiness attitudes (Nathan, 1983). It was easy for him to encourage free and open discussion among his aides because of their shared attitudes. When conflicts arose, he would reduce tension with a joke from his extensive repertoire of jokes. He had a high tolerance for listening to hotly contested issues. His agenda and priorities were simple and clear. The most

memorable lines in his speeches were his own when he rewrote his speechwriters' efforts. He focused on big issues and avoided spending time on less important ones. He enabled the introduction into his administration of many private business practices, such as like new systems of credit management and cash management and the use of private collection agencies. He changed the federal budgeting process; instead of agencies submitting proposals to meet their anticipated needs, which then would be reviewed and sent to Congress for approval, Reagan introduced a top down budgetary process to reflect his plans to cut taxes and shift priorities. The White House set goals and priorities and the agencies had to fit their requests to the president's plan. He organized committees of cabinet members to propose ways he should deal with suggested policies; they could work out the differences among their various agencies. When they could reach consensus, he accepted their decisions as if they were a board of directors (Fishel, 1985). When they could not agree, he made a decision and stuck to it, even when it was likely to be unpopular with the public. Reagan handled disasters such as the terrorist bombing of a Marine barracks in Lebanon by going public quickly with a full account, taking the blame as if he were at fault, and defusing the crisis (Dowd, 1986). He could be highly directive, as in the case where he declared that it was illegal for aircraft controllers, as federal employees, to strike and ordered the FAA to fire and replace them.

### ***President's Personality***

Winter (1987) used previous findings to form a composite of presidents' performance: consensus of greatness, avoidance of war, entry into war, and great decisions. The composite measure of greatness was correlated with the extent to which the presidents' inaugural addresses projected the needs for power, achievement, and affiliation. Need for affiliation was negatively related to greatness; presidents who were overly concerned with close relations with their friends, advisors, and subordinates correlated .53 with scandals in their administrations (Winter & Stewart, 1977). House, Spangler, and Woyke (1991) showed that performance based on Simonton's (1987, 1988) list of 31 presidents from Washington to Carter was related positively, according to path analysis, to a need for power (.52) and negatively to a need for affiliation (-.37). For 39 presidents ranked by Simonton (from Washington to Reagan) on their tendency to take direct action, ranking is related significantly to a need for power (.62), and a need for affiliation (-.21). A need for power correlated .36 with international relations performance, .19 with economic performance, and .51 with social performance. Other significant path coefficients were negative between the performance measures need for achievement and need for affiliation. The power motive was stronger than the achievement motive in F. D. Roosevelt, Truman, Kennedy, and Reagan. These presidents found ways to deal with subordinates whom they had not appointed but could not fully trust or get rid of. Roosevelt assigned the same task to several different such appointees and let them compete for his favoring of one decision over the others. The achievement motive was higher than the power motive in Presidents Wilson, Hoover, L. B. Johnson, Nixon, and Carter. (Need for achievement correlated .51 with idealism.) These presidents were unable to fully implement their idealistic goals (Winter, 2002).

Rubenzler, Fashingbauer, and Ones (2000) arranged for up to 13 students to score 41 presidents on the five-factor personality questionnaire NEO-PI-R. The presidents' mean factor scores were more extroverted, less open to experience, and less agreeable than American norms. They had high average facet scores on achievement striving, assertiveness, and openness to feelings; they had low average facet scores on openness to values, straightforwardness, and modesty. As an example, Washington showed an unusually high factor score for conscientiousness, but his scores were lower than the present American norms on openness, extraversion, and agreeableness. His facet scores were high in achievement striving, competence, assertiveness, discipline, and deliberation. Other facet scores compared to current American norms revealed him to be low in vulnerability

(he was able to tolerate adversity and stress), low in openness to values (he was traditional in morality), and low in tender-mindedness (he was less concerned about the unfortunate). Conscientiousness correlated .17 with presidential characters listed by Ridings and McIver (1997). Lower in conscientiousness than other presidents were Andrew Jackson, Kennedy, and FDR. T. Roosevelt was high in the facet of achievement striving, setting ambitious goals, and trying to meet them. (achievement striving correlated .32 to .39 with presidential greatness). Grant and Harding were not high in achievement striving. The facet of assertiveness correlated with greatness from .34 to .44. T. Roosevelt, Jackson, and Harding were highest in assertiveness, and Harding and Coolidge were lowest. Competence correlated with greatness ( $r = .30, .39$ ).

Lyndon Johnson grew up in the hardscrabble country of Texas with a knowledge of the history of the political careers of his forebears and father. Early on, he developed a strong need to dominate his peers whatever the cost. He conducted a single-minded pursuit of power, which he achieved by striking alliances with Texas moneyed interests and powerful congressmen such as Sam Rayburn, speaker of the House of Representatives (Caro, 1987).

Bill Clinton, highly intelligent, well educated, ambitious, and interpersonally competent, overcame his childhood in a troubled family from a small town, but effects on his personality remained. He compartmentalized his public and private lives. He could deny reality at times, block out problems, try to overcome almost any obstacle, and feel a continuing need for affirmation. He could remain optimistic in the face of serious problems and readily recover from setbacks. (Optimists do not ignore adverse information but use it to change their strategy.) Like many powerful leaders and presidents before him, such as JFK and Lyndon Johnson, he had a strong need for sex. Clinton was easily tempted by women attracted to powerful figures (Maraniss, 1998). He was regularly condemned for inconsistency and indecisiveness. Sometimes this stood him in good stead, such as when he announced that he had no further options but a military invasion of Haiti and then, the next day, sent peace negotiators (Sonnenfeld, 1994). In the 1996 presidential election, voters who rated Bill Clinton as charismatic-transformational and identified with the Democratic Party voted for Clinton; Republican voters did the same for Bob Dole (Pillai & Williams, 1998). Elsewhere, diagnostic profiles (Millon, 1990) of Clinton suggested that he was highly assertive/self-promoting, outgoing/gregarious and charismatic/extraverted, while Dole was highly controlling/dominant, conforming/dutiful, and deliberative/conscientious but low on interpersonality/agreeableness (Immelman, 1998).

Avolio (1999) extracted from Simonton's (1988) list the best and worst twentieth-century presidents in selected leadership styles. Ford scored highest in interpersonal style, which contributed to his success with Congress. Wilson and Nixon were lowest. A weakness in all these findings is that politicians, in particular, have different public and private personae. Truman's public image of irascibility and feistiness, for instance, was very different from his behavior with his staff and friends (McCullough, 1992). Consistent with what we noted earlier, Franklin Delano Roosevelt was highest in charisma and Coolidge lowest. McKinley and Kennedy were most deliberative, Truman least so. The two Roosevelts were most creative, Taft least so. Lyndon Johnson scored highest in neuroticism and Ronald Reagan lowest. Caprera and Zimbardo (2004) found a great deal of empirical support for the hypothesis that people vote for presidential candidates whose personality traits fit with the ideology of their preferred political party. Voters tend to elect presidents whose publicly expressed traits and values are congruent with voters' self-reported traits and values. Thus George W. Bush remains in favor with rightwing fundamentalist Christians despite the many failings of his administration.

### ***Charisma of American Presidents and Canadian Prime Ministers***

George Washington, because of his highly principled conduct as a military leader, was a great moral symbol in the new republic. The populace was suspicious of all forms of power. For it, virtue was the cure for

corruption. His refusal to accept the role of monarch or dictator made him the opposite of a personalized charismatic but a hero with socialized charisma and tremendous idealized influence. He was worshiped by his individualistic, republican countrymen. Writing on the death of the charismatic president Franklin D. Roosevelt, Walter Lippmann (1945) noted that the final test of such a leader is the conviction and will left behind for others to carry on. FDR's New Deal left a lasting legacy of liberal reforms. House (1985) content-analyzed the inaugural addresses, speeches, and writings of 10 charismatic and nine noncharismatic U.S. presidents along with four charismatic Canadian prime ministers. Judgments of charisma were based on how much the content referred: (1) values and moral justifications rather than tangible outcomes; (2) the collective identity rather than individual self-interests; (3) distant rather than close goals; (4) history; (5) positive worth and efficacy of followers; (6) high expectations of followers; (7) self-confidence. Charismatic presidents were more likely to be seen as effective by their cabinets (House, Woyke, & Fodor, 1988). Charisma was correlated with the overall performance, both economic and social, of 39 presidents (House, Spangler, and Woyke, 1989, 1991). According to content analyses of the writings of cabinet members, the judgments of presidential charisma for 31 presidents had path analysis coefficients of .51 with presidential direct action, .56 with personal use of power, .46 with domestic economic performance, and .46 with domestic social performance (House, Howell, Shamir, et al. 1994). John F. Kennedy was a highly charismatic president. His inaugural address set the tone for his administration: "The torch has been passed to a new generation." He emphasized contributions to the public good rather than private gain: "Ask not what your country can do for you, ask what you can do for your country." Kennedy's addresses were direct, factual, specific, and spellbinding with his visions of the future, such as putting a man on the moon in nine years to provide assurance that the Soviets would not remain ahead in the space race. Although in office less than three years before he was assassinated, he made many effective crucial decisions, except for the Bay of Pigs fiasco, which the previous administration had planned but for which he took responsibility. He was well prepared in advance to force the steel companies to rescind a 30% price hike after government mediation resulted in removing the need for large wage concessions to labor. Although he endorsed and sympathized with the Civil Rights movement, he introduced little legislation on the subject but paved the way for his successor, Lyndon Johnson, to do so in 1965. In 1962, he avoided a possible nuclear war with the Soviets after learning that the Soviets had installed a base in Cuba that could launch missiles to most parts of the United States. After thorough deliberation, based on photointelligence as evidence, he warned Nikita Khrushchev that he would embargo Soviet ships bringing missiles to Cuba and told the American public and the Soviets what Soviet actions would and would not be permitted. U.S. missiles in Turkey, on the Soviet Union's southern border, were subsequently withdrawn (Manchester, 1967). The crisis ended with a peaceful settlement. In 1963, Kennedy was planning to reverse the course of the U.S. commitment in Vietnam and American intervention, which eventually ended in 1975 in failure and the loss of 55,000 American and an estimated million Vietnamese lives (Sorensen, 1965). He was a strong supporter of the arts, sciences, and literature, and the White House, metaphorically, became "Camelot." His weaknesses were glossed over by the public in the reality and myth of his greatness (Lasky, 1966).

Among the 39 presidents through Reagan, Deluga (2001) found that charismatic presidents were also Machiavellian, according to prepared profiles of their behavior, which were then rated by 117 undergraduates. The presidents could and would engage in political expediency and duplicity. Highly Machiavellian presidents, as measured on the Mach Scale (Christie & Geis, 1970), were high in their levels of expressive activity, self-confidence, emotional regulation, and desire to be influential. For them, the ends justified the means. They could be deceptive. They exhibited both personalized and socialized charisma. They were opportunists. They built favorable images of themselves. Their public pronouncements were often at odds with their private opinions. When President Kennedy was told that black African ambassadors to the United Nation and the United States got into trouble driving through segregated Maryland to reach Washington, D.C., his response was "Tell them to fly." In the struggle for civil rights, both blacks and whites thought he was supporting their

opposing sides. President Eisenhower was personally opposed to the 1954 *Brown v. Board of Education of Topeka* Supreme Court decision, which declared school segregation unconstitutional, but publicly he did not voice his opinion (Reeves, 1995).

According to Rubenzer, Faschingbauer, and Ones (2000), great presidents earned lower scores on the facet of Straightforwardness on the NEO Personality Inventory, according to judgments of their biographies. When necessary, both Lyndon Johnson and Franklin Roosevelt tricked, cajoled, bullied, or lied. The correlation between Machiavellianism and charisma was .32. (Deluga, 2001). After the terrorist attacks of September 11, 2001, George W. Bush became more charismatic, according to content analyses of his speeches before and after the attack (Bligh, Kohles, & Meindl, 2004). Like many charismatic leaders, he was both loved and hated. In 2000, he lost the popular vote by more than 500,000 votes but won the disputed electoral count by four electors: The Supreme Court had stopped the Florida recount when Bush was ahead of Al Gore by 300 votes. As his father, President George H. W. Bush, had done, George W. Bush surrounded himself with top management team members who, except for his secretary of state, Colin Powell, thought alike. Long before the war with Iraq began in 2003, he ordered military planning for it in 2002, despite his public pronouncements that he had been reluctant to begin it (Woodward, 1994). George W. Bush lost many opportunities to improve the domestic economy because his chief of staff felt nothing needed to be done, his OMB director blocked ideas not his own, and his advisors kept telling him that more studies of the issues were needed. His vice president, Richard Cheney, was the secretive "power behind the throne." Adding to the lack of action were the stifling of debate within the team and the atmosphere of purposelessness in the presidential office (Kolb, 1993).

Twelve presidents were included in a student survey of biographies of world-class leaders by Bass, Avolio, and Goodheim (1987). After reading one or more biographies, students completed the Multifactor Leadership Questionnaire on one of the 12 presidents. On the transformational scales, of the 12 presidents, Kennedy, Theodore Roosevelt, Franklin D. Roosevelt, and Ronald Reagan were rated highest in charismatic leadership. Truman, Theodore Roosevelt, and Eisenhower were rated most individually considerate. Kennedy, Theodore Roosevelt, John Adams, Eisenhower, and Reagan were rated the most intellectually stimulating. On the transactional scales, John Adams and Theodore Roosevelt most practiced contingent reward; Gerald Ford most practiced management by exception. A more rigorous and extensive study of all 39 presidents was completed by Simonton (1986, 1988). Descriptive profiles were prepared from abstracts of standard biographical sources and presidential fact books. Individual biographies were omitted as sources of abstracts due to possible author biases. Seven students independently assessed each presidential profile using the Gough Adjective Check List (1985). Five factors were extracted: interpersonal, deliberative, neurotic, charismatic, and creative. Simonton's list correlated highly with previous lists and was used as the basis of other studies of greatness and effectiveness.

House (1985) asked eight historians to classify U.S. presidents and Canadian prime ministers as charismatic or noncharismatic. Seven of the eight historians were in complete agreement. The historians identified Thomas Jefferson, Andrew Jackson, Abraham Lincoln, Theodore Roosevelt, Franklin Delano Roosevelt, and John F. Kennedy as charismatic presidents and Calvin Coolidge, Warren Harding, Chester A. Arthur, James Buchanan, Franklin Pierce, and John Tyler as noncharismatic presidents. They also listed the following charismatic Canadian prime ministers: Ramsey MacDonald, Sir Wilfred Laurier, John George Diefenbaker, and Pierre Elliott Trudeau. Biographies of these presidents, prime ministers, and their cabinet members were content-analyzed to compare the effects of the charismatics and the noncharismatics on the cabinet members. To measure the presidents' behavior, House coded passages that indicated the leaders' display of self-confidence and their expression of expected high performance by their followers, confidence in their followers' ability and performance, strong ideological goals, and individualized consideration for their followers. The presidents' inaugural addresses were similarly content-analyzed to assess the presidents' achievement, power, and affiliation motives. The cabinet members of charismatic presidents and prime ministers attributed more positive affect to

them than did the cabinet members of noncharismatic presidents. The need for achievement and the need for power were higher among the charismatics than among the noncharismatics. The charismatic leaders were more likely than the noncharismatics to be seen as great and as effective (House, Woycke, & Fodor, 1988). In another analysis, charisma, combined with power and other needs, accounted for 37% of the variance in the overall performance of 39 presidents, 41% of the economic performance of their administrations, and 45% of their domestic social performance (House, Spangler, & Woycke, 1989).

Pillai, Williams, Lowe et al. (2003) replicated Pillai and Williams' (1998) study of what prompted 342 matched preelection and postelection choices of candidates in the 1996 presidential election. Again, the investigators found that attributions of charisma and transformational leadership were associated with their choices beyond party affiliation. Trust was an important mediating variable.

### ***Presidents' Effectiveness***

Franke and New (1984) showed that presidents' effectiveness from William McKinley to Ronald Reagan, as measured by policies that led to more efficient use of resources and increased employment and capacity utilization, was correlated with active presidents like T. Roosevelt rather than passive presidents like Calvin "Silent Cal" Coolidge. People were frustrated when they tried to get Coolidge to talk. He was elected vice president and assumed the presidency on Harding's death. He was elected for another term, having made neither enemies nor friends. He seldom solicited advice but showed concern for the workingman even though he was conservative. He practiced a laissez-faire style, intervening only when absolutely necessary. He believed that the chief business of America was business and government should not interfere with it (McCoy, 1967). He was neither aggressive nor self-confident and did not anticipate any future but the continued prosperity of the "Roaring Twenties" (Fuess, 1940).

Pritchard (1983) measured each president's effectiveness by the extent to which the senators and representatives of both parties voted for his proposals. Hargrove (1987) indicated that presidents' effectiveness depended on their manipulative skills in: (1) creating bargaining coalitions, (2) establishing authority over subordinates, (3) keeping prospective opponents off balance, (4) maintaining alternate sources of information and advice, (5) using power to leverage available institutional forces to influence other powerful figures, (6) remaining sensitive to the politics of policy making. Equally important for effectiveness were the abilities to (1) define the policy questions of consequence to the nation in terms of their historical emergence and felt necessities of the time; (2) suggest solutions and a policy agenda; (3) gain widespread support for the solutions. Timing was crucial. According to Adam Yarmolinsky, Lyndon Johnson never decided where he wanted to go until he could figure out how to get there. Jimmy Carter was seen as unsuccessful because he mostly ignored playing politics and tried to know and do what was right. He waited for his staff to provide information and failed to mobilize the political strength needed to take action. He failed to win a second term in office. While the average for the success of presidents from Wilson to Nixon in fulfilling their campaign promises was 75%, Carter was successful in fulfilling only 60% of his promises (Krukones, 1985).

Tourigny (2002) obtained the effectiveness ratings on the American Presidential Management Inventory by surveying 98 scholars in political science and American history. Each rated one president. She uncovered six higher-order factors that accounted for the variance in presidential effectiveness: (1) principle-guided actions (wisdom, judgment, impartiality) (44.8%), (2) vision (inclusive, responsive to constituents, and individually considerate of congressmen's needs and interests) (10.5%), (3) acknowledgement of differences (recognized ideologies, minorities, and protection of constitutional rights), (4) consultative and participative style (fostered collaboration between cabinet and Congress and collaborative decision making with subordinates) (5.2%), (5) moving Congress forward (clear guidance and monitoring of subordinates' efforts) (4.4%), (6) nondeceptive

means to achieve objectives (did not bypass the cabinet or use subordinates for personal benefit) (3.9%).

Franklin Delano Roosevelt is high on every presidential ranking for effectiveness. He led the United States into war when the country was isolationist. The country did not see the need to become involved in what was regarded as a war that the western hemisphere could stay out of. Roosevelt saw that if totalitarian forces prevailed in Europe and Asia, the United States would inevitably suffer the same fate. Using political credit, deception, manipulation, cajolery, coercion, haranguing, and enticing, he led Congress to pass needed legislation to help Britain against Germany, such as the Lend-Lease Act of 1940, which transferred 50 aged destroyers to Britain in exchange for granting bases in British possessions to the United States. He said, with tongue in cheek, "We'll take the ships back after the war." Gradually he increased support for Britain and its empire, which in mid-1940 were fighting almost alone against Germany and Italy. In 1941, he embargoed shipments of American oil to Japan and got the Dutch in the Dutch East Indies to do the same. Without oil, the Japanese economy and military machine would have collapsed. Japan's response was the attack on Pearl Harbor and the invasion of the Dutch East Indies. He provoked Adolf Hitler with taunts that led Hitler and subsequently Benito Mussolini to declare war on the United States, ensuring the demise of totalitarianism in Italy in 1943 and in Japan and Germany by 1945. Roosevelt allowed the different ideologies, identified problems, and solutions of his staff to compete with one another until a practical solution appeared. He said a leader should not get too far ahead of his followers; otherwise, when he looked around, nobody would be there.

Bill Clinton lacked discipline in his daily routine. He procrastinated after lengthy meetings and would return to the same question again at the next meeting with his advisors. He might delay necessary decisions for months, which drove his advisors to despair. He was knowledgeable and highly educated and conceived many alternative answers to a question. His public speaking made members of big audiences feel as though they were being addressed personally. He was a political centrist, sought conciliation and consensus, and employed military force sparingly despite many international provocations. He was hated by a large right-wing minority and was close to being impeached and convicted for lying about his sexual peccadilloes. Nevertheless, his policies made him an effective president. His 1993 spending cuts and tax increases set into motion economic prosperity to the end of the century. His welfare reform legislation in 1996, counter to the philosophy of his political allies, was effective in moving many welfare recipients to seek training and work. His military and diplomatic interventions in Bosnia, Kosovo, and Serbia brought peace to the Balkans after 10 years and war criminals to trial (Harris, 2005).

Ronald Reagan was a highly popular president and an extremely effective communicator. He had an informal style of delivery that made him attractive and successful at winning elections and getting most of the legislation his administration endorsed accepted by Congress. He cut inflation, taxes, and regulations but greatly increased the deficit and the national debt. Critics accused him of playing the role of president, during his two terms in office, from outlines prepared for him (Slansky, 1989). Liberal evaluators questioned whether his administration's probusiness, antienvironmental, and military goals were in the best interests of the country. He hired many business friends and delegated too much. He was unable to discharge people. He was controlled too much by his staff, wife, and friends. He was easily influenced when he was unconcerned about an issue yet stubbornly held to his position on issues about which he lacked knowledge but felt strongly (G. Winter, 1987). He was outspoken and made many gaffes in expressing himself, both in his words and in his behavior (Gates, 1989). He failed to control his subordinates adequately and was too impulsive. He committed faux pas ranging from confusing events in movies with real events to falling asleep in an audience with the pope. One of many Reaganisms referred to the Nicaraguan contras, whom he illegally tried to support against the Sandinista government, as "the moral equal of our Founding Fathers." Nevertheless, he was labeled "the Teflon president," as none of these mistakes in policy and speech stuck to him. His popularity remained high during his two terms in office.

Given the negative impact of laissez-faire leadership detailed in [Chapter 25](#), how does one explain the effects of President Ronald Reagan's generally laissez-faire leadership style, which was based on his stated belief that he was properly delegating when he sat back and let his subordinates proceed as they thought best? Reagan was able to leave office in 1988 with one of the highest popularity ratings (64% to 68%) of any U.S. president in a public opinion poll. One explanation may be his choice of subordinates. With subordinates, such as David Stockman, who were highly competent, great achievements were possible. With sleazy or incompetent subordinates, like Edwin Meese, the results were disastrous. The disaster was compounded when a subordinate cabinet officer, such as Samuel Pierce of the Department of Housing and Urban Development, was an extremely laissez-faire executive himself (Waldman, Cohn, & Thomas, 1989). The astute management of the news by his staff helped make it possible to credit Reagan with the successes of his subordinates and to distance him from their failures. He remained the "Teflon president," immune to the many scandals that marred his administration. Furthermore, although Reagan exemplified the laissez-faire leader in much of his behavior, he was also a mass of contradictions in his orientation and style. He did a lot of homework after hours; nevertheless, he was described as the "least informed of the presidents I have known," by former Speaker of the House Tip O'Neill. He remained highly charismatic. He derided the plight of the disadvantaged as a group yet often exhibited compassion for an unfortunate individual.

Although it is obviously impossible to evaluate Reagan's overall success and effectiveness as a president at the time of this writing, from this vantage point, his presidency appears to have been a highly mixed bag. The end of the cold war and the Soviet Union was attributed partly to Reagan's policies and speeches. Popular tax reform was matched with a mounting gap in the distribution of income between the rich and the poor. Diplomatic victories were matched by the transformation of the United States from the world's largest creditor nation to its largest debtor nation. The perceptions of Reagan's building of U.S. military strength and power were matched by the country's relative economic decline related to Japan and western Europe. Although Reagan's administration exerted leadership in developing improved relations with and solutions to problems in Canada, Angola, and the Middle East, it followed, rather than led, the way to improved outcomes in the Philippines, Latin America, and the Soviet Union, for which the administration was quick to take credit. The subsequent breakup of the Soviet Union was credited to his policies, leaving the United States without a rival world superpower. An archproponent of a balanced budget, Reagan nevertheless instituted policies that resulted in a budget deficit that was larger than the deficits created by all his predecessors combined. The good feelings the American majority had for him when he left office were coupled with the worsening problems of land despoilation, drugs, child care, care of the elderly, homelessness, health costs and insurance, education, acid rain, of savings and loan bankruptcies, and nuclear waste. Many of these problems were left to be addressed seriously by his successors. To conclude, Ronald Reagan's laissez-faire style did not seem to hurt his overall popularity, but it no doubt resulted in considerable ineffectiveness, especially when he had to depend on irresponsible, incompetent, or laissez-faire subordinates and when he made statements or deals without consulting with more knowledgeable colleagues.

### ***Presidents' Greatness***

Arthur Schlesinger, Sr. (1948), asked 55 experts, mostly historians, to use their own criteria to judge the greatness of the presidents from Washington to F. D. Roosevelt. He repeated the effort in 1962 using an additional 20 experts, mainly political scientists. In both polls, the top five presidents in greatness were Abraham Lincoln, George Washington, Franklin D. Roosevelt, Woodrow Wilson, and Thomas Jefferson. At the bottom of the list were Ulysses Grant and Warren Harding. Thomas Bailey, in 1962, created 43 tests of greatness to apply to each president. His list of presidents was close to Schlesinger's: Lincoln, Washington, and

Roosevelt came out as greatest. A similar consensus of greatness was obtained by Maranell (1970) and the American Historical Society in 1977. The society asked 100 history department heads to name the ten greatest presidents. Lincoln, Washington, and Roosevelt topped the list. In 1982, the *Chicago Tribune* asked 49 leading historians and political scientists the same thing. The same three presidents were at the top (Neal, 1982). With similar findings, D. Porter (1981, unpublished) also asked 41 American historians for the presidents with the lowest ratings. Those named were Nixon, Buchanan, and Harding. Murray and Blessing (1983) provided some of the preceding information and also conducted a poll of their own. They sent 1,997 questionnaires to PhDs in history with the rank of assistant professor or higher. They received 953 completed returns. From the mean ratings, four presidents were considered by the investigators to be great: Lincoln, F. D. Roosevelt, Washington, and Jefferson. Considered near great were Theodore Roosevelt, Wilson, Jackson, and Truman. Above average were John Adams, Lyndon Johnson, Eisenhower, Polk, Kennedy, Madison, Monroe, John Quincy Adams, and Cleveland. At the bottom of the list were Andrew Johnson, Buchanan, Nixon, Grant, and Harding.

### ***Revisions in Reputation***

Often it takes years following a president's time in office to judge the effectiveness of his policies while in office. President Eisenhower was regarded as mediocre during his time in office, with an image of caring more for playing golf than leading the country. Although he delegated much work to his subordinates, he was actually active and successful and set a high standard for integrity and trust in domestic politics. He reached a truce with North Korea in 1953 that has lasted more than half a century and in 1955 began the Interstate Highway System, which revolutionized suburbia and intercity travel. He had the foresight to warn against the military-industrial complex. Judgments of his effectiveness have been revised upward considerably (Hoxie, 1983). Among presidents from Truman to Reagan, Eisenhower was rated highest (and Nixon lowest) in 2000, in effective servant leadership decision making by a sample of Canadian and American scholars (Tourigny, 2000). As a former military commander, Eisenhower understood the limits of power in international affairs and considered the use of overt military force as a last resort (Saunders, 1985). The same was true of Harry Truman, who, when he took office in 1945 after the death of FDR, was seen as a failed haberdasher. Without experience and without knowledge of FDR's plans and commitments, Truman was seen as totally unprepared for the office. A strict party man, he was perceived as beholden to big-city political bosses. His popularity plunged further when he dismissed Douglas MacArthur as commanding general of U.N. forces in the Korean War for failing to bring peace. Nevertheless, although his responsiveness to public concerns decreased (K. Smith, 1983), Truman's reputation was revised upward by his performance as a statesman and for the many tough decisions he made, such as using the atom bomb on Hiroshima and Nagasaki in 1945 to bring World War II to a speedy end, avoiding a predicted million American casualties from invading Japan. He was behind the Marshall Plan, which set a prostrate Western Europe back on its feet. He promulgated the Truman Doctrine in 1948 to halt the Communist takeover in Greece. This was an early example of support for containing Soviet expansion, which was U.S. foreign policy until the breakup of the Soviet Union in 1991 (Coffey, 1985). He racially integrated the military forces in 1948, a time when segregation was in force in the South and de facto in much of the rest of the country. He also took decisive action to deal with a national coal strike that threatened a large percentage of industrial operations and home heating. He was equally forceful in avoiding long, injurious national steel and railroad strikes (Gardner, 1987; McCullough, 1992). Also, among presidents from Truman to Reagan, he was almost the highest in his relations with Congress as a servant leader in principle-guided action, moral empowerment, and universal, constitutional, and humanitarian values, according to a sample of Canadian and American scholars (Tourigny, 2000).

While in office, Gerald Ford was seen as a nice guy, a plodder, whose public speaking style was unanimated, who stumbled when walking downstairs, who was appointed, not elected, and who pardoned Richard Nixon after he had resigned, to avoid Nixon's impeachment over the Watergate scandal. But Ford was the right man to take over the office, as required by the Constitution, for the 30 months he served. His pardon of Nixon, the amnesty program for 50,000 Vietnam War draft evaders, and healing some of the other wounds of the Vietnam War moved public attention away from these virulent media issues and redirected public attention to the future. Ford picked qualified people for his cabinet and as advisers. For instance, he chose Edward Levi, dean of the Law School at the University of Chicago, to be his attorney general, and Henry Kissinger to head the State Department. He was a manager without much vision, but he got his cabinet to work by encouraging expressions of differing views and vigorous debate. He defined realistic objectives, established principles to reach the objectives, determined the path to the goals, and as the former speaker of the House was flexible in his negotiations with Congress. He inherited and turned around an economy that was suffering rampant double-digit inflation when he came into office. To some degree, he went beyond political expediency (Hersey, 1975; Casserly, 1977; Nessen, 1978; Hartmann, 1980).

### ***Why Presidents Fail***

Many of the presidents' failures could be attributed to their tendency to ignore warnings from their many sources of information. The federal government had a large early warning system to watch the oil industry but the Nixon administration failed to take early action that could have mitigated the 40-fold increase in prices engineered by OPEC. Instead, Nixon and Secretary of State Kissinger suggested that the shah of Iran, a member of OPEC, should raise oil prices to pay for armaments to be used to defend the oil-rich Persian Gulf region. Continued warnings of the public unrest in Iran went unnoticed. Carter did not pay attention to his State Department Iranian experts, who warned him in advance of the Iranian attack on the U.S. Embassy in Tehran, after which Americans were held hostage for 444 days. The CIA issued five advance warnings that Fidel Castro was planning to ship Cuban criminals and mental patients to Florida from Cuba, which Carter could have prevented. Carter was taken by surprise by the Soviet invasion of Afghanistan. He had made the mistake of believing Leonid Brezhnev, who lied to him. With intelligence reports about the plans of Argentine generals, Reagan might have prevented the Argentinian invasion of the Falklands by disabusing the generals of their impression that the United States supported their invasion. Reagan wanted policy memos and alternative proposals reduced to a single page. Top advisors showed their loyalty by telling him what they thought he wanted to hear. He took the wrong steps in dealing with the civil war in Lebanon. In the Iran-contra scandal, cash was obtained by Reagan administration staff by secretly and illegally providing Iran with missiles. Then the money was used illegally to support the Nicaraguan contras fighting the Sandinista government forces. Reagan apologized, admitted failure and took personal responsibility. He acknowledged that that mistakes had been made and appealed for America to move on (J. Anderson, 1983).

Reagan favored reducing federal regulations and relying more on free markets to allocate resources, giving freer rein to business. He cut the budget for environmental protection and weakened enforcement. States and localities were to be more responsible for the environment. Ideology and loyalty determined his appointments. Policy planning was centralized in the White House (Kraft & Vig, 1984).

Ulysses S. Grant was a victim of pressures from Republican Party bosses to avoid taking a stand against robber barons' raids on railroad property. William Howard Taft had been T. Roosevelt's efficient assistant. He was the charismatic Roosevelt's successor as president in 1908, and Roosevelt expected him to carry on with his plans and policies, which he did not do. Taft came in a distant third when seeking reelection in 1912. Roosevelt formed the Bull Moose Party to run against him, allowing Woodrow Wilson, a Democrat, to win

the election. Taft would not engage in political bargaining and scheming. He would not play party politics but remained concerned for the public good. He was honest and friendly but unfortunately surrounded himself with Roosevelt's enemies. He did succeed in enacting legislation that was highly beneficial to the country (Cotton, 1932).

Warren Harding is at the bottom of most lists of presidential accomplishment, prestige, activity, and strength of action. His failings included his loyalty to corrupt friends (Trani & Wilson, 1977), his poor cabinet appointments, his lack of education, and his political ineptness (Murray, 1969). Herbert Hoover had the misfortune to take office 10 months before the stock market crash of 1929 and the onset of the Great Depression. The unemployment rate was 25% when the time came for him to seek reelection. As a conservative Republican, his attitude toward government intervention was that the economy would recover by itself. But the economy kept getting worse during his administration. Hoover failed because he was extremely introverted, sensitive, and proud of his integrity, which led him to try to work for the best interests of the country as he saw it. He lacked the kind of persona to speak out with confidence that FDR, his successful successor in 1932, demonstrated extremely well. Hoover blamed his Quaker background for his desire for privacy, which led him to prefer to work as much as possible behind the scenes of administration, which he did very well. He was a mining engineer who gained his fame by effectively organizing and administering Belgian war relief. He raised the necessary funds and arranged for the transportation of millions of tons of concentrated food for four years at the end of World War I. He preferred to credit his subordinates and newspapers for the success rather than himself (Burner, 1979; Hoff, 1975). But he did little to ameliorate the Great Depression or its effects, which began soon after he took office. He was opposed to government intervention and believed the business cycle would take care of itself.

Richard Nixon's Quaker background had a different effect. Like Hoover, he distanced himself interpersonally. Although Nixon had won reelection in 1972, was highly intelligent like Hoover, and was the statesman who established relations with China, at the time of his resignation, Nixon was the least loved modern president. It was a relief when he resigned in 1974. He was seen as a self-aggrandizing exploiter without principle. He was secretive, manipulative, self-righteous, hypocritical, insecure, untrusting, and self-righteous. He used innuendo, trickery, fraud, and ruthless single-mindedness in winning elections. He was determined to succeed at all costs. But he was unable to make close friends. He was uncomfortable making social conversation and being onstage. He often supported both sides of an issue (Ambrose, 1987). He was in constant conflict emotionally between his extreme ambition and what he felt he needed to do socially as a politician (Abramsen, 1977). He never seemed able to run a clean election campaign. The Watergate break-in was not the only Nixon scandal. Incidents of sabotage, extortion, forgery, and slander were reported in his earlier campaigns for Congress. In office, he was autocratic and controlling (Mankiewicz, 1973).

Jimmy Carter was a puzzle as president. He attempted to be a transformational leader, with lofty ideals and principles of ethics and the common good that were not understood by transactional politicians, for whom trading favors was more important. He avoided the dramatic, rhetorical style of his predecessors, played down his own importance, and did not show up on television as a powerful leader (Meyrowitz, 1980). He was seen by his critics as indecisive, rigid, and unable to be practical and accept compromise in order to take necessary actions (Mollenhoff, 1980). According to interviews by Mazlich and Diamond (1979) with those close to Carter, he was tied down by self-imposed constraints, such as a concern for human rights. From his mother came a strong social consciousness. From his father came a strong competitiveness. After success in business, he turned to politics, where he could satisfy both drives. Coming late to a political career, he was always an outsider in Washington. He was close only to his family. He was emotionally conflicted between his southern heritage and his moral and rational support for African Americans' civil rights. He was a populist who believed that people were inherently good; they would know and do what was right without his needing to explain his intentions to them. But Congress was another matter. He read all the details of every legislative bill that came

to his office before signing or vetoing it. Believed to have a photographic memory, he stored a lot of data in his head. As a former nuclear engineer and naval officer, he used systematic problem solving, weighing the alternatives, to choose the best solution to a problem. However, he saw each problem in isolation from other issues. He was modest about his abilities but was expected to find the answers to the nation's problems. Despite his highly orderly, disciplined, and hardworking character, and despite his empathy for the less fortunate, he lost the confidence of the public by making forceful speeches about matters he could do little about. Like George W. Bush, another "born-again" Christian, he tried to appeal to moral and religious values, but, unlike Bush, he failed to be reelected (Mazlich & Diamond, 1979). Although Carter espoused democracy in the abstract, he was actually a highly directive leader. His failures to consult with his staff and Congress led to many mistakes. His model for leadership was the highly directive and controlling perfectionist Admiral Hyman Rickover, who was known for not providing subordinates with feedback unless it was negative (Glad, 1980). Carter was seen by his subordinates as the sole decision maker. He was a demanding boss and retained tight control. When he had to delegate minor projects, his delegation was done poorly because he failed to provide sufficient information about what was needed (Jordan, 1982). Critics saw this as evidence of administrative disorganization despite Carter's retaining tight control. According to a survey of 212 career civil service executives in his administration, he lacked the political and personal skills to convince them of his legitimacy as a manager (Benze, 1981). Carter used his advisors to teach and facilitate, but not to provide answers. Despite his failure in office, he became one of America's best *ex-presidents*. He began this next career while he was still president by mediating a peace agreement between Israel and Egypt that has lasted since 1977. Since then he has served as a successful mediator of many international conflicts in other countries, such as that between Indonesia and East Timor.

George H. W. Bush neglected domestic economics and in the 1992 campaign for reelection failed to judge the public mood. One of George W. Bush's failings was his unwillingness to admit mistakes. Genovese (1996) suggested that presidents' failure could be avoided if the traits of many presidents could be combined in one person: Kennedy's vision, Johnson's political skill, Nixon's in-sights, Ford's integrity, Carter's trustworthiness, Reagan's personality, G. H. W. Bush's experience, and Clinton's interpersonal skills. Aside from Clinton's private mis-steps, which cost him dearly, Clinton tried to maintain moderation in his decisions and policies but failed to arouse legislative support from his strong stands on positions (Burns & Sorenson, 2000). Always wanting to be liked, he responded almost daily to public opinion polls in determining his actions. George W. Bush sunk to the lowest public approval ratings of 30% for a president since Nixon, he even lost the confidence of many among his Republican congressional majority. Despite the continued optimistic spin on his many domestic and foreign policy failures, the realities of mishandling, incompetence, and arrogance of his administration set in. But conservative commentators disagree about whether he continues to be successful or is starting to fail (Kakutani, 2006).

## Prime Ministers and Chancellors as Leaders

---

Several dilemmas face prime ministers in parliamentary forms of government. How should they maintain control over policy while other members of their cabinet are delegated authority? How much can they shape the policy agenda when problems and opportunities can be posed by other members of the government? (Karbo & Hermann, 1998). They may pursue a leadership style of relating to constituents and other leaders and management strategies that is reinforced by their first and subsequent political successes (Barber, 1977). They may consult with their cabinet as a whole, a smaller committee of cabinet members, or individual members. They may impose or advocate a position, bargain, or be participative. A hundred press conferences and parliamentary question period news reports were content-analyzed by Karbo and Hermann (1998) for

British Prime Ministers Margaret Thatcher and John Major and again for German Chancellors Konrad Adenauer and Helmut Kohl. The leaders' responses were scored for responsiveness to political constraints, openness to information, motivational orientation, and expansionist or opportunistic political orientation. Thatcher and Adenauer challenged political constraints; Major and Kohl respected them. John Major was more open to information than were the other three leaders. Thatcher and Adenauer were more concerned about tasks and problems; Major and Kohl were more oriented to relationships. Thatcher and Adenauer had an expansionist political orientation. They wanted to increase their control over people and resources. Major was most opportunistic, and Kohl was most politically oriented toward being influential. Tony Blair stands out as a prime minister who was truly transformational. Neither extremely conservative nor extremely liberal, he was able to take a middle position that transformed the Labor Party and enabled his domination of politics in Britain for 12 years as prime minister. Seen as the giant of his age in Britain, he has appeared as extremely earnest and ambitious rather than cynical. He willingly took on unpopular causes such as the war in Iraq. He advanced a morally idealistic, communitarian vision with the family as the most important institution in society. His political style was to reconcile opposites: fiscal discipline with social spending, tough anticrime and antiterrorism policies with compassionate welfare assistance, free-market policies with government activism.

## Summary and Conclusions

---

Providing strategic leadership is an important role for CEOs and senior executives. They are challenged by the need to honor the past and present while considering the future of the organization and its environment. They need to support both continuity and change. By scanning their organizations and the surrounding environment, strategic leaders formulate the goals and directions of the organization and communicate them. Using consultation, intuition, and a long-term perspective, they make strategic decisions that affect corporate profitability and the success of nonprofit organizations. Strategies can follow a variety of approaches ranging from purely economic considerations to emphasis on good human and customer relations. Modern strategies will need to fit the environment and organizations to which the leaders belong.

---

# Environment and Organizational Effects

As recognized by Jenkins (1947) and Stogdill (1948), the traits required in a leader are related to the demands of the situation (Jenkins, 1947; Stogdill, 1948). In a review of situational aspects of charismatic leadership, Shamir and Howell (1999, p. 258) took the more qualified view that the principles and processes of charismatic leadership “—apply across a wide variety of situations; however, there are situations in which they apply more than in others. ... [Leadership] emergence and effectiveness ... may be facilitated by some contexts and inhibited by others.” Individuals differ in their motivation to lead, but their motivation will depend on whether they are in a hierarchical, professional, or entrepreneurial organization (Smith & Miner, 1984). U.S. presidents are more likely to be successful if they introduce administrative actions and proposals for legislation as early as possible in their terms (Barber, 1985). Sayles (1958, 1979) and Osborne (1999) focused attention on the interaction between managers’ roles, organizational designs, and organizational environments. Nebeker and Mitchell (1974) found that differences in leaders’ behavior could be explained by the leader’s expectations that a certain style of leadership would be effective in a particular kind of situation. For example, the success of the careers of 310 British and U.S. managers in 28 different companies corresponded to the extent to which the managers’ achievement orientation matched their companies’ support of risk taking. The managers’ success was evidenced by the progress of their salaries compared to their age. On the other hand, other matches of orientation and the company situation that were expected to make a difference in the managers’ advancement failed to do so (Ansari, Baumgartel, & Sullivan, 1982).

The preceding chapters have examined the personal and situational aspects that account for leadership. In these chapters, we have put more emphasis on general effects across situations and on personal predispositions. Now we will accent situations and contexts, keeping generalities and personal predispositions in mind. Contingencies of situation and predispositions of leaders and followers can give rise to hypotheses about the emergence of successful transformational leadership. For instance, inspirational leadership is likely to arise if the leaders are articulate, the followers are inexperienced, and they are faced with ambiguous tasks, goals, and reinforcements. Considerate leadership is more likely with caring, empathic leaders and inexperienced subordinates with unmet needs. Intellectual stimulation will more likely be generated by a rational and unconventional leader with inexperienced subordinates. Contingent reinforcement will appear if a materialistic leader is in control of material reinforcements and materialist subordinates. Active management by exception will be more likely to appear with a task-oriented leader and inexperienced subordinates working in a context of objective, measureable performance. Passive and laissez-faire leadership are more likely to emerge where tasks, goals, and reinforcements are unimportant, where the leader is neither task-nor relations-oriented, and the subordinates are experienced.

O’Connor and Farrow (1979) illustrated the significance of fitting leaders’ behavior to the situation. They demonstrated the personal satisfaction that accrued from matching the amount of structure required by managers in research and production and the managers’ preferences for such structure. Similarly, managers reported that they needed to engage in political and manipulative behavior most often in organizations that lacked structure, where there was much continuing ambiguity about goals and processes and a great many technological uncertainties (Allen, Panian, & Lotz, 1979; Madison, Allen, Porter, et al., 1980). While transformational leadership of department managers predicted business unit performance a year later, the effect

was moderated by support provided for innovation (Howell & Avolio, 1993). Yet, based on 37 years of observation and membership in the U.S. Army and large civilian organizations, Ulmer (1997, p. 78) declared, "Good leaders in our Army look very much like good leaders elsewhere." Such leaders show flexibility in responding to different situational requirements. Quinn (1988) provided a competing values framework that set forth that leaders need to focus on predictability and order in situations requiring centralization and integration. But they need to value spontaneity and flexibility if situations call for decentralization and differentiation. Hunt and Phillips (1991) were able to apply Quinn's model to illustrate the various attitudes, values, and behaviors needed by military commanders for successful leadership in garrison and in combat.

## Trait Approach versus Situation

---

As was noted in [Chapter 4](#), the trait approach is not enough for understanding leadership. Above and beyond personal attributes of consequence, the situation can make a difference. Whereas some types of leadership are reported or expected of leaders in all situations, other types are more specific to particular types of situations (Hemphill, 1952). For instance, according to a survey by Hemphill, Seigel, and Westie (1951), when a group has a high degree of control over its members, the leader is expected to dominate and actually does so. In groups whose members participate to a high degree, however, these expectations and reports of leader domination do not occur.

What is required for leadership in a stressful situation is likely to differ from what is needed in calm and steady circumstances. For a given leader in one situation or the other, some subordinates are likely to be more experienced, more motivated, or better adjusted to their situation. The leader may need to deal differently with various kinds of subordinates. Some leadership behavior is a function of individual differences, but other leadership behavior appears to depend mainly on situational differences or on the interaction of the individual and the situation. Any full account requires the "within-and-between" analysis (WABA) advocated by Dansereau, Alutto, and Yammarino (1984). WABA allocates the percentage of variance in leadership behavior and the percentage of the effects of the leadership on performance and satisfaction to the leaders across situations, across the groups led, and to the individual leader-follower relationships within the groups led. Thus for 116 insurance agents in 31 work groups, Yammarino, Dubinsky, and Hartley (1987) showed that 28 percent of the average correlation of subordinates and supervisors about the subordinates' performance was attributed to the differences among the work groups and their leaders. Fourteen percent was attributed to differences among the subordinates within the work groups led by the same supervisor. The remaining variance was attributed to fluctuations of the followers' relations with some leaders but not with others. For a sample of 83 retail sales associates in 26 work groups, only 14% could be attributable to differences among the supervisors, while 7% was due to supervisor-subordinate relations within the groups.

Stogdill's (1951b) study of transferred naval officers suggested that some behaviors of the transferee in the new situations were characteristic of the transferee himself rather than of the position. Such behaviors included a tendency to delegate authority; to spend time in public relations; to evaluate, read, and answer mail; to read technical publications; and to spend time with outsiders. But other behavior, such as the amount of personal contact time; time spent with superiors; and time spent in supervision, coordination, and writing reports, was more a matter of demands of the situation. Barnlund (1962) rotated 25 participants in differing combinations in differing groups dealing with differing tasks and erroneously concluded that the individual participants were less important than the situations involved in the emergence of the leaders of the groups. Kenny and Zaccaro (1983) recalculated Barnlund's statistics and showed that 49% to 82% of the variance in who emerged as leader was due to some stable aspect of the individual leader. Again, Zaccaro, Foti, and Kenny (1991) conducted a similar experiment using 108 undergraduate students who rotated through four different group

tasks. Fifty-nine percent of the variance in the leadership that emerged was due to the individual students across the four group task situations. The students' self-monitoring was of consequence.

## ***Patterning***

W. O. Jenkins (1947) reviewed a large number of military studies that indicated that the traits required in a leader are related to the demands of the situation. Stogdill's (1948) review of 124 studies from a broader array of situations suggested that although there may be general traits associated with leadership, the patterns of those traits required for leadership differ with the situation.<sup>1</sup> Subsequently, DuBrin (1963) found that a leadership inventory, consisting of both trait and situational items, correlated significantly with a leadership criterion, whereas neither set of items alone was significantly related to the criterion. Again, O. L. Campbell (1961) reported significant differences among leaders in eight different situations when described on the Consideration and Initiating Structure scales of the Leader Behavior Description questionnaire (LBDQ).<sup>2</sup>

## ***Leadership Styles***

[Chapter 19](#) examined the premium placed on the maturity of subordinates by the Hersey-Blanchard (1977) situational leadership model in determining what style of leadership is appropriate. Even Blake and Mouton (1964) would agree that how the 9,9 style—integrated, highly task-and relations-oriented leadership—properly manifested itself in a leader's behavior depended on a subordinate's maturity. Vecchio (1981), among many others, concluded, from an analysis of LBDQ data from 107 subordinates' descriptions of their supervisors, that a matching of the leader's style to the needs of subordinates and the work setting yielded the maximum satisfaction of subordinates with the leadership. Such matching was seen as the reason that when each of four CEOs displayed a different pattern of traits, all four emerged as effective leaders in their four different organizational cultures (Free, 1983). Again, in Fiedler's (1967a) contingency model detailed in [Chapter 19](#), relations-oriented leadership is optimal when the situation is neither highly favorable nor highly unfavorable to the leader in terms of his or her esteem and power and the situation's structure. Task-oriented leadership is optimal when the situation is either highly favorable or highly unfavorable to the leader.

*Situations Alter Leadership Styles.* Much has been learned about how the demands of a task and the characteristics of immediate group members modify the type of leadership that occurs. The *external environment*, the *organization* in which the tasks are to be accomplished, and the *leader's group* may exert important effects on the leader's behavior. Modern theories of leadership style take note of how the leader's behavior is systematically changed by changes in situational conditions (Evans, 1974). Changes in the complex organization and its external environment will ordinarily bring on changes in its leadership. As organizations mature, the charismatic founders of social movements usually give way to bureaucratic successors.

In the case of the union movement in the United States, unions had to struggle first for recognition, then to become established institutions. Now many are struggling for survival. In each stage, the requirements for leadership differed. The low-paid, lower-skilled immigrants with limited English who made up the members of the United Steel Workers changed to a new generation of highly paid, skilled, English-speaking, better-educated members. Leading them required new approaches. Patronage had to give way to persuasion. Newer issues involving the match between the leader and the situation emerged. These issues reflect societal changes, the sharp increase in political and legislative intervention into the world of work, and the changed relations between employers and employees. Further changes in the leadership of the steel union were necessary to deal with the impact of foreign competition and new technologies.

Again, doing business successfully in the competitive and rapidly changing global market and its rules required leadership that was visionary and dedicated with “a balanced scorecard, corporate accountability, (creation of) dynamic capabilities, (and) effective management of intangible resources and assets.” (Zahra, 1999, p. 36). The importance of the situation was illustrated in the case of a successful and effective transformational Minnesota school superintendent who greatly improved her distressed district. She became less successful as a leader when she was appointed a state commissioner in a bureaucratic agency, larger and more complex than her district, that provided her with less freedom to take initiatives and display her transformational qualities (Roberts & Bradley, 1988).

*Leaders Change Situations.* In all this, one must keep in mind that leaders are not merely reactive to situations; often they can change the situation to suit their own proclivities (Yukl, 1971; Fiedler, Chemers, & Maher, 1976; Wofford, 1982). Graen and Uhl-Bien (1995) advised that leaders could improve the quality of their group’s performance by developing better relations with all of the members. In 1917, the German leaders sent the exiled Lenin from Zurich to Saint Petersburg, enabling him to initiate the Bolshevik Revolution and achieve a peace treaty with Germany. Many of the world’s most eminent leaders could not be deflected from their pursuits by environmental, organizational, or collegial considerations.<sup>3</sup> Thus, Singh (1982) argued that Indian managers must avoid allowing the situation to dominate them to such an extent that normlessness results. Fiedler advocated training the leader to make the situation better fit the leader’s LPC orientation. What leaders do can predict long-term organizational alignment, adaptability, and excellence (O’Toole, 1995). Dan Wiens (Dyck, 1994), the Canadian farm movement ecodevelopment leader, envisaged changing the agrifood system to fit environmental and democratic values and principles. He set an example by building his leadership on participative involvement and empowering collaboration. The organizational climate and financial performance of 50 Dutch supermarkets were improved if their store managers were charismatic and considerate in their leadership (Koene, Vogelaar, & Soeters, 2002).

## Theories, Models, and Prescriptions

---

Increasing attention has been devoted to providing rationales for understanding the connections between personal and situational effects. Katz and Kahn’s (1966) introduction of systems theory to the study of leadership and social interaction is illustrative. Most efforts to develop theories, models, and prescriptions for directly fitting the leader’s behavior to the situational requirements appear somewhat like Ashby’s (1957, 1960) Law of Requisite Variety that the functions evolving within a brain or created within a computer must be differentiated to match the different elements in the outside environment with which they must deal. The variety of the leader’s behaviors must coincide with the situational demands that parallel them. Or the explanations take the form of tautologies. The appropriate leadership is that which serves to fix, or get five others to fix, whatever is malfunctioning or less than optimal in the system.

One also has to remain alert to the possibilities of coincidental correlations between leadership attributes or behavior and situations, since theories may inadvertently be built on them. One needs to see the link of direct or indirect causation of the situation on the leader or the leader on the situation. An organization’s size itself may correlate with a more directive leadership style but cannot account for it. Mediating organizational and psychological processes that are connected with both size and leadership are needed to confirm and understand the relationship (Indik, 1965b).

Kerr, Schriesheim, Murphy, and Stogdill (1974) reviewed how situational elements determined whether consideration or initiation of structure was more effective.<sup>4</sup> Among the situational variables found to determine whether initiation of structure or consideration yielded satisfaction and productivity were the subordinates’ need for information, job level, expectations of the leaders’ behavior, and perceived

organizational independence. Also important were how similar the leaders' attitudes and behavior were to the managerial style of higher management and the leaders' upward influence. In addition, the effects of the task, including whether there were pressures to produce and provisions for intrinsic satisfaction, were significant.

Yukl (1981) specified the situations in which 19 leadership behaviors would be most essential. For task-oriented behaviors, for instance, Yukl put forward that the leaders' emphasis on performance is needed more when subordinates' errors and deficiencies in the quality of products are costly and difficult to correct or would endanger the health and lives of people. Leaders can structure reward contingencies better when it is possible to measure the subordinates' performance accurately. More role clarification is desirable when the organization has elaborate rules and regulations and subordinates are not familiar with them. Goal setting by leaders is more effective when the outcomes of performance are highly dependent on the subordinates' efforts and are not strongly affected by fluctuating conditions that are beyond the control of subordinates. The dissemination of information by the leaders is most important when the work of subordinates is strongly affected by developments in other parts of the organization and subordinates are dependent on the leaders to keep them informed about the developments. The facilitation of work by leaders is required more when shortages of inputs or inadequate support services would result in the serious and immediate disruption of the work.

Yukl also prescribed a number of relations-oriented leadership behaviors for particular situations. The need for more consideration by the leader occurs, according to Yukl, when the leader works in close proximity to subordinates or must interact frequently with them owing to the nature of the task. Praise and recognition by the leader become more important when subordinates are not able to get much direct feedback about their performance from the work itself or from clients, customers, or coworkers. The facilitation of interaction by the leader is essential when the organizational unit is large and contains competing groups or factions.

## Leadership, Organization, and the External Environment

---

Conger (1999) noted some of the variables of the external environment that are likely to affect the organization's and leader's behavior. The effect of crisis conditions on the emergence of charismatic leadership is well documented. Closer proximity to followers may make more relationship building possible. The external environment may provide a variety of opportunities for entrepreneurial leadership to appear. Environmental uncertainties will bring out demands in leadership that restores order.

### ***Stable, Turbulent, and Dynamic Environments***

Systems theory postulates that what takes place outside a system is likely to affect what takes place inside it. External environmental forces interact with the organization and continuously modify what is going on inside it. Thus, if a business operates in a stable environment, it is likely to have more consistent leadership and stable organizational policies and departments that are similar in structure. If an environment is unstable, policies are less uniform and greater differences emerge among the various divisions of the firm (Lawrence & Lorsch, 1967b). Leadership is likely to be less consistent over time and place. Shamir and Howell (1999, p. 265) hypothesized that "charismatic leadership is more likely to emerge and be effective in dynamic organizational environments that require and enable the introduction of new strategies, markets, products and technologies."

The failure of organizational structures to change in response to changing environmental processing requirements led J. A. Miller (1974), who studied leadership behavior in 10 organizations, to propose and find support for the argument that the optimal degree of initiation of structure by the leader depends on how much the processes demand such structure when the organization has not already provided it. Osborn, Hunt, and Bussom (1977), like Miller, proposed to extend Ashby's (1957, 1960) Law of Requisite Variety to understand

the relationship between environmental demands on the organization and the organization's structure. The organization must possess as much required variety as the variety that can be expected from the environment. Internal variety of organizational structure should correspond to the environmental variety of demand on the organization. Organizations in environments with numerous disturbances should, therefore, contain an equally sophisticated capability to vary important internal characteristics. Similarly, leaders in environments that vary should show more varied behavior than leaders in stable environments. Osborn, Hunt, and Bussom (1977) tested whether the consistency of the matching of the leader's behavior with environmental conditions was more valid than an alternative model indicating that the leader's behavior offsets and compensates (as Miller argued) for the environmental demands. In 60 chapters of a business fraternity, within-chapter variations across selected environmental dimensions gave a measure of environmental variety. Five leadership dimensions from the LBDQ-XII<sup>5</sup> for each leader of a fraternity chapter yielded a measure of leadership variety. The overall performance of the fraternity was best when environmental variety was low and was mismatched with high leadership variety. However, leadership variety that matched high environmental variety was associated with better performance by the fraternity, but the effects were much smaller.

An attribute of the outside environment that is likely to influence the behavior of leaders inside an organization is the stability of the market in which a firm or agency operates. If the firm operates in a stable marketplace, less total leadership is needed and more substitutes for leadership can be employed. Matters can be programmed; policies can be set; and leadership, when needed, can be directive.<sup>6</sup> In a turbulent market, more leadership, particularly consultation, will be needed on a continuing basis.

Entrepreneurial leaders of new ventures need to adapt to the stability or turbulence of their environments. The success of 66 new ventures, according to Ensley, Hmielesky, and Pearce (2006), was greater if the leaders were transactional in stable environments and transformational in dynamic environments. Again, according to Wu, Levitas, and Priem (2005), the number of successful patents filed by 97 pharmaceutical firms from 1992 to 1995 was greater if their technological environment was dynamic rather than stable and their CEOs held shorter tenures of office. Burns and Stalker (1961) found that executives in a sales engineering company were required to deal repeatedly with the same customers, suppliers, and regulatory bodies. The demand for direct interaction with the environment was greater for the sales engineering executives than for those in a clothing company where interaction with outsiders was accomplished indirectly, mainly in written form. Executives had less autonomy in an environment when there was less differentiation of customers, greater feedback, and indirect communication with the environment. The executives in the clothing company spent less time in decision making and more time dealing with routine tasks. Their autonomy was more restricted, both horizontally and vertically, than that of the sales engineering executives (Burns & Stalker, 1961).

Firms that had to operate in turbulent fields were more likely to share the power of decision making inside their organization (Emery & Trist, 1965). In agreement, Lawrence and Lorsch (1967a) compared decision making in the stable container industry with decision making in the more turbulent plastics industry. Again, in a stable environment, the decision-making processes within the container firm were likely to be directive; in the more turbulent environment of the plastics firm, decision-making processes were more likely to be consultative.

### ***Mechanistic versus Organic Organizations***

Conceiving organizations as machines or as organisms goes back to the nineteenth century. *Mechanistic* organizations appear to work better in a stable environment; *organic* organizations, in a turbulent environment. Burns and Stalker (1961) interviewed key people in 20 organizations in a variety of industries. They classified the management methods as either *mechanistic* or *organic*. The mechanistic organization was

characterized by rule-based, vertical communication patterns, with decision and influence centered at the top levels. Cooperation depended on understanding, conforming to, and agreeing with the rules. Organic forms featured lateral communication, adaptability based on learning, and less rigidly defined jobs. Cooperation depended on understanding, alignment, and acceptance of the organization's goals. The mechanistic style was more appropriate for dealing with stable environments, whereas the organic style was more suited to turbulent environments. The effective firms in relatively stable environments were mechanistic in their concentration of decision making and influence at the top level of management. Lower-level managers in such stable environments and mechanistic organizations found satisfaction from being able to get a quick decision from those at higher levels. The organic organization was more satisfying as it provided more autonomy, more discretionary opportunities, and appropriate involvement in relevant decisions. The effective firms in a rapidly changing, complex environment were more organic. They involved their lower-level managers in joint departmental decisions. Managers who possessed the competence and knowledge to deal with the environment had more decision-making influence than did those who did not.

Dickson (1998) considered mechanistic–organic as a continuum and extracted six items from the Globe Organizational Policies and Practices questionnaire (House, Hanges, Dickson, et al., 1996–1998) and the responses of 9,527 persons from 225 organizations and 42 countries. He demonstrated that the continuum was reliable and generalizable across organizations and that agreement about their organization was higher among members of mechanistic than organic organizations. Howell (1997) suggested that exchange/transactional leadership was more likely to emerge in mechanistic organizations; charismatic/transformational leadership, in organic organizations. Pillai and Meindl (1998) found that for 596 personnel from 101 work units, compared to generation by crisis conditions, the emergence of charismatic leadership was favored by an organic unit organization and a collectivistic orientation. A study of 45 manager-subordinate dyads in two plants, one organic, the other mechanistic, showed that consultation was most practiced in the plant with an organic organization; a directive style of communication was the most common form of interaction in the plant that was mechanistic (Courtright, Fairhurst, & Rogers, 1989).

*Strong versus Weak Organizational Cultures.* Organizations with *strong* and *weak* cultures were differentiated by Deal and Kennedy (1982). The values of what is right, good, and important are more fixed and fully shared by members in a strong culture, and norms are more fully crystallized. According to Tosi (1991, 1992), mechanistic organizations, with their authority structures and elaborated control systems, are strong in situational effects, for they allow less leeway for individual differences and preferences. In comparison, structurally weaker organic organizations permit individual personalities, competencies, beliefs, and preferences to have more effect. Organic organizations are structurally weaker, as they impose fewer constraints on members and offer less specific mandatory direction on how to deal with problems. They encourage the individual expression of solutions by leaders and followers. O'Regan and Ghobadian (2003) surveyed a sample of 194 small and medium-sized British enterprises and showed that the firms in the upper 25%—in strength of their cultures of external and internal orientation, departmental cooperation, and empowerment—compared with the lowest 25%, were more likely to meet performance objectives, avoid problems, and be more innovative. The same was true for the effects of strong leadership styles.

### ***Economic, Ecological, Political, Social, and Legal Influences***

Studies of legislative leadership by Peabody (1976) and Rosenthal (1974) suggested that a variety of environmental forces strongly affects the stability of political leadership. The same variables can be seen to operate even more intensively in the private sector, where market forces and technological changes often dramatically affect the stability and succession of leadership (Bryson & Kelley, 1978). Performance reviews, in

the form of annual elections for the board of directors, periodic audits, and stockholders' meetings by outsiders, can influence the actions of the leadership and the stability of the dominant coalition inside the organization (M. P. Allen, 1974). A change in the law, in resources, or in competing organizations also may force changes in leadership (Pfeffer, 1972b). Groups of clients, unions, professional associations, and regulatory agencies affect how and what will be discussed and decided, both in legislatures and in private organizations, especially with regard to visible and emotional questions. Feature stories, publicity, and exposures can be used to support or destroy the leadership in both locations (Ilchman & Uphoff, 1969).

Using factored questionnaires, Bass, Valenzi, and Farrow (1977) asked 76 managers to rate the extent to which economic, political, social, and legal forces outside their organization influenced them and their immediate subordinates. Each of the 277 subordinates described the leadership behavior of the managers. Production, accounting, and finance managers saw economic forces as most important; service, sales, marketing, and personnel managers saw economic forces as least important compared to political, social, or legal forces. But even after separating out the effects of the managers' personality, background characteristics, and managerial function, Bass, Valenzi, and Farrow found that managers who perceived external economic forces as important to their supervisor-subordinate relations tended to be more *directive* and manipulative, according to their subordinates. On the other hand, managers who felt that external political, social, and legal forces were more important tended to be more consultative, according to their subordinates.

In a follow-up analysis, Farrow, Valenzi, and Bass (1980) examined 250 managers in profit-making organizations and 95 in nonprofit organizations. In the nonprofit firms, the leaders' styles, as seen by the subordinates, were affected more by the managers' perceptions of outside environmental influences. Their perceptions of strong economic influences were correlated  $-.30$ ,  $-.25$ , and  $-.21$  with consultation, *participation*, and delegation, respectively, in the nonprofit organizations. The parallel correlations in the profit-making organizations were  $-.05$ ,  $-.11$ , and  $-.02$ . Egri and Herman (2000) interviewed and surveyed 73 leaders in ecological products and services in for-profit and nonprofit organizations. Transformational leadership was more likely to appear in nonprofit than for-profit organizations engaged in ecological activities. Compared to the for-profit environmental industry leaders, the nonprofit leaders also attached significantly more importance to the values of self-transcendence, benevolence, and universalism and less importance to power. Again, the case of the Safety-Kleen Corporation (Flannery & May, 1994) revealed how moral norms, values, environmental attitudes, constituent influence, and behavioral controls influence environmental leadership and strategy.

Community leaders differed in their thoughts about which influences affected the developmental needs of their communities, depending on their regional location. Although those in the Southwest believed that local businesses determined their communities' needs, far fewer leaders from the Northeast did believe this. At the same time, leaders from the Northeast thought that nonlocal governments and nonlocal businesses exerted more influence on developmental needs (Olien, Tichenor, & Donohue, 1987). These regional findings, no doubt, have been affected by the expansion of business and industry from the Northeast and the Midwest to the South and West and overseas in the twenty-first century, and by the change in the U.S. business structure in the previous decades.

*Economic Conditions.* A commonly observed reaction of management to economic recession, loss of markets, and reduced sales and profits is to cut programs that contribute to the improvement of leadership and interpersonal relations within the organization. Training and development are seen as overhead that can be sacrificed to assist the firm's economic balance. During these times, security needs rise, among both workers and managers, that affect their relationships and problems that must be addressed, such as layoffs, retraining, early retirement, and reductions in compensation and benefits. Franke and Kaul (1978) stirred up controversy over the Hawthorne studies (Roethlisberger, 1947). The heightened productivity of the Western Electric personnel at the Hawthorne Works had been attributed by Roethlisberger to the increased attention by

supervisors to human relations and the concerns of the workers. Franke and Kaul, in contrast, accounted statistically for the results by an economic downturn in the late 1920s that resulted in an increase in closer supervision and workers' fearing that they might lose their jobs.

In the 1980s and the 1990s, there was an escalation of mergers, acquisitions, and leveraged buyouts, aided by favorable investor attitudes and increased tax advantages for company debt over equity,<sup>7</sup> which some economists applauded for shaking up complacent managements. But others saw mainly predatory business practices that benefited entrepreneurs and management at the expense of other constituents of the organization. Commitment, loyalty, and involvement suffered. Long-term investment for research and development had to be sacrificed in favor of marshaling resources to maintain short-term strength and elevated stock prices. Confusion and anxiety permeated the members of organizations, threatened by the loss of their jobs, policy changes, plant closings, and general uncertainty.

*The Sociopolitical Ethos.* In an interview survey by Bruce (1986), CEOs noted that the political environment was important to what they could accomplish. Mergers in the preceding 25 years could not have been possible in the antitrust environment of the 1960s. Maccoby (1983) pointed out the need to consider the continual change in societal attitudes toward the ethics of work. He identified four ethics in earlier U.S. history, each of which was replaced when its ideals could no longer meet society's social and economic needs. The four dominant ethics were: (1) the Protestant or Puritan ethic, (2) the craft ethic, (3) the entrepreneurial ethic, and (4) the career ethic. Each ethic generated different predominant styles of leadership, respectively: work orientation, expert orientation, risky competitiveness, and careerism. Likewise, Bass (1960) saw leadership styles affected by the dominance of task orientation in the United States before 1950 giving way to concern in the 1950s for getting along with others, followed by an increasing self-orientation, which began in the 1960s. The same cycle repeated itself between 1975 and 2000. Each, in turn, had different effects on the practice of leadership in U.S. organizations. Production and the heroes of production are paramount in a task-oriented society. Marketing, conformity, and interpersonal relationships became the predominant issues of the 1950s, followed by the predicted self-oriented focus of the "me-too" outlook from the late 1960s onward, in which issues ranging from individual alienation to careerism surfaced. At the same time, concern for human relations in management and leadership grew. By the turn of the century, we saw a generation of working adults concentrating on family relations and security.

A longer psychohistorical focus of societal effects on leadership was proposed by Demause (1982). Demause noted that the common practice of infanticide and infant abandonment in classical and medieval times promoted the survivors' view that their parents and the leaders who displaced the parents were their saviors. The ambivalence toward children that followed in the next centuries fostered the model of parents and leaders as benevolent autocrats. Between 1800 and 1950, the prevailing practice of treating children as subjects for training and socialization created the model of the leader as the source of contingent reinforcement. Finally, the post-1950 Dr. Spock generation created a model of parents and leaders as helpers.

*Regulatory Agencies.* Ungson, James, and Spicer (1985) surveyed 89 firms in two industries—wood products and high technology—about the effects of regulatory agencies on their planning and goal setting and the need to adjust their organizations to the regulatory agencies' actions. In both industries, managers saw governmental regulatory agencies as more unpredictable and uncontrollable than they did their suppliers of raw material, competitors, customers, and labor. Generally, in the wood products industry, adjustments in personnel were most likely to occur because of governmental regulatory agencies and least likely to occur because of competitors or investors. But in the high-technology industry, none of the outside factors was as important in affecting the adjustments of personnel.

Legal actions often determine an organization's future. In 1984, after 10 years of work by the antitrust division of the Justice Department, AT&T was ordered by a federal court to break up into competitive sectors. It met the court order by divesting "Ma Bell" from the seven "Baby Bells," the regional local

exchanges, leaving long-distance and global activities to AT&T. The new CEOs emphasized competition between the units and their personnel, shutting down the former free-flowing communications among units. They placed a premium on competing for customers rather than continuing concern for service and cooperation. To improve finances, they acquired many new firms to enter the highly competitive computer business and similarly entered the highly competitive cable business. By 2005, AT&T had lost most of its experienced managers. The regulated monopoly shrank from a million personnel in 1984 to a prospective subsidiary of one of its former divisions. The former “widows and orphans” secure AT&T shares were hitting rock bottom, and the remnants of the firm expected to be acquired by one of its own Baby Bells.

*Ownership.* Agency theory (Meckling & Jensen, 1976) argues that managers are agents of the owners and shareholders and therefore have divergent economic interests. In 2005, CEOs were taking in compensation equal to as much as a fifth of the annual corporate profits after expenses, allowing the owners and shareholders just four fifths. By 2005, the average CEO in the United States was earning more than 450 times more than the average employee in the firm. These extreme results could be dampened only by concerns for social justice, continuing transparency, and stronger regulation by the SEC, and by boards of directors and their audit committees. The treatment of executives by a higher authority in 71 large manufacturing firms depended, according to Gomez-Mejia, Tosi, and Hinkin (1987), on whether the firm had dominant outside shareholders. Conyon and Peck (1998) reached the same conclusion for Britain. Outside shareholders are owners who view the firms primarily as financial investments. They use their power to compensate hired CEOs according to the economic performance of the firms. Firms without such dominant shareholders are controlled more by the management itself. Here, the compensation awarded to CEOs depends more on the size of the firm’s operations than on its performance. In the scandals of 2002, the compensation of some senior executives was increased substantially even as the firms were moving toward declarations of bankruptcy! There was some semblance of rationality found by Finkelstein and Boyd (1998), who reported that the performance of firms was higher when the CEO’s pay was congruent with the CEO’s latitude of action. Balkin, Markman, and Gomez-Mejia (2000) found, in 90 high-tech firms, that CEOs’ short-term compensation was related to innovation as measured by the firm’s number of patents and spending for R & D. No such relationship of compensation with innovation was found for long-term CEO compensation, nor was there any linkage, long or short term, of CEOs’ compensation with innovation in 74 low-tech firms. Nonetheless, as is usually found, compensation depended on the size of the organization and its operations.

*Socioeconomic Status of the Community.* [Chapter 10](#) detailed the general contribution of accorded status to leadership. Osborn and Hunt (1979) created an index of the socioeconomic level of a community and showed it correlated with the leadership among college students. A community’s status was based on its median income per family, mean educational level of its residents, the tendency of residents to vote, and other socioeconomic conditions. For the 60 chapters of a national business fraternity mentioned earlier, the investigators obtained a correlation of .40 between the socioeconomic community status of the college chapter leaders and their initiation of structure, and .68 with their consideration, as measured by the LBDQ. Again, secondary school students were affected by the socioeconomic status of their communities. Philbin (1997) reported that secondary school students’ learning increased if the principal was transformational, but only if the students came from the highest socioeconomic levels. However, the transformational leadership of principals was satisfying to teachers in schools of both high and low socioeconomic status.

