(p. vii) Preface

Corporate law and corporate governance have been at the forefront of regulatory activities and scholarly attention across the world for several decades, but the field has drawn increased public attention in light of the alleged role of corporate governance in the 2007–2009 Global Financial Crisis. There is a growing need for a global framework through which to understand the aims and methods of legal research in this field. The aim of this *Oxford Handbook of Corporate Law and Governance* is to supply scholars, students, and the educated layperson with a comprehensive resource, a common point of entry into cutting edge work in corporate law and governance while not giving priority to a particular view. The approach is cross-jurisdictional, interdisciplinary, and functional. In doing so, we are proud to say, this handbook is unique; a comparable resource for corporate governance and law does not exist.

Experts and leading scholars on corporate law and governance from across the globe were given the mandate to contribute a critical reflection on scholarship in their respective subfields. It turned out that the approaches used by the various contributors are as diverse as their substance: We are happy to assemble contributions that develop groundbreaking new insights, provide critical literature reviews, explain scholarly developments and methodological controversies, and make policy contributions. In sum, the fruit of this approach is an extremely rich resource of the current state of play of scholarship in the field across a broad range of topics.

The task of putting together a volume of this ambition has been challenging. Our contributors come from different disciplines and many different jurisdictions around the globe. They bring a broad variety of approaches and methodologies to corporate law and governance, and they come with divergent cultural and historical traditions. That in itself poses a number of formidable challenges for the editors. But the greatest trial has been to cope with the dynamics and the internationalization of the field. Corporate law, as seen through an economic lens, is not anymore the simple, bi-polar conflict over power in the corporation as epitomized by the principal-agency conflict between managers and own-

Preface

ers. Research is mushrooming on different patterns of ownership, of different legal approaches that are tested and dismissed, of competition between firms and between regulators, of standard-setting by international agencies, of trade integration and disintegration, of different negotiations of the gap between sovereigns and the firm. Globalization is penetrating into the forays of the law with an unprecedented force. Non-legal issues, practices, and mechanisms are becoming more important for both scholarship and corporate practice. This brings up a number of new challenges and poses questions of legitimacy, of law enforcement, and of market pressure.

We can make advances on these questions only with a common canon of scholarship that is grounded in international and interdisciplinary dialogue. Only by listening to each other, (p. viii) by understanding each other's economic problems and legal solutions, will we learn from each other. The contributors to this volume are all leading scholars in their fields and provide an international, non-parochial approach to research that is indispensable for deep dialogue. During the genesis of this Handbook, we held an authors' conference under the auspices of the Ira M. Millstein Center for Global Markets and Corporate Ownership at Columbia Law School, funding for which we acknowledge gratefully. This conference facilitated exchange and dialogue between the authors and helped to create a joint effort with a coherent trajectory.

We hope that this *Oxford Handbook* will provide a valuable resource for scholarship and research, but also for practitioners or students who seek to familiarize themselves with the latest findings from a particular field of interest. The consequence of our ambition has been a very hefty book of more than 1000 pages. But the book is also available on-line on a chapter-by-chapter basis at www.oxfordhandbooks.com.

Abstract and Keywords

In the 1960s and 1970s, corporate law and finance scholars gave up on their traditional approaches. Corporate law had become “towering skyscrapers of rusted girders, internally welded together and containing nothing but wind.” In finance, the theory of the firm was recognized as an “empty box.” This essay tracks how corporate law was reborn as corporate governance through three examples of how we have usefully complicated the inquiry into corporate behavior. Part I frames the first complication, defining governance broadly as the company’s operating system, a braided framework of legal and non-legal elements. Part II adds a second complication by making the inquiry dynamic: corporate governance as a path dependent process that co-evolves with the elements of the broader capitalist regime. Part III considers unsuccessful efforts to simplify rather than complicate corporate governance analysis through static single factor models: stakeholder, team production, director primacy, and shareholder primacy. Part IV concludes by highlighting the tradeoff between a governance system’s capacity to adapt to change and its ability to support long-term investment.

Keywords: corporate law, corporate governance, comparative corporate governance, varieties of capitalism, team production, director primacy, shareholder primacy, stakeholders, path dependency, short-termism

1 Introduction

IN 1962, Bayless Manning, the Yale Law School corporate law scholar and later Stanford Law School dean, announced the death of corporate law. Writing evocatively about a subject that was at the time deadly boring, Manning wrote:

[C]orporation law, as a field of intellectual effort, is dead in the United States. When American law ceased to take the “corporation” seriously, the entire body of law that had been built upon that intellectual construct slowly perforated and rotted away. We have nothing left but our great empty corporation statutes—tower-

ing skyscrapers of rusted girders, internally welded together and containing nothing but wind.¹

Manning bemoaned that the corporate statute—the rusted girders of his metaphor that provided the formal structure of the enterprise—no longer was enough to understand what really mattered: how the corporation performed. Once the formalism of the statute was recognized as insufficient itself to explain the true matter of concern, the conclusion followed: nothing was left but wind.

Manning's lament could be written off as just a law professor's realization that his discipline no longer explained enough about actual corporation behavior. But the concern was not limited to legal scholars; the same realization was coming to the surface in financial economics. In 1976, Jensen and Meckling provided what became the canonical account of the corporation in "Theory of the Firm: Managerial Behavior, Agency Costs and the Theory of (p. 4) the Firm."² Addressing a different literature, Jensen and Meckling educed a metaphor similar to Manning's: the theory of the firm in economics was an "empty box."³

While the literature of economics is replete with references to the 'theory of the firm,' the material generally subsumed under that heading is not a theory of the firm but actually a theory of markets in which firms are important actors. The firm is a "black box" operated so as to meet the relevant marginal conditions . . . Except for a few recent and tentative steps, however, we have no theory which explains how the conflicting objectives of the individual participants are brought into equilibrium so as to yield this result.⁴

Jensen and Meckling focused centrally on the concept of agency costs—the cost of techniques to align the incentives of the different participants necessary to conducting the corporation's business. From their perspective, the corporation was a "form of legal fiction which serves as a nexus for contracting relationships and which is also characterized by the existence of divisible residual claims on the assets and cash flows of the organization which can generally be sold without permission of the other contracting individuals."⁵ Reframed in current Silicon Valley terminology, the corporation is a multi-sided platform that integrates inputs on the one hand and customers on the other.