*Religious Affiliation.* L. B. Ward (1965) completed a large-scale survey of top managements in the United States that suggested that the religious affiliation of the top managers in a firm affected the personnel policies promoted within the firm. Personnel practices were more likely to be liberal when the top management was not restricted to members of one religious group. Policies were more likely to be liberal if the top management was exclusively Jewish than if it was exclusively Protestant. The most conservative managements were exclusively Catholic.

## Reference Groups

Other environmental influences on leaders and members of any organization are their reference groups—those people with whom they compare themselves. Hyman (1942) asked subjects to estimate their status along several dimensions: social, economic, intellectual, physical, and the like. He found that individuals estimated some aspects of their status in relation to family members, others in relation to friends or peers at work, and still others in relation to people in general. Small reference groups were usually more important than were people in general in determining the subjects' satisfaction with their status. Satisfaction with their income was highly dependent on the reference group with which the individuals compared themselves.

*Local versus Cosmopolitan.* Merton (1949/1957) showed that the identification with different reference groups was associated with variations in patterns of leadership behavior. In a community study, 86 informants identified 379 individuals as persons of some influence. The 30 most influential members of the community were interviewed. Of these 30, 16 were classified as *locals* and 14 as *cosmopolitans* in their reference group identifications. The two groups differed in attitudes and behavior that were of consequence to their serving as leaders or followers. Locals were reared locally. They were reluctant to leave the community. They focused on their community interests and fellow members of local fraternal and business groups. They wanted to know many people. Their influence rested on a complex network of personal relationships. They wanted to understand their community. Cosmopolitans were mostly newcomers, willing to leave the community, interested in the world at large, and members of national professional societies. They were selective in their choice of organizations, and their influence derived from their prestige and professional position. They wanted to understand their job.

*Multiple Reference Groups.* If asked, "What are you?" people usually see themselves as members of several reference groups. In Texas, a Texan may say first that he is an American. Outside Texas, the Texan may first say Texan, then American, businessman, father, and Episcopalian. Each is a reference group, and the effects are complex. Thus, when Festinger (1949) brought Catholic and Jewish girls together in a small club and asked them to elect officers before the girls' religion was identified, both groups voted as much for nonmembers as for members of their own religion. In a control situation, in which religious identities were publicly disclosed, 64 percent of the Catholics voted for Catholic girls, but the Jewish girls continued to vote equally as often for members of either religion. However, in a large group in which the voters were only privately identified by religious affiliation, Jewish girls showed the same tendency to vote for members of their own religion as did Catholic girls. The same effects were observed when confederates were identified alternately as Catholics and Jews for the benefit of different groups of voters to rule out any influences of the individual nominee on the outcomes.

To understand and predict a person's interpersonal behavior in a designated social situation, one has to determine his or her various reference groups. For example, if two people collide in a crowded street, they may ignore the collision, they may beg each other's pardon, or one may shove the other. What each person does will depend, to some extent, on whether the interacting persons are male or female; white or black; and upper, middle, or lower class; and whether the situation occurs in North America or Zambia.<sup>8</sup>

## Real Outside Networks of Relationships

Leaders usually belong to more groups than do followers. They integrate the various subgroups of a larger group and mediate between the membership groups and the wider community. J. B. Marks (1959) found that leaders maintained significantly more extraclique friendship links than did followers and tended to mediate

between their groups and the surrounding social environment. Schiffman and Gaccione (1974) found that the opinion leaders in the nursing home industry were administrators who interacted more often with administrators from other nursing homes. However, the leaders who identified with the norms of the in-house group were more strongly supported by members than were the leaders who identified with the norms of the external groups.

The effects of leaders' outside connections are well known. Interlocking company directorates can take considerable advantage of such linkages for the good of their organizations, even though doing so has the potential for corruption. When the boards of social service organizations were composed of high-status (business leaders) rather than middle-status (middle management and professional) members, the organizations were found to be more effective, better financed, and able to provide a higher quality of service (Zald, 1967). Pettigrew (1973) observed that developing and maintaining a network of contacts outside as well as inside the organization is the means by which many leaders help their subordinates reach their desired objectives. Xoulack (1977) involved 44 undergraduates in simulated bargaining situations. Leaders who did all the bargaining were treated by out-group members either with friendliness or with hostility. The leaders who were treated in a friendly manner by the out-group members were rated as more effective by the in-group members.

## Organizations and Leadership

---

Xenophon's *Anabasis* told how 13,000 Greek mercenaries were stranded in Mesopotamia in 401 b.c.e., when the Persian prince who had recruited them was killed and their Greek military leaders were treacherously slain. Nevertheless, their military organization and training and their common Greek culture made it possible for them to march 1,000 miles through hostile territory to safety despite the enemy's efforts to stop them (Aupperlie, 1996).

Influenced by David Hume and other eighteenth-century fellow Scots philosophers (Herman, 2001), Adam Smith (1776) in his famous *Wealth of Nations*, observed that civilizing social improvement and merchants, bankers, engineers, and industrial and business organizations developed out of subsistence farmers, fisherman, and miners as a result of the division of labor. Specialization arose from enlightened self-interest and the need for cooperation. Order and good government were required, along with individual liberty and security.

Leadership in an organization is determined by the organization's legitimating principles and cultural norms and by the social structure within which it occurs. Pawar and Eastman (1997) posited four organizational considerations that influence its leadership: (1) the organization's structures, (2) the organization's governance, (3) an emphasis on adaptation or efficiency, and (4) dominance of the organization's technical core or its boundary-spanning units. They suggested that charismatic/transformational leadership was more likely to succeed in an ad hoc structure of temporary task groups or if the structure was simple and governed by a single entrepreneurial leader rather than by a complex bureaucracy. In the adaptive organization, leadership had to overcome resistance to change and to align the organization's members to new goals and values. If the emphasis was on efficiency, goal stability would be sought and more transactional leadership would be required. Transactional leadership was more prevalent when the technical core emphasized stability, standardization, and routinization. More transformational leadership is likely if the focus is on boundary spanning and keeping ahead of the external environment.

As the organization matures, so will the strategies of its leadership change (Biggart & Hamilton, 1987). Pellegriin (1953), Weinberg (1965), and Philipsen and Cassee (1965) observed that institutional requirements determine the characteristics of members who are accepted as leaders. It is apparent that the kind of leader who emerges in an organization and the individual who is successful as a leader and is evaluated as effective as a leader depends on the philosophy of the larger organization in which the leader's group is embedded. The

philosophy influences the organization's directors. In turn, its effects move down to successively lower levels of management and contribute to the constraints that are imposed, the structures that are created, and the ways in which people are mobilized, resources are allocated, and performance is evaluated. These, in turn, affect the patterns of leader-member relations in the organization.

## ***Organizational Philosophy***

The organization's philosophy includes its assumptions, values, foci of attention, priorities, goals, and the techniques it promulgates to implement its efforts. Clearly, its philosophy and culture overlap and reinforce each other in determining what is the right thing to do and what is important and good. McGill and Slocum (1993) labeled the *knowing* organization as believing in the one best way to organize, to manage, and to get the job done; the *understanding* organization as making only those changes compatible with the organization's core values and culture; the *thinking* organization as identifying, analyzing, and fixing problems as they occur; and the *learning* organization as creating and fostering experimentation, open communication, constructive dialogue, and processing of experience.

*Nonprofit Organizations.* Carl and Stokes (1991) listed seven elements of value to the nonprofit organization: (1) workshops and formal educational experiences; (2) two-way feedback; (3) teamwork; (4) psychological recognition and rewards in the absence of unaffordable high salaries and bonuses; (5) high standards; (6) a well-functioning board of directors; and (7) high levels of collaboration with the private sector. Without the measure of profitability, nonprofits need to adopt indicators of success in their mission, service, and efficiency. Their accomplishments may be indicated by prevention and control of negative incidents, compliance with standards, timely delivery of services, fairness to access of services, public satisfaction with agency and service, and management of available resources (Gustafson, 1999).

*For-Profit Organizations.* Some firms concentrate their attention on their financial or physical resources in the search for long-run success. They may adopt Williamson's (1975) view of organizations as internal markets in which members are opportunistic and self-interested rather than trusting. Conflicts are resolved by fiat or costly bargaining. Some firms may concentrate on their intellectual capital and its exploitation at strategic and operational levels. They take advantage of the extent that knowledge grows exponentially. They can leverage their intellectual capital with a few top professionals who can multiply applications and development of knowledge at lower levels. They can foster intellectual challenges (Quinn, Anderson, & Finkelstein, 1996). Still other firms try managing meaning for their members to arouse their existential needs for satisfying self, family, and life. Attention is on aligning individual members' and the organization's goals (Sievers, 1986). The corporation of the twenty-first century may still be seen as legitimate, although scandals are eroding its social legitimacy. Many still vest it with more authority and influence than political party, church, or community. Corporations create, control, and distribute much of society's wealth (Ghoshal & Bartlett, 1997).

*Scientific Management and Its Alternative.* Frederick W. Taylor's (1911) *Scientific Management* described how production was to be accomplished in the organization. Work on the shop floor was to be subdivided into the smallest and simplest task units possible. Workers were to follow instructions as they were told by their supervisors, who similarly were given little discretion and were expected to be motivated by higher wages. Favored by Taylor were job specialization, short training requirements, and little autonomy. But the lesser-known Ernst Abbe (1900), at the Zeiss optical instruments company in Germany, formulated principles that involved employees in how work was to be done. Knowledge, legitimacy, and intrinsic motivation were emphasized, which better suited the firm's objectives of making the highest-quality instruments and developing new applications of science. To enable long-term growth of the firm, employees'

skills were to be enhanced. Management decision making was to be rationalized. Progressive labor relations and enlightened social policies were stressed (Buenstorf & Mur-mann, 2003).

*Social Capital.* Social capital means different things to different writers (Santos, 2003). It may be the organization's resources, based on any of the following: reputation, entrepreneurship, exchange opportunities, networking, strategic alliances, public-private connections, performance-based trust, career opportunities, compensation plans, and favorable attitudes of its suppliers, clients, consumers, shareholders, managers, employees, and their families. It may refer to the quality of its human resources. The democratic practices of McGregor's (1960) Theory Y have increased, but some firms are still ruled with an iron hand. Theory X is still in evidence.

Then there are Theory Z firms. Ouchi (1981) described Theory Z as the basis for Japanese management and recognized a number of U.S. firms, such as Procter & Gamble, IBM, and Hewlett-Packard, for following Theory Z in their own systems. These firms at the time were characterized by long-term employment, intensive socialization, and clear statements of objectives and values emphasizing cooperation and teamwork. Management policies to implement these approaches included slow promotion from within, the rotation of jobs, the creation of generalists rather than specialists, complex appraisal systems, emphasis on work groups rather than individuals, open communication, consultative decision making, and a relations-oriented concern for employees. In comparison to top-down, Theory X (authoritarian) organizations, Theory Z organizations are more decentralized and have flatter structures—fewer levels of management. When Roberts (1986) compared the reports of 97 managers in a Type Z business firm with those of 147 managers in a Type X organization, she found, not unexpectedly, that subordinates exercised more upward influence in dealing with their bosses in the Type Z than in the Type X organization.

According to Robbins (1983), although Theory Z gives the impression of greater equalization of power and control and “bottom-up” management, in fact, it actually has mixed effects on top management's power and control and, for the most part, increases rather than decreases its top managers' power and control. The decentralization and team decision making of Theory Z increase the equalization of power, but employee-organization lifelong commitments may increase employees' tolerance for what ordinarily might be subjects of complaints. The emphasis on good human relations may reduce constructive confrontation; generalist career development may reduce the ability to move to another company; and the flatter Theory Z organizations eliminate middle managers, who, in taller structured bureaucracies, for example, filter and control what information gets to top management. Interest in Theory Z and its practice declined with the 15-year recession of the Japanese domestic industries, which in 2006 appeared to be close to ending by 2007. Its export industries did not experience the same decline.

*Differing Views of Organization.* House (1991) presented a theory to explain how the distribution of power in a complex organization depends on the organization's environment, form, and the personal characteristics of its members. Organizations may be viewed as *rational-structural systems*. Metaphorically, in such a view, they are machines composed of interdependent parts, and leadership is a matter of specifying who does what for whom and why. A second view is that organizations are *extended families* with networks of relations and obligations. In this view, leadership is more concerned with relations, with the socialization and development of subordinates. A third view is that organizations are a *political system*, a jungle of coalitions and conflicts of interests. According to this view, leadership is based on power and the allocation of scarce resources. A fourth view of organizations is *symbolic*. It sees organizations as theaters, with members continually trying to play roles that communicate meaning to others about what is happening. In such a view, the leaders are artists and actors (Bolman, 1986).

Variations in 1,200 managers' and subordinates' perceptions of their organizations had systematic effects on the organizations' leadership styles. A factor analysis by Farrow (undated) of managers' and subordinates' descriptions of their organizations using the Bass-Valenzi Management Styles Survey found that the views

could be factored as follows: (1) well managed (harmonious, clearly organized, orderly, clear task objectives, warm, and trusting), (2) amount of management (management activity, importance of external influences, commitment of members, interdependence of members and units, complexity of operations), (3) mechanistic (many organizational constraints, strong organizational structure, much routine work), (4) bottom-up (subordinate power, discretionary opportunities, independence of members, absence of routine work); (5) top-down (superior's power, superior's information). The frequency with which different styles of leadership appeared was related to the factored descriptions. For example, more consultative leadership was seen in well-managed firms, more directive leadership in top-down firms, and more participative leadership in bottom-up firms.

*Effects of Stated Policies.* The effects of stated organizational policies on a supervisor's use of reward and punishment were examined experimentally by Greenberg (1978) and Leventhal and Whiteside (1973), who found that experimental subjects rewarded low performers more when they were instructed to encourage high future performance than when they were instructed to reward on the basis of past performance.<sup>2</sup> Leventhal, Michaels, and Sanford (1972) found that experimental subjects who were given the policy of minimizing conflict allocated more rewards to low performers than did those subjects who were advised to ignore conflict. Landau and Leventhal (1976) reported that subjects who were required to retain only the best performers, compared to those who had to try to retain all workers, gave fewer rewards to low performers.

*Moderation of Organizational Policies.* Complicating matters was Liden and Graen's (1980) finding that the relationship between organizational policies and supervisors' behavior may be moderated by the severity of the policy and the supervisor's attributions of the causes of the subordinate's behavior. An experiment was set up so that subjects had to deal with a "subordinate" who had missed a production deadline. The failure to make the deadline was due to the subordinate in one experimental treatment and was outside the subordinate's control in the other treatment. Company policy was mild in one case and severe in the other. The mild policy required the supervisor to issue a verbal warning that the subordinate's pay would be docked if the deadline was missed again. The severe policy was to dock the subordinate for one day's pay. The results demonstrated that the subjects who acted as supervisors were more likely to follow the policy when the cause of missing the deadline was attributed to the subordinate than when it was attributed to a cause outside the subordinate's control and when the stated company policy was mild rather than severe.

In a field study, Hammer and Turk (1985) showed that when the management philosophy resulted in intentional pressure on 160 first-line supervisors by higher-ups to supervise strictly, there was a significant unique, negative correlation with the supervisors' attention to the maintenance of the work group. The supervisors' perceptions of their authority to fire subordinates were also significantly affected.

*Organizations' Phases and Life Cycles.* Baliga and Hunt (1988) reviewed the literature on organizations' life cycles. Like organic organisms, they transit from one stage to another—from gestation to birth to growth to maturity and finally to revitalization or death. Each stage creates its own demands for constraints on, and choices in, the leaders' and managers' roles (Stewart, 1982). For instance, in the birthing phase, the demand is to establish the organization. Choices include selecting the needed resources, and constraints arise in obtaining them. The most effective leaders and managers fulfill demands with the least amount of resources and constraints. They create future favorable demands and the most future organizational slack. Decisions are cost-effective. A viable strategy is developed. Stakeholder confidence is maintained. Key personnel are recruited and committed to the organizational vision and objectives. Lower-level managers socialize their subordinates to the organization's goals and objectives and design information, control, and appraisal systems. They identify needed technology. Shamir and Howell (1999) suggested that charismatic leadership is most likely to emerge in the early stages in the organization's life cycle of birth and growth and again in the late stage of renewal.

*Organizational Objectives and Functions.* The values, beliefs, and rationales that make up an

organization's philosophy affect and are affected by the organization's mission—its purposes and objectives and the functions it performs to accomplish its mission. In turn, the purposes and functions of an organization affect and are affected by its leadership. Systematic differences have been seen among departments of larger organizations, such as those concerned with manufacturing, personnel, finance, marketing, and R & D. Much has also been written about the different types of leadership that are required for different types of organizations and institutions to meet their systematically different purposes, functions, and membership. For instance, Shamir and Howell (1999) inferred that charismatic leadership is most likely to emerge and be effective when an organization's members face challenging and complex tasks. Such tasks require initiative, responsibility, creativity, and intense effort if the organization's goals are ambiguous and extrinsic rewards cannot be linked to performance. A number of person-situation examples have been observed in universities, schools, libraries, cooperatives, unions, and the military. Attention needs to be paid to the local organizational scene and what it requires for leadership.

*Goals Differ by Functions.* Goals depend on a manager's functions. C. G. Browne (1950a, 1950b, 1950c) and Dearborn and Simon (1958) found that top-ranking executives of a business firm tended to perceive organizational goals in terms of the functions of their own departments. Manufacturing managers believed that the quality of a product and keeping the costs of production low were goals that were important to the firm; sales and marketing managers saw effective advertising, customer service, and keeping the price of the product low as more important goals.

In a survey of British managers, Heller (1969a) found that those in personnel and general management functions typically used less directive procedures than did their colleagues in finance and production. Managers who led groups in purchasing, stores, and sales tended to be in between. This finding was consistent with earlier work by Fleishman, Harris, and Burt (1955). They noted that supervisors in manufacturing departments or other departments that worked under time constraints were likely to receive higher merit ratings if they tended to initiate structure more often, while the reverse was true for supervisors in service departments. In addition, in non-manufacturing service departments with fewer time constraints, considerate supervisors were seen as more proficient. More supervisory initiation contributed to greater absenteeism and grievances mainly in manufacturing departments and to turnover in service departments.

Forbes (1985) divided a sample of 246 British and American managers according to their functional areas. He ranked the functional areas according to the presumed degree of uncertainty in the work as follows: personnel and training, R & D, sales and marketing, production, and finance and accounting. The more uncertainty in the function, the more managers reported concern for rules, use of authority, search for learning opportunities, and breadth of focus. An international sample of managers' interpersonal orientation was recorded in a data bank of results of simulated training exercises (Bass, Burger, et al., 1979). It involved human relations concerns, the ability to listen, trust in others, willingness to discuss feelings, tolerance of conflict, and acceptance of affection and feedback. Interpersonal orientation was higher for 123 managers in sales, marketing, personnel, and training—functional areas with more “people content” in the work to be done. It was lower for the 123 managers in the functional areas of finance, accounting, production, and R & D, where jobs were lower in people content.

*Manufacturing versus Service.* Manufacturing usually demands more routinization and coordination than do service functions. In a study of 787 managers, Child and Ellis (1973) found that managers in manufacturing organizations saw their roles as more formal, better defined, and more routine than did managers in service organizations. Consistent with this, Solomon (1986) found that Israeli firms that engaged in production, public or private, were more oriented toward performance-based rewards and to contingent rewarding than were public or private firms engaged in services.

*Utilitarian versus Voluntary Organizations.* Etzioni (1961) suggested that different dynamics of leadership would be at play in *utilitarian* organizations that produce goods or services than in normative

organizations such as *voluntary* professional societies. Activity may be personally costly, and the rewards are different for office holding in voluntary organizations. Relations are likely to be more personal and informal in voluntary organizations (Walker, 1982). But the expected greater power differentials of the leaders and the led in utilitarian as compared to voluntary organizations did not surface in an interview and questionnaire survey by Pearce (1983). Pearce (1982) compared four volunteer organizations (newspaper, poverty relief, family planning, and fire department) with four counterpart organizations staffed by regular employees. Interviews with random samples in each organization concluded that the workers in the volunteer organizations were much more variable in their performance than were the employees of the utilitarian organizations. In the volunteer organizations, workers were much more likely to ignore their leaders and to work when they wanted and in the way they wanted. Paid employees of utilitarian organizations were more likely to work within the constraints of organizational policies and leaders' directives.

Leaders of voluntary organizations differed systematically from those in utilitarian organizations. In voluntary organizations, authority was invested in the membership as a whole. Their leaders were the representatives of the membership who could assume some of its authority. It was a bottom-up process. Volunteer followers reported having significantly more personal influence than did utilitarian employee followers. In the utilitarian organizations, employers had the authority to direct top-down to the leaders in the organization. Leaders in the voluntary organizations depended much more on their subordinates than did the leaders in the utilitarian organizations.

Leaders in voluntary organizations are likely to be reluctant to be too directive or controlling for fear of losing volunteers (LaCour, 1977). This reluctance results in their tendency to be relations-oriented (Rawls, Ulrich, & Nelson, 1973). But Kellogg and White (1987) suggested that matters are more complex. Volunteers exchange their time and service for social and psychic rewards such as recognition, worthwhile work, sense of belonging, socializing, and personal growth. The directiveness of volunteer leaders to facilitate the achievement of goals and the satisfaction of the volunteers' needs may be quite appropriate. Many volunteers are intrinsically motivated by their organizations' accomplishment of worthwhile purposes. In a survey study of 127 volunteers in 10 voluntary organizations, Kellogg and White (1987) found that, as expected, the leaders' relations orientation, in the form of support, contributed to the volunteers' satisfaction. But at the same time, directive role clarification by the leaders enhanced the volunteers' satisfaction with their work, more so if they originally were lower in intrinsic motivation. Presumably, such leaders gave more meaning and purpose to the work for those who were not particularly motivated by it initially. But specifying the work to be done did combine with high intrinsic motivation to promote the volunteers' satisfaction.

### ***Some Illustrative Public Institutions***

Governments, universities, schools, and libraries provide evidence of the extent to which organizational policies, purposes, and functions systematically relate to the leadership required.

*Governments and Government Agencies.* As with most long-standing institutions, governments have a history and sphere of operation of their own, apart from the constituencies they represent. Government institutions maintain ideals, values, and expert capacities across time. Although their constituencies can influence what the government does, the government may also affect the politics of its constituents and how they are represented (Hargrove, 1988).

Even more than in utilitarian organizations, leaders of government institutions, as well as their agencies and departments, are likely to be much more than rational actors pursuing calculated self-interest, knowing their preferences, and how to achieve them. Rather, they are strongly influenced by institutional norms, symbols, and rules that have developed historically. Activities may be carried out as a duty or obligation as well as for

self-interest. Helping to maintain the institution may be seen as more important than helping to implement a particular policy. Leaders may have solutions that are looking for problems just as much as problems that are searching for solutions (March & Olsen, 1984). Civil servants, with expert and legitimate power, working within their own professional and institutional norms, may shape policies that depart considerably from a simple balancing of the interests of a diverse constituency (Heclo, 1974).

The leader, manager, or administrator in a government agency begins with a different overall mission than his or her counterpart in a private for-profit firm. The public agency survives as a function of its services in serving the public, legislatures, elected officials, and political power blocs. The private firm survives (if it is not subsidized by public money) by producing wanted goals, services, and profits that satisfy its owners, managers, employees, and community.

The public sector firm or agency differs from the private firm in its lack of dependence on its market, immunity from bankruptcy but not from deficit budgets, different legal and formal constraints, greater exposure to political influences, stronger relations with political authorities, greater exposure to public scrutiny, and greater accountability (Lachman, 1985). Also, executives of public organizations operate with more formalization and less autonomy in hiring, firing, and rewarding than do executives in the private sector (Rainey, 1983). But in an interview of 141 Israeli chief executive officers (40 public, 91 private), all engaged in production, the expected differences about political and market influences did not appear. Likewise, according to Kaminitz (1977) and Palgi (1984), differences in workers' participation in public versus private industries in Israel also failed to appear. As expected, however, satisfaction was lower for public sector than private sector leaders. An unexpected finding was that the CEOs of public firms had longer time spans of discretion. According to still another comparison of Israeli public and private businesses and industries, managers from private industries were more likely to consult coworkers when they needed help on their own jobs than were managers in government-owned firms (Erez & Rim, 1982). Solomon's (1986) survey of 240 top Israeli executives, half from the public and half from the private sector, found that the differences in perceptions and satisfaction were in line with expectations. There was much greater emphasis on contingent rewards in the private sector. Also, in the private sector, executives were more likely to promote efficient work methods, task clarification, and task autonomy.

Guyot (1962) compared 100 business managers with 147 public administrators. Contrary to expectations, the public administrators were higher in need for achievement and lower in need for affiliation than the business managers. They were equal in need for power. U.S. managers, like Israeli managers, have generally been more satisfied in the private sector. For example, managers in business organizations were seen to be better satisfied than those in military or governmental organizations (Porter & Mitchell, 1967).<sup>10</sup> Rainey (1979) found that, compared to business managers, governmental managers: (1) express weaker expectations of extrinsic reward for performance; (2) are lower on measures of satisfaction; (3) perceive rules about personnel and civil service regulations as constraints on incentives; (4) show no difference in role perceptions and motivation.

Farrow, Valenzi, and Bass (1980) compared the perceptions of managers in 250 profit-making and 95 nonprofit U.S. firms and agencies about their environment, organization, task, work group, and leadership styles. As noted earlier, those in the private sector reported significantly more economic and less political social influence on leader-subordinate relations than those in the public sector, but the same amount of legal influence. The felt constraints, and amount of order and structure were significantly higher in the public sector. The managers in the private sector reported more discretionary opportunities, more complex tasks, and more managerial activities. The managers in the public sector reported more routine work. The power of subordinates was seen to be higher in the public sector. Private sector managers, in comparison to public sector managers, saw themselves as more active as leaders. They perceived themselves to be more *directive*, negotiative, consultative, and delegative. These results differed from those of an Israeli survey by Chitayat and

Venezia (1984), who reported that senior executives in business organizations displayed less direction and more participation than their counterparts in the public sector. As in all earlier studies, the U.S. managers were more satisfied with their own jobs and with their supervisors.

The Israeli kibbutz organization is a mix of service and production-oriented purposes and of utilitarian and normative character. Kibbutzim have strong social and political components. In a simulation study of the work performance of 135 first-level Israeli supervisors from the public and private sectors and from kibbutzim, the kibbutzim leaders, compared to those in the private sector, were most effective when they used direct group participation. Private sector leaders were most effective when they assigned goals; public sector leaders did best with participation from representatives (Erez, 1986).

*Educational Institutions: American Universities.* Universities contrast greatly with mainline utilitarian organizations and have been described as organized anarchies. According to Cohen and March (1974), who interviewed 42 university presidents, universities are likely to have problematic goals, unclear technologies, and fluid participation in decision making. Inertia is high. Most issues are of little consequence to the members as a whole. Decisions depend on who happens to be involved at the time they have to be made. There is a weak base of information available. Effective decision making in universities requires overcoming inertia by: (1) managing unobtrusively, (2) providing arenas for discussing a wide variety of problems, (3) facilitating the participation of opposing points of view, (4) persisting in attempts to accomplish objectives.

It makes a considerable difference to the leadership of a U.S. university if it is a rich private one or a less well-endowed public university. Roberts (1986) reported that the charismatic, inspirational style of leadership was more likely to be seen in 45 administrators in a rich private university than in 61 administrators in a counterpart public university that operated with fewer resources and had to be mainly transactional rather than transformational in leadership.

The leadership styles of administrators in university settings appear to differ from those of managers in business organizations. Roberts (1986) also compared 106 administrators from two universities with 244 managers from two businesses. She found that the administrators in the universities, in contrast to the business managers, reported using much more competitive impression management to create favorable impressions on others. This was done by working effectively behind the scenes by taking action without the relevant others' awareness.

*Educational Institutions: European Universities.* Drenth (1986) noted that European colleges and universities can be structured to provide more organization and less anarchy. The different structures impose different demands on the leadership. Before 1968, the European university was a collegial organization that tended to be run by a fraternity of scholars organized into autonomous departments. Decentralization, informality, and a low level of programming and standardization were intended to provide self-fulfillment and the achievement of personal objectives, particularly the objectives of the departmental chairpersons. The rector fulfilled primarily a ceremonial role, representing the university, chairing traditional sessions, and presiding at other ritual formalities. The rare central decision making was generally based on consensus. Trust, seniority, acceptability, and respect were more effective than managerial direction and task-oriented leadership.

After the student revolution of 1968, the European university emerged as a political organization in which the power of the individual autonomous chair holder was replaced by that of departmental boards with substantial representation by all layers of participants. The forming of coalitions and alliances and use of bargaining, delaying tactics, resistance, and procedural manipulation became normal parts of organizational decision making. Leadership required participation, negotiating, and conflict management, along with inventiveness and initiative.

Some European universities operate as traditional bureaucracies with standardized and formalized work processes, rules, and prescriptions. The influence of the technostructure is strong, with planning and regulation, forms and records, registration and control. The role of the leader involves timing the bureaucratic machinery

and using the control systems available from the standardization of processes, output, and skills. Emphasis is placed on regulations and the routine handling of problems.

Almost opposite in organization are those universities, often newly created, whose structure remains simple. These universities emphasize the centralization of decision making and pay relatively little attention to the formalization and standardization of procedures. There is a sense of mission, an identification with common objectives, dependence on one person, and instability. The rector is often a dynamic, powerful, task-oriented individual with charismatic features.

*Educational Institutions: Public Schools.* Many studies of school principals and superintendents have been cited in the context of other leadership issues. This section summarizes what is known about the particular elements in the school principal's personality and situation that are of consequence to his or her leadership and administration and their effectiveness. Anecdotes and cases imply that "strong" leadership of a school enhances the effectiveness of the school, but there is no consensus on what is meant by either strong leadership or an effective school (Firestone & Wilson, 1985; Hoy & Ferguson, 1985). Dwyer (1984) interviewed and observed 42 "successful" principals but found no single factor that could account for the success of those principals. According to Goldberg (1984), however, as with transformational leaders in general, successful school leaders establish challenging expectations that force students and teachers alike to work harder to support a vision that they collectively adopt and whose implementation they share. For instance, in a case study of nine New York City elementary schools, Sweeney (1982) found a strong association between the high expectations of the principal and staff and positive school outcomes.

Manasse (1984) reported that in effective school systems, principals build and shape their vision. Simultaneously, they involve the staff and students in the development and implementation of that vision and the expectations to support it. Morphet, Johns, and Reller (1982) argued further that by increasing followers' involvement and responsibility in the administration of the school, the principal can adopt a more positive, proactive role as a change agent. Less effective principals react to the demands and constraints in their school systems but do not create them (Firestone & Wilson, 1985). Effective principals indicate to their staffs and students the important and valuable goals for the school. They recognize individual differences not only in *what* individuals can learn but in *how* they learn (Cole, 1984). J. S. Brown (1970) compared 84 public school administrators with 63 business managers. The school administrators made choices in a simulation with lower payoff coupled with lower risk. They were lower in assessed initiative and achievement orientation but were no different from the business managers in decisiveness and self-assurance.

*Libraries.* Libraries are more circumscribed educational institutions with distinctive patterns of the emergent and successful leadership by their directors and departmental supervisors. Although service should be the main goal of libraries, the goal is in conflict with a sense of elitism and self-serving preservation (Sager, 1982). New information technologies to enhance the quality-of-service conflict with budgetary constraints, acquisitions of books, and political considerations. In addition, conflicts may arise between the libraries' two levels of employees, professional and clerical, whose interests may differ.

Dragon (1979) surveyed administrators in three large public libraries with the LBDQ and concluded that the directors and supervisors tended to be higher in initiating structure and lower in consideration than were their counterparts in many other types of organizations. Sparks (1976) found that library administrators, like most other leaders, saw themselves on the LBDQ as more considerate than their subordinates thought them to be. Consistent with this finding, Hall (1979) noted that students who were graduating from library school preferred consultation to more directive styles of leadership. In the same way, R. J. Solomon (1976) demonstrated that the directors of university library departments who earned higher leadership scores (according to their subordinates) led library departments that were more effective in serving other departments, according to the directors of the other library departments. On the basis of the results of administering the Jackson Personality Inventory and the Ghiselli Self-Description Inventory to library directors, Moore (1983)

described several traits that are essential for success as an academic library director: flexibility and adaptability, willingness to accept change, a stable and equable temperament, emotional balance, and endurance.

## ***Other Institutions***

Other kinds of institutions have their own special effects on leadership. For instance, in hospitals and health clinics, in competition with the inside supervisors, outside physicians with expert power exert a strong influence on in-house administrators, nurses, and paraprofessionals. In prisons, the role of guards increases their authoritarian tendencies, tempered by the special exchange relationships that guards develop with inmates. In the military, technical readiness for combat competes with the maintenance of high-quality relationships for career advancement in a bureaucracy. Ulmer (1993) notes that army officers spend at least twice as much time in their career in training and education as their civilian counterparts. Promotion is always from within. Character is more important than expertise.

Many other organizations in both the public and private sectors, such as recreational cruise ships, circuses, extended families, clans, and friendship groups are subjects for leadership study. Some, like voluntary community organizations, require members who can establish relations across organizational boundaries and networks of unity in diversity. Values need to be shared, and a sense of mutual trust and obligation must be developed, along with a sense of responsibility for the community (J. W. Gardner, 1997).

*Criminal Organizations.* Much still needs to be known about the leadership of terrorist organizations such as the Islamic Al Qaeda. It is quite different in the way its leadership is organized: It does not need to maintain a specific organizational structure. Members appear and disappear. Any member with assets can find volunteers, support, prospects, and purposes. There is no command or control center, no set agenda. Small transient groups of zealots meet fairly openly in mosques and schoolrooms. Continuing aid may be provided from many divergent sources, ranging from governments to individuals. Founded by Osama bin Laden and still a powerful influence, it was more a “field of potential” rather than a tangible single structure of cells and agents. It became more like the nineteenth-century anarchist movement. It still had the potential to generate operational organizations such as schools, secret militias, and illicit financial institutions. Brutal suppression was required to deal with it (J. B. Bell, 2002). By 2006, efforts to suppress and splinter Al Qaeda further made it more of a philosophical, militant, Islamic movement and less of an active operational terrorist network although it can regenerate its most violent component at any time, in either the main body or in splinter groups.

Criminal organizations such as the Mafia, the Columbian drug gangs, the Japanese Yakuza, and the Crips and Bloods street gangs are widely publicized but are less often the study of formal leadership research. Developing better understanding of their nature may emerge from the principles of leadership extracted by Himsel (2004) about the fictitious Sopranos, the television Mafia family, and its leader, Joe Soprano.

*Athletic Teams.* Leadership by athletic coaches and managers has become an important subject for research in its own right (Maby & Brady, 1996). Coaching practices have been seen as dehumanizing and coaches as autocratic and insensitive (Hendry, 1974). Ogivie and Tutko (1966) found that more successful basketball, football, baseball, and track coaches rated themselves as aggressive, dominant, and inflexible as well as sociable, conscientious, open, trusting, and emotionally stable. Based on House’s Path Goal Theory, Vos Strache (1979) showed that the leadership behavior of losing coaches failed to identify the path to success for team members. Chelladurai and Carron’s (1978) multidimensional theory of sports leadership noted the need to distinguish between the coaching of players of individual and team sports. It suggested that the more the coach’s behavior matched players’ preferences, the better was their performance and satisfaction. The Leadership Scale for Sports was developed to test the theory (Chelladurai & Saleh, 1980). The contribution of

the coach's leadership behavior to task and social cohesion of teams was demonstrated, along with the effect of the team on the coach's behavior (Westre & Weiss, 1991).

*Labor Unions.* Leadership research has tended to ignore labor and professional unions and important union leaders. The unions they led had major impact on our economic, political, and social environment as well as private organizations and public agencies. Their leadership shaped politics, modern industrial relations, the lives of their constituents, business, industry and public institutions. Among the most prominent of these leaders were Samuel Gompers, founder of the American Federation of Labor (AFL); Eugene V. Debs, U.S. Socialist Party candidate in five elections for U.S. president; William D. Haywood of the militant Industrial Workers of the World; John L. Lewis, cofounder of the Congress of Industrial Organizations (CIO); Sidney Hillman, cofounder and president of the Amalgamated Clothing Workers of America; César Chávez of the United Farm Workers; Philip Murray of the United Mine Workers; A. Philip Randolph of the Brotherhood of Sleeping Car Porters; Walter Reuther of the United Automobile Workers; and George Meany of the AFL-CIO (Dubofsky & Van Tine, 1987). While membership has declined a great deal in postindustrial United States, labor unions have been replaced to some extent by unions of government employees, schoolteachers, and agricultural workers.

## Leadership and the Organization's Internal Environment

---

Leadership in organizations is affected by the organization's philosophy, size, structure, objectives, functions, complexity, and institutional characteristics. Additionally, some aspects of leadership in business, military, educational, and religious organizations may stem from the nature of the leader's organization.

### *Size of an Organization*

The size of an organization was recognized early on as a variable that is of consequence to its leadership. The CEO of a hundred-person organization can get to know each member individually and act accordingly, but this is impossible in a thousand-person organization. Nevertheless, based on his experience leading both an army corps of 120,000 soldiers and a complex civilian organization of 120 professionals, Ulmer (1997) felt that both organizations required from him the same amount of energy to fulfill the role of leader.

The size of an organization can be gauged from the number of its members, the amount of its assets, and its output of product or services. Ordinarily, larger organizations require more structure to constrain the geometrically expanding possibilities of connections and interactions among the growing number of units and members.

CEOs' compensation is likely to be determined by the size of their operations, not by their profitability, particularly if their boards of directors are mainly members of the organization's management and shares in the firm are widely held by the public. Leading an infantry squad has different requirements from leading an infantry division. Emergent and appointed leadership within these respective organizations are likely to be systematically different. Erez and Rim (1982) found that compared to managers in smaller Israeli firms, those in firms with more than 600 workers turned more frequently to their coworkers for assistance on their own jobs. In firms with 600 to 4,000 workers, in contrast to larger or smaller firms, managers were most concerned with getting coworkers to do the jobs to which the coworkers were assigned. In firms with 4,000 to 6,000 workers, managers most often sought the assistance of their own bosses than did managers in the larger or smaller firms. And managers in firms with up to 600 employees were least likely to use rational tactics with their bosses compared with those in larger organizations.

L. W. Porter (1963a) reported that the overall satisfaction of managers was greater in large companies than

in small ones. However, lower levels of management were better satisfied in small companies than in large ones. Higher levels of management were better satisfied in large companies than in small ones. But ElSalmi and Cummings (1968) found that small companies fulfilled the needs of top managers more than did large ones. For middle and lower managers, the reverse was true. Nonetheless, size was not the critical factor. Cummings and ElSalmi (1970) reported that the diversity of roles and the level of the position were more highly related to managers' satisfaction of their needs than was the size of the department or company.

*Confounds.* Size itself does not really make the difference. What matters is what size brings with it. Larger organizational size is ordinarily accompanied by a greater need for structural complexity, more filtered and delayed information, geometric increases in the number of dyadic and group relationships, greater social distance, and additional constraints on change. Although many correlations between organizational size and leadership can be singled out for attention, ordinarily they are discussed in the context of other related mediating variables. For example, Koene, Vogelaar, and Soeters (2002) examined the positive effect of charismatic, considerate, and structuring leadership of managers of 50 stores of a Dutch retail chain varying in size from 16 to 120 full-time "personnel equivalents." Managers' initiation of structure had little effect on store performance. In the larger stores, it was neutralized by the availability of structures, procedures and systems. Compared to the smaller stores, overall, larger stores showed better results and better organizational climate than smaller stores. Managers in small stores tended to display more leadership in the aggregate. Controllable costs were reduced by charismatic and considerate leadership mainly in the smaller stores. Organizational climate was particularly better under considerate leadership in the smaller stores. In the smaller stores, the manager was the center of communication and had one-to-one contact with employees. In the larger stores, the managers' charismatic and considerate leadership could influence only the organization's climate. In the same way, Friesen (1983) needed a combination of organizational size, organizational structure, and organizational auspices to account for subordinates' descriptions of leaders' behavior in 23 public and private mental health agencies. The Dover Corporation was divided into many small independent autonomous corporations to provide flexible response to customers, a fair system of compensation, fast decisions, more satisfied managers and employees, and the elimination of corporate politics (G. D. Smith & Sobel, 1989)

*Downsizing.* It seems logical that when revenues slacken, shrinking the size of the firm will reduce its costs. The payrolls of managers and their staffs can be reduced if the organizational hierarchy is flattened or delayed. But Cascio (1995, 2003) has demonstrated that such involuntary shrinkage may be more costly in many ways, compared to available alternatives. The immediate savings in wages and salaries are offset directly by the increased costs of severance pay and bonuses, accrued vacation and sick pay, pension and benefit payoffs, and administrative processing costs. Indirect costs are the lowered morale, loss of commitment, increased insecurity, and reduced productivity of the remaining workforce, increased employment tax rates, and potential discrimination suits. Additionally, there is the cost to families and the community. When a turnaround in the economy or market occurs, new costs are incurred in recruiting, employing, and training new hires. A lot of experience and knowledge will have been lost. Employee turnover cost 1.5 to 2.5 times an employee's annual salary at Merck, a pharmaceutical company (J. Solomon, 1988). At the same time, in 25 large companies over a seven-year period, the expected improvements in financial performance failed to materialize from downsizing (Cascio & Morris, 1994). On the other hand, firms that dealt with declines in demand by instituting *responsible restructuring* instead of downsizing illustrated that financial as well as social benefits accrue from avoiding downsizing. For instance, faced with a seasonal decline, instead of laying off employees, Brooks Beverage Management maintained their benefits and arranged for their transfer to Haworth, a nearby furniture manufacture. In the 1990s, Ford Motor Co. delayed and flattened its organizational hierarchy without layoffs by realigning its worldwide automotive processes and management as well as by instituting early retirement plans. But in 2006 as SUVs fell out of favor, Ford had to plan to close plants with a total of 30,000 employees by 2009. Chase Manhattan Bank changed its organizational culture to increase its efficiency

and use of its resources through teamwork across departmental boundaries. The Eaton manufacturing corporation, instead of downsizing, introduced continuous improvement, involving its employees in cost control. IBM arranged, with other firms, buyouts of whole plants and their labor force that no longer fit IBM's business strategy to other firms and management groups. Employment continued under new managements. The United Steel-workers helped firms reduce immediate labor costs without downsizing by agreeing to contracts with significant wage reductions in exchange for employee stock ownership plans (ESOPs). Intel was able to redeploy employees rather than lay them off, using development centers, self-assessment tools, career counseling, temporary assignments, and skill training. Employees were thus enabled to transfer within Intel from manufacturing to sales and from obsolete technology divisions to new centers. Outplacement services were also provided when internal transfer was not feasible. Between 1991 and 1994, Intel placed 90% of its employees through internal redeployment. Finally, in times of sales declines, days worked per month can be reduced and unpaid voluntary leaves of absence (with state unemployment benefits) can be encouraged to reduce costs temporarily. This was done by the Reflex-ite Corporation (Cascio, 1995).

### ***Structure and Formalization***

Many more obvious differences in leadership patterns occur in organizations that differ substantially in size. One striking difference is how much relationships have to become more structured and formalized in larger organizations. As Robbins (1983, pp. 70–71) noted, "Decision making is different for an organization (of) ninety thousand employees than ... ninety ... As size increases, so does departmentalization, job specialization, the height of the structure, the number of horizontal units, and the number of rules and regulations."

On the basis of empirical factor studies, Pugh, Hickson, Hinings, and Turner (1968) developed the Aston model. The model included two major organizational factors: structuring of activities (prescribed work roles) and centralization of decision making (limits on discretion). These factors represented the two principal strategies of administrative control. Both usually increase as an organization enlarges.

Along with increasing size, the routineness of operations also leads to greater standardization and structuring of relations. Convenience food restaurants represent the ultimate in routine service, accompanied by a high degree of standardization and structure. In addition, as was noted earlier, stable, predictable environments permit organizations to formalize and structure themselves to a higher degree than those in unstable or uncertain environments.

Chapin and Tsouderos (1955) concluded from the case histories of 91 organizations that as organizations increase in size and differentiation, rank-and-file members become more passive and farther removed from the policy-making centers. Likewise, the executives become farther removed from the activities they plan and initiate. The long lines of command impose problems in communication. Robbins (1983) noted that structure also reflects the needs of the top leaders of the large organization to maintain maximum control over it. As a consequence, a bureaucratic structure is favored, with specialized jobs, standardization, rules and regulations, and centralized decision making. But as was mentioned before, even when the top managers favor a more humanistic organizational philosophy, such as with Theory Z, they may do so because they can still maintain their desired power and control. Compliance can be maintained through commitment at the lower levels rather than through sanctions. Middle managers do not have to be dominated; they can be eliminated.

Katz and Allen (1985) illustrated the importance of structure in a study of the 86 R & D teams embedded in matrix managements in nine firms. The performance of these teams was best when their project manager had more organizational influence and their functional boss had more influence over the technical details of their work. Their performance was also better when the team members perceived that the project manager and the functional manager had equal influence over their salaries and promotions. Lanzetta and Roby (1955)

contrasted antiaircraft crews of three men, each performing all functions, with the crews arranged in a hierarchical structure. They found that the performance of crews improved with the structure in place, particularly when the workload was heavy. Results also depended on how relations are structured within a group. Naylor and Dickinson (1969) observed that arranging the way the task was to be carried out, but not distributing the work components among the group members, was positively related to the effectiveness of the group.

*Organizational Design.* In designing an organization, a balance needs to be struck among three variables: centralized control, decentralized autonomy, and cooperation and teamwork. Control and cooperation need to be balanced between consistency and flexibility. Cooperation and autonomy need to be balanced between synergy and accountability. Autonomy and control need to be balanced between distant and local perspectives (Keidel, 1990).

Utilitarian organizations are usually designed according to functions and products, or a mix of the two. In a functionally designed production organization, people are grouped into units such as marketing, manufacturing, R & D, human resources, finance, and accounting. A functional service agency is similar. Client relations and consulting are substituted for manufacturing. The functional organization is expected to make efficient use of scarce resources, to better develop its personnel, and to centralize decision making. Its disadvantage is the creation of logic-tight silos of thinking, slower responses to change, and too much top-down direction. Units are grouped by products (or services) in product design, e.g., men's wear, women's wear, and children's wear. Coordination is better across necessary functional skills but not as good across product units. Organizational rather than functional goals are stressed. Control over diverse products or services is better. However, there is duplication of resources.

In a mixed design, such as the *matrix* organization, the manager of the product must obtain necessary resources from functional specialties. But there is better utilization of the needed specialists. On the other hand, the specialist needs to satisfy two bosses at the same time: the product manager and the specialties manager (Hughes, Ginnett, & Curphy, 1993).

*Hierarchical Level.* Efforts to change organizations are expected to flow through hierarchical levels (Griffin & Mathieu, 1997), usually from the top down but sometimes starting with initiatives from the bottom or the middle. A leader high in the hierarchy and at a social distance from followers needs to be visionary to be seen as charismatic, but a leader lower in the hierarchy and closer to followers needs to be considerate to be seen as charismatic (Shamir, 1995). At higher organizational levels, charismatic leaders rely on image building, strategic envisioning, rhetorical skills, and symbolic activities to influence followers; at lower levels, role modeling and building confidence and a collective identity become salient (Shamir & Howell, 1999). Along with transformational leadership, information technology firms also have need of transactional leadership at higher and middle levels to create structures and systems to deal with knowledge (Stross, 1998).

Pence and Dilts (2003) compared the survey responses of 32 project managers and their 24 senior executives about decisions to terminate a project. The *sunk cost bias* (the tendency to want to continue a project once an initial investment of money and effort has been made) of the 32 project managers was driven by their own personal efforts. The executives, who heavily weighed their initial expectations, revealed more of a *hindsight bias* (the tendency to distort a previous judgment in the direction of new information).

*Structural Clarity.* An important role for leaders is to provide structural clarity for their followers. E. E. Smith (1957) studied experimental groups in which both productivity and satisfaction were found to be related to the degree of role clarity of the members. Similarly, Lenski (1956) noted that group members with low degrees of *status crystallization* tended to experience difficulty in establishing effective, satisfying patterns of interaction with others. Dyer and Lambert (1953) observed that bomber wings were more efficient when members had a clear recognition of the status structure. In a study conducted by the Life Insurance Agency Management Association (1964a), it was found that agents who reported that the job was accurately described

before they were hired were less likely to quit than those who had been less clearly informed. Similarly, Wanous (1973) showed that newly recruited telephone operators who were told both the good and the bad about the job were less likely to quit than those who were told only about the good aspects. After a study in two companies, Trieb and Marion (1969) agreed that the extent to which new employees had been fully oriented to their jobs was highly related to the employees' subsequent job satisfaction and loyalty to their companies.

*Timing and Need for Structure.* Kinder and Kolmann (1976) found that self-actualization gained from sensitivity training groups<sup>11</sup> was greatest when leaders' and members' roles were highly structured at first and less structured later on. Similarly, Bridges, Doyle, and Mahan (1968) found that hierarchically undifferentiated groups were more effective than differentiated groups in the analysis of problems but not in the synthetic phases of problem solving. Ambrose and Schminke (2003) obtained the responses of 506 individuals from 98 departments in 64 organizations. They indicated the extent, on a seven-item survey of Khandwalla (1976–1977), to which their organization was *mechanistic* or *organic*. As expected, effects were somewhat stronger in mechanistic than organic organizations; perceived organizational support correlated .52 and .53 respectively, with perceived procedural and distributive justice.

*Individual Differences.* Some leaders work better in unstructured situations, while others work better in structured ones. According to Maas (1950), leaders who projected blame on others exhibited a desirable behavioral change when they led relatively informal, unstructured groups. On the other hand, leaders who absorbed blame showed the desirable change when they led formal, structured groups. When placed in reversed situations, both types of leaders exhibited anxiety and signs of stress. Overall, highly structured organizations, both public and private, were expected to determine the types of individuals to work within them. Individuals who choose to join such bureaucracies are also particular types of individuals. Most important, highly structured organizations socialize those who work within them.

*Bureaucratic Leadership.* In line with Weber's arguments about bureaucracies (1924/1947), Merton (1940) suggested that bureaucrats are likely to be inflexible. They are likely to overemphasize the importance of goals for those whose attainment the rules were established. The goals will be displaced by attention to outmoded rules. When bureaucratic leaders are inflexible, actions will continue to be bound by inapplicable rules. The career orientation of bureaucrats makes them cautious, conservative, and protective of an entrenched position. They are unwilling to be innovative or to take risks. They are impersonal in their thinking and ignore the concerns of clients and their individuals needs. Their formal authority breeds arrogance. Furthermore, the selection and socialization processes induce a bureaucratic personality without a sense of personal identity. There is little intrinsic interest in work and uncompromising adherence to rules (Bensman & Rosenberg, 1960).

While the above descriptions of bureaucrats fit the conventional wisdom about them, Goodsell (1983) marshaled considerable evidence to support a contrary argument: bureaucrats are human, too. In fact, citing Kohn's (1971) structured interview study of 3,101 men working in public and private bureaucratic organizations, men who worked in bureaucratic firms and public agencies were more, not less, self-directed than those who worked in nonbureaucratic firms and agencies. They were more open-minded, had more personally responsible standards of morality, were more receptive to change, and showed greater flexibility in dealing with problems. In explaining why Weber's, Merton's, and Bensman and Rosenberg's expectations about the bureaucratic mind were unsupported, Kohn suggested that bureaucratic organizations tend to select better-educated personnel, who are challenged to a great degree by their assignments and whose education makes for greater intellectual flexibility. Also, within the bureaucracy, they are freer from arbitrary actions by their superiors.

*Structural Complexity.* The more an organization increases in age, size, and structural differentiation, the more complex it becomes. More specialization develops within it. Special staffs that often have different

interests arise. More political behavior becomes necessary, requiring more compromise and accommodation. Decision making and implementation processes also become more complicated (Thompson, 1967). As the complexity of the organization increases, the dynamics within it must change. For example, the number of possible coalitions increases. The greater an organization's complexity, the more leadership positions are required. The positions will be arranged hierarchically, with carefully delineated roles and responsibilities. Additional power is attached to each position that is higher in the hierarchy (Bryson & Kelley, 1978).

The complexity of the organization will affect the pattern of succession.<sup>12</sup> The greater the complexity, the more levels any candidate needs to climb to reach the top of the hierarchy. Complexity probably also has an effect on the nature of accession to office. As complexity increases, so does factionalism (Tichy, 1973; Tushman, 1977). A structurally complex organization, such as a major corporation, gives rise to officials who are oriented more toward Theory X in their outlook and who are more concerned than usual about their need for safety and less concerned about ego and self-actualizing needs (Applebaum, 1977).

Hunt, Osborn, and Martin (1979, 1981) completed a line of investigation of that part of a leader's behavior that is required—that is, determined by the structured relationships imposed by the organization—and that part which is discretionary. In a study of 68 army telecommunication units, they found that greater complexity in the structure of the unit coincided with more discretionary leadership to improve role clarity and provide support. However, such discretionary leadership did not deal with work assignments or with rules and procedures. In addition, the amount of discretionary leadership correlated with both performance and satisfaction. At the same time, the role clarity required from the leadership correlated .25 with the subordinates' involvement in their jobs and  $-.24$  with subordinates' intentions to quit (Osborn & Hunt, 1979)

*Tall versus Flat Structures.* Flat-structured organizations have few hierarchical levels and many members or units at each level; tall-structured organizations have many more levels but fewer members or units at each level. Findings are mixed about the relative effects of tall and flat structures. Worthy (1950) maintained that flat-structured organizations resulted in greater satisfaction of employees than did tall-structured organizations. Richardson and Walker (1948) studied a company (IBM) when the number of vertical levels of organization was reduced and concluded that the reduction of social distance between the management and workers resulted in improved satisfaction and teamwork. Ghiselli and Johnson (1970) obtained some support for Worthy's contention by showing that satisfaction of the needs for esteem, autonomy, and self-actualization was higher in the flat than in the tall organizations they studied. However, satisfaction of the needs for security and social relationships did not differ in the two types of organizations. At the same time, ElSalmi and Cummings (1968) found that at the top levels, tall structures produced less fulfillment than did flat or intermediate structures. For lower levels, tall structures resulted in greater fulfillment.

In an analysis of experimental organizations with tall and flat structures, Carzo and Yanouzas (1969) found that tall structures required more time to process decisions, but flat structures required more time to coordinate efforts and resolve conflicts. However, tall organizations were superior in profits and rate of return. Porter and Lawler (1964) and Porter and Siegel (1965) surveyed managers in tall or flat organizations that varied in size. In small organizations, the satisfaction of managers was greater in flat than in tall structures, but the findings were reversed for large companies (with more than 5,000 employees). Generally, tall organizations yielded greater satisfaction of security and social needs, while flat organizations gave greater satisfaction of self-actualization. But structure was not at all related to satisfaction of the needs for esteem and autonomy. Esser and Strother (1962) found no relationship between the orientation toward rules by managers and the size or flatness of their organization.

*Span of Control.* Another way of looking at the effects of tall and flat structures is by examining the effects of the average number of subordinates supervised by each manager. Each manager must supervise many

more subordinates in a flat structure than in a tall structure.<sup>13</sup> For example, Kipnis and Cosentino (1969) found that as the supervisory span of control of 131 supervisors from five manufacturing firms increased, the number of official warnings the supervisors used to correct employees' undesirable attitudes and behavior also increased. Goodstadt and Kipnis (1970) experimentally manipulated the leaders' span of control so that subjects were led to believe they were supervising either three or eight subordinates. The subjects who believed they were supervising eight subordinates spent significantly less time talking to problem workers and threatened to fire them on earlier trials than did subjects who believed they had only three subordinates. Likewise, Ford (1981) found that when supervisors had larger departments to manage, subordinates felt they were shown less consideration by their supervisors. These results are all consistent with the expectation that when faced with a larger number of subordinates who are reporting directly to them, supervisors will be forced to reduce the amount of time they can spend individually with each subordinate. Although it may be possible to remedy the situation with more group meetings, delegation, and the granting of more autonomy, as was seen in the three just-cited studies, management by exception often emerges. With a large span of control, the supervisor tends to concentrate on deviations from standards in efforts to remedy the situation.

Leavitt and Whisler (1956) first recognized that organizational hierarchies would be flattened into shorter structures with wider spans of control as a consequence of the introduction of computers. They forecast that middle management was likely to shrink, as in fact it did in the next half century. A national survey of Australian employers by Littler, Hede, Bramble, et al. (1995) found that 44% of firms had cut out layers of managers, particularly middle managers. One CEO remarked that "Middle managers' ... main effect is to stuff up the business" (p. 2). The flattening organizations were seen to make careers "shorter, sharper and harder." Career laddering was less prevalent. There was less long-term security in a one company career. Flattened organizations represent a particular challenge to first-line supervisors. For instance, they may have more difficulty dealing with an ethical question, as they are faced with less guidance from a distant impersonal senior management (Sims, Veres, Jackson, et al. 2001).

*New Organizational Configurations.* Quinn-Mills (1991) proposed a self-managing workforce that could use available technologies of production and service to replace the usual organizational hierarchy, even if flattened. They suggested introducing a flexible, adaptive, semipermanent, residual hierarchy and clusters of 30 to 50 employees from different disciplines working in subclusters of five to seven without direct reporting relationships. Leadership would be rotated depending on competence. Members would be responsible and accountable to their cluster or subcluster linked through employee contacts and with the firm through the residual hierarchy. As with Bennis's (1959) *adhocracy*, Gerstein and Shaw (1992) agreed on the need for fluid, transitory organizations that form teams of participants to meet the requirements of different situations with freedom and authority to optimize their work processes. Furthermore, Doloff (1999) argued that rather than depending on job titles and the formal hierarchy of formal channels and protracted process, one must attend to the informal network to determine who is really making the decisions and advancing the work to be done. And Ellerman (1999) advised that much more than codified knowledge transmitted top-down is needed in the new circumstances. More implicit knowledge must be transferred horizontally.

### ***Centralization versus Decentralization***

Centralization implies that more leadership accrues in the headquarters, nucleus, or central authority of the organization and fewer decisions are possible in the peripheral units. Centralization promotes greater coordination of efforts and activities among the units, and more uniform policies with respect to the common goals of the larger organization. It makes possible a more rapid, concerted reaction of the whole organization. Centralization or decentralization may be a consequence rather than a cause. Blau (1968) investigated 250

government agencies and found that decentralization was most prevalent in agencies that employed a large number of highly qualified personnel. On the other hand, the presence of automation and poorly qualified personnel in large agencies was accompanied by more vertical levels of organization and tighter managerial control. Centralization of legislative leadership was seen by Bryson and Kelley (1978) as being likely to give greater enforcement power to the leadership and more stability. But more conflicts are also likely because of reduced consultation and a lack of information sharing. (A. Rosenthal, 1974). Consensual decision making becomes less frequent with centralization (Mechanic, 1962; Pettigrew, 1972). Adversarial relationships are greater (R. A. Gordon, 1961), unless statesmen appear at the top of the centralized leadership (Selznick, 1951). Centralization promotes coups (S. Kahn, 1970).

Baker and France (1954) examined the personnel and industrial relations departments of a sample of firms. They observed that top managers tended to prefer the decentralization of industrial relations functions so that local problems arising in a specific plant could be solved as they arose. Union officials, on the other hand, preferred the centralization of industrial relations functions as an aid in industrywide bargaining. M. Whitehill (1968) surveyed companies in the meatpacking industry and found that union negotiations with centralized structures by means of contacts with the main office resulted in more benefits for employees than did negotiations with decentralized structures involving contacts with local plants.

Decentralization usually brings with it more opportunity for its leaders to react quickly and flexibly to opportunities and threats to the organization. Less filtering of information can occur that is of consequence to the decisions made by the decentralized units. The decentralized organization is more likely to adopt an open learning philosophy and recognize the need to invent local adaptations of best practices. It can experiment with new ideas more readily than can the centralized organization (Ellerman, 1999). More "ownership," sense of responsibility, and commitment are expected for the decentralized-designed organization.

But there are costs to decentralization. Kanter (1982a) described decentralized units that were so concerned about operating issues that their definition of "long range" was the next quarter. T. A. Mahoney (1967) surveyed 283 organizations, obtaining managers' perceptions on 114 variables. Decentralization was found to be correlated negatively with most criteria of organizational effectiveness. In a survey of 217 executives in 109 firms, Stagner (1969) found that the decentralization of business enterprises was not related to profitability from sales. However, profitability from capital was significantly higher in centralized than in decentralized firms. Nevertheless, Newman and Summer (1961) outlined a set of guides for determining the degree of decentralization that is desirable for an organization, and W. T. Morris (1967) formulated 40 propositions, along with a set of mathematical models, for evaluating the factors involved in the consequences of decentralization.

*Dispersion of Authority and Power.* Dispersion of authority and power and empowerment to the lowest possible hierarchical levels is made possible with suitable selection and training of personnel (Conger & Kanungo, 1988). To further the possibilities and potential of empowerment, organizational policies can promote emphasis on self-determination, collaboration, and high performance standards (House, 1988). Furthermore, empowering organizations provide loosely committed resources at operational levels, opportunities for networking, and open communication systems (Kanter, 1983). But such policy is not necessarily dependent on decentralization, although it is more easily facilitated by senior managers when they work through the fewer layers of authority of the decentralized organization (Cordiner, 1952; Newman & Logan, 1965; Zald, 1964). Thus, decentralization has been advocated as a method for reducing the concentration of authority in high-level positions and for filtering it down to employees (Kline & Martin, 1958; Kruisinga, 1954). However, the major reason that managers are motivated to decentralize is that they are concerned about coordination problems. As organizations become larger, with many geographically dispersed subunits involving numerous products, the problems of coordination and response to local changes induce a tendency toward decentralization (Chandler, 1956, 1962). Globalization of organizations has probably

increased their decentralization, although information technology has made more centralization possible. Mergers and acquisitions have also probably increased decentralization in the enlarged corporations.

Legitimate power is usually disseminated outward when an organization decentralizes. The effects were seen by Baum (1961), who studied the U.S. Civil Service Commission and eight other dependent federal agencies. The commission formulates and enforces policies that must be applied by the agencies in hiring and promoting personnel. Baum found that the decentralization of hiring and promotion were handled effectively only when the agencies accepted and attempted to comply with the policies of the controlling commission. Executives in the more successful agencies regarded decentralization as providing them with the authority they deserve, but the executives in the less successful agencies saw the decentralized function as more work for them. In Baum's study, decentralization was accompanied by an increase in the decision-making authority of those in the higher levels of administration. Likewise, M. W. Meyer's (1968) survey of 254 city, county, and state departments of finance found that with the size of the organizations held constant, the number of organizational subunits decreased, but the number of levels of supervision within the subunits increased with the decentralization of decision making. Most important, decentralization was associated with more rules for the evaluation of decisions.

### ***Stable versus Dynamic and Changing Organizations***

The importance of organizational stability was seen to vary according to the size of organizations. En gland (1976b) reported that managers of middle-sized companies rated organizational stability generally higher in importance than did managers of small companies. Stability was of least importance to managers of large firms.

Using data from 215 governmental departments, M. W. Meyer (1975) found that the stability of an organization's structure was lower when the leaders had changed a great deal in the past, when leaders were dependent on a higher authority, and when the leaders maintained close contact with their superiors. The top managements of stable firms were found by T. Burns (1957) to differ from those of firms that were growing. Burns (1957) collected diaries for three to five weeks from 76 British top managers in medium-sized companies. Top managers in expanding firms spent relatively more time in discussions with one another. There was less flow of information up and down the hierarchical structures in the growing than in the stable firms. Again, Kerr (1985) demonstrated, in 89 interviews about the managerial compensation systems of 20 large industrial firms, that compensation was hierarchically based in the stable, steady-state firms that were committed to existing products and markets. On the other hand, compensation was more likely to be performance-based in less stable "evolutionary" firms that were involved in acquisitions, mergers, and joint ventures, sometimes in unfamiliar external markets and technologies.

House (1995) noted that employee commitment to unstable organizations in environments of uncertainty was higher when the organizations were led by charismatic leaders. Again, Bass (1998) reported that transformational leadership ratings were higher in dynamic, changing organizational environments than in stable organizations. But Hinken and Tracy (1999) concluded from a modeling analysis of the Multifactor Leadership Questionnaire that while the transformational leadership factors of inspirational motivation, intellectual stimulation, and individualized consideration are generally relevant for organizational performance improvement, the factor idealized influence (charismatic leadership) may be limited in relevance to unstable organizations, if at all. They were in agreement with Bennis and Nanus (1985), who did not find in interviews that otherwise transformational leaders were charismatic.

### ***Leaders' Latitude and Constraint in Organizations***

Managers have considerable supportive latitude to act within boundaries and rules but must also operate under many organizational constraints that will systematically affect their styles of behavior, performance, and satisfaction. The various task-related, interpersonal, and policy barriers to getting work done are also constraints that affect supervisors' style, performance, and satisfaction. Also constraining are the extent to which organizations require secrecy, restrict employees from bypassing the chain of command, and are scarce in resources. Latitude and constraint often create conflict. Managers must keep both broad and specific objectives in mind; plan, but be flexible; centralize some activities and decentralize others; and provide subordinates with autonomy. Collaboration and maintaining control is expected, yet delegation is to be practiced.

*Organizational Support.* Approximately 370 recent graduates of a Belgian university responded to a mail survey. If the organization in which they were working was supportive, they were more likely to see their supervisor as representing their organization (Sucharski, 2002). Among 263 manufacturing supervisors and employees working in a Fortune 100 Best Company, perceived organizational support contributed to job dedication and interpersonal communications. The effects were mediated by job satisfaction and affective commitment (Muse & Stamper, 2003). Among 185 pharmaceutical sales representatives, perceived organizational support mediated the effects of situational factors on affective commitment to the organization. The factors included procedural and distributive justice, and satisfaction with communication and supervision and the labor-management climate. (Moideenkutty, Blau, Kumar, et al., 2001).

*Organizational Constraints.* Hare (1957) observed that self-oriented and group-oriented leaders among groups of boys did not differ in aggression at an adult-supervised playground at school, but self-oriented leaders were significantly more aggressive in unsupervised neighborhood play conditions. There were more differences between the situations than between the leadership styles. Disagreement was higher in both styles on the supervised playground, while tension and antagonism were higher in the unsupervised neighborhood play conditions. Similarly, Farrow, Valenzi, and Bass (1980) found that the leadership styles of direction and consultation were greater when more organization, order, and imposed constraints were present. But less manipulation by leaders was observed under these conditions if goals were clear and levels of trust among the members were high.

Leadership and patterns of social interaction in an organization will be affected by how difficult or easy it is for its members to identify with the organization and its purposes and what outsiders believe about it (Dutton, Duke-rich, & Harquail, 1994). According to Fukuyama (1997, p. 156), "managers ... instill a ... sense of pride in their employees, [and that] they are part of something larger than themselves. People feel ... motivated to do their share if ... their company's purpose is ... to push back the frontiers of knowledge rather than ... to maximize their stockholders' return on equity."

Peters and O'Connor (1980) identified a number of situational variables likely to interfere with supervisors' accomplishment of tasks, such as lack of ready availability of materials and supplies. Laboratory studies confirmed the importance of this factor to job satisfaction and getting the work done (Peters, Fisher, & O'Connor, 1982). Field studies yielded more complex results. From an open-ended questionnaire, completed by 300 national managers of a chain of convenience stores, O'Connor, Peters, Pooyan, et al. (1984) identified 22 organizational constraints on the managers' work. Some of these constraints included: (1) shortage of help; (2) lack of authority to enforce company standards; (3) bypassed authority; (4) insufficient training; (5) inadequate equipment; (6) inadequate help; (7) frequent, long, and inappropriate meetings; (8) excessive paperwork; (9) un-scheduled activities; (10) ignorance of company policies and procedures; (11) an inadequate amount of merchandise; (12) lack of job-related information; (13) inadequate response time and budgetary support; (14) inappropriate work space; (15) unkept appointments; (16) excessive or wrong inventory; (17) insufficient materials and supplies; (18) theft by customers and by employees; (19) work overload; (20) wrong inventory. For a sample of 1,450 first-, second-, and third-level managers of the chain of convenience stores,

the investigators obtained a correlation of  $-.40$  between the managers' satisfaction with supervision and the extent to which they perceived overall that these constraints were operating in their work settings. These relations held for all three levels of management, although, as expected, satisfaction with supervision was greater at each successive level of management. In the same way, Mathieu, Tannenbaum, and Salas (1992) developed a 10-item instrument that measured the situational constraints perceived by the leader, such as the leader's need to correct others' mistakes, which correlated  $-.33$  with sales performance and  $-.36$  with the quality of leader-member relations (LMX). Nevertheless, Shamir and Howell (1999) hypothesized that charismatic leadership was more likely to emerge when the technology in a situation was difficult to analyze.

Along with institutional constraints, an important constraint on a mental health care staff was the lack of collegial support (Corrigan, Kwartarini, & Pramana, 1992). Situational constraints may place managers under a double handicap. In addition to making their assignments more difficult, the managers may also be appraised as performing less adequately than is justified by the objective evidence. Steel and Mento (1986) investigated the impact of situational constraints (job-induced obstacles, interpersonal obstacles, environmental policy, and procedural constraints) on objective performance. Also obtained were supervisors' appraisals and self-ratings of 438 branch managers of a finance company. The constraints were highly intercorrelated and formed a single factor scale. The district manager's supervisory appraisals of the branch managers correlated  $-.36$  with the situational constraints faced by the managers. That is, the more constraints faced by the branch managers, the lower the appraisals they earned. But the constraints had little actual effect on the objective performance of the managers except possibly on their ability to control past due accounts.

*Requirements of Secrecy.* Required secrecy has impaired communications within and between government agencies in the struggle against terror and crime. A constraint that limits whether managers can be participative with their subordinates is the extent to which the organization requires secrecy concerning products, techniques, and business strategies. Employees cannot be asked to participate in decisions if much of the information required to discuss such decisions cannot be revealed to them (Tannenbaum & Massarik, 1950). Pay secrecy is justified by privacy concerns, by the potential reduction of labor mobility, and by a desire to avoid conflict. But that secrecy may be at the expense of an unwarranted sense of injustice and impaired performance (Colella, Zardkoohi, Paetzold, et al. 2003). Also, some evidence is available to suggest that "open-book" management may be more efficacious than maintaining secrecy. When a campus newspaper of a public university listed the salaries of all its professors (which was actually available for the asking), overall the effect was positive on faculty and students in providing a realistic picture rather than an exaggerated one. Goitein (2004) described the positive effects of open-book management practiced by the employee-owned Springfield ReManufacturing Corporation. Employees were educated about the financial requirements for success and the operational variables critical to meeting the financial requirements. Progress in doing so was shared. For firms with publicly traded securities, regulations of the Securities and Exchange Commission govern disclosures.

*Chain of Command.* The ability or lack of ability to bypass formal organizational lines of communication appears to affect leaders' evaluations of their subordinates. On the basis of the responses to a questionnaire, of 395 white-collar employees and managers of the engineering division of a public utility, Hunt, Osborn, and Schuler (1978) concluded that a manager's approval of subordinates was predicted by the adequacy of the organization's general communication and planning and how frequently the manager received orders out of the chain of command. The manager's disapproval of subordinates was also affected by these out-of-the-chain-of-command orders, over which the manager had no control.

*Unionization.* Labor and professional unions provide alternate channels of influence, both upward and downward. Although leader-subordinate relations within an organization would seem to be mediated by whether the subordinates belonged to a strong or weak union or to none at all, few empirical comparisons have been made. One would expect, for example, that arbitrary, capricious, coercive management would be highly constrained if workers had a second route to upward influence via a strong, effective union. It is more likely

that such management would result in unionization that, in turn, would reinforce management's rule-bound leadership in place of arbitrariness. A rare empirical study of the effect of unionization on supervisory-subordinate relations within a firm was completed by Hammer and Turk (1985), who collected data from 160 first-line supervisors in 12 sections of a factory with an employee union. The percentage of workers who belonged to the union varied from 0% to 82%, depending on the section they were in. Regression analyses showed that the "density" of union members in a section contributed uniquely to the section supervisor's emphasis on performance, "going by the book," and sense of a clear authority to discipline. This last result could be explained by the union contract. The supervisors' use of discipline and penalties against subordinates was regulated. It was power granted to the supervisor through negotiations between management and labor, specified in the union contract. Supervisors, abiding by the contract, knew the rights they had both to reward and to punish; so did their unionized subordinates. Union stewards, as well, according to E. L. Miller (1966), need to remain mindful of the employees' rights and interests.