The intellectual impact of the agency cost characterization is hard to overstate: for the last 40 years, the mission of American corporate law, and of corporate scholarship more broadly, has taken the form of a search for the organizational Holy Grail, a technique that bridges the separation of ownership and control by aligning the interests of shareholders and managers through a series of techniques, over time highlighting the role of independent directors, hostile takeovers, and activist shareholders in this effort.⁶ This coalescence around corporate law as a vehicle to produce shareholder profits hit its high point when Henry Hansmann and Reinier Kraakman, in an article confidently titled "The End of History for Corporate Law," concluded that "in key commercial jurisdictions . . . there is no longer any serious competitor to the view that corporate law should principally strive to increase long-term shareholder value."⁷

From Corporate Law to Corporate Governance

The result of Jensen and Meckling's seminal reframing of corporate law into something far broader than disputes over statutory language was that both Manning's empty skyscrapers and Jensen and Meckling's empty box began to be filled. And it was no coincidence that the term "corporate governance" appeared at about this time.⁸ Over a reasonably (p. 5) short period, corporate governance codes appeared, like that of the OECD,⁹ which ranged much more broadly than the limited coverage of a particular national (or state) corporate statute. Perhaps most aggressively, in 1997 during the East Asian financial crisis the International Monetary Fund and the World Bank included corporate governance reform as a condition to assistance alongside traditional macroeconomic restraints such as deficit reduction.¹⁰ Academic attention followed the same growth pattern. For example, more than a quarter of all articles published in the *Journal of Financial Economics*, one of the two leading finance journals, from 1995 through August 29, 2013 were related to corporate governance.¹¹

But with what have the empty skyscrapers and boxes been filled? The short answer is that the new content has addressed the variety and interaction of contracts—formal contracts, implicit contracts,¹² and the braiding of the two¹³—that Jensen and Meckling's treatment of the corporation as a nexus of platforms invites. In the remainder of this chapter, I will address three somewhat idiosyncratically chosen but nonetheless related examples of the implications of the shift from corporate law to corporate governance, from legal rules standing alone to legal rules interacting with non-legal corporate processes and institutions. Of course, the point is not to be exhaustive, nor even to provide a taxonomy covering the categories of the new content that is filling empty skyscrapers and boxes; the number and breadth of the chapters in this book make obvious that either effort necessarily exceeds my ambition here. Rather, my more limited goal is to provide examples of how this shift from (p. 6) corporate law to corporate governance—from a largely legal focus to one that focuses on the corporation's inputs, outputs and how they are managed and, ultimately, the manner in which governance interfaces with other institutional elements that make up a capitalist system—complicates the problem corporate scholars, of whatever mix of disciplines, have to confront.¹⁴

The chapter proceeds by tracking how corporate law became corporate governance through three examples of how we have come to usefully complicate the inquiry into the structures that bear on corporate decision making and performance. Section 2 frames the first level of complication in moving from law to governance by defining governance broadly as the company's operating system, a braided framework encompassing legal and non-legal elements. Section 3 then adds a second level of complication by treating corporate governance dynamically: corporate governance becomes a path-dependent outcome of the tools available when a national governance system begins taking shape, and the process by which elements are added to the governance system going forward—driven by what Paul Milgrom and John Roberts call "supermodularity."¹⁵ That characteristic reads importantly on both the difficulty of corporate governance, as opposed to corporate law, reform, and the non-intuitive pattern of the results of reform: significant reform leads to things getting worse before they get better. Section 3 then further complicates corporate governance by expanding it beyond the boundaries of the corporation, treating particular

governance regimes as complementary to other social structures—for example, the labor market, the capital market, and the political structure—that together define different varieties of capitalism.

Section 4 then considers commonplace, but I will suggest misguided, efforts to take a different tack from sections 2 and 3: to simplify rather than complicate corporate governance analysis by recourse to now familiar single-factor analytic models in academic corporate law and governance: stakeholder theory, team production, director primacy, and shareholder primacy. Section 4 suggests that these reductions are neither models nor particularly helpful; they neither bridge the contextual specificity of most corporate governance analysis nor address the necessary interaction in allocating responsibilities among shareholders, teams, and directors. In addition, these “models” are static rather than dynamic, a serious failing in an era in which the second derivative of change is positive in many business environments and Schumpeter seems to be getting the better of Burke. Section 5 concludes by examining the importance of a corporate governance system’s capacity to respond to changes in the business environment: the greater the rate of change, the more important is a governance system’s capacity to adapt and the less important its ability to support long-term, firm-specific investment.

2 Corporate Governance as the Corporation’s Operating System

In teaching corporations, I ask at the beginning of the first class a seemingly simple question: what is a corporation? After a predictable series of ever more complicated and sophisticated responses from very smart students, I dramatically display¹⁶ a copy of a California corporation’s articles of incorporation together with the Secretary of State’s certifying cover page, on which appear attractive pictures of the California state animal (the grizzly bear) and state flower (the California poppy).¹⁷ The corporation is nothing but a few pieces of paper I say, leading up to a point similar to that made by Jensen and Meckling: corporations are best understood not as a single thing but as the intersection of different things—recall that Jensen and Meckling describe them as “legal fictions.”¹⁸ To be sure, the formalities are thin and incomplete, but they are nonetheless important. For example, the corporate statute gives the entity limited liability and unlimited life, features that caused the Economist in 1926 to equate the corporation’s invention with the industrial revolution’s most important technological innovations.¹⁹ But these are passive characteristics. Something more is necessary to bring the golem to life.

This sets the stage for my real point. A corporation should be defined functionally by reference to the structure that allows a legal fiction to operate a business and makes it possible for third parties to confidently do business with it. Some of these structures are legal rules that, in specified circumstances, allow the corporation to be treated, like Pinocchio, as if a real boy. However, the mass of the business operation, both in importance and in bulk, is not legal at all. It is processes of information flow, decision making, decision implementation, and decision monitoring: how people operating the corporation (1)

From Corporate Law to Corporate Governance

obtain the information they need to make, implement, and monitor the results of business decisions (including information relevant to regulatory compliance); (2) distribute information from information originators to managers with sufficient expertise and experience to evaluate it; and (3) make decisions, communicate decisions to the employees who implement them, and then gather information about the consequences, for the next round.

It is obvious that the formal corporate legal skeleton covers only a very small part of how the corporation actually operates to carry out its business and continually adapts to its business environment. In Bernard Black's terms, most of the legal rules concerning the corporation's operations are "trivial,"²⁰ in the sense that the rules are important only if (p. 8) they are ignored despite how easy they are to satisfy. The rest and obviously most important part of the governance structure—the dark matter of corporate governance—is the realm of reporting relationships, organizational charts, compensation arrangements, information gathering, and internal controls and monitoring, all largely non-legally dictated policies, practices, and procedures that do not appear in the corporate statute or the corporation's charter or bylaws. To be sure, non-legal governance processes can morph into the "legal" when legislatures conclude that self-generated governance is less effective than social welfare demands. A familiar example: after the Enron/WorldCom accounting scandals, Sarbanes-Oxley imposed a set of governance requirements over financial reporting, which included external monitoring of internal controls, a specified board committee structure and composition, and mandatory officer responsibilities. But, in general, even where the board has compliance responsibilities, the implementation is for the firm to work out.

Put differently, corporate governance is the corporation's operating system. This characterization of governance in operational terms is reflected in the description of corporate governance offered by the Business Roundtable, an organization composed of the CEOs of many of the largest US corporations:

A good corporate governance structure is a working system for principled goal setting, effective decision making, and appropriate monitoring of compliance and performance. Through this vibrant and responsive structure, the CEO, the senior management team and the board of directors can interact effectively and respond quickly and appropriately to changing circumstances, within a framework of solid corporate values, to provide enduring value to the shareholders who invest in the enterprise.²¹

The end of the odd journey from corporate law to a more complex corporate governance system would give Dean Manning solace. His skyscrapers have been filled to overflowing, but formal law—the corporate statute and cases interpreting it—occupy far fewer floors in the building. The outcome of this integration of law and managerial mechanisms puts law in an important but plainly subordinate role in the corporation's operating system:

Investors provide to a corporation the funds with which it acquires real assets. The investors receive in return financial claims (securities) on the corporation's future cash flows. The size of these future cash flows then depends importantly on

management's choice of what real assets to acquire and how well these assets are managed over time. The capital market's pricing of the financial claims acquired by investors is in effect a valuation of these future cash flows. Corporate law provides a framework within which a firm's managers make these investment and operating decisions. Properly designed, this legal framework helps spur management to choose and deploy assets in ways that maximize the value of the firm's expected future cash flows . . . The better corporate and securities law perform these tasks, the more valuable the corporation's underlying business and correspondingly, the financial claims that the corporation issues.²²

(p. 9) **3 Path Dependence: Corporate Governance, Complementarity, and Supermodularity**

The second effort to complicate corporate governance adds a dynamic dimension. Corporate governance is path dependent—history matters significantly.²³ In a path-dependent environment with factors such as increasing returns and network externalities, an observed equilibrium may be inefficient compared to arrangements possible at the time of the comparison that were not available when the arrangements arose. Initial conditions, determined by fortuitous events or non-economic factors such as culture, politics, or geography, can start the system down a specific path. For example, Silicon Valley's development near to the San Francisco Bay next to Stanford University, as opposed to the shores of Lake Michigan where Northwestern and the University of Chicago are about the same distance from each other as Stanford and the University of California at Berkeley, depended importantly on initial conditions. These included, importantly, Stanford's hiring Frederick Terman as dean of the engineering school shortly after World War II. Terman had directed one of the Cambridge, Massachusetts wartime labs that sought to bring cutting-edge science to bear in support of the war effort and so recognized the value of translational research, that is, the link between university research and its practical application.²⁴ Put simply, "history matters."²⁵

That history matters influences the dynamics of the system to be understood. In particular, history's shadow can make it difficult to reform existing institutions or adjust to changes in a company's product market even if current alternatives exist that, absent transition costs, would be more efficient. In the context of corporate governance as defined here, the role of complementarities drives the system down a path from which it is difficult later to depart. By "complementarities" I have in mind governance elements that create value because they make the existing system work better as a whole, and the fact that the "efficiency" of an element cannot be separated from the question of "fit."

One of the major corporate governance questions to which path dependence and complementarity gives rise can be usefully framed in terms of the operating system metaphor: in a world of increasingly global product and capital markets, is there room for multiple corporate operating systems? Do particular corporate governance systems give rise to sus-

tainable competitive advantage in particular product markets? What happens if a particular (p. 10) governance system is efficient until a change in the market renders it less efficient than that of new competitors and path dependency slows adjustment?²⁶

3.1 The Japanese Example

The development of Japanese corporate governance exemplifies the influence of complementarities on the persistence of corporate governance structure as broadly defined in section 2. Suppose one begins with an initial condition of a commitment to lifetime employment for a large number of employees, as was the case in the development of post-war Japanese corporate governance.²⁷ The next question relates to the influence of that initial condition on a corporation's production process. Because the norm of lifetime employment makes human capital a long-term asset, the company will sensibly make substantial firm-specific human capital investments in its employees, thus developing a work force that supports team and horizontal coordination.²⁸

In turn, the need to protect this long-term investment in human capital fits best with bank, as opposed to stock market-based, financing, to prevent the stock market from upsetting the company's implicit commitments to labor. Bank-based finance elevates the role of the bank as the monitor of managerial performance, rather than the public shareholders; this means suppressing public shareholders' rights and expectations relative to those of the bank. The need to monitor the performance of a management freed from stock market oversight thus led to the post-World War II Japanese main bank system. A single bank (typically leading a syndicate of banks) directly monitored a company's investment choice through the company's need to borrow to fund new projects, and through the information about the company's cash flow and performance that came to the bank through its provision of the company's general banking services.²⁹ Commonly, the main bank and the other banks that participated in providing loans to the company also held significant amounts of the company's equity, again out of a concern that a hostile takeover might upset the company's labor and financing arrangements.

(p. 11) Should the company fall on hard times, the main bank was expected to bail it out, through the provision of additional funds, but at the price of displacement of management with bank employees. The main bank bailout expectation was understood to be "an institutional arrangement complementary to the system of permanent employment." Bailout "helps to preserve the firm-specific human assets accumulated in the framework of the lifetime employment system and hence provides incentives for them to be generated in the first place."³⁰ In turn, this package of attributes and the related internal production methods are complementary to particular kinds of activity. The Japanese governance system, with its large investment in firm-specific employee human capital, is very effective when innovation is linear, and depends importantly on team work, but it is much less effective when innovation is discontinuous—the Japanese structure does not lend itself to Schumpeterian (or Christensen-like³¹) disruption.³² The overall result has been a tightly

From Corporate Law to Corporate Governance

integrated system of production that has been difficult to change in response to changing business conditions and opportunities for innovation.