## Leadership and Organizational Culture

---

Intertwined with the philosophy, purposes, functions, and structure of the organization is its culture. Pericles identified the four aspects of the culture of Athens as an organized polity for its citizens that made it so valuable to them. First, it was open, democratic, and optimistic about its citizens' individual capabilities. Job assignments and promotions were based on merit, and the individual's dignity was upheld. Everyone was equal before the law. Second, its culture promoted beauty, good taste, and personal satisfaction in home, work, and play. Third, it was a culture of innovation; it provided the models for others to follow. Fourth, it encouraged an alignment of the interests of the individual citizen with those of the state (Clemens & Mayer, 1987).

### ***Organizational Culture Defined***

For Schein (1992), an organizational culture is the language, stories, customs, traditions, and rites shared or held in common by its members. It also includes its norms and implicit standards. The culture contains the organization's espoused values, formal philosophy, and implicit rules for getting along in the organization. To the meaning of culture, Trice (1984) adds its myths, sagas, legends, gestures, and the artifacts it creates to express activities. For Schein, also involved is the organizational climate—the way members feel about how they interact with one another as well as with outsiders. Further included are the knowledge, skills, and habits of thinking that are displayed in getting things done. The integrating symbols, ideas, feelings, and images that characterize the organization are another factor. They become consciously or unconsciously embedded in the organization's offices, sales rooms, plants, and products.

For Weick (1979), the primary function of organizations is *sense making*. An organization's members develop a set of mutually acceptable ideas and beliefs about what is real, what is important, and how to respond. The members learn shared patterns of behavior that are transmitted from one generation to the next (Deal & Kennedy, 1982). Along with the values that are shared by the members are the heroes who exemplify the organization's values, the rituals that inculcate the expressive bonding of members, and the stories that transmit the culture's values and ideas.

Martin, Feldman, Hatch, and Sitkin (1983) collected three types of stories that members told to assert the distinctiveness of their own impact on how the organizational culture communicates what is expected from its leadership. The stories described: (1) whether the boss was human and, when presented with an opportunity to perform a status-equalizing act, did or did not perform it; (2) rule-breaking (for instance, a senior manager broke a rule and was confronted by a junior person); (3) how the boss reacted to mistakes. Rosen (1985)

completed an ethnographic study of an advertising agency that demonstrated how senior management manipulated the language, gestures, and context of a breakfast ritual to ensure acceptance of the goals and practices of the company. This ritual reinforced and reaffirmed the bureaucratic structure of the organization and its capitalistic values.

Jung's (1971) psychological classification provides a useful fourfold view of widely divergent organizational cultures. These four cultures are: bureaucracies, with *sense-thinking* managers; matrix organizations, with *intuitive-thinking* leaders; organic organizations, with *intuitive-feeling* leaders; and familiar cultures, with *sensing-feeling* members (Mitroff, 1983). Schein (1985, 1990) provided a fuller set of dimensions along which organizational cultures differ: (1) Relation to its environment—dominant or submissive, harmonizing, searching for a niche? (2) Nature of human activity—proactive, harmonizing, or passive? (3) Determination of truth and reality—pragmatic, relying on wisdom or social consensus? (4) Nature of time—orientation to the past, present, and/or future? (5) Human nature—good, neutral, or evil; fixed or perfectible? (6) Human relationships—competitive or cooperative, favoring individualism or groups, autocracy and paternalism, or collegiality and participation? (7) Homogeneity or diversity—encouragement of similarities or differences; conformity or innovation?

*Assumptions.* Basic assumptions about the nature of reality, time, space, human nature, and the environment are taken for granted at a preconscious level by those who are embedded in an organization's culture. There is a greater level of awareness about the interrelated values. The art, technology, and behavior that emerge are visible but not necessarily decipherable. It often takes an outsider to understand the cultural connections of the observable products and behavior to the underlying values and preconscious assumptions. Early in its development, an organization's culture is the glue that holds the organization together as a source of identity and distinctive competence. But in an organization's decline, its culture can become a constraint on innovation, since it is focused on the organization's past glories (Schein, 1985). Hatch's (1993) model of cultural dynamics is a framework involving processes of manifestation, realization, symbolism, and interpretation. What members of the organization assume to be true influences their values. Their values affect their assumptions and are realized in their artifacts. Symbols and interpretations follow. A visionary culture is able to align its core values and their preservation, "to reinforce its purposes, and to stimulate progress towards its aspirations" (Collins, 1996, p. 19).

*Describing Different Organizational Cultures.* Ethnographic and case studies have provided the most common means of depicting organizations. To describe a particular organization's culture, Kilmann and Saxton (1983) listed eight questions that the organizational culture answers: (1) What makes sense; what can be talked about? (2) Who am I; where do I belong? (3) Who rules; how, why, and by what means? (4) What are the unwritten rules of the game for what really counts; how do I stay out of trouble? (5) Why are we here, and for what purposes? (6) What are our history, geography, and the structure we build? (7) What are the stories about ourselves and others? (8) What are our morality and ethics? Are people basically good or evil? As a quantitative survey, the Kilmann-Saxton (1983) cultural gap survey asked organizational members to assess the strength of their organization's norms. The norms dealt with task support, task innovation, social relationships, and autonomy of individual members, all of which are expected to contribute to an organization's performance and satisfaction. Low scores reflected gaps in the organization's culture required for better performance and satisfaction. Cooke and Lafferty (1983) constructed the Organizational Culture Inventory (OCI), asking what was the extent an employee was expected to fit into the organization, such as "Be a good listener," "Look for mistakes," and "Keep on top of everything." Twelve variables could be generated describing the organization's values culture. They could be factor-analyzed into three types: (1) constructive (humanistic, achieving, affiliative, and self-actualizing), (2) passive/defensive (conventional, approval-seeking, and dependent), (3) aggressive/defensive (power-oriented, competitive, and perfectionistic) (Cooke & Szumal, 1992). Anthony (1994) obtained 585 raters, including 83 managers from first-line to

executive. They used the OCI to describe the culture of their 11,000-person telecommunications firm and the Multifactor Leadership Questionnaire (MLQ) to rate the transformational and transactional leadership of their immediate superior. The four constructive culture variables correlated between .42 and .55 with the four MLQ transformational leadership scores, between  $-.03$  and  $.05$  with MLQ transactional active management by exception, and between  $-.41$  and  $-.39$  with passive management by exception. O'Reilly, Chatman, and Caldwell (1991) developed the Organizational Culture Profile (OCP) to provide a measure of the extent which there was a match between individual organizational members' preferences for 26 cultural norms that characterized their organizations. The factors that emerged were: (1) innovation, (2) attention to detail, (3) out-come orientation, (4) aggressiveness, (5) supportiveness, (6) emphasis on rewards, (7) team orientation, and (8) decisiveness. A year later, the fit of personal preferences and organization norms correlated .28 with commitment, .36 with job satisfaction, and with greater retention after two years.

To assess the aspects of a corporate culture that contribute to organizational excellence more specifically, Sashkin (1986, 1988) extracted seven explicit and three implicit core values or beliefs from Peters and Waterman (1982). Included were task-relevant values, such as being the best at what the company does, attending to details in doing a job, importance of superior quality, service, economic growth, profits, and managers as "hands-on doers," not just planners and administrators. Other values were more concerned with relationships: people, as individuals, are important; people in the organization should be innovators and should be able to take risks without feeling that they will be punished if they fail; informality is important, as is improving the flow of communication throughout the organization; and people should have fun doing their work. All these values need to be made explicit in a recognized organizational philosophy that is developed and supported by those at the top. Sashkin constructed the Organizational Beliefs Questionnaire to measure respondents' estimations of whether others in their organization subscribed to such beliefs as "people in this organization believe in being the very best at what we do." Construct validation was obtained by showing greater variance among rather than within 46 organizations. A total score reflecting the endorsement of values that promote excellence was found to be higher in more effective organizations.

*Transformational Cultures.* Bass and Avolio (1993) applied the transformational/transactional paradigm to portray organizational cultures. A *transformational* culture emphasized such concepts as: "we trust each other to do what's right," people go out of their way for the good of the department or organization," and "new ideas are greeted with enthusiasm." In a *transactional* culture, the concepts were: "rules and procedures limit discretionary behavior," "decisions often require several levels of authorization," and "we negotiate with each other for resources." Cultures can be typed according to their transformational and transactional scores on the Organization Description Questionnaire (ODQ), as was done for 69 organizations, ranging from hospitals and police departments to civil service agencies and manufacturing firms. In a high-transformational-high-transactional *contrast* culture, there is much leadership and constructive conflict about the best ways to proceed. In a high-transformational-low-transactional organizational culture, there is much talk about purpose, vision, values, and fulfillment, without much need for formal agreements. Trust has been internalized, and expressiveness and creativity are high. Leaders emphasize confidence and improvement. *Bureaucracies* are opposite in type: low-transformational-high-transactional. A *coasting* organization is a mix of moderate-transformational and moderate-transactional values and behaviors. The leadership fails to make full use of the organization's resources and opportunities. The *garbage can* organizational culture is neither transformational nor transactional. Leadership, consensus, and cooperation are absent. The organization is anarchic, without clear purposes or rules to control activities. The *pedestrian* organizational culture, with moderate-transactional rules and regulations but no transformational qualities manages to stagger along as a consequence of formal arrangements but with few improvements and risks (Bass & Avolio, 1993b). Not surprisingly, there is a strong linkage between the ODQ and the MLQ. As expected, leaders earn higher MLQ transformational leadership ratings from their followers in organizations assessed as transformational in culture

on the ODQ. They earn higher transactional ratings in bureaucracies. Such high correlations were reported by Corrigan, Lickey, McCracken, et al. (2001) for 118 staff members in four Illinois mental health outpatient service agencies.

### ***The Leader as Culture Builder***

An organization's culture derives from its antecedent leadership. Anecdotal evidence and discourse abound in considering how an organization's leadership influences its culture. For Sayles and Wright (1985), the CEO's behavior is the most important determinant of the organization's culture. For Schein (1985), leadership is critical to the creation and maintenance of culture. One is likely to see a constant interplay between culture and leadership. Leaders create the mechanisms for cultural embedding and cultural reinforcement. Cultural norms arise and change because of what leaders attend to, their reactions to crises, their role modeling, and their recruitment strategies. For Schein, the organizational culture is taught by its leadership.

Bass (1988) observed that charismatic leaders create new cultures for their followers by creating new meanings for them. The process is advanced by *frame alignment*, or shared interpretive orientations of leader and followers (Snow, Rochford, Worden, et al., 1986). While transactional leaders work within their organizational culture, transformational leaders change them (Bass, 1998). Tichy and Ulrich (1984) thought that the transformational leader needs to understand and realign the organization's culture as a way of providing meaning, by making sense of symbols and events. The transformational director of Food for the Hungry/Kenya, an NGO, has been its servant leader as well and has built an organizational culture of shared responsibilities and leadership roles, a strong organizational identity, and a healthy sense of community (Kroll & Vandenberg, 1996).

Hickman and Silva (1984) argued that the two bases of effective organizational performance are strategic thinking and culture building by the leaders. Strategic thinking creates the vision of a firm's future. The vision becomes a reality when the leaders build a culture that is dedicated to the vision. In contrast to transactional leadership, the leaders here are visionary executives who integrate creative insight and sensitivity to "forge the strategy-culture alloy." These leaders combine versatility, focus, and patience to maintain the organization's highly effective performance over the long term. According to Kiefer and Senge (1984), such leadership pushes for a "metanoic" organization, building on such assumptions as those that say that people are inherently good, honest, trustworthy, and purposeful; everyone has a unique contribution to make; and complex problems require local solutions. Leaders who build such cultures need to have personalities with a deep sense of vision and purposefulness. They are aligned around that vision and can balance reason and intuition, as well as empower others (Kiefer, 1986; Senge, 1980). Such leaders display much individualized consideration (Bass, 1985a). They facilitate and teach. They create rather than maintain and are personally involved with the development of key managers (Senge, 1984, 1986). Quinn (1988) applied his competing values model to set forth four alternate ways a leader orients an organization's climate or culture. A climate or culture with a *supportive* orientation arises if the leader focuses on flexibility rather than control in the internal organization's environment; an *innovative* orientation is built for the external environment with the same flexibility. On the other hand, if the leader is more concerned about control than flexibility, the internal environment will be rules-oriented and the external environment will be goal-oriented. Den Hartog, Muijen, and Koopman (1996) found, for 330 Dutch employees in 28 departments from five different organizations, that rules and goals orientations correlated more highly with transactional leadership (-.54, .61) than with transformational leadership (.42, .54). An innovative and supportive orientation correlated more highly with transformational leadership (-.72, -.69) than with transactional leadership (.52, .48). But emphasizing cultural rather than individual issues did not add to the impact of transformational leadership. In a survey of 4,454 executives rated

by approximately 40,000 subordinates, Colvin (1996) reported that transformational leadership had the same positive effects on subordinates whether the executives focused on cultural issues such as setting visions and shaping values or on individual issues such as coaching and empowering. Organizational cultures can also create the negative effects of resistance to change and rejection of innovation and implementation.

*The Leader as Cultural Transmitter.* Kouzes and Posner (1987) emphasized the importance of the leader in transmitting the organization's culture and values. An organization contains a network of "priests," who maintain and bless the values; "storytellers," who watch over the values; and "gossips," who are key transmitters of the culture (Deal & Kennedy, 1982). Kotter and Heskett (1992, p. 84) argued that "the single most visible factor that distinguishes major cultural changes that succeed from those that fail is competent leadership at the top." Leaders act as effective role models, articulate ideologies, and inspire commitment to both old and new values. They use cultural forms to communicate new values and help to institute cultural change (Trice & Beyer, 1991).

*Leadership and Organizational Climate.* As noted earlier, an important feature of an organization's culture is its *climate*—the subjective feelings about the organization among those who work within it. Leaders influence the organizational climate through their behavior and decisions (Van Muijen, Koopman, et al., 1992). The climate directly affects how organizational members relate to one another and the culture within which they work (Den Hartog, Van Muijen, & Koopman, 1996). As might be expected, Kozlowski and Doherty (1989) showed that the quality of leader-subordinate relations was directly related to the satisfaction felt about the organization's climate. Halpin and Croft (1962) found systematic connections among scales measuring different aspects of a school's organizational climate and leadership and the response of teachers. Sheridan and Vredenburg (1978a) showed that head nurses' consideration and initiation of structure in a hospital could be explained partly by the turnover among staff members and the administrative climate, as measured by an instrument developed by Pritchard and Karasick (1973). J. L. Franklin (1975) examined similar relations in a broader organizational context. Particularly important to an organization's climate is how clear its leaders make the organization's goals to the members and convey a sense that the climate is one in which there is a high degree of trust.

For 78 executives described by 407 subordinates, Bass, Valenzi, Farrow, and Solomon (1975) used stepwise regression to determine that in organizations described as more trusting, more participative leadership behavior was observed. In organizations where the subordinates perceived clear goals, the managers were described as more directive, more likely to consult with their subordinates, and more likely to share decision making with the subordinates. In a follow-up, with descriptions by more than 1,200 subordinates of their superiors' leadership behavior and aspects of the organization, Farrow, Valenzi, and Bass (1980) found that consultation was most frequent when an organization's goals were clear and levels of trust were high. Similarly, according to Hunt, Osborn, and Schuler (1978), an organization with overall practices that promoted the clarity of jobs and clear standards increased the leaders' supportive behavior toward their subordinates. Child and Ellis (1973) concluded that more delegation by the superior was seen if work roles were clear and much discretion was perceived in the organization's climate.

In a survey study of 440 Indian managers from seven organizations, Ansari (1988) found that whether the climate was favorable or unfavorable affected the managers' efforts to influence. If the climate was favorable, participative managers said they were more individually considerate to their subordinates and less likely to try to block or defy their bosses; task-oriented managers said they increased the use of their expertise and reasoning with both their bosses and their subordinates; and bureaucrats said they were more likely to challenge their subordinates and be ingratiating toward their boss. If the climate was unfavorable, participative managers said they were more likely to use coalition tactics, to manipulate their subordinates, and be more ingratiating with their bosses. The task-oriented managers said they were less defiant toward their bosses, and the bureaucrats said they were more assertive with their subordinates and more transactional and diplomatic with their bosses.

## ***Founders of Organizational Cultures***

The creation of much of organizational culture is attributed to companies' entrepreneurial founders (Pettigrew, 1973, 1979). Schein (1983) noted that a founder creates a culture from a preconceived *cultural paradigm* in his or her head. Then the founder's and successor's leadership shapes the culture and the mechanisms to restrain it. Schein and others assumed that a monolithic culture of shared values emerges that is guided and controlled by the founder. Martin, Sitkin, and Boehm's (1985) detailed interview study with 700 employees of a young and growing electronics manufacturing firm in Silicon Valley, California, implied that the founders' values may conflict to some extent with those of various constituencies in the firm. In this case, although 72% of the employees' explanations of the company's origins, quality control, and turnover agreed with the founders' interpretations, 19% did not.

Some founders, such as Steven Jobs of Apple Computer, who do not have previous leadership and management experience or much formal education, form companies and originate corporate cultures that they then must leave to others to manage. Jobs subsequently returned to further continue Apple's unique culture. Among the CEOs of the fastest-growing companies in the United States, three fourths were founders of their companies, and 83% like Walt Disney of Disney Productions and Ray Kroc of McDonald's, never made plans to retire. They were not just inspired originators; they also had the credentials for long-term tenure. Most were highly educated. All but 19% were college graduates; 46% held graduate degrees, mostly in engineering. Bill Gates of Microsoft, a dropout from Harvard, was an exception. Half had managerial experience in a Fortune 500 company before founding their own company (Nicholson, 1983).

## ***Founders of Countercultures***

John DeLorean and Hyman Rickover are examples of founders of countercultures. Martin and Siehl (1983) described DeLorean's counterculture, built within General Motors (GM) in reaction to GM's dominant cultural values of deference to authority, invisibility, and loyalty. GM's division heads, despite some degree of autonomy, were expected to conform closely to GM's dominant values. Deference to authority was expressed, for instance, in the way subordinates were expected to meet their superiors from out of town at the airport, carry their bags, pay their hotel and meal bills, and chauffeur them around day and night. The higher the status of the superior, the more people would accompany him on the flight and the larger the retinue that would await him at the airport (p. 57).

DeLorean enraged his boss by failing to meet him at the airport, and thereby signaling disrespect for his boss's authority. He also created and recounted stories about the foolish extravagances of subordinates who catered to the whims of visiting VIPs. In the GM culture, invisibility was expressed in such ways as maintaining standardized offices; eating together in the executive dining room; and adopting a uniform dress code of dark suit, white shirt, and blue or black tie. Again, DeLorean violated these rules—for example, in requesting a brighter, more modern and attractive office decor and dressing in a more fashionable but still conservative continental mode. Loyalty in the GM culture was expressed by not voicing criticisms in front of the corporate management. DeLorean invented stories to interpret the costs to GM of "group-think" and conformity.

DeLorean's counterculture was an attempt to support the value of productivity instead of deference, of objective measures of performance instead of subjective indicators of conformity, and of independence instead of blind loyalty. But his deviance remained within tolerable limits until he left to found his own company, which had notorious consequences. It remained for Roger Smith, a new CEO, to reshape GM's dominant

culture. Ultimately, GM's inflexibilities in management, marketing, and labor contracts forced radical reductions in size in 2006 to keep up with its competitors.

Hyman Rickover almost singlehandedly constructed a powerful naval counterestablishment in the Nuclear Reactors Branch of the U.S. Navy (Polmar & Allen, 1982). This branch became a separate elite nuclear establishment in de facto control, by 1980, of one third of the U.S. naval fleet! Rickover formed this counterestablishment for his self-satisfaction and to coincide with his personal views of what was wrong with the U.S. Navy's values and practices, in general, and the U.S. Naval Academy at Annapolis, in particular. His manufactured culture included horrendous stress interviews that were of questionable validity for applicants, generally favoring graduates of NROTC rather than of the academy. Discipline was extreme, focused on overlearning and dedication. There was an intense emphasis on both detailed directive leadership and the practice of management by exception, which involved the bypassing of channels and weekly reports written personally to Rickover. There was an unrelenting pressure to work and study. Rickover, himself, set the workaholic pace in a spartan office with spartan lunches. He was almost always in civilian dress. Expertise took precedence over rank and specialization over general management.

As civilian chief of the Naval Reactors Branch of the Atomic Energy Commission and later, of the Department of Energy, then as the U.S. Navy's chief for nuclear propulsion, Rickover was the nuclear organization's network center. For two decades after he would have been retired by the U.S. Navy, he maintained his power, authority, and budget, bypassing the Navy and going directly to Congress. Although experiments with nuclear reactors for propulsion preceded him, he made himself the mythological originator. He rejected cost considerations in the decisions as to whether to build nuclear or conventional fleets. Only nuclear submarines and surface vessels were valued. The result of all this was a large, first-rate nuclear navy, built at the expense of a larger, possibly more nationally useful conventional fleet. A higher price was paid in financial and human costs than was necessary. The human costs were ultimately evidenced in the failure to maintain a sufficient number of volunteers for the nuclear submarine fleet (Polmar & Allen, 1982).

### ***Promoting Changes in the Dominant Culture***

One does not have to construct a counterculture to improve the existing culture. The issue to which top management is particularly sensitive is the leadership required for managing organizational change in its culture. Such change is necessitated by new marketing requirements, new technologies, and new kinds of personnel (Bass, 1985a; Bennis & Nanus, 1985).

Leavitt (1986) and Tichy and Devanna (1986), among others, provided book-length advice, consistent with research results about transformational leaders, on how to accomplish the needed changes in the organizational culture. It is essential for top management to articulate the change that is required. The message may be of a vision that entails *directive* and persuasive leadership; it may permit modifications and contributions from others. Changes, consistent with the message, are introduced in the structure, processes, and practices. Sufficient participation is encouraged to generate commitment, loyalty, and involvement, accompanied by full, two-way communication with adequate feedback loops. Desired role and behavioral models of leadership begin at the top and are encouraged at each successive level below. Furthermore, leaders who are concerned about organizational renewal will seek to foster organizational cultures and climates that are hospitable and conducive to creativity, problem solving, risk taking, and experimentation. To foster cultural changes in an organization, say to shift it from a service to a market orientation (as with AT&T), leaders should first honor the past, returning to it for inspiration and instruction and identifying past objectives, principles, and still-successful approaches that will be maintained (Wilkins & Bristow, 1987). Kane (1984) described how the General Electric culture was changed in this way by the transformational leadership of Jack Welch. First, there

was articulation of the changes that were desired. Next, the necessary changes in structure, processes, and practices were made and were widely communicated. Finally, new role and behavioral models were established. "Leaders must understand the interweaving of continuity and change ... in long-term purposes and values." Promotions should be made to ensure that these older values can survive despite the oncoming changes. Ceremonial events are needed to mourn the loss of the cherished past. Finally, changes should be organic, developing out of new ways that are already desired and providing reinforcement for new incremental efforts that are attempted and successful (J. W. Gardner, 1988b, p. 6).

*Organizational Culture and Manipulation by Management.* Mitchell (1985) contrasted the values explicit in two empirical studies of successful enterprises. One was Peters and Waterman's (1982) *In Search of Excellence*, which identified 62 firms that had a history of growth, economic success, and innovativeness over a 25-year period.<sup>14</sup> The other was Levering, Moskowitz, and Katz's (1984) *The 100 Best Companies to Work for in America*. These were the 100 companies that employees most said they liked to work for. Only 21 of the 100 best-liked firms showed up among the 62 excellently managed companies mentioned by Peters and Waterman (1982). (There was considerable change in the lists between 1982 and 2006.) Management of the task-effective culture appeared to be manipulative. That is, in such a culture, people are valued not for themselves but as being instrumental to productivity. Employees' values are shaped to increase their commitment to productivity, the institution, and the maintenance of the work ethic. The manipulation is done not through conviction but through myths, fables, and fairy tales about values that the management itself does not necessarily believe in.

The effort to manage meaning is a case in point. Charismatic leaders give meaning to employees' efforts and goals by linking them to the employees' values (Shamir & Howell, 1999). Although finding meaning in one's work is intrinsically satisfying, an existential view of organizations and the importance of meaning in understanding organizational life has led to efforts to manage meaning at the cost of individual members' authenticity (Maddi, 1989). A manager of meaning "is concerned with the tricks of the pedagogue, the mentor, the linguist, the more successfully to become the value shaper, the exemplar, the making of meanings" (Peters & Waterman, 1982, p. 82). In contrast, many of the 100 best companies to work for, according to their employees, stressed more truly relations-oriented values, such as making employees feel they were part of a team or family, encouraging open communication, encouraging suggestions, promoting from within, enabling people to feel pride in their products or services, sharing profits, reducing social distance, making the workplace as pleasant as possible, encouraging the employees' participation in community service, matching employees' savings funds, avoiding layoffs whenever possible, showing concern for employees' health, and providing training and reimbursement of tuition.

Specific policy statements about these values were found among many of the 100 best-liked firms. For instance, Apple Computer stated that employees should be able to trust the motives and integrity of their supervisors. Armstrong declared that management should respect the dignity and inherent rights of the individual, maintain high moral and ethical standards, and reflect honesty, integrity, reliability, and forthrightness. According to the policy statements of Doyle Dane Bernbach, employees and the firm may refuse to work on advertising accounts for ethical reasons or on accounts that may have negative effects on the public. Other firms, such as Rolm, focused on honesty; Moog, on statements about the need for mutual trust and respect; and Celestial Seasonings, on dignity, fairness, kindness, and the professional treatment of all individuals and organizations with whom it works. Mitchell (1985) concluded that what seems to be the best-managed firms may be different from those for whom employees most like to work. The best-managed firms create a culture, with symbols and myths, to get employees to work harder and better; managements of the best-liked firms seem genuinely to care about the quality of the experience of everyone in the firm. In the former, management may practice consideration but really believe in exploitation; in the latter, a truer concern for others is seen in their employees' evaluations. Showing the influence of positive psychology, Luthans (in

press) concluded that management should focus on the strengths and capabilities of its people instead of trying to fix what is wrong with them. Singled out for attention would be an organizational culture that encourages self-efficacy, hope, optimism, subjective well-being, and emotional intelligence.

### ***The Effects of the Organization's Culture on the Leader***

Schein (1985) suggested that culture manages management more than management manages culture. For instance, a strong organizational culture, with values and internal guidelines for more autonomy at lower levels, can prevent top management from increasing its personal power at the expense of middle management (Rubin & Berlew, 1984). Osborn and Ashforth (1990) concluded that the culture of complex high-technology organizations laden with high-risk liability, such as nuclear energy plants, affects its managers as well as its workers with myths and institutionalized structures that the leaders use to focus the attention of their subordinates. Trice and Beyer (1984, p. 666) noted that "managers need to learn to ... assess not only the technical consequences of any activities and programs, but also ... they need to learn ... effective ceremonial skills. Some flair for the dramatic and the ability to be expressive in speech, writing, and gestures could be an asset in meeting ... ceremonial requirements."

*Adaptive* organizational cultures emphasize innovation, risk taking, open communications, teamwork, and enthusiasm. *Nonadaptive* cultures stress order, efficiency, and aversion to innovation and change. It follows that transformational leadership is more likely in adaptive organizational cultures and transactional leadership in nonadaptive cultures (Kotter & Heskett, 1992). In addition to individual cognitive processes, organizational culture affects the tendency of managers to "throw good money after bad" and continue failing courses of action. Rathburn, Miller, and Aniolek (2003) hypothesize that failing actions are often escalated as a consequence of cultural norms such as dishonest reporting, the valuing of impression management, and ambivalence about ethical considerations. Escalation is limited if the cultural norms diffuse blame for failure and stimulate generation of alternatives. Managers particularly need to attend to the conservativeness, reflected in rites and ceremonials, that can hinder efforts to change the organization. They need to modify the rites and ceremonials, when it is possible to do so, to fit with the desired new directions for the organization. They can invent new rites to replace the old, some of which symbolize the value of change itself (Hedberg, Nystrom, & Starbuck, 1976). One example is the ceremonial introduction of a new product or process to replace an older one.

Lombardo (1983) described three corporations, each of whose different cultures (highly task-oriented, highly pragmatic, and highly considerate of others) resulted in the development of parallel differences among their respective managers. In the same way, Roberts's (1986) survey described earlier, of the styles used by 350 business managers and university administrators with their subordinates, peers, and bosses found that managers in Type Z organizations (Japanese-style organizations) were less likely to be directive than were their counterparts in Type A (authoritarian, top-down organizations). Shamir, Zackay, and Popper (1998) asked soldiers in 50 field companies of the Israel Defense Forces to what extent their company had special slogans, special songs, special nicknames, special rituals, special jargon, and internal jokes. These provided a measure of each company's culture. This soldier-rated company culture correlated .31 with the staff's ratings of the company leader's *supportive* leadership behavior (openness, friendliness, sensitivity toward their needs and feelings, giving them autonomy, and deemphasis on social and power distance from followers). Organizational culture also correlated .30 with the leader's emphasis on *collective identity* using symbols and emphasis on differences from other companies. But culture did not correlate with exemplary leadership or with the leader's emphasis on ideology.

*Effects of Clan and Market Cultures.* Kerr and Slocum (1987) identified two types of corporate

reward systems that give rise to two different cultures—clan and market—and characteristically different leadership experiences. The clan is fraternal. Commitments are long-term; interests are mutual. There is stress on teamwork and pressure to conform. Socialization takes a long time, superiors are agents of socialization, and the culture governs a wide range of behaviors. The marketing culture is contractual, commitment is short-term, and self-interests dominate. There is less socialization, superiors are distant, and the cultural norms govern few behaviors. In the *clan* culture, one's superior defines and evaluates, usually subjectively, one's managerial performance. There is promotion from within, often connected with one's need for further development. People are expected to do more than just what is agreed in contracts. Loyalty to the organization is exchanged for commitment to it. A contrasting *market* culture develops from a performance-based contingent reward system. One's role is specifically defined and evaluated by objective financial outcomes. There is much less need for superior-subordinate interaction or concern for subordinates' socialization and development. Presumably, the clan culture provides more potential for transformational leadership and the market culture, for more transactional leadership.

*Effects of Kibbutz Ownership.* The effects of the culture of kibbutzim on their top officials' leadership of firms that the kibbutzim owned as cooperatives was contrasted to the leadership of counterpart publicly and privately owned Israeli business firms. Among a sample of 224 Israeli senior executives, the business executives were more *directive*, negotiative, and delegative and less *participative* than were the general managers of firms owned by the kibbutzim. They also had relatively greater power and were more assertive, but they did not differ from the executives of the kibbutzim-owned firms in the amount of consultation they did or how well informed they were (Chitayat & Venezia, 1984).

*Instrumentality and Expressiveness in the Culture.* Santner (1986) used the High School Characteristics Index to describe two schools, one with a low-instrumental–low-expressive school climate and the other with a high-instrumental–high-expressive school climate,<sup>15</sup> to show the different effects of the two climates on the character of those who emerged as student leaders in the two situations. In the low-instrumental–low-expressive school, personality-tested dominance and friendliness discriminated the formal leaders of official school groups as well as the informal leaders whom their peers distinguished from the nonleaders. In addition, in this low-instrumental–low-expressive school, highly achievement-oriented girls were most likely to be the formal leaders and lower-achievement-oriented boys were more likely to be the informal leaders. But in the high-instrumental–high-expressive school, tested dominance was the only significant factor that differentiated the leaders from the nonleaders.

## Summary and Conclusions

---

Situational contingencies that influence the behavior of leaders and followers are emphasized in this chapter. Leader-subordinate relations within a group depend on societal influences, real outside relationships, and reference groups in the minds of both. Leaders who see economic externalities as most important tend to be more directive, whereas leaders who believe social or political influences from the outside to be more important tend to be more participative. The surrounding organization and its policies, size, structure, and culture are of special consequence to leader-subordinate interactions. Although an organization and its culture influence what is expected of the leaders and what they will do, the leaders in turn, shape their organizations and culture to fit their needs. Environmental factors external to the organization and cultural factors, both external and internal, influence leader-subordinate relations inside the organization. Small-group, task, and other situational factors of consequence will be examined further separately in the following chapters. The leader's discretionary and non-discretionary behavior depend on organizational and environmental considerations. But equally important is the immediate group in which the leadership occurs—the subject that

is discussed next.

<sup>1</sup> See [Chapter 4](#).

<sup>2</sup> See [Chapter 20](#).

<sup>3</sup> See [Chapter 21](#).

<sup>4</sup> See [Chapter 20](#).

<sup>5</sup> See [Chapter 20](#).

<sup>6</sup> As defined in [Chapter 18](#), *direction* (italic) refers to giving orders with or without explanation; direction (roman) includes ordering, persuading, and manipulating. *Participation* (italic) refers to sharing in the decision process; participation (roman) includes consulting, sharing, and delegating.

<sup>7</sup> High-risk, high-interest junk bonds were floated to provide the leverage for purchases of an acquisition. Such interest was fully tax-deductible as a business expense. The bonds were to be paid from the earnings and sales of assets of the acquisition, whose reduced profits, due to the payments and sales of its assets, would result in lower tax liabilities.

<sup>8</sup> Chapters 31 to 33 examine the effects of these affiliations of sex, race, ethnicity, and national identity on the emergence and success of leaders and managers.

<sup>2</sup> As will be seen in [Chapter 33](#), this use of rewards to energize future efforts appears to be more common in developing countries, such as Colombia and India, than in developed countries, such as the United States and Sweden (Ryterband & Thiagarajan, 1968).

<sup>10</sup> See also Buchanan (1974); Paine, Carroll, and Leete (1966); Rainey (1983); and Rhinehart, Barrell, DeWolfe, et al. (1969).

<sup>11</sup> See [Chapter 34](#).

<sup>12</sup> See [Chapter 30](#).

<sup>13</sup> See Van Heet (1983) for a further discussion of span-of-control research.

<sup>14</sup> Excellently managed firms actually do not appear to provide greater returns on investment to shareholders than do their less well managed counterparts. However, they do seem to be less risky investments in that the price of their stocks is less variable (Simpson & Ireland, 1987).

<sup>15</sup> A highly instrumental climate is one in which rewards are contingent on the appropriate performance of subordinates and means are more important than ends. In an expressive climate, there is more spontaneity, more actions based on sentiments and feelings rather than on carefully thought out means to ends.

---

# Leadership in Groups and Teams

I commented to an Egyptologist at the Temple of Luxor how remarkable it was to see four fellahin with only ropes skillfully maneuvering a ten-ton stone block. “Oh,” he replied, “they have been doing that kind of teamwork for the past five thousand years!” (Bass, 1995). The team or small group may be permanent or temporary. Contact is usually face-to-face but increasingly may take place through e-mail and conference television. Regardless of whether they arise spontaneously or are elected or appointed, the members who emerge as leaders perform two essential functions: (1) they deal with the groups and the member’s performance, and (2) they provide socio-emotional support to the group members (Bales, 1958a; Bales & Slater, 1955).

## Roles of the Leader

---

Any or all members can emerge as leaders, depending on how much of the functional roles they enact—the particular patterns of behavior they display in relation to the performance of the group or its socioemotional development. Leaders enact these task-relevant and socioemotional group-building and maintenance roles. Nonleaders are more likely to enact individual roles. These are less functional for the group’s development and maintenance. As formulated by Benne and Sheats (1948), task roles include those of initiator of the activity, information seeker, information giver, opinion giver, elaborator, coordinator, summarizer, feasibility tester, evaluator, and diagnostician. Group-building and maintenance roles include patterns of behavior such as encouraging, gate-keeping (limiting monopolistic talkers, returning the group to the agenda, and keeping the group on course), standard setting, expressing group feelings, consensus taking (sending up “trial balloons”), harmonizing, reducing tension (joking, “pouring oil on troubled waters”), and following. (This last role is consistent with what was said in earlier chapters about the positive correlation of leadership and followership.) Nonfunctional individual, self-concerned roles involve patterns of behavior such as aggression, blocking, self-confessing, competing, seeking sympathy, special pleading, disrupting, seeking recognition, and withdrawing.

## Functions of the Leader

---

Roby (1961) developed a mathematical model of leadership functions based on response units and information load. According to Roby, the functions of leadership are to: (1) bring about a congruence of goals among members; (2) balance the group’s resources and capabilities with environmental demands; (3) provide a group structure that is necessary to focus information effectively on solving the problem; (4) make certain that needed information is available at a decision center when required. Consistent with this view, Stogdill (1959) suggested that it is the function of the leader to maintain the group’s structure and goal direction and to reconcile conflicting demands that arise within and outside the group. For Stogdill, the functions of leadership also included defining objectives, providing means for attaining goals, facilitating action and interaction in the group, maintaining the group’s cohesiveness and the members’ satisfaction, and facilitating the group’s performance of the task. According to Schutz (1961b), the leader has the functions of: (1) establishing and

recognizing a hierarchy of group goals and values; (2) recognizing and integrating the various cognitive styles that exist in the group; (3) maximizing the use of group members' abilities; (4) helping members resolve problems involved in adapting to external realities, as well as those involving interpersonal needs. Bowers and Seashore (1967) maintained that the functions of leadership are the support of members, the facilitation of interaction, the emphasis on goals, and the facilitation of work. For Cattell (1957), the leader maintains the group, upholds role and status satisfactions, maintains task satisfaction, keeps ethical (norm) satisfaction, selects and clarifies goals, and finds and clarifies the means of attaining goals. For Hollander (1978), goal setting was a particularly important function of the leader. And P. J. Burke (1966a, 1966b) showed that antagonism, tension, and absenteeism occurred when the leader failed in this function. According to Hollander, the leader also provides direction and defines reality, two more functions that are necessary for the group's effectiveness. If successful, such direction by the leader is a valued resource. As a definer of reality, the leader communicates relevant information about progress and provides needed redirection to followers.

Earlier chapters explored the interacting nature of leader-follower relations. This chapter concentrates on the effects of the followers as a group or team on its leadership and the effects of the leadership on the group or team. It concludes with sharing of leadership of the team. What the leadership does depends on the nature of the team. In the same way, the team depends on the nature of the leadership. Its leadership often makes the difference in the success or failure of the team's efforts (Katzenbach, 1997). In the last century, there were several revolutionary changes in how work and service were to be done. The job of an individual became less a single bundle of tasks and more a varying set of tasks in coordination with other members of a team. Increasingly, work is done in teams. Even when individuals still have much work to do by themselves, they must still join *parallel* teams to complete it or for other reasons, such as to contribute to quality improvement, committees, and task forces. A single person may be a member of many parallel teams while still responsible for individual assignments (Campion, Pappas, & Medsker, 1996). Lawler and Cohen (1992) estimated that 85% of Fortune 100 firms used parallel teams.

## Teams versus Groups

---

A *group* is a collection of people with common boundaries, sometimes with broad objectives. A *team* is a group that is focused on a task with a narrow set of objectives (Hackman & Johnson, 1993). A group may have a task, such as to follow directions or to find answers to problems. But a group is less likely to be focused like a team primarily on specific tasks. Before 1990 many studies of groups were actually studies of teams. Both groups and teams exhibited mutual and reciprocal influence among members. But usually there is a stronger sense of identification by members of a team than a group. Team members share common goals and tasks; group members may belong to the group for personal reasons that are in conflict with the group's objectives. Team members usually work interdependently; group members may work independently. Team members have more specialized and differentiated roles, although they are likely to play a single primary role; group members more often play a variety of roles (Hughes, Ginnett, & Curphy, 1993). Team-work more often requires monitoring performance of self and other members, self-correcting errors, providing task and motivation reinforcement, adapting to unpredictable occurrences, closing communication loops, and predicting other team members' behavior. Mental models need to be shared (Salas, 1993). Much of the leadership in teams may be provided by the members themselves.

In the third edition of *Handbook of Leadership*, this chapter focused on leadership of small groups. In the fourth edition, the chapter reflects the rapid growth in interest from the 1980s onward in organizing teams, team-work, and team leadership and the declining research interest in leading informal, transient small groups (Ilgen, 1999). However, much of what was learned about small groups remains relevant to teams and team

leadership. Research about work and leadership in groups is now more likely to be called work in teams. Among other things, to be an effective *team*, members in their interdependence must pursue shared and valued objectives. They must pay more attention to processes and their shared roles and responsibilities must be more clearly defined (Dyer, 1984).

### ***From Division of Labor to Teamwork***

The use of teams by utilitarian organizations has increased since the 1990s (Lawler, 1998). Authority has been decentralized. Traditional chains of command have been replaced by empowered teams (Ray & Bronstein, 1995). We are in the midst of a changeover from dividing the tasks of labor into their simplest components, as advocated by theorists ranging from Adam Smith (1776) to Frederick Taylor (1912). Work has been reengineered from production in assembly lines to teamwork in policy-making decisions, therapeutic efforts, family assistance, and education (McGrath, 1997). The reason is that teams ordinarily achieve more than pooling the individual efforts of the members working alone (Bass, 1965). “The growing interdependence of human functioning is placing a premium on the exercise of collective agency through shared beliefs in the power to produce effects by collective action” (Bandura, 2000, p. 75).

*Early Interest in Group Effort.* There were early instances of the changeover in interest from individual to group effort. De Toqueville (1832/1966) commented on how American settlers formed voluntary, temporary teams to get work done. LeBon (1897) explained what happens when people are in groups rather than alone. People in groups were found by H. Clark (1916) more suggestible than when isolated. Bechterew and Lange (1924) completed numerous experiments on the influence of the group, a topic of considerable political interest in a Soviet society aiming to develop collectivism in the workplace. Elton Mayo’s familiar Hawthorne studies begun in 1924 to show the importance of good lighting in the workplace, publicized the importance of interpersonal relations between supervisor and workers (Roethlisberger & Dixon, 1947). Burt (1929) made explicit the case for working in groups rather than alone: “We are essentially social animals and most of us find it more agreeable to do things in company than to do them alone” (p. 193). Moreno (1934/1953) introduced sociometry to show the influence on group performance of choice of partners. Lewin’s (1939) theory of group dynamics was seminal in demonstrating the value of participation and team goals.

Trist and Bamforth (1951) described the teamwork in long-wall coal mining. Bamforth had been a miner and came from a village of coal miners. He won a scholar-ship to work with Trist. Assigned by Trist, he returned to the same mine in which he had originally worked to find that its individually assigned jobs had been replaced by working in teams. Productivity and satisfaction had increased. Bamforth told Trist that work in the mine had returned to the way the miners’ fathers had worked before “rationalization” had introduced inflexible individual assignments (Fox, 1990)! Our earlier chapters noted developments from the mid-twentieth century onward, exemplified by military leadership research ranging from army squads to air force aircrews, and Coch and French’s (1948) study of the effects of goal setting and participative practices. By the 1960s, Nonlinear Systems, a small California electronics firm, had eliminated its assembly line in favor of an organization of teams, and Volvo’s automobile engine assembly was changed from assembly lines to teamwork (Bass, 1965). Teamwork was encouraged by System 4 of Likert’s concept (1961a) of organized overlapping groups from one echelon to the next in decision-making hierarchies. Each leader of a group participated in a decision-making group of his peers at the next higher organizational level (see [Chapter 17](#)).

*Prevalence.* Teams have been employed in Japan since the days of the Samurai. Small-group research in the mid-twentieth century attested to the greater effectiveness of team over individual work. Lawler, Lawler, Mohrman, and Ledford (1995) estimated that as many as 85% of large Western firms were using some form

of teams, many self-managed. Team decision making is more effective than the decisions of its individual members. Among 222 project teams solving problems, the decision based on the group process was better than that of the team's most proficient member in 97% of the cases. Only 40% of the superior decisions could be explained by the average member's decision (Michaelson, Watson, & Black, 1989).

Teams permit each member to take on larger tasks. With cross-training and reengineering of tasks, members can substitute for one another. They are better motivated when given wider latitude than operating on a traditional assembly line. The greater productivity in the United States with fewer employees is usually attributed in the popular press to technological advances, but some of it may be due to the switch from assembly lines to team-work. The attitudes and activities of the group transcend those of its individual members. Group and team norms can survive even if all the members are changed. Members behave differently when they are isolated from one another than when they are all together. The leader's dyadic relations with each of his or her subordinates may not reflect the leader's relations with the same subordinates as a team. The team's relationship to the leader may be more important than the individual employee's relationship to the leader (Bramel & Friend, 1987). The team approach has had to be extensively modified from its application in collectivistic Japan to individualistic North America. In Japan, harmony is of singular importance. In the United States, dissent has to be endorsed and valued, allowing for productive controversy and constructive thinking. Team structure has to be fluid, incorporating core members with part-timers. Teams have to be encouraged and enabled to make decisions for themselves (Nahavandi & Aranda, 1994).

The team's drive, cohesion, collective efficacy, potency, selection, alignment, and attainment of goals are likely to be influenced by its leadership. Its leadership is likely to be influenced by the team's drive, cohesion, collective efficacy, selection, and attainment of objectives. The overall evidence points to greater accomplishment in teams with greater collective drive, cohesion, efficacy, and potency. For example, a group's beliefs in its collective efficacy have been shown in banking to make an important contribution to continuing effort and performance accomplishment (Lewis & Gibson, 1998). Comparable results have appeared in both experimental teams and natural groups in business, athletics, military combat, and urban neighborhoods (Bandura, 2000). A meta-analysis by Gully, Beaubien, Incalcaterra, et al. (1998) found a strong relationship between collective capability and team performance. These results go beyond the performance of the individual members and generalize across tasks and cultures (Gibson, 1999).

*Deindividuation.* The group effect becomes especially strong if *deindividuation* occurs, that is, if the group members lose their identity as individuals and merge themselves into the group. In such a case, the members lose many of their inhibitions and behave uncharacteristically (LeBon, 1897). The *disinhibition of deindividuation* makes it easier for team members to discuss intimate problems with a stranger whom they expect never to see again than with friends or relatives. Festinger, Pepitone, and Newcomb (1952) studied groups of students who were required to discuss personal family matters. They confirmed that the students experienced less restraint in doing so under a condition of deindividuation. They minimized the attention they paid to one another as individuals. When it was present, deindividuation was a satisfying state of group affairs associated with increased group attractiveness. In the same way, Rosenbaum (1959) and Leipold (1963) found that participants preferred to maintain a greater psychosocial distance between themselves and their partners when potentially unfavorable evaluations might be fed back to them than when no such information was anticipated. The disinhibition of deindividuation may help explain how members of special operations teams can take on extremely dangerous, life-threatening missions.

Individual identity is ordinarily stressed if rewards are anticipated; deindividuation is more likely to occur if punishment is expected. Furthermore, deindividuation increases with anonymity, the level of emotional arousal, and the novelty of the situation. The loss of inhibition is reflected in less compliance with outside authority and more conforming to the demands of the group or team. Responses are more immediate, and there is less self-awareness and premeditation. The collective mission is stressed over the individual's needs.

Disinhibition and the loss of self-identity unleash the energy to accomplish great feats if they have constructive direction. They also facilitate the rabble-rouser. We become disinhibited from ordinary social constraints when we lose ourselves in a crowd. A riot-inciting leader can generate mindless mob violence.

Emotional contagion occurs even in a two-person conversation. People automatically mimic and synchronize their own movements with the facial expressions, postures, vocal utterances, and behaviors of other people. Subjective feelings are induced in the same way (Hat-field, Cacioppo, & Rapson, 1993).

*Overt and Covert Effects.* Particularly in collectivist societies such as China, Japan, and Korea, the group is likely to have a strong influence on its leader. Thus, Furukawa (1981) showed, in a survey of 1,576 Japanese managers, that managers establish their primary management objective from among a set of possibilities after judging how well it fits with their work team's interests and favorability to them.

Leader-member relations are also affected less overtly by the team or group. Some of the assumptions that determine an organizational culture are fantasies that are shared by members of a group that is embedded in the larger organization (Kets de Vries & Miller, 1984a). Ide-alization or devaluation of the leader and dependence on him or her is one such shared fantasy. One group, as a group, in the same larger organization will be dependent on whoever is assigned the job of group leader. Another group, without the same assumptions, will display more independence or counterdependence, regardless of who is appointed leader. A leader of a group with a clique who behaves the same way as the leader of another team without a clique will be evaluated differently by the two groups. E. R. Carlson (1960) showed that groups that contain cliques are less satisfied with their leaders than are groups that are free from such cliques.

*Team-Member Exchange Effects.* Team effects appear to augment the leader's impact on the satisfaction of individual members. Thus Seers (undated) extended Graen's (1976) concept of the quality of the dyadic leader-member exchange to the quality of the team-member exchange. Items that correlated most highly with the factor of the quality of the team-member exchange among 178 hourly employees who worked in one of 19 teams included "how often I volunteer extra help to the team" and "how often others on the team help me to learn better work methods." Eighteen percent of a team member's work satisfaction was accounted for by the favorable quality of the member's exchange relationship with the team leader. An additional 4% was due to the quality of the exchange relationship with the team. The comparable figures for a member's satisfaction with coworkers were 11% owing to the quality of the leader-member exchange and 27% owing to the quality of the team-member exchange.

*Characteristics of the Group's Members.* The means and variances in the attributes of individual members make a difference to the leadership of the group and its patterns of influence. Thus, Dyson, Godwin, and Hazelwood (1976) were able to link members' consensus to the influence of decisions in homogeneous but not in heterogeneous groups. D. G. Bowers (1969) found that the leaders' importance is greater for teams composed of particular kinds of employees. Among 1,700 work groups from 22 organizations, Bowers observed that groups made up of longer-service, older, and less educated members attached greater importance to the supervisor and his or her direct influence on their behavior. The effects were especially relevant in administrative, staff, production, and marketing groups. In better-educated, shorter-service, younger groups, especially those whose members were primarily female, such as clerical and service groups, less importance was given to the role of the supervisor and greater importance was given to the behavior of peer members of the group.

*Caveat.* The return for effort needs to be an equitable exchange for the team members (Naylor, Pritchard, & Ilgen, 1980) and must also meet social and transformational objectives (Sivasubrahmaniam, Murray, & Avolio, 2002). Group efforts are superior to the average individual operating alone. However, there are notable exceptions. A survey of 15% of 4,500 teams in 500 organizations mentioned inadequate conflict management and group problem solving as barriers to team effectiveness. And 80% noted as shortcomings of team organization instances where rewards, appraisals, and compensation were based on individual, not team

performance. Also, group effectiveness was limited by individuals' competitiveness (Koze & Masciale, 1993). Carless, Mann, and Wearing (1995) reported that team cohesion was even more highly correlated with team performance than transformational leadership. But Erwin (1995) failed to find that team cohesion predicted team performance.

*Leadership and Team Performance.* The team narrows the range of possible leader-individual subordinate interactions in the interests of equity and time and because of the team's expectations about its leadership. The leadership is evaluated on the basis of the team's quantity and quality of productivity, service, and costs, the team's ability to work together, the team members' satisfaction and development (Hackman, 1990), and the performance of the teams rather than on the performance of their individual members (Schriesheim, Mowday, & Stogdill, 1979). The leader's contribution to the team's productivity is likely to be reduced by faulty group interaction processes (Steiner, 1972) or enhanced by "assembly bonus effects" (Collins & Guetzkow, 1964), which occur mainly with difficult tasks (Shaw & Ashton, 1976). That is, above and beyond individual members' capabilities to deal with the task they face, faulty leader-team interactions may result in performance that is worse than if the members had been free to work alone and to remain uninfluenced by the leader. Nonetheless, when members work in a well-led team, their performance is likely to be better than what might have been expected from a simple pooling of their individual capabilities as members (Bass, 1980).

### ***Measuring Team Attributes***

By the late 1940s, Hemphill (1949b) and Hemphill and Westie (1950) had published reliable and valid measures of group dimensions, such as status differentiation, group potency, and cohesion. Fleishman and his colleagues completed a program of investigations about team performance involving refined measures of human abilities, tasks, and contexts (Fleishman & Quaintance, 1984). Seven dimensions of team performance and refined ways to measure them were developed: (1) orientation, assignments, and exchange of information; (2) distribution of resources to match tasks; (3) timing and pacing; (4) response coordination; (5) development and acceptance of team performance norms, reinforcements, conflict resolution, and balanced competition and cooperation; (6) monitoring system and individual adjustment to errors; (7) monitoring individual and team level procedures and adjusting to nonstandard activities (Fleishman & Zaccaro, 1992). Two among the many team survey inventories that have been created since then are the Bass and Avolio (1993) Team Multifactor Leadership Questionnaire (TMLQ), and the Elliott (1997) Linking Skills Index (LSI). The TMLQ deals with the shared transactional and transformational leadership behavior within the team as a whole. Team variables such as collective efficacy, team trust, team potency, and team cohesiveness have been added. The LSI measures 11 dimensions, including the extent to which the team displays quality standards, setting objectives, participative decision making, delegation, active listening, and satisfactory work allocation. At a more microanalytical level Coover, Campbell, Cannon-Bowers, et al. (1995) applied graph theoretical *petrinets* (Reisig, 1992) to quantitative analysis of effective and ineffective laboratory team coordination. Petri-nets made it possible to describe moment-to-moment interactions among team members and to distinguish between effective and ineffective processes, strategies, and behaviors (Salas, Dickenson, Converse, et al., 1992).

### ***Team Development***

*Stages in the Development of Groups into Teams.* The consistency and importance of the phases in a group's development were noted and observed by many investigators. Leaders have to learn to respect these phases. Thus, Terborg, Caetore, and DeNinno (1975) demonstrated that groups must work together for some

time before they can begin to behave as a team. The early period is crucial. Eriksen (2003) compared high-and low-performing teams. The high-performing teams, early on, started off well and progressed well until completion of their projects. The low-performing teams faltered in getting started and never fully recovered.

In one of the early studies of group development, Bales (1950) observed that small groups consistently exhibit phases in their problem-solving behavior. Bales and Strodtbeck (1951)<sup>1</sup> demonstrated that after an introductory polite stage, the second phase in the development of small groups tends to involve a great deal of tension because of the members' competition for leadership and the stabilization of the status structure. Thus, Heinicke and Bales (1953) observed that emergent leaders tended to be rated high in initiating suggestions and opinions in the first session and at the beginning of the second session, but during the second session, they began to engage in an active struggle for status. After consolidating their position in the second session, they became less active in the third and fourth sessions, permitting other members to play more active roles. But the leaders' opinions and suggestions were still accepted. The leaders did not have to make as much effort to win their points.

In a detailed study of the first two stages of unstructured small experimental teams, Geier (1967) instructed some participants in a team task. Members entered their teams without an assigned role. The leader was the member whom the members perceived by consensus as having made the most successful attempt to influence the team. Stage 1 involved the rapid and painless elimination of contenders with negative characteristics. The second stage involved an intense struggle for leadership and the further elimination of competitors. Only 2 of 80 members in the various teams studied made no effort to gain leadership. Those who were uninformed, unparticipative, and rigid and hindered the attainment of goals were eliminated first. Attempts to recruit lieutenants and to gain the members' support were most obvious in Stage 2. The roles of lieutenant developed in 11 of 16 teams. Of the 11 lieutenants, 7 had been contenders for leadership in Stage 1.

Tuckman (1965) reviewed some 60 studies involving experimental, training, and therapeutic groups. An analysis of these studies suggested two additional stages of development through which the groups had to go to reach full group maturity. The first two stages of *forming* and *storming* were like stages of politeness followed by conflict. Forming was characterized by testing and orientation; storming was characterized by intragroup conflict, status differentiation, and emotional response. The third stage was norming, characterized by the development of group cohesion, norms, and intermember exchange; and the fourth stage was performing as a team, marked by functional role interrelations and the effective performance of tasks. These stages of forming, storming, norming, and performing could overlap in some groups and alternate in others (Heinen & Jacobsen, 1976). The emergence and success of the different kinds of leadership that were needed could clearly be connected to each of these phases. For example, Erwin (1995) suggested that during the stages of norming and storming, compared to any external leadership, the internal team leadership was more important to the team's effective development. Nevertheless, Pearce and Rode (2001) showed that for 71 teams in a program of change, the amount of *enablement* by higher-level management (providing needed resources, training, and support) correlated from  $-.28$  to  $-.35$  with the teams' prosocial behavior, commitment, effectiveness, and absence of social loafing.

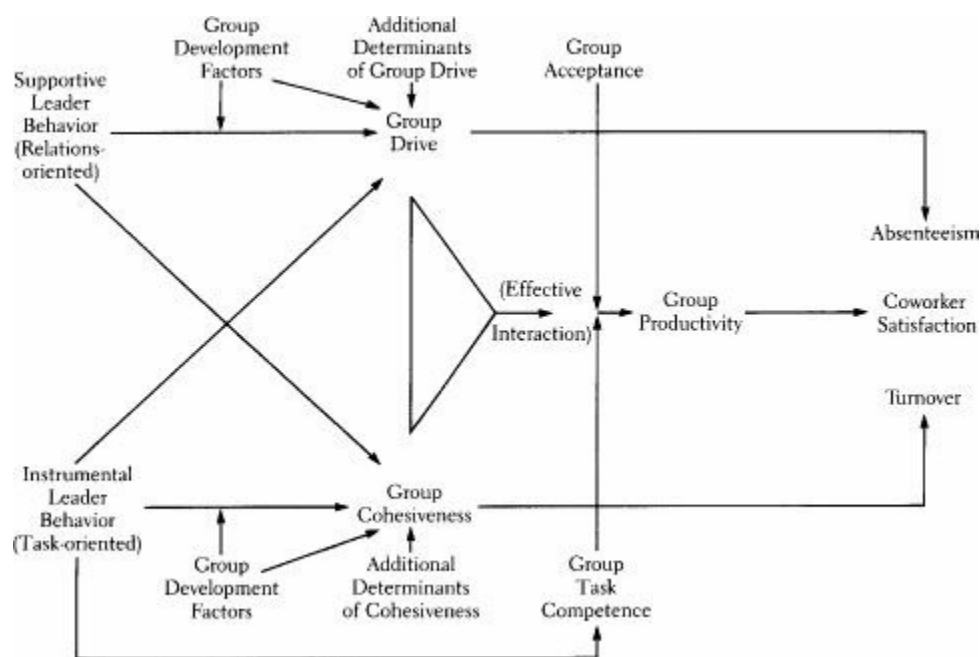

*Re-forming.* The development of teams continues into further stages (Gersick, 1985). About halfway through the life cycle of problem solving as groups and teams (which presumably have reached the fourth, performing, stage), the teams reform themselves. During this re-formation, groups reevaluate their progress to date, reach agreement on final goals, revise their plans for completing their assigned task, and refocus their effort toward completing the task. Following this re-formation, they concentrate more of their efforts on the critical aspects of performing the task and focus on accomplishing their task to meet the stated requirements. Near the completion of the task, efforts are made to shape the team product so it will fit environmental demands. Work is finalized, consistent with the requirements of the situation.

*Structure and Purpose.* Avolio and Bass (1994) conceived the stages in group development as going

from unstructured *groups* to highly structured *teams* based on sharing of purposes, commitments, trust, drive, and expectations. In unstructured groups, there is no clear agenda or assignments; members are confused or conflicted about responsibilities and perspectives. Direction may be irrelevant to the group's reason for existence. In highly structured teams, there is close monitoring by the members of one another for any deviations, which are then addressed. Rules are strictly enforced. Members are unwilling to take risks.

A team begins as a group without a necessarily shared purpose, commitment, trust, or drive. It becomes structured into a team and becomes fully developed when it reaches a high degree of shared purpose, commitment, trust, and drive (Avolio & Bass, 1994). The mental stage of the team as a team is important to the emergence of leaders and the effects of leadership. For example, different leaders emerged in successive stages of therapy in a psychiatric ward (S. Parker, 1958). Likewise, Sterling and Rosenthal (1950) reported that leaders and followers changed with different phases of the group process; the same leaders recur when the same phases return. Kinder and Kolmarm (1976) found that in 23-hour *marathon groups* (night-and-day-long sensitivity training groups), gains in self-actualization were greatest when initially highly structured leadership roles were maintained early in the groups' development and switched to low-structured leadership roles later in the groups' development. Okanes and Stinson (1974) concluded that more Machiavellian persons were chosen as informal leaders early in the development when groups could still improvise; once the groups became more highly structured teams, however, Machiavellian persons were less likely to be chosen as leaders. Vecchio (1987) concluded that the one aspect of the Hersey-Blanchard model (1977) that had validity was the utility of using directive leadership early in the group's development and then employing more participative leadership for the group as it matured.

Figure 26.1 Model Linking Leadership to Group Outcomes

SOURCE: Adapted from Schriesheim, Moday, and Stogdill (1979). (Modifications are shown in parentheses. Effects of leadership on group outcomes are not shown.)

On the basis of a review of the literature, Stogdill (1959, 1972) identified three possible main effects of the leader on organized groups: productivity, drive, and cohesiveness. The rational model (Figure 26.1) created by Schriesheim, Mowday, and Stogdill (1979) proposed that a group's drive and cohesiveness interact with each other to generate a group's productivity. In the model, supportive or relations-oriented leadership behavior interacts with instrumental or task-oriented leadership behavior to promote a group's drive and cohesiveness. All this occurs in the context of the group's development, which also contributes to the group's drive and cohesiveness and results in more effective interaction among its members. Then, if the group as a team has the

competence to complete the task and accepts the responsibility for doing so, its productivity increases; the satisfaction of members with one another is greater; and the members' tendency to be frequently absent or to quit is reduced. According to a meta-analysis by Salas, Mullen, Rozell, et al. (1997), role clarification and structuring relationships were keys to successfully developing teams and their performance.

*Leaders Make a Difference in Team Structure.* Leaders differ in how much they affect the extent to which the intended structure of relations within a team and its input and outputs is actually the enacted structure. In a study of 39 work groups in three organizations, Inderrieden (1984) found that, along with the uncertainty of the task, the leaders' need for power and self-actualization were the strongest predictors of the actual structure of the work groups.

Effective leadership allows groups to move systematically through the necessary developmental stages. Groups that are unable to develop a differentiated leader-follower role structure will be unable to engage in the effective performance of tasks (Borgatta & Bales, 1953b). Conversely, groups with a high degree of consensus about their leadership will be more effective and better satisfied than will those that do not reach such a consensus. De Souza and Klein (1995) conducted an experiment using 468 college students in initially leaderless quartets of four with tasks and goals. Groups with emergent leaders outperformed groups without such leadership. The emergent leaders had greater ability for the task and commitment to the group goal. The clarity of leadership in 170 health care teams was related to clear team objectives, high levels of participation, commitment to excellence, and support for innovation (West, Borrill, Dawson, et al. (2003).

*Stages and Outcomes.* Avolio, Jung, Murray, et al. (1996) studied the shared team leadership of 188 undergraduates in teams of five to seven members early and late in the semester. They used the Team MLQ. The expected correlations with outcomes in extra effort, effectiveness, and satisfaction declined from the early phase to the late phase, but inspirational motivation increased in correlation with collective efficacy from .33 to .63 and with potency from .49 to .66. For contingent reward, increases were recorded from .11 to .63 with collective efficacy and .18 to .63 with potency. Passive and active management by exception showed little change.

Stogdill (1972) suggested that the cohesiveness, drive, and productivity of a team are closely related to its developmental stage and what is required of the team leader. The team's drive appears in every stage, but the arousal and tensions of the second stage of storming most closely reflect the amount of that drive. The specific tasks that the team is motivated to perform, however, may differ across the stages. Thus, for instance, in the second stage, the team's drive is directed toward evolving a structure for the team. In the third stage, it operates to develop greater cohesiveness. In the third stage (norming), roles have finally been accepted and communication has improved; team cohesiveness emerges. In the fourth and final stage, effective performance of the task, team productivity is seen.

The functions of the leader depend on the stage of a group's development. For instance, relations-oriented leadership behavior will contribute to the team's need to develop cohesiveness in the third stage (norming), and task-oriented leadership behavior will facilitate the team's accomplishment of the task in the fourth stage (performing).

*Stages and Role Boundaries.* The team's development can be seen in the stabilization of the role boundaries of the individual members, including those of the leader. The role boundary set of any member encompasses the acts that the other group members will accept. Boundaries are established by fairly stable role expectations that are often conveyed by the leader. In group experiments by Gibb (1961), one leader with a permissive leadership style was followed by another with a restrictive style, and vice versa. In other groups, one leader was followed by another with the same style. Group members accepted and responded more readily to leaders who followed other leaders with the same style of either latitude or restriction in the members' prescribed range of behaviors. The members were also less defensive and more productive in problem solving. Expectations were built quickly, with minimum cues, and survived over long periods. Esteemed and influential

members—those frequently nominated as such in sociometric tests—tended to stay within the realistic boundaries prescribed by the group. Individuals who were less frequently chosen were those more likely to violate the boundary specifications. (Perhaps those who were chosen more often had a wider range of behaviors and more role space in which to move.) The members responded to an individual member's role actions outside the role's boundaries by pretending not to see or hear the behavior, ignoring it, engaging subtle fighting or open rebellion, isolating the member, or forcing his or her withdrawal.

Given the power of norms, groups tended to select goals and perform activities that were commensurate with the norms. To exert influence, the behavior and goals of the leader had to be consonant with the group's goals. But high levels of defensiveness in the group prevented the effective exercise of such influence. The leadership also needs to take into account whether members conform to avoid criticism, to serve their own interests, to fulfill obligations, or to fit with the member's values and principles.

Groups undergo an orderly reduction in defensiveness as they mature, according to J. R. Gibb (1964). While a group is forming, its members remain superficial and polite to each other and trust is low. After members have learned to trust one another (presumably after some storming), they learn how to make effective decisions and gain greater control over the choice of goals in the norming phase. With these better goals, they can make better use of the group's resources.

### ***Leadership and a Stable Structure***

A stable structure of relations must be developed for a group or team to become cohesive (Heinen & Jacobsen, 1976; Sherwood & Walker, 1960; Tuckman, 1965). A leader has important effects on a group's development of a stable structure (Heslin & Dunphy, 1964). Recognizing this fact, Bion (1961) found that if the discussion leader of a therapy group failed to provide structure, the members, striving to arrive at a structure, sought a leader among themselves. As was discussed in previous chapters, during the early stages of a group's development, members may want and accept more direction. At this time, leaders may exert a greater influence on the stabilization of a group's role structures and thus have a greater impact on the group's cohesiveness.

In a study of Japanese nursery school children, Toki (1935) observed that early separation of an emergent leader from the group resulted in a disintegration of the structure of the group. The structure was more likely to hold up when the emergent leader left late in the group's development. When an adult leader was introduced, the structure built around the child leader collapsed.

## **Effects of Groups and Teams on Their Leaders**

---

Differences among groups that are likely to affect what the leader can and will do include the group's drive, cohesiveness, size, compatibility, norms, and status. Earlier chapters looked at some of these effects from a variety of different perspectives.

### ***Effects of Drive***

Grant, Graham, and Hebeling (2001) noted from 32 case study reports about team projects that when the team members dedicated all of their time to the project and the project was of singular importance to the leader, the leader had to dedicate a great deal of time to the careful selection of skilled, compatible, and collaborative members. Bass, Flint, and Pryer (1957b) demonstrated that the motivation of all the members of a team affected the success of the leader. When all members are initially equal in status, an individual is more

likely to become influential as a team leader if he or she attempts more leadership than others do. However, among highly motivated members, such attempted leadership was found to exert little effect on who emerged as a leader to influence the team's decision. In the same way, Hemphill, Pepinsky, Shevitz, et al. (1954) showed that team members attempted to lead more frequently when the rewards for solving a problem were relatively high and they had a reasonable expectation that efforts to lead would contribute to the accomplishment of the task. Durand and Nord (1976) observed subordinates in a textile and plastics firm who felt that their success or failure was in the hands of forces outside their control. (Presumably they were lower in team motivation. They tended to see their supervisors as initiating more structure and showing less consideration.)

A team's drive is likely to be high when members are highly committed. Members are more likely to want to expend energy for such teams. Gustafson (1968) manipulated members' commitment to their student discussion teams by varying the extent to which grades for a course depended on the team's performance. Less role differentiation into leaders, task specialists, and social-emotional specialists was perceived by members with either a strong commitment or a weak commitment; that is, the three functions were not differentiated, but the teams showed less social-emotional behavior when their members were highly committed. In an analysis of 1,200 to 1,400 subordinates' descriptions of their teams, Farrow, Valenzi, and Bass (1980) found that directive leadership and delegative leadership were seen more frequently when the subordinates' commitment to the teams was high.

### ***Effects of Cohesiveness***

Group cohesiveness has been defined in many different ways. It has been defined as the average member's attraction to the group (Bass, 1960) and as all the forces acting on members to remain in the group (Festinger, 1950). It has been conceived of as the level of the group's morale (C. E. Shaw, 1976), the individual needs satisfied from group membership (Cartwright, 1965), and the extent to which members reinforce one another's expectations about the value of maintaining the identity of the group (Stogdill, 1972). It has been identified by highly correlated variables such as the members' commitment to the group, the presence of peer pressure, the felt support from the group, and the absence of role conflict in the group. For some, it has meant valued group activities, group solidarity, willingness to be identified as a member of the group, and agreement about norms, structure, and roles.

Podsakoff, Todor, Grover, et al. (1984) collected data from 1,116 mainly male employees working in a variety of city and state government agencies. Cohesiveness significantly increased the employees' satisfaction with supervisors who practiced a good deal of contingent rewarding. It significantly decreased satisfaction with supervisors who engaged in a lot of noncontingent punishment. Cohesion had no significant effect on satisfaction with supervisors who were contingent punishers or noncontingent rewarders. According to Dobbins and Zaccaro (1986), cohesiveness moderated the effects of leaders' consideration and initiation of structure on subordinates' satisfaction among 203 military cadets. Leaders' consideration and initiation of structure was correlated more highly with subordinates' satisfaction in cohesive compared to uncohesive groups.

*Drive and Cohesiveness.* The motivation of a group includes its drive along with its cohesiveness. The drive of a group refers to its level of directed energization; the cohesiveness of the group is the level of attachment of the members to the group and its purposes. Clearly, the two are related in that both increase with the extent to which the group and its activities are valued by the members. Nevertheless, many investigations have focused on one or the other. The drive and cohesiveness have been merged by focusing on the members' loyalty, involvement, and commitment to the group (Furukawa, 1981). Stogdill (1972)

conceived group drive to be the arousal, freedom, enthusiasm, or esprit of the group and the intensity with which members invest their expectations and energy on behalf of the group. Steiner (1972) defined group motivation similarly as the willingness of members to contribute their resources to the collective effort. Zander (1971) found such motivation to depend on the members' desires to achieve success and avoid failure, as well as their previous history of success (Zander, 1968) and pressures for high performance (Zander, McDow, & Dustin, 1964).

Although drive and cohesiveness ordinarily are correlated, Stogdill (1972) concluded, from a review of 60 studies, that under certain circumstances, the level of group drive (or team drive) conditions the relationship between productivity and cohesiveness. Under routine operating conditions and low drive, team productivity and cohesiveness tend to be negatively related, while under high drive, they tend to be positively related. The seemingly paradoxical findings are readily explained when group drive is studied along with productivity and cohesiveness. When the team's drive is high, members' energies are directed toward its goal. If the team is also cohesive, the members will work collectively and productively toward that goal. On the other hand, if the group's drive is low, the members' energies will be directed elsewhere. If the team also remains cohesive, the members will reinforce one another's tendencies to ignore the team's productive goals and seek satisfaction from nonproductive activities.

*Expectations, Solidarity, and Identification.* Avolio and Bass (1994) observed that the expectations of unstructured, uncohesive groups were lower than those of more structured, cohesive teams and that expectations were exceeded in high-performance, highly cohesive teams. Borgatta, Cottrell, and Wilker (1959) studied groups that differed in the members' expectations about the value of group activities. The higher the initial expectation, the higher the final level of satisfaction for groups as a whole. Leaders of low-expectation groups changed their assessments more than leaders of high-expectation groups did.

The ease of the flow of influence between the leader and followers was expected to be associated with cohesive social relations (Turk, Hartley, & Shaw, 1962). Theodorson (1957) found that the roles of task leader and social leader were combined in cohesive groups but were separated in poorly integrated groups. Weak group cohesiveness provided a condition under which those who scored high in sociability attempted to develop cooperation through increased interaction, while those who scored low in sociability tended to remain passive (Armilla, 1967).

Gergen and Taylor (1969) demonstrated that high-status participants, when presented to a group in a *solidarity setting*, tended to meet the group's expectations but failed to meet expectations when they were presented in a *productivity setting*. Low-status participants in the productivity context presented themselves more positively; in the solidarity condition, they became more self-demeaning.

Acceptance of a group's leaders is linked to identification with the in-group. Bulgarian or Yemenite immigrants to Israel identified themselves first as Jewish, then second as Bulgarians or Yemenites. As a consequence, they could more easily support and follow Israeli leaders. On the other hand, Israeli immigrants who identified themselves first as Germans, Americans, or Moroccans were more likely to accept the Israeli leaders only if their self-evaluation was not rooted in the old country (Eisenstadt, 1952).