In Milgrom and Roberts' terms, the relationship between these governance and associated organizational characteristics is supermodular. By that term they mean that at each decision node where a new governance or characteristics must be added to the existing system, the corporation will choose from among the alternatives that which best "fits" with the already present elements. That fit, in turn, is a function not just of the efficiency of the new element standing alone—the increased productivity that results simply from its addition—but also of the new element's capacity to improve the performance of the existing elements—the extent to which it is supermodular.³³

The complementarity among elements of the system, then, is a barrier to reform of the system because changing one element in the system results in degrading the performance of all other system elements to which that element was complementary. Just as adding a complementary element increased system performance by more than its own contribution, removing an element, by regulatory design or voluntarily in response to changed economic conditions, reduces performance of all elements. Like financial leverage, supermodularity steepens the performance curve both on the upside and on the downside: short of changing all elements of the system at once, reform will result in reduced system performance until enough of the system changes to recreate complementarities among the new and remaining elements.

Continuing the Japanese example, the combination of allowing Japanese companies to access non-Japanese sources of capital through the Eurodollar market and the enormous success of Japanese companies such that projects could be financed through cash flow rather than bank-provided project finance, eroded the role of the main bank. The contemporaneous drop in the value of the Nikkei reduced the value of the banks' cross-holdings in its (p. 12) customer companies, which necessitated sales of significant amounts of those holdings to maintain bank compliance with capital requirements.³⁴ At the same time, conditions in many product markets came to favor discontinuous innovation rather than linear innovation. Reduced performance of any part of a governance system built on complementarities reduced the performance of the entire Japanese governance system, yet the previously efficient complementarities create a barrier to reform.

This analysis provides background to understanding why the recent corporate governance reform proposals of Prime Minister Shinzo Abe represent more than tinkering with the formal relationships between shareholders and managers. The main bank system has not functioned for years, cross-shareholdings are of lesser significance, and Companies' Act revisions provide a better framework for activist investors and reflect a conscious effort to use government intervention to overcome path dependencies that sustain a no longer advantageous system of governance and production. Nonetheless, there has been little change in the labor market, including especially the continued absence of an external market for managerial talent and the actual operation of Japanese corporate governance—the Japanese corporation's operating system—remains familiar.

3.2 Expanding the Complementarity Concept: Varieties of Capitalism

The transformation of corporate law into corporate governance discussed in section 2 and the recognition of the impact of complementarities within a single country's governance system were importantly expanded through a literature that has been styled "the varieties of capitalism."³⁵ A governance system experiences path-dependent complementarities, not only internally among a company's factors of production, but also among a country's corporate governance system and other social and economic institutions including, importantly, the state. Simplifying the more complex yet elegant structure of the literature, different countries have different varieties of capitalism. A capitalist system necessarily has more or less coordination among labor markets, corporate governance arrangements, capital markets, and the educational system that provides worker training both outside and inside the firm consistent with the skill sets associated with firm organization and production. The state's political and social system—for example, the government's role in the economy both directly through state ownership and also more indirectly through the regulatory structure—must fit with the overall structure dictated by the interaction of the other elements. In turn, the institutions through which government and social influences operate are both forged through the relationships among the various inputs to the particular form of capitalism, and serve as the field on which those controlling the input strategically interact.³⁶

(p. 13) The result is a stylized typology of two general forms of economic and political organization. Each displays, although the term is not used, supermodularity—the pieces evolve to facilitate the variety's functioning and to reinforce each of its elements. In this account, the two rough forms of political economy are called "liberal market economies" (LME) and "coordinated market economies" (CME). In LMEs, firms coordinate their activities largely through hierarchies within the firm and through competitive markets outside the firm.³⁷ The basic tools are said to be contracts and arm's-length arrangements.³⁸ In CMEs, firm activities operate importantly through non-market arrangements, relying on relational arrangements supported by reputation and, more generally, through incomplete contracting supported by public and private regulatory institutions. Firms and markets are organized through strategic interaction among firms and other institutions. "In some nations, for instance, firms rely primarily on formal contracts and highly competitive markets to organize relationships with their employees and suppliers of finance, while, in others, firms coordinate these endeavors differently."³⁹ It will be obvious, for example, into which category the Japanese main bank system falls.

The last element in the analysis is dynamic: each system's political, social, and corporate governance institutions evolve in a path-dependent fashion from an initial condition to a coordinated structure of complementary institutions driven by choices based on supermodularity and complementarities: "nations with a particular kind of coordination in one sphere of the economy should tend to develop complementary practices in other spheres as well."⁴⁰ For example, a stock-market-based capital market implies market-based institutions in the financial sector consistent with the development of a vibrant venture capital market not generally present in countries with a bank-centered capital market⁴¹ and a

labor market characterized by employment at will, while extensive employment protection is associated with non-market coordination of industrial relations.⁴² Similarly, stock-market-based capital markets are associated with market monitoring of company performance through control contests, while bank-centered capital markets are associated with bank-mediated monitoring and the absence of stockholder-driven control contests. On this account, the United States and the United Kingdom exemplify LME nations while Germany and Japan are CME nations.

My goal in this section was to further complicate our understanding of corporate law and corporate governance by embedding governance in a broader framework whose components are complementary and by highlighting the dynamics of that broader system. The “varieties of capitalism” approach takes us part of the way. On the one hand, it stresses how different systems came to their present form. On the other, however, it does not fully (p. 14) address the tension between path dependency and the need for a particular variety to respond to changes in markets and products. For example, the capacity of globalization and technology to disrupt existing industry and employment patterns highlights the importance of the extent to which particular varieties (and sub-varieties) of capitalism are adaptively efficient.⁴³ The US system is said to be adaptively efficient but at the same time criticized for being too “short-term” oriented, while the Japanese system was praised for its capacity to credibly commit to long-term investment horizons, but appears to be slow in adapting to significant changes in markets and technologies.⁴⁴

This poses what now may be the most interesting question—can a single system be both adaptive and committed? To close with a speculation, corporate governance serves to support risk transfer. As capital markets become more complete, additional mechanisms of transfer become available. The ability to transfer risk in slices through derivatives, in contrast to a broadband risk-bearing instrument like common stock, creates the option of a company remaining privately held as a commitment device to a particular investment horizon that matches its markets and skills.⁴⁵ From this perspective, adaption takes place through self-selection at the company level, rather than at the system level.

A final qualification remains. The “varieties of capitalism” approach dates from the turn of the millennium. We now observe new governance patterns evolving from scratch where there is no prior path. Chinese state capitalism offers a form of coordinated system, but one in which the resolution of tensions among stakeholders more directly flows through the state and party apparatus rather than through the interaction between the company and other relational institutions, and where a question remains whether corporate governance and its formal components serve the same function in the Chinese system that they do in other varieties of capitalism.⁴⁶

4 Analytic Models in Corporate Governance

To this point, I have broadly summarized the evolution of corporate law into corporate governance and then from corporate governance as a stand-alone concept into a component of (p. 15) a particular capitalist system made up of complementary subsystems and

whose path dependency defines the characteristics of the broader system's adaptive dynamics. Like evolutionary systems more generally, the movement was towards greater complexity. Section 4 now further emphasizes complexity by critically assessing recent efforts to simplify, rather than complicate, our understanding of corporate governance through single-factor governance models. As can be predicted by my account in sections 2 and 3, I view these models as interesting and intriguing, but inevitably partial, the equivalent of a painter's studies for a larger work. For the kind of analytic non-formal models used by legal academics, the right methodological move is to complicate, not simplify. Perhaps most important, these single-factor models are largely static, immune in their positive and normative analysis to the influence of the broader concept of governance addressed in section 3.

4.1 Models in Corporate Law

Some 40 years after economics began making important inroads into corporate law scholarship, a significant amount of academic, but not judicial, attention is still directed at devising the right "model" of corporate law and governance.⁴⁷ The "shareholder primacy" model contests with the "stakeholders" model, which in turn confronts the "team production" model and the "director primacy" model. In section 4 I argue that this debate, as engaging, interesting, and extended as it has been, is ultimately a blind alley, both theoretically and practically. The reasons are not complicated, although as I have suggested in sections 2 and 3, we have come to understand that the behavior that this dialogue has sought to explain is quite complicated. Indeed, it is the very complexity of the phenomenon to be explained that allows a simple critique of singular static explanations.

Each of these "models" seeks to explain the structure and performance of complex business organizations—law is relevant only to the extent that it interacts with other factors in shaping the corporation's operating system—by reference to a single explanatory variable. The single variable character of the contending accounts has resulted in an oddly driven circular debate that is prolonged because those proffering each model defend it by emphasizing the limits of the others—something like an academic perpetual motion machine. In fact, each of the models is part of a more complicated description of a very complex phenomenon.

Stephen Bainbridge, whose entry into the single factor horse race I will address later in this section, invokes the fable of the blind men and the elephant in arguing that an overarching concept of the corporation is needed.⁴⁸ An account of corporate organization that does not feature prominently each of the contending model's central features—shareholders, managers, and employees, stakeholders and directors—is limited to explaining only (p. 16) part of the phenomenon. Elephants have trunks, tails, ears, and legs; corporations have shareholders, managers, and employees, stakeholders and directors. Making the elephant walk and the corporation function effectively requires that all of these parts work together—the task is organizational intelligent design or, as I have called the exercise more generally, transaction cost engineering.⁴⁹ And that requires an explanation that focuses on more than one factor, however overarching. The problem of understanding

corporate organization is interesting and hard because it requires explaining the interaction of multiple inputs in a dynamic setting, a problem that vexes both formal and informal modelers.

I should pause for a moment to clarify what I mean by a model. Of course, none of the accounts I address here involves a formal mathematical model of the sort familiar from the economic and finance literatures. They are more in the style of an informal analytic narrative,⁵⁰ which persuades because its explanation rings true rather than because the equations balance.⁵¹ This technique is a kind of verbal regression that restricts the degrees of freedom in explaining a phenomenon by complicating rather than simplifying. A real regression first simplifies the problem as the interaction of two variables, and then measures the power of the explanation by the closeness of the data point—the dots—to the least square line.⁵² An analytic regression operates in exactly the opposite fashion: by increasing the number of dots that must be connected, but now by a narrative rather than by a regression line. A workshop question that asks “what about” a particular fact challenges the verbal regression with a dot the presenter’s explanation of a phenomenon cannot explain, and so limits the degrees of freedom in constructing a narrative explanation.

In the remainder of this section I will briefly survey the contending models—stakeholders, team production, director primacy, and shareholder primacy—highlighting both why each model’s animating factor is important and why it is partial. In doing so I will not do justice either to the extensive literature associated with each model or the sophistication of some of the debate.⁵³ My point is simply that, standing alone, none of the single-factor models explain the complex phenomenon of the governance of corporations in a dynamic context.

4.1.1 Stakeholder Model

A stakeholder model of corporation law or governance recognizes that the corporation is a major social institution that is at the core of a capitalist system. In the United States, large public corporations produce the bulk of GDP, employ vast numbers of workers and so support the stability of families and communities, and pay taxes at every level of the nation—local, state, and federal. It has become commonplace to credit the corporate form with a (p. 17) significant role in economic productivity. For example, writing in 1926, the *Economist* magazine trumpeted this role:

Economic historians of the future may assign to the nameless inventor of the principle of limited liability, as applied to trading corporations, a place of honor with Watt and Stephenson, and other pioneers of the industrial revolution. The genius of these men produced the means by which man’s command of natural resources has multiplied many times over; the limited liability company the means by which huger aggregations of capital required to give effect to their discoveries were collected, organized and efficiently administered.⁵⁴

It then follows simply enough that all those affected by the performance of the corporation have an interest in its operation, which leads in turn to an economic measure of so-

cial welfare against which a corporation's performance can be measured: as framed by economists Patrick Bolton, Marco Becht, and Alicia Roell, the net gain to all those doing business with the company, thereby requiring a netting of gains and losses among, for example, customers, suppliers, employees, and shareholders.⁵⁵