*Implications for Structuring.* Arguing that norms, structure, and roles are clearer in cohesive groups, J. F. Schriesheim (1980) proposed that initiation of structure by the leader is redundant in cohesive groups. But more initiation by the leader is likely in groups in which cohesiveness is low, groups that have less of a normative influence on members, and groups in which the members are more likely to be dependent on the leader than on the group. An analysis of data from 43 work groups in a public utility supported Schriesheim's proposition by showing that satisfaction with supervision, role clarity, and self-rated performance correlated much more highly with initiation of structure by the leader if the groups were low rather than high in cohesiveness. Schriesheim also expected that the leaders' consideration would contribute to the subordinates' role clarity only in groups whose cohesiveness was high. Again, her supposition was borne out. She found a

correlation of .31 between the leaders' consideration and the subordinates' role clarity in highly cohesive groups but corresponding correlations of  $-.05$  and  $-.04$  in groups in which cohesiveness was medium or low. Schriesheim inferred from these results that highly cohesive groups provide members with clear roles and that clarity is reinforced by supportive, considerate leaders. Such groups have little need for additional initiation from their leaders. Leaders need to structure such groups less tightly (House & Dessler, 1974). Again, consultative leadership will yield more subordinates' satisfaction if the leaders feel that members are highly committed to the group and its goals (Farrow, Valenzi, & Bass, 1980).

*Effects of the Group's Agreement about a Leader.* The leadership process is affected by whether the immediate group is in agreement on who will lead it. Agreement among the members about who should lead was found to be correlated with greater group cohesiveness (Shelley, 1960a) and with more frequent attempts to lead (Banta & Nelson, 1964). Bales and Slater (1955) obtained results showing that three different roles of members tended to emerge in groups that did not reach a consensus on who should lead: an active role, a task specialist role, and a best-liked-person role. In groups that had attained such a consensus, less role differentiation occurred; the active and task specialist roles were performed by the same member. Harrell and Gustafson (1966) reported that in groups lacking consensus, an active task specialist role emerged along with a best-liked-member role. Role differentiation occurred less in both their high-and low-consensus groups than in Bales and Slater's study. In addition, attractive groups and those with the most interesting tasks tended to exhibit the least role differentiation.

*Harmony and Cooperativeness.* Consultation by the group leader was more frequent in work groups that were described by their members as harmonious and free of conflict (Bass, Valenzi, Farrow, & Solomon, 1975). Groups with cooperative members, compared with groups with competitive members, were more likely to develop leaders, evaluate fellow members more favorably, show less hostility, and solve their problems as a group more rapidly (Raven & Eachus, 1963). This finding is consistent with the conventional wisdom that suggests that it usually benefits the organization to encourage competition among groups with independent tasks but that competition should be discouraged within the groups.

*Compatible Members.* Groups composed of compatible rather than incompatible members are better able to elect competent leaders. They are also better able to use the resources and abilities of their members, since they are more likely to elect leaders who allow the highly competent members enough freedom to express themselves and to influence the groups' performance (W. C. Schutz, 1955). Lester (1965) found that the emergent leader among the highly task-oriented members of an American Mount Everest climbing expedition was able to be more relations-oriented.

Thelen et al. (1954) factor analyzed the self-and group descriptions made by members of a discussion group. Five clusters of members were identified. Cluster A, composed of members who rejected fighting and pairing, made significantly more leadership attempts than did any other cluster. It preferred structure and cohesiveness, which prevent undue domination and intimacy. Cluster B, with ego needs for intimate relationships, showed little interest in differences in status. Cluster C, which preferred to avoid power struggles or responsibility, rejected competition for leadership. Cluster AC, which rejected fighting, supported and looked to the leader to support their status needs. Cluster BC, which accepted fighting, supported the leader and attempted to mediate conflicts to maintain the group's cohesion.

### ***Effects of the Group's Size***

Increased size affects a group's leadership. It brings with it reduced opportunities to lead, more responsibilities and demands on the leader, and a possible widening of the span of control.<sup>2</sup> As the size of the group increases, the number of interactional relationships among members increases at an extremely rapid rate. Graicunas

(1937) deduced that a leader with two subordinates can interact with them both singly and in combination. The contacts can be initiated by the leader or by the subordinates, so that six relationships are possible. With four subordinates, the number of possible relationships is 44. With six subordinates, the number of possible relationships is 222. Graicunas concluded that executives should not have more than four or five subordinates reporting to them directly; because of the time required for personal contacts. Nevertheless, surveys of industrial executives<sup>3</sup> indicated that corporation presidents may have from 1 to 25 assistants reporting to them. The average in the several surveys ranged from five to nine immediate assistants. But the evidence accumulated over the years indicates that five to seven is an optimum size for most groups, with the task determining whether smaller or larger size is most efficient (Bass, 1981). Data collected between 1993 and 1995 for 74 software product teams were found by Carmel and Bird (1997) to have a median membership size of five. The researchers accounted for the effectiveness that results from keeping team size small. It makes possible close communication and participation of all members in decisions.

*Opportunities to Lead.* The size of the group affects the emergence of a leader. Bass and Norton (1951) reported that the opportunity of any single member to take on the functions of leadership in a group decreased as the number of members increased.<sup>4</sup> In agreement, Hare (1962) reviewed several studies that suggested that as the size of the group increases, individual members have less opportunity to talk and to attempt to lead. Fewer members can initiate leadership acts. Again, Warner and Hilander's (1964) study of 191 voluntary organizations in a community found that the involvement and participation of members decreased as the size of the organization increased. To the contrary, J. H. Healy (1956) found that for chief executives of corporations, subordinates' involvement in policy making was greater as the number of immediate subordinates increased.

As the size of a group increases, more differences appear in the members' tendency to be talkative and in their attempts to be influential (Bales & Slater, 1955). In groups that ranged from 2 to 12 members, Bass and Norton (1951) reported that such differences increased directly with the increase in the size of the groups, and reached the maximum in groups of six members. But contrary to most researchers, Kidd (1958) found no relation between the size of a group and increases in the differences among members' influence in groups of two, four, or six members. Blankenship and Miles (1968) also noted that the size of the units they led was less important to the decision-making behavior of executives than was their organizational level.

*Changes in Leadership Style and Effects.* Hemphill (1950b) studied groups with leaders whom the group members considered to be superior. He found that as the size of the groups increased, the members made greater demands on the leaders. Larger groups made significantly stronger demands on the leaders' strength, reliability, predictability, coordination, impartial enforcement of rules, and competence to do the job. At the same time, larger groups required less consideration from the leaders for individual members.

Pelz (1951) observed that small groups were better satisfied with leaders who took their part than with those who sided with the organization. Larger groups (10 or more members) were better satisfied with leaders who supported the organization. Medalia's (1954) results indicated that as the size of the work unit increased, workers' perception of their leaders as "human relations-minded" decreased. Goodstadt and Kipnis (1970) found that as the size of the groups increased, supervisors tended to spend less time with poor workers and to give fewer pay raises to good workers. In 100 randomly selected chapters of the League of Women Voters, J. Likert (1958) found that officers engaged in more activities as the chapters increased in size, but the chapter presidents exhibited less interest in individual members' ideas. Consistent with all these findings, Schriesheim and Murphy (1976) found that the leaders' initiation of structure was related to satisfaction of members in larger work groups and that the leaders' consideration was related to the satisfaction of members in smaller groups. However, Greene and Schriesheim (1980) showed that instrumented leadership was actually most influential in affecting drive and cohesiveness in larger work groups, while supportive leadership was most

influential in smaller work groups.

A meta-analysis by Wagner and Gooding (1987) of 7 to 19 studies of the effects of participative leadership on various outcomes found that the positive correlation of perceived participative leadership with perceived satisfaction of subordinates remained at .44 and .42, respectively, in small and large groups, but the correlation between participative leadership as perceived by members and their acceptance of decisions fell from .44 in small groups to .31 in large groups. When independent sources of leadership and outcome data that were free of single-source bias were correlated, the results again fell for the acceptance of decisions, from .27 to .20, and for satisfaction from .25 to .03. Thus overall, participatory leadership practices generally had more salutary effects in smaller than in larger groups.

Kipnis, Schmidt, and Wilkinson (1980) reported that when trying to be influential, supervisors of large groups were likely to choose impersonal tactics such as assertiveness and appeals to a higher authority instead of more personal influence tactics such as ingratiation and bargaining. In small groups, relatively more personal and fewer impersonal tactics were employed by the same supervisors. This finding may explain why a small span of control does not produce close supervision (Bell, 1967; Udell, 1967).

*Changes in Requirements.* Thomas and Fink (1963) reviewed several studies that concluded that as groups enlarged, the leaders had to deal with more role differentiation, more role specialization, and more cliques. Slater (1958) noted that the stabilization of a group's role structure became increasingly difficult with increasing size of the group.

Hare (1952) studied boys in groups ranging from 5 to 12 members. Leaders were found to exert more influence on decisions in the smaller groups, but the leaders' level of skill was not related to influence. The larger groups demanded more skill from their leaders. In large groups, the leaders' skill was positively correlated with the increased movement of members toward group consensus. Yet, in a comprehensive summary of personal factors found to be associated with leadership in natural and experimental groups, R. D. Mann (1959) noted that in groups of seven or smaller, intelligence seemed a little more important to leadership than adjustment; but in larger groups, adjustment increased slightly and intelligence decreased slightly in correlation with leadership.

*Antecedents.* Guion (1953) and G. D. Bell (1967) found that first-level supervisors tended to supervise fewer subordinates as the complexity of the job increased. The number of subordinates of chief executives tended to increase with the growth of the size of firms, according to J. H. Healy (1956). His results suggested that individuals differ in their ability to interact and that many who become leaders of very large organizations are able to interact with 12 to 15 or more assistants without feeling overburdened or pressured for time. Indik (1964) surveyed 116 organizations that ranged in size from 15 to 3,000 members and found that as organizations increase in size, they take on more operating members before they add new supervisors.

*Confounds.* Indik (1963, 1965a) cautioned that most generalizations about the effects of size are confounded by other factors. Two of these factors are the greater cohesiveness to be found in the smaller group, and the optimum size for the group's task. In a survey of 5,871 workers from 228 factory groups that ranged from 5 to 50 members, Seashore (1954) found that the smaller groups were also more cohesive. The same was true for the conference groups studied by N. E. Miller (1950).

As was noted, demands on a leader's initiatives increase along with the group's size, and the potential of the leader or members to interact individually with one another decreases as the group enlarges. If additional members are superfluous and unnecessary as far as the completion of a team's task is concerned, effectiveness and satisfaction are likely to suffer with an increase in the number of members. For any given task, there is an optimum-size team. Two people or even one person may be adequate and optimal for many tasks; five or six appear to be optimal for discussion groups (Bass, 1960). A larger number of different kinds of experts are likely to be needed for complex tasks whose completion requires skills and knowledge from many disciplines. The leader may need to deal with teams that are suboptimal in size or too large for the team's task. When the

team is too large for the task, the leader may need to initiate more structure so members do not get in each other's way. When the team is too small for the task, the leader may need to provide for more time and resources or reduce the team's goals.

### ***Effects of the Status and Esteem of the Group or Team***

Some groups in a large organization are seen as more valuable and critical to the organization's success than are other groups. For example, line groups are likely to be considered more important than staff teams. Prestige also may vary. Thus the biology department may be perceived as more prestigious than the agriculture department at a university. Groups of skilled craftsmen may be thought of as more prestigious than groups of assembly line operatives. The reputations of groups of the same type may vary as well. For instance, one biology department may be viewed as ossified, while another is seen as being at the forefront of the field. Similarly, one group of skilled craftsmen may be seen as quarrelsome, recalcitrant, and hard to please, whereas another group may be considered highly efficient, competent, and dependable. Fried (1988) showed that within organizations like hospitals, the relative power of the nurses group, administrative staff, and physicians' group were seen, particularly by the nurses, to depend on the centrality, nonsubstitutability, and coping with uncertainty of their respective roles.

Leadership within these different groups is likely to be affected in several ways. It will be easier to attract and hold members in the groups that have higher status and esteem. Members of these more highly valued groups will have relatively more influence with their leaders. In turn, their leaders will have more influence when they represent their groups in dealings with higher authority and with representatives of other groups at the same organizational level.

*Functionally Diverse, Cross-Functional, and Multi-functional Teams.* Leading a faculty group from different departments and disciplines is described as akin to herding cats. Yet diversity of education, profession, interest, knowledge, abilities, and departmental location in organizations is commonplace. Such functional diversity is witnessed in bringing together, on a regular or ad hoc basis, the vice presidents from the different divisions of the organization to generate policy suggestions; the scientists, engineers, and production heads to staff a functionally diverse team to innovate a new product; or the psychologist, social worker, psychiatrist, and nurse to discuss treatment of a mental health patient. Functionally diverse teams are expected to make better, more informed decisions but have a harder time reaching consensus. They help the leadership by facilitating organizational processes (Bantel & Jackson, 1989). They can help the top management interpret environmental ambiguities and reduce uncertainty (Zaccaro, Rittman, & Marks, 2001). As expert teams, they contribute to surveillance of the outside environment for the leadership and provide boundary spanning (Ancona & Caldwell, 1988). The leaders of cross-functional teams need to be technically competent and particularly skillful politically and interpersonally. They need to understand how the different functions are relevant to the success of the team (Yukl, 1998). Additionally, Jassawalla and Sashittal (1999) suggest, cross-functional team leaders should emphasize informal, intense meetings and exchanges of information. Forums should be provided for airing of issues and clarifications. Every member's response to decisions should be treated as important. Members should be replaced if they are unable to overcome protecting their own turf or show mistrust of others or lack of commitment to collective intentions. Constructive conflict and delays should be tolerated.

Waldman (1994) noted some problems of multifunctional teams. At Honda, they generated procrastination and divisiveness (where harmony is prized). Leaders had to intervene to avoid costly delays. Waldman mentions seven roles of these leaders: (1) careful staffing; (2) coordinating and facilitating rather than directing; (3) encouraging members to form links with one another and the team's clients; (4) establishing

group-based evaluation and incentives; (5) anticipating and tolerating mistakes; (6) eliminating impediments to team performance; (7) aligning individual members' and team goals. The leaders also need to maintain the vision, to be inspiring, to question assumptions, and to carry on in many other transformational ways.

### ***Effects of the Group's Norms***

The group's norms (its definition of tasks, goals, the paths to the goals, and the appropriate relationships among members) strongly affect what a leader can accomplish in the group as well as who will emerge as the leader. In turn, the leader often has an impact on group outcomes by influencing the group's norms.

*Frame of Reference.* Sherif's conception of the social norm exerted a marked influence on research on leadership. In an autokinetic experience, Sherif (1936) seated a subject in a darkened room and asked the person to observe a spot of light projected on a screen. The subject reported the distance that the light appeared to move. The average distance for several trials was recorded as the subject's individual norm. When the subject was later placed with a confederate of the experimenter who uniformly reported a distance that varied markedly from that reported by the participant, the subject tended to change his or her estimates to conform to the group norm. Asch (1952) obtained similar results when a subject was asked to judge the length of lines after six confederates of the experimenter had rendered judgments that defied the senses. The confederates uniformly declared that the shorter of two lines was longer. It was the norm of the confederates, not any single emergent leader, that influenced many of the subjects.

Other demonstrations of the effect of group norms showed how these norms moderate whether actual leadership behavior will be perceived as such. Thus, in an experimental comparison, Lord and Alliger (1985) found that the correlation of group members' perceptions of emergent leadership with actually observed leadership behaviors was greater when norms were established for members to be systematic rather than remaining spontaneous. Likewise, Phillips and Lord (1981) demonstrated that if a group was described as effective but members were led to believe that the group's success could be explained by other factors than the leader, the group's performance had less of an effect on the members' ratings of the leader.

*The Group's History of Successes or Failures.* Some groups and organizations have histories of success and high performance that contribute to their esteem, while others have histories of failure and low performance. For instance, different United Fund agencies were found by Zander, Forward, and Albert (1969) to be consistently successful or consistently unsuccessful in meeting the goals of their fund drives. In the same way, Denison (1984) reported consistencies in the rate of return on investments by companies over a five-year period. Some companies tend to do well continually; others always do poorly. Histories of success give rise to norms of success and high performance, while histories of failure give rise to norms of failure and low performance. Thus, Farris and Lim (1969) found that high-performance groups had higher expectations of their future success as groups than did low-performance groups. Leaders whose accession to office coincides with a failure when the groups have been accustomed to success will no doubt earn more blame than ordinarily. Conversely, leaders whose accession coincides with the success of previously failing groups will gain an unusual amount of credit, which may not be justified. According to experimental results obtained by Howell (1985), a role conflict condition will arise for members when performance norms are low but the leader is high in the initiation of structure, particularly in the pressure to produce.

*Conformity and Deviation.* Ordinarily, when a discrepancy exists between the opinion of one member and the rest of the group, the deviating member tends to move closer to the group norm. But if an extreme deviate refuses to yield, he or she will be rejected by the other members (Festinger, 1950, 1954; Schachter, 1951). Gerard (1953) and Berkowitz and Howard (1959) obtained results to indicate that leaders directed most of their communications to such deviates. If a deviate was unreceptive to accepting the majority point of

view, the group tended to expel the deviate from the group psychologically. Raven's (1959a) report of the results of an experiment noted that deviates would shift toward the norm if they could express their opinions both privately and in public. Presumably, the leader could make a difference by encouraging such expression by the deviates.

*Conformity to Norms and the Leader.* Scioli, Dyson, and Fleitas (1974) found that when conformity was demanded by college groups, the most dominant members became the groups' instrumental (task-oriented) leaders. Thibaut and Strickland (1956) obtained results indicating that as the group's pressure to conform increased (often pushed by the leader), more members increased in conformity under a *group set*, while more decreased in conformity under a *task set*.<sup>5</sup> At the same time, McKeachie (1954) reported that the members' conformity to the norms of their groups and liking for the groups were greater in leader-oriented than in group-oriented classes.

Newcomb (1943) conducted a study of social values on a college campus. He found that the most influential members represented the dominant values of the campus. Those who conformed in conduct but not in attitude possessed social skills but maintained close ties to their families. Those who conformed in attitude but not in conduct tended to lack social skills but regarded conformity of attitudes to be a mark of community acceptance and superior intelligence. Similarly, Sharma (1974) found that Indian students who were activists and prominent as leaders of demonstrations were concerned primarily with student issues, not with social change. The attitudes of these student activists tended to reflect the traditional values of their communities regarding religion, caste, marriage, and family. Likewise, in a study of modernization in India that sampled 606 heads of households engaged in agriculture, Trivedi (1974) found that although opinion leaders may have accepted innovations in agriculture, they, like Sharma's (1974) student activists, adhered to traditional religious beliefs and convictions. They differentiated agricultural from religious activities more fully in the process. (But in the United States in the late 1960s and early 1970s and in France in 1968, as in China in 1919 and 1989, the norms of student activists placed them in the vanguard of reform and revolutionary change.)

In a Hungarian study, Merei (1949) formed groups that were composed of submissive nursery school children. When placed in separate rooms, each group developed its own role structure, rules for play, and routine of activities. After these had become stabilized, a child with strong propensities to lead in play activities was introduced into each group. Although the new members were widely successful in gaining leadership positions, they were not able to change the norms and procedural rules of the groups. The groups had more of an impact on the leaders than the leaders had on the groups. Consistent with this finding, Bates (1952) showed that the closer that the behavior of individuals comes to realizing the norms of the group, the higher these individuals' likely position as leaders in the group. However, many other investigators found that group leaders ranked higher in the assimilation of group norms because they were highly influential in the formation of the norms.<sup>6</sup> Although leaders may be influential in establishing group norms, once the norms are adopted, they are expected to observe the norms (Hare, 1962).

O. J. Harvey (1960) found that formal leaders conformed more to group norms than did informal (sociometrically identified) leaders or other group members, especially under conditions of uncertainty. Mulder (1960) also found that the judgment of leaders was most influenced by other members when they, the leaders, were appointed in an ambiguous situation. But the emergent, informal leaders were the least influenced in the ambiguous situation without established norms.

*When the Leader Can Deviate.* The fact that leaders tend to be prime exemplars of their groups' value systems is not to suggest that they are slaves to the groups' norms (Rittenhouse, 1966). In fact, they may deviate considerably from the norms in various aspects of their conduct. In a study of sociometric cliques among teachers, Rasmussen and Zander (1954) found that leaders were less threatened than were followers by

deviation from their subgroup's norms. Leaders appeared secure enough to feel they could depart from the norms without jeopardizing their status. Similarly, Harvey and Consalvi (1960) found that the member who was second highest in status as a leader of a group was significantly more conforming than was the member who was at the top or bottom of the status hierarchy. The leader conformed the least, but not significantly less than the lowest-status member. Likewise, Hughes (1946) observed that members of industrial work groups let *rate busters* know in forceful terms that their violation of group norms would not be tolerated. However, the leaders of the work groups were allowed more freedom to deviate from certain group norms than were other members whose positions were less secure.

*The Leader's Need for Early Conformity.* As was detailed in previous chapters, Hollander (1958, 1960, 1964) suggested that the early conformity of leaders to the norms of their groups gains for them *idiosyncrasy credits* that enable them to deviate from the norms at later dates without their groups' disapproval (Hollander, 1964). The lesson for would-be leaders who wish to bring about changes in groups is that they must usually first accept the groups' current norms to be accepted. Practical politicians often can bring about more change by first identifying with a country's current norms and then moving the country ahead with statesmanship that takes the country where it would not have gone without the politician's direction. Franklin Delano Roosevelt's leadership of the isolationist United States into World War II is an illustration.

*Acceptance and the Leader's Freedom to Deviate.* In a study of personnel in the U.S. Air Force, Biddle, French, and Moore (1953) found that the closer the attitudes of crew chiefs were to the policies of the U.S. Air Force, the stronger were their attempts to lead. Chiefs who accepted their role as supervisors used their influence to further the institutional goals and purposes. But the amount of such attempted leadership was not related to the extent to which the chiefs were accepted by the crew members. However, crew chiefs who were accepted by their groups deviated further from the norms and policies than those who were not accepted.

*Effects of the Group's Goals.* Without doubt, the group's purposes, objectives, or goals are predominant as norms of the group. Studies of experimental groups indicate that members readily accept or commit themselves to the defined task and seem to develop other norms in support of the norms of the task. Once the members understand and agree on the group's goal, the goal operates as a norm against which the members evaluate one another's potential for leadership. Goode and Fowler (1949) observed, in a small industrial plant, that the informal groups supported the company's production goals despite the workers' low satisfaction with their jobs. The authors attributed this outcome to leadership that provided clear statements of the groups' goals; clear definitions of the members' roles; and strong, congruent group pressures toward conformity from within and outside the informal group.

Members differ in their commitment to the goals of a group. The greater a member's responsibility for attaining a goal, the stronger his or her commitment to the goal. Ordinarily, leaders exhibit more concern than do followers for the group's attainment of its goals. The attainment of goals is used by members as a criterion for evaluating the group's performance. Once members agree on their expectations for a group, these expectations operate as a norm that induces pressure for compliance. This makes routine leadership easier. The expectations also make leadership that attempts to move the group away from its chosen paths more difficult.

### ***Stability of the Group***

The group's stability affects its leadership. B. D. Fine (1970) studied 151 members of an unstable pool of workers and 582 workers who were assigned to stable groups in a refinery. The groups did not differ significantly in coordination, communication, participation, decision making, satisfaction, or mental health.

The unstable groups were higher than were the stable groups in motivation and the resolution of conflict. Leaders of stable groups were significantly stronger in facilitating interaction but not in support, the emphasis on goals, or the facilitation of work. Leaders of unstable groups exercised less control, and the workers in these groups expressed less need for freedom.

### ***Other Group Effects***

The group variables affecting leadership that have been discussed so far should be considered suggestive rather than exhaustive. For example, the source of information makes a difference. On the one hand, Woods (1984) observed more participative leadership in quality circles than in other group activities in manufacturing firms. Likewise, significantly more quality circles than other types of groups perceived their leaders to be highly participative. Nevertheless, the leaders themselves perceived no differences in their own behavior in the two situations. How the members are the same or different in attributes makes a decided difference in group outcomes. For instance, according to a meta-analysis by Bowers, Pharmer, and Salas (2000) the effectiveness of team heterogeneity depends not only on the nature of the task but also upon which variables the team members vary.

Experience in another group affects the attitudes toward leadership of those who subsequently become leaders. It also presumably affects their performance as leaders. Akhtar and Haleem (1980) showed that newly promoted superiors in an Indian hydroelectric power station exhibited the same attitudes toward initiation and consideration as the attitudes that had been the norm in the groups of employees from which they had come.

Bushe (1987) studied 415 managers' attitudes toward quality-of-work-life (QWL) projects. Those who were involved in *permanent* problem-solving groups were most favorable, and those in *temporary* groups were least favorable toward such projects in comparison to those with no experience in problem solving in QWL groups. The quality of the team leader's *linchpin* relationship linking each team project member with his or her superior was shown by McComb, Green, and Compton (2003) to correlate positively with the team project's efficiency, members' abilities, upper-management support, leader continuity, and team size.

## **The Effects of Leaders on the Group or Team**

---

Just as characteristics of the group or team affect their leadership, the leadership of the team, whether from a single individual or shared among individuals, makes a difference in the team's development. Leadership sets and achieves team goals, drive, cohesiveness, and the way the members work together and interact with each other. According to a meta-analysis of 50 empirical studies by Burke, Stagl, Klein, et al. (2006), task-focused leaders' behavior-averaged (size-corrected) correlations of .36 with rated team effectiveness and .20 with team productivity. Person-focused leader behavior correlated .36 with team effectiveness, .28 with team productivity, and .56 with team learning. A detailed book of suggestions by D. Tjosvold and M. Tjosvold (2000) indicates the many and varied ways in which leaders can help their teams to become more effective.

### ***Team Effectiveness***

*Leadership.* The preceding chapters were replete with illustrations of the impact of the leader's competence, personality, and style on the outcomes of the group. Leadership makes a difference in the team's effectiveness, drive, and cohesiveness and on closely allied variables like the team's collective efficacy and potency. For example, based on 32 cases, Grant, Graham, and Heberling (2001) concluded that where project

managers lead a number of projects that compete for their attention, the credibility of the managers may suffer, there may be more competition for leadership among the team members, and the member's commitment may falter. To further illustrate, Remdisch (1995) concluded from a German interview and survey study at an Opel automobile manufacturing plant of 86 shop floor leaders and 360 workers that the leaders played an important role in implementing group work. The *meisters*, the traditional supervisors, already had a history of good relations, trust, mutual regard, and respect from the individual workers, like that occurring between the noncom and the soldier in the *Wehrmacht* (Fukuyama, 1997). Nonetheless, those leading teams rather than individuals spent more time on cooperation, communication, and making decisions with workers. They needed less time to control line jobs, coordination, work performance, and quality. Again, the transformational leadership and contingent reward by platoon leaders and platoon sergeants significantly predicted observer-rated potency, cohesion and unit performance in 11 days of "on the ground" near-combat exercises of 72 U.S. Army light infantry rifle platoons (Bass, Avolio, Jung, & Berson, 2003).

*Importance of Network Connections.* According to a meta-analysis by Balkundi and Harrison (2006) of 37 teams in natural settings, team leaders are central in the network of relations among members within the teams that are effective. Their teams are central in the networks they share with other teams. A team's effectiveness is affected by its social network structures. Teams with "densely configured" interpersonal ties are more effective and more committed. Team performance and viability are greater. Strong networks facilitate the timing of required sequences of members' performance and members' familiarity with them.

*Obstacles to Avoid and Actions to Take for Effective Team Leadership.* Team leaders need to avoid faulty decisions. They need to watch out for *collective traps*, where individuals, but not the teams, are rewarded and to avoid *collective fences*, where individual members ignore one another and fail to share information. The leaders need to deal with *social loafing* and *free riders*. They need to avoid *groupthink* (Janis, 1972). They need to suppress their own egos and go beyond their self-interests for the good of the team. They need to encourage the team members to do the same.

McGrath (1962) proposed that team leaders define the team's goals and structure the team to enable maintenance and task activities to proceed (McGrath, 1962). For Kinlaw (1991), team leaders must manage with the teams' norms and values in mind. They need to initiate actions, set examples, and join efforts. Team leaders need to champion the teams and be directive or participative as circumstances require (Bassin, unpublished). According to Zaccaro, Rittman, and Marks (2001), team leaders are responsible for making judicious choices in solving the problems facing the team. The leaders need to search for, organize, and evaluate information for use by the team in problem solving. They need to translate their mission into a plan and communicate it to the team. They have to acquire and utilize their personnel and material resources, ideally matching individual abilities and selected resources with team requirements (Hackman & Walters, 1986; Fleishman, Mumford, Zaccaro, et al., 1991). They have to help their members share a mental model of a team that gives, and make sense about the team and its mission (Zaccaro, Rittman, & Marks, 2001).

As Tannenbaum, Smith-Jentsch, and Behson (1998) found for team effectiveness, the group dynamics technologies developed in the 1950s need to be applied by team leaders. Leaders of effective teams facilitate their members' discussions about teamwork, their critiques, and their feedback to each other. Giles and Mann (2003) showed that among 56 teams of 350 employees, boundary spanning was best done by the team leaders, not the teams. Morgeson (2000) found that the assistance of 34 leaders was needed by their 293 team members when disruptive, critical, urgent, and long-enduring team events, occurred such as a deficiency in resources, task-performance failures, missed deadlines, accidents, and conflicts. Leaders were more effective when they were proactive and assessed potential problems. In semiautonomous teams with external leaders (see below), event criticality and urgency were more disruptive and required the external leader to spend more time intervening (Morgeson & DeRue, 2006).

*Leader Coordination.* Leaders also contribute indirectly to team effectiveness by influencing team

coordination that facilitates team effectiveness. First, they identify, plan, and integrate the team members' prospective contributions that are likely to contribute to team effectiveness (Fleishman, Mumford, Zaccaro, et al., 1991). Then the team leaders develop, regulate, standardize, and monitor the necessary patterns of interaction among the members for team effectiveness (Zaccaro, Rittman, & Marks, 2001). Leaders' briefings and team interaction training produced mental models, in 237 undergraduates in three-member simulated tank teams, that enhanced performance, especially in novel versus routine situations (Marks, Zaccaro, & Mathieu, 2000).

*Integrating Athletic Cooperation and Competition.* Sports team leaders are more effective and their teams are more successful if they: (1) integrate cooperation and competition among the team members—the team members are encouraged to help one another as well as strive to outdo each other; (2) try for early success, such as scoring the first goal in a hockey game; (3) avoid sustaining downward spirals of failure based on attributions of stable uncontrollability—the coach needs to influence the team members to consider a more optimistic outlook; (4) make practices opportunities for experimentation and innovation and accept that it is okay to try but fail; (5) use rest intervals such as half-times to review the preceding performance and decide on what might be improved in the remainder of the game; (6) keep the team membership stable so that teammates can learn to work together and combine their efforts—for all teams in the National Basketball Association between 1980 and 1994, those most stable were most likely to win games; (7) arrange for the team to study the videos of each game to provide different ways of analyzing what happened.

*Effectively Organizing.* The 149 British Iron and Steel Trades Confederation workplace representatives who indicated, compared to their peers, that their management introduced teamworking by delayering management, creating flexible job descriptions, and maintaining fewer pay grades, achieved greater product quality, more customer satisfaction, and greater market competitiveness (Bacon & Blyton, 2000). The extraordinarily gifted leader J. Robert Oppenheimer, led the Los Alamos laboratory team in the creation of the atom bomb. The highly effective team combined highly talented experts into an expert team. Invariably, the leaders of such "great groups," according to Bennis (1997), call attention to what is important and why the group's work makes a difference. They promote trust of the group in itself and the processes of turbulence. They favor curiosity and risk taking. They convey hope in tangible and symbolic ways that the group and team can overcome the obstacles to success. The leaders make more effective use of the team by assigning subparts of the task to individuals whose competencies best match the requirements of the subparts (Bass, 1960). They can also prevent premature closure in the team's evaluation of alternatives (E. R. Alexander, 1979).

*Cross-Training.* More of the positive effects of working in teams and groups can be obtained by arranging for the cross-training of members so that one can fill another's shoes in case of absence. Regularly scheduled meetings will ordinarily help (Dyer & Lambert, 1953), as will other ways of improving communications among the members. But many changeovers from individuals to teams are failures. They tend to lack quality leadership and management support. They are difficult to integrate into the management hierarchy. Many employees may feel that teams are a waste of time. They are unable to deal appropriately with freeloaders. The best workers may feel their performance goes unrewarded (Nahavandi & Aranda, 1994).

*Leader Intervention.* A leader's questioning set can help members evaluate alternatives systematically. What current resource could be substituted, modified, combined, omitted, or reversed? (Osborn, 1953). The "rush to judgment" that often occurs can be avoided. Frequently, a single solution gets most of the group's attention. Leaders can encourage more even participation by giving inactive members confidence and discouraging monopolizers. On the other hand, the leadership can achieve a more effective group outcome by recognizing differences in the competencies of the members. To some degree, the leader may have to encourage participation by the more competent members and discourage participation by the less competent members. Leaders can clarify the group's goals and ensure agreement about them and an understanding of them. Leaders can help get the group to view its problem in such a way that the problem can be reorganized to increase

efficiency. Even when the group feels satisfied with its solution, its return to the same problem a second time is likely to generate an even better solution (Maier & Hoffman, 1960b).

*Optimizing Efficiency of Meetings.* Leaders can make the difference in whether a team meeting optimizes its time, effort, and achievements. Leaders may be efficient or inefficient in their uses of group meetings. In discussing how he made interagency meetings more efficient, Colin Powell (1995, p. 332) remarked that when he was given the authority to chair functionally diverse meetings, after suffering “through endless, pointless, mindless, time-wasters for years,” he set rules for increasing the efficiency of interagency meetings he chaired: “Everyone could recommend items for the agenda, but I controlled the final agenda, which I distributed before the meeting. Once the meeting started, no one was allowed to switch the agenda.” The meeting was to last exactly one hour. In the first five minutes, Powell reviewed the purposes of the meeting and the decisions that had to be reached. In the next 20 minutes, participants presented their positions without interruption, followed by free discussion until the last 10 minutes, in which Powell summarized conclusions and decisions for five minutes and participants could state one-minute disagreements. Those remaining in disagreement could complain to their bosses. The meetings were certainly more efficient than the usual uncontrolled, rambling affairs, but were effectiveness and satisfaction sacrificed?

Leaders need to actively monitor whether meetings are on the right course and make corrective changes as needed. They need to pay attention to foot-dragging, signs of boredom, convoluted ways of getting things done, frustrations about individual roles, pessimistic attitudes about ability to carry out assignments, too much or too little structure, poor external relations, and lack of organizational support (Kanaga & Browning, 2003). Hackman and Johnson (1993) suggest that meetings should be called when necessary for clarifying, sharing objectives, and reaching consensus, but not if alternative communications that can achieve the same results are available or personal matters can be better handled individually. They agree with Powell about the need for clear agendas on which the meeting is focused and for the leader’s active, attentive listening. The advantages and disadvantages of virtual rather than face-to-face meetings will be detailed in [Chapter 29](#).

### ***Impact of Leadership on the Group’s Drive and Motivation***

The preceding chapters were replete with illustrations of the impact of the leader’s competence, personality, and style on the outcomes of the group. Here I wish to call attention to the effects of leadership, in general, on the group’s effectiveness, drive, and cohesiveness and the variables that are closely allied with them, such as the group’s collective efficacy and potency.

As discussed earlier, charismatic and inspirational leadership has strong effects on the drive of a group since it correlates highly with individual members’ reports of extra efforts. Team leaders persuade their members to work hard for their own or the team’s benefit (Bass, 1985) and raise the collective sense that the team is capable of achieving its goals (Zaccaro, Blair, Peterson, et al., 1995). The leaders’ persuasiveness is aided by their nonverbal expressiveness and their emotional state (El Haddad, undated). Collective efficacy beliefs underlie the team’s drive. The beliefs derive from prior success experiences, observation of team performance, and the influences of leaders and members (Bandura, 1982). Leaders use the beliefs to build confidence (Kozlowski, Gully, Salas, et al., 1996). Drive is increased further by the leader encouraging the exchange of ideas and mutual support (Zaccaro, Rittman, & Marks, 2001). Jung, Butler, and Baik (1998) demonstrated that for 47 groups of 217 employees of a large South Korean firm, transformational leadership correlated .36 with collective efficacy, which in turn correlated .66 with perceived group performance.

*Cross-Lagged Effects.* Greene and Schriesheim (1977, 1980) examined leadership behavior and group drive using a longitudinal design with 123 work groups. Using cross-lagged correlational, cross-lagged path, and corrected dynamic correlational analyses, they found that both instrumental (task-oriented) and supportive

(relations-oriented) leadership behavior were causally antecedent to the groups' drive.

*Location.* Medow and Zander (1956) found that group members who were in positions of centrality—and therefore more likely to exert leadership—exhibited more concern for the group's goals than did members in peripheral positions.<sup>7</sup> Central members selected goals in terms of the group's probability of success, were more insistent that the group be correct, exhibited a stronger desire for the group's success, and perceived themselves as having more influence than other members perceived them having.

*Leader Presence.* The presence of a leader can help team members remain interested in the goal of a task. Zander and Curtis (1965) reported that team members whose task performance was poorer than they expected tended to lower their aspirations. But they did not down-grade or reject the task as much when a leader was present.

Those who exert leadership tend to feel more responsible for the outcomes of their groups. E. Pepitone (1952) found that the more responsible a member's role, the greater his or her concern for the success of the group. E. J. Thomas (1957) reported that when members were highly dependent on each other for the performance of a task, those who were able to facilitate the performance of other members worked harder for the group.

Zander (1971) showed that the leader's feedback about the group's performance and the leader's reward practices had a positive impact on the group's desire to achieve success. The absence of a leader to clarify the requirements of the task and the goals of the group resulted in the group's spending considerable time in clarification and the quest for orderliness. Members of unorganized groups (J. R. P. French, 1941) and members of groups under a laissez-faire type of leadership (Lippitt, 1940a) frequently expressed a desire to get things organized, to buckle down to work, and to stick to the job that was supposed to be done.

*Leaders' Intentions.* In a large-scale Swedish study, Norrgren (1981a) observed that the positive behavioral intentions of managers exerted considerable influence on the quality of the relations among the members of their work groups. The positive intentions also motivated subordinates to perform and increased how much challenge and stimulation the subordinates felt that they received from their jobs. J. Likert's (1958) previously cited study of the chapters of the League of Women Voters showed that members were more active when the presidents were interested in their ideas (as in the smaller chapters). The members were also more active when the officers of the chapter believed that the members should have more influence on policies and activities. The members participated less actively in chapter activities when they felt pressure from the president but participated more actively under peer pressure and pressure from the leaders of their project discussion groups.

*Transactional and Transformational Leadership.* Transactional leadership can enhance team members' drive and motivation in three ways. First, leaders make members aware that their contributions are necessary if the team is to reach its goals. Second, leaders arrange to reward individual members' contributions to the team reaching its goal. Third, leaders arrange for the benefits to outweigh the costs. Free riding and social loafing are discouraged (Shepperd, 1995). Transformational leaders animate team members by highlighting the values of the team's efforts to the members and to others, and the importance of the team's success to the organization, community, or society.

### ***Impact of the Leadership on the Group's Cohesiveness***

*Leadership Style.* Democratic, participative, and relations-oriented leadership behavior was found to contribute to the cohesiveness of groups in a number of studies.<sup>8</sup> Smith (1948) obtained a positive correlation between group cohesion and supportive leadership in area management teams in English social agencies but not among local social work groups in these agencies. Similarly, task-oriented, directive leadership behavior was seen to increase cohesiveness according to many other investigations.<sup>9</sup> Both types of leadership behavior were

ascertained to contribute to the cohesiveness of groups in still other studies.<sup>10</sup> In the Korean study noted above, Jung, Butler, and Baik (1998) found that transformational leadership correlated .65 with group cohesiveness, which in turn correlated .36 with collective efficacy. Linear regression programs for 72 U.S. Army platoons and their platoon leaders and sergeants showed that in addition to the strong direct effects of transformational leadership on the readiness of the platoons and the rated performance of the leaders and sergeants in simulated combat, platoon cohesion added indirectly to the effects on the platoons' effective performance (Bass, Avolio, & Berson, 2002).

*Regard for Mission and Leaders.* According to a review of military leadership, Manning (1991) concluded that leadership promoted unit cohesion by providing clear and meaningful group missions. The missions and the risks undertaken needed to be seen by the unit soldiers as worthwhile. The unit cohesiveness of soldiers of the German Wehrmacht in the face of defeat in World War II was due not to the sharing of ideology but to the mutual regard and respect of the soldiers, noncoms, and officers. The cohesiveness supplied a sense of power, regulated relations with authority, and minimized self-concerns in battle (Shils & Janowitz, 1948). To promote cohesion in other military settings, units have been rotated as units so as to maintain bonding among the members, commitment to the unit, and mission accomplishment despite combat or mission stress (Meyer, 1982). In Vietnam, the U.S. military ignored the importance of unit cohesiveness; as a result, unit effectiveness deteriorated because of the rotations in and out of combat soldiers and their replacements. The lesson was learned, and now whole brigades are rotated simultaneously into and out of Iraq.

*Cohesion of Leaders.* Mael and Alderks (1993) found the importance of the cohesion of squad and platoon leaders in 60 platoons as they engaged in simulated combat. The 49 platoon sergeants, 54 platoon leaders (usually lieutenants), and 166 squad leaders were rated by the squad members of their platoon on whether "the leaders in this platoon work well together as a team," "really care about each other," and "pull together to get the job done." This leader cohesion was rated somewhat higher by those higher in rank in the platoon. For the 1,012 squad members' ratings, leader cohesion correlations of .48 were obtained with platoon-simulated combat effectiveness, .47 with job involvement and motivation, and .43 with identification with the army. The findings were consistent with the results for the ratings by the leaders and specially trained observer-controllers.

*Integrated Concerns of Leaders.* A leader of a work group who combines high concerns for the task with high concerns for relations, such as Misumi's high-performance (P) and high-maintenance (M) leader, was expected to establish shared attitudes favoring a high level of performance. Indeed, such performance norms were the highest under Japanese high-performance and -maintenance leaders—PM types (mean = 17.3), followed by M-type leaders (mean = 16.5), P-type leaders (mean = 16.3), and low-performance maintenance—pm-type leaders (mean = 15.8). Using Jackson's (1960) return-potential model of norms, Sasaki and Yamaguchi (1971) obtained results that were parallel to Misumi's for 160 second-year Japanese junior high school students in 32 groups—16 groups of boys and 16 groups of girls. The point of maximum return (the point maximally approved by the group members) varied as follows: PM, 25.0; P, 20.0; M, 16.3; and pm, 18.8. The degree of agreement among members about a behavioral norm differed with the styles of their leaders as follows: PM, 3.02; P, 1.71; M, 1.63; and pm, 1.99.

### ***Impact of Leadership on Collective Efficacy and Potency***

An experiment with 268 undergraduates assigned to one of 59 teams showed that collective efficacy was enhanced when the leaders and members had confidence that they could fulfill the role requirements. The teams with the best performance had the highest collective efficacy (Taggar & Seijts, 2003). A transformational leader directly influences a team's potency by raising its confidence of success (Guzzo, Yost,

Campbell, et al., 1993). As noted above, the potency of 72 platoons in joint readiness simulated combat was raised if their platoon leaders were transformational (Bass, Avolio, Jung, & Berson, 2003).

### ***Impact of the Leadership on Team Conflict and Emotions***

Leaders may generate cognitive conflict with and among members over ideas and information. Such conflict can be constructive and help the group reach its objectives, but the leaders need to help the team reduce or eliminate affective and emotional conflicts that involve personal arguments, incompatibilities, and attacks (Zaccaro, Rittman, & Marks, 2001). Amason (1986) surveyed 48 top management teams and found that cognitive conflict, usually task-oriented, and matters of differences in opinion and judgment about how the team should achieve its objectives contributed to the team's quality, understanding, and satisfaction with decisions. Emotional conflict had the opposite effect, as noted earlier by Katz (1977). Pirola-Merlo, Hartel, Mann, et al. (2002) demonstrated that transformational and facilitative leadership mainly had an indirect effect on the performance of 54 Australian R & D teams in the face of negative events and obstacles preventing team success. In the face of such frustrating obstacles, the path coefficient between leadership and team climate for excellence and safety was .52, and the path coefficient between team climate and team performance was .71, while the direct prediction from leadership to team performance was only an insignificant .09.

*Team Satisfaction.* Although the team leader makes the final decision, when members can make suggestions to the team leader, they are more satisfied if the decision reflects their recommendation. Such teams perform better, according to a controlled experiment by Phillips (2001) using 76 confederate-led teams of four undergraduates each assigned to a computer task.

*Impact of Leadership on Team Climate.* A survey of the weekly team climate of 187 Australian participants in 19 teams stationed at one of four permanent Antarctic stations between 1996 and 2001 found that effective leadership was the most important variable affecting weekly team climate, according to team results. Age, sex, and other individual variables were of little consequence (Schmidt, Wood, & Lugg, 2003). Wilson-Evered, Hartel, and Neale (2001) showed in a longitudinal study of hospital teams that the climate of morale mediated the effect of transformational leadership. Pirola-Merlo, Hartel, Mann, et al. (2002) completed a complex analysis of the mediation of team climate on the effects of transformational leadership (instilling a sense of vision and pride) and facilitative leadership (building working relations among the members) on the reactions to obstacles to performance of 54 R & D teams with a total of 313 team members. Obstacles included technical problems, staff availability, member relationships, and funding shortages. For 34 teams, climate for excellence correlated directly ( $r = .49$ ) with team effectiveness. Leadership did not correlate directly with team performance ( $r = .09$ ), but most of the positive effect of leadership ( $r = .32$ ) was due to team climate. Leadership appeared to serve to suppress the negative impact of obstacles on team climate.

### ***Other Mediators of the Impact of the Leadership***

How a leader's behavior affects the group's drive and cohesiveness depends, to some extent, on the characteristics of the group. The same leadership that may contribute to motivated and cohesive subordinates in one kind of group may fail to do so in another. Greene and Schriesheim's (1980) analysis of 123 work groups revealed that instrumental leadership had strong effects on drive and cohesiveness, particularly in large and new groups. The reverse was true for supportive leadership, which exerted the most influence on drive and cohesiveness in small and recently established groups.

Leana (1983) manipulated the same variables in an experiment on how the style of leadership and cohesiveness affected *groupthink*. Groupthink is the extreme seeking of concurrence in decision-making

groups (Janis, 1972). Concurrence seeking overrides the realistic appraisal of alternative courses of action and vigilant information processing (Janis & Mann, 1977). It results in faulty decision making. Janis (1982) hypothesized that concurrence seeking or groupthink would occur more readily in cohesive groups with directive leaders. Other conditions that would generate groupthink included stress and pressure for a solution, insulation of the group from outside sources of information, and lack of adequate procedures for finding and evaluating information. Leana (1982) created experimental conditions for groupthink but varied whether the leader was directive or participative and whether the four-member groups that were drawn from a total of 208 college students were high or low in cohesiveness. In contrast to participative leadership, directive leadership produced more groupthink, which was reflected in incomplete canvassing of alternatives, failure to discuss alternatives, and decisions that were strongly based on the leader's preferences. Unexpectedly, high cohesiveness did not result in more groupthink than did low cohesiveness. In fact, high cohesiveness actually widened the search for information. The effects of style of leadership and cohesiveness were independent of each other. Bunderson (2003) found that *power centralization*, based on work flow within teams, served to moderate effects on 44 business unit managers' teams in a large consumer products firm. He examined how much team members' expertise and the similarity of their functional backgrounds determined the influence of their involvement in decisions. When decentralization was high, expertise became of increasing importance to involvement in decisions. The reverse was true for highly centralized teams. With decentralization, functional background similarity decreased in importance to member involvement in decisions, while with centralization, it increased.

*Team-Member Exchange (TMX)*. Analogous to Leader-Member Exchange (LMX) is Team-Member Exchange (TMX), the quality of the relations between the individual team member. According to Seers (1989), among 123 blue-collar employees TMX was better when their teams were given more autonomy by management. The leaders can make more efficient use of the team by assigning subparts of the task to those individuals whose competencies best match the requirements of the subparts (Bass, 1960). The leaders can also prevent premature closure in the team's evaluation of alternatives (E. R. Alexander, 1979).

The leader can pursue a questioning set, which helps members evaluate alternatives systematically. What current resource could be substituted, modified, combined, omitted, or reversed? (Osborn, 1953). The "rush to judgment" that often occurs can thus be avoided. Frequently, only one solution gets most of the group's attention. The leader can encourage a more even distribution of participation by encouraging inactive members and discouraging monopolizers. On the other hand, the leader can make for a more effective group outcome by recognizing differences in the competencies of members. To some degree, leaders may have to encourage the participation of the more competent members and discourage the participation of the less competent members. The leaders can clarify the teams' goals, ensuring understanding and agreement about them. The leaders can help get the teams to view their problems in such a way that the problems can be reorganized for more efficient handling. Even when the teams feel satisfied with their solutions, their return to the same problem a second time is likely to generate even better solutions (Maier & Hoffman, 1960b).

Team leaders can obtain more of the benefits of working together by arranging for the cross-training of team members. One member can fill another's shoes in case of absence. Regularly scheduled meetings will usually help (Dyer & Lambert, 1953), as will other ways of improving communications among the members.<sup>[11](#)</sup>

### ***Self-Managed Teams***

In addition to the shift from individual work to teamwork (Lawler, Mohrman, & Ledford, 1995), there has been a shift to some extent away from supervision by a formally appointed leader one level up in the hierarchy

from the team members supervised. Instead, appointed leaders may remain team members, or the members share some or all of the leadership among themselves (see below) in self-managed, self-directed, or autonomous teams. A leader, external to the team, serves as a coach, advisor, and liaison with the organization and may be responsible for several self-managed teams. Team members are linked together by process, not function. A self-managed consumer products innovation team is made up of an engineer, a product designer, a technical specialist, and a marketer (Benson, 1992). The teams may have autonomy in some tasks but not others. However, as of 1997, in the automobile industry, Murakami (1997) noted that in 13 plants owned by U.S., European, and Japanese automakers, while autonomy was present for several of nine tasks, there were no *fully* autonomous teams to be found. As early as 1924, Mary Parker Follett proposed that leadership in a group should come from the person with the most knowledge of the situation. Bales and Slater (1955) observed that although the formal task functions of an appointed leader were carried out by a single person, several group members could provide socioemotional leadership. Bowers and Seashore (1966) recognized that leadership could emerge from individual team members as well as the appointed leader. Manz and Sims (1980) introduced their pioneering line of investigation about *self-managing* work teams. They devised a 21-item questionnaire to measure leadership in self-managed teams (Manz & Sims, 1987). Shared leadership is a group process. As detailed below, it is distributed among the team members and derives from them (Pearce & Sims, 2002). Position power and status are less important than esteem to the informal, plural leadership that emerges. Leaders arise by being perceived as prototypical team members (Hogg, 2001). The teams have a great deal of autonomy and flat organizational structures. Vertical hierarchies of leaders and the led are replaced by networks of relationships (Seers, 2002). The teams are considered the fundamental units of the organization's work, supplementing or replacing the vertical structure (DeSanctis & Poole, 1997). Barry (1991) has enumerated the functions that can be carried out by cross-functional teams. Self-management and self-leadership are correlated concepts, but Manz and Sims (1986) distinguish between their theoretical underpinnings. *Self-management* is concerned with externally generated standards about how the team ought to be working. *Self-leadership* is part of self-management but is also concerned about the direction of efforts as well as how to achieve them (Manz, 1992). Akin to the effects of participative leadership, the increased level of decision making is expected to enhance satisfaction and performance. Members become "masters of their own fate."

*Internal Leaders.* Self-managed team members lead themselves. They meet as a team to make collective decisions. One or more team members may be emergent, elected, appointed, or automatically rotated to serve as internal team leaders in a highly equitable team structure. They can represent the team in meetings with other team leaders. Their appointments may be temporary (Manz & Sims, 1987). They become *superleaders* (see below) when they maximize the contributions to the team of other members and bring out the talents of other members (Manz & Sims, 1989). According to a review by Gummer (1988), the most important components of self-managed team leadership are encouragement of self-reinforcement and self-evaluation by team members. Basu, Simmons, and Kumar (1997) examined data from 238 self-managed work teams in seven subsidiaries of a Fortune 500 organization. Teams rated by their members as high in self-direction were higher than average in performance. Yukl (1998) listed other conditions in self-led teams that can be facilitated by their leadership: adequate socialization of the members, appropriate task design, adequate information distribution, appropriate rewards and recognition, adequate human and material resources, clarification of team goals, alignment of team goals with the organization's objectives, and a gain in support from top management. The internal leaders that emerge in self-managed teams and their effectiveness depend on individual members' personalities. Humphrey, Hollenbeck, Meyer, et al. (2003) administered the Five-Factor Model personality inventory to 198 MBA students formed in self-led teams of five or six who worked and studied together for two semesters. The academic performance, including group coursework grades and GPAs of the originally matched teams, was better if, within the teams, there was more variance among the members in extroversion,

and the extroverted members were high-scoring rather than low-scoring on conscientiousness. More leadership emerged, resulting in better performance, when the extroverts were also high in agreeableness. Wolff, Pescosolido, and Druskat (2002) found that among 382 MBA students in 48 self-managing teams working on a project for an academic year, those somewhat higher in empathy, support for developing of others, perspective taking, and pattern recognition were more likely to engage in team task coordination. They were also more likely to emerge as team leaders.

*External Leaders.* The organization usually appoints a former supervisor, manager, or specialist as an external leader who serves as a facilitator, coach, advisor, or consultant, usually for several self-directed teams. The external leader is the primary catalyst for the sharing of team activities within the teams (Conger & Pearce, 2002). The external leader's most important function is to facilitate the team's own observations, evaluations, and reinforcements. But the roles and status of external leaders are often unclear (Manz & Sims, 1984). External leaders may be criticized by teams for controlling too much, and by their bosses for controlling too little (Walton, 1982). Prodded by their bosses, external leaders will increase their control over the team (Klein, 1984). External managers may maintain responsibilities, such as allocating resources. The team may make the final decision, but the external leader can still indicate how much can be afforded. Nevertheless, the hardest part of changing to self-managing teams may be changing the external leader's role from manager to coach. Constant learning is required (Benson, 1992).

Druskat and Wheeler (2001, 2003) completed a study of the behavior of 19 external advisers responsible for external leadership of five to eight of 300 self-managed teams in a Fortune 500 durable goods manufacturing plant. Superior-performing external leaders of high-performance teams were compared with average-performing leaders of average performing teams. Interviews and focus groups with 119 members of the organization provided the data. Compared to average external leaders, superior external leaders were more aware socially and politically. Superior leaders paid more attention to building team trust and caring for team members. They did more scouting for information from managers, peers, and specialists. They investigated problems systematically. They did more to obtain external support for their teams and to influence the teams. They also did more coaching and delegating of authority and were more flexible about team decisions.

*Empowerment of Teams.* Teams and individual members may be empowered to do their own planning and organizing. Control comes from commitment and social pressure to conform. Wellins, Byam, and Wilson (1991) suggest that teams should be empowered in stages. First they can be assigned to take care of their own housekeeping, training one another, and scheduling production. Managing suppliers and external customer contact can come later. Finally, when the team is fully mature, it can handle its own performance appraisals, disciplinary processes, and compensation decisions. Burpitt and Bigoness (1997) found in 20 firms that team-level innovation among 60 project teams was enhanced by leader-empowering behavior. Barker (1993) noted that in a small manufacturing company, the self-managed teams applied social pressure on any member who violated the standards they had collectively set for themselves.

*Shared Leadership.* Arguments for sharing leadership come from a variety of theories, such as those dealing with group cohesion, influence tactics, social exchange, and social networks (Seibert & Sparrowe, 2002). Innovation is greater in project innovation teams when members share a vision of what is required (Pearce & Ensley, 2003). The dynamics, moderators, appropriateness, contingencies, and implementation of shared leadership have been presented by Pearce and Conger (2002). Following principles enunciated in the group dynamics movement, team members play many of the task and relations roles of leadership listed by Back (1948). Leadership is shared in that any member who sees a need by the team for a leadership role to be played, and believes she or he is competent to do so, calls attention to the problem and attempts to enact the leadership role or encourages other members with more knowledge and expertise to do so. The leadership function is transferred to take advantage of the different team members' competencies, perspectives, attitudes, contacts, and available time (Burke, Fiore, & Salas, 2002). Australian case studies compared six hotel units

with plural leaders who were successfully implementing quality service programs, with six that were not satisfactorily doing so. The successful units benefited from plural leaders who were either task-oriented or relations-oriented (Waldersee, Simmons, & Eagleson, 1995).

Ensley, Hmielski, and Pearce (2006) compared 220 top management teams in new venture start-up firms that were vertically organized, with appointed leaders and teams that shared leadership. Both kinds of teams performed well, as measured by employee and revenue growth. However, aspects of the teams that shared leadership contributed more to better performance. Again, Mehra, Smith, Dixon, et al. (2006) failed to find that shared leadership generally contributed to team performance, but some kinds of decentralization arrangements were better for performance than others.

Unlike leaderless groups, in which members compete in attempts to lead the group, *shared leadership* is a cooperative endeavor in which different members take initiatives that they see are needed for self-directed team success (Ray & Bronstein, 1995). Much training and coaching of team members and leaders is essential for shared leadership. Incentive programs and regular measurements are needed as self-directed teams with shared leadership become accountable for discipline, human resources, and setting and meeting goals. The team needs to avoid wandering off course (Benson, 1992).

*Superleadership.* Manz and Sims (1989, 2001) created the concept of *superleadership* to describe the facilitation of the self-leadership of other team members. Members can be helped to lead themselves effectively. Other team members need to achieve self-motivation and self-management. They need to observe themselves, set goals for themselves, manage cues, reward themselves, and rehearse in the context of teamwork. The superleader serves to reinforce such self-leadership and gets the team members to be the best self-leaders they can be. The authors assume that all team members want to be leaders and are free of traits that would inhibit them.

*Effectiveness of Self-Managed Teams.* In self-managed teams, compared with traditional work groups, there is a more constructive challenge to the status quo with the intention to improve the situation rather than to merely criticize (LePine & Van Dyne, 1998). Cohen and Ledford (1994) completed a quasiexperimental analysis to evaluate the effectiveness of self-management teams in a telecommunications firm. The teams came from various locations and included technical support, customer service, administrative support, and management involving 1,044 employees, 142 supervisors, 136 managers, and 15 union presidents. Self-managing teams were found to be more effective compared with traditionally managed teams performing the same kind of work in that: (1) output at Honeywell increased by 2809; (2) processing of lease applications at AT&T Credit doubled; (3) turnaround time at Carrier was reduced from two weeks to two days; (4) the defect rate at Corning Glass was reduced from 1,800 parts to 9 parts per million; (5) package losses and incorrect bills at Federal Express were reduced by 13%; (6) productivity at Xerox increased by 30%; (7) case-handling time at Shenandoah Life Insurance was reduced from 27 to two days (Benson, 1992; Dumaine, 1990; Fisher, 1993). *Semipermanent* management teams in a large automobile manufacturing firm, unlike temporary task forces, were expected to initiate and contribute new ideas on an ongoing basis for improving product quality, productivity, and quality of work life. Although not completely self-managing, the 71 teams were sufficiently empowered, with considerable autonomy. They were expected to identify opportunities for positive change as well as to implement them. The shared leadership had a stronger effect than hierarchical leadership on their success (Pearce & Sims, 2002).

Shared leadership is not the same as multiple leadership, for it implies common purposes. Neubert (1999) did not find that performance was better in 21 self-directed manufacturing teams if the appointed leader was supplemented by member-identified informal leaders. Several studies found that team performance and satisfaction were higher in self-directed teams (see, e.g., Wall, Kemp, Jackson, et al., 1991). Absenteeism and turnover were also higher rather than lower than among counter-part groups, but there were other differences between the self-managed and traditional groups that might explain the effects on absenteeism and turnover

(Basu, Simmons, & Kumar, 1997)

*Mixed and Negative Effects.* Cordery, Mueller, and Smith (1991) reported that, consistent with previous studies, as noted above, members of autonomous work groups were more satisfied than those working in traditional groups but at the same time the members were higher in absenteeism and turnover. Additionally, Allender (1993) argued that the costs of implementing the changeover to self-managed teams outweigh the benefits. Narrowly skilled employees have to be trained in a much wider set of skills. Implementation takes two to five years.

## Summary and Conclusions

---

Team-leader effects go beyond effects of individual members interacting with the leader. There may be an assembly bonus effect for the team so that the team does better than the sum of its members. Or faulty processes may result in the team doing worse. The leader makes a difference in which outcome occurs. In turn, the leader is affected in many ways by the group. Thus, leadership systematically depends on the phase of the group's development in which the leadership is occurring, as well as on the group's history. As newly formed groups progress, they find it necessary to resolve contests for influence and to develop role structure and cohesiveness before they can engage in the effective performance of tasks. Leaders are expected to provide role structure, maintain goal direction, and resolve interpersonal problems. If leaders fail to fulfill their expected roles, new leaders tend to emerge.

Group drive and group cohesiveness make considerable differences in what is required of the leader and what the leader is able to do. Likewise, the size of the group affects the leadership. The larger the group, the more difficult it becomes for any member to acquire leadership. Large groups make greater demands on their leaders than do small ones.

Groups develop norms that define the appropriate conduct of the members. Once a norm has become stabilized, in the mutual expectations of members, members bring strong pressures to bear on any individual who deviates from the norm. The greater the extent to which members assimilate a group's norms and values, the greater the probability of their emergence as leaders. As leaders, they tend to act as strong exponents of these group norms and tend to conform to them. However, once leaders have consolidated their position, they are likely to be granted considerable latitude in departing from the same norms. The goals of a group operate as group norms in terms of how the members evaluate the group's performance. Leaders exhibit a stronger concern for and commitment to their groups' goals and work harder for their groups' success than do followers. Other aspects of the group, that affect the requirements for a leader's success include the group's stability, the group's status and esteem, the group's frame of reference, and the group's past history. Many other attributes of groups, are likely to influence the results with their leaders and managers: the sources of information; the age of the groups; the leaders' and members' earlier experiences elsewhere; whether the groups are part of a larger organization, are temporary or permanent, and are easy or difficult to enter; and whether the membership is homogeneous or heterogeneous. Each of these attributes is likely to influence what is required of the persons who emerge as the leaders and what leadership behavior is most likely to be effective.

Leaders have systematic effects on the drive of their groups, although little attention has been paid to this aspect of charismatic and inspirational leadership. Both directive and participative leadership can contribute to group cohesiveness, as can the interest and concern the leader shows for the group. Inspirational leadership would be expected to increase the group's cohesiveness. The leader can make more effective use of the group by assigning subparts of the task to individuals whose competencies best match the requirements of the subparts (Bass, 1960). He or she can also prevent premature closure in the group's evaluation of alternatives (E. R. Alexander, 1979).

We now turn from attending to the team and its members to a concentration on the effects of the tasks faced by the team.

# Effects of Task and Technology

Effective leadership is influenced by the requirements of the tasks faced. But the same individuals tend to emerge as leaders as the tasks change. There seems to be a generalized competence for task leadership. Nevertheless, the competence needed for effective leadership differs from one task to another. The tasks faced by the group, the organization, and its individual members affect and are affected by the leadership. The leadership roles required by the tasks have consequences for the outcomes of the members' satisfaction, the group's productivity, and the organization's performance. In the same way, the leadership involved in the tasks to be accomplished is linked to the technology used. Doing business is shifting from making and distributing products to providing services. Work is being redefined, calling for "constant learning, more higher-order thinking, and less 'nine-to-five' " limits on concerns about the tasks to be accomplished (Bedone, 1993, p. 39).

Singled out for special attention has been the extent to which the task is structured or unstructured and the members' roles to accomplish the task are clear. This, in turn, is expected to moderate the leader's directive or participative style and its effects on outcomes. By 1986, at least 48 reasonably rigorous laboratory and survey efforts to verify this *path-goal theory* had been reported (Indvik, 1986b). However, before I conclude this chapter with a review of path-goal theory and its validity, I will first examine the more general issues of the extent to which various requirements of tasks and technologies have been linked with leadership and its effects. Ordinarily, technology facilitates improvements. The ability to make such improvements in products and services are important in determining whether firms remain competitive (Bedone, 1993) and government administrations and NGOs remain effective.

## Leadership in a Technology-enabled Working Environment

---

Life and work have been transformed in the postindustrial world by advances in technology. For instance, the telecommunications industry has swung full circle. Early in the twentieth century, AT&T's CEO Henry Vail set the company's major goal as a regulated monopoly to provide customer service. Cost was secondary. Profits were regulated. With its breakup in 1984 into Baby Bells and the advent of the Internet, the telecommunication business became driven by the competitive marketplace and technology. Now quality and convenient customer service are not only seen as a good in their own right but provide important, if not most important, competitive advantages as a shrunken AT&T now competes with its former subsidiaries.

The Associated Press reported in mid-April 2008 that AT&T, the nation's largest telecommunications provider, planned to cut about 4,600 jobs, or 1.5 percent of its work force. Most of the layoffs will be among managers, particularly in wire-line operations, including local service for large corporate customers. The company also reported its shares for the first quarter of 2008 had fallen.

### ***Optimum Reengineering***

*A Wake-up Call.* In 1956, Leavitt and Whisler predicted that by the 1980s technology would replace middle-management decision making. Middle management has indeed shrunk in numbers. In successfully

coping with the change in the past several decades, the telecom firms must have adaptable cultures. Firms that were slow to adapt in the 1980s were Texaco, Coors, and General Motors. Texaco was seduced by its dominant position in the market and its prior successful growth and profits. Coors did not place enough value on its customers, shareholders, and employees. General Motors did not promote managers who showed too much leadership. On the other hand, firms with adaptable cultures such as those of Wal-Mart, PepsiCo, and Hewlett-Packard more quickly made the transition into the competitive 1990s. They conceived of leadership as an engine of change. They stressed the value of addressing constituents' needs. They introduced adaptable new systems and favored adaptable managers.

*Optimal Use of Technology.* Simply regarding technology as a black box to replace personnel does not provide for optimization. Full automation is not usually the answer. What is to be sought is optimization of the human-technological interface. Sometimes there is too much human intervention with automated systems, as in the case of the automated thermostatic controls on the German cruiser *Prinz Eugen* being taken in 1945 to Kwajalein as an H-bomb target. Fearful of blowing up the boilers, one of two U.S. Navy cardinal sins, the American captain assigned one seaman to monitor the thermostat and a second seaman to monitor the first seaman. This resulted in continuing overcorrection.

Also suboptimal is the introduction of overengineered information systems without sufficient regard for the human user. For example, fully automated telemarketing and teleinterviewing may generate a lot of annoyed customers and poorer survey response rates than do human callers. Nonetheless, the efficiency of the human callers can be enhanced with automatic dialing, automatic recording, keyboard tallying, prompting, and so on. On occasion, Luddites may have had the right idea about technological advances for the wrong reasons. The costs of technological advancement may be greater than the anticipated gains. This is particularly so if we look for the hidden costs and unintended consequences of technological advances. Automation brings many other problems with it. For example, *automation complacency* may set in. A systems operator responsible for monitoring automated equipment as well as manual tracking will focus attention continuously on the tracking display and "look at but not see" the automated displays, like an inattentive listener at a dull lecture with blank stares on their faces.

*Intellectual Stimulation and Dealing with Resistance to Change Needed.* Some, but fewer, middle managers sufficiently educated in information technology (IT) are in place to implement systems of service that optimize the human and IT capabilities. The required mix of human and IT differs in each situation. Some, such as in the case of calling card dialing, may work best with full automation; others, such as handling an irate customer, may require a fully sympathetic human counselor. In two ways middle managers are challenged by the need for effective use of IT and human resources. First, they can solve the problems of optimization of IT and personnel by being intellectually stimulating as transformational leaders. Second, they can systematically review with their team and colleagues the obstacles and resistances to change and how to overcome them. They can prepare their colleagues to be ready for continuing new applications and improvements in IT.

To intellectually stimulate their direct reports, leaders and managers can reformulate the specific problem; turn to metaphors or analogies; imagine alternative states; widen, shrink, or split context; or uncover and challenge hidden, deeply rooted opinions and assumptions. They can work with direct reports to avoid premature conclusions, match competencies with subparts of the problem, and play devil's advocate. They can do much the same with colleagues and supervisors. To deal with resistance to change, they can answer such questions as: Is the need to change perceived, and by whom? Who is the sponsor? How ready is the person, unit, or organization for change? What motives underlie resistance? How will change be implemented, supported, and maintained? Are leaders and managers engaged in continuous learning to prepare to deal with the technological imperatives they face? What needs to be done to shape the vision of a business's future state? How much have middle managers and others bought into the new technology? How will career interests be

aligned with the organization's vision of its future state? (Bass, 1999).

## The Leader's Competence and the Requirements of Tasks

---

The requirements of tasks affect whether a leader is needed, who emerges as a leader, how the leader behaves, and what kinds of leadership behavior result in the better performance and greater satisfaction of the followers. Early on, the evidence was mixed about how requirements of the task situation determined the traits that distinguish those who are chosen to lead. Some of the earliest research on leadership in small groups was carried out in the Soviet Union by Chevaleva-Ianovskaia and Sylla (1929), who observed that no leadership arose in spontaneous preschool groups unless special problems occurred. Caldwell and Wellman (1926) showed that the basis of choice varied according to the activities for which leaders were picked by their junior high school classmates. For example, physical abilities determined the selection of athletic leaders. Nevertheless, among the students who were studied before 1950, scholarship was high among chosen leaders in all designated situations. Dunkerley (1940) found that college women who were selected as intellectual leaders were superior in judgment, initiative, and intellectual ability and those who were picked as social leaders were superior in dress and appearance. Those who were chosen as religious leaders were least neurotic, while those who were chosen as social leaders were most neurotic. Again, some consistency was found in a leader's performance in different situations, but there was also systematic change in what happens when a leader is transferred to new assignments and tasks.

### *Influence of Task Assignment on Leader*

Stogdill, Shartle, Scott, et al. (1956) studied 20 naval officers who were to be transferred to new positions and the 20 officers whom they were to replace. After several months in their new positions, the transferred officers were found to have shifted their patterns of work performance, but not their interpersonal behavior, to resemble the patterns of the officers they had replaced. In other words, the officers tended to transfer their patterns of interpersonal behavior from one assignment to another but changed their patterns of work performance in response to the task requirements of the new assignments. In a similar way, the individual who emerged as the leader in one group tended to become a leader when placed in other groups, particularly if the different groups were performing similar tasks. Boyatis (1982) conceived such individuals as having the *competencies* to lead others—the necessary abilities, motives, drives, and behaviors. A change in task may permit new leaders to emerge.

*Rotation Experiments.* Barnlund (1962) rotated group members through a set of different tasks and through groups with changing memberships. The highest degree of leadership transferability occurred between literary and construction tasks and the lowest degree between coordination and mathematical tasks. Barnlund attached too much importance to changes in both task and group membership as to who emerged as leader; as Kenny and Zaccaro (1983) reported when they reanalyzed Barnlund's data, 49% to 82% of the variance was attributable to individual consistencies and not as much to changes in tasks and group members. The correlation was .64 in the ranking in leadership across the different situations. Borg and Tupes (1958) and Blake, Mouton, and Fruchter (1954) also reported consistency of behavior in the same leader performing in different groups with varying tasks. Evidently, leaders tend to change certain aspects of their behavior in response to changes in the demands of the group's task.<sup>1</sup>

*Relevance of Ability to Task.* One can think of some competencies such as effective listening linked to leadership in decision making (Johnson & Bechler, 1998), which would correlate with leadership in many

different situations. And so, while we find the same individuals emerging as undergraduate leaders in different task situations, we also find that the emergence of leadership is correlated with how much the emergent leader's abilities are relevant to the tasks the group faces. Different tasks call for different abilities, and the leaders who emerge have different competencies that are relevant to the requirements of the different tasks. Thus, Carter and Nixon (1949a) performed a complicated experiment in which the leadership performance of 100 high school boys was measured by teachers' ratings, nominations by students, school activity records, and observers' ratings in three group tasks. A seven-hour battery of tests was also administered. It was found that the boys' scores on the mechanical ability test coincided with leadership in mechanical tasks on all criteria. Scores on the numerical test and for persuasiveness were correlated with leadership in intellectual tasks, while the scores on the work fluency and clerical tests predicted leadership in clerical tasks on all criteria. Scores on the reasoning test were positively related to leadership in all tasks on all criteria, while the scores on the musical interest test were negatively related.

Clifford and Cohn (1964) described how different attributes of group members, according to colleagues, correlated with nine different leadership positions. Nominations for the role of planner were significantly related to having ideas and being smart, friendly, liked, empathic, and a good influence. Nominations for swimming captain were significantly correlated with being good at swimming and being a good influence. A different pattern of characteristics was associated with each role, but none of the attributes was significantly related to being chosen for the role of banquet chairman.

*Effects of Different Tasks.* Different tasks had different effects. Hemphill, Pepinsky, Shevitz, et al. (1956) observed the effects of task ability on leadership processes by providing different amounts of advance information to different members of a group. Outcomes were different with different types of tasks. Individuals who were given task-relevant information before an experiment scored higher in attempted leadership in assembly and construction tasks but not in strategic and discussion tasks. Kellett, Humphrey, and Sleeth (2002) noted that some individuals are recognized as leaders because of their mental abilities and competence in dealing with complex tasks. Others are recognized as leaders because of their empathic ability, their emotional intelligence as observed in their socioemotional competence to deal successfully with problems of relationships among people. Still others are recognized as leaders for their competence in both tasks and relationships (see [Chapter 19](#)).

*Competence Relative to Subordinates' Abilities.* The competence of the leader for the task and how the leader behaves as a consequence are moderated by the subordinates' ability to handle the task. If supervisors believe their subordinates have the requisite skills, the supervisors are more likely to be consultative, *participative*,<sup>2</sup> or delegative (Heller, 1969a), and so they should be (Hersey & Blanchard, 1977). It seems equally true that if subordinates do have the skills and interest for the particular tasks of consequence, their productivity and satisfaction will be greater if supervisors permit them to participate partially or fully in the decision-making process. Full participation will be less than optimum when subordinates do not have the requisite skills and interest.

### ***The Leader's Personality and the Requirements of Tasks***

Not only do group tasks affect which abilities are important for leadership, they are also linked to personality factors that seem to promote the choice of leaders. Wardlow and Greene (1952) reported that adolescent girls with high scores on tests measuring their adjustment to school and home and health problems were preferred by peers who were working with them on an intellectual task. Megargee, Bogart, and Anderson (1966) asked pairs of participants, one with a high score and one with a low score on a dominance test, to perform two different tasks. When the instructions emphasized the task, the dominant participants did not emerge as leaders

significantly more often than did their partners. However, when leadership was emphasized in the instructions, the dominant members emerged as leaders in 90% of the pairs.

*Effects of Task Structure.* B. B. Roberts (1969) administered a battery of personality tests to leaders and followers who were studied under different conditions. Concrete and practical-thinking persons were chosen as leaders in structured tasks by all group members, but they were chosen only by the practical and concrete choosers for unstructured tasks. The theoretically oriented members were chosen as leaders in unstructured tasks by abstract, theoretical followers. Although more frequent leader initiation and direction may actually be seen in structured task situations (Stech, 1981; Wolcott, 1984), they also may be superfluous when task structure is already sufficient. More leader task orienting and objective setting may be necessary for effectiveness when tasks are ill defined (Taggar, 2001; Bain, Mann, & PirolaMerlo, 2001). But when innovation and creativity are sought and tasks are ill defined, overcontrolling leaders with too much initiation may stifle the autonomy conducive to creativity (Trevelyan, 2001). There is some optimum direction and participation for maximizing performance with ill-defined problems and problems calling for creative thinking (Mumford, Scott, Gaddis, et al. 2002).

*Effects of Different Task Requirements.* W. W. Burke (1965) found that followers who worked under a socially distant leader rated their groups as more satisfying and productive in a decision-making task than on a code-solving task. Dubno (1963) obtained results indicating that the effectiveness of groups was higher when quality rather than the speed of performing a task was emphasized by their leaders and when the leaders reached decisions more quickly than did the other members. But Hoyt and Stoner (1968) failed to confirm that the risky decisions made by groups were due to the leadership of risk-prone members. With leadership effects held constant, group discussions still produced group decisions that were riskier than the mean of the individual decisions of members. Nevertheless, as will be detailed later, the risk behavior of the leader is likely to depend on his or her speed in reaching decisions, on the organization's stage of development, and on whether the group is at an early or late phase in problem solving. The task requirements of newly formed groups and organizations are different from those of mature groups and organizations, and what is required of their leaders at different stages is also likely to be different. Furthermore, just as the patterns of interpersonal behavior do not change substantially but the patterns of work performance do change when leaders are transferred, the leader's initiation of structure and directive leadership are more likely to shift with the changing demands of tasks than are the leader's consideration and relations orientation (Ford, 1981).

### ***Effects of Followers' Personality and Task Preferences***

Indvik (1986b) surveyed 467 nonacademic staff at a university and found that followers' perceptions of their ability and preference for structure systematically affected what kinds of leadership behavior, under various task circumstances, generated elevated expectations, satisfaction, and meritorious performance. For followers who preferred structure, participative leadership messages were most effective when formalization of the organization was low and the importance of the work group was high. For followers who did not prefer structure, participative leadership messages enhanced their satisfaction when the task was highly structured, the importance of the work group was low, and the formalization of the organization was high. (More will be said later about leading creative followers.) Again, Keller (1992) found among 462 personnel in three R & D departments led by charismatic and intellectually stimulating project leaders that project quality was higher for research projects than for developmental projects.

*Cynicism.* Reichers, Wanous, and Austin (1997) conducted interviews, surveys, and follow-ups with approximately 2,000 unionized workers and their managers. Forty-three percent of the hourly workers and 23% of the managers were classified as cynical about change. (Many previous change efforts had been

unsuccessful.) The results pointed to the detrimental effects of followers' cynicism about leaders' efforts to make changes in the organization. The cynics were likely to be pessimistic about the success of changes and accused those responsible for the change efforts to be lazy and incompetent. The cynics felt that they lacked information about the changes, respect from supervisors and union representatives, and opportunities to participate in decisions making. They had experienced failures in previous change efforts and were personally disposed to be cynical. They lacked commitment, satisfaction, and motivation to make the changes.

*Followers' Competence.* There is an obvious correlation between followers' competence and their effectiveness unless they are in conflict with one another about objectives, have contrasting values, and are poorly led and poorly motivated. However, an extremely competent follower may usurp the leadership, "take control and then begin to undermine the influence of others. The work climate is poisoned, and morale declines. Cooperation turns to competition, then ill-will, and then into subtle forms of sabotage" (Quinn, 1996, p. 116).

## Important Dimensions of Tasks

---

Task interdependence has been found to be an important determinant of whether leaders should be appointed or elected. Basik, Gershenoff, and Foti (1999) reported that when members' tasks were highly interdependent, team performance was high if team leaders were elected, but when members' tasks were low in interdependence, the teams did better with assigned leaders. Valenzi, Miller, Eldridge, et al. (1972) reviewed previous research on the impact of leaders' behavior on task requirements. They concluded that task interdependence, structure, routineness, complexity, and intellectual (but not manipulative) requirements systematically alter the amount and kind of leadership that is most effective. On the basis of this review, a survey was conducted. Using stepwise regression analyses, Bass, Valenzi, Farrow, and Solomon (1975) found, for 78 managers described by their 407 subordinates, that tasks with clear objectives were seen to result in more *direction* and consultation by the managers. Routine tasks were associated with less *participative* leadership. More complex tasks correlated with negotiative leadership and more frequent delegation. Delegation was also reported to be more frequent among executives if their subordinate managers had to engage in planning, coordination, and other managerial activities. I confirmed more frequent leader *direction* in an unpublished follow-up of the effect of structure on 340 managers and 1,300 subordinates. As noted just below, more frequent direction may occur with strong structure, when actually direction is less needed.

### **Structure**

Leaders of groups and individuals with structured, as opposed to unstructured, tasks have been considered in a great many studies.<sup>3</sup> For instance, Hill and Hughes (1974) reported that leaders displayed more socioemotional behaviors, both positive and negative, when subordinates performed unstructured as opposed to structured tasks. Widely used to examine the effects of structure is House and Dessler's (1974) measure of task structure, a ten-item questionnaire on which respondents describe the extent to which their tasks are simple, repetitive, and unambiguous.

*Task structure* varies in how much is specified, is certain, and has to be done. For example, Lawrence and Lorsch (1967b) assumed that task structure went from the lowest to the highest as one moved from fundamental research to applied research, to sales, and finally to production. In six organizations, they found that production personnel (whose work was most specified and certain) and fundamental research personnel (whose tasks were least specified and certain) both preferred task-oriented leaders. Members in the sales

subsystem (which had moderately specified and certain work) preferred more interpersonal, socially oriented leaders. Structure may be strong or weak, tightly or loosely arranged, clear or ambiguous (Mischel, 1977). When it is strong, tight, and clear, everyone sees the situation in the same way. It induces uniform expectations and provides clear incentives for appropriate responses. Less guidance and directive leadership are needed. When structure is weak, loose, and ambiguous, there is more acceptance of guidance, direction, and charismatic leadership (Shamir & Howell, 1999).

*Fiedler's Task Structure.* A tenet of Fiedler's (1967a) contingency model was based on the effect of task structure. For Fiedler, task structure creates a more favorable situation for the leader. A task-oriented leader will be more effective when there is either a great deal of task structure or very little task structure. A relations-oriented leader will be more effective if task structure is moderate. Although the conclusions remain controversial (see, e.g., Graen, Alvares, Orris, & Martella, 1970; Graen, Orris, & Alvares, 1971), considerable empirical support for this proposition was presented in [Chapter 19](#). However, the effects of task structure may be much weaker than other contingent situational elements that favor the leader (W. Hill, 1969a).

*Some Effects on Leadership Behavior and Outcomes.* Wofford (1971) observed that unstructured tasks elicited more achievement-oriented and organizing managerial behavior than did structured tasks. Lord (1975) found that the degree of task structure in a situation was negatively related to the occurrence of facilitative leadership behavior. An unexpected curvilinear effect emerged. Instrumental (task-directed) leadership was most effective with tasks that were moderate in structure. Shaw and Blum (1966) found that structured problems were better served by directive supervision. Thus, when the problem on which five-person groups were working was highly structured so that clear procedures could be followed, directive supervision led to quick results. Yet when leaders initiated structure a great deal, as was seen in a study by Badin (1974) of 42 work groups in a manufacturing firm, their effectiveness was reduced if the groups were already highly structured. The correlation of effectiveness and Initiating Structure was  $-.56$ . But in the less structured of the 42 groups, the effectiveness of the groups correlated  $.20$  with the extent to which the first-line supervisors initiated structure.

Filley, House, and Kerr (1979) found that task structure moderated the relationship between participation and performance and between participation and the attitudes of subordinates. Participative leadership had no effect or was contraindicated when tasks were machine-paced, mechanized, and highly structured in other ways. But when tasks were unstructured, the effects of participative leadership on both the attitudes and productivity of subordinates were consistently positive. Hanaway (1985) examined the effects of the uncertainty of tasks on the initiating and search behavior of 18 upper-level and 32 lower-level administrators of school districts. The lower-level administrators were observed to be more reticent to take actions when conditions were uncertain, but the results for the upper-level administrators were less clear.

*Role Clarity.* Generally, people, particularly those with a great need for structure, prefer to work in clear task settings. Valenzi and Dessler (1978) showed that among 284 employees in two electronics firms, satisfaction was uniformly high when role clarity was high. The leaders' consideration promoted even more satisfaction. In addition, Benson, Kemery, Sauser, and Tankesley (1985) found that a high need for clarity was related to low job satisfaction among 370 university employees above and beyond the effects of their role ambiguity on the employees' dissatisfaction.

The determination of perceived role ambiguity or perceived role clarity is a way to discern how much structure exists in a group. Kinicki and Schriesheim (1978) studied the role clarity of 173 freshmen in 16 classes. Role clarity was measured by Rizzo, House, and Lirtzman's (1970) scale dealing with clear objectives, responsibilities, expectations, and explanations about what has to be done. They found that students were more satisfied with relations-oriented teachers, particularly when role clarity in the situation was low. But the students were more productive with directive teachers when role clarity was low, not when it was high. As Siegall and Cummings (1986) demonstrated, satisfaction with supervision is enhanced if a subordinate's role is

initially ambiguous and if the supervisor contributes to clarifying the role by issuing instructions and directions. Fulk and Wendler (1982) found, among 308 clerical and managerial employees, that role clarity was associated with nonpunitive, task-oriented leadership and contingent reward. Such leadership was satisfying. But role clarity could also emerge as a consequence of arbitrary and punitive leadership behavior that was dissatisfying. However, Schriesheim and Murphy (1976) failed to find that role clarity moderated the relationship between any kind of leadership behavior and the satisfaction and performance of subordinates. To help further in the understanding of the above evidence, later in this chapter, when the path-goal theory and the specific tests to validate it are reviewed, more will be said about the extent to which structure and role clarity affect the impact of leadership on performance and satisfaction.

*Clarity of Objectives.* Nagata (1965) observed that groups with goal-relevant tasks enabled leaders to exercise more influence on the members than on members in groups in which the tasks were not relevant to the goal. To some extent, clear objectives may substitute for structured relationships or clear role relationships in getting a job done, particularly if little coordination is required. Multiple regression analyses by Bass, Farrow, and Valenzi (1977) for 250 managers and their 924 subordinates suggested that the effectiveness of work groups was significantly greater if the managers had clear objectives. Furthermore, when these organizational members were competent and motivated to attain their objectives and could operate independently or in cooperation with one another, the effectiveness of their performance was strongly associated with the clarity of their objectives and the adequacy of their resources.

*Error criticality* is the extent to which mistakes at work produce negative outcomes. In health care, error criticality is high for those in nursing and pharmacy departments, for their mistakes can lead to patient injury or death. Their motivation to perform well is not increased or decreased by the quality of their supervision or by job design (autonomy and variety). On the other hand, error criticality is generally low for those in hospital administrative units. Compared to nursing or the pharmacy, mistakes in administrative work ordinarily are not life-threatening. Administrative employees' motivation to work is more strongly affected by the quality of their supervision, by their morale, by their job autonomy, and the job variety in their jobs, according to a study by Morgeson (2005) of 189 hospital employees.

### ***Autonomy and Discretionary Opportunities***

One's felt autonomy and discretion to do one's job appear to be complex perceptions that are affected by various factors, such as the organization's technology and the frames of reference shared with coworkers, as well as the style of leadership employed. Presumably, leaders who initiate a great deal of structure by definition, reduce their subordinates' autonomy. But leaders' consideration should enhance subordinates' feelings of autonomy. Ferris and Rowland (1981) suggested that the leaders' initiating structure and consideration systematically affect the subordinates' perceptions of autonomy in this way, which, in turn, may or may not contribute to the subordinates' performance.

The same leadership will have different effects depending on whether subordinates' autonomy is high or low. Johns (1978) found a correlation of .29 between leaders' initiation of structure and subordinates' job satisfaction when 232 union employees reported that their autonomy was high, and a correlation of .01 when they indicated that their autonomy was low. The leaders' consideration and the subordinates' job satisfaction correlated only .20 when the subordinates' autonomy was high but .52 when it was low. More than 1,300 subordinates' descriptions of 340 managers indicated that if managers were viewed as delegative and negotiative, their subordinates felt in possession of more discretionary opportunities (Bass & Valenzi, 1974). Managers were also less likely to be seen as directive under such conditions (Bass, Valenzi, Farrow, & Solomon, 1975).

*Innovation and Creativity.* Discretionary opportunities enhance innovation and creativity. Such opportunities are likely when leaders and subordinates have good relations with each other. Scott and Bruce (1994), Scott and Bruce (1998), and Tierney, Farmer, and Graen (1999) reported positive correlations between the quality of leader-member exchange (LMX), task innovation, and creativity of managers, scientists, and engineers. Amabile and Grysiewicz (1987) interviewed 120 R & D scientists to elicit two critical incidents from each of them, one to illustrate the occurrence of high creativity, the other to provide an instance of low creativity. Consistent with what has been said about participative leadership and creativity, in describing the incidents of high creativity, more than 74% of the interviewees mentioned freedom to decide what to do and how to do one's work, a sense of control over one's work and ideas, freedom from constraints, and an open atmosphere. This finding agrees with conclusions reached by Andrews and Farris (1967) and others, although Amabile and Grysiewicz hastened to add that there is a limit to the amount of such freedom, for it must be bounded by the team supervisor's coordination of the team's overall efforts (Pelz & Andrews, 1966b). In presenting these incidents of high creativity, one-third to one-half the 120 scientists revealed that their leaders' enthusiasm, interest, and commitment to new ideas and challenges encouraged their creativity.<sup>4</sup> Supportive leadership was seen in the willingness to take risks, provide recognition for success, and clarify what was needed. The leaders accepted failure without destructive criticism and avoided excessive evaluations. Such leaders did not dwell on the status quo. Keller (1989) reported that the productivity of 30 project *research* teams correlated .57 with the intellectual stimulation of their leaders but close to zero with the same leadership in 36 project *development* teams. According to Allen, Katz, Grady, et al. (1988), the performance of 181 project teams was greater when their leaders kept them current in the science and knowledge they needed to know. Frischer (1993) found that when 38 managers of new product development empowered and gave a sense of responsibility to their subordinates, the subordinates perceived a greater innovative climate. In agreement, Judge, Grysell, and Dooley (1997) noted that R & D managers enhanced innovation by giving their subordinates operational autonomy, personal recognition, cohesiveness, and a continuity of slack resources.

### ***Routineness versus Variations in Tasks***

Jobs can require that employees carry out the same few tasks in a repetitive cycle or may involve a greater variety of tasks that are more variable in sequence. Optimal performance by leaders depends on whether the work involves uniform, recurring, repetitive tasks or considerable variability (Valenzi, Miller, Eldridge, et al., 1972). In their classic study of workers on the assembly line, Walker and Guest (1952) emphasized the extent to which supervision was likely to be more directive when the tasks to be performed were extremely routine. Likewise, Bass, Valenzi, Farrow, and Solomon (1975) reported more directive leadership as well as less supervisory delegation in work groups that were carrying out routine tasks. Similarly, Ford (1981) showed that in 35 departments in a book-publishing firm, a bank, and a university, the routineness of work uniquely correlated .36 with the extent to which the departmental manager initiated structure but only .05 with his or her consideration as a leader.

In a study involving 16 departments in 10 organizations, R. H. Hall (1962) distinguished between uniform, easily routinized, standardized activities and nonuniform, difficult-to-routinize, creative activities. He found that departments and hierarchical levels whose activities were more nonroutine were also less bureaucratic than were those departments and levels that were oriented toward routine activities. In nonroutine situations, the atmosphere was more personal, had less hierarchical emphasis, and required fewer procedures and regulations. Consistent with all these findings, Heller and Yukl (1969) found that production and finance managers (who supervised more routinized work) tended to use centralized decision making, while general and personnel

managers (who supervised less routinized work) were more participative.

The linkage of routineness to the greater initiation of structure by leaders is consistent with the hypothesis, verified by Kipnis (1984) for several levels of managers in Australia and the United States, that employees who work on routine tasks are likely to be undervalued by their supervisors. Despite this finding, Jiambalvo and Pratt (1982) reported that in four large accounting firms, considerate leadership behavior by senior accountants increased the involvement in tasks among staff assistants who performed relatively simple tasks more than it did among those who performed relatively complex tasks.

*Variety.* Hackman and Oldham's (1975) Job Diagnostic Survey included job variety as an important variable that was likely to relate to the motivation to work. Using ratings based on the survey, Johns (1978) showed that with job variety, the leaders' initiating structure generated greater job satisfaction and fewer intentions to quit among subordinates. Without such variety, the leaders' initiation was unrelated to the subordinates' satisfaction and increased their intentions to quit. However, the leaders' consideration was strongly associated with satisfaction, regardless of whether the job was varied or routine. Yet only when variety was absent was the leaders' lack of consideration associated with the subordinates' intentions to quit. In contrast, Brief, Aldag, Russell, and Rude (1981) found, in an investigation of police officers, relatively little of the expected effects of the variety of job skills on the favorability of police officers' attitudes toward the citizenry.

In a study that distinguished working on uniform and nonuniform tasks, Pelz (cited in Litwak, 1961) found a higher correlation between the motivation to work and productivity when those engaged in nonuniform tasks were permitted by their supervisors to make their own job decisions. But for those involved with uniform tasks, there was a higher correlation between motivation and productivity when freedom to make decisions was restricted. Nonetheless, Katz, Maccoby, and Morse (1950) found that supervisors of high-producing sections were significantly more likely to provide general rather than close supervision, even though they were supervising routine clerical work in a life insurance company. However, in a subsequent study of less routine railroad work (Katz, Maccoby, Gurin, & Floor, 1951), little difference was found between the closeness of supervision by supervisors of high-and low-producing sections. In these and the many other related studies that followed,<sup>5</sup> R. Likert could find no diminution in the utility of participative (System 4) leadership in routine jobs as compared to those with more variety. But Griffin (1980) suggested otherwise. He contrasted the leadership-outcome relations among employees who had "high-scope" tasks (varied, involving, and autonomous) and those who had "low-scope" tasks (simple, routine). In his first survey of 129 employees, the scope of the employees' tasks did not correlate with the leadership style of their supervisors. However, for a subset of employees with high-scope jobs *but a low need for personal growth*, directive supervision subsequently resulted in greater satisfaction. On the other hand, employees with low-scope jobs were more satisfied with their subsequent supervision if their supervisors were more supportive and practiced more management by exception. Such supervisors were described by such statements as "My supervisor doesn't bother me as long as I do a good job" and "My supervisor leaves me alone and lets me work."

*Low-Scope Tasks and Passive Leadership.* Although passive management by exception has generally been downgraded by subordinates as a satisfying style of supervision,<sup>6</sup> the results suggest that employees in low-scope jobs prefer and feel better when their supervisors practice management by exception. This suggestion was confirmed in a survey of 195 full-time employees by Algattan (1985). When the scope of the tasks that subordinates performed was low and the subordinates had little need for growth, leaders' maintenance of the status quo was more positively related to outcomes than was more active directive, participative, or task-oriented leadership.

### ***Complexity of Tasks and Technologies***

Technologies are simple if they can readily be understood and communicated between experts. Complex technologies cannot. As they move from simple to complex technologies, leaders need to shift from gatekeepers of information to facilitating and insulating information networks. These networks have to create knowledge, not just transfer information and knowledge (Kash & Ry-croft, 1996, 1997). Bell (1967) viewed the complexity of tasks in terms of the degree of predictability of the demands of the work, the amount of discretion exercised, the extent of responsibility, and the number of different tasks performed. When informal groups face complex tasks, leaders emerge who have the cognitive abilities to handle the tasks and to help others to do so. They may also have the socioemotional skills to deal with the others facing the complex tasks (Kellet, Humphey & Sleeth, 2002). Among supervisors in a hospital, Bell (1967) found that the more complex the subordinates' tasks or the supervisor's job, the narrower the supervisor's span of control. But the complexity of tasks did not influence how closely the subordinates were supervised. Barrow's (1976) study indicated that leaders exhibited more task orientation when faced with more complex tasks, but the complexity of the tasks did not affect their tendency to be punitive. However, Cuthbertson (1982), in a survey of 175 subordinates and their 25 supervisors in a central office of a school district, found more directive leadership than she expected in relation to the complexity of the tasks involved. Among 61 to 68 telecommunications units, Osborn and Hunt (1979) obtained contrasting patterns of correlations with leadership, the structural complexity of the units led, and the difficulty of the units' tasks. They found that the leadership that was required was unrelated to the complexity of the units led or the difficulty of the tasks. However, the actual amount of support and role clarification by the leaders, as expected, correlated between .24 and .31 with structural complexity of the units but unexpectedly between  $-.30$  and  $-.42$  with the difficulty of the task.

Barrow (1976) observed, in a simulation using 120 male college students as leaders, that more initiation of structure was caused by increasing the complexity of the task but autocratic behavior was generated more by workers; poor performance than by increasing the complexity of the task. Considerate leadership was evoked by improvements in the workers' performance. Relevant to these results, Wofford (1971) found that a personal interaction (relations-oriented) manager was more effective for complex operations. A self-oriented, autocratic manager was more suited to situations with simple work schedules. Hammer and Turk (1985) showed that supervisors were less likely to perform group maintenance activities if they supervised employees who worked with *intensive technology*, as in a repair shop or an R & D laboratory where tasks were complex and nonroutinized. On the other hand, supervisors of workers who were engaged in *long-linked technologies*, such as mass production assembly lines, and whose tasks were interdependent were more likely to engage in network activities. In addition, supervisors in the intensive-technology situation felt, to a greater extent, that they had the authority to reward subordinates, whereas supervisors in the long-linked technology settings felt they had more authority to discharge employees and, in turn, were less likely to be seen as experts.

The effects of the increasing complexity of tasks on requirements for leadership are illustrated by the changing military scene. Those who are now being selected to serve as military leaders in the next several decades will have to operate under conditions for which there is less public consensus than existed during World War II. They will be expected to know how to use minimal force in unconventional conflicts in which they will be trying to keep the peace. Fighting, as it continues in Iraq, is intense, lethal, and destructive. For this type of fighting, an understanding of the local values of what is right, good, and important, along with intellectual sensitivity, is particularly important. Officers are required to respond thoughtfully to increasingly ambiguous circumstances. They need to inspire subordinates with a vision of the future that strengthens the subordinates' loyalty and commitment rather than merely fosters the subordinates' grudging obedience. Gal's (1986) forecasts fairly accurately described the task and technology requirements for coalition forces in the Persian Gulf War in 1991 and the wars in Afghanistan and Iraq and their continuing insurgent aftermaths.

*Difficulty of Tasks.* A factor analysis of 104 different experimental tasks by M. E. Shaw (1963b) disclosed three factors that contribute to the effects of the complexity of tasks: (1) the difficulty of a task (the number of operations, skills, and knowledge required to complete the task); (2) the multiplicity of correct solutions; and (3) the requirements for cooperation (integrated efforts). C. G. Morris (1966a, 1966b) found that as the difficulty of the tasks increased for groups, there was a concomitant increase in leaders' and members' attempts to structure answers, propose solutions, and seek evaluations. However, tasks of intermediate difficulty generated the highest frequency of attempts to structure the problem, followed by tasks that were the most difficult. Easy tasks produced the most irrelevant interactions. At the same time, Nagata (1966) found that groups with easy tasks exhibited more role differentiation and permitted leaders to exercise more influence than did groups with difficult tasks. Nevertheless, Bass, Pryor, Gaier, and Flint (1958) observed fewer attempts to lead in groups with easy problems. But it is important to recognize that the difficulty of a task is in the eye of the beholder. Manz, Adsit, Campbell, and Mathison-Hance (1988) surveyed 3,580 managers in a large firm about the hindrances to their performance. Better-performing managers paid more attention to external hindrances, such as inadequate appraisal systems and the absence of opportunities for promotion. Poorer performers focused more on deficiencies in skills, such as the lack of interpersonal or technical abilities.

When it was arranged for students to instruct others on easy and hard tasks in a laboratory setting, the "instructors" used less punishment when trainees performed difficult tasks than when they performed easy ones. A meta-analysis by Tubbs (1986) of 87 studies tested Locke's (1968) hypotheses on how the difficulty and specificity of goals enhance the speed and quantity of work that subordinates perform. Motivating leaders (in this case the experimenters) were more structuring with specific, difficult goals than were leaders who told subordinates just to do their best or did not tell them anything about the goals. Difficult goals resulted in higher motivation and performance of participants in short-term laboratory studies, but according to the meta-analysis, such results were somewhat less likely to materialize in survey studies of workers in longer-term assignments, perhaps because sometimes assignments might be too difficult, as noted next.

Fast pace, time pressure, and the need to meet deadlines contribute to the difficulty of tasks. For research scientists and engineers, Hall and Lawler (1971) found that the pressure to do high-quality work and to help their company attain its financial goals contributed to the successful performance of their research laboratories. Andrews and Farris (1972) also reported that time pressures experienced by scientists and engineers correlated positively with their subsequent performance. However, pressure that was perceived as unreasonable or excessive resulted in poor or decreased performance. Such excessive pressure could result in the setting of unrealistically high goals (Forward & Zander, 1971). Excessive pressure by a supervisor is likely to be contraindicated when tasks become more difficult with multitasking by operators who are novices and when the pace is conducive to errors because of its speed. Nonetheless, Shamir and Howell (1999) argued that a charismatic leader could emerge and be effective if the followers faced challenging and complex tasks, required intense efforts, and if performance goals were ambiguous and extrinsic rewards could not be linked to performance.

*Temporal Complexity.* Halbesleben, Novicevic, Harvey, et al. (2003) called attention to the importance of time and timing to giving organizations competitive advantage. Awareness of the dimensions of temporal complexity is an important competency for leading in creativity and innovation. Leaders need to be aware of the *time frame* of a task, such as the deadline for completing it. They need to pay attention to the timing of required activities. They need to be aware of the limited time spans of processes and events within the *time scope* of the task. They need to be aware of individual differences in pauses and gaps in the work and to support the simultaneity, sequence, and synchronization of operators, events, and processes. Leaders need to appreciate *timelessness*, losing one's sense of time while engaged in creative thinking, which contributes to optimal *flow* (Csikszentmihalyi, 1997) for creativity and innovation (Sosik, Kahai, & Avolio, 1999).

*Uncertainty of Tasks.* Wilson and Rhodes (1997) found in a set of experiments that coordination among followers facing uncertainty depended on particular kinds of leadership. According to De Mayer, Loch, and Pich (2002), there are four kinds of uncertainty and the leadership required as a consequence: (1) *Variation*. A task may vary, causing uncertainty, for example, about the time needed for completion. Here the leader needs to monitor deviations, set limits, or take corrective action, and arrange for buffers at critical points. (2) *Foreseen uncertainty*. A few known factors may influence carrying out the task in unpredictable ways. The leadership needs to plan for contingencies and alternate ways of completing the task. (3) *Unforeseen uncertainty*. Some factors influencing the task cannot be predicted. The leadership needs to plan for foreseen uncertainty but also scan for and recognize unexpected influences and arrange new contingent actions accordingly. (4) *Chaos*. Unforeseen events completely invalidate previous plans and efforts. The leadership needs to reexamine its assumptions, redefine the task, and do contingent planning based on incremental learning, constant feedback, and continual iterations, to gradually select the final approach.

*Multiplicity of Solutions.* Shaw and Blum (1966) noted that directive supervision was more effective if the problem called for agreement on a single solution, whereas participative leadership paid off when multiple, divergent solutions were needed. Experimental groups of five members each performed three tasks that required different types of solutions. Directive supervision was more effective when the problem called for a single final decision or involved the convergence of judgments into some final product. On the other hand, when the problem required multiple, divergent final solutions, participative approaches were more effective.

Participative leadership is suggested by the *assembly bonus effect*—groups achieve better solutions to problems with multiple alternative possibilities than does their average member working alone (Bass, 1960; Steiner, 1972). (The group decision may, however, not be as good as the decision achieved by the best member working alone.) This assembly bonus effect occurs unless individual members already have the requisite information to solve the problem alone, for instance, when every member is a professional expert who is highly trained to deal with the same standard types of problems in the same way. There will be less of an assembly bonus if the addition of members produces interference rather than nonredundant information. According to Heller (1969a), the primary reason managers in 15 firms reported using participative leadership was to improve the technical quality of complex decisions. In fact, some form of consultation is mandatory in highly technically oriented organizations, for the available technical expertise does not fully reside with supervisors but is distributed, to some degree, among subordinates.

*Required Cooperation and Interdependence of Tasks.* Adam Smith, in *The Theory of Moral Sentiments*, called attention to the paradox he had noted in *The Wealth of Nations* that the economy was driven by self-interest, yet people also recognized that the pursuit of self-interest required cooperation from others. Conflicting evidence has emerged here. To emerge as a leader in an initially leaderless group, one needs to both compete with and cooperate with the other members of the group (Bass, 1954). Cooperation and the interdependence of task performance among subordinates have been found to be promoted by participative leadership in some research studies. Other investigations have failed to find any effects, and evidence from still other laboratory and survey studies suggests that when subordinates engage in interdependent tasks, directive leadership and initiation of structure by the leader are more efficacious.

O'Brien (1969b) theorized that the equalization of power and participative leadership would be appropriate for tasks that require a great deal of cooperation. A power differential between the superior and the subordinates would be more effective in situations in which subordinates carry out tasks independently of one another. Vroom and Mann's (1960) results were illustrative. Vroom and Mann studied drivers and positioners in a package delivery company. The positioner's job required a high degree of interdependence and considerable interaction with coworkers and with the supervisor. The driver's job involved little interpersonal interaction and considerable independence in work activity. In line with expectations, the positioners favored democratic leaders and the drivers preferred authoritarian leaders.

Bass, Valenzi, Farrow, and Solomon (1975) failed to find statistically significant correlations between leadership styles and the interdependence of tasks of work group members. But larger-scale follow-up analysis by Bass and Valenzi (1974) indicated that more *directive* leadership and consultative leadership were associated with the interdependence of tasks. Nevertheless, negotiative leadership was greater when members worked independently of one another.

In a survey of 25 departmental managers and their 445 departmental associates, Ford (1981) did not find that the amount of interdependence in the workflow within the departments did not account for initiation of structure or consideration by the managers beyond that already explained by the routineness or uncertainty of departmental tasks. On the other hand, Lord and Rowzee's (1979) laboratory experiment with four-person teams showed that when tasks required a high degree of interdependence among the subjects, more frequent directive leadership behaviors emerged to develop orientation, plans, and coordination. Consistent with these results, Fry, Kerr, and Lee (1986) found that among 22 high school and college teams in eight sports, winning coaches of highly interdependent sports teams (like basketball) were described by their players as displaying more initiation of structure and less consideration than were winning coaches of sports teams, such as golf, that required little or no interdependence. Coaches of winning teams that were highly interdependent also displayed more initiation and less consideration than did coaches of losing teams that were highly interdependent.

To adequately explain these results requires attention to another variable: the competence of the team members. Directive leadership to clarify roles may be needed more when team members must work in collaboration but the team members are novices. Participative leadership that is focused on commitment becomes more important for high-quality collaborative efforts when the members are already trained and experienced.

*Required Interdependencies among Members.* Thompson (1967) distinguished among three kinds of interdependencies: pooled, sequential, and reciprocal. In the *pooled* circumstance, each individual, such as a baseball player at bat, performs alone, but the results have collective effects. In the *sequential* effect, one person, such as a running quarterback in a football play for whom others will block the opposition, depends on others earlier in a sequence. *Reciprocal* interdependence occurs when each person must interact with others, such as in basketball. Leadership and management in conditions of pooled interdependence require continuing attention to tactical judgments and the development of individual performers, but cohesiveness may not be as important. In sequential performance, leadership and management must attend more to planning and the preparation of the team. The requirements for performance are tighter and more highly specified and scheduled. Cohesiveness is more important. In reciprocal interdependence, satisfactory mutual adjustments are of the greatest importance and necessitate that the most attention be paid to relationships and continuing cooperation (Keidel, 1984).

Kabanoff and O'Brien (1979) studied leadership when members of a team either had to *coordinate* their efforts (work on subtasks arranged in an order of precedence) or *collaborate* (work simultaneously with one another on every subtask). Teams that had to coordinate their efforts were more productive, especially when the leaders were more task-competent. But the leaders' task competence was irrelevant to productivity in the collaborative task situation. This finding may be explained by a suggestion by Hill and Hughes (1974) that there is a greater emphasis on the leaders' socioemotional function than on their task function in the collaborative situation. As a consequence, their task competence is relatively less important when collaboration is required.

### ***Socioemotional versus Task Requirements***

As was just observed, a distinction that is important for understanding what type of competence will be

demanding of a leader is whether socioemotional or task requirements will be emphasized for leadership. This is the most frequent role differentiation that occurs in discussion groups. In groups, when the demands of the task are high, being liked does not contribute much to leadership and socioemotional skills are not highly valued (Slater, 1955). On the other hand, in social and personal development groups, such as therapy groups, sensitivity training groups, social clubs, and gangs, the socioemotional function is emphasized. As was concluded in [Chapter 19](#), in most kinds of groups, both types of leadership usually need to be present. A. S. Miles (1970) reported that student leaders who rated high on both task ability and socioemotional ability were considered most influential. Empirically, the differentiation between the two types of abilities often is not found. For instance, Gustafson and Harrell (1970) observed relatively little differentiation between task and socioemotional roles in experimental groups. Similarly, V. Williams (1965) noted that some types of group structures were able to operate effectively without differentiating task specialists from socioemotional specialists. Kellet, Humphrey, and Sleeth (2002) noted that either or both could be identified as a leader.

To sort out the effects, Olmsted (1954) gave one set of groups instructions that were designed to induce socio-emotional concerns for group processes and the satisfaction of members. The directions given to the second set of groups emphasized the accomplishment of tasks and maintenance of impersonal relationships among members. The most talkative members in the task-directed groups talked longer than did their counterparts in the socioemotional groups, perhaps as the result of a group norm related to the intensity of participation. Task-directed groups tended to develop stable leadership status structures. Members of socioemotional groups continued to jockey for position for a longer time. Olmsted (1955) later found that the amount of agreement among members in discussion groups moderated the effects. In groups that achieved a high degree of consensus on solutions to problems. The highest participator (who was more likely to be a leader than a follower) usually received the highest rating for helping the group meet the requirements of its task. In low-consensus groups, the highest participator was not rated high.

## Sociotechnical Systems

---

Adam Smith (1775) noted that civilization arose with the division of labor. Instead of the same primitive humans both farming and fishing, one farmed and another fished. Such specialization of energies made for more efficiency. A merchant trader specialty emerged when the farmer bartered or sold his corn to the fisherman through the merchant trader. With the advent of the Industrial Revolution, instead of one craftsman making an entire pin, efficiency was increased by dividing the work in the pin factory into various simpler subtasks, each carried out by a different worker (Herman, 2001). Unfortunately, *job simplification*, as opposed to crafting a whole product, also brought with it boredom and dissatisfaction, which leaders had to deal with until it was widely recognized in the mid-twentieth century that making the same worker responsible for a whole, more meaningful task, product or process, a sociotechnical design of work, was likely to be more satisfying and efficient. There was less need for coordinating leadership among subtasks carried out by different workers. There has been an increasing interest in designing tasks and work to take account of both the task and the socioemotional requirements.

### ***Sociotechnical Designs***

When technical and social systems are integrated, joint optimization is needed. Bamforth observed that long-wall coal miners became much more productive and satisfied when they were able to return to the earlier, traditional premechanization methods of working as a team instead of on individual assignments as directed by a supervisor (Trist & Bamforth, 1951). Along with Fred Emery (1959, 1967), Trist (1971, 1981) set out the

principles of socio-technical systems design. They were consistent with Lewin's (1939) theories and experiments in group dynamics (Fox, 1995).

The critical dimensions, methods, and principles of socioeconomic systems concern control and coordination and who was mainly responsible for them—managers or workers. The principle was that decisions should be made at the lowest organizational level possible. Instead of specialists, engineers, or supervisors making the decisions for corrections and changes in the production process or production line, the operators themselves, suitably trained, make the corrections and recalibrations and perform preventive maintenance. Operators are empowered to load, unload, and monitor machinery as well as to program them. In Britain, this change from specialist to operator control in an electronics company resulted in reducing downtime in computerized equipment that saved 10 hours of production time. In time, it became a 70% reduction as workers became more skilled and increased their intrinsic job satisfaction. Machine reliability was increased (Wall, Corbett, & Clegg, 1990; Jackson & Wall, 1991). In Japan, this was seen as “giving wisdom to the machine” (Ralls, 1994, p. 36). In 1987, a survey of 584 machine-manufacturing plants found that plants where machine operators routinely programmed the machines were 30% more efficient than plants where they did not. Such worker control in the more efficient plants depended on providing workers with technical training (Kelly, 1995).

According to Salzman (1992), the introduction of operator control met with a lot of resistance. Of 200 engineering design and engineering textbooks published between 1938 and 1989, only 42 mentioned worker roles in production and technology. The roles were mainly subservient to the machinery. Illustrative of the prevailing orientation in engineering design was the admonition that “the operator should not read an (*ohm*) meter. She should not be told what an *ohm* is. She should not be asked to make borderline judgments—Any adjusting may upset (her) ... any slight gain in efficiency will be lost in retraining time” (Gibson, 1968). Nevertheless, as computers and technology have become more user-friendly, operators have become able to maintain, modify, and program their own equipment and machinery. This allows computer specialists and engineers to serve as coaches and to do more specialized work (Ralls, 1994).

Considerable consultation with the workers is seen as fundamental to establishing the bases for meeting both the requirements of the task and the workers' socioemotional needs. Participative leadership becomes mandatory in the actual operations and is built into the design. For instance, *minimal critical specification* is a principle of sociotechnical design. According to this principle, the design process should identify what is essential to be accomplished in a task, and no more should be specified than what is essential. For example, although the design process may be precise about what needs to be done, it should leave maximum latitude about the method the employee may use to accomplish the task. Again, the *multifunctional* principle of sociotechnical design proposes that for an organization to be sufficiently adaptive to meet environmental demands, it is necessary for its members to be willing and able to perform more than one function or to perform the same function in a variety of ways to meet changing circumstances. Clearly, both task-oriented and relations-oriented leadership are needed to obtain the requisite employee performance and the commitment of employees to such fluid arrangements (Bass & Barrett, 1981).

Sociotechnical principles are consistent with E. E. Lawler's (1986) high-involvement management practices that promote more effective uses of technology and the introduction of new technologies. With suitable training, operators are enabled to make relevant decisions about maintaining and improving their technology-assisted work. Their involvement and alignment with organizational productivity goals are fostered by gain sharing, skill-based pay, teamwork, flexible assignments, reduced status differentiation between operators and supervisors, and engagement in problem solving. Such practices are key to successful implementing of technology in the work place (Klein & Ralls, 1994). At first, sociotechnical designs were applied only to routine, linear work. But by 1995, they had been found useful for improving services and noncontinuous processes, processing transactions, and nonroutine and professional work (Fox, 1995).

# Leadership and Phases in Group Problem Solving

---

The requirements of the task change as a group progresses in its solution of a problem. Given these changing requirements during the course of group problem solving, Valenzi, Miller, Eldridge, et al. (1972) concluded that effective leadership for one phase of problem solving may be different than it is for another phase. Early on, the group usually engages in the divergent generation of alternatives. In this phase, broad participation is needed. As a consequence, Doyle (1971) considered democratic leaders to be most effective. But in the convergent, final, synthesizing phase, when coordination becomes more important, groups with leaders of high status were particularly effective. Becker and Baloff (1969) also suggested that optimal leader-subordinate relations may depend on whether the group's immediate task involves information processing, the generation of alternatives, or decision making.

Ghiselli (1966a) observed experimental groups at various stages of problem solving. The presence of a strongly self-confident decision maker, along with highly intelligent, confident, and cohesive followers, was associated with the better performance of the group in the later stages of the group's development. Nonetheless, initial performance was poor in its early, storming phase. Presumably, such confidence, competence, and motivation generated many conflicting alternatives that later formed the basis of high-quality decisions. Sample and Wilson (1965) also studied groups in different phases of problem solving. They found that task-oriented leaders quickly structured the group procedures during the planning phase and were then able to play a more relaxed role in the operational phase. Relations-oriented leaders, on the other hand, tended to hold group discussions during the planning stage, and the work did not get organized. As a result, these leaders had to try to organize procedures during the operational stage, with only partial success. In such circumstances, groups under task-oriented leaders performed more effectively.

## Effects of Type of Task

---

Korten (1968) advised that if the final product of a task was practical, more directive supervision was in order. If the outcome was theoretical, participative leadership was likely to be more useful. Carter and Nixon (1949b) found that different participants emerged as leaders, depending on whether intellectual, clerical, or mechanical assembly tasks were involved. Carter, Haythorn, and Howell (1950) studied the effects of six types of tasks (reasoning, intellectual construction, clerical, discussion, motor cooperation, and mechanical assembly) on leadership in initially leaderless groups. Although there was some generality of leadership performance across all tasks, two clusters of tasks made a difference in who emerged as a leader. The leaders of the intellectual tasks were different from the leaders of the tasks involving doing things with one's hands. As was mentioned earlier, C. G. Morris (1966a, 1966b) varied the type of task and the difficulty of the task for 108 groups. The variance in the leaders' behavior was related more to the type of task than to the difficulty of the task. Discussion tasks elicited significantly more structuring of problems and more explanatory and defensive comments by leaders. Production tasks resulted in more structuring of proposed solutions, disagreement, and procedural comments. Problem-solving tasks were similar to discussion tasks but led to more irrelevant activity and less structuring of problems.

### ***Creative and Innovative Work***

Among others, Mumford and Gustafson (1988) saw an upsurge in organizations of an interest in stimulating creativity, generation of new ideas, and their conversion into action. Traditionally, such creativity had usually

been seen as the product of a lone individual with a flash of insight about gravity as he observed an apple falling from a tree. Nonetheless, the research of Pelz (1963) and Pelz and Andrews (1966a, b) recognized early on the importance of the leadership of laboratory directors and leaders at the National Institutes of Health to the productivity of their scientists. Suggestion systems had been around since the end of the nineteenth century, but the interest in leaders who fostered creativity and innovation among their followers as a core purpose was sparked by rapid advances in technology, the information revolution, and global competition (Dess & Pickens, 2000). Tierney and Farmer (2003) developed a reliable and valid Creativity Leadership Index using five samples to assess the leadership of creativity. The data were based on responses from 1,219 employees.

The importance of autonomy and discretion was mentioned earlier in promoting innovation and creativity. Supervisory support was important to the generating of patents by 171 design and manufacturing engineers, design drafters, tool makers, and technicians in two manufacturing plants (Oldham & Cummings, 1996). On the other hand, when their group leader's supervisory control was tight and the introduction of new ideas was discouraged among 200 scientists, the scientists' creativity was squelched (Andrews, 1967). Mumford, Scott, Gaddis, et al. (2002) noted dilemmas facing the leader of creative people. Creative tasks are ill defined. To optimize creativity, the leader needs to avoid imposing too much or too little structure. Followers' goals need to be aligned with the organization's. Furthermore, the leader must evaluate the proposed work but not be overrestrictive in what is to be done.

Slusher, Van Dyke, and Rose (1972) found in a small sample study of nine engineering design groups that it was more important to group productivity for group leaders to initiate structure and be considerate than to be technically proficient. However, in most subsequent studies, it was seen as more important for creative group leaders to be technically proficient as well as expert problem solvers. Additionally, they needed to have general planning skills (Mumford, 2000). Glassman (1989) suggested that leaders of creative workers need to be able to negotiate disagreements and to listen nonevaluatively. Leading R&D activities requires the ability to communicate clearly with colleagues and top management. The R&D leader must appreciate the values and intrinsic motivation of professionals and the importance to them of challenging work and freedom to explore promising lines of inquiry.

According to Strohmeier (1998), technical leaders and senior scientists are specialized experts. They keep abreast of the literature in their field, value being recognized for patents, publications, and conference presentations, and are highly task-oriented and less concerned with relationships. Technical leaders need broad technical competence to maintain credibility with their technical followers. Yet they need to depend on their followers for additional specialized knowledge. Jaussi and Dionne (2003) showed experimentally, with 364 undergraduates in 79 groups, that leaders who were unconventional in their behavior tended to contribute indirectly to the creativity of their groups. Mumford, Scott, Gaddis, et al. (2002) provided more details about satisfying and effective leading of creative and innovative people.

*Tasks at Different Organizational Levels.* Systematic changes in the type of tasks that are performed occur as leaders move up the organizational ladder.<sup>2</sup> Different types of tasks call for different kinds of leadership. At the production and operations levels, the processes are direct and concrete. Work and service are with tangible materials and methods that are accomplished by people, tools, and machines. At these levels, leaders deal with issues of routines, pacing, meeting deadlines, and balancing the need for immediate production or service with the need for the development of individual subordinates and the need to prepare subordinates for future operations. Trust is based on personal contact and knowledge. Leadership involves face-to-face interaction and interpersonal skills. At higher organizational levels, leadership deals much more with buffering the rational production and service at lower levels from the turbulence of the external environment. At these levels, the subordinates' operations are monitored indirectly, and the coordination and integration of efforts with the market and the external environment become the tasks of consequence (Jaques, 1978). Not

unexpectedly, Bass, Valenzi, Farrow, and Solomon (1975) found that the more subordinates' work involved planning, coordination, evaluation, and other managerial activities, the more frequently their superior was likely to delegate decision making to them. However, follow-up analyses on a larger scale added that such subordinates were also given more direction.

*Changes in the Organization's Tasks.* As the organization matures, its tasks change. Consequently, the type of leadership that is needed also changes, especially at higher organizational levels. Brenner (1972) and Lavoie and Culbert (1978), among others, described the commonly observed progression of organizations through development, maturity, and decline as different tasks arise. Different stages of an organization's development call for the emergence of different styles of executive leadership in the different phases. Early on, the tasks of a business enterprise, for example, are to develop products, processes, and procedures; create a demand for them; build loyalty to a brand; find a significant niche in the market; attract financing; develop personnel and new technology. Later, the tasks may require more attention to cost containment, divestment, maintaining the share of the market, and integrating new product lines with older ones. The founders who conceive and originate organizations that grow and thrive, for example, are more prone to take calculated risks than are their counterparts who must deal with old, declining organizations.<sup>8</sup> Leadership that is predictable and that works within the established rules and procedures and under greater formal constraints is more characteristic of mature organizations than of those in the early stages of their development.

In the established organization in a stable environment, the executive must be able to serve as a transactional leader who works within the institutionalized values and systems. The executive leader serves as a steward, balancing out the strongly developed interests of the different constituencies that may be in conflict with each other. Much political compromise and accommodation are needed. During periods of gestation, birth, development, resolution, re-formation, and renewal, the executive's tasks require more transformational leadership, greater persistence and effort, and greater inspirational and charismaticlike behavior.<sup>2</sup> New strategies and commitments to new values and new systems are required. The cycle of development, maturity, and decline is not inevitable. Rather, intervention by transformational managers can provide for the renewal of an organization through reform or revolution (Normann, 1977).

*Computerized Work.* By 1990, more than 80% of office workers were using computers. In the developed world in 2006, it would have been difficult to find office workers operating without them. Office supervisors need to be familiar with computers and the complexities of computer systems. The same is true for workers and bluecollar supervisors as automation continues to increase in factories, mills, and warehouses. Public agencies are now among the biggest users for documentation and dissemination of information. In addition to the rapid expansion of technological capabilities are the concomitant changes in organizational arrangements and leadership. In the U.S. military, online instant communication makes it possible to link the U.S. president with the local combat commander on the battle site, bypassing many organizational echelons. Likewise, fax and e-mail make for instant communication and potential control across continents, oceans, and organizational levels. Increasingly, the centralization of decision making or overcontrol of the local commander is the result. Similarly, tighter reins by higher-level civilian executives are made possible by computer systems. Although the greatest emphasis has been placed on the impact of automation on stable, repetitive, processing systems, computer-assisted creative designing and engineering are now commonplace for production and service processes. Computerized planning and control models are also available for real-time planning and control. Word processing and office automation increase the productivity of individual typists. Nevertheless, supposedly to take advantage of the automation, the individualized dyadic relationship of the manager and the typist may be severed and replaced with an anonymous pool of typists or by eliminating most of the pool by having each manager using his own personal computer. First-line supervisors become more like area supervisors when advanced manufacturing computer technology or computer integrated manufacturing is put in place.

Area supervisors are shop floor experts or engineering trained personnel with some shop experience who serve as consultants and coaches to the operators. Minimally, the new technology brings about changes in the roles of first-line supervisor and middle managers (Ettle, 1986).

*Supervisory Relations.* According to Kraemer and Danziger (1984), computerization at the workplace increases the closeness of the supervisor with those at the bottom of the hierarchy. The supervisors lose some of their potential for upward influence, while those who are higher up feel a greater sense of control. The pressure of time and the importance of deadlines increase. These changes enhance the possibilities of bureaucratic management. But the effects may be counterproductive. Applebaum (1982) noted that computer programming applied to the construction industry resulted in the reliance on authoritarian and mechanistic procedures. For a while, the outcome was inefficient and irrational; control of the work process was decreased instead of increased.

However, Kerr, Hill, and Broedling (1986) offered a more balanced perspective. They suggested that automation should have its biggest effects on workers whose work had been labor-intensive and closely supervised and required little discretion and judgment. Obviously, the supervisors of such workers would be responsible for more sophisticated equipment. Nevertheless, computerized systems directly give upper management detailed information on the individual worker, such as his or her error rate and missed deadlines. Upper-level managers can bypass the first-level supervisor to obtain such information. The supervisor will then be expected to explain the reasons for the worker's deviation from the production plans. Further conflicts of interest arise for the first-level supervisor, who now faces demands from a specialized staff of systems analysts and programmers, along with those from the traditional line superiors, subordinates, and staff personnel: "first-line supervisors will have to be more technically proficient, as well as more highly skilled in human relations than their predecessors" (p. 114).

*Other Changes in Supervising.* Computerization shortcuts the need for management controls, for it can provide direct feedback from work performed on the task without any supervisory intervention. The self-managed employee can be provided by computer with continued feedback about his or her performance along with the information needed to improve it. In contrast to the findings of Kraemer and Danzinger (1984), Kerr, Hill, and Broedling (1986) inferred that first-line supervisors have moved farther from their subordinates and closer to middle managers. They reasoned that computerization reduces the time that supervisors need to spend in planning and scheduling work; documenting records and reports; engaging in coordination and control; organizing subordinates' work; and maintaining quality and efficiency, safety and cleanliness, and machinery and equipment. Presumably, spans of control can be increased. Nonetheless, the first-line supervisor's role does not seem to be diminished, for computerization facilitates his or her service as a boundary spanner; a maintainer of relations with other units; or a selector, trainer, and motivator of subordinates. Computerization makes it possible for first-line supervisors to operate more like middle managers, relative to the total organization, rather than remain oriented toward dealing mainly with subordinates (Hill & Kerr, 1984). [Chapter 29](#) will detail how computerized networks have replaced human real ones.

*Shift from Power to Achievement.* The increasing technology and computerization of tasks suggests that in more technologically advanced organizations, the power motive may become less important than the need for achievement as a predictor of success in advancement to higher levels of management. As was noted in [Chapter 8](#), McClelland (1975) demonstrated that individuals who scored high on the Thematic Apperception Test in the need for power and the inhibition of power tended to emerge as more successful leaders in a variety of situations. However, when McClelland and Boyatzis (1982) examined whether the leadership motive pattern was predictive of the long-term managerial success of technical and nontechnical managers at AT&T, the power motive pattern was related to significantly higher levels of advancement after 8 to 16 years with the company only by nontechnical managers. For technically trained and experienced managers, the need for

achievement, rather than the power motive, predicted advancement into the next several echelons of the firm.

## Path-Goal theory: the Explanation of Task Effects on Leadership

---

Beginning with Georgopolous, Mahoney, and Jones (1957) and delineated by M. G. Evans (1970a) and House (1971), path-goal theory stimulated the search for an explanation of how the nature of the group's task systematically affects whether leader consideration, initiation of structure, or interplay makes a contribution to the group's satisfaction and effectiveness. Rightfully, the theory has been modified on a continuing basis by experimental failures. According to T. R. Mitchell (1979), path-goal theory calls for the leader to provide subordinates with coaching, guidance, and the rewards necessary for satisfaction and effective performance necessitated by the subordinates' abilities to meet the particular task requirements and attain the designated goals. Focus is on ways for the leader to influence subordinates' perceptions of the clarity of the paths to goals and the desirability of the goals themselves. Leadership behavior that is best suited for increasing motivation depends on the subordinates' personal characteristics and the demands of the task. Valued rewards should be awarded contingently on effective performance.<sup>10</sup>

### ***Path-Goal: An Exchange Theory of Leadership***

Path-goal theory is an exchange theory of leadership. It attempts to explain why contingent reward works and how it influences the motivation and satisfaction of subordinates. In its earliest version by Georgopolous, Mahoney, and Jones (1957), it focused on the need for leaders to "point out the paths to successful effort" (Bass, 1965, p. 150). Leaders do so by "increasing personal payoffs to subordinates for workgoal attainment, and making the path to these payoffs easier to travel, by clarifying it, reducing roadblocks and pitfalls, and increasing the opportunities for personal satisfaction en route" (House, 1971, p. 324).

*Path instrumentalities* are the subordinate's subjective estimates that his or her performance will lead to the accomplishment of the goal. Achievement of the goal will result in ends desired by the subordinate. The leader enhances the subordinate's motivation, performance, and satisfaction by clarifying and enhancing path instrumentalities (Van Fleet & Yukl, 1986). This cognitive-perceptual explanation of path-goal theory can be matched in terms of operant behavior and reinforcement theory (Mawhinney & Ford, 1977).

*The Leader's Role.* Leaders can affect a subordinate's efforts in several ways in the path-goal process. They can clarify the subordinate's role, that is, state what they expect the subordinate to do. They can make the rewards to the subordinate more dependent on his or her satisfactory performance. They can increase the size and value of the rewards (M. G. Evans, 1970a). Specific leadership behaviors can contribute to their followers' attainment of the goal by coaching, providing direction, and support to followers, alleviating their boredom and frustration with work, and fostering their expectations that their efforts will result in the successful completion of the task (Fiedler & House, 1988).

But early on, House and Mitchell (1974) recognized that path-goal leadership, as such, was needed and useful only in certain circumstances. The leader needs to complement only what is missing in a situation to enhance the followers' motivation, satisfaction, and performance. What is missing is determined by the environment, the task, and the competence and motivation of the followers (Fiedler & House, 1988). Thus, the followers' productivity is enhanced if the leader provides needed structure to clarify means and ends if they are missing or unclear to the followers. This contribution of the leader is particularly apparent in jazz ensembles. A deviation-counteracting loop is observed in jazz that involves the leader's interpretation, criticism, and adjustments of the ensemble. The need for such correction is increased by the variety of selections the

ensemble plays, the availability to them of new musical numbers, the difficulty of the numbers played, and the lack of rehearsal time (Voyer & Faulkner, 1986).

Given clear tasks and roles, the supervisor contributes to continued productivity by consideration, support, and attention to the followers' personal and interpersonal needs for satisfying relationships (Fiedler & House, 1988). If what is missing can be supplied in other ways by the organization through policies, regulations, improved communications, channels of information, contingent reward schemes, and counseling services, such substitutes for the leadership<sup>11</sup> may result in the same outcomes that would have been expected from the appropriate leadership.

*The Path-Goal Linkage.* The exchange involved in path-goal theory is seen when subordinates perceive high productivity to be an easy "path" to attain personal goals and, as a consequence, the subordinates are productive. Directive leadership increases the promise of reward to the followers for their performance and makes the paths to their goals clearer and easier. Accordingly, such directive leadership is needed only if the task is complex, difficult, or ambiguous and its goals are unclear. Whether the followers are self-reinforcing and have a great need for autonomy, growth, achievement, or affection will also make a difference. On the other hand, if subordinates are faced with simple but boring tasks, a leader may do better by being supportive and considerate rather than directive. Too much motivation among followers, evidenced by a state of high anxiety, may call for calming support from the leader rather than any talk about contingent (uncertain) rewards, which will increase such anxiety. Supportive confidence building may be required rather than more drive (Yukl, 1981).

### ***Efforts to Test the Theory***

Translated into experiments, considerate leadership behavior or supportive relations-oriented leadership was expected to correlate more highly with satisfaction and productivity in structured than in unstructured situations. The leader's initiation of structure was expected to correlate more highly with satisfaction and productivity in unstructured than in structured situations. These expectations fit with the conventional wisdom that "chaos is the midwife of dictatorship" (Durant, 1957).

*Supportive Results.* Reviews of the empirical literature by House and Mitchell (1974) and Schriesheim and Kerr (1974) tended to confirm the theory, as did a meta-analysis by Indvik (1986a) involving 87 empirical tests. In addition, House and Dessler (1974) demonstrated that, as predicted, the available task structure generally determined whether the initiating structure and consideration by the leader would contribute to the followers' satisfaction, positive expectations, and role clarity. Earlier, House (1971) found support a posteriori in several studies cited in earlier chapters.<sup>12</sup> In specific a priori tests of the theory, House found, as expected, that the satisfaction of followers was associated with the extent to which the leader's initiating structure reduced role ambiguity. Likewise, Meheut and Siegel (1973) observed that the leader's initiation that was role clarifying was positively related to the followers' satisfaction with management by objectives. A more complicated finding was that the more autonomous the followers, the more the leader's initiation of structure correlated with followers' satisfaction but the less the leader's initiation correlated with the followers' performance. At the same time, as the scope of the subordinates' task decreased, the leader's consideration correlated more with the followers' satisfaction and performance. Also supportive were direct tests of the theory by Dessler (1973), who found that with the leader's consideration held constant, the leader's initiation of structure correlated less with the followers' satisfaction and role clarity as the ambiguity of the task decreased.

Schriesheim and DeNisi (1981) studied how the variety of tasks in a job, feedback, and dealing with others moderated the impact of the initiation of structure on satisfaction with supervision among 110 employees

who were working in a medium-size plant and among 205 employees of a medium-size manufacturer. The variety of tasks was expected to require more initiation of structure for employees' satisfaction with supervision. Such initiation would be redundant with routine jobs (House & Dessler, 1974) and when feedback was already structured and followers dealt with others a lot. The results confirmed the moderating effect of all three task variables.

*Mixed and Nonsupportive Results.* Szilagyi and Sims (1974) obtained data from 53 administrative, 240 professional, 117 technical, and 231 service personnel at multiple levels of occupational skills in a hospital. Although the results supported path-goal propositions concerning the demands of the task and the relationship between the leader's initiating structure and the followers' satisfaction, they failed to do so for the relationship between the leader's initiation and the followers' performance. Similarly, Stinson and Johnson (1975) tested hypotheses derived from the path-goal theory of leadership that the correlations between the leader's initiating structure and satisfaction and role clarity are more positive under conditions of low task structure, low task repetitiveness, and high task autonomy than under high task structure, high task repetitiveness, and low task autonomy. The leader's consideration and the subordinates' satisfaction and role clarity were expected to be more positively related under structured, repetitive, dependent conditions than under unstructured, unrepertitive, autonomous conditions. The subjects were military officers, civil service personnel, and project engineers. The results were consistent with path-goal theory with respect to consideration but tended to be contrary to the theory regarding the initiation of structure.

Contrary to path-goal theory, the leader's consideration was still generally found to result in the higher satisfaction of followers, regardless of the characteristics of the task (Johns, 1978; Miles & Petty, 1977). Thus, J. F. Schriesheim and C. A. Schriesheim (1980) surveyed 290 managerial and clinical employees in nine different jobs at five levels in the operations divisions of a large public utility. Contrary to path-goal theory, they found that regardless of the task structure, organizational level, or type of job, supportive (considerate) leadership explained 63% of the variance in the followers' satisfaction with their supervisors after instrumental leadership (initiation) was partialled out. But, as predicted, instrumental leadership (after supportive leadership was partialled out) contributed 17% to accounting for the variance in role clarity. However, again this covariance was unmoderated by the task structure, organizational level, or type of job. Likewise, Seers and Graen (1984) found that without reference to leadership, performance and satisfaction outcomes directly depended on the characteristics of the task, as well as on the followers' need for growth. In the same way, the satisfactory quality of the leader-followers relationship independently added to the prediction of the outcomes of performance and satisfaction without reference to the task and the followers' needs, which were also related to the outcomes.

Wolcott (1984) tested path-goal predictions for library supervisors and the performance of their reference librarians and catalogers. Contrary to path-goal predictions, the initiation of more structure contributed to better performance when the task structure was already high than when it was low. The librarians' high educational level and low need for independence were seen to be possible explanations for the results.

More initiation of structure is likely to be seen when the group task is already structured (Bass, Valenzi, Farrow, & Solomon, 1975). It may be that a leader's initiation may be easier to accomplish if subordinates' tasks are already structured but actually may be useful when tasks are unstructured. Generally, initiating structure still frequently increases tensions, especially when consideration is low (Miles & Petty, 1977; Schriesheim & Murphy, 1976) and when the initiation of structure measure continues to contain coercive, threatening items, along with direction and order giving. In turn, this linkage of direction and coercion is a consequence of dependence on empirical rather than conceptual analyses for developing measurements. Although autocrats tend to want to structure situations, conceptually one can give orders without being a threatening autocrat. For more than 1,300 subordinates of their 340 managers, the correlation between being coercive and being directive was only .38 (Farrow, Valenzi, and Bass, 1980).

In a first study, Greene (1979a) showed that, as expected, instrumental (structuring) leadership behavior was correlated positively with the satisfaction and performance of 119 engineers, scientists, or technicians if they faced tasks with little structure. But such instrumental leadership was negatively correlated with satisfaction and minimally with performance when the tasks were more structured. Considerate or supportive leadership, as expected from the theory, increased the correlation with intrinsic satisfaction (but not with performance or extrinsic satisfaction) as the task structure increased. In a second study, Greene (1979b) tested several assumptions about causation that underlie the theory. The findings supported the theory, except, again, for the hypotheses concerning the followers' performance. Downey, Sheridan, and Slocum (1975) found only partial support for the path-goal predictions, and J. P. Siegel (1973) and Szilagyi and Sims (1974b) found none. Dessler and Valenzi (1977) failed to find moderator effects across supervisory levels. T. R. Mitchell (1979) concluded that the findings were stronger for the consideration hypothesis than for the structuring hypothesis and stronger for satisfaction as a criterion than for performance.

Indvik (1985, 1986a) completed a meta-analysis of 48 path-goal studies involving 11,862 respondents. Task structure, as such, was measured directly in some of the studies. In the rest of the studies, low job level was accepted as an indicator of high task structure, as was large organizational size. As predicted, when structure was absent from the work environment, directive, structuring leadership behavior contributed to the intrinsic motivation of followers, their satisfaction with the leader, and their overall satisfaction, but, surprisingly, it failed to add to role clarity, as such. However, contrary to predictions, directive, structuring leadership contributed to the subordinates' performance when the structure was high but not when the structure was low.

Considerate, supportive leadership behavior in a highly structured work setting did enhance motivation, satisfaction, performance, and role clarity, as predicted. In a related meta-analytic report, Indvik (1986b) concluded that participative leadership provided the most overall satisfaction to subordinates who preferred and experienced a low task structure. Furthermore, when the task structure was high, achievement-oriented leadership behavior was related to increased intrinsic satisfaction among subordinates but decreased extrinsic satisfaction and performance for those subordinates with a high need for achievement.

### ***Efforts to Reconcile Path-Goal Theory with the Mixed Results***

Johns (1978) suggested that much more is "missing" that the leader may supply efficaciously than just task structure, as measured by House and Dessler's (1974) scale about the extent to which tasks are simple, repetitive, and unambiguous. Johns (1978) argued for using a broader measurement of the scope of a job for determining what could be missing from it. Such a measurement would be Hackman and Oldham's (1975) index based on variety, autonomy, the significance of the job, feedback from the job, and the identity that the job provides to its occupant. Johns (1978) found that Sims, Szilagyi, and Keller's (1976) Job Characteristics Inventory, which measures the scope of a job, provided a measure to moderate more consistently the relationships between leadership behavior and the satisfaction of subordinates than task structure alone could do.

*Coercive versus Noncoercive Initiation of Structure.* The measures of leadership behavior are obtained most often from the Leader Behavior Description Questionnaire—Form XII (LBDQ-XII) and less from the Supervisory Behavior Description Questionnaire (SBDQ).<sup>13</sup> Schriesheim and Von Glinow (1977) first noted that path-goal predictions of job satisfaction were less likely to be supported when a more coercive measure, such as the SBDQ initiation of structure, had been used.<sup>14</sup> Schriesheim and Von Glinow then demonstrated, with 230 maintenance workers, that if a coercion-loaded scale was used, reverse results were obtained for the path-goal predictions for job satisfaction. But when coercion-free scales (the LBDQ and the LBDQ-XII) or items from them were employed, path-goal predictions were confirmed if task structure and

role clarity were used to moderate the relationship between the leader's consideration and initiation of structure and the followers' job satisfaction.

*Conditions Affect What Leaders Can Do.* A second source of contradictory findings results from the fact, as noted above, that leaders tend to be more directive when it is easier for them to do so, such as when roles are clear, conditions are structured, and jobs are routine (Bass, Valenzi, Farrow, & Solomon, 1975). But such structuring would seem to be redundant for subordinates' productivity when conditions are already structured. Rather, it would seem that such direction is needed more when conditions are unstructured, for in such unstructured situations, it might be argued that the group wants some direction from the leader, not just the leader's sympathy. Nevertheless, Indvik's (1985, 1986a) previously mentioned meta-analysis proved otherwise: directive, structuring leadership contributed to followers' performance when structure was high, not when it was low.

*Attributes of Leaders and Subordinates.* The leader's personality also needs to be taken into account in the structured situation, given Farrow and Bass's (1977) finding that highly *directive* leaders tend primarily to be satisfied authoritarians. In addition, the subordinates' personalities need to be considered. Griffin (1979) proposed a set of prescriptions combining path-goal theory and the subordinates' need for achievement and self-actualization. Griffin called for achievement-oriented, consultative leadership for self-actualizing followers with "big" jobs. But for self-actualizers in routine jobs of little scope, supportive leadership (consideration without consultation) was required. For "big" jobs performed by occupants who are uninterested in self-actualization, directive leadership (structuring without threat) was seen as most needed. For occupants of routine jobs who have no need for self-actualization, maintenance leadership behavior (management by exception) was suggested.

Schriesheim and Schriesheim (1980) added other subordinate variables that are likely to act as path-goal moderators of the leader-outcome relationships. These variables included the followers' authoritarianism, ability, training, need for affiliation, and experience relative to the demands of the task and their internalization of professional norms and standards. Similarly, Abdel-Halim (1981) found that the subordinates' locus of control (internal or external) had important effects on the path-goal leader-outcome relationships associated with the ambiguity of the role and the complexity of the job.

Algattan (1985) examined the extent to which the scope of the followers' task, strength of the need for growth, and locus of control moderated leader-outcome relationships for two periods, two months apart. At each time period, if the subordinates' locus of control was external, the scope of their tasks and the strength of their need for growth increased the extent to which both participative and directive leadership contributed to their satisfaction and performance. But if the subordinates' locus of control was internal, task-oriented leadership, as such, was of more importance to their satisfaction and performance. However, a cross-lagged analysis of the correlations for the two time periods failed to support the existence of causality in the relationships.

Craig (1983) attempted to show the importance of subordinates' self-esteem to path-goal leader-outcome relationships but failed to find the expected interactions. Wolcott (1984) found no effect on the relationships from differences in the subordinates' need for independence. Keller (1987) argued that the discomfort of role ambiguity may differ from one follower to another. Some people who may want to clarify and structure their roles themselves are unlikely to be enthusiastic about a leader who initiates structure even if the task is unstructured or ambiguous. Followers with high levels of education, such as R & D professionals, who may have internalized professional norms that provide them with role clarity, may not need or want the leader to initiate structure. Some followers may actually enjoy the unstructured nature of a task; they may have a low need for clarity and prefer to create their own structure. For Keller, compared to task structure, the followers' need or lack of need for clarity was seen to be a more important moderator of the correlations between the leader's initiation of structure and the subordinates' satisfaction and performance.

In a survey of 477 professionals employed in four R & D organizations, Keller (1988) employed Rizzo, House, and Lirtzman's (1970) role ambiguity scale to measure the subordinate's perceived task clarity, as well as Ivancevich and Donnelly's (1974) scale to measure the subordinate's felt need for clarity on the job. He found that the need for clarity had a moderating effect on the initiation of structure-satisfaction relationship for both concurrent data and data gathered one year later. The higher a subordinate's felt need for clarity, the stronger was the relationship between the leader's initiation of structure and the subordinate's job satisfaction. The subordinate's need for clarity was similarly found to moderate the initiation-performance relationship in the largest of the R & D organizations. But, as proposed, the actual clarity of the task for the subordinates, as such, failed to serve as a moderator for these leader-outcome relationships. In the same way, Kroll and Pringle (1985) failed to find the expected effects of the leader's directiveness on the satisfaction of 43 middle managers in marketing. Kroll and Pringle explained the results by noting that managers rated the ambiguous situation as a positive experience, particularly if they judged the amount of direction they received to be the amount they actually desired.

*A Comprehensive Study.* Using data from a survey of 467 nonacademic staff at a university, Indvik (1988) completed tests of 17 hypotheses that involved directive, supportive, participative, and achievement-oriented leadership behavior, plus the expectancies that increased effort would improve performance and that improved performance would yield valued outcomes. Also measured were intrinsic satisfaction with work, extrinsic satisfaction with pay and promotion, and satisfaction with one's superior. The subordinates' performance was appraised by their superiors. Indvik examined the task structure, norms of the work group, and organizational formalization as situational moderators of the relations between superiors' leadership behavior and subordinate outcomes. Personal subordinate moderators included the need for achievement and preference for environmental structure. Hierarchical stepwise regression analyses<sup>15</sup> provided support for seven of the 17 hypotheses tested. Moderators that had significant effects included the subordinates' preference for structure and need for achievement. However, Indvik concluded that generally, because of its low reliability, the subordinates' preference for structure had a weak moderating effect on the relations of leadership behavior to subordinate outcomes. Directive and achievement-oriented leadership behaviors were too highly correlated with each other to be distinguishable. Indvik recommended that future studies should measure transformational leadership behavior instead of the transactional leadership behavior on which path-goal research has concentrated, for it is likely that transformational leadership behavior is more sensitive to task structure and the characteristics of subordinates.