Intertwined with this measure of overall productivity, however, is a distributional concern. If the gains arising from the corporation's activity are not shared among stakeholders in a fashion perceived as equitable, the social legitimacy necessary to support efficient production breaks down, a framing that resonates with the current income equality debate and the populist themes now current in US politics across both the Democratic and Republican parties.⁵⁶ In the more recent governance debate, the stakeholder model is situated as a response to the position Hansmann and Kraakman describe as now dominant: that the corporation should be run to maximize shareholder value.⁵⁷

What is missing in the stakeholder account, however, is the link between the stakeholder model and production. While production may depend on a broad perception that the fruits of production are equitably distributed, in the absence of efficient production, that task is made more difficult because there is less to distribute. A fair criticism is that too little attention is given to the governance mechanisms through which stakeholder interests can be taken into account consistent with efficient production. To be sure, stakeholder board representation has been a matter of debate but hardly implementation in the United States, and co-determination is a familiar but narrow European phenomenon.⁵⁸ And as Henry (p. 18) Hansmann pointed out some years ago, there is no legal reason why large corporations are capital rather than labor cooperatives.⁵⁹

Yet the problem with a stakeholder model remains: it is a one-factor model, largely concerned with distributional issues as a counterpoint but not as an alternative to shareholder primacy. To be sure, behavioral economics provides evidence that perceptions of fairness may in some circumstances be complementary to, rather than in tension with, maximizing production⁶⁰ and that framing the corporate purpose only in terms of shareholder value may dissuade boards of directors from taking action that increases the size of the pie if it reduces the piece shareholders receive. However, what remains largely unaddressed in the stakeholder discussion is how to hold accountable the corporate decision makers, composed largely of white, older men and, almost without exception, wealthy people, whatever their ethnicity or gender, for the size of the pie the corporation creates or for its distribution.

4.1.2 Team Production

A team production theory of corporate governance, energetically advanced by Margaret Blair and Lynn Stout, seeks to fill the gap in stakeholder theory by directly linking a concern with non-shareholder constituencies, especially employees, to firm productivity.⁶¹ The model, stated simply, is that efficient production is a function of firm-specific investment by a wide range of stakeholders—a team, rather than a hierarchy. However, if the stakeholder's firm-specific investment is subject to opportunistic grabbing by a different stakeholder—for example, the shareholders—the stakeholder will be less willing to make

the efficient level of investment. For example, employees may be reluctant to make firm-specific human capital investments if shareholders can subsequently renege on the firm's promise to pay the employee a return on that investment.⁶²

(p. 19) The need to protect all stakeholders' firm-specific investments gives rise to the team production model's governance implications. The model calls for a decision maker who will coordinate the contributions of different stakeholders to protect their expectations of a return on their investments, i.e., to see that the stakeholders play well together and so increase the size of the pie rather than squabble over the efforts of one stakeholder group to expropriate a different group's piece. Blair and Stout assign this function to the board of directors who operate, in their somewhat awkward term, as "mediating hierarchs," balancing the various stakeholders' interaction, and so facilitating the right ex ante level of specific investment by all parties.

The reader will recognize that the team production model closely tracks the efficiency analysis of the Japanese main bank governance model considered in section 3; Japanese horizontal organization of production is framed, as is the team production model, in contrast to US vertical organization. In the Japanese governance model, lifetime employment, protected by limited reliance on equity financing and main bank monitoring, encourages employees to make firm-specific human capital investment by protecting them from opportunistic behavior by shareholders, and so provides a foundation for a very efficient manufacturing system that is built around horizontal planning, decision-making, and production processes. But the reader will also recall that the advantage of Japanese horizontal organization of production is contextual. First, it is more effective than US-style hierarchical organization when innovation is linear, as in precision manufacturing, but inferior to the US style when innovation is discontinuous. Second, team production's stability depends on conditions in the capital and product markets—increasing alternative sources of capital, for example, degraded the critical role of the main bank, as did the success of the companies themselves, who then could avoid main bank monitoring by financing projects through internally generated funds.

Unlike Aoki's development of "J form governance,"⁶³ Blair and Stout's claim for team production is largely acontextual. The problem is that, as analysis of Japanese governance shows, team production is a strategy, not the "right" way to organize governance or production; it fits some industries, some production techniques, and some clusters of complementary elements of one variety of capitalism at particular times, but not others. Indeed, in some contexts, horizontal teams and vertical non-teams both may work. The difference in strategies between Costco and Sam's Club, both US big-box-membership grocery and sundries stores, is a good example. They are direct competitors but they treat their workers quite differently. Costco pays higher wages, provides healthcare, etc. Costco's position is that company profits are higher if their workers like their jobs and want to keep them (a business person's account of an efficiency wage story). Sam's Club (owned by Walmart) treats its workers materially worse than Costco, but nonetheless performs adequately.⁶⁴

A second problem is more directly governance related: who polices the behavior of the mediating hierarchs even in a team production context? In the US governance model, the only formal source of constraint is the right of only one stakeholder—the shareholders—to vote. However, as Blair and Stout stress, so long as the corporation resembles the Berle and Means pattern of widely distributed ownership, the right to vote and so the power to monitor the hierarchs, is dramatically diluted by coordination costs: proxy contests are expensive (p. 20) and while their costs are borne by the proponent of the fight, the gains are shared by all shareholders. This leaves the hierarchs on a very long leash indeed.

The problem with hierarchs, then, is that strategy and governance follow changes in the capital market rather than lead it.⁶⁵ The wide discretion Blair and Stout claim for the hierarchs was first challenged by the development of junk bonds in the 1980s.⁶⁶ The availability of financing to corporate outsiders allowed a large increase in hostile takeovers that were used to take apart the residue of the failure of the 1970s conglomerate experiment. The result was to significantly shorten management's leash. Non-statutory monitoring techniques, like tender offers, provided a shortcut around the coordination costs associated with widely distributed shareholdings: Even small shareholders could recognize a large premium when one was offered, although the need to secure financing to purchase the target limited the size of the companies that were potential targets. The debate over efforts to constrain capital market monitoring through target company defensive tactics—the extent to which mediating hierarchs could prevent shareholders from accepting a hostile bid—then raged on for 30 years.

More recently, the capital market fault line shifted again—ownership of equity became increasingly intermediated through institutional investors holding stock as record owners for widely dispersed beneficial owners. Shareholdings in US public corporations are now quite concentrated as a result of equity intermediation—a number of institutions whose representatives could be seated around a large boardroom table collectively hold voting rights that effectively control most corporations—ushering in what Jeff Gordon and I have called “Agency Capitalism.”⁶⁷ At this point, activist hedge funds and other specialized shareholder activists entered the fray as complements to the new ownership concentration. Rather than buying targets themselves, such activists tee up strategic business choices for decision by “reticent” rather than passive institutional shareholders and in that way serve as a catalyst for the expression of institutional shareholder voice. This further erodes the coordination costs barrier to monitoring mediating hierarchs. Because an activist's own stock purchase need be only large enough to credibly signal its conviction in its proposals, even the largest public corporations are potentially “in play.” Put differently, the activist shareholders differ from the raiders of the 1980s in that instead of leveraging the target's balance sheet to finance a takeover, they leverage the equity holdings of institutional investors to win a proxy contest conditional on convincing the institutional investors that the activist's proposal is sound.⁶⁸ And here context is again central. If the mediating hierarchs are largely walled off from capital market monitoring, now through proxy fights rather than takeovers, companies' responses to changes in the business environment are slowed down, a very undesirable result if, as appears to be the

case, the rate of change in the business environment is increasing. Bad governance then leads to bad strategy.

(p. 21) 4.1.3 Director Primacy

Stephen Bainbridge proffers a director primacy model as a counterpoint to both the stakeholder and the team production models on the one hand, and as an element of a shareholder primacy model on the other.⁶⁹ The differences among those models are nicely organized around two simple concepts proffered by Bainbridge: the corporation's ends and the means by which those ends are achieved. Director primacy differs sharply from the stakeholder model and somewhat more obliquely from team production on the ends sought. It includes an undiluted commitment to "shareholder wealth maximization"⁷⁰ as the measuring rod of a corporation's performance. The significant difference between director primacy and team production, conceptually but not necessarily operationally, concerns the means by which shareholder wealth maximization is achieved. Both team production and director primacy share a commitment to a very long leash for boards of directors, relegating shareholders to a limited role as a vehicle for constrained capital market intervention. The shareholders' cameo role is expected to be limited to those unusual circumstances when the shortfall in corporate performance, whether in its use of existing assets or in its failure to reach out for new opportunities, exceeds the coordination costs of energizing shareholders either directly through a takeover or indirectly through elections. In this important respect, team production and director primacy share a central feature of Aoki's description of Japanese corporate governance discussed in section 3:⁷¹ capital market intervention, in Japan through main bank intercession and in the US through the stock market, should be triggered only by very poor performance.⁷²

Thus, central to both models is the limited role of shareholders; under both team production and director primacy, management and directors are on a very long leash. Team production and director primacy differ, however, not only in the intellectual foundation of their respective models—Blair and Stout channeling Alchian and Demsetz⁷³ and (p. 22) Holstrom⁷⁴, and Bainbridge building on Coase⁷⁵ and Arrow⁷⁶—but also in the breadth of their claim. Fairly assessed, team production is a particular production strategy, not a governance model for all seasons. Director primacy makes the broader claim: it purports to be a generally applicable governance structure. In striking the governance balance between, in Arrow's terms, "authority" and "responsibility," it plainly favors authority—management over shareholders. But this broader claim founders on the same rock that scuppered team production's broader claim.

Japan's main bank primacy model, like director primacy protecting management save in dire circumstances, no longer worked when the structure of the Japanese economy changed as a result of Japanese corporations' success and the contemporaneous opening of the Japanese capital market. Director primacy's stability and its normative appeal depend on circumstances in the capital market: the cost of shareholder coordination sets the limit on director discretion, in Arrow's terms again, setting the efficient trade-off between authority and responsibility. The reconcentrated ownership of large public US corporations as catalyzed by activist investors dramatically reduced the shareholder coordi-

nation costs in challenging managements and boards; this shortened the leash. But the critical new feature of “coordination” was the activists’ role as credible information intermediaries. Insofar as the board’s claim to “authority” rested on both a purported informational advantage and the cost of informing widely dispersed shareholders, the activists’ information-based counterview shifted the balance, as evidenced by the voting behavior of sophisticated institutional investors. Arrow himself anticipated that if smaller groups could assess specific claims of error on the part of those in authority, responsibility could be achieved without so general a scope of review that authority was dissipated and information costs multiplied.⁷⁷

Stated most simply, the “right” governance model is contextual. It depends on what the particular company does and on conditions in the capital market; in other words, a governance model must be dynamic. One-factor models that cannot accommodate changes in either the product market or the capital market are too simple to accommodate the complexity of the business environment in which corporations function.⁷⁸

(p. 23) 4.1.4 Shareholder Primacy

Setting out the shareholder primacy model is somewhat more complicated than the description of the stakeholder, team production, and director primacy models. In Bainbridge’s nice dichotomy, shareholder primacy is used as a label for both an end and a means; it is at once the corporation’s goal but also how that goal should be achieved. Thus, there is a need to be precise about the subject under examination. With respect to the end of corporate governance, I start with a broad definition of social welfare in the organization of public corporations: the net impact on all those effected by the company, thereby requiring a netting of gains and losses among, for example, customers, suppliers, employees, communities, and shareholders, in effect Kaldor-Hicks efficiency with a broad reach of whose utility counts.⁷⁹

With respect to means, my focus in this section is the role assigned to shareholders. For this purpose, we have to bring in another literature, beginning in the early 1980s and continued to date by the energy of Lucian Bebchuk among others, who argues for a much broader role for shareholders than contemplated by either Blair and Stout or Bainbridge.

In important but unfortunate respects, the debate over shareholder primacy was clouded by some of its early framing. Two characterizations are particularly regrettable: that the allocation of authority through the corporate governance system turns on shareholder ownership or, alternatively, on the specificity of different stakeholders’ contribution to the corporation. The ownership claim—that the corporation should maximize shareholder wealth because shareholders “owned” the corporation—was straightforward but far too simple. In fact, we have known better than that from the beginning of the debate. Ownership is a bundle of rights; which elements of the bundle we give to a particular party depends on what we want to accomplish; the inquiry is instrumental not normative. That distinction was drawn sharply in the corporate governance context as early as 1981. The shareholder’s governance role depends on the organizational design needed to give residual claimants the power to assess management and the board’s performance. “[I]ndeed, if

From Corporate Law to Corporate Governance

the statute did not provide for shareholders we would have to invent them.”⁸⁰ Debates about the specificity of different stakeholders’ contributions to the corporation were also little help; the relative character of those contributions depended on the particular and changing character of the corporation’s business environment, so it was difficult to generalize based on this characteristic. (p. 24)