*Integration of Findings.* Neider and Schriesheim (1988) constructed a comprehensive path-goal model, shown in [Figure 27.1](#), that attempts to incorporate many of the consistent findings about the process and the variables of consequence.

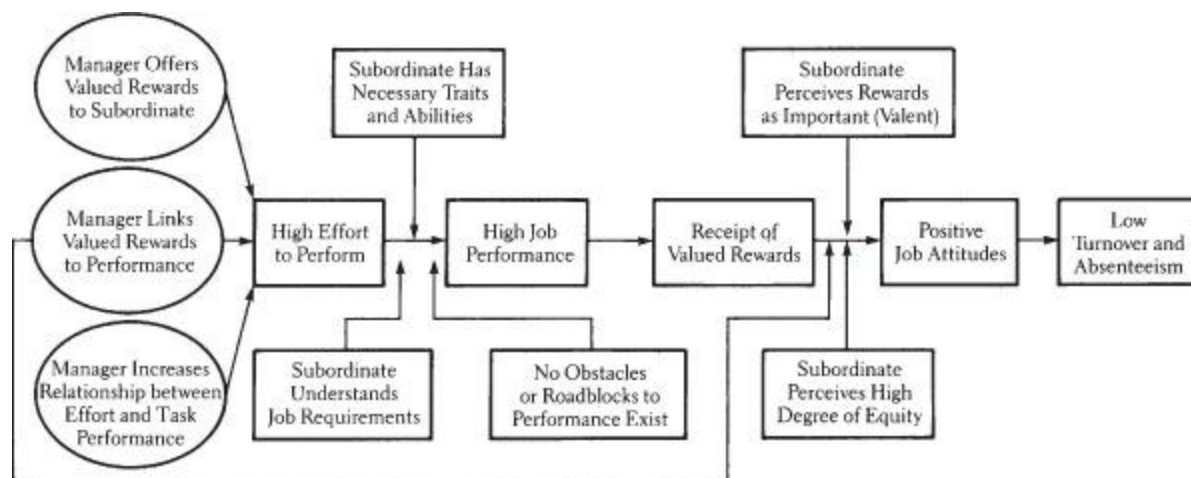

In the model, the manager stimulates the subordinate's effort by offering valued rewards and linking them to the subordinate's effort and performance. How much the effort yields high performance depends on the subordinate's knowledge, skills, and abilities, as well as on the absence of hurdles to performing the job. The rewards received by the subordinate, if valued and equitable, create satisfaction and encourage the subordinate to remain on the job.

By 1993, Wofford and Liska had located 120 studies that tested aspects of path-goal theory, not counting reviews and expositions. Jermier (1996) explained the continuing popularity of the theory as being that it rejected a single best way to lead and focused attention on situational contingencies. It placed more emphasis on the effects on leaders and followers of dyadic than group relationships. Although in some instances its derived propositions were sometimes invalidated, they remained interesting and stimulating to scholarly research. Raw empirical publication in leadership was no longer acceptable or convincing without guidance from theory and hypothesis testing. Path-goal theory provided a more sophisticated way to examine leadership processes.

*Caveat.* Despite a considerable amount of general empirical support for it, path-goal theory is complex,

which makes it difficult to test the theory's deduced relationships. Furthermore, too much rigor may be required of such tests, and sampling and measurements may be inadequate to meet the requirements (Yukl & Van Fleet, 1986). It is not surprising that a wide array of empirical results, sometimes contradictory, have emerged from the surveys and experiments that tested various propositions derived from path-goal theory.

Figure 27.1 An Integrated Path-Goal Perspective of Motivation and Leadership

## Summary and Conclusions

The leader's and subordinates' competence, personality, and autonomy and the requirements of the task systematically moderate how different leadership behaviors affect what happens in the group. The characteristics of the task that make a difference include its structure, clarity, provisions for the subordinate's autonomy and use of discretion, routineness, variety, complexity, difficulty, interdependencies, automation, multiplicity of solutions to problems, and task requirements for cooperation. As the task is different at different phases in a group's development and at different organizational levels, so is the requisite leadership. Socioemotional and task requirements call for sociotechnical designs of the workplace.

Path-goal theory has been widely tested and modified to account for the impact of the task on optimum leader-subordinate relations. Currently, it suggests that to obtain subordinates' effective performance and satisfaction, the leader must provide structure if it is missing and must supply rewards that are contingent on the adequate performance of the subordinates. To do so, leaders must clarify the desirability of the goals for the subordinates, a role seemingly suited for transformational leaders. But their efficacy in doing so will depend on such personal characteristics as the subordinates' need for clarity. However, the lack of clarity and ambiguity of the situation may also be sources of stress—to be examined next.

<sup>1</sup> A further examination of how the change in the requirements of a task from one situation to another affects the transfer of leadership appears in [Chapter 30](#).

<sup>2</sup> As defined in [Chapter 18](#), *participation* (italic) refers only to sharing in the decision process; participation (roman) includes consulting, sharing, and delegating. *Direction* (italic) refers only to giving orders with or without explanation; direction (roman) includes ordering, persuading, and manipulating.

<sup>3</sup> See, e.g., Fiedler (1964), Hunt (1967), Shaw and Blum (1966), and Wofford (1971).

<sup>4</sup> Here there is consistency with the effects of the transformational leadership factors of inspirational leadership, intellectual stimulation, and individualized consideration.

<sup>8</sup> See [Chapter 25](#).

<sup>2</sup> See [Chapter 21](#).

<sup>10</sup> See [Chapter 15](#).

<sup>11</sup> See [Chapter 29](#).

<sup>12</sup> The studies were by Fleishman, Harris, and Burt (1955); Halpin (1954); Mulder, van Eck, and de Jong (1971); Mulder and Sternerding (1963); Rush (1957); and Sales (1972).

<sup>13</sup> See [Chapter 20](#), which discusses the coercive elements in the SBDQ that are absent from the LBDQ.

<sup>14</sup> See, e.g., Downey, Sheridan, and Slocum (1975, 1976); and J. P. Siegel (1973).

<sup>15</sup> In a stepwise regression analysis, predictors are added according to their contribution to the overall prediction of outcomes. In a hierarchical regression, they are added in a predetermined order. The order used was based on path-goal propositions.

## CHAPTER 28

---

### Stress effects

Individuals, groups, and organizations confronted with threats to their well-being will experience stress. Rowney and Cahoon (1988) noted that the burnout scores among individuals who work in the same unit are more similar than those of individuals who work in different units doing similar kinds of work. In many instances, the available leadership makes the difference in the prevention or occurrence of stress and burnout. Leadership can be the source of increased stress, negative emotions, and negative outcomes. But leadership can provide for avoiding stress or coping with it. Thus Graham (1982) found that with professional employees of a county extension service, job stress was lower when the leaders of their district program were described as higher on the Leader Behavior Description Questionnaire (LBDQ)<sup>1</sup> in both initiation of structure and consideration. Leadership can also be the source of positive emotions; when, threats are converted to opportunities, stress may yield positive outcomes (Folkman & Moskowitz, 2000).

### The Nature of Stress

---

#### *Signs of Stress*

Rodney Lowman advised that signs of stress in the work-place that need to be recognized by the leader include: (1) absenteeism, whether due to illness or other reasons; (2) workers who have become more irritable and hard to get along with; (3) more confusion is appearing and mistakes are more frequent on tasks that usually are performed well; (4) stress is felt by the leaders and felt and expressed by the workers (Perry, 1999).

Stress symptoms include increased emotional arousal, frustration, defensiveness, faulty decision making, and physiological symptoms like sweating, heavier breathing, and increased heartbeat. A state of anxiety is a perceptual manifestation of such objective conditions of stress (Spielberger, 1972). Well known is the extent to which stress is generated in subordinates by hostile, abusive superiors (Roberto, 2002). The hostile, abusive leader who uses power to bully, humiliate, intimidate, and threaten subordinates is a major source of stress (Aquino, 2000; Tepper, 2000). Deadlines are set that are impossible to meet. There are inordinate pressures to produce and constant unnecessary disruptions of work by the supervisor. The stress shows itself in subordinate dissatisfaction, negative emotional reactions, moods, and feelings, and psychosomatic and physical symptoms, particularly if quitting is not possible. Anxiety, anger, depression, negativity, and loss in self-esteem may be further consequences of the continuing stress.

*Assessments.* Among many assessments of stress and anxiety, the anxiety state was measured on the job by Schriesheim and Murphy (1976) with the 20-item State Anxiety subscale of the State-Trait Anxiety Inventory (Spielberger, Gorsuch, & Lushene, 1970). The Job Stress Survey (Spielberger, 1994) was applied by Spielberger and Reheiser (1994) to measure job stress in business, university, and military organizations. The Maslach Burn out Inventory (1986) assessed stress and burnout in MBAs, professionals, and employees.

*Faulty Decision Making.* Decision making under stress becomes faulty. Instead of careful analysis and calculation or the effective use of the intuition of the expert based on learning and experience, stressed decision

makers fall back on nonproductive intuitive reactions that satisfy their immediate personal emotional needs rather than the objective requirements of the situation. As Simon (1987, p. 62) noted, "Lying, for example, is much more often the result of panic than of Machiavellian scheming." When Sorokin (1943) examined reports of the reactions of groups and communities to the calamities of famine, war, and revolution, he found that a calamity tended to intensify emotional arousal, distort cognitive processes, focus attention on the dangers and away from other features of the environment, hasten disintegration of the self, and decrease the rationality of decision making. The erroneous decision that resulted in the shooting down by the U.S. Navy ship *Vincennes* in the Persian Gulf of an Iranian commercial jet liner was attributed to the stressed personnel misreading and misinterpreting their radar displays as a descending attacking aircraft instead of a plane taking off on a routine commercial trip between Iran and Saudi Arabia.

The ordinary healthy reaction of an individual, group, or organization to dissatisfaction with the current state of affairs is to examine fully what prevents the attainment of the more desired state, then to consider various alternative courses of action, and finally to take appropriate steps to achieve the goal. But if motivation is high, if obstacles are severe, or if remaining in the current state is threatening to one's welfare or survival, malfunctions in the coping process occur. There may be no time to deliberate about choices among actions. There may be communication outages or severe information overloads. The mobilization of autonomic energy occurs with the felt emotional arousal and related symptoms of stress. Such arousal narrows perceptions and limits the ability to think creatively (Lazarus, 1966). Memory and cognitive functions become impaired (Weschler, 1955). Stress is an evolution-based reaction that prepares the individual for fight or flight in the face of danger and threat. When one is unable to cope with the threat, the autonomic symptoms appear. A year after the Katrina disaster of 2005, more than 100,000 residents who fled have been unable to rebuild because of the severity of the flooding or lack of personal resources. They have not returned to New Orleans. Those still in temporary shelters remain depressed.

Stress may generate positive emotional arousal. With personal control, prolonged distress may be reduced when those affected can focus on the good in the situation by reappraising it or finding humor in it; by viewing the situation as a problem to be solved; or by taking a time-out to concentrate on some positive emotional arousal or finding humor in it to provide relief from the stress (Moskowitz, Folkman, Colette, et al., 1996).

*Frequency of Felt Stress among Managers.* In response to 17 questions, such as how much in the last month they had felt nervous and stressed (0 5 never to 4 5 very often a problem), several hundred each of Japanese managers registered an overall mean of 1.59; Indian managers, a mean of 1.37; and American managers, a mean of 1.33. The average manager in the three countries experienced a stressful experience at least once a month (Ivancevich, Schweiger, & Ragan, 1986). The figures for U.S. managers were much lower in response to questions about their experiencing stress daily, somatic symptoms, anxiety, and social dysfunctioning and much higher for their reports of job-induced stress ("I am not sure exactly what is expected of me") and the discharge of job tension off the job (Matteson & Ivancevich, 1982). The use of tobacco, alcohol, tranquilizers, sedatives, and other drugs is commonly an effort by managers and professionals to cope with job stress, as are physical exercise, socializing with friends, and recreational activities (Latack, 1986). In an Indian study, workers were found to be subjected to significantly more stress (boredom, frustration, bereavement, and physical stress) than their supervisors and managers (Biswas, 1998).

*Causes of Stress.* Stress occurs to individuals, groups, and organizations when their situation is overly complex, ambiguous, unclear, and demanding in relation to the competence, resources, or structural adequacy available to deal with the demands. Compared to Europeans, U.S. workers work longer hours to maintain higher output than elsewhere. Higher productivity due to technological advances is accompanied by the insecurities of layoffs and unemployment. The same insecurities accompany the movement of factories and offices to regions with lower labor costs, less taxation, fewer environmental controls, cheaper energy, and

government subsidies. In order to remain competitive, management pushes for faster and more efficient production. Currently the shibboleth is *continuous improvement*.

Continuous improvement means continuous change. Organizational change is stressful. In a Swedish survey, Arvonen (1995) found psychosomatic reactions of stress in employees under supervisors who were change-oriented if the employees lacked commitment. As Stuart (1996, p. 11) surmised, "having one's department reorganized, one's responsibilities outsourced, and several tiers of one's peer managers taken out ... would stress a manager in the same way as a natural or man-made catastrophe." The threat of downsizing and actually being laid off is an important source of insecurity and its accompanying fears and anxieties. Additionally, the survivors of an organizational downsizing, although perhaps relieved for the moment, are also likely to reveal feelings of fear, anxiety, and distrust. Less well known are the effects of denial of their feelings of guilt and the depression that denial can cause (Noer, 1993). A sudden unexpected promotion might be stressful in a positive way. Roskies and Lewis-Guerin (1990) found that 1,291 Canadian managers who were insecure in their jobs reported poor health. Their health was worse depending on their level of insecurity. They mainly were anxious about the long-term threat to their jobs and the deterioration of their positions. According to Judge, Boudreau, and Bretz (1994), among 1,309 executives using a search firm for possible opportunities to change jobs, job stress correlated  $-.21$  with life satisfaction,  $-.29$  with job satisfaction,  $-.26$  with family matters that caused conflicts at work, and  $-.44$  with job conditions that caused conflicts in the family.

The need to make changes in themselves and their work is often a source of stress to managers as well as their employees. They may be stressed by feeling that they increasingly need to face unfamiliar products, services, and situations and that they will increasingly need more skills (Rago, 1973; Frew, 1977). The pressure for change correlated  $.46$  with stress for 88 Tennessee state government supervisors (Rohricht & Rush, 1977).

The most commonly reported sources of stress in the working environment are lack of good relations and lack of support from supervision, according to a Job Stress Survey of 209 managers reported by O'Roark (1995). (Arvonen (1995) reported the same effect.) The results were the same for all personalities as assessed by the Myers-Briggs Type Indicator (MBTI). Conversely, Crawford (1995) noted that the socially supportive leader mediated the effects of stress. O'Roark also found that for executives in a regional medical center, the difficulties that generated the most stress for them were meeting deadlines, frequent interruptions, dealing with crises, and having to make on-the-spot decisions. Among 781 Swedish personnel, creative leaders were found by blue-collar workers to generate more stress (Arvonen, 1995).

This was consistent with Seltzer, Numerof, and Bass (1987), who observed that burnout among employees was higher when their leaders were more intellectually stimulating. The Swedish managers and white-collar workers felt more stressed if they described their immediate managers as bureaucrats. This fitted with Crawford's (1995) opinion that stress among their followers was likely to be generated by transactional leaders.

Workplace violence, such as shooting incidents in the U.S. Postal Service, is an extreme case of the effects of stress resulting from the confluence of stressed-out employees, autocratic and punitive leadership, and a high degree of tension in the environment. Simple, repetitive tasks have often been replaced by complex job demands, yet employees remain under a high degree of control. The perpetrators felt a sense of injustice and had low self-esteem and paranoid tendencies. They came from unstable families, had few outlets for rage, called for help many times but did not receive any, and felt poorly treated by their supervisors. Most unfortunately, they were fascinated by guns and the military (DeAngelis, 1993). The symptoms of aggression begin early. Garcia and Shaw et al. (2000) observed aggression in two-year-old boys engaged in a clean-up task with mothers whose parenting style was rejecting, critical, hostile, and physically punitive.

### ***Stress Is Multifaceted***

A variety of different antecedent conditions may give rise to stress in groups. To some degree, the observed and appropriate leadership behavior will depend on the particular antecedents that were involved. Bass, Hurder, and Ellis (1954) identified four emotionally arousing stress experiences with different antecedents: (1) *frustration* is likely to be felt when highly prized positive goals are unattainable because of inability or difficulties in the path to the goals; (2) *fear* occurs when escape from noxious conditions is threatened by obstacles in the path; (3) *anxiety* is aroused when these paths, obstacles, and goals become unclear (fear and frustration turn to anxiety with increasing uncertainty); and (4) *conflict* arises when one faces incompatible choices of goals. Potentially high risks and costs compete with the anticipated benefits of a course of action.

After examining the physiological reactions and the cognitive and psychomotor performance of 200 college men under experimentally induced frustration, fear, anxiety, and conflict, Bass, Hurder, and Ellis (1954) concluded that performance under these various stress conditions would decrease or increase in contrast to a stress-free condition depending on which tasks and skills were involved, which type of stress was imposed, and the initial level of arousal of the participants. Differences among the men were also large.

### ***Individual Differences***

Leader-subordinate dyadic analysis would seem particularly important in understanding leadership in threatening situations. What one subordinate may see as an invigorating challenge, another may perceive as a stress-laden threat. It is all in the eye of the beholder. As McCauley (1987, p. 1) put it, "A challenging, rewarding task for one person may be flooded with stress and anxiety for others. How one appraises self and situation makes all the difference."

According to Bunker (1986), less stress in the same threatening conditions are felt by those who are generally optimistic, who believe that such conditions are matters of their own fate and not controlled by external forces, who can tolerate ambiguity and uncertainty, and who feel they can improve their own abilities. In agreement, Spector, Cooper, and Aguilar-Vafaie (in press) found that among both Iranian and U.S. managers, those with higher locus of control reported less strain from job pressures. Such confidence is enhanced with experience. The effects of stress and anxiety are reduced as experience is gained with the same threats (Benner, 1984). The effect of experience is similar to the effects of preparation, overlearning, and overtraining. Smith (1994) notes that managers and business leaders are most often thinking-judging (TJ) personality types on the Myers-Briggs Type Inventory (Myers & McCauly, 1985). TJs are likely to be more comfortable in a structured and organized environment. But those who are not TJs—artists who emphasize feeling-sensing, for instance—are more likely to be stressed by the manager's role.

Stress can also vary from one individual to another as a consequence of deep-seated feelings of inadequacy that surface in aggression or overdependence when real or imagined threats occur. People differ from each other in this intrapsychic tension.<sup>2</sup> Levinson (1980) conceived of stress as a consequence of such intrapsychic tension—the increased gap between one's ego ideal (the partly conscious image of oneself at one's future best) and one's current self-image. Among both U.S. and Iranian managers, those who had a greater internal locus of control showed less feelings of strain due to the pressures of their roles, work-family conflict, constraints, and lack of support (Spector, Cooper, & Aguilar-Vafaie, in press).

To some extent, the loss of 5 of a party of 23 climbers on Mount Everest in 1996 could be attributed to the overconfidence of the leader, expectations of continuing good weather, lack of cooperation, failure to observe the rule to turn around before reaching the top if it was 1 or 2 p.m. to avoid being caught descending to camp in the dark. But a sudden storm came up, changing the situation.

*Resilience.* People differ in their ability to restore their equilibrium after an event or period of stressful

adversity. They learn to grow out of their adversity (Bonanno, 2005). Many handicapped and disadvantaged children overcome their handicaps and disadvantages to become successful and effective adults. Eleanor Roosevelt, for example, was treated as an “ugly duckling” by her family. She overcame her shyness and thin voice to become a world-class leader.

### ***Situational Differences***

The study of leadership under stressful conditions has often treated stress as a homogeneous situation. Yet the same stressful experience can stem from a variety of precipitating conditions, and the variety of possible reactions to it may depend on the different precipitating conditions. Thus, research on disasters has found systematic differences in community reactions to warnings of tornadoes and warnings of floods. Communities react much more quickly to threats of tornadoes than to threats of floods.

*Other Situational Stressors.* The pace of work can become a source of stress, particularly if the operators are inexperienced novices. Workplace relocations can be disruptive and stressful, as shown when supermarket personnel were transferred from one store to another (Moyle & Parkes, 1999). Downsizing is stressful not only to the employees who lose their jobs but also to the survivors. About half of the survivors after downsizing, according to Cascio (1995), reported feelings of anxiety and insecurity. The volatility and instability of family incomes have increased substantially since the 1970s. Instability was five times greater in the 1990s than the 1970s. Stability peaked in 1972. The spread between the rich and the poor increased. Lower-paid workforce income failed to keep up with inflation. Many families faced a new level of insecurity and stress as they became two-earner households to maintain the same standard of living as was once possible with just the single wage earner (Lind, 2004).

Frequent business and government travelers reveal emotional upset, physical strains, irritability, and impaired performance before, during, and after trips (De-Frank, Konopaske, & Ivancevich, 2000). Many face an overstimulating lifestyle. Before the trip there are the distractions of planning the trip, making suitable work and family arrangements, and preparing to visit different cultures and climates. Almost 75% of married people and 50% of travelers on business say it is difficult to be away from home for extended periods. Fifty percent say they worry about what is happening at home and in the office (Fisher, 1998). Particularly stressful are airline delays and cancellations, needing to visit numerous locations in one or two days in a single city with heavy traffic, a lack of opportunity for healthy exercise, sleep deprivation, and eating too much or too little while on the road.

Reactions to changing time zones and jet lag are often discomforting aspects during and after travel. On returning home, travelers have to make up for what they missed. On returning to their office, they are faced with an overloaded in-box, finding out what happened during absence, catching up with changes, and completing expense account reports (DeFrank, Konopaske, & Ivancevich, 2000).

### ***Role Stress***

Kahn, Wolfe, Quinn, et al. (1964) showed that two distinct sources of stress could be identified in organizations: role conflict and role ambiguity. Each has different antecedents and consequences. *Role conflict* involves contradictory requirements, competing demands for one's time, and inadequate resources. *Role ambiguity* involves lack of clarity about tasks and goals and uncertainty about the requirements of one's job.<sup>3</sup> Latack (1986, p. 380) noted how managers and professionals tried either to control role ambiguity, role conflict, and role overload or to escape from them. To control role ambiguity, they “try to see the situation as an opportunity to learn and develop new skills” (p. 380). To escape from role ambiguity, they “try to do their

best to get out of the situation gracefully.” To control role conflict, they “work on changing policies which caused this situation.” To escape from role conflict, they “separate themselves as much as possible from the people who created this situation.” Deluga (1989) found that 106 to 109 employees in a metal-fabricating firm who experienced role conflict in the demands their jobs placed on them used upward influence tactics on their supervisors to alleviate the stress. Specifically, as the role conflict increased they first tried to influence their supervisors to change the conflicting demands on their jobs with friendliness, bargaining, reasoning, assertiveness, appeals to higher authority, and coalitions with other employees. When the attempted influence failed, they resorted a second time to assertiveness, friendliness, and coalition efforts.

*Role Overload.* To role conflict and ambiguity, Latack (1986) added *role overload* as a source of stress. To control role overload, managers and professionals “try to be very organized so they can keep on top of things.” To escape from role overload, they “set their own priorities based on what they like to do.” When the Job-Related Tension Index of Kahn, Wolfe, Quinn, et al. (1964) was completed by 113 Canadian managers for R. E. Rogers (1977), four factors were extracted from the results. These factors were (1) too heavy a work load, (2) self-doubts, (3) sense of insufficient authority and influence upstairs, and (4) need to make unpopular decisions against their better judgment.

Shaw and Weekley (1985) also found actual qualitative overload to be stressful. Nonetheless, other investigators did not conclude that work overload was necessarily stressful to managers. S. Carlson (1951) found that it was normal for most Swedish executives to report being overloaded and having little time for family or friends.<sup>4</sup> A business management survey of 179 company presidents and board chairmen obtained results indicating that the average executive worked approximately 63 hours per week but did not feel overworked, although more than 70% thought they did not have enough time for thinking and planning (Anonymous, 1968). But W. E. Moore (1970) observed that detailed chores involving problems in communication and operations interfered with the managers’ effective use of their time. Yet Jaques (1966) noted that hard work and long hours were not sufficient conditions for producing stress symptoms in executives. Rather, stress conditions are generated from within the manager as responses to impossible standards of achievement or tasks that are perceived as overly difficult.

The conclusions about work overload are seen in the extent to which some harried executives are aggressively involved in achieving more in less time. As discussed in [Chapter 8](#), such executives habitually have a sense of urgency (Friedman & Rosenman, 1974). They are labeled Type A personalities; many are highly stressed, as is evidenced by their proneness to heart disease. Nevertheless, many other harried Type As are not under such stress. The difference is that those Type As who are subject to heart disease are also depressed, tense, and generally prone to illness. They are not generally healthy, talkative, self-confident, and in control of their situations (Friedman, Hall, & Harris, 1985).

*Combat Conditions.* Military combat is illustrative of both the situational and personal elements that are of consequence to the generation of stress and the reactions to it. The actions and coping of soldiers in conditions of combat stress are responses to a situational and personal complex of antecedent and mediating variables. Whether soldiers and their leaders actively carry out their duties, become passive, or collapse will depend on the amount of surprise and uncertainty in the battle; the weather and terrain; and particularly whether the operations are mobile and offensive or static and defensive. Stress is likely to be higher in the enforced passivity of the static or defensive condition, which generates a feeling of helplessness (Gal & Lazarus, 1975). Again, individual differences in personality, family problems, and prior exposure to combat will be of importance. Active “fighters” are more intelligent and masculine and have more leadership potential (Egbert, Meeland, Cline, et al., 1957). Winners of medals are more persevering, decisive, and devoted to duty (Gal, 1983).

One’s role in combat makes a difference. The higher physiological responses of Israeli officers compared with those of enlisted men are coupled with fewer somatic complaints and breakdowns among the officers.

Leaders are more emotionally aroused but appear to suffer much less decrement in their performance during combat than do enlisted men, although in general, as in the Israeli-Arab confrontations, the officers were much more at risk than were the enlisted personnel. Gal and Jones (1985) suggest that one's perceived role as a leader provides a sense of mastery and control and causes one to concentrate on tasks that distract attention from the realistic dangers.

### ***Stress and Motivation***

As already noted, stress occurs when the group's drive is too high for the demands of the task. When members are blocked from obtaining a goal or from escaping from a noxious condition, their stress increases with their increasing motivation to obtain the goal or escape the situation. Tjosvold (1985b) found that although executives made effective decisions under moderate levels of motivation, when faced with a crisis, their performance deteriorated and quick solutions requiring the least effort were chosen instead of high-quality ones.

Since cohesiveness and commitment imply heightened motivation to attain goals, more stress should be seen in cohesive than in noncohesive groups. When J. R. P. French (1941) frustrated groups of cohesive teammates and groups of strangers who were lower in cohesiveness, the more cohesive teams experienced greater fear and frustration. Similarly, Festinger (1949) reported that more complaints that were suggestive of stress appeared among more cohesive groups. Also, M. E. Wright (1943) found that more cohesive pairs of friends exhibited more aggression when frustrated than did pairs whose cohesiveness was lower.

Given a high degree of group drive, the group members' sensed inability to obtain the group's goals or to escape from danger increases the likelihood of stress. Groups that are unable to interact easily or that do not have the formal or informal structure that enables quick reactions are likely to experience stress (Bass, 1960). Panic ensues when members of a group lack superordinate goals—goals that transcend the self-interests of each participant. Mintz (1951) found that when members of an experimental group in a crisis sought uncoordinated individual reward (or the avoidance of individual punishment), panic was likely to ensue. If the group was organized and perceived a single goal for all, such panic did not materialize. Similarly, in an analysis of anxiety in aerial combat, D. G. Wright (1946) concluded that an aircrew could cope with stress when a common threat was perceived and when a common goal and action toward it were maintained under an apparent plan of action. Clearly, the leader who can transform a group of members with different self-interests into a group with goals that transcend their own self-interests will make it possible for the group to cope more effectively with potentially stressing circumstances.

### ***Stress and Structure***

An individual is stressed when he or she is highly motivated to escape threat or to obtain highly valued goals but is unable to respond adequately, unready to react, untrained, and inexperienced. Increased preparedness and overlearning are ways of helping the individual to cope with anticipated stressful situations. At the group or organizational level, the reliability and predictability of the group's response become essential. Everyone needs to know what everyone else is likely to do. Roles must be clear and free of conflict and ambiguity. Structure, through an informal or formal organization, becomes important. Thus, Isenberg (1981) demonstrated, in an experiment with four-person groups who were making decisions under the stress of the pressure of time, that the structure of relations increased and leadership became more salient. Differences in how much time the members were able to speak increased. Again, Gladstein and Reilly (1985) found that when stress was induced in a business simulation by introducing threats and time pressure, decision making became centralized. A small

number of members had much more influence than did others in the group than when time pressure and threatening events were absent.

When a group does not have the necessary structure to meet emergencies and threats, the initiation of such a structure by a strong leader is seen as needed and useful to the group. Path-goal formulations<sup>5</sup> examine such requisite leadership behavior when the roles of workers are unclear. When subordinates have clear perceptions of their work roles, the leader's initiation of structure is redundant. However, the leader's initiation of structure should help highly motivated subordinates with less clear role perceptions to perform their jobs and thus increase their satisfaction and performance. Schriesheim and Murphy (1976) found that job stress, like the lack of structure, moderated the initiation of structure–job satisfaction relationship, as expected. In J. R. P. French's (1941) previously cited investigation, eight organized groups (with elected leaders) and eight unorganized groups were studied. Frustration was produced by requiring the groups to work on unsolvable problems. Unorganized groups showed a greater tendency to split into opposing factions, whereas the previously organized group exhibited greater social freedom, cohesiveness, and motivation. The greater the differentiation of function that occurred with organization, the greater was the interdependence of members and unity of the group as a whole.

The need for structure at the macro level, as well as at the individual level, was seen by Sorokin (1943). In times of disaster, ideal human conduct depends on a well-integrated system of values. The values conform to the ethics of the larger society. There is little discrepancy between values and conduct. But individuals who engage in antisocial and delinquent behavior (murder, assault, robbery, looting, and the like) tend to be guided by self-centered, materialistic, disillusioned ideologies. They are not integrated into a larger organized effort. The wanton massacre of inmates of a penitentiary in New Mexico in early 1980 by berserk fellow prisoners was partly attributable to the lack of organization in the prisoners' rebellion and the sudden complete availability of drugs (Hollie, 1980).

Gal and Jones (1985) noted that a strong informal structure within a military unit helped reduce the perceived stress of combat. Elite units, with strong bonds between comrades and leaders, were found to suffer less stress, as evidenced by much lower psychiatric casualty rates, despite greater exposure than ordinary units to the risks of high-intensity battle.

## A Model of Group Responses to Stress

---

Janis and Mann (1977) looked at responses under stress that were induced by conflict in the face of an impending threat and the risks and costs of taking action to avoid stress. They argued that the completely rational approach to an authentic warning of impending danger would be a thorough examination of objectives, values, and alternative courses of action. Costs and risks would be weighed. A final choice would be based on a cost-benefit analysis. Included in the effective process would be development, careful implementation, and contingency planning. But such vigilance, thorough search, appraisal, and contingency planning are likely to be short-circuited as a consequence of emotional arousal and the socio-emotional phenomena generated by the impending threat. Various defective reactions to the warnings of danger are likely to occur. These reactions include adherence to the status quo, too-hasty change, defensive avoidance, and panic.

### *Unconflicted Adherence to the Steady State*

One inadequate reaction is the hasty decision that dealing with the threat involves more serious costs and risks than doing nothing. The threat is disbelieved and disregarded. People remain in their homes despite slowly

rising floodwaters and warnings to evacuate. An inadequate analysis, in which appropriate information is ignored, sees the costs of evacuation as greater than the risks of remaining. This response is less likely in the case of sudden threats, such as tornado warnings. Analogously, the energy crises of 1973 and 1979 had built up for 20 years in the face of inertia to cope with them adequately. The threats to the environment of the depletion of the ozone layer, acid rain, and the greenhouse effect likewise failed in the 1980s to mobilize the necessary public support for a political effort to deal with the threats. But in 1941, full national commitment and mobilization to deal with the Japanese threat, signaled by the attack on Pearl Harbor, was instantaneous.

Staw, Sandelands, and Dutton (1981) pointed to the increased rigidity in organizations when they are threatened. Consistent with this, Gladstein and Reilly (1985) engaged 128 MBA students in a full six-day business simulation to show that threatening events and the pressure of time each systematically constrain decision-making processes by reducing the amount of information used by the groups before they reach their decisions.

### ***Hasty Change***

If the costs and risks of taking action to deal with a perceived threat are thought to be low, a new course of action is adopted, often too hastily, without an adequate examination of the threat, risks, and long-term implications. People who experience a high degree of tension from an intense structural strain in the social or political fabric become susceptible to the influence of rebel leaders who promise to restructure the situation quickly, particularly if the established leadership fails to do so (Downtown, 1973). A field investigation by Torrance and staff (1955) reported that air crews who were “forced down” and faced simulated difficulties of surviving in “enemy” territory tended to turn to immediate but ineffective solutions to their problems and to concede more to comfort as their stress level increased. For example, as the hardships increased, they chose to travel on roads in “enemy” territory instead of traveling over routes where they were less likely to be seen.

Rapid, decisive leadership is valued highly under conditions of perceived threat to the group. Executives and politicians incrementally “put out one fire after another,” drifting into a new policy to cope with each successive threat, rather than formulating a new policy based on a thorough search, appraisal, and plan (Lindbloom, 1959).

### ***Defensive Avoidance***

When the risks of change are seen to be high and the current course of action is maintained because of fatalism and a sense that no better course can be found, the various Freudian mechanisms, such as rationalization, displacement, fantasy, and denial, provide psychological defenses to avoid the threat, rather than to cope rationally with the danger. Particularly common to managers in large organizations, according to Janis (1972), are procrastination, shifting responsibility (buck passing), and bolstering—providing social support for quickly seizing on the least objectionable choice. These are defective ways of dealing with a threat.

### ***Hypervigilance (Panic)***

If the threat contains time pressures and deadlines and if individual motivation to escape the threat is high, hypervigilance (panic) may set in. Defective search is illustrated by the failure to take the time to choose a satisfactory escape route from a fire. Instead, a person in panic, in a highly suggestible state, simply starts imitating what everybody else is doing, failing to anticipate the consequences of blocking common exits.

According to a review by A. L. Strauss (1944), the major factors in panic are: (1) conditions that weaken individuals physically; (2) reduced mental ability and lessened capacity to act rationally; (3) heightened emotionality, tension, and imagination, which facilitate impulsive action; (4) heightened suggestibility and contagion, which may precipitate flight; and (5) loss of contact with previous leaders and a predisposition to follow those at hand.

When disaster strikes, panic is not most people's first reaction. Acute fear and attempts to flee the disaster occur only when immediate danger is perceived and individuals see their escape routes blocked (Quarantelli, 1954). Exacerbating the panic reaction is a strong sense of isolation. For some, the unadaptive reaction is to freeze in place or to become blinded to the events occurring around them. (When the atomic bomb was dropped on Hiroshima, many people ceased to feel [Lifton, 1967].) Nevertheless, despite their sense of panic, some people do begin trying to cope with the disaster if they receive no formal directions from authorities.

## Leadership under Stress

---

Informal leadership and temporary groups may emerge if the formal authorities and emergency services cannot deal with the crisis (Mileti, Drabek, & Haas, 1975). The direct removal of the threats and obstacles that are the source of stress may be facilitated. Drive and anxiety may be reduced by providing informal and formal leadership support and an increasing sense of security. Individuals, groups, and organizations that are frozen into inertia and disbelief when they are seriously threatened may be aroused and alerted. Faced with hasty, poorly thought-out decisions, leaders may delay the premature disclosure of options and call for a reconsideration of proposals. When their followers are engaged in defensive avoidance, leaders may bring them back to reality. Panic can be reduced or avoided by strong leadership that points the way to safety.

Thus, leaders can help their groups to cope with stress in many ways. Nonetheless, they also can cause more of it. Yet, as shall be seen, in general, groups with leaders are likely to cope better with stress than are those without leaders. Groups and organizations that are under stress expect and desire more directiveness from leaders. Moreover, whoever takes the role of leader during times of social stress will be expected to revise goals, define common objectives, restructure situations, and suggest solutions to deal with the sources of stress and conflict (Downtown, 1973). But, as shall also be seen, although directive leadership is most expected, desired, and successful when stress is high, it may not always be the most effective style.

The personality-leader linkage will be affected by stress. Under conditions with short, unpredictable time pressures in which unusual physical and emotional exertion is required, such as in military combat, more charismatic leadership will be seen, in contrast to military leadership in noncombat operations (Bass, 1985a). Personal assertiveness may be a stronger determinant of emergence as a leader under stress. It may be less important in determining emergence as a leader in unstressed circumstances.

### ***Leadership May Contribute to Stress***

Unfortunately, as noted above with abusive leaders, leadership may be the cause, rather than the amelioration, of stressful conditions that result in emotionally driven actions by the followers and poorer long-term outcomes. And the leaders who emerge are likely to be different from those in unstressed situations. They may actually contribute to the stress. Political leaders manufacture crises to enhance their own power, to divert public attention from the real problems, and to gain public support for their arbitrary actions.

Those who are elected to office may be more prone to stress themselves. Sanders and Malkis (1982) manipulated the importance and difficulty of a problem and external incentives involving recognition of esteem and success. They found that Type A (stress-prone) personalities were nominated more often as leaders

than were Type B personalities. However, the fewer Type Bs who were chosen as leaders tended to be more effective as individuals in the assigned task than were the Type As (Bass, 1982, p. 135).

Many studies have reported that for subordinates, their immediate supervisor is the most stressful aspect of their work (e.g., Herzberg, 1966). The tyrannical boss is the most frequently mentioned source of stress (McCormick & Powell, 1988). Shipper and Wilson (1992) obtained a correlation of .49 in supervisory goal pressure behavior and perceived tension, according to their 85 hospital employees. Supervisory controlling of details and time emphasis also contributed to tension. Numerof, Seltzer, and Bass (1989) unexpectedly found that when other transformational factors<sup>6</sup> were held constant, intellectually stimulating leaders increased the felt stress and job “burn-out” of their subordinates. Misumi (1985) reported the results of a series of experiments that showed that production-prodding leaders giving instructions such as “Work more quickly,” “Work accurately,” “You could do more,” and “Hurry up, we haven’t much time left” generated detectable physiological symptoms of stress. The systolic and diastolic blood pressure of experimental subjects increased, as did their galvanic skin responses. In similar laboratory experiments, such production-prodding leaders caused feelings of hostility and anxiety about the experiment.

In a sample of police officers, half of their “harmful stressors” were the administrative styles of their superiors (Griggs, 1985). Stressful conditions affect what is expected of a leader, who attempts to lead, and who emerges as a leader. In stressful conditions, leaders differ in the extent to which they promote the attainment of goals, the satisfaction of members, and the survival of their groups.

Nystrom and Starbuck (1984) suggested that top managers can guide organizations into crises and intensify the crises by blindness, rigidity, and the inability to unlearn their inadequate old ways of doing things. In the same way, Sutton, Eisenhardt, and Jucker (1986) thought that the Atari Corporation’s decline and imminent collapse was due to its management’s rigidity in continuing to market products that no longer were selling and their failure to develop new products.

Sometimes the decrement in leadership performance may be a consequence of the external imposition of handicaps on the leaders. Thus, loss of support from a higher authority may weaken the leaders’ influence, control of needed resources, and continued attention to the organization’s purposes. During the early years of the Reagan administration, under James Watt, a director who emphasized deregulation and showed a lack of sympathy for environmental concerns, the Environmental Protection Agency (EPA), came under both clear and unclear threats to its mission from its own leadership, coupled with serious staff and budget cuts. A survey of 181 EPA managers and staff showed a consequential deterioration in their optimism, satisfaction, and identification with the organization and in the quality of supervisor-subordinate relations (Morganthau & Hager, 1981). Again starting in 2001 under the George W. Bush administration, the EPA once again suffered a loss of much of its experienced staff and performance effectiveness.

### ***Effects of Prolonged Stress***

Prolonged stress from internal or external challenges that are too great for the group to deal with can result in the group’s demise. What leads to the death of some groups and the survival of others over a long period of time? Survival of a group, organization, or community under prolonged stress is closely dependent on leadership that is able to maintain the group or organization’s integrity, drive, and goal direction. Such leadership needs to work with increasing the cohesion and dealing with the reduced performance of tasks by groups that are under continued threat.<sup>7</sup> But instead of helping to stave off decline and death, ineffective leaders contribute to the prolonged stress of the group, organization, or community and to its eventual demise.

F. E. Parker (1923, 1927) sent questionnaires to some 3,000 consumer cooperative societies. Among those that had failed, the most frequent reasons were: (1) inefficient leadership and management; (2) declining

interest and cooperative spirit among the members; (3) factional disputes among the members; and (4) members' interference with the management. Blumenthal (1932) attributed the decline of social and fraternal groups in small towns to the departure of young people (the towns' best leadership potential) for the cities.

Munro's (1930) study of community service organizations found that ineffective organizations that were less likely to survive were characterized by ineffective leadership, lack of political sagacity, unwise policies and tactics, spasmodic work, and overorganized and duplicated services. Kolb (1933) and Sorokin (1943) observed that without religious purposes and a commitment to an integrative ideology of religion, such as were fostered by leadership, rural communities were less likely to survive disasters. In reviewing the decline and fall of special-interest groups in rural communities, Kolb and Wileden (1927) pointed to factional competition for leadership and irreconcilable differences between leaders and followers.

Most communes cannot survive for any considerable period without strong leadership to maintain discipline and control (Gide, 1930; May & Doob, 1937). Conversely, a whole commune can commit suicide when led to it by a highly charismatic, paranoid leader, as was the case in Jonestown, Guyana, in 1978. The same situation almost occurred in Germany in 1945, when Hitler pleaded for a *Götterdämmerung* for all Germany, turning in frustration from his fantasy of being Odin the Savior to becoming Odin the Destroyer.

## Successful but Not Necessarily Effective Leadership

---

In [Chapter 21](#), we noted that charismatic leaders emerge in times of crisis. They successfully influence their followers but may lead them astray. The leadership that succeeds in influencing followers may not be most effective in stressful situations, particularly in the long run. It may result in faulty decisions made too hastily or defensive reactions, although it is likely to contribute to escape from panic situations. In crises, political leaders and politically adept executives often win the plaudits of their constituents in the short run, but their decisions may turn out to be ineffective and unsatisfying in the long run:

succeeding in ... managing stressful organizational environment is ... partially due to the exceptionally good political skills possessed by many executives ... manifested in social astuteness and ... behaviors (foster in followers) feelings of confidence, trust and sincerity. ... Executives with political skills ... (allow) ... followers to interpret the stressors in less aversive ways. (Perrewé, Ferris, Frink, et al., 2000, p. 115)

### ***Stress, Hasty Decision Making, and Directive Leadership***

Crisis provokes a centralization of authority (Hermann, 1963). Berkowitz (1953b) found that both governmental and industrial groups were more likely to accept leadership when the problem was urgent. When followers are under stress, they are likely to accept readily the speedy decisions of directive, task-oriented, structuring leaders. However, Goldstein and Hoffman (1995) suggested that followers in crises who see themselves as efficacious may not accept directive leadership as readily. Additionally, speedy decisions do not necessarily provide the best solutions to the problems facing the followers.

It is not the speed of the decision or the leader's directiveness that may result in inadequate solutions to the stressful circumstances. It is rapid decision making without the opportunity for careful structuring and support in advance. For, as shall be seen, rapid decision making is generally sought in crises and disasters but is effective if the decisions are not hastily made at the last minute but are based on advance warning, preparation, and organization, along with commitment and support.

As Janis and Mann (1977) noted, when a threat is finally perceived, it generates the desire for prompt, decisive action. Leadership becomes centered in one or a few persons, who gain increased power to decide for

the group. The price of the rapid, arbitrary dictation is abuse, corruption, and the loss of freedom when power is placed in the hands of the dictator. Hertzler (1940) examined 35 historical dictatorships and concluded that they arose during crises and when sudden change was desired. In addition, Downton (1973) suggested that followers who are stressed by ambiguity become easily influenced by aggressive, powerful leaders who promise to reduce the ambiguity and restructure the situation.

Alwon (1980) argued that administrators of social agencies must adopt a strong, directive style (even if it means changing their leadership style) during times of crisis to avoid dangers and to seize opportunities. In emergencies, when danger threatens, subordinates want to be told what to do and to be told in a hurry. They perceive that they have no time to consider alternatives. Rapid, decisive leadership is demanded (Hemphill, 1950b). Five hundred groups were described on questionnaires by members on a variety of dimensions formulated by Hemphill. The adequacy of various leadership behaviors was correlated with the groups' characteristics. Hemphill concluded that in frequently changing and emerging groups, leaders who failed to make decisions quickly would be judged inadequate.

Considerable evidence is available to support the contention that leaders speed up their decision making as a consequence of stress. Their failure to do so leads to their rejection as leaders (Korten, 1962; Sherif & Sherif, 1953). Acceptance of their rapid, arbitrary decisions without consultation, negotiation, or *participation*<sup>8</sup> is also increased. A leader who can react quickly in emergencies will be judged as better by followers than one who cannot.

Flanagan, Levy, et al. (1952) found that, according to respondents, "taking prompt action in emergency situations" was a critical behavior that differentiated those who were judged to be better military officers from those whose performance was judged to be worse. Large-scale surveys by Stouffer, Suchman, DeVinney, et al. (1949) of American soldiers during World War II confirmed that particularly at lower levels in the organization, the military stressed rapidity of response to orders from a higher authority despite the fact that a unit actually operated under battlefield conditions relatively infrequently.

When rapid decisions are needed, executives are likely to become more directive than participative (Lowin, 1968). Consistent with this finding, the more organizations wish to be prepared for emergency action, the more they are likely to stress a high degree of structure, attention to orders, and authoritarian direction. Fodor (1976, 1978) demonstrated that industrial supervisors who were exposed to the stress of simulated, disturbing subordinates became more autocratic in dealing with the situation. College students did likewise (Fodor, 1973b). Half to two-thirds of 181 airmen, when asked for their opinions about missile teams, rescue teams, scientific teams, or other small crews facing emergencies, strongly agreed that they should respond to the orders of the commander with less question than under normal conditions. In an emergency, the commander was expected to "check more closely to see that everyone is carrying out his responsibility." A majority felt that "the commander should not be 'just one of the boys' " (Torrance, 1956–1957).

In a survey of Dutch naval officers' performance by Mulder, de Jong, Koppelaar, and Verhage (1986), the officers were more favorably evaluated by their superiors if they were seen to make more use of their formal power in crisis situations than in noncrisis situations. In crisis conditions, both the superiors and the subordinates of the officers looked for more authoritative direction from the officers. At the same time, the officers were evaluated more favorably by their subordinates if they were seen to be more openly consultative in noncrisis situations than in crisis situations. Moreover, the referent power of the officers in the eyes of the subordinates correlated .55 with their consultativeness under noncrisis conditions, but the corresponding correlation was .10 in crisis conditions. The officers relied more on formal and expert power in crisis conditions than in noncrisis conditions, according to their subordinates.

Similarly, militant, decisive, aggressive leadership is demanded during the unstable period of a labor union's organization as it goes from one emergency to the next. Under stress, strength and activity take on more importance for leadership. After the struggle for survival is over and the union is recognized, the leadership is

required to change. Now it must exhibit more willingness to compromise and to cooperate (Selekman, 1947). Confrontation must change to consultation.

Individuals who are more predisposed toward direction and the initiation of structure are more likely to try to take charge when their groups are stressed. They will preempt the leadership role from members who would consult with others before taking action. Given the authoritarian-submissive syndrome, authoritarians who are assigned to the roles of subordinates will be more ready to submit unquestioningly to the dictates of whoever has been assigned the role of leader. Lanzetta (1953) found that aggressive members were more likely to emerge as successful leaders when laboratory groups were stressed by harassment, space, and time restrictions than when no stress was induced. Along similar lines, Ziller (1954) concluded that leaders who accepted responsibility for their groups' action under conditions of uncertainty and risk were also relatively unconcerned about what the groups thought about the issues.

The same results appeared in still a different context. Firestone, Lichtman, and Colamosca (1975) showed that initially leaderless groups with assertive leaders responded more frequently and more rapidly to a confederate member's "diabetic reaction" than did groups whose leaders were less assertive. In such emergencies, unassertive leaders tended to be replaced. The holding of the American embassy staff in Teheran in 1979–1980 is a classic example of how an external threat dramatically increased the followers' (in this case, the American public's) support for strong leadership to deal with the threats. Ranks were closed, dissension was muted, and rapid decision making was sought from President Jimmy Carter with little examination of the causes, intensity, and risks of the threats or of the costs of taking actions to deal with them. If anything, President Carter failed to come on as strongly and decisively as demanded, although he was effective in ultimately obtaining the release of the hostages. In the face of crises, nations condemn the vacillating, indecisive leader and applaud the would-be hero-savior (Hook, 1943). President Ronald Reagan was much more popular for being seen as bold and decisive in dealing with the Lebanese crisis in 1983, yet his actions were disastrous. Again, George W. Bush's boldness and decisiveness after the World Trade Center calamity of September 11, 2001, gave him soaring popularity, with more than 90% public support. But when, in the five years that followed, his reactions led to the quagmire in Iraq, his popularity plummeted to only 30%.

When calamity threatens, followers want immediate action to escape. The leader's attempts to influence them will be accepted and complied with more readily than when such stress is absent. Although a participative discussion may make for better solutions, holding one to generate a high-quality decision to which the group is committed may be unacceptable. The commitment will come from the followers' restriction of the options they think they have. The leader who shows initiative, inventiveness, and decisiveness is valued most (Barnard, 1948). Helmreich and Collins (1967) observed that participants who faced a fearful experimental situation showed less of a preference for the company of peers and favored being in a leader-dominated group. Polis (1964) also found that under stress, individuals tended to manifest a need for strong leadership and to continue their association with the group. Again, Wispe and Lloyd (1955) concluded that of 43 sales agents, those who generally were less secure and more anxious were also more in favor of their superiors making decisions for them.

One reversal of the call for rapid-decision leadership in crisis conditions was found by Streib, Folts, and LaGreca (1985) in 36 retirement communities. Most residents were ordinarily satisfied to let others make decisions for them, but they wanted the chance to be involved in decision making if crises arose or the stability of the community was threatened. Another contingency was demonstrated in an experiment by Goldstein (1995). When followers had high self-efficacy, they desired less directive leadership no matter how they perceived the leaders' efficacy. But if the followers were low in self-efficacy, they sought mainly a directive leader when they perceived that the efficacy of the leader was high.

### ***Directive Leadership and Prolonged Stress***

When stress is chronic or prolonged, the same tendencies toward directive leadership and acceptance of it are observed. During World War II, Japanese-American residents of California were interned and subjected to isolation, loss of subsistence, threats to loved ones, enforced idleness, and physiological stress. As a consequence, the internees were apathetic and blindly obedient to influence (Leighton, 1945). Similarly, Fisher and Rubinstein (1956) reported that experimental participants who were deprived of sleep for 48 to 54 hours showed significantly greater shifts in autokinetic judgments, which indicated that they were more susceptible than normal to the social influence of their partners.

Hall and Mansfield (1971) studied the longer-term effects of stress and the response to it in three research and development organizations. The stress was caused by a sudden drop in available research funds, which resulted in strong internal pressures for reduced spending and an increased search for new funds. As would be expected, the response to the threat was to increase the control and direction by the top management and to reduce consultation with the researchers. Subsequently, the effect on the researchers over two years was to decrease their satisfaction and identification with the organization. However, their research performance was unaffected.

To conclude, directive leadership is preferred and will be successful in influencing followers under stress. But such leadership may be counterproductive in the long run.

### ***Leadership and Defensive Avoidance***

As was already noted, often it is the political leadership that contrives the threats, crises, and ambiguities. For centuries, political leaders have used real or imagined threat to increase the cohesiveness among their followers and to gain unquestioning support for their own dictates. The common scenario begins with economic weakness and dislocation, followed by international complications, revolution and sometimes civil war, and finally a breakdown of political institutions. The dictator organizes ready-made immediate solutions that soothe, flatter, and exalt the public but do not promote its well-being. Blame is directed elsewhere.

When business and governmental leaders are seen to consult and share decisions with subordinates in times of crises (Berkowitz, 1953b), it is often because they seek bolstering from their subordinates about the wisdom of their already-chosen solutions. Also, they would like to spread the responsibility for the decision from themselves to their group.

*We-They Relations.* “We-they” discrimination is encouraged by leaders of groups that are in competition and conflict with each other. In-group and out-group differences are magnified. The power of the leaders of the groups is strengthened. Deviants are not tolerated. Thus, Mulder and Sternerding (1963) found, as expected, that when individuals feel threatened from outside, they tend to depend on strong leaders. The leaders, in turn, promote a variety of defense mechanisms as pseudosolutions to the stressful problems facing their constituents. Scapegoats are found to account for the social malaise and economic failures. Fanciful promises of a bountiful future are put forth and accepted. Real social, economic, and political issues are avoided and imagined dragons are slain.

Avoidance can be accomplished by physical self-segregation. This was observed by Hayashida (1976) in the in-group and out-group relations of leaders in organizations under the stress of conflicting ideas with outsiders. The leaders of 146 students in an evangelical Christian organization, whose stated beliefs diverged from the cosmopolitan culture of the campus, isolated themselves formally and informally from the rest of the campus. They coped with intergroup conflict by avoiding it.

### ***Leadership and Panic***

The ready acceptance of leadership, which may encourage maladaptive hasty decision making and defensiveness, is also seen in panic conditions. But here, leadership generally seems to offset maladaptive reactions to the panic. Kugihara, Misumi, Sato, and Shigeoka (1982) simulated a panic situation of 672 undergraduates in groups of six. In each group, one student was elected leader. Successful escape from the panic was more likely when the leader was in the same room as the other members than when the leader was placed in another room and was unable to determine the disposition of the members. Conceding to others was higher, and less jamming and aggression occurred, when the leader was present. Other Japanese experiments with simulated panic demonstrated that the greater the ratio of trained leaders to followers, the faster was the escape and the less the jamming and aggression (Misumi & Peterson, 1987).

Hamblin (1958b) found that followers were more willing to accept the influence of leaders during crises than during noncrisis periods. They gave leaders more responsibility and were seen as more competent in coping with the panic that had been induced experimentally. In the same way, A. L. Klein (1976) observed, in an experimental study of panic conditions of too many people trying to escape through the same door, that the stress group preferred a strong leader rather than a leader who was elected under low stress and was more highly acceptable. Acceptance and election, which gave the accepted legitimate leader control of the group's fate under conditions of low stress, was replaced under conditions of high stress by the group's choice of a less legitimate but stronger leader, whom the members thought was more competent.

## Stress and Effective Leaders

---

Leadership that is effective in coping with stress implies leadership that results in rationally defensible, high-quality decisions; the appropriate use of available information, skills, and resources; and the enhanced performance of followers in reaching their goals, despite the threats and obstacles to doing so. Reducing stress in the workplace increases productivity (Perry, 1999). House and Rizzo (1972b) and Gillespie and Cohen (1984), among others, showed the importance of leaders in helping their groups cope effectively with conflict and stress. In this respect, individual differences among managers are apparent. Lyness and Moses (1989) were able to separate 258 high-potential AT&T managers by the managers' comfort in ambiguous environments. According to Moses and Lyness (1988), adaptive managers cope far better with stress in assessment centers than those who are overwhelmed by ambiguity. They have a broad perspective, are sensitive to feedback, and use both intuition and logic to deal effectively with ambiguity. They are comfortable in doing so. Managers who are inflexible in their approach also react to ambiguity but are uncomfortable and ineffective in dealing with it. Still other managers ignore or are overwhelmed by ambiguity.

Among the many ways the leader can effectively reduce stress among followers are: (1) identifying sources of stress and encouraging followers to speak up; (2) encouraging positive language and making affirmative thinking contagious among them; (3) organizing flexibility in the followers' schedules and arranging for them to maintain control of what they do; (4) organizing the followers in high-risk groups such as nuclear plant operators, hospital trauma teams, and aircraft carrier flight deck crews into high-reliability teams whose members engage in "heedful interaction," share responsibilities for each other's safety, cross-monitor each other's performance, and track each other's focus of attention (Weick & Roberts, 1993; Weick, Sutcliffe, & Obstfeld, 1999; Xiao, 2002). Among hospital employees using Wilson's Survey of Management Practices to rate their 85 managers, Shipper and Wilson (1992) found that their tension was significantly lower when there was upward communication and participation ( $r = -.54$ ), orderly work planning ( $r = -.55$ ); control of details ( $r = -.24$ ) and emphasis on time ( $r = .31$ ); when the manager was expert ( $r = -.64$ ), delegative ( $r = -.48$ ), and facilitative ( $r = -.59$ ); and when the manager provided feedback ( $r = -.59$ ), recognized for good performance ( $r =$

= -.58), and made goals clear and important. On the other hand, tension was rated significantly higher with goal pressure ( $r = .49$ ). Some of these results may have been attributable to the hospital setting. Decreased tension among 46 employees a year later was associated with highly committed managers who practiced instrumental leadership.

Constant with what we have already noted, Burgess, Riddle, Hall, et al. (1992) concluded from a review of 13 articles on the subject of leadership and stress that increased workload, increased time pressure, and increasing task difficulty degrade team performance, communications, team spirit, coordination, and cooperation. But effective team leaders offset these effects with acceptance of input from other members; collecting performance information; and planning, coordinating, facilitating, and structuring the team to work together. Also, the leaders are approachable and unthreatening. They justify and explain their decisions and actions. They use strategic communication to prepare for crises. They justify and explain their actions. The converse was found for ineffective leaders with stressed teams.

Summing up earlier research, Zaccaro, Rittman, and Marks (2001, p. 471) declared that “team members are likely to display less emotional reactions to stressors if leaders provide clear team goals, clear specifications of member roles, ... unambiguous performance strategies ... and foster a climate where disagreements about team strategies can be aired constructively.”

### ***Requirements Vary with Different Stressful Conditions***

Leadership that deals effectively with stress cannot be summed up in one simple proposition. For instance, anxious groups and groups that are in conflict call for different types of responses from the leader. For anxious personnel, the leader needs to direct attention to the specifics of their problems. For groups that are facing severe conflicts, the leaders must make possible a full analysis of the costs and benefits of pursuing one goal rather than another. Although active, directive, structuring, and transformational leadership are needed, the nature of conflict—socioemotional, interpersonal, or task-related—may make some difference in the extent to which initiation of structure by the leader will contribute to effectiveness (Guetzkow & Gyr, 1954; R. Likert & J. Likert, 1976). But if the leader has the ability and authority and if the situation generates stress, pressure, and tension to achieve success, directive leadership is still the most likely to be effective (Rosenbaum & Rosenbaum, 1971).

In dealing with inertia or defensive avoidance among followers, the leader must challenge outworn decisions and stimulate the followers to rise beyond their own self-serving rationalizations. Followers need to be made aware of their rationalizations and defense mechanisms that conflict with their true values and interests (Reed & Janis, 1974; Rokeach, 1971). Radical speakers attempt to do so by confronting audiences with the contradictions and inconsistencies of popular, accepted points of view.

In dealing with layoffs, managers can help deal with the stress by fair, equitable treatment, employees' participation, advance notification, and taking care of the employees to be laid off with severance pay and outplacement programs. The survivors may also be helped by their leaders through empowering, listening, and coaching (Noer, 1993).

Tsur (2003) demonstrated in a content analysis of 202 speeches that the six Israeli prime ministers between 1949 and 1992 used *anesthetic* rhetoric in Knesset speeches to calm the public in times of Arab-Israeli crises. They pointed out that the causes of the stress were under control and that the leader knew best how to handle the situation. They tended to use only carefully examined, selective information. During such crises, the rhetoric was likely to be less *informational* about past or future events, *mobilizing* of support for actions and policies, *motivating* for future action, *apologetic* to explain mistakes, or *ceremonial* to influence identification with common values.

## ***The Nature of the Task***

The task makes a difference in the effects of leadership in groups under the pressure to reach decisions quickly. Dubno (1968) assembled experimental groups, some with fast-decision-making leaders and others with slow-decision-making leaders. Congruent groups were those with fast-decision-making leaders and tasks that required speed and quick decision making. Incongruent groups were those with slow-decision-making leaders but with tasks that still required speedy performance and quick decisions. With appointed leaders, the most effective groups were those with slow-decision-making leaders who urged the members to arrive at high-quality solutions under the pressure of speed. For groups with emergent leaders, the most effective were those with fast-decision-making leaders who emphasized the high quality of the members' performance.

Butler and Jones (1979) also saw that the task made a difference for 776 U.S. Navy ship personnel. They found that when the risks of accidents were high and hazards from equipment were evident (as among engineering personnel), leadership was unrelated to the occurrence of accidents (presumably, structure was already very high). But in the work setting of deck personnel, in which environmental hazards were less evident and personnel were less experienced and hence less clear and competent about tasks, hazards, and goals, the occurrence of accidents was lower when leaders emphasized goals and facilitated interaction. More of any kind of leadership (support, emphasis on goals, and the facilitation of work and interaction) seemed to reduce multiple accidents for deck personnel but was irrelevant to the accident rates of engineering personnel.

## ***Dealing with Conflict***

Among 84 randomly selected faculty members from 20 departments of two universities, R. Katz (1977) found that the amount of affective and substantive conflict in departments contributed to the felt tension (.49 and .47) and the department's perceived lack of effectiveness (–.28 and –.29). At the same time, for departments that were in conflict, the leader's initiation of structure correlated more highly with the department's effectiveness than when such conflict was absent. The correlation between the leader's initiation of structure in a department and its effectiveness was .63 when affective conflict was high and only .29 when affective conflict was low. The correlation between initiation of structure and effectiveness was .51 when substantive conflict was high and .38 when substantive conflict was low. In an experiment to confirm these findings, participants were hired to perform routine tasks. For a routine coding task, initiation of structure correlated .46 with productivity when conflict was high and –.62 when conflict was absent. Less clear results materialized with a cross-checking task. Consistent with these findings, Katz, Phillips, and Cheston (1976) demonstrated that more directive, structured, peremptory forcing can often be more effective in resolving interpersonal conflicts than more leisurely problem solving.

## ***Task-and Relations-Oriented Leadership***

Although many studies have found that task-oriented leadership is most likely to be effective under stressful conditions, more often, both task-oriented and relations-oriented performance make for effective leadership under stress. Thus, Numerof and Seltzer (1986) showed that having a superior who scored high on the LBDQ in both initiation of structure and consideration was associated with lower felt stress and burnout among subordinates. And as will be seen, leaders who were high in both task-and relations-orientation were most effective in coping with stress conditions in a series of Japanese experiments. At the same time, task-oriented leaders, those who scored low on Fiedler's Least Preferred Coworker (LPC) Questionnaire, were found by

Kim and Organ (1982) to be more sensitive to choosing competent subordinates when stressed by the pressure for effective task outcomes. Sample and Wilson (1965) also found that groups with task-oriented leaders performed better than those with person-oriented leaders under conditions of stress but not under routine conditions. Long-term psychosomatic stress reactions among workers were found in Arvonen's (1995) Swedish survey when immediate supervisors lacked a relations orientation. However, reversed results were obtained by Fiedler, O'Brien, and Ilgen (1969), in a study of American volunteers in Honduras, who found that low-LPC, task-oriented leaders were more effective in relatively stress-free villages, whereas high-LPC, relations-oriented leaders exerted a more therapeutic effect in villages that were under more stress. The reversal may be a function of how task orientation was measured. It may be that in both stressed and nonstressed situations, although relations-oriented, supportive, considerate leadership generally contributes to adaptive performance and satisfaction in the groups and organizations that are led, task-oriented, instrumental, structuring leadership becomes essential, especially when stress and conflict are high. Such task structuring may still contribute to performance in the nonstressed condition, but it may be less essential.

Bliese, Ritzer, and Thomas (2001) pointed out that the reason that evidence is mixed about the importance of leader behavior such as leader support as a buffer against stress among followers is due to: (1) the lack of statistical power in the studies using too few subjects, (2) the lack of connection between the support and the specific source of stress, and (3) the need for WABA analysis to tease out the individual personalities of the stressed raters. They obtained ratings of both commissioned officer and noncom support from 2,403 U.S. Army personnel from 31 companies in two brigades. The assessed stress perceived was interpersonal conflict.

Soldiers in units with a high degrees of leadership support had high continuance commitment to the army even when they perceived a high degree of stress in their work. Cummins (1990) showed that the job stress in their workplace of 96 business students was buffered by supportive (high-LPC) supervisors.

### ***The Intelligence and Experience of the Leader***

In coping with conflict with their own superior officer, subordinate leaders' experience and intelligence appear to have opposite effects (Fiedler, Potter, Zais, & Knowlton, 1979; Potter & Fiedler, 1993).<sup>2</sup> Among 158 infantry squad leaders who perceived a very high degree of stress in their relations with their immediate superiors, the squad leaders' experience, but not their tested intelligence, correlated with their rated performance as leaders (Fiedler & Leister, 1977b). When perceived stress was low, experience correlated between  $-.20$  and  $.00$  with rated performance. When perceived stress was high, experience correlated between  $.39$  and  $.66$  with rated performance. For 45 first sergeants in the U.S. Army who were studied by Knowlton (1979), correlations between their rated performance and their intelligence were between  $.51$  and  $.78$  when they perceived little conflict between themselves and their superiors. The correlations ranged from  $-.04$  to  $.24$  when such perceived conflict was high. Similar findings were obtained by Zais (1979) for line and staff officers in nine army battalions; by Frost (1983) for 123 first-level and second-level superiors in an urban fire department; by Potter (1978) for 103 Coast Guard officers; and by Borden (1980), who collected data from 45 company commanders, 37 company executive officers, 106 platoon leaders, 42 first sergeants, and 163 platoon sergeants in a combat infantry division. Here, the leaders' intelligence correlated  $.44$  with their performance when their conflict with their own superior was low;  $.31$ , when the conflict was moderate; and  $-.02$ , when the conflict was high.

Given the importance of preparedness in coping with stress, the positive impact of experience in dealing with conflict is not unexpected, but the reverse effects for intelligence are yet to be explained. In a bureaucracy, the highly intelligent subordinate leader may be a threat to his or her superiors, who, in turn, downgrade the subordinate's performance. Conflict with superiors appears to be more disturbing to the potentially creative,

intelligent, subordinate leader. The leader who is in conflict with higher authority is likely to have less “influence upstairs,” which reduces the leader’s likely effectiveness and ability to use his or her intelligence.

Fiedler’s (1982) cognitive resource theory is an effort to explain the findings. Fiedler assumed that the intelligent leader’s contributions to the group’s effectiveness depend on his or her direction of plans, decisions, and ideas. But under stressful conditions, the quality of such plans, decisions, and ideas is associated more highly with the leader’s experience than with his or her intelligence. The highly intelligent leader will focus on problems that are not directly relevant to the task and will rely on intellectual solutions to tasks, when the tasks may not be amenable to intellectual solutions. A nondirective intelligent leader will make even less of a contribution to groups under stress, primarily because he or she will prolong the decision-making process, be inactive, or perform poorly.

The cognitive resource interpretation was supported by data about the effectiveness of staff leaders of U.S. Army mess halls, U.S. Army squad leaders, and leaders of public health teams (Fiedler, 1986). Cognitive resource theory explained why leaders with fluid intelligence (the ability to solve new and unusual problems) contributed to high-quality decisions and effective analyses of problems when stress was low but leaders with crystallized intelligence (the ability to solve problems on the basis of previous learning and experience) did better when stress was high (Fiedler & McGuire, 1987). An in-basket simulation, completed by 34 ROTC cadets either in a threatening military atmosphere or under relaxed conditions, found that the contribution of the cadets’ crystallized intelligence to the effectiveness of their leadership remained the same under high or low stress. However, the contribution of their fluid intelligence (analysis of problems, decisiveness, and planning and organizing) to their effectiveness was significantly lower under the high stress (McGuire, 1987).

In a study of 130 Coast Guard officers, Potter and Fiedler (1981) found that the contribution of intelligence to performance was not related to conflict with one’s boss in carrying out routine staff work, but it was negatively correlated with the effectiveness of decision making for those officers who engaged in policy making when conflict with their own boss was high. Fiedler, Potter, and McGuire (1988) concluded that the stress of conflict with one’s superiors may interfere with the leader’s ability to develop plans and make sound judgments, to communicate these plans to the group, and to supervise and monitor their implementation. However, they noted that the available evidence suggests that such conflict primarily interfere with the leader’s ability to analyze the problem and make sound judgments and decisions rather than with the communication or implementation of decisions, plans, and strategies.

### ***Dealing with Losses***

If a sales crisis hits, business crumbles, and a large number of employees have to be laid off, management can do much to alleviate the resulting distress. Managers can set realistic expectations, keep employees informed, and implement even-handed layoff policies. They can allow employees to leave with dignity, help displaced employees find new jobs, and provide ceremonies to reduce frustration and anger. In handling the reduced demand for products and plant closings, the management of IBM in the 1980s tried to maintain the employees’ felt and actual job security by redeploying displaced employees elsewhere, encouraging early retirement, and discontinuing overtime. They found temporary employment with others and contracted out work to subcontractors in times of temporary surplus loads (Greenhalgh, McKersie, & Gilkey, 1986). This is the model that larger and better-known Japanese firms pursued before the economic downturn of the 1990s.

### ***Mergers***

Schweiger, Ivancevich, and Power (1987) noted that when one firm is acquired by another, the employees in

the firm that was taken over are stressed by the loss of identity, purpose, and ego ideal. Shock, anger, disbelief, depression, and helplessness are frequent responses, as is anxiety because of the lack of information. The employees see the resignations and forced departure of others as a loss of talent as well as a threat to their own security. Survival in the reorganization becomes an obsession. Transformational leadership is needed to deal with the merger of the acquired firm's culture and that of the firm that is taking over. It may contribute to creating a new culture in the acquired firm or to a new one that transcends both firms. The contingent reward system for the future needs to be clearly communicated as well as feedback on how it is working. Again, support, consideration, and commitment at each level of supervision in the acquired firm are essential to cope with subordinates' stress. It is particularly important, if it is possible to do so, for those with leadership responsibilities in the acquired firm to "get information about the acquiring firm for their subordinates; identify counterparts in the other firm and make contact and help subordinates to understand that their counterparts in the acquiring firm are not the bad guys and, in many cases, are in a situation similar to their own." (Schweiger, Ivancevich, & Power, 1987, p. 135).

At all levels in the firm, transformational leadership can help subordinates and colleagues end their previous attachments to the scene before the takeover. It can help reduce the tensions of disengagement accompanied by the disidentification with the old situation and disenchantment with the new that may produce disorientation without anchors to the past or the future. Leaders can help colleagues and subordinates work through their denial and anger and move toward acceptance of the new situation (Tichy & Devanna, 1986). Assistance with out-placement may buffer the losses experienced by those squeezed out of the organization by the merger.

### ***Change of Leaders***

Lanzetta (1953) found that different leaders emerged in the same groups as more stressful conditions were imposed. Groups, organizations, and communities under stressful conditions may remedy the inadequacies of their leadership by changing either the group or the leaders. Hamblin (1958b) observed that members of experimental groups, when facing genuine crisis situations, tended to replace their old leaders with new ones if the old leaders were unable to cope with the crises.

### ***Combat***

High morale and less stress are found in soldiers in combat who have confidence in their commanders (Gal & Jones, 1985). This confidence is seen in the judged professional competence of the commander, the belief in his credibility, and the perception that he cares about his troops. But under continuing combat stress, professional competence becomes particularly important, according to Kalay's (1983) study of Israeli soldiers in combat in Lebanon in 1982.

According to an initial draft of a special edition of U.S. Army Field Manual FS-100 (1997), leaders are responsible for protecting their subordinates from the stress of battle fatigue by ensuring that their subordinates know what they are capable of doing. Training must be realistic, tough, and demanding. Exaggeration of the enemy's capabilities should be avoided. The leaders should conduct after-action mission reviews after every mission to keep subordinates informed and involved. They should also help their subordinates to talk through personal and mission problems. Both leaders and subordinates need plans for sleep, rest, and standing down to an area of lower risk. The leaders' superiors need to be advised of the needs. Replacements of casualties need to be welcomed and integrated quickly. Above all, the leaders need to look and be calm and in control. They must handle subordinates' anxiety by keeping them informed (pp. 8–17, 18). They also need to be authentically authoritative (Gal, 1985).

## ***Dealing with Panic***

Strauss (1944) observed six elements that reduce panic. These elements were (1) calm, intelligent leadership; (2) group discipline and morale; (3) rational action according to a plan; (4) prior training; (5) sound physical health; and (6) attention directed toward a realistic appraisal of conditions and alternatives.

The effect of clear, unambiguous direction can be seen in Japanese experiments by Sugiman, Misumi, and Sako (1983) and by Sugiman and Misumi (1984). These experiments demonstrated that in an emergency, a speedier evacuation from a simulated underground shopping arcade of a railroad station by city employees was obtained when the leader told one of the subjects, "Follow me," and led the way to the exit. Evacuation was slower when the leader gave instructions to the subject, indicating the exit in a loud voice and with large gestures. The investigators suggested that the "follow me" method using one subject worked because small groups tend to congregate around leaders. However, the "follow me" method worked better when one leader was involved with four other persons rather than eight others (Sugiman & Misumi, 1988).

The most effective leaders in helping groups to escape from panic conditions display high performance maintenance (PM) leadership. In the previously mentioned study by Kugihara, Misumi, Sato, and Shigeoka (1982) in which a panic situation was simulated in six-person groups, aggressiveness, the percentage of successful escaping, and the degree of jamming were measured. Four styles of leadership were compared. The percentage of successful escaping was highest and aggression was lowest in the PM condition, in which leaders focused on both performance planning and the maintenance of relationships, rather than on only one or the other or neither. PM leadership behavior was seen as most appropriate by the subjects. In addition, Misumi and Sako (1982) found that it was important first to provide the support and encouragement and then to concentrate on the requirements of performance, rather than vice versa.

Kugihara and Misumi (1984) compared subjects who dealt with a maze under fearful and unfearful conditions. Consistent with the previously cited Japanese experiments of reaction to simulated panic, they found that PM leadership generated the least fear, the largest amount of planning, and the least unreasonable felt pressure from the leader compared with P leadership or M leadership alone or the absence of both.

## ***Dealing with Disasters***

A body of observation, commentary, and research on coping with disasters points to the critical contributions of leaders and public managers who are well organized, well prepared, and well trained to provide both the needed instrumental and supportive leadership (Harman, 1984). At the mass populace and community levels, this translates into leadership that provides credible warning systems and advanced preparation for when disasters actually strike. The absence of such effective leadership and management is marked by maladaptive coping, defensiveness on the part of the public, and exacerbation of panic reactions. At the organizational level, Mitroff, Shrivastava, and Udwadia (1987) advocated both technical and behavioral preparation for crisis by organizations. Management needs early warning systems, high-quality control, and crisis command centers. Among other things, employees need training in security and detection, as well as emotional preparation for emergencies. Weinberg (1978) reviewed 30 cases of the behavior of groups during disasters: earthquakes, blizzards, accidents, and hurricanes. Trained judges examined each case history. Weinberg found that breakdown occurs in situations of high stress when there is an absence of appropriate leadership. Effective coping occurs with leadership that provides the needed support, structure, and preparations. For example, according to Hammerschlag and Astrachan (1971), in the Kennedy Airport "snow-in" of February 1969, the assembled people became passive, compliant, helpless, and without initiative and indigenous leadership.

Salvation was predicted on the arrival of some technical authority who could ensure their deliverance—a “leader,” the “omnipotent one,” who would clear runways, facilitate their departure, feed the hungry, and make everyone happy. The persons in the snow-in never became collaborating groups. There was no task that could have unified them. They developed a sense of abandonment, which was internalized as a retribution for some fantasized wrongdoing. Food swindling and hoarding began to occur. The people did not see the need to initiate planning and coordinating with others.

*Initiating and Maintaining Structure.* Tests of the Lawrence-Douglas County, Kansas, emergency preparedness system demonstrated that the structure needs to be ready for future disasters and that there must be a strong chain of command. Resources must be well organized and the staff highly trained (Watson, 1984). Citywide drills for ambulance drivers were seen to have paid off in the handling of the Hyatt Regency disaster in Kansas City (Ross, 1982). Similar conclusions about preparation for emergencies were reached in Alexandria, Virginia’s, dealing with a disastrous flood (Harman, 1984).

The need for structure and prepared response is the reason why local public service agencies, such as police, fire, ambulance services and public works departments, are the critical human resources whose effective utilization is paramount in times of crisis (Dynes, 1970; Kartez, 1984). Furthermore, the available leadership of these resources makes a difference in the effectiveness of the organized response to disasters. The most effective organizations maintain their own identity and do not depend on outside help from volunteers. The least effective organizations have an amorphous structure, and their leadership is elected or composed of quasi-professional persons who operate with volunteers who are not subject to discipline (Form & Nosow, 1958). In metropolitan Dade County, Florida, emergencies are dealt with by stripped-down administrative processes, rapid decision making, and emergency powers to mobilize resources when needed, as occurred in handling the Mariel boat lift and the influx of Haitians (Stierheim, 1984). Informal social networks can serve as the needed structure, according to an experiment using computer simulation of linkages of friends (Harvey, Kelloway, & Duncan-Leiper, undated). The delay and inadequate response of the Federal Emergency Management Agency to Hurricane Katrina, which devastated New Orleans and much of the Gulf Coast in August 2005, could be attributed in part to severe budgetary cuts and loss of much of FEMA’s experienced personnel, its becoming part of the larger Homeland Security Agency, and the political replacement of its effective director with a director without credentials for the position. Both effective leadership and structure were missing.

*Planning for Contingencies.* Crises can be prevented or their stressful effects mitigated by effective political leaders who plan ahead (Yarmolinsky, 1987). Effective transactional leaders set up early warning mechanisms to avoid surprises that arise from hasty, ill-conceived responses. Active practice of management by exception can result in the rational recognition of potential crises. By planning ahead, anticipating potential crises, and preparing the group for crises, leaders will be more effective than if they deal only with immediate problems. Studies of leadership behavior in a public utility company, an insurance office, an automobile plant, and heavy industry found that supervisors of groups with better production records more often engaged in longer-range planning and anticipated future problems instead of limiting themselves to day-to-day operations (D. Katz, 1951).

Failure to plan ahead for contingencies such as loss of access to the disaster site, as occurred in the Flixborough, En gland, disaster in 1974 with the explosion at and destruction of a chemical plant, resulted in chaotic evacuation and impeded the arrival of emergency services (Bodycombe, 1982). Yet a preset structure and roles can be vulnerable to destruction and may prove too rigid for appropriate responses to disasters, such as earthquakes (Lanzara, 1983). Contingent planning, which sets response priorities on the basis of past experiences and future expectations of natural and man-made calamities, is necessary (Spencer, 1981). Minor crises, such as the shortage of supplies, that disrupt work can be the subject of similar planning (Bensahel, 1981).

*Establishing and Maintaining Communication Plans.* Planning for emergencies calls for planning

communication strategies. The news media overreact at first. The available information is likely to be sketchy or incorrect, and the location and timing of an emergency are likely to be inconvenient. Communication plans are essential for the effective management of a crisis (Clark, 1986). Potentially destructive rumors need to be squelched (McSweeney, 1976). A center can be set up to provide frequent news about the disaster to the public (Kemp, 1984), along with an emergency resource catalog of suppliers of services and equipment (Ross, 1982). A survey of 1,500 companies to find who was responsible for getting crisis information to employees indicated that 55% of the corporations had such a plan to alert personnel and deal with emergencies (Anonymous, 1984).

Communication plans should be prepared for the worst possibilities. They should be formulated especially in developing countries, where information is distributed mainly by word of mouth (Hall, 1985).

*Using Past Experience.* Recurrent disasters can be the source of learning and improvement of responses to them. Personnel managers learned how to handle pay for employees who are trapped by a snowstorm and what kinds of nonperishable supplies should be stored (Garlitz, 1983). In reviewing the Mount St. Helens volcanic disaster, Kartez (1984) suggested that responses to emergencies can be more effective when recurring individual and organizational patterns have been recognized and institutional plans are developed with these patterns in mind.

The importance of learning is also demonstrated by the fact that the most highly organized preparation exists in communities that have had repeated and recent experiences with similar types of disasters (Mileti, Drabek, & Haas, 1975). Furthermore, organizations that deal with predictable kinds of disaster, such as recurrent floods, are likely to be more effective than are those that attempt to cope with unfamiliar or erratic calamities, such as volcanic eruptions or once-in-a-lifetime earthquakes (Cuny, 1983). But learning may also have negative consequences. Community leaders will increase their delay in communicating warnings depending on the amount of prior experience they have had with such warnings. Previous experiences with a disaster may condition a false sense of security ("We had our 'once-in-a-hundred-years flood' last year") (Mileti, Drabek, & Haas, 1975).

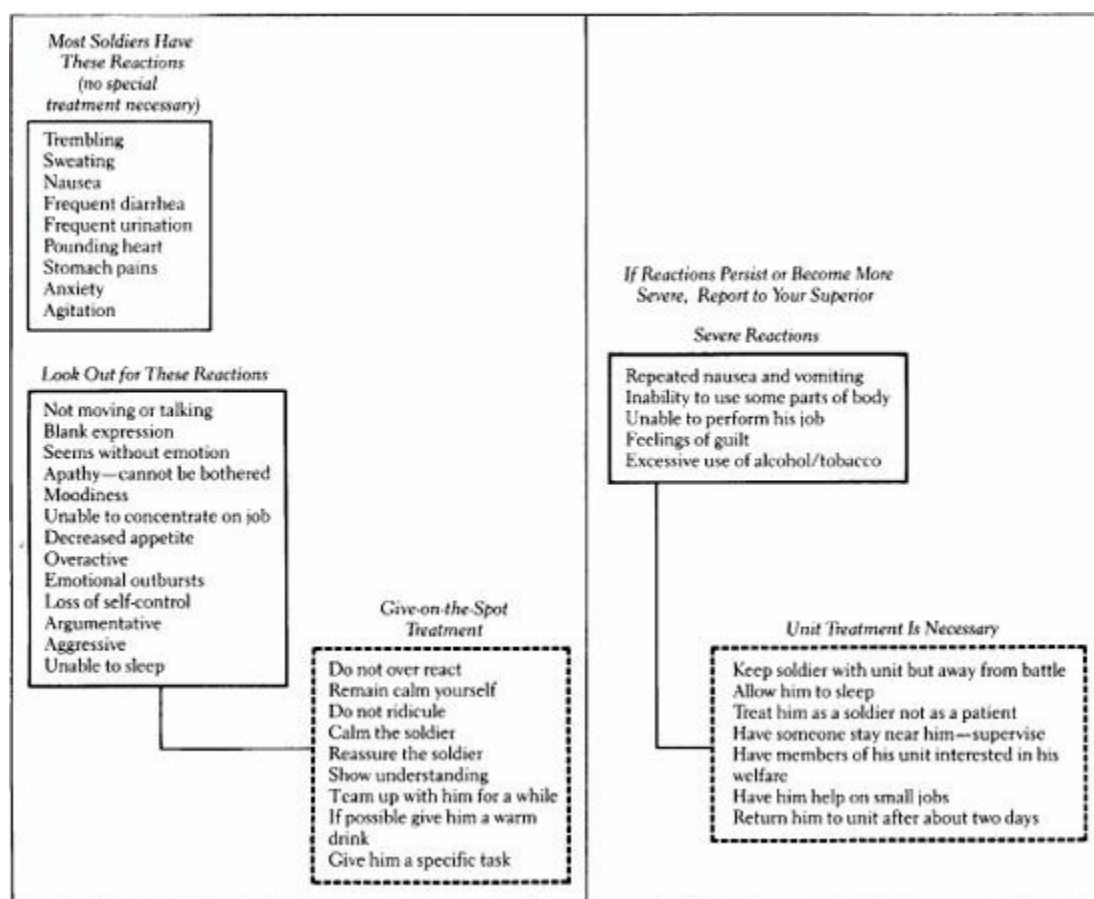

### ***Dealing with Prolonged Stress***

The survival of a group under conditions of extreme hardship depends on the competent exercise of the leadership role and the maintenance of the group's unity, goal direction, and communications. Under conditions of extreme hardship and stress, a group's chances of survival are enhanced when it has a leader who maintains its integrity, keeps it realistically informed of the situation confronting it, fulfills members' expectations, is willing to act outside the bounds of stated authority, maintains its commitment and goal direction, and is able to transform members' personal concerns into concerns for achieving the group's goals. Evidence of the importance of this type of leadership is contained in Stockdale's (1987) autobiographical account of how, as the senior ranking American officer in an extremely stressful Vietnamese prisoner-of-war camp, he provided a purposeful and meaningful structure for the prisoners, establishing priorities and rules, stressing the need to resist early, and determining the conditions under which to take torture. He emphasized cohesion with the rule that all were to go home together.

To illustrate both the task-oriented and supportive actions that leaders can take to help subordinates who are reacting maladaptively to continued stress, [Figure 28.1](#) shows an actual packet guide, *Stress in Battle*, prepared by the British Army's Personnel Research Establishment for noncommissioned officers and junior commanders to carry into combat. Note that some stress reaction is considered normal and requires no remediation. Note also the importance of leaders' being both supportive and attentive to keep stressed soldiers assigned to specific tasks or to help with small jobs.

The detrimental effect of the inadequate performance of leaders of groups that are under stress—that is, their failure to provide the needed support and structure—was observed by Torrance (1961). Torrance conducted an extensive, outstanding program of research on military groups that were undergoing training for survival. The following leadership behaviors and group conditions were found to produce an adverse effect on the survival of a group: (1) conflict between various echelons of leadership; (2) failure of the formal leader to accept the informal leadership structure; (3) formation of cliques, some with resources and others without; (4) the leader's isolation from the remainder of the group; (5) reduction of the power of the group, with the resulting hostility toward the leader; (6) the leader's abdication of customarily performed leadership roles or functions; (7) unwillingness of the designated leader to act outside authority; (8) the group's attempt to function without a designated leader; (9) the leader's failure to fulfill the group's expectations; and (10) the leader's failure to resolve the members' feelings of isolation and loneliness. Stress resulting from differences in values among members or between the leader and the members, the failure of members to give realistic information to others about what they were doing, and the members' failure to give mutual support and to sacrifice their personal goals for the group's goals also tended to jeopardize survival.

Figure 28.1 Combat Stress and Treatment

SOURCE: Adapted from "Part 1: Combat Stress and Treatment," in *Stress and Battle: A Guide for NCO's and Junior Commanders* (courtesy of the Army Personnel Research Establishment, United Kingdom).

## Dealing with Role Stress

LaRocco and Jones (1978) concluded that for 3,725 U.S. Navy enlisted personnel, supportive leadership and facilitation of interaction contributed to job satisfaction and satisfaction with the U.S. Navy. Nonetheless, more initiation of structure was needed to alleviate the effects of stress, such as by structuring work and emphasizing goals, increasing role clarity, and reducing role ambiguity. Consistent with these results, 54

subordinates of 19 unit heads in a national black social services organization, who revealed little on-the-job anxiety, generated a correlation of  $-.45$  between their unit head's initiation of structure and a 17-item measure of their unit's performance (Schriesheim & Murphy, 1976). But the corresponding correlation was  $.15$  for subordinates with strong job anxiety. For the leader's consideration, the figures were reversed:  $.41$  between consideration and performance when anxiety was low and  $-.24$  when anxiety was high.

In a hospital emergency room, problems must be diagnosed correctly and dealt with as quickly as possible to alleviate role stress among ER personnel (Auerbach, 2002). Ziegart (2002) conducted a 15-month observational study of a trauma resuscitation team at an urban shock trauma center. The team was a medical staff of attending surgeons, surgical fellows, anesthesiologists, residents, and students, as well as consultants, nurses, and specialists. The leader might be the attending surgeon or another staff member. Outcomes depended on the team's success in coordinating their abilities and efforts. Computer displays or visual display boards were set up to coordinate personnel by keeping them up to date with incoming surgery patients and changes needed in immediate staffing (Xiao, Lasome, Moss, et al., 2001). According to Ziegart, problem solving, strategizing, teaching, monitoring, and providing contingent reward were seen by members as leader behavior that contributed to team effectiveness. But motivational and inspirational leader behaviors were rare and had no impact on the performance of the team. Murphy (2002) demonstrated that leaders who are socially and emotionally intelligent cope with their roles in such stressful conditions by exhibiting self-regulation and efficacy.

### ***Dealing with Burnout***

As assessed by the Maslach Burnout Inventory (1986), prolonged stress manifests itself in *burnout*, the feeling of being exhausted by one's work, the development of depersonalization (impersonal responding to service), and indifference to personal accomplishment. Among 90 Japanese airline employees, *exhaustion* and *depersonalization* were moderated by supervisory support (Tourigny, Baba, & Lituchy, 2005).

### ***Transactional and Transformational Leadership***

Denston and Sarros (1995) reported that 12% less emotional exhaustion and 3% less burnout on the Maslach inventory among 480 Australian law enforcement officers was accounted for by their ratings of their superiors' transformational idealized influence and transactional contingent rewarding. Intellectual stimulation accounted for 4% of the variance in depersonalization. Burnout was greater among junior-ranking officers, in larger departments, and among those with less supportive families. Seltzer, Numerof, and Bass (1989) asked 277 part-time MBA students to complete the Personal Stress Symptoms Assessment (Numerof, Cramer, & Shachar-Hendin, 1984) to indicate how often they experienced headaches, fatigue, irritability, loss of appetite, insomnia, and inability to relax. They also completed the Gillespie-Numerof Burnout Inventory, responding to such items as "I'm fed up with my job" and "My job has me at the end of my rope." Felt stress and burnout correlated  $.58$ . The 277 respondents described their immediate superiors on the Multifactor Leadership Questionnaire (Bass, 1985c). [Table 28.1](#) shows the first-order correlations of the MLQ scores for the transformational and transactional leadership of the superiors and the felt stress and burnout of their subordinates. Seltzer, Numerof, and Bass concluded that 14% of the variance in the symptoms of stress and 34% of the variance in feelings of burnout could be attributed to the lack of transformational leadership. But intellectual stimulation increased burnout when other transformational factor scores were held constant.

In regard to transactional leadership, contingent rewarding was modestly associated with less stress and management by exception with more stress. The pattern was the same for feelings of burnout, but the relations

with transformational leadership was much stronger (Bass, 1988d). In addition to ameliorating the effects of stress and burnout, transformational leaders tend to keep their “cool” when faced with threats to their lives. Mahatma Gandhi, Franklin Delano Roosevelt, Kemal Atatürk, Benito Mussolini, Kwame Nkrumah, and Ronald Reagan displayed composure and presence of mind when faced with attempts to assassinate them. They were not easily frightened, disconcerted, or thrown off balance but remained calm and maintained their sense of humor in the face of danger or crisis (Willner, 1968). They were like medal-winning heroes of military combat. According to Gal’s (1985a) analysis of 77 Israeli medal winners in the Yom Kippur War compared with ordinary soldiers, the medal winners exhibited more leadership, perseverance under stress, decisiveness, devotion to duty, and emotional stability.

Table 28.1 First-Order Correlations of Transactional and Transformational Leadership of Superiors and the Stress and Burnout Felt by Their Subordinates

<i>Leadership</i>	<i>Symptoms of Stress (N = 285)</i>	<i>Felt Burnout (N = 296)</i>
<i>Transformational</i>		
Charisma	-.17**	-.53**
Individualized consideration	-.18**	-.47**
Intellectual stimulation	-.11*	-.36**
<i>Transactional</i>		
Contingent rewards	-.09*	-.43**
Management by exception	.11*	.22**

\*\* $P < .01$ ,  $r = .14$ .

\* $P < .05$ ,  $r = .10$ .

SOURCE: Adapted from Numerof, Seltzer, and Bass (1987).

While transactional leadership can provide for structure and reward, transformational leadership adds to it by helping the followers transcend their own immediate self-interest, increase their awareness of larger issues, and shift their goals away from personal safety toward the safety of the group. Transformational leaders may convert crises into developmental challenges. They may provide intellectual stimulation to promote subordinates’ thoughtful, creative, adaptive solutions to stressful conditions, to replace hasty, defensive, maladaptive ones. The transformational leader may have the charisma<sup>10</sup> to satisfy the followers’ frustrated need for identity and feeling of the lack of social support. In a study of 57 communes over a four-year period, Bradley (1987) showed that the presence or absence of charisma in the commune’s leader contributed to the commune’s likelihood of survival. Communes were least likely to survive if their members were strongly seeking charismatic leadership that was not provided. Those with charismatic leaders were most likely to survive, as were those that did not seek such leadership.

*Transactional Leadership.* Transactional leaders can also be influential in groups that are under stress. They can supply solutions for the immediate needs that members perceive they have. They can set up rapid

reaction systems of active management by exception to deal with emergencies, disasters, panic, and combat conditions. They can employ contingent reward to coordinate reactions to threat. Such leadership will provide perceived efficacy but may not be effective in the long term. What may be required is a transformational leader who can evoke higher-level needs, such as for the common good, and who can move the group into a fully vigilant search for long-term solutions. Mulder, Ritsema van Eck, and de Jong (1971) studied leadership patterns in a Dutch navy flotilla on active duty. The usual interpersonal and task-oriented factors emerged, but what distinguished crisis from noncrisis leadership was that in crises, the leadership was intense, powerful, and self-confident (leadership that characterizes the transformational leader<sup>11</sup>). In non-crisis situations, it took the form of the “mild” person-leader relationship.

As noted in [Chapter 22](#), the best leaders are both transformational and transactional. They deal with stressful conditions by transforming crises into challenges, enhancing the group identity of their followers, providing social support for them, helping to meet material and psychological needs, transcending the immediate circumstances, and planning ahead.

*Transforming Crises into Challenges.* According to Reilly (1990), crises are harmful and disruptive for organizations. She confirmed this conception of crises in interviews and surveys with 71 bank executives and 87 industry experts, plus archival data from 35 banking organizations. Crises are sudden, acute, and of great magnitude, and demand a timely response. They are outside the organization’s typical operations, but they place extreme demands on the organization, especially on managers’ time and attention. To ready itself to meet crises, an organization must have suitably prepared people and technology beyond that required for routine operations. The response to the crisis and its effective implementation are crucial. For this, timely availability and flow of information are essential, and in the aftermath, the strategic implications must be considered by the leadership.

Effective transformational leaders can halt crises by disclosing opportunities, arousing courage, and stimulating enthusiasm. The key here, according to Nystrom and Starbuck (1984), is the need for the leaders to be intellectually stimulating, to foster unlearning, and to eliminate the fixation on old ways of doing things. When the lacing of Tylenol with cyanide struck Johnson & Johnson in 1982, the public relations department had no plans for dealing with such a crisis. The CEO rejected any halfway steps to gloss over the disaster and converted the marketing disaster into an opportunity to gain credit for good citizenship. The firm regained its market share by introducing a more tamper-proof Tylenol package at a time of great public consciousness and publicity about the problem (Snyder, 1983).

Pines (1980) summarized the ways leaders can provide support to make subordinates “hardier” and maintain their high-quality performance and decision making despite the presence of stressful conditions. Dramatic changes can be presented as challenges, not as disturbances. Stress can become challenging if the leaders select subordinates for the stressful conditions who prefer a vigorous, fast-paced lifestyle and have the knowledge, intelligence, and preparation to cope adequately with the stress. Subordinates’ sense that they control their fate can be enhanced and their sense of powerlessness can be lessened. Subordinates’ involvement and commitment can offset their focus on the deleterious effects of the stress. For example, rather than paying attention to the dangerous exposure that he or she sees when looking up or down a vertical cliff face, a climber should focus on the holds and grips that are available immediately in front of him or her.

McCauley (1987) pointed to a number of transformational and transactional ways leaders can enhance subordinates’ performance by converting a potentially stressful situation into a challenging one. The leader needs to ensure that there will be positive outcomes and that the subordinates know what they are. Although it may be difficult, goals can be set that are clear and attainable. Interim rewards for progress can be given. More generally, taxing conditions can be converted into problems to be solved. Self-confidence can be increased, as can the tolerance for ambiguity, uncertainty, and working in new and unfamiliar conditions. Situations that are beyond one’s control can be faced with the recognition that one may be unable to change an undesired state of

affairs. The situation may need to be redefined, goals may need to be changed, and patience may be needed (seemingly insurmountable problems sometimes disappear when they are ignored).

Aside from their better effects on subordinates, leaders who view situations as challenges, rather than crises, tend to be more open to ideas and suggestions from their subordinates, which enables them to make more effective decisions. This tendency was shown by Tjosvold (1984a), who conducted an experiment in which the focal “managers” led confederates of the experimenter in dealing with an issue of the rotation of jobs, which was a crisis condition, a challenging condition, or of minor consequence. The “managers” who thought they were in a crisis situation were most closed-minded. Not only did they feel that they disagreed most with their subordinates, but they were the least interested in hearing more from their subordinates, demonstrated less knowledge of their subordinates’ arguments, and were least likely to change from their original position. In contrast, the managers who thought they were in a challenging situation were most likely to explore and incorporate subordinates’ views (even opposing ones) into their own. They were most likely to indicate the desire to hear more arguments. They most incorporated specific information from subordinates to make a complex integrated decision that would likely promote both the simulated company’s profits and the employees’ satisfaction.

Consistent with Tjosvold’s results, Blake and Mouton (1985a) observed that flight captains were able to respond to a crisis situation more effectively if they readily received information and feedback from their flight crews and were receptive to the information. Similar results were obtained for supervisors of fighters of forest fires. To deal with crises effectively, subordinates need to be ready and willing to provide their leaders with information and feedback and the leaders need to be ready and willing to consider it.

### ***Transcending the Immediate Circumstances***

Instead of autocratic, rapid decisions to make a stressed group ready to accept a leader’s demands, effective leadership in stressful situations organizes group efforts of followers in ways that promote vigilance, thorough search, thorough appraisal, and contingency planning to avoid defective coping with a threat. Bolstering can be minimized by encouraging devil’s advocates. Heterogeneity, rather than homogeneity, can be pursued by selecting members for the group who will promote harder-to-attain creativity rather than quick and easy decision making. Considering the distinctions between frustration, fear, anxiety, and conflict, the leader must be transformational to be effective under stress—able to rise above what the group sees as its immediate needs and appropriate reactions. The leader must arouse an inert group about the significance of threats and the group’s lack of preparedness. The leader must alter the inert group’s willingness to live with frustration rather than make efforts to deal more adequately with obstacles in its path to positive goals. To be effective, instead of catering to the group’s immediate needs and fears, the leader may need to calm the demands for hasty change. An effective leader may need to be transformational in identifying and publicizing the inadequacy of defensive pseudosolutions. The effective leader is transformational in providing superordinate goals that transcend the self-interests of the hypervigilant group in a state of panic. Clear, confident direction is important for effective leadership when panic is imminent. But transactional leadership may also be important in planning ahead.

### ***Enhancing Identification and Social Support***

Felt stress is likely to be reduced if individuals can be made to feel part of a larger entity. The insecurity of feeling isolated is replaced by the security of a sense of belonging. Transformational leaders can create a sense of identity with a social network of support. Pines (1980) cited research that demonstrated that people with the

social support of close friends, relatives, and group associations have lower mortality rates than do those without such social support.

During prolonged bombardments, the social support of children in kibbutzim made them less anxious than urban Israeli children. Loss of such social ties, ostracism, and isolation can be deadly among primitive peoples. Ganster, Fusilier, and Mayes (1986) reported that for 326 employees of a large contracting firm, social support from their supervisors, coworkers, family members, and friends moderately buffered the experience of strain. The strains included somatic complaints, depression, role ambiguity, role conflict, and frustration about the underutilization of skills. Nelson's (1978) surveyed the experiences of 30 child care workers in dealing with child care crises. Nelson found that crises were dealt with most effectively when the leader was supportive, respectful, and calm; had confidence; clarified the situation; and prepared for future crises. On the other hand, crises were dealt with ineffectively by leaders who displayed authoritarian attitudes and behavior, lack of support, loss of control, and poor communication.

As was seen in [Chapter 21](#), followers may be under their own intrapsychic tensions, feeling personally inadequate because of the gap between their self-perceived images of what they are and what they ideally should and would like to be. Their stress will be increased if they feel they cannot reduce the gap. The frustration may result in aggression and feelings of dependence. To help followers cope with their frustration, self-aggrandizing leaders make themselves the object of identification for the followers (Downtown, 1973). Socially concerned leaders show individualized consideration by providing opportunities for their followers to develop themselves (Levinson, 1980).

Information about threats to safety and well-being can be instituted without hasty defensiveness. Transformational leaders can sound the alarm, articulate the need for early caution, and mobilize the organization to avoid the threat or prepare for it (Tichy & Devanna, 1986). Such leaders devise strategies to avoid or defuse the crisis. They persuade immediate subordinates and peers to accept the proposed strategies and mobilize support for them. In this regard, transformational political leaders take on an important teaching function (Yarmolinsky, 1987).

## Summary and Conclusions

---

Leaders may have to deal with teams and groups that are frustrated by unattainable goals. Leaders can help to reduce the stress caused by fear of impending dangers. They may be needed to relieve the anxiety of groups caused by unclear and ambiguous demands. They may help teams in conflict over competing demands or with other groups. Leaders can arouse groups from a state of inertia where they perceive inaction as less risky and costly than an active response to warnings of danger. They can help groups avoid responding impulsively, defensively, or in panic. These groups may be facing stress caused by threats to survival that are internal or external, substantive or interpersonal.

It is not necessarily the speed of decision making nor the directiveness of leadership that is sought or commonly found during crises that makes a decision mal-adaptive. Rather, the inadequacy of the decision is due to the hastiness with which it is formulated and evaluated and to the lack of preparation for and commitment to it. Such hasty directive leadership will also be sought when followers must endure prolonged stress. In the same way, real or imagined threat will result in the acceptance of leaders who encourage defensive avoidance. Likewise, panic will heighten the followers' susceptibility to be influenced by decisions that will be maladaptive.

The emergent leader will do what is immediately required to provide the group with ways of coping with the stress. Rapid direction, initiation of structure, and task-oriented leadership will make the leader more likely to successfully influence the group to succeed. At the same time, the group will be more susceptible to such

influence.

Both demagogues and statesmen can be influential but not necessarily effective in times of crisis, as can transactional and transformational leaders. The transactional demagogue can assure inactive followers that warnings are unimportant and persuade impulsive followers that simple solutions are acceptable. He or she can convince defensive followers by bolstering them and shifting responsibility for the crisis, and he or she can sway panicking followers with otherworldly solutions. The demagogue can successfully lead the popular, easier search for internal subversion when complex external problems are paramount.

The effective leader (who, of course, must also successfully influence followers) is a transforming statesman who addresses the inert followers by shaking them out of their torpor in the face of impending dangers or by rousing them to work toward what, at first, may seem to be unobtainable goals. The transforming statesman shows followers the inadequacies of simple solutions and defensive avoidance. Superordinate goals are provided for the hypervigilant, and motivation and initiation of structure are provided for the adequate search, appraisal of alternatives, and contingency plans.

The survival of a group is dependent on a type of leadership that is able to keep members and subgroups working together toward a common purpose, to maintain productivity at a level that is sufficient to sustain the group or to justify its existence, and to satisfy members' expectations of the leader and the group. Competent leadership is especially needed in times of crisis to unite the efforts of members and to strengthen the group's cohesiveness around a common purpose. A group that desires to survive will prevent leaders of contending factions from destroying its legitimacy.

Different types of stress call for different types of leadership behavior. More task-oriented structuring may be required in many stressful circumstances; the creation of supportive groups will be important to the leader's effectiveness in other situations. Ordinarily, both are important. Stress can also arise from dysfunctional structuring of work and interpersonal space.

# Effects of Space, Virtuality, and Substitutes for Leadership

Leadership depends on interaction. Interaction depends on physical proximity, social and organizational propinquity, and networks of open channels of communications. And so, not surprisingly, the emergence and success of leadership depend to some degree on physical and social arrangements. Such arrangements may also be substitutes for leadership.

## Interaction Potential

---

Interaction potential is the likelihood that any two individuals will interact with each other. The more the individuals interact, the more one is likely to influence or lead the other. Although the purpose of interaction with another person may often be to give or receive information, to play, or to do other things that are unrelated to attempts to lead, many interactions are attempts to influence and to lead. Whatever increases the potential for interaction is also likely to increase attempts to lead. Successful leadership requires such attempts and thus is likely also to be correlated with interaction potential.

Physical proximity and the availability of channels of communication increase interaction potential. Thus, in reviewing studies of the effect of the spatial arrangement of participants in a small group, C. D. Ward (1968) concluded that the distance between participants was the most important single factor that influenced interaction. It was even more important than friendship. But friendship, familiarity, similarity, and other social factors also increase the potential to interact (Bass, 1960). Furthermore, the interaction of individuals may be a consequence of their freedom and autonomy from a higher authority. Some jobs permit more autonomy from a superior. This greater autonomy, in turn, increases the time that individuals spend communicating with others (Yammarino & Naughton, 1988).

Organizational proximity of members also increases their potential to interact and to communicate. With *ecco analysis*, members of an organization report whether they received a particular message and, if they received it, the time of receipt and the immediate source of the message. Using *ecco analysis*, Davis (1968b) showed that organizational proximity makes a difference in the extent to which informal communications for a particular oral message will be received. Thus the percentage of higher-level supervisors and managers who reported receiving information about parking or layoffs originated by those at the top of the organization was more than was reported by assistant foremen and foremen at lower levels. As messages moved downward through the system, the time of receipt increased along with delays and blockages.

Physical barriers would be expected to decrease the interaction between those with such barriers between them. But the opposite seems to be true, according to 99 employees in two high-tech firms surveyed by Hatch (1987). Interaction appeared to increase with the height of partitions between offices and the use of a secretary and a door between the offices. The only negative effect on interaction (which would be expected, according to Stech, 1981) was when a desk was positioned away from the office entrance. Nonetheless, fences and walls have been built to protect property, to control the borders of countries, to protect cities from attackers, to cut off the free flow of aliens illegally into the United States, to provide privacy of homeowners from neighbors,

and to block uncontrolled movement from the West Bank into Israel.

## Leadership and Physical Space

---

The *spatial proximity* of the leader to the led systematically enhances the influence process and the quality of the exchange between them. Conversely, the distance between them reduces the possibilities of influence and the quality of their exchange. It is not surprising that the traditional Inuit culture was highly individualistic rather than cooperative or competitive (Mead, Mirsky, Landes, et al., 1937). The low population density of the Arctic meant that the opportunity for contact among people was low. And without such an opportunity, the amount of influence and leadership was severely limited. Worthy (undated) noted that the rise of organized civilizations required the development of management that could occur only with denser settlements. Stable agriculture, animal husbandry, and fishing were needed to support the requisite density of population in which such organizing leadership was possible, as well as for civilization to emerge. Density was particularly important to agriculture, which needed irrigation works to support it.

### ***Leadership and Physical Proximity***

Schrag (1954) found physical proximity to be an important determinant of leadership among prison inmates. Toki (1935) studied the effects on groups of children of the introduction of physical distance to separate them from their adult leaders. The early separation and distancing of the leaders had much more deleterious effects on the groups that were early in their development than did such separation later on. Podsakoff, Todor, Grover, and Huber (1984) analyzed<sup>1</sup> 1,946 employees' descriptions of the reinforcement behavior of their superiors. The greater the spatial distance between the superior and the subordinates, significantly more likely was the superior to practice noncontingent punishment and less likely was the superior to practice either contingent or noncontingent reward. Other direct and indirect effects of the leader's physical proximity to followers were observed in territorial behavior, choice of friends, communication patterns, and physical arrangements. When followers were more physically distant than close, charismatic leaders were seen to be more ideological in their visions and opinions. If closer, they were seen to be more open, considerate, and task-motivating (Shamir, 1995). Also, distant charismatic bank leaders demonstrated greater effects on financial performance than did closer charismatics (Howell, Neufeld, & Avolio, 1998).

*Leadership and Territoriality.* Territoriality implies ownership of physically closer space and has similar effects on efforts to influence and the processes of influencing. Our interaction is higher with those who are within the boundaries of what we consider to be our territory. Our interaction and potential for leadership expand if we can stretch those boundaries. Leadership will contract if the boundaries are contracted. Territoriality is one of the major phenomena of interest to students of animal behavior. One of the primary functions of leadership in animal societies appears to be the location and protection of territory (Allee, 1945, 1951; Allee, Emerson, Park, et al., 1949). It has its counterpart in the attitudes of delinquent gangs about their own "turf" and domestic firms about foreign imports.

*Proximity and Friendship.* The potential to influence others is seen indirectly in the effects of proximity and distance on choice and acceptance. Willerman and Swanson (1952) found that sorority girls who lived in the same house chose each other as friends significantly more often than did girls who lived in more scattered locations in town. Proximity contributed to mutual choice. Maisonneuve (1952) and Priest and Sawyer (1967) also found proximity to be a factor in interpersonal choice. Gullahorn (1952) examined the interactions of female clerks seated in rows separated by filing cabinets. Interaction within rows was greater

than that across rows. Within rows, the clerks related more with those near them than with those seated at a distance. When distance did not operate as a factor, friendship was the next most important influence on the clerks' choice of others with whom to interact.

Proximity of distance between persons may also be a consequence, rather than a cause, of the relations between those who are engaged in interactions. Willis (1966) observed that individuals stand closer to one another when talking to friends and assume a greater distance when talking to strangers or persons of high status. It may be a matter of custom and habit. Latin Americans stand closer to each other than do Anglo Americans. Again, Little (1965) observed pairs of individuals in various situations. The distance between pairs of individuals in interaction was found to increase as their relationship changed from that of friend to acquaintance to stranger. Distance between pairs increased as the impersonality of the situation increased from living room to office to street corner. Streufert (1965) indicated that attitudes toward a member who deviates from group norms become more unfavorable as the distance between the member and the respondent increases. In the same way, attitudes toward a conforming member become more favorable as the member's proximity to the respondent increases.

*Effect of Distance on Communication.* Indirect evidence of the effects of distance on influence processes is also seen in studies of communication. Gullahorn (1952) observed that greater distance between the work locations of clerical personnel led to less communication among them. Allen and Gerstberger (1973) discovered that communication among product engineers was significantly higher with an open, nonterritorial office layout than with the traditional arrangements of office walls and assigned permanent workplaces. To the contrary, Hage (1974) found that the more the departments of an organization were physically dispersed, the more intensive were committee and departmental meetings and unscheduled communications. Also, there were fewer interactions *within* physically dispersed departments and more frequent interactions *between* physically dispersed departments. In explanation, Klauss and Bass (1982) concluded that physical distance among organizational entities increases the physical need for coordination, as shown by the increased volume of communication between distant organizational units. Although physical distance may initially hamper interpersonal communication, over time social structure compensates for physical distance and barriers (Barnlund & Harland, 1963). Similarly, modern technology provides alternative modes of communication to help overcome the factors of distance. Conrath (1973a) noted that when authority was involved in an interaction, communications were in writing; when task issues were involved, the telephone was used instead. The impact of information technology on eliminating the effects of distance will be discussed later.

Bass, Klauss, and DeMarco (1977) found that as physical distance increases among members of an organization at the same organizational level, there is a direct increase in the use of the telephone instead of face-to-face meetings for interacting with colleagues. But as the hierarchical distance in the number of organizational levels between a manager and a colleague increased along with physical distance, agreeing with Conrath's (1973) findings, Bass, Klauss, and DeMarco, found an increase in the use of memos instead of face-to-face contact or the telephone. The introduction of electronic mail moderated these effects of physical distance as such on collegial efforts to influence one another.

*Leadership and Physical Location.* The respective physical locations of individuals make a difference. The group discussant who grabs the chalk and controls the blackboard at a meeting can influence what ideas are singled out for attention. A. M. Rose (1968) identified job occupants who, because of their physical locations, take on "ecologically influential" roles of leadership. Their leadership is not based on personal, social, or psychological traits. These persons may be somewhat influential because they occupy a position that permits them to mediate ideas among several societal groups. Beauticians, barbers, bartenders, and traveling salespeople are examples of such leaders. In the same way, those who settled at the crossroads of several communities before the advent of the telephone were more likely to emerge as leaders. As will be noted later, those at the center of a network are more likely to lead those at the periphery.

As was noted in the last chapter, the physical presence of formal leaders helped their groups to cope better with a panic situation. Likewise, Ronan, Latham, and Kinne (1973) demonstrated that when supervisors of timber workers stayed on the job with the workers after assigning goals, they generated more output from their crews than did supervisors who assigned goals but did not stay on the job. Supervisors who remained on the job could effectively emphasize the importance of reaching or exceeding the goal and serve as reminders and monitors.

*Seating Arrangements.* Seating arrangements are not as trivial a matter as they might seem. A major difficulty in beginning serious peace negotiations among the United States, the Viet Cong, the South Vietnamese, and the North Vietnamese was disagreement over the shape of the table, round or square. A considerable amount of research has been completed on the extent to which one's influence in a small discussion group is dependent on the location of one's seat in relation to the rest of the group. Traditionally, the appointed leader took his or her place at the head of the table and those who were near in status to the appointed leader were grouped around him or her. Low-status people, as in feudal times, gathered "below the salt." This pattern is still maintained in informal groups, according to several studies. Leaders in small discussion groups tend to gravitate toward the head of the table (Sommer, 1959).<sup>2</sup> In simulated juries, Strodtbeck and Hook (1961) found that those who sat at the end of the table were more likely to be elected jury foreman. For U-shaped arrangements, those with higher status outside the group gravitate toward the apex (Bass & Klubeck, 1952). When the leader does not occupy the head position, other members tend to sit opposite, rather than alongside, him or her. When more than one leader or person of high status is present, these persons tend to seat themselves symmetrically around one end of the table (Sommer, 1961). Members as a whole tend to seat themselves closer to peers in status than to members who are higher or lower than themselves in status (Lott & Sommer, 1967). In a study of 88 supervisors and their managers, Bass and Wurster (1953b) found that the first-level supervisors seated themselves on one side of a long table while their second-level superiors sat down on the other side of the table. More dominant members of a group were observed by Hare and Bales (1963) to choose central seats and to do most of the talking. Group members sitting at end positions of a rectangular arrangement participate more and were rated as wielding more influence than are those seated at the sides (Strodtbeck & Hook, 1961). Lecuyer (1976) found, with French undergraduates, that the leader's position at the end of a rectangular table enhanced the leader's ability to direct the group.

H. Harris (1949) suggested that a semicircular or U arrangement, such as for a panel discussion, isolates those at the ends and spotlights those at the center. But Bass and Klubeck (1952) failed to find any such differences when the status of participants outside the group was taken into account. Howells and Becker (1962) seated two group members on one side of a table and three members on the opposite side. A greater number of leaders than would be expected by chance emerged on the side with two seats. C. D. Ward (1968) studied groups of strangers seated in a circle with several empty seats. The individuals facing the largest number of other members were most likely to be judged as leaders by other group members.

Are you more likely to interact with and influence someone sitting next to you or across the table from you? The evidence is mixed. Steinzor (1950) noted that when members of a discussion group were seated in a circle, an individual seated opposite a member who had just stopped talking, rather than one alongside the member, tended to speak next. Similarly, Festinger, Schachter, and Back (1950) showed that individuals who were positioned opposite each other interacted more than did those who were side by side. However, Sommer (1959) found that persons in neighboring seats interacted more than did persons in distant locations. Those in corner positions interacted more than did those who sat side by side or opposite each other. Felipe (1966) also found that such spatial arrangements similarly affected the rates of interaction. It may be that one is more likely to speak to the group after someone else across the table has just finished but to respond privately to those adjacent.

Seating arrangements are also a consequence of the purposes of meetings. Sommer (1965) reported that casual groups prefer corner seating, cooperating groups sit side by side, coacting groups sit at a distance, and competing groups sit opposite each other.<sup>3</sup> Stech (1983) suggested that managers who preferred relations-oriented leadership or task-oriented leadership could affect their success by choosing various layouts for their offices that determine the seating arrangements of themselves and those who visit their offices. Some of his differentiations are shown in [Table 29.1](#)

## Leadership and Psychosocial Space

The impact of psychosocial space on leadership is mapped by sociometry. The choice of friends, work partners, and leaders can be displayed in two or three dimensions of space and the correlated networks and linkages can be seen. Moreno (1934/1953) invented this approach to examine patterns of interaction. He asked each member of a group to choose among the others according to some criterion such as whom he or she liked best. Usually, the large share of choices was garnered by just a few individual members. [Figure 29.1](#) presents a sociometric diagram for a group of eight members. Only the first and second choices are shown. Member A, who received five choices, is the most highly preferred member of the group. Members B and E, who did not receive any choices, are isolates.

Table 29.1 Office Layout to Enhance a Manager’s Relations Orientation or Task Orientation

<i>Relations-Oriented Layout</i>	<i>Task-Oriented Layout</i>
1. The desk is placed against the wall. The manager turns away from the desk to talk with vistiors.	1. The desk is placed so the visitors are seated across from the manager.
2. An informal conversation area is used. For example, the manager and visitor can sit side by sie at a coffe table.	2. Most of the space for visitors consists of large, formal furniture.
3. All participants in a conversation are seated on the same level	3. The manager’s chair elevates him or her to a physically higher level that of others.
4. The office door is open.	4. The office door is closed, and a secretary acts as a buffer.
5. The office space is relatively small and the seats are fairly close together.	5. The office space is large, and furniture is placed so that there are large distances between persons.

SOURCE: Stech (1981, pp. 73–74).

Here are some of the kinds of questions asked members of groups and organizations from which interaction and the influence process can be discerned and mapped: With whom do you spend your work time? Whom do you contact in your organization if you have a particular problem? Whom do you avoid? We are more likely to contact and to spend more time with those we esteem, those we regard as important, those with whom we are more familiar, those whom we regard as friends, and those whom we think are more like us than different from us. Those who are esteemed, competent, knowledgeable, familiar, friends, or similar to us have more potential to interact with us than do those who are unesteemed, incompetent, strangers, and different from us. The latter have less potential to interact with us and, therefore, are less likely to be able to influence us. This conclusion is supported by considerable evidence.

## ***Effects of Psychological, Structural, and Functional Distance***

*Psychological distance* between leaders and followers is due to differences between them in status, power, demography, and perceived dissimilarity. *Structural distance* is physical or organizational. *Functional distance* is a matter of the distance of leaders and followers in working relationships (Antonakis & Atwater, 2002). The authors offered 17 propositions about the effects of such distances on leader-follower relations. For instance, they expected that power distance between leader and followers would correlate with their distance in social status. Leaders with strong need for power would maintain greater social distance from their followers than leaders low in need for power. Leaders with strong need for affiliation would do the opposite, while leaders with strong need for achievement would be expected to interact more with followers about their tasks.

*Status Differences.* Differences in status can be either emphasized or minimized in the search for organizational effectiveness. Status differences can be accentuated by the physical characteristics of one's office, dress, and privileges, as well as more subtle social calibrations, such as the use of "Sir" or "Madam" by a younger person addressing an older one. Status differences can be minimized by uniform offices, dress, and privileges, as well as by casual speech, familiar address, self-disclosure, and humor. Claims of common views, common leadership, cooperativeness, sympathy, and understanding also reduce the perceived differences in status (Drake & Moberg, 1986). (For more details about accorded status, see [Chapter 10](#).)

Seeman (1960) studied teachers' and principals' perceptions of the differences in their status in 27 public school systems and found that teachers who perceived wide differences between their status and that of the principal tended to describe the principal as being more changeable in leadership but less dominating. Principals were identified who rated themselves high in status. They saw sharp differences between their status and that of their teachers. Such principals were described by their teachers as communicative, changeable in behavior, and effective as leaders. In an earlier study, Seeman (1950) found that teachers who favored wide differences in status in society and in organizations tended to prefer a directive rather than a group-oriented style of leadership. The number of teachers with these preferences was considerably greater than expected.<sup>4</sup> Rettig, Despres, and Pasamanick (1960) obtained results indicating that persons in professional positions who perceived wide differences in status among various occupations tended to attach greater importance to personal freedom than did those who perceived narrow differences in status.

Differences in status can give rise to physical, psychological, and social distancing. McKenzie and Strongman (1981) compared the way British police superintendents, inspectors, and constables placed figurines to indicate how each of them would be positioned for an ordinary conversation between them. The figurines were placed at a greater distance for conversations with those of higher status (the superintendents). The superintendents then set up figurine placements with larger distances between themselves and those of lower status.

*Utility of Psychosocial Distance.* Psychosocial distance in sentiment appears to increase for high-status

persons who have coercive power over low-status persons and decrease for low-status persons. Prison guards distance themselves from prisoners (Zimbardo, 1973), but prisoners and hostages, in time, come closer in sentiment to their terrorist captors (Eckholm, 1985)—the “Stockholm Syndrome.” Controversy continues about whether such distance is necessary or desirable for leadership and organizational effectiveness. Social and behavioral theorists like J. R. Gibb (1964) and Argyris (1962) and many others in the Human Relations Movement saw greater costs to leaders and organizations when psychosocial distance was maintained. More virtue was seen in reducing the psychosocial distance among organizational members and in maintaining close, personal relations among those of different status and at various levels in the organization. On the other hand, Martin and Sims (1956), Jameson (1945), and Pfiffner (1951) argued strongly for maintaining such psychosocial distance to promote organizational effectiveness.

In a questionnaire on what respondents thought was required to succeed in business, administered to 107 MBA students, Bass (1968c) found a factor endorsing the maintenance of social distance and prerogatives. This factor was correlated with the students’ perceptions of the importance of personal gain as a motivator to students with strong economic values and to students with less human or social concerns, as revealed in simulated budgeting decisions. Working managers saw somewhat less utility in maintaining such psychosocial distance than did the MBA students. Also less supportive of maintaining social distance were managers with human relations training (Bass, 1970b).

Proponents of the maintenance of psychosocial distance from followers suggest that by doing so leaders enhance their power and effectiveness. To maintain distance, leaders limit access to themselves and accent the difference between their status, esteem, ability, and power and those of their followers. They avoid personal self-disclosures and intimacy with their followers and employ various symbolic separations. (Emperors, sultans, and kings raised the height of their thrones above their audience chambers so they could literally talk down to their subjects from “on high.”) Such social distance may either promote the legitimacy of the leader and follower roles or be a consequence of it.<sup>5</sup> By maintaining psychosocial distance, a leader can remain impartial, task-directed, and free of emotional concern for individual followers. A general can order individual groups of soldiers to a high risk of death for the sake of expected victory. A manager who would have difficulty discharging an incompetent personal secretary might find it easier to lay off a hundred employees several levels below in the hierarchy.

Barnard (1946a) suggested that the maintenance of psychosocial distance in an organization serves several other functions. It may help coordination, protects members from the need to compete for leadership, and acknowledges the importance of each individual’s special contribution. It also protects the integrity of the individual in that it acknowledges certain rights, privileges, and obligations that pertain to his or her position. Furthermore, it obviates the necessity of unfavorable comparisons between individuals who differ in training and ability.

Social distance can reduce the amount of extraneous talking between employees that may interfere with their productivity. Such extraneous talking may, on occasion, replace work and thus have distracting and deleterious effects on the productive efforts of individual members. Thus, Ingham, Levinger, Graves, and Peckham (1974) observed that individuals did not work quite as hard when they were paired with one or two others than when they worked alone.

### ***Costs of Maintaining Distance***

The costs of psychosocial distancing can be high. They can include more defensive behavior by followers, loss of contact, poorer quality of communications, poorer selection of goals, less commitment to the group’s goals, incipient revolt, and organizational rigidity. Barnard (1946a) observed that psychosocial distance can limit the

adaptability of the organization, distort the system of distributive justice, and exalt the symbolic function at the expense of efficient performance. In the same vein, Reykowski (1982) inferred that the more socially distant from us are other persons, the less is our tendency to maintain equal exchange relationships with them. One may dehumanize psychosocially distant persons and show less concern for justice in dealing with them.

*Variations in Preferences and Effects.* The optimal social distance between the leader and the follower appears to vary from one leader-follower relationship to another. Differences in preferences occur for both leaders and followers. The effects of psychosocial distance depend on such personal factors as the leader's and followers' motivation to achieve and their degree of friendship. The effects of distance also depend on situational factors such as the favorableness of the situation to the leader.

There seems to be some optimal psychosocial distance between the leader and his or her subordinates. Carp, Vitola, and McLanathan (1963) found that effective leaders have a perceptual set that enables them to maintain optimal psychological distance from subordinates—neither so close that they are hampered by emotional ties nor so distant that they lose emotional contact. Consistent with this finding, in writing about what it takes to be a successful captain of a ship in the U.S. Navy, Mack and Konetzni (1982, p. 3) described this optimum: "The successful commanding officer ... must learn to become as one with his wardroom and his crew; yet, at the same time, he must remain above and apart. ... It is a skill that must be mastered in turn by each commander if he is to carry out his task with success." To reduce the social distance between a senior executive and operating employees, to move it closer to the optimum, the executive practices *walk-around* management. General Joseph Stilwell went much further to reduce the psychosocial distance between himself and his enlisted personnel. He was known for his tendency to wear an unmarked private's uniform, lead infantry marches on foot, and eat in the enlisted men's mess (Tuchman, 1971).

*Effects of Follower Motivation to Achieve.* W. W. Burke (1965) studied different combinations of leaders and followers, each combination differentiated by social distance and the need to achieve. In a group situation that varied in tenseness, followers with a strong need to achieve rated the situation as more tense under a socially close leader than did followers with a strong need to achieve who were under a socially distant leader. Followers with a weak need to achieve rated the situation as less tense under a socially close leader than under a socially distant leader. Followers with a strong need to achieve rated socially close leaders as more autocratic than they did socially distant leaders. Followers with a weak need to achieve rated socially distant leaders as more autocratic. At the same time, regardless of the followers' needs for achievement, socially distant leaders were rated more effective in a coding task and socially close leaders were rated more effective in a human relations task. Overall, followers with a socially distant leader considered their groups to be less productive and less satisfying than did those with a socially close leader.

## ***Sociometrics of Leadership***

Sociograms are sensitive to interaction potential because they show the choices members make about other members of the group. Some members are overchosen; others are underchosen. The patterns of choice point to interpersonal attractiveness and familiarity among members and help to identify the leaders. Different uses have been made of sociometry in the study of leadership. H. H. Jennings (1943) used sociometry to distinguish the choice of leaders from the choice of others. She found that group members are much more selective in choosing leaders than they are in choosing friends or roommates. R. L. French (1951) studied the choice patterns of companies of naval recruits. The frequency of sick bay attendance was negatively related to sociometric choice by peers; leadership ratings were positively related to being chosen. In a study of bomber crews, Roby (1953) found that the sociometric choices of members were unrelated to ratings of the effectiveness of the crews. Nevertheless, as with the preponderance of military studies, Levi, Torrance, and

Pletts (1954) observed that the effectiveness of aircrews was enhanced when the officially designated leader was also the sociometrically chosen leader of the crew. The formal and informal structures were congruent.<sup>6</sup> (see [Figure 29.1](#))

Massarik, Tannenbaum, Kahane, and Weschler (1953) used five sociometric indexes in studying an organization. The indexes were (1) relations prescribed by the organizational chart, (2) perceived relations, (3) reported interactions, (4) preferred interactions, and (5) rejected interactions. Preferred interactions were more highly related to members' satisfaction than were prescribed or reported interactions. The members related more freely and were better satisfied under participative than under more directive leadership.

*College Presidents' Relationships.* The leadership role of college presidents can be more fully appreciated by examining with whom they spend their time, according to interviews with 44 presidents. The average university president is fairly isolated. Most of his contacts center on his inner circle of staff and vice presidents. The isolation is broken mainly by contacts with students. Only 11% of the 44 presidents reported daily contacts with faculty members, while 18% to 21% reported daily contact with visitors and students. A factor analysis of these data uncovered four types of college presidents: bureaucrats, intellectuals, egalitarians, and counselors. The *bureaucrats* spent more of their time with their academic and fiscal vice presidents and their staffs. They tended to communicate to others indirectly, through their staffs. These presidents were perceived by faculty members and other administrators as remote, ineffective, and closed. The *intellectuals* spent relatively more of their time with faculty members and other administrators whom they perceived as intellectuals. *Egalitarians* and *counselors* spent more time with students and faculty, respectively, and those individuals involved in student and faculty affairs. They tended to be more highly rated by both faculty and students (Astin & Scherrei, 1980).

*Communal Relationships.* Bradley (1987) found that different sociometric patterns emerged in communes with different types of leaders. Sociograms were constructed of the responses to the questions of whether the relations with each other member in a communal network were loving, optimistic, and exciting. Systematic differences in sociograms were found when the commune's charismatic leader lived in the commune or was an absent and distant leader. They showed when it was possible for charismatic leadership to emerge. Charismatic leadership, particularly when the leader is in residence, coincided with many more members' being in affectionate connection with each other. Other relations were more loving and exciting when the charismatic leader was charismatic. The least communal linkages were seen in a commune without the potential for the emergence of a charismatic leader.

*Effects of Interpersonal Attractiveness.* Sociometric analyses and other interpersonal assessment procedures make possible the study of interpersonal attractiveness and its effects. Variables of consequence here include esteem, popularity, likeability, and perceived friendliness. Each of these variables has been found to increase interaction potential and therefore attempts to lead and successful leadership. Frequency of contact may increase esteem and less often may decrease such admiration. Some interaction between individuals is usually necessary before they can increase or decrease their evaluation of each other. If the interaction or its effects are unrewarding, mutual esteem between the individuals is likely to lessen.

Individuals are more likely to interact the more they value each other and the more they value the interaction among them (Bass, 1960). Thus, Blau (1954a) found that the more esteemed members of a law enforcement agency were contacted by the rest of the group more frequently. Conversely, Festinger and Hutte (1954) reported that people tended to talk least with those toward whom they felt indifferent.

Mutual esteem, familiarity, contact, and influence are interdependent. When 140 sorority women chose the seven most and seven least valued members of their sorority, correlations of .48 to .58 emerged between the tendency to be mentioned at all and to be selected as a competent leader (Bass, Wurster, Doll, & Clair, 1953). Similar results were obtained with salesmen.<sup>7</sup> The tendency to be mentioned (visibility) correlated positively

with sociometrically rated value, ability, and influence as a salesman (Bass, 1960). Bovard (1951b) reported that more pleasant interactions yielded greater attraction among members. But Festinger and Kelley (1951) found that unpleasant interactions resulted in no change in mutual attraction. However, according to Seashore (1954), a longer duration of shared group friendship yielded greater cohesiveness among 228 factory groups. Similarly, a mean increase in "likeability" among dramatics participants over an 11-week rehearsal period was found by Timmons (1944). If mutual esteem increases interaction, it should also increase effectiveness, and such was found by Van Zelst (1952a). Carpenters and bricklayers were paired either arbitrarily or with work partners they chose sociometrically. Sociometrically assembled pairs were considerably more productive than were pairs who were assembled arbitrarily.

Kelley (1950) presented information to some college students that a visiting instructor would be warm but told other students that the visiting instructor would be cold. The students asked more questions of the "warm" instructor than of the "cold" one. They formed more positive impressions of the "warm" instructor and more negative impressions of the "cold," instructor even though the visiting instructor behaved in the same way in both conditions.

Generally, physically attractive persons tend to make more favorable impressions on others and to be contacted more frequently and for longer periods (Berscheid & Walster, 1969). But the converse has also been seen. Subjects tend to terminate interactions with physically handicapped persons more quickly (Kleck, Ono, & Hastorf, 1966). Similarly, subjects working with supposedly mentally ill persons talk less, initiate less conversation, and express opinions that are less representative of their beliefs (Farina, Allen, & Saul, 1966).

*Hierarchical Effects.* T. Burns (1954) reported that middle managers spent more time with superiors than with subordinates, while the reverse was true for first-level supervisors. Likewise, Guest (1956) and Piersol (1958) reported that first-level supervisors spent more time with their subordinates than with their superiors. Zajonc and Wolfe (1966) found that managers in high-level positions and those performing staff functions maintained the widest range of formal contacts within the organization, but these informal contacts did not seem to follow a distinct pattern associated with hierarchical level or function.

*Effects of Familiarity.* The potential to interact with another particular member increases as the group becomes smaller. Open network connections among members also increase the likelihood of interaction. In addition, familiarity, as such, breeds interaction, and interaction breeds familiarity. (Neither necessarily breeds contempt.) The more intimate or familiar we are with one another, the more likely we are to interact. The more we interact, the more intimate we become (Bass, 1960). Thelen (1954) noted that subgroups that are composed of friends are likely to have more energy to spend in participation with each other than are subgroups composed of strangers.

Intimacy and familiarity are not identical. Caplow and Forman (1950) found that the length of residence in a college community merely increased the number of one's acquaintances rather than the intensity of relationships with one's neighbors. We can be familiar without being intimate, although they are likely to be correlated. According to Klauss and Bass (1982), data from a large governmental agency indicated that the familiarity of a colleague with a focal person was associated directly with the frequency of their contact during any given week, as well as with the length of their acquaintanceship. Likewise, intimacy among 75 college students was a function of the frequency and amount of hours of contact among the students (Fischer, 1953).

In studying a rumor's origin and spread, Festinger, Cartwright, Barber, et al. (1947) observed that people were less restrained in talking about such rumors to close friends than to mere acquaintances. Similarly, Hare and Hare (1948) noted a positive correlation between the amount of social activity and the number of family friends among 70 families in a veterans' housing project. Increased congeniality of members was observed by Curtis and Gibbard (1955) with the members' increased experience with one another in both voluntary and compulsory college groups. Likewise, Seashore (1954) found that members' attraction for each other was greater in factory groups in which the members were friends for longer periods of time. Finally, Faunce and

Beegle (1948) found that cliques at a teenage farmers' camp gradually developed on the basis of newly emerged familiarities, although they were initially formed around homogeneity of age, sex, and country of origin. Bass (1960) advanced two reasons for interaction among members of groups as their familiarity and intimacy increased: (1) members feel more secure in interacting with friends than with strangers and (2) since they can predict each other's actions, they can interact with less difficulty.

Morgan and Sawyer (1967) found that schoolboys prefer strict equality in the distribution of rewards, both with friends and with others. (We see this preference repeatedly when conducting experimental gaming with students.) Nevertheless, although they prefer equality, friends are willing to accept inequality if one friend thinks that the other friend may want it. But ordinarily friends are less willing to accept inequality. Familiarity with what the other expects facilitates the ability to reach agreement about how rewards should be distributed.

Effectiveness in the form of goal attainment tends to be associated with increased interaction. If so, it should also be associated with increased familiarity and/or intimacy. Husband (1940) found that pairs of close friends took less time than pairs of strangers to solve problems in code, puzzles, and arithmetic. Similarly, Goodacre (1953) reported that the members of the most effective of 26 infantry squads in handling field problems had a greater tendency to socialize together after hours. However, Horsfall and Arensberg (1949), in a study of a shoe factory, failed to find any relationship between productivity and the tendency of its supervisors to interact frequently.

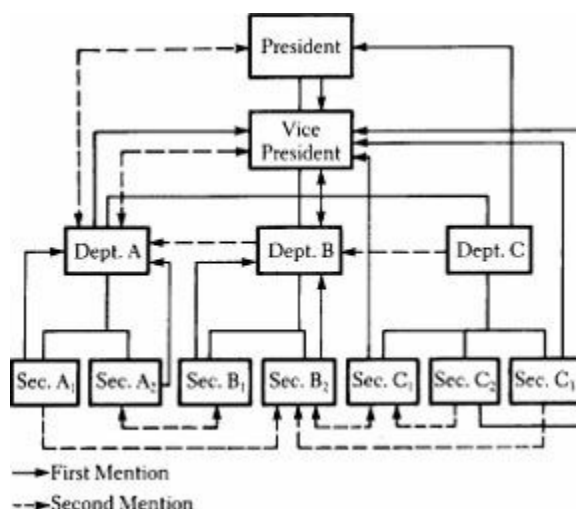

Klauss and Bass (1982) reported that colleagues of 577 governmental professionals thought that the more familiar focal colleagues were more trustworthy, informative, and dynamic than were the less familiar focal ones. Colleagues also felt more satisfied in their relations with the more familiar focal persons. A correlation of .27 emerged between familiarity and perceived effectiveness of relations. But the length of acquaintanceship between the colleagues and the focal persons was unrelated to measures of effective communication. A higher frequency of interaction between colleagues and focal persons, however, correlated with satisfaction and effectiveness but not with the colleagues' judgments of the trustworthiness and informativeness of the focal persons.

*Effects of Similarity.* Individuals interact more with those who are like them than those who are unlike them (Bass, 1960). The effect can be seen in student cafeterias, where students are attracted to eat at tables according to sex, race, ethnicity, class, age, and status. Pfiffner (1951) observed that employees of the same age, physical attractiveness, marital status, education, and race tended to group together. Strangers associate first on the basis of their homogeneity of sex, age, and place of origin, according to Faunce and Beegle's (1948) study of campers. Likewise, Caplow and Forman (1950) found that interaction among neighbors in a university community was greater if families were homogeneous in occupation, number of children in the family, length of residence, and type of housing. Similarly, in the more turbulent neighborhoods of Chicago, leaders of 181 public and private human service organizations who had similar racial or educational backgrounds were more likely to establish cooperative relations with one another than were those from different backgrounds (Galaskiewicz & Shatin, 1981).

*Formal versus Informal Organization.* Stogdill (1949) asked members of organizations to estimate the amount of time they actually spent with other members. Socio-metric charts of these working relationships were superimposed on the formal organizational chart to determine the correspondence between the formally specified and actual working relationships. Such a determination would make it possible to diagnose communication and interactional problems within the organization. Such a chart is shown in [Figure 29.2](#). It should be noted that in this figure, the vice president, rather than the president, is the focus of working interactions. Department heads A and B also tend to be foci of interactions. Department head C is bypassed by his subordinates, who do not interact much with each other, which suggests that the department head is not an effective leader of his group. With such a pattern of interactions, it is apparent that coordination is effected either by the vice president or by the cross-departmental contacts among section heads. The dominant trend of

contact here is upward rather than downward. This trend is consistent with the commonly observed latent pressure to communicate upward more than downward. Such efforts to initiate interactions with superiors may serve more to reduce anxiety and to increase feelings of security and less to communicate about issues of work (A. Kadushin, 1968; Schwartzbaum & Gruenfeld, 1969).

Figure 29.2 Sociometric Diagram Superimposed on Organization

SOURCE: Author

Stogdill (1951a) plotted the number of times each of 22 officers in a small U.S. Navy organization was mentioned as a work partner by his peers. Officers who occupied high-level positions tended to mention subordinates and outsiders more frequently and superiors less frequently than did officers in lower-level positions. The same trend was observed in the number of mentions received. High levels of responsibility were related to more total mentions given and received and to more mentions received from members inside one's own unit and from superiors. Scope of authority was not significantly related to any sociometric scores. Those who delegated most freely tended to be mentioned most frequently as work partners by members inside their own units.

## Networks

Social distance and status differences can be increased or decreased by the network available or imposed. A network is a set of people connected by friendship, influence, work, or communications.<sup>8</sup> Networks are composed of people or stations and links between them. Within organizations, it is a reciprocating set of relationships that stabilizes the manager's world and gives it predictability (Sayles, 1964). As shown in [Figure 29.3](#), a manager's network is likely to include vertical, horizontal, and diagonal segments, with mutual contacts with his or her boss, his or her subordinates and their subordinates, and many other colleagues at the same level or at higher and lower levels. It is also likely to include individuals outside the organization, such as consultants, clients, and suppliers. Network analysis is the study of the links that bind such people and their positions.

Figure 29.3 Organizational Network

SOURCE: Adapted from Graen and Scandura (1987, p. 203) by permission of JAI Press Inc., Greenwich, CT.

Networks can be formed in a variety of ways and for a variety of purposes. Clearinghouses of information can serve as the centers of networks of influence. The insurance industry encourages social responsibility and community leadership by its individual member companies in this manner (Karson, 1979). Brown and Detterman's (1987) longitudinal study of the community networks of leaders in a large metropolitan center found that a formal leadership program increased contacts among the white but not among the black participants. New networks emerged and old ones were strengthened for addressing community problems. Underlying the networks were the social establishment, political leaders, business leaders, and community activists.

The vertical, diagonal, and lateral dyads, each of which may be formal or informal, make up the organizational network shown in [Figure 29.3](#). The dyadic relations particularly important to the focal manager are displayed. It can be seen here that relations between other members of the organization may be important to a third member. For instance, the dyadic relations between a director and his associate director may have consequences for a staff scientist, who has no direct connection with either person. A more powerful analysis of networks may be provided by triadic analysis (Holland & Leinhardt, 1976). An analysis of three members might show, for instance, two members linked to a third, but the third member not reciprocating. Bradley (1987) reported systematic differences in which the type of triads appearing in communes was a function of whether the charismatic leader of the commune was in residence or was an absentee leader.

The typical supervisor's communications network is composed of links to his or her subordinates, to one or more peers and superiors, and to outsiders, as well as to libraries, databases, and computers. The links may be oral, written, and electronic. Unless replaced by e-mail, at least one-third of the supervisor's time is spent mainly in face-to-face contact with subordinates (Jablin, 1985), but these links may not be seen as being as important and challenging as those with outsiders (Whitely, 1984).

### ***Importance of Networks***

Ordinarily, a manager's network operates on a transactional exchange relationship: managers receive information, services, and resources in exchange for promises, returned favors, support, and recognition (Kaplan & Mazique, 1983). Nonetheless, networks are important to both transformational and transactional leaders. For instance, in a changing organization, old networks are broken up and new ones are established. The transformational leader manages "to foster a new set of social networks with new flows and ties" (Tichy & Devanna, 1986, p. 193). Managers also develop networks of lateral reciprocal exchanges with their peers. Such trading connections enable them to get their own department's work done (Kaplan & Mazique, 1983).

Networking supports one's image in the organization. Managers earn esteem by linking themselves to

winning causes (Kotter, 1979), and such alliances promote their advancement. Few managers can function without the linkage of their networks (McCall, Morrison, & Hanman, 1978). With the exponential increase in knowledge and the knowledge worker, communication networks have taken on an ever-increasing role of importance in the success or failure of organizations (Cleveland, 1985). Networks connecting managers in separate organizations play an important role in the hiring of members for top management teams (Williamson & Cable, 2003).

In the absence of finding much research about managerial and professional networking, Hall-Merenda and Howell (undated) proposed that the networks are a form of socialized exchanges. Networkers concentrate their boundary spanning to identify useful ties for projects. They find gaps in the organizational structure in which to establish ties. An exchange at first is based on a formal agreement; subsequent exchanges can be based on trust. Successful completion of projects increases trust and the retention of partners and creates wider opportunities for partnering. Yukl (1998, p. 39) concluded that best practices for networkers are to seek opportunities to make contacts, to do unconditional favors, to become a valuable trading partner, and to keep in touch with network members.

### ***Effects of Network Centrality on Leadership***

Leaders' performance and effects depend on their centrality in networks, their domain of influence, and their contacts and connections in the networks (McElroy & Schrader, 1987). In an analysis of 140 full-time nonsupervisory employees of a newspaper publishing company, Brass (1984) showed that perceived influence and promotion to a supervisory position depended on one's location in the networks of work flow, communication, and friendship. Contacts beyond the normal work requirements were important in the acquisition of influence, particularly by technical core employees. Also important to perceived influence were the critical importance of one's position to operations and one's centrality in the networks. The leadership potential of professional members of a Russian high-tech consulting firm, as assessed by their superiors, was significantly related to their centrality in advice and friendship networks based on socio-metric nominations (Korotov & Onyemah, 2003).

Insko, Thibaut, Moehle, et al. (1980) showed that when 432 students were organized into trading groups, the group through which all trades had to be channeled made the most money and emerged as the leading group. Such functional centrality was also seen to be important to leadership by Tropp and Landers (1979), who examined the relationship of emergent leadership to the frequency of passing to field hockey teammates. *Spatial* centrality was not as important as *functional* centrality to effective plays. As hypothesized for 308 executives in 32 firms by Liang, Ndofor, & Picken (2003), network centrality in their communication patterns was more effective if it fit with the uncertainty of their environment. And although the leader of a jazz ensemble is its central figure, the role is tempered by the number of criticisms received and disagreements on interpretations that affect the quality of the performance (Voyer & Faulkner, 1986).

*Open and Closed Channels.* The mutual influence of leaders and followers depends on how open or closed the channels of communication are between them. Thus, those who have access to the political leaders and decision makers in a community are more likely to be influential in the community (Brockman & Gayk, 1977). Group members can also influence each other more readily if they are in open communication with each other.

The openness of a channel between superior and subordinate must be two-way. That is, both must be perceived as being ready both to communicate and to listen (Redding, 1972). Both verbal and nonverbal behavior (such as eye gaze, posture, tone of voice, and facial expressions) can signal such readiness or lack of it (Tjosvold, 1984b). Subordinates' satisfaction with their work and with their superiors is strongly related to

their perception of the possibilities of open communication with their superior (Pincus, 1986).

The direction of the flow of information in a channel between the superior and the subordinate and the superior's style of relating to the subordinate will depend on who initially has more information that is relevant to their joint task. Shapira (1976) confirmed that if the superior initially possesses more information than the subordinate about what needs to be done, the superior will be more *directive* with the subordinate. If the superior initially possesses less information about what needs to be done, he or she will be more consultative or *participative*.<sup>2</sup>

The use of a channel appears to depend more on its openness and accessibility than on the perceived quality of the information that can be obtained from it (Allen, 1966) or the ease of its use (Gerstberger & Allen, 1968). Thus, neighborhood leaders who have common membership in different organizations tend to have more open cooperative relations with one another (Galaskiewicz & Shatin, 1981). More upward communication channels will be used in hierarchical organizations if trust is present and aspirations for mobility are high (Level & Johnson, 1978; O'Reilly & Roberts, 1974). Horizontal flows of unsolicited information will be increased by reductions in organizational constraints (Albaum, 1964) and increases in the organization's technological certainty (Randolph & Finch, 1977).

*Network Preferences.* To accommodate their own influence and work preferences, U.S. presidents differed in the networks of staff assistants they constructed. Dwight D. Eisenhower's immediate staff reported to him indirectly through his chief of staff, Sherman Adams. John F. Kennedy was the center of a network of his immediate staff. Lyndon B. Johnson used the telephone extensively to extend his network of direct contacts. Jimmy Carter created groups of staff assistants, each of whom dealt comprehensively and independently with a single different source, and he related directly to each group. Ronald Reagan, like Eisenhower, depended heavily on a chief of staff to screen and funnel the staff's recommendations.

The self-interests of the senders and receivers of information will contribute to distorting or shutting down channels by tactics of overloading, circumventing, or reinterpreting the organization's policies and regulations (P. J. Frost, 1986). Leaders can expand their networks informally to increase their own influence. For instance, Admiral Hyman Rickover greatly increased his control and influence by building a large network of his nuclear-trained officers, all of whom reported directly to him each week, bypassing the official channels (Polmar & Allen, 1981).

### ***Effects of Group or Organizational Task***

Networks of communication in an organization can result from the demands of authority, the demands for information, the demands of particular tasks, the bonds of friendship, or the more formal status characteristics of organizations. The purpose served by a network affects how information is transmitted within it. For example, communication in an authority network is typically more formalized than is communication in a friendship network (Bass & Ryterband, 1979). Heise and Miller (1951) concluded that the task faced by the network is a determinant of the leadership and the group behavior that are likely to occur. The uniqueness of the solution, the number of decisions to be made, and the amount of previous structure are all involved. For example, G. B. Cohen (1969) studied groups who performed an information-processing task and found that centrality facilitated their performance most when the tasks were highly interdependent.

### ***Effective Network Communications***

Systematic effects on the leadership effectiveness of those led emerge as a consequence of the communication pattern fostered by the leader, policy, motivation, and training.

*Leadership and Styles of Communication.* An important aspect of a manager's leadership style is the way he or she communicates with colleagues and subordinates. Thus, under authoritarian managers, networks with restricted communications take less time to plan than do groups led with less direction and structure. However, the results of the planning are likely to be less efficient in accomplishing the required tasks (Snadowsky, 1972).

Table 29.2 shows the correlations between leadership and communication styles that Klauss and Bass (1982) obtained when 71 subordinates described the leadership and communication styles of their 28 focal managers. It can be seen that participative leadership styles<sup>10</sup> correlated highly with the leader's being seen as an informal, frank, open, two-way communicator, careful transmitter, and careful listener. Trustworthiness and informativeness, but not dynamism, were also highly correlated with participative styles of leadership. *Directive* leadership was less highly correlated with careful transmission, being open and frank and a careful listener, but not at all with being informal and a careful listener. Dynamism was highly correlated with *directiveness* but at the expense of trustworthiness. Being negotiative and manipulative was unrelated to the style of communication.

Table 29.2 Correlations between Communication Styles, Credibility, and Leadership Styles as Seen by 71 Subordinates of 28 Focal Managers

SOURCE: Adapted from Klauss and Bass (1982).

Posner and Kouzes (1988b) obtained even stronger linkages between transformational leadership and the communication styles of 146 senior managers, according to their 998 subordinates. Transformational leadership was measured by the Leadership Practices Inventory (Kouzes & Posner, 1987). The five factors (challenging the process, inspiring a shared vision, enabling others to act, modeling the way, and encouraging the heart) correlated between .40 and .68 with the trustworthiness, informativeness, and dynamism of the leaders' communication styles, as measured by Klauss and Bass (1982). For instance, inspirational envisioning correlated .56 with trustworthiness, .58 with informativeness, and .68 with dynamism.

Ordinarily, open, easy, ready communications contribute to the extent the leader and the group can influence each other and to the extent to which they will be effective. On the basis of research with B-29 aircrews, Roby and Forgays (1953) noted that crews who could send information faster to decision stations could solve problems faster. In a report on maintenance in four medium bomber wings, Bates (1953) inferred that in the two better-performing maintenance systems, there was more contact among subgroups. The system's leaders were usually involved in such contacts. Torrance (1954b) ascertained that plane crews in simulated survival exercises were most likely to "survive" if communications were resumed quickly among scattered crew members, leading to a clarification of the situation. Again, such resumption of communication was usually connected to the initiatives of the formal or emerging leadership.

The leadership is often responsible for the ease with which members of a group can communicate with one another. Thus, O'Reilly (1977) found that decision making by subordinates was improved if they could readily make use of their supervisors as sources of information. Such easy communication correlated highly with the described effectiveness of 500 work groups (Bass, 1954b) and teams engaged in naval ordnance testing (Weschler & Shepard, 1954). Leaders who scheduled regular meetings with their groups made for more effective group operations. Dyer and Lambert (1953) found that in two medium bomber wings, regular personnel meetings were scheduled in the wing with a better record of performance and effectiveness but not in the less effective wing. In addition, the executive officer of the superior wing was a more active communicator of information to others in the wing. Likewise, Habbe (1952) noted that in an individual plant with regularly scheduled meetings of work groups, workers felt freer to talk about their problems with the supervisor and favored such meetings more than did workers of a plant without such regular meetings.

Generally, the imposition of a complex hierarchical structure tends to impede the flow of information, particularly the flow upward. The formal channels may need to be bypassed to reduce the difficulties of

communication (Wilensky, 1967). The formal authority structure supposedly enables the necessary flow of technical information, but an informal structure may be needed to increase the ease of the flow, according to a study of an R & D organization by Allen and Cohen (1969). Upward communication that must be relayed through intermediate levels often suffers greatly from filtering by officials at these intermediate levels. The problem is particularly severe for U.S. presidents. The advice and judgment of foreign-area experts at the working level, for example, are blocked or filtered by intermediates to give the president more of what the intermediates believe is consistent with the presidents' beliefs and stated policies than with the realistic facts about pending crises (L. R. Anderson, 1983). Much of the faulty U.S. decisions about Iraq's intentions and capabilities leading to war in 2003 and its aftermath could be attributed to blockages and filtering of intelligence in its upward flow from field agents, analysts, and policy experts to the White House political staff and the president.

*Communication and Successful Performance.* The successful performance of social service professionals, industrial managers, and military officers<sup>11</sup> was found by Klauss and Bass (1982) to relate to aspects of the way they were seen to communicate. However, the results depended on whether the questionnaire descriptions were obtained from their subordinates, peers, or supervisors. The more successful social service professionals were seen as more open and two-way communicators by their subordinates and peers but less trustworthy by their supervisors. The more successful industrial managers were described by their supervisors as more careful transmitters, more frank, and more informative. The more successful military officers were described by their subordinates as more careful listeners and more open and two-way in their communications. They were less careful transmitters, according to their peers.

Successful leadership hinges on access to information. Leaders who successfully influenced community opinion about public affairs, education, and family planning in 450 households in a South African black township were found by Heath and Bekker (1986) to have greater exposure to newspapers and television than were those who were not influential. In comparison with the nonleaders, the leaders were more active in interpersonal communication. The network opinion leaders also had more contact with white change agents.

### ***Media of Communication***

Networks may be built on consistent patterns of oral, written, or electronic contacts or combinations thereof. The medium will make a difference in what happens and how. Channels of oral communication are favored over channels based on written messages. Face-to-face meetings are favored over telephone conversations (Lee & Lee, 1956). Oral communication is promoted by the cultural norms of information sharing in the organization. Written communications are substituted in the absence of such norms (Dewhirst, 1971b). Crucial information can be communicated orally through successive channels more readily than can routine information, which is better transmitted in writing. Thus, Davis (1968b) found that routine information on parking was poorly communicated orally down the managerial hierarchy, while information on a production-oriented layoff was very well communicated orally. Nevertheless, in a survey of 72 business supervisors, Level (1972) found that in dealing with each of 10 problems at the workplace, the supervisors thought that oral communication followed by written communication was likely to be most effective. E-communication has become a favored and effective addition to networking.

## **Electronic Communication Networking**

---

The mass application of electronic networking to work and life came along with more than a half century of

computer and Internet development, greatly accelerated by the availability of the personal computer and the World Wide Web. The first teleworker was a Boston bank manager who installed a telephone in his home in 1876. In 1966, I forecast that in the year 2000, employees working at home would be supervised by telecommunications; supervisors in the business office and supervisees at home would be connected by cable networks (Bass, 1966). By 1996, in fact, 10% of the U.S workforce was doing some telecommuting. Two of three employees and almost all managers of Fortune 500 companies were teleworking to some degree by 2000, 137 million worldwide (Rivenbark, 2000) and by 2004, more than 30 million in the United States alone (Gibson, Blackwell, Dominicus, et al., 2002). In 2005, an estimated 400,000 U.S. federal tax returns were processed for the IRS in India. A hamburger order at a McDonald's drive-through window off of a Missouri highway goes to a Colorado call center and is ready in a few minutes at the pickup window in Missouri. A call center operator in Bangalore may service your airline reservation request for a ticket from Dallas to Atlanta (Friedman, 2005).

## ***Teleworking***

We are familiar with the extent to which work can be supervised at a distance. E-communication makes possible continued instant interaction and networking between home and office, between distant shops, between distant speaker and audience, and between diagnostician and patient. With e-communication, the network of the individual organizational member is greatly expanded. Boundaries of time, geography, and organization disappear. Time and distance to information about resources, customers, markets, remote operations, and personnel are eliminated (Mohrman, 1998). When the oral and written channels of networks are joined by e-communication and information systems, the network of the individual organizational member is greatly expanded. The time spans between interchanges are greatly decreased, and overload of information becomes a much greater problem than does underload. Although the concern for privacy and security is heightened, some of the problems that are due to organizational distance decrease. With the filtering and transmission of information by e-mail, delays are eliminated. What originates at a high managerial level in the organization can quickly reach those at the lowest managerial level. Likewise, e-mail provides instant contact between physically distant employees at the same organization level (Bass, 2005). A physically networked organization can be replaced by a virtual one using desktop videoconferencing, collaborative software, and the Internet, as well as the intranet within the virtual organization (Townsend, DeMarie, & Hendrickson, 1998). Global organizations whose units are located in many different time zones can carry on work by moving developing information from zone to zone as each unit becomes available for work. Firms can integrate organizational functions in different time zones to fit organizational purposes. Radiologists in Stockholm can give diagnosticians in Montreal second opinions about X-ray results in a few hours. Work by Trend Micro on a computer antivirus program can begin in New York, to be ready for application when an office opens in California three hours later. Wipro Technologies has 17,000 of its 20,000 engineers and consultants in India—at one fifth the labor costs of those in Silicon Valley—connected to its executives in the United States, where most of its customers are located (Hamm, 2003).

*Jobs Best Suited for Teleworking.* The jobs best suited for teleworking are dynamic and service-oriented, like those in management, sales, marketing, consulting, design, and project engineering (Cascio, 2000a). According to a survey of 350 executives by Lee, Hecht, Harrison, Inc. (1999), 90% of the executives used e-mail, 88% used voice mail, 81% used fax, and 53% used the Internet. When Hewlett-Packard transferred its sales force to virtual workplaces, revenue doubled (O'Connell, 1996). Teleworking at US West improved productivity by as much as 40% (Matthes, 1992). Firms like Ford and Delta Air Lines have given personnel computers for home use (Cascio, 2000a).

*Telecommuting from Home.* The need for business office space is reduced and home-to-office commuting time and personal and environmental costs are eliminated when workers telecommute from home. More time can be spent by home-based sales personnel visiting with customers face to face. Some members of the sales and customer relations department of Florida Power & Light operate out of their homes (Parks, 1998).

A better *work–family life balance* can be achieved with teleworking from home. When 212 teleworkers were compared with 922 nonteleworkers in telephone interviews, the teleworkers were more satisfied with their jobs and more committed to their organization. Those who worked at home had greater autonomy and were most satisfied with their jobs (Davis & Polonko, 2003). When 157 IBM office teleworkers were compared with 89 traditional workers, productivity, flexibility and work–life balance were significantly better for the teleworkers with home offices, according to a quantitative multivariate analysis (Hill, Miller, Weiner, & Colihan, 1998). While only 9% of 769 managers surveyed worked regularly from their homes, four of five in a survey of 769 managers said they would telecommute from home if they had the option (Lee, Hecht, Harrison, Inc., 1999).

*All-Channel Linkage.* James Barksdale, CEO of Netscape, noted that with all its personnel linked, every Netscape manager and employee could be informed directly and immediately about another major organization's announcement that might have a large impact on Netscape's business. In the past, he would have called a meeting of the top executive team for consultation about the competitive development. Then meetings would be called at lower levels until everyone in the organization had been consulted. Barksdale was now able to get a message to every Netscape employee in the world in a few minutes.

*Disadvantages of Teleworking.* Costs include setup and maintenance of the equipment, loss of socializing, and feared loss of visibility when it comes to personal advancement (Cascio, 2001). Other costs are information overload, duplication of effort, message ambiguities causing conflict, frustration by the loss of face-to-face (FTF) communication, and not knowing the effect on the receiver of an e-mail message. A survey of 350 executives reported that a majority felt that they are bombarded with more information than they can handle. They see much duplication of effort and unnecessary actions. They suffer from information overload and the intrusion of e-communications into their personal lives. E-communications can lack clarity and cause unnecessary conflicts. Customers are frustrated by machine responses to their telephone inquiries. Executives can be frustrated by being unable to discuss matters FTF with their subordinates. The loss of socialization is expected to be offset as people become more comfortable with the Internet, e-mail, pagers, chat rooms, instant messaging, blog information, instant exchanges about daily life, and an enlarging set of e-mail acquaintances (Abernathy, 1999).

### ***E-Mail and Its Effects***

Electronic mail provides a communication channel through which people communicate more equally. Early in its use, electronic mail was more likely to be originated by those with keyboard skills. Social and business status differences are minimized as is the ability to judge others by visual clues. When rating others by e-mail, there is less bias due to liking the other person (Weisband & Atwater, 1999). E-mail was more likely to be sent to known users and its use was encouraged by company policy.

By 1989, R&D supervisors were being E-rated more than nonsupervisors. The ratings were also having more impact on the supervisors (Fulk, Schmitz, Ryn & Steinfeld, 1989). A successful experience with one application like income tax preparation was conducive to adapting other applications (Martins & Kambil, 1999). When electronic and paper surveys were compared, little difference was found in rate of response, but response time is shorter and more comments are produced in Web-based surveys.

*Absence of Nonverbal Cues.* Eye contact, dress, facial expression, voice modulation, and physical gestures that are available in face-to-face (FTF) interactions are missing in E-mail without video. What are likely to be affected when FTF interactions and their nonverbal cues are absent are the clarification of the transmitted information and contextual embellishments (Birdwhistell, 1970). With E-mail, senders may be less inhibited because their feelings can be disguised more readily. This adds to the need for supervisors to provide more empowerment and trust in their subordinates (Ahuja, Robert, & Chudoba, 2003), more trust of their superiors by subordinates (Speitzer & Mishra, 1999), and peer colleagues trust in each other. Identification with their organization needs to be strengthened. But, Hallowell (1998) argues that voice mail and e-mail cannot substitute for the *human moment* of FTF interaction to allay the anxieties caused by voice mail and e-mail which often can raise uncertainties to brood over. When possible, an FTF meeting should precede the initiation of an electronic network.

E-mail and teleconferencing both eliminate many of the nonverbal cues that help clarify the information transmitted and the support for continued interaction among senders and receivers.

*Effects on Influence and Leadership.* Siegel, Dubrovsky, Kiesler, et al. (1986) compared the efficiency of communication, participation, and interpersonal behavior of 144 undergraduates in trios who discussed their career choices in one of three ways: FTF, by computer mail, or mediated by computer. When the trio members were linked by computer, they made fewer remarks than they did face-to-face and took longer to make their group decisions. The amount of participation in the discussion was more evenly distributed, and the members' behavior was more uninhibited (the members felt freer to use strong and inflammatory expressions). More overall influence appeared to occur in the computer-mediated condition. The group decisions shifted farther away from the members' initial individual choices than did the decisions that followed FTF discussions.

### ***Teleconferencing and Videoconferencing***

As just noted, computer-supported collaboration can be provided for FTF or physically distant individuals. Rawlins (1983) found that with audio-only teleconferencing by 20 four-person groups, the assigned leaders did not retain as much of their leadership roles as they did in FTF meetings. Rather, the leadership roles were more widely shared if the groups had a teleconference with-out an FTF meeting. U.S. and German engineers could avoid numerous transatlantic trips using audio and video-conferencing, although FTF meetings were required for some technical exchanges (Hart & Kamath, 1996). Craig and Jull (1974) and Rawlins (1983) all reported that FTF problem solving took longer than did problem solving by means of audio telecommunications.

Teleconferencing can be organized into different kinds of more restricted or less restricted channels of communication. For example, Pagery and Chapanis (1983) compared problem solving by closed-circuit television when central switching made it possible for only one participant to talk at a time and participants at each station were freer to intervene. Although members in the groups under the central-switching arrangement took longer to solve problems and used fewer and longer messages than did those in the less controlled condition, there was little difference in the effects of the two arrangements on the leadership processes. Integrated Voice Response (IVR), telephone touch-tone keypad inputs, and replies with voice, fax, callback, e-mail and other media can still be frustrating when you can't talk to humans except after a long delay.

Videoconferencing comes much closer to FTF communication in its ability to supply the nonverbal cues that Mehrabian (1968a) found important. Mehrabian concluded that facial expression ordinarily accounts for half of what is communicated. When eye contact is low or absent, individuals come across as less positive, warm, and friendly (Kleck & Nuessle, 1968). Short (1973), Craig and Jull (1974), and Rawlins (1983) all reported that FTF problem solving took longer than did problem solving by means of audio

telecommunications.

Although videoconferencing makes more of the visual nonverbal cues possible, there are still differences between it and FTF meetings as media for linking members in problem-solving tasks. Teleconferencing is less likely to provide the same amount of opportunities for social feedback, the sociopsychological distance among members is likely to be greater, and the ability of individual members to control the flow of communication is limited. But the evidence of the differential effects of FTF meetings and teleconferencing is mixed. Strickland, Guild, Barefoot, and Paterson (1978) found that when members of a problem-solving group are linked by closed-circuit television networks, rather than by FTF meetings, they are less likely to agree on a leader. However, Nicol (1983) reported that a clearer task-leadership hierarchy emerged for 20 groups that held closed-circuit television conferences than for 13 groups who met FTF to solve a problem. No differences were seen in the extent to which socioemotional leaders clearly emerged in the two media. Teleconferencing comes still closer to an FTF meeting with the use of whiteboards and fax for the instantaneous exchange of documents.

### ***Group Decision Support Systems (GDSS)***

Bass, Gaier, Farese, et al. (1957) constructed and ran experiments on a rudimentary group decision analog computer, made possible by the newly available transistor. We correlated the responses of five participants with their group decisions and the correct answers before and after discussion. The leadership of a member was assumed to be higher if others moved closer in agreement to the member from before to after the discussion and the group decision was closer to the members'. These correlations provided an index of leadership for each of the five participants. By 1990, a highly sophisticated group decision support system (GDSS) was commercially available from the Ventana Corporation, based on continuing research (Avolio, Kahai, & Dodge, 2001). Each participant had a keyboard and monitor linked to all other member stations and the central station for an administrator. The basic software toolbox of GDSS makes possible electronic brainstorming in which participants rapidly submit comments to a question or issue to a central file and to each other. They can reorganize, evaluate, and modify ideas, proposals, and policies. Meeting Manager is the control panel of the network, which allows the administrator to prepare agendas, save session information, and edit and generate reports. Advanced software can be used to examine and quantify the relations between two sets of ideas in a matrix. The software can provide a test of the practicality of a plan. Participants identify the plan's assumptions and their importance to stakeholders, and consensus is graphed. Other software facilitates creation of outline structures, editorial processes by the group, and agreements about terminology. Groups up to 20 or more in size can be accommodated. (Basecamp is one of several similar, more current products available from 37 signals.)

*Anonymity.* In an experiment with 36 four- or five-person undergraduate student groups, GDSS responses either remained anonymous or were identified. The groups were treated to either *transformational* or *transactional* comments by an administrator. The transformational leadership comments were observed to encourage more fluency, flexibility, and elaboration. Inspirational leadership comments and perceptions of transactional goals contributed to creativity, but intellectual stimulation and individualized consideration comments correlated negatively with creativity. Anonymity amplified the effects of transformational leadership on group potency and group effectiveness (Sosik, Avolio, & Kahai, 1997). By itself, anonymity was less important, although in general, leadership effects were stronger under anonymity (Sosik, 1997; Sosik, Avolio, & Kahai, 1998). From a literature review, Kahai, Avolio, and Sosik (1998) concluded that the effects of anonymity on participation and satisfaction depended on the kind and degree of anonymity and whether the virtual team members initially differed in their opinions.

*Style of Leadership.* Kahai, Sosik, and Avolio (1997) reported that both *directive* and *participative* leadership improved group performance in the GDSS meeting environment. Consultative comments by the administrator fostered support. Directive leadership promoted more proposals for fairly structured problems; participative leadership promoted more proposals for structured problems.

*Influences of GDSS on Effectiveness.* Similar experiments established that compared to FTF meetings, GDSS produced better decisions (Steeb & Johnston, 1981; Lewis, 1981; Gallupe, DeSanctis, & Dickson, 1988). However, no differences in decision quality were found in favor of GDSS by others (e.g., Ruble, 1984). Hiltz, Johnson, and Turoff (1991) used GDSS with 24 groups of professionals and managers with and without an elected leader and with and without statistical feedback. Decisions were better with a leader but not with statistical feedback. George, Eastman, Nunamaker, et al. (1990) studied assigned leadership and anonymity in GDSS in comparison to manual discussion groups. Assigned leaders in GDSS groups resulted in unequal participation rates among members. Such leaders had strong influences on outcomes in a study in Singapore (Lim, Raman, & Wei, 1994). In another study in Singapore, Ho and Raman (1991) found with 240 undergraduates that in a preference task, GDSS groups with consensus before decisions exhibited more equality of influence but members were willing to let one member dominate the final solution.

In larger groups, GDSS was found to reduce the process losses in traditional brainstorming due to production blocking, evaluation apprehension, and free riding. However, when GDSS was used in 12-member brainstorming groups, more ideas were generated than in nominal groups. However, there were no differences in productivity in six-member brainstorming groups. Small nominal groups where individuals work by themselves were more productive than members trying to produce ideas together (Dennis & Valacich, 1993).

## E-Leadership

---

Computer and telecommunication technology make possible *e-leaders* who can exert influence on linked individuals. One or several leaders may be linked with one or several teleworkers at a distance to form virtual teams (Cascio & Shurygailo, 2002). Virtual teams make for flat organizational structures (Townsend, DeMarie, & Hendrickson, 1998). What does it take to be a successful and effective leader in the electronic environment? Much is the same as for leadership in nonelectronic circumstances. The focus is still on people (Avolio & Kahai, 2003), but particular aspects of e-networking must be considered.

### *The E-Environment*

In the electronic environment, real-time information is available. There is greater opportunity for sharing knowledge with organizational members and outsiders. Relationships can be customized. More pressure is put on leaders from inside and outside the organization (Avolio & Kahai, 2003). With e-technology, social and technical systems are more interdependent than postulated by Trist's (1993) sociotechnical systems theory. The e-environment and the organization's structure are built and changed in coordination with each other (Orlikowski, 1992).

*Temporal Coordination.* Some types of e-communication are *synchronous*. Telephone conversations, desktop networks, real-time audio and videoconferencing, electronic meeting system, and electronic displays are synchronous between leaders and followers. Other types of e-communication—for example, telephone messaging, e-mail, group schedules and calendars, e-bulletin boards, workflow applications, and non-real-time database sharing—are *asynchronous*. Replies and answers to comments and questions are not immediately forthcoming (Duarte & Snyder, 1999). When communications are across many time zones, the problems are exacerbated. Nevertheless, temporal coordination for 35 experimental virtual teams was found to moderate the

negative effects of such problems (Montoya-Weiss, Massey, & Song, 2001). As noted earlier, temporal coordination makes possible continuous teleworking as teams in time zones such as Britain, India, Japan, and the United States pass on the work near the end of their respective work spells (Kimball & Eunice, 1999).

E-communications are intermittent. Instant messaging comes closest to spontaneous conversation. Ordinarily, only a “snapshot” is sent between sender and receiver. Spontaneous interaction and nonverbals are missing (Thompson, 2000; Cooper & Kurland, 2002). The social status and diversity of senders and receivers are less apparent. Personality cues are absent (Bekson & Eveland, 2000). Without full video, there is *behavioral invisibility*. Traditional forms of control and monitoring are absent (Wilson, 2001). Collegial and subordinate efforts cannot be observed. Participants can cheat, neglect team interests, and fail to anticipate others’ actions (Sheppard & Sherman, 1998). Maynard (2003) suggests that ethicality may be helped by increasing trust, team tenure, and transformational leadership and by reducing team size.

*Evaluation.* Subordinates are evaluated less favorably in electronic than in FTF environments. Evaluations must depend on results rather than perceived effort (Perlow, 1997). Friendships formed FTF are weakened in computer-mediated environments, according to a Japanese study of a 25-person network (Fujishima & Murata, 1998).

*Needs and Limitations.* Leaders and their virtual teams need well-indexed, automated central data files accessible from remote locations, and a way to track tele-workers if they are mobile (Cascio, 1998). Some Internet companies, such as eBay, can be mainly online, with no particular physical identity. Brown and Gioia (2002) tracked and interviewed the top managements of a prototypical online division of a Fortune 500 firm over the first 22 months of the launch of a business venture. The investigators concluded that the online business environment was characterized by extraordinary speed, complexity, and ambiguity, requiring the leadership to become a learning organization and to deal with the tensions of image and identity with the offline parent organization. In their review of 10 kinds of e-communications, Duarte and Snyder (1999) concluded that no online was as effective as FTF communications for resolving interpersonal conflict, especially when issues were highly ambiguous and emotional. Knowledge networks, such as in research institutions, are sources of potential conflict among virtual workers. They may compete instead of cooperating if rewarded for knowledge generation, and identifying sources of ideas becomes murky (Jarvenpaa & Tanriverdi, 2002).

### ***Required Competencies for E-Leadership***

E-leaders need specific competencies to deal with the challenges of e-networks. Systematic differences in knowledge, skills, and attitudes emerged when 41 successful e-leaders were compared with 50 traditional leaders (Higgins, Jones, & Paddock, 2002). E-leaders must be role models for using e-communications. They must be comfortable in working with and through e-networking (Spreitzer, 2003). The *telepresence* of the leader needs to be felt by means of the vividness of a rich telecommunications environment and the influence effects of interactivity with team members (Steuer, 1993). E-leaders must understand what key stakeholders expect of their teams. They need to understand receivers’ agendas, priorities, and motives (Cohen & Gibson, 2000). E-leaders need to be able to diagnose what is happening quickly. They need to be particularly sensitive to differences as they network across cultures and organizations. They must be more directive in leading some individuals and groups and more participative in leading others. At times, they must sense whether more direction or participation is needed with the same individuals. They must have a clear vision of what needs to be done (Thompson, 2000). In global networks, they must consider time zones, national holidays, cultural differences, and the immediate local needs and pressures as opposed to world-wide global concerns (Kerber & Buono, 2003). E-leaders must know how to use e-technology, but they also need to know how to stimulate

their networks into using it.

The use of Lotus Notes increased collaboration among office workers only if the workers had previously collaborated without the software (Vandenbosch & Ginzberg, 1997). Leadership was needed. E-leaders need to know how to avoid or resolve the conflicts that arise in knowledge networks about responsibilities and credit for knowledge creation (Jarvenpaa & Tanriverdi, 2002).

Most e-leaders continue to have FTF relations with some of their nearby associates as well as from mutual visiting with distant ones. They need to know how to balance their concerns and time between close and distant followers. Those depending on e-communications need to be made to feel they can carry as much weight as those engaged in FTF. E-leaders need to remain alert for mis-communications and misinterpretations. They need to communicate their intentions (Avolio & Kahai, 2003a). Until they receive reassuring replies, they have to live with uncertainties created by their initiations, suggestions, and advice. Cascio (2000) summed up five requirements for e-leaders: (1) an open, positive attitude focused on solutions to issues; (2) the ability to lead in the absence of structure and control; (3) a results-oriented management style; (4) effective formal and informal communication skills; and (5) the ability to delegate and follow up effectively.

### ***Other Necessary Factors in Effective E-Leadership***

To expedite teleconferencing, Solomon (1998) suggested that for conference effectiveness, a rotating leader be chosen by the group and written agendas be distributed before the meeting, including the length of time allotted to it. The leader should recap the discussion goals at the beginning of the meeting and encourage everyone to participate. Notes on the main points of the conference should be distributed afterward.

Although interpersonal trust among managers and employees in 631 groups was found to be even more important in FTF groups than virtual teams, *cognitive* trust (as distinct from *affective* trust) in the e-leader was of particular consequence. E-leaders promote cognitive trust by demonstrating their competence, responsibility, and professionalism to their virtual team members (Staples, 1999). Nevertheless, affective trust is also important. Jarvenpaa, Knoll, and Leidner (1998) compared the trust in 29 global virtual teams that communicated solely by e-mail. Compared to the low-trust teams, the higher-trust teams began by introducing themselves and providing information about their personal backgrounds. They were led to set clear roles for one another.

E-leaders need to establish norms that emphasize the appropriateness of sharing perspectives and the acceptance of task-based conflict. Personality conflict is to be avoided. E-leaders need to help deal with adversity and provide substitutes for the social support available in FTF teams (Zaccaro & Bader, 2002). They also need to make sure that communications are secure. They need to provide training time for their subordinates to learn e-networking (Thompson, 2000). They need to confirm what they understand in communications they receive (Cooper & Kurland, 2002). Meetings of all connected members and leaders are important and should begin with a roll call of all members announcing themselves. Senders always need to identify themselves and know how to ensure needed follow-up communications (Cascio, 2002).

As with initially FTF leaderless groups, in a longitudinal study of six virtual project teams, there were early struggles for leadership (Furst, Rosen, & Blackburn, 2003). Appointed or elected e-leaders need to begin a virtual team by learning more about its purpose and its individual members. E-leaders need to try to select internally motivated self-starters for the virtual team. If possible, they should first meet FTF (Cascio, 2000; McDonough, Barczak, et al., 2000). Early on, E-leaders need to clarify whether decisions will be by consensus or otherwise and whether all will share responsibility for implementing the final decision (Cascio, 2000). They especially need to work with virtual teams to reduce the members' feelings of isolation by creating a shared

mental model (Kurland & Bailey, 1999) and shared expectations (Maznevski & Chudoba, 2000). They need to ensure that the team members jointly define and commit to the team's identity, goals, and routines. Both familiar and new technologies need to be implemented (Kerber & Buono, 2003). E-leaders need to cope with the self-limiting behaviors of some members that inhibit their participation due to pressures to conform or lack of self-confidence. They should do less supervising of work content and more supervising of overall performance (Cascio, 2000). E-leaders need to monitor progress toward the fulfillment of each expectation and to publicly recognize success. They also need to negotiate with partner groups and organizations for resources and support for their team (Cohen & Gibson, 2000). (For additional detailed suggestions on effectively managing virtual teams, see Cascio, 2002; Zigurs, 2003.)

### ***Leaders' Relations***

Hart and McLeod (2003) studied seven virtual teams of professionals, national and global. The investigators examined e-mails, diaries, interviews, audioconference transcripts, and rated strength of relations with others. They inferred that in virtual teams, close personal relations were developed one message at a time. But most messaging was task-related and not about relationships. Personal content had little to do with developing strong personal relations. This suggested that virtual team-building activities should follow, not precede, work on tasks. Those linked with strong rather than weak relationships communicated frequently, with short messages. Those in weaker relations used longer messages, as they needed to add opinions, reasons, and explanations. Leaders needed to encourage communications among the members to work together on tasks and problem solving. Relations were strengthened by working together to solve problems. Leaders assumed fewer roles in teleconferences than in FTF meetings (Rawlins, 1989). E-leaders of projects in six high-tech firms had to change from their FTF roles. They had to give up some of their technical work and take on more negotiating to help different virtual teams work together.

*Shared Leadership.* The rated potency, social integration, problem solving, and effectiveness of *elected* leadership in approximately seven-member virtual teams were compared with *informally shared* leadership. The participants were 206 social workers developing community revitalization plans. The social workers were linked by e-mail, groupware, fax, and telephone for 10 weeks. The informally shared leadership had a positive effect. According to hierarchical regression analyses, the shared leadership of the virtual team members did add significantly to the four outcomes ( $\Delta R^2 = .43, .46, .36, .15$ ) (Pearce, Yoo, & Alavi, 2004). Avolio and Maritz (2000) concluded that the models of e-leadership to deal with virtual interactions need to be based on the fundamental principles of effective leadership. With e-leadership, command and control leadership will need to give way to more sharing of leadership and shared mental models by leaders and followers of how they can collaborate and what they need to accomplish.

*Organizational Actions.* At the organizational level, many e-leader actions are needed. E-leaders of global networks have to provide strategic direction and focus. They need to set organizational goals and align them with strategies. They need to provide virtual teams with organizational support. They need to ensure early experiences with new technologies. Transformational leadership is an effective style for e-leaders. Passive, laissez-faire leadership is contraindicated (Davis & Bryant, 2003).

## **Leadership in Experimental Communication Networks**

---

Communication networks circumscribe who can communicate with whom, thereby affecting interactions, the group's performance, and the potential leadership process. The control of the channels of communication

among members of a group has been used widely to examine systematically the effects on performance and leadership of the network of arrangements provided. Bavelas (1950) originated a laboratory experiment to study the effects of systematic changes in who among five participants could communicate directly with each of the other participants. Bavelas dealt poker hands to the five members of a group. The members could communicate with each other only by written messages. The object was to select the one best poker hand from the combined cards of all the members. The groups differed in communication channels, as shown in [Figure 29.4](#). In the circle arrangement, the members had an equal opportunity to send messages to and receive messages from the member in the position to their left and the member in the position to their right. In the chain, members in peripheral positions could send messages through intermediaries toward the position in the center. In the wheel, four of the members had equal opportunities to send messages to the person in the center and could also communicate with adjacent members. In the Y, three members could send messages to a fourth person in the central position, but the fifth member was required to communicate with the member in the center through another member. In the star, all communications had to flow through the central position. The kite added an open channel between two of the peripheral positions. These networks contrasted with the all-channel network, in which any member could send messages to any other member.

## The Standard Design

Subsequently, Leavitt (1951) developed a standardized task that was free of the potential bias that could occur from differences among members who knew how to play poker. At the beginning of each trial, each of five participants was given a card on which five of six symbols were printed; one symbol was missing from each card, and each card lacked a different symbol. The problem each time was to have the group discover and record the one symbol that everyone had in common. The participants were seated around a circular table and were separated from one another by five vertical partitions. They passed messages to one another through open interconnecting slots—the only way of communicating. Leavitt analyzed the pattern of messages that developed and the speed with which the problem was solved when a particular network of channels was open for use.<sup>12</sup>

*Centrality.* Organizational centrality was greatest in the wheel and decreased in the following order: Y, chain, and circle. The star network was more centralized than the kite network. The greater the inequalities in the opportunities for different members of the network to communicate, the more the members differed in centrality. The star and Y networks are most centralized because one member has a central position and all the others occupy peripheral positions. The circle and all-channel networks are least centralized, since all members have equal opportunities to communicate. Individual member centrality exists in three ways: a person in a network is more spatially central, more central in the exchange of information in the network, or more central in the decisions of the network. Ordinarily, central positions and those who occupy them have greater position power because of their greater access to information and the control of its distribution. This power makes those in central positions more influential with those who occupy peripheral positions in the Bavelas-Leavitt networks—a finding that was confirmed in numerous studies.<sup>13</sup> The network member who occupies a position of centrality is most likely to emerge as the network leader. However, Abrahamson (1969) removed the partitions that prevented group members from seeing one another. In the FTF situation, central members emerged as leaders only when no dominance owing to personality was present. Abrahamson concluded that an individual's centrality contributes to his or her emergence as a leader only when physical isolation prevents personality factors from having an impact.

*Effects of Network Centralization.* Centralization of a network has important effects on the network's performance. Bales (1953) observed that since the group member who was able to control the communication network was most likely to emerge as the leader, the emergence of leadership was more frequent in the star network, with its one central position, than in other networks (see also Shaw & Rothschild, 1956).

Leavitt (1951) found that speed in solving problems, agreement on who is the leader, satisfaction with the group, and development of an organization were highly correlated with the organization centrality of the network. That is, it took the least time to solve problems and to agree on leadership when there was one clear central position, such as in the Y network. It took more time in the chain and the most time in the circle, in which there was no central position. The circle network experienced difficulty in developing a stable structure for problem solving. However, Burgess (1969) showed that differences in the performance of the various networks tended to disappear once groups had worked under a given arrangement for a time and had attained a steady state—particularly if contingent reinforcement was used to influence member performance.

*Development of Centralization.* Consistent informal roles emerged within the restrictions of the formal networks, more in some networks, less in others. Little informality was possible in the wheel network. The highly restricted wheel network rapidly developed a stable hierarchy that conformed to the formal demands of the system. In that network, the central person sent out information to all participants once he or she had received information from all. In contrast, all-channel groups could display much more variety in the informal organizations they built, particularly in distributing answers. Some evolved a system in which each person sent answers to every other member, while others developed patterns identical to the wheel or to the chain. The groups that were formally restricted to the circle network had the greatest difficulty developing and maintaining a single formal pattern of communications. Over many trials, they tended to fluctuate in the particular patterns of communication they used, especially in exchanging answers (Guetzkow & Simon, 1955).

Usually, a network that began with a central position or informally developed a centralizing procedure was able to complete the task faster, with fewer errors (Mulder, 1960). Thus, Cohen, Robinson, and Edwards (1969), who studied groups that were required to solve experimental problems of organization, found that centralized problem-solving systems were developed by 211 subgroups in both the wheel and the all-channel networks. However, such centralization was likely to give rise to less satisfying peripheral jobs. There was less opportunity for members as a whole to modify their own organization, to learn about how the organization operated, to be flexible, and to be creative when new challenges were imposed on the group (Bass & Ryterband, 1979). More will be said about this later.

*Roles and Role Structures.* Participants who occupy peripheral positions carry out different tasks from those who occupy central positions. For example, those in peripheral positions spend more of their time receiving information (Guetzkow & Simon, 1955). Only the participant in the central position spends a great deal of time compiling data, forming solutions, and transmitting answers.

Using 76 five-member groups with Leavitt designs, Guetzkow (1960, 1961) found that three types of roles and role structures tended to emerge. The central participant tended to receive information, formulate answers, and send answers. The peripheral participant sent his or her own missing information and received answers. The relayer passed on his or her and other information and relayed answers. The wheel and all-channel networks tended to develop two-level structures consisting of a central person and four peripheral members. One-third of the circle groups developed three-level structures consisting of a central person and four peripheral participants. One-third of the circle groups developed three-level structures consisting of a central participant, two relayers, and two peripheral participants. Two-thirds of the circle groups did not develop organized structures of mutually supporting roles. Groups with differentiated role structures solved the problem faster than did those that remained undifferentiated. The central participants and the relayers perceived the structure more accurately than did the peripheral participants in all except the all-channel groups. The central participants also sent more messages containing proposals for the organization and nominated themselves more often as leaders.

*Stability of Leadership.* A. M. Cohen (1962) observed greater continuity of leadership in communication networks when members could elect their leaders. Cohen and Bennis (1961) studied groups with changing structures. They found that groups that had changed from a wheel to a circle network tended to organize themselves into a more efficient chain system, but with different leaders than had been present in the wheel network. Also, networks with elected leaders retained the same leaders longer than did those that were not permitted to elect leaders.

*Central versus Peripheral Involvement.* Zander and Forward (1968) found that participants who were in central positions developed a stronger desire for their groups' success than did participants in peripheral positions. Participants whose need to avoid personal failure exceeded their need for personal success tended to become more concerned about their group's performance than participants whose need for personal success was greater than their need to avoid failure.

*Centrality and Satisfaction.* Centralized groups typically have one member at their hub, who is likely to be the most satisfied. In routine tasks, the more centralized the structure, the more efficiently members solve problems, but those in the more numerous peripheral positions may remain less satisfied (Cohen, 1964). Shaw and Rothschild (1956) found that the occupant of the central position in a star design was more satisfied; otherwise, the other participants' dissatisfaction did not differ in the various network structures. Using the same designs, Shaw, Rothschild, and Strickland (1957) determined that the satisfaction of participants was a joint function of centrality and the amount of support the participants received. Central members, more than peripheral members, tried to change the opinion of those who disagreed. However, if the central members failed, their satisfaction changed more than did that of the peripheral members. Cohen, Robinson, and Edwards (1969), like many others, found that the satisfaction of members differed with their position in the system. Also, it was somewhat higher in decentralized networks. Vannoy and Morrisette (1969) obtained results suggesting that although satisfaction with a role in the network was related to its centrality, satisfaction with one's group was related to the effectiveness of the group's network operations.

In an experimental effort to detect the underlying elements that were of consequence, Trow (1957) studied groups of participants who were matched according to their scores on the need for autonomy. Some members were led to believe that they occupied positions of centrality, and others were led to believe that they occupied positions of dependence. The autonomous situation provided greater satisfaction than the dependent situation. The effect of centrality on satisfaction was positive but not significant.

*Access to Information and Its Distribution.* Trow (1957) analyzed the interacting effects of providing the occupant of a position in a communications network with access to information and with access to communication channels with others. Perceived status was more a matter of access to the communication channels than to knowledge. On the other hand, Guetzkow (1954) found that persons in central positions had better knowledge and understanding of the network than did persons in peripheral positions. Changing the information available to members had an effect similar to that of changing the centrality of their position or the channels available to their position (M. E. Shaw, 1954a). In a follow-up of this earlier finding, M. E. Shaw (1963a) studied the influence of the availability of information in various networks. Compared to group members with no previous information about the problem, members with an informational advantage were found to enter the discussion earlier, to initiate more task-oriented communications, to find their suggestions accepted more frequently, and to be rated by others as contributing more to the group's task. Likewise, Gilchrist, Shaw, and Walker (1954) varied the information available to the four members of a wheel network. They found that the centrality of a position rather than available knowledge of the problem generated the emergence of the leadership and the satisfaction.

*Other Contingent Factors.* Planning opportunities made a difference. Members were more likely to learn how to use their own position to the best advantage of the group when the group was given the opportunity to plan between trials, particularly if members were connected with each other by open channels (Guetzkow & Dill, 1957). The members were also likely to develop different patterns of communication, depending on the amount and type of previous experience they had with alternative networks (A. R. Cohen, 1964).

The placement of persons of lower or higher status or esteem in key positions could alter the outcomes of communication networks. For G. B. Cohen (1969), the presence of high-status members in positions of centrality facilitated the networks' performance. Nevertheless, low-status members became more effective in positions of centrality. Cohen concluded that in a pluricentral social system, the various centers of influence should have easy access to communication with all parts of the organization. Consistent with this conclusion, Mohanna and Argyle (1960) assigned sociometrically popular and unpopular participants to wheel and circle networks. They found that wheel groups with esteemed central members learned faster than did the other groups and required less time and fewer messages to solve the problem.<sup>14</sup>

### ***Networks and Effective Leadership Style***

M. E. Shaw (1955) compared democratic and authoritarian (order-giving) leaders of the different communication networks and found that the type of network made less of a difference than did leadership style. Speed and accuracy of performance were greater under authoritarian than under democratic leadership, but the members' satisfaction with and nominations for leadership were greater under a democratic style of leadership. Nevertheless, the type of communication network imposed on the group also determined which kind of leadership would be most effective. The central member of the wheel or yoke network and a designated member in the all-channel network were instructed to be coercive (to use the power of their position to require compliance) or to be persuasive by convincing with logic and information. Fewer errors in information were made in all three types of networks. However, the relative superiority of coercion over persuasion was greatest in the wheel network, was less great in the yoke network, and was least apparent in the all-channel network. But under all three conditions, as might be expected, members were less satisfied with coercion than with persuasion. In the all-channel and yoke networks, the same or similar amounts of decision-making errors occurred with persuasive and coercive leadership. Only in the wheel network were there fewer decision-making errors under coercive than under persuasive leadership (Shaw & Blum, 1966; Shepard, 1956).

## ***Influence of Personal Factors***

The placement of individuals with particular personal attributes in central positions or the use of participants who have some strong personal characteristics may systematically affect the outcomes of a communication network. However, M. E. Shaw (1960) failed to find that the homogeneity of members of a network in such attributes as intelligence, acceptance of authority, and individual prominence changed depending on whether centralized or decentralized structures resulted in more satisfaction and efficiency. But Trow (1957) observed that the stronger the participants' desire for autonomy, the higher was the correlation between the participants' satisfaction and the extent to which they believed they occupied positions of centrality.

Cohen and Foerst (1968) studied groups composed of *repressors* (members who repress or deny anxiety) and *sensitizers* (members who react to anxiety and worry). They found that leadership was significantly more continuous in the groups of repressors than in the groups of sensitizers. The groups of repressors developed centralized systems earlier than did the groups of sensitizers. Nevertheless, when given the opportunity, both types of groups rejected the all-channel network in favor of the centralized structure.

The centralized networks produced the fastest solutions with the fewest errors in the simplest kind of problem-solving situation, such as finding the common symbol. But the superiority of the centralized star, wheel, or yoke disappeared when the problem was made more complex by adding "noise" to the communications. For instance, when participants had to solve anagram problems for which they might or might not need information from one another, noise and irrelevant information in the communication system resulted in differences in the efficiency of the various networks. The effectiveness of a communication network depended on the characteristics of the task. No one type of network was always best (Glanzer & Glaser, 1961).

## ***Implications for Organizational Leadership***

Organizations are composed of networks that contain one or more of the types above. Moreover, the networks in a particular organization are interrelated and may vary from well-structured networks carrying regular task-related messages to loose, informal networks (Guetzkow & Simon, 1955).

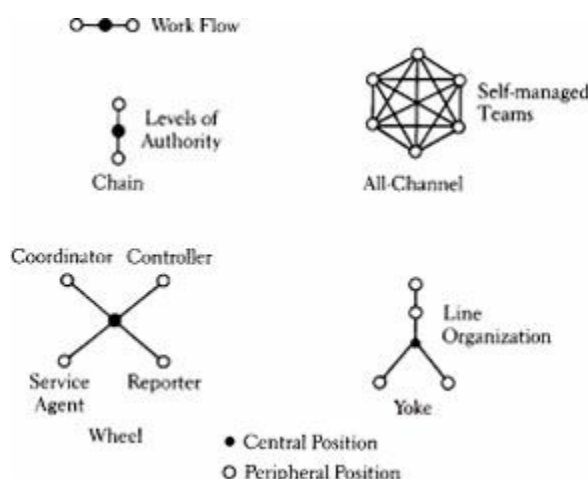

In real-world organizations, communications are involved in the exercise of authority, the exchange of information, the completion of specific tasks, friendship, and status. In communication networks based on authority and those based on information, the information typically flows in opposite directions. That is, information in networks that are based on authority flows from the persons who are in positions of authority down to subordinates. In contrast, in many networks that are based on information, the information flows primarily upward from those who provide information to those who collect that information for use in decision making; as a consequence, the potential for conflict is great.<sup>15</sup>

*Uses.* Network experiments can be used to simulate some particular organizational problem. In one such simulation by Hesseling and Kormen (1969), five participants represented each of five separate departments of a manufacturing company: sales, R & D, planning and production, organizational methods, and purchasing and subcontracting. All participants received complete information about the procedures of the company and a functional description of their respective departments. They were also given the necessary information to contribute to the decision-making process in their respective departmental roles. The purpose of the simulation was to discover, within a time limit of five 15-minute periods, the best working combination of the product's design, delivery time, and price so they would be able to accept or reject a customer's order. The participants were given sufficient time to discuss as a team how to organize the different departments' roles. Only written communication could be passed among the five department heads. The participants were left to form their

own network. The analysis focused on what kinds of networks emerged in such circumstances to yield the best combination of outputs. Centralization might promote speed of decision, but quality of decision depended on other factors.

It may be impossible to translate laboratory and simulation findings directly to large organizations. Yet these experimental networks are analogous to real organizational ones. The chain is seen in the vertical and horizontal serial communication linkages in an organization shown in [Figure 29.5](#). The meeting of the board of directors is an all-channel network. The typical line organization is a yoke. For many specific operations in an organization, persons find themselves at the hub of the wheel (Dubin, 1958).

Figure 29.5 Examples of Operational Networks

## Statistical Proxies

Kerr (1977) and Kerr and Jermier (1978) reasoned that social, organizational, and physical arrangements can be organized to improve the performance of individuals, teams, and organizations when the demands of a task are known. Also, ways can be found to provide mechanisms and alternatives for the various functions of the formal leader.

### *Proxies for Leadership: Forms of Circumstantial Moderators*

Howell, Dorfman, and Kerr (1986) classified moderators of leadership performance and its effects as neutralizers, enhancers, supplements, and substitutes for leadership.<sup>16</sup> *Neutralizers* do not directly correlate with the outcomes but cancel the leader-outcome relationship. *Enhancers* augment the leader-outcome relationship. *Supplements* contribute to effects on the subordinates' performance but do not cancel out or augment the leader's direct effects. Of most interest to subsequent research were *substitutes* for leadership, variables that make the leadership impossible or unnecessary.

*Neutralizers.* Neutralizers make it impossible for leaders to influence the outcomes of subordinates' performance (Howard & Joyce, 1982). For instance, a leader who is supportive and considerate may have little or no impact on highly authoritarian subordinates. The subordinates' authoritarianism neutralizes the leader's support. Supportive leadership would ordinarily promote better performance outcomes (Weed, Mitchell, & Moffitt, 1976). In examining data from 558 staff members of 25 nursing homes, Sheridan, Hogstel, and Fairchild (1985) expected and found that the effects of the supervisors' leadership activities were neutralized. They were significantly weaker in nursing homes with policies and practices that resulted in uncertain work

goals and the lack of sufficient rewards for the subordinates' good performance. Another potential neutralizer was the location of the nursing home. The responses of staff members to poor leadership behavior, such as quitting, were expected to be neutralized in small-town locations because there were few alternative jobs available to staff members. Other neutralization of supportive leadership might occur when: (1) cohesive work groups had antimanagement norms; (2) subordinates failed to respect the leader's competence; (3) subordinates were antiauthoritarian with an internal locus of control and a strong need for independence; (4) subordinates did not share the leader's or the organization's goals and objectives; (5) subordinates did not depend on the leader for resources; (6) subordinates worked at a physical distance from the leader; (7) the supportive leader lacked upward influence; and (8) union, civil service, or other institutional constraints prevented the leader from influencing the distribution of organizational rewards (Howell, Bowen, Dorfman, Kerr & Podsakoff, 1990).

*Enhancers.* A supportive leader who also has influence with a higher authority will have more of an impact on the outcomes of subordinates' performance than one who does not have such influence. Influence with higherups will enhance the effect of supportive leadership on the subordinates' performance.

The same variables, such as the norms of a cohesive work group, may neutralize or enhance the leader's effect. If the cohesive group's norms are counter to the leader's and the organization's objectives, the cohesion will offset the effect of the leader on the member's performance. If the cohesive group's norms are in alignment with the leader's and the organization's objectives, the cohesive norms should enhance the leader's effects on the members. Summarizing research through 1988, Howell, Bowen, Kerr, et al. (undated) concluded that the following enhancers should increase the impact of supportive leaders: (1) cohesive work groups with promanagement norms; (2) the leader with important, highly visible organizational responsibility; (3) leaders with a great deal of upward and lateral influence; (4) leaders with a strong resource base; (5) subordinates who are highly dependent on the leaders for resources; and (6) an organizational culture that is supportive of management. The effects on outcomes of the leaders' task-oriented guidance should be enhanced by (7) the subordinates' respect for the leaders' competence; (8) the leaders' reward power; (9) visible, influential champions of the leaders within or outside the organization;<sup>17</sup> (10) a crisis atmosphere; and (11) superordinate goals. Dorfman, Howell, Cotton, et al. (1992) found that the higher rank and expertise of company-grade commissioned officers supervising NCOs in the air defense artillery could enhance the impact of the COs' supportive leadership.

*Supplements.* Computerized decision support systems exemplify designed supplements to leadership. These are preplanned approaches to solving designated kinds of problems that attempt to parallel systematically the behavior and thought processes of decision makers and can be used to supplement leaders' judgments. They do not substitute completely for the leaders. Rather, they are used by leaders to make a final integrated decision (Wedley & Field, 1984). Howell and Dorfman (1981) demonstrated that for 220 hospital workers, such supplements could be seen in the extent to which their intrinsic task satisfaction, routinization, and task feedback contributed directly to the employees' commitment or satisfaction or both without inhibiting or augmenting the leaders' more direct influence on the same outcomes. Again, in a study of university counselors, Howard and Joyce (1982) demonstrated that good peer relationships supplemented the leaders' consideration and initiation.

*Substitutes.* When substitutes for leadership are present, they replace supportive leadership. Leadership by itself will be expected to be of little or no consequence to the satisfaction and performance of subordinates. Logically and empirically, substitutes directly affect the performance of subordinates, while the leadership does not. The substitutes act like neutralizers to cancel the leader's effect on the outcomes of subordinates' performance (Howell, Dorfman, & Kerr, 1986). Interviews with those who were responsible for supervisory professionals, such as research directors and nursing supervisors, talked repeatedly about substitutes for leadership in professional settings. The work itself emerged and directed the professional worker without the

need for the leaders to intervene (Wall, 1986). A highly predictable work flow, as a consequence of bureaucratization and centralization, could substitute for control by supervisors (Comstock & Scott, 1977).

In predicting subordinates' commitment to an organization, both Kerr and Jermier (1978) and Howell and Dorfman (1982) found that the formalization of an organization is a strong substitute for the leader's assigning of work. Dorfman, Howell, Cotton et al. (1992) showed that organizational formalization could substitute for directive, participative, and representative leadership of previously mentioned air defense artillery commissioned officers. Formalization is less of a substitute for the leader's specification of the rules. It is also less of a substitute for role clarification by the leader in the prediction of employees' satisfaction. Howell and Dorfman (1986) ascertained that organizational formalization was a weak substitute for the leader's specification of procedures in the prediction of the satisfaction of professionals. Further indirect support showing that organizational formalization could moderate and substitute for leadership in affecting outcomes for subordinates was obtained by Freeston (1987) and Podsakoff, Todor, Grover, and Huber (1984). Kerr and Jermier (1978) and Kerr and Slocum (1981) found that the subordinates' ability, professional orientation, and desire for autonomy made the addition of task direction from the leader counterproductive. In the same way, Sheridan, Vredenburg, and Abelson (1984) reported that for 98 supervisors and head nurses and their 670 nurses in four hospitals, the nurses' education, group cohesion, and available work technology substituted for the head nurses' leadership in directly and indirectly affecting the nurses' job performance. The administrative climate of the hospitals acted as a neutralizer.

*Other Substitutes.* Much of what are considered conscious acts of leadership today were attributable in static traditional societies to highly internalized norms, rules, and values. Compliance was a matter of habit, as was the avoidance of guilt or shame. Except for outlaws, one did what one was expected to do, without explicit direction, monitoring, and reinforcement by a leader (Gardner, 1986a).

Group processes could substitute for leadership. P. B. Smith (1984) found that the manager's role in area management teams of British social workers was relatively unimportant in predicting the effectiveness of the team compared to group process variables such as the personal involvement of members and the low denial of conflict. Substitutes for leadership were also seen as possible when reward systems could operate independently of the leader based on commissions, piecework, incentives, and profit sharing for work done. Also, expert staff personnel could serve as substitutes directly to subordinates without the leader's intervention (Howell, Bowen, Kerr, et al., un-dated).

Pitner (1988) validated 11 of 13 hypotheses concerning possible substitutes for leadership in the educational context. Staff contributions, differences in teaching, and the structure of the organization could serve as substitutes for leadership in affecting subordinates' performance and attitudes, according to 450 surveyed teachers from 47 schools.

The features of sociotechnological jobs and organizational designs like those advanced by Cherns (1976) are a particularly important source of substitutes for leadership. The computer display itself can give immediate, direct feedback to the employee who is working at a computer terminal about the employee's absolute speed and errors as well as the employee's performance. The display can be contrasted with previous work, standards, and norms. Organizational feedback about performance, which is ordinarily transmitted through supervision, can be sent directly to the employee to promote self-monitoring and self-evaluation. Team operations in which members share responsibility for achieving team objectives can be rewarded on the basis of the team's productivity without supervisory intervention. The team as a whole and its individual members, instead of a supervisor, become the substitute sources for planning, directing, and controlling.

Jones (1983) showed that workflow could be controlled as much by the task structure of the role formalization as by the leader's use of reinforcement. In a study of 220 hospital personnel, Howell and Dorfman (1981) dealt with role ambiguity and conflict. They used the subordinates' ability and experience and the formal organization to substitute for specific supportive leadership behaviors that ordinarily boost the

subordinate's job satisfaction and organizational commitment.

*Other Analyses of Proxies for Leadership.* Proxies for leadership were analyzed as moderators of leader-outcome relationships. Podsakoff, Todor, Grover, and Huber (1982) used moderated regression analysis to test for the effects of substitutes for leadership on the relationship between leaders' contingent reward behavior and subordinates' satisfaction. Change in the variance explained by the addition of the interaction term (leadership behavior multi substitute) to the regression equation was an indicator of the effect of substitution. In line with suggestions of Howard and Joyce (1982) Sheridan, Vredenburgh, and Abelson (1984) used path analysis to detect substitutes for leadership. To obtain path coefficients, they treated leadership as a function of expected substitutes and outcomes, as a function of leadership, of substitutes, and of substitutes combined with leadership. Thus, they used substitutes as a predictor of both the leadership behavior itself and of the outcomes. Podsakoff, MacKenzie, and Bommer (1996) showed, in a hierarchical regression analysis for 1,539 employees of the statistical proxies for transformational leadership, that a few substitutes had unique effects on follower job attitudes, role perceptions, and citizenship behaviors. The employees came of various industries, levels, and organizational settings.

## ***Applications***

Neutralizers, enhancers, supplements, and substitutes can be designed into systems as needed. Jacobs and Jaques (1987) pointed to the extent to which supervision can be more effective if, independent of supervision, the structure in the situation is designed to exert demands on the individual employee that are relevant to accomplishing the work to be done. Howell, Dorfman, and Kerr (1986) suggested that coercive, autocratic leadership can be neutralized by removing the control of rewards and penalties from the leader. Inadequate leadership can be enhanced by team building to increase supportive norms. Selecting mature subordinates may provide a substitute for stable leadership. Assigning an assistant to a manager may supplement the manager's leadership.

A study by Tyagi (1985) of 168 life insurance salespersons showed that variations in jobs, such as in the opportunities they provided for using a variety of skills, enhancing the significance of the task, and allowing for autonomy, combined to account for 47% of the variance in the intrinsic motivation of the salespersons. But these variations in jobs had far less effect on the salespersons' extrinsic motivation, accounting for only 18% of it. In contrast, the leaders' trust and support, interaction facilitation, and psychological and hierarchical influence combined to account for 38% of the salespersons' extrinsic motivation but only 16% of their intrinsic motivation. The variety of skills, significance of the task, and autonomy that were built into the job could substitute more for the leadership in intrinsically motivating the salespersons and less in extrinsically motivating them. Both types of motivation contributed to improvements in the salespersons' work performance.

## **Self-Management**

---

### ***Autonomous Work Groups***

Self-managing teams were discussed in [Chapter 12](#) as illustrative of redistributing power, and again in [Chapter 26](#) for converting the leader to becoming an external consultant and advisor to the self-managing team. Substitution for formal supervision and leadership occurs when autonomous work groups are created and self-

management is introduced. Autonomous work groups and self-management by individual members of an organization are two ways in which group processes and individual dynamics are structured to eliminate formal supervision, yet achieve or better the results obtained with formally assigned leaders.

Autonomous work groups can operate without direct supervision. For the omitted supervisor's contribution, they substitute collective control by the work group members of the pace of work, distribution of tasks, and training of new members (Gulowsen, 1972). The supervisor is made redundant if the members of the work group have functionally interrelated tasks and are collectively responsible for the end products. Roles may still be differentiated. One member may still be central, others peripheral. The members must have a variety of skills so they can handle many or most of the groups' tasks. Feedback, along with evaluation of the work group as a whole, is also necessary. Wall, Kemp, Jackson, and Clegg (1986) completed a study of the long-term effects of using such autonomous work groups in manufacturing in Britain. They found that supervisory routines could be eliminated with no noticeable effects on subordinates' motivation or performance. They also found enhanced intrinsic job satisfaction among the members but only temporary increases in extrinsic job satisfaction.

### ***Self-Managing Individuals***

Building on Bandura's (1977) social learning theory, Manz (1986) argued for fostering self-planning, self-direction, self-monitoring, and self-control, which could replace otherwise needed supervision. For both the individual and the group, self-management calls for self-observation, specification of goals, cuing strategies, rehearsal, self-evaluation, and self-reinforcement (Manz & Sims, 1980). After difficult or unappealing but necessary tasks are identified, each of these processes can be incorporated into an individual's everyday job performance. Self-observation can be promoted by keeping a daily log of what one has discussed with others by e-mail or telephone. Goal specification occurs when one sets schedules and priorities for oneself. Cuing is illustrated by the example of a checkout board that was placed at the exit of a manager's office to remind her to leave word for her secretary where she was going and when she would be back. Rehearsal occurs when one records a sales presentation on a tape recorder and then listens to one's performance, correcting it as necessary. Self-evaluation is aided by keeping charts of one's progress in improving the quality or quantity of one's performance. Self-reinforcement is accomplished by building natural rewards for the performance of tasks. It may be done by searching for features of the task activities that give one a feeling of purpose, competence, and self-control (Manz, 1983). Contrary to what might have been expected, Manz and Angle (1985) noted from what was seen in an insurance firm that such self-management resulted in increased compliance by sales personnel with the company's procedures and goals.

### ***The Paradox: Higher Authority Is Required for Self-Management***

To a considerable degree, self-management by groups and individuals requires considerable delegation by a higher authority. Furthermore, higher-ups provide examples, guidance, encouragement, and support. Manz and Sims (1986b) note that self-managed autonomous groups require a *superleader* who is external to the groups. Such an external leader helps the groups become self-monitoring, set their own goals, criticize and reinforce themselves, and plan and assign tasks by themselves instead of depending on the superleader.

Helping others to shift to self-control from external control requires dealing with a variety of problems. There is a self-serving bias in attributing one's poor performance to situational rather than personal factors. Coordination may suffer. Individuals differ in their need for autonomy. Whether the concern is about the employee's developing proficiencies or the employee's current results makes a difference. Self-control with

guidance from an external leader is likely to be more directly relevant to the individual's development and internalization of the desired and required job behavior. External control may be sufficient for monitoring results (Manz, Mossholder, & Luthans, 1983). With no formally appointed leader in each group, members have to be willing and able to take on the leadership task and maintenance functions as needed by the group.

## Summary and Conclusions

---

Physical, organizational, and spatial factors have direct and indirect influence on leader-member relationships. Advances in electronic communication have made virtual leadership common. Studies of interpersonal space indicate that individuals interact more frequently with those who are located close to them than with those who are farther away. The member who occupies the head position at the table tends to assume leadership. Leaders tend to gravitate toward head positions and are expected to do so. Members who occupy head positions tend to be more influential than do those who occupy side or peripheral positions. Members tend to maintain greater physical distance between themselves and members who are of a higher or lower status than between themselves and their peers in status. Differences in status and social distance tend to be valued when the consequences of social interaction may be unpleasant and when effective group performance is desired by group members. Socio-metric preferences for contact, communication, and work map the actual patterns of influence in an organization. They may be quite independent of the authority structure and are more likely to correspond with friendship, familiarity, and mutual esteem. Sociometric descriptions of actual contacts, communicants, and work partners do the same.

Individuals who live or work in close proximity to one another also exhibit a higher rate of mutual sociometric choice than do those who are situated at a greater distance from one another. At the same time, the quality of personal interaction in and achievement by the group may be facilitated by some degree of psychosocial distance between the leader and the followers. Individuals prefer greater social distance between themselves and their competitors than between themselves and those with whom they cooperate.

Virtual leadership and virtual teams are replacing face-to-face arrangements on a global scale. Electronic networking between e-leaders and their virtual teams has increased rapidly with the advent of the Internet and the personal computer. Experiments pointed to advantages and disadvantages of e-networking and e-leadership compared to face-to-face (FTF) meetings and leadership. Compared to FTF leaders, e-leaders need to have particular capabilities and to carry out particular actions. Efficient computerized group decision support systems (GDSS) have become available.

Networks are replacing hierarchical communications in importance to organizations. Research on networks in organizations and in experimental communication networks has indicated that the member who occupies a position of centrality tends to emerge as the leader. That member has greater access to communication than do other members and is thus better able to coordinate and direct the group's activities. Groups with positions of centrality within them are more efficient than those with un-differentiated role structures. The openness of network channels is directly related to the information available to a leader and therefore to the leader's ability to exert influence. Regular meetings usually (but not always) provide more continuing communications and promote the group's performance. The member who occupies a position of centrality is better satisfied with the group than are members in peripheral positions. Personal factors, such as the need for autonomy and ascendancy, moderate these effects. The experimental results tend to confirm parallel real-world organizational networks.

Experimental groups with a member in a position of centrality are more efficient than groups without differentiated role structures. Members who occupy positions of centrality that enable them to exercise control over the flow of information are most likely to emerge as leaders. They are also better satisfied with their

groups than are the peripheral members. Several studies have suggested that personality factors might be influenced by the relationship between centrality and leadership. A highly submissive member was likely to become a more active participant in the group's activities when placed in a position of centrality.

Social, organizational, and physical rearrangements of how work is accomplished can be used to neutralize, enhance, supplement, or substitute for leadership. Such rearrangements may include setting up autonomous work groups and encouraging self-management. These rearrangements can benefit organizations by reducing the costs of supervision and increasing the employees' commitment and contribute to the persistence and transfer of leadership.

<sup>2</sup> See also, Lécuyer (1976), Lott and Sommer (1967), and Sommer (1961).

<sup>3</sup> For more on the effects of propinquity and location, see the reviews by Barker (1968), Dogan and Rokkan (1969), Klopfer (1969), Mehrabian (1968a), M. Patterson (1968), and Sommer (1967, 1969).

<sup>4</sup> This number has fallen substantially since 1950, as evidenced by the increasing demand of teachers to participate in the design of curricula and the governance of schools.

<sup>5</sup> See [Chapter 13](#). Conversely, when presidents walk down the street in their inaugural parades or move into a crowd to chat, they are ceremoniously reducing social as well as physical distance.

<sup>6</sup> This congruence, as noted in [Chapter 13](#), is likely to minimize conflicts between status and esteem. [Chapter 35](#) provides a detailed review of the utility of peer nominations, or “buddy ratings,” for forecasting success as a military officer.

<sup>7</sup> See [Chapter 10](#).

<sup>8</sup> Networks can obviously be mapped in sociograms produced by sociometry.

<sup>2</sup> As defined in [Chapter 18](#), *direction* (italic) refers only to giving orders with or without explanation; direction (roman) includes ordering, persuading, and manipulating. *Participation* (italic) refers only to sharing in the decision process; participation (roman) includes consulting, sharing, and delegating.

<sup>10</sup> Consulting, participating, and delegating.

<sup>11</sup> Success was measured by the extent to which their salaries were greater than predicted by their age, sex, education, and years of service, and by the size of the operations for which they were responsible.

<sup>12</sup> Reviews of the method and outcomes of research can be found in Cartwright and Zander (1960), Glanzer and Glaser (1961), and Mulder (1963).

<sup>13</sup> See, for example, Cohen, Bennis, and Wolkon (1961); M. L. Goldberg (1955); and Shaw, Rothschild, and Strickland (1957).

<sup>14</sup> As was noted in [Chapter 13](#), efficiency is increased and conflict is reduced in organizations when one's self-esteem is congruent with the importance of the position to which one is assigned.

<sup>15</sup> Detailed in [Chapter 13](#).

<sup>16</sup> In terms of multiple regression analysis, employed to test for these moderators of the effects of leadership on outcomes, if  $y = ax + bz$ , when  $x$  is leadership behavior,  $z$  is the moderator, and  $y$  is predicted subordinate performance, then:  $z$  is a *neutralizer* if  $b$  is negative and  $z$ , although correlated with  $x$ , does not correlate with  $y$ ;  $z$  is an *enhancer* if  $b$  is positive and  $z$  does not correlate with  $y$ ;  $z$  is a *supplement* if it correlates with  $y$ , adding to the correlation of  $x$  with  $y$ ;  $z$  is a *substitute* if it correlates with  $y$  while  $x$  adjusted for  $z$  does not.

<sup>17</sup> Both J. Edgar Hoover's and Hyman Rickover's postponed retirement and continued success as leaders over many decades within the FBI and the U.S. Navy, respectively, depended, in great part, on the extent to which they had many congressmen to champion their causes.

---

# Transfer and Succession

The efforts of many leaders to reach the top begin with initiatives displayed in childhood that continue unabated through adolescence into adulthood. Lyndon Johnson and Margaret Thatcher are illustrative. As adults, they obtained their reputations as successful leaders in one situation and then transferred that reputation for successful leadership to other similar situations. They and some others gained sufficient esteem and experience in their early efforts to succeed as leaders in almost any situation they entered (Bogardus, 1928; Cowley, 1931). Success in one political office served as a stepping-stone to other offices. But failure in one office could destroy one's political career (Burns, 1978), although before Abraham Lincoln was elected president, he suffered a number of defeats in earlier campaigns for lesser offices. The persisting effects of charismatic founders can dominate an organization's culture long after the founders are gone. Salaman (1977) illustrated this effect in a small, successful manufacturing firm that continued to be influenced by a charismatic leader even after he had retired and was no longer on the scene.

Although tasks and goals can be different from situation to situation, some amount of interpersonal competence is required from any leader. So there is likely to be some amount of transfer of who emerges as leader in different situations. In the same way, personal characteristics, such as energy, intelligence, assertiveness, task orientation, need for power, and other personal traits promote the persistence of the same persons emerging as leaders in a variety of times and places. Since considerable consistency is found in intelligence and various personality traits from childhood to adulthood, consistency will also be found in children's trait-associated tendencies to become leaders and their potential to become leaders as adults. For example, C. M. Cox's (1926) analyses of the biographies of 300 outstanding military, religious, and political leaders frequently found above-normal behavior traits in their childhoods, such as the desire to excel, intelligence, insight, self-esteem, and forcefulness—traits usually related to leadership. Analyses that followed subjects from early childhood to retirement found that conscientiousness and mental ability predicted career success, while neuroticism was contraindicated (Judge, Higgins, Thoresen, et al., 1999).

## Persistence

---

The persistence of an individual's attempts, success, and effectiveness as a leader across situations and time periods may be augmented by a consistent "ability to perceive the needs and goals of a constituency and to adjust one's personal approach to group action accordingly" (Kenny & Zaccaro, 1983, p. 678). It is also strengthened by the continuous power that a leader may hold during the various stages in a group's development (Quiggins & Lashbrook, 1972). In 36 firms, Miller (1993), as expected, found that long-tenured executives accumulate power and legitimacy. Their long-term followers respond more favorably to them. Persistence in leadership is further bolstered by the implicit beliefs of followers that regardless of the environmental complexities to be faced, more persistence is a virtue in leaders and shows their sense of responsibility (Graves, 1985). Such persistence in leadership behavior is often seen as characteristic of successful chief executives, manifested in their consistent support of a theme, shifting attention to that theme, granting authority down the line to support the theme, encouraging experimentations about the theme, and developing and maintaining contacts about it throughout the system (Peters, 1980). Such persistence may pay off. Staw