Table 1.1 A Stakeholder Income Statement

Line item	Amount	Stakeholder
Sales	XXXXXX	Customers
Wages	XXXXXX	Employees
Cost of goods sold	XXXXXX	Suppliers
Taxes	XXXXXX	Community
Net Income	XXXXXX	Shareholders

Once we recognize that the problem with the firm specificity branch of the shareholder primacy argument is that all stakeholders make contributions and the character of those contributions, and hence the various stakeholders’ investment in the corporation, depend on the firm’s strategy, the second characterization problem appears: it follows that the right governance structure is also going to depend on context. Sometimes the contributions, driven by the nature of the business and the corporation’s strategic response support horizontal team production; sometimes they support vertical hierarchical organization and sometimes a mix. This appears from Table 1.1 above, a stylized income statement. The figure illustrates that each line item in an income statement reflects the participation of a different category of stakeholders. And it requires little imagination to think of how all but the shareholders’ interests are conditional on circumstances. Different events will differentially affect the value of different stakeholders’ inputs. Only the shareholders have an incentive to adjust the returns other shareholders receive for their inputs, because the residual returns will depend on the success of that adjustment. Put differently, one could substitute for the term “shareholder primacy” that of “Kaldor-Hicks efficiency” as a description of the operative governance model, and so match the label to the measure of social welfare.⁸¹

It is apparent that, as the reference to the blind men and the elephant fable reveals, corporate performance depends on the complex coordination of all stakeholder groups, taking into account the particular context of the company’s business. We return to where we started this part: the corporate elephant needs customers, employees, suppliers, communities, and shareholders to perform. That implies a basic structure of management monitored by directors, with shareholders in the position of residual owners and having the

vote—the right to disrupt existing management through their influence on the identity of the directors. It is at this point that the issue around shareholder primacy takes form. The team production and director primacy models, for different reasons, share the view that shareholders' role in changing management should be formally limited—management's leash must always be long. As we've seen, the two positions as so framed share a more than passing relation to Aoki's description of Japanese management. The main bank in Japan (during its (p. 25) prominence) and shareholders in the US can replace management, but only when things get very bad.

But the Japanese experience also teaches that the efficient length of the leash depends on history, strategy, and conditions in the capital market. The evolution of complexity in our understanding of corporate governance highlights that the role of shareholders—and so the length of management's leash—depends on the circumstances. In the 1970s, management and directors experimented with conglomerate strategies. Consistent with the team production and director primacy models, management and directors had the autonomy to carry out the experiment. In the end, the experiment failed and changes in the capital market—Michael Milken and Drexel Burnham's development of junk bonds—shortened management's leash by facilitating shareholder-dependent bust-up hostile takeovers. The length of management's leash was shortened again in the new century by the growing intermediation of equities and the rise of activist shareholders who levered institutional investors' equity holdings to extend capital market oversight to firms that were too big to take over in the 1980s.

The lesson of this section is that one-factor corporate governance models are too simple to explain the real-world dynamics we observe. Hansmann and Kraakman are descriptively correct that there seems to be convergence around a governance structure that generally contemplates shareholders as the residual owner. In equilibrium, directors oversee management's efforts to coordinate the inputs of all stakeholders and their competing claims on corporate revenues, with the particular resolution depending on the corporation's product market and strategy; shareholders have a limited function. When performance is lacking, management's leash shortens based on the techniques available to shareholders through the capital market. Corporate governance matters when the leash shortening is triggered by changes in the product market in which the company participates, in the instruments the capital market provides, and in the pattern of shareholdings that results from conditions in the capital market.

5 Conclusion

In the end, governance is messy, complicated, and contextual because that is the character of dynamic markets. And that is the point of this chapter. The move from corporate law to corporate governance reflects a move from a simple legal view of the corporation to one that became increasingly complex and dynamic, hand in hand with the increased complexity and dynamics of the capital market, input markets, and product markets that corporations inhabit. And therein lies the problem with corporate governance models: at

best they are snapshots, stills of a moment in a motion picture. Corporate governance is part of the structure of an economy whose behavior, and hence whose architecture, is dictated by the interaction among all of the markets in which the corporation operates, each of which is itself in motion. In a sense we are confronted with a corporate governance version of the physicist three-body problem: the interaction of the bodies that influence the structure of corporate governance are too complex to allow a prediction of the optimal governance structure going forward.⁸²

(p. 26) Is there a lesson from recognizing the complexity of real world corporate governance? I think so. It is the centrality of change. As discussed in section 2, there is a trade-off between a governance system that encourages long-term firm-specific investment and one that is mutable, quickly adapting to changes in the business environment.⁸³ This tension between stability and change is baked into a capitalist system. Change is a source of progress, but it is always risky since the established order more or less works, sometimes seemingly well.⁸⁴ Reinier Kraakman and I characterized the tension as a debate across the years between Burke and Schumpeter:⁸⁵ should we preserve what is working against a potentially disruptive innovation?

Burke cast this tension in terms that anticipate today's tendentious long-term versus short-term debate. Remarking on the leaders of the French revolution, Burke stressed their short-term orientation: "Their attachment to their country itself is only so far as it agrees with some of their fleeting projects; it begins and ends with that scheme of polity which falls in with their momentary opinion."⁸⁶ In contrast, Burke has a great respect for the French aristocracy who were threatened by the purported short-termists: "Of my best observation, compared with my best inquiries, I found [the French] nobility for the greater part composed of men of high spirit, and of a delicate sense of honor, both with regard to themselves individually, and with regard to their whole corps, over who they kept, beyond what is common in other countries, a censorial eye."⁸⁷

Schumpeter's riposte to the Burkean fear of chaos has become familiar:

The opening up of new markets—and the organizational development from the craft shop to such concerns as U.S. Steel illustrate the same process of industrial mutation— . . . that incessantly revolutionizes the economic structure from within, incessantly destroying the old one, incessantly creating a new one. This process of Creative Destruction is the essential fact about capitalism.⁸⁸

(p. 27) From this perspective, the governance trade-off—between stability and mobility—depends on the predicted range of future change in a particular industry and company. If the second derivative of change is positive but whose direction is difficult to predict, then a governance system that privileges mutability over stability will outperform. And here path dependency raises its head a final, pessimistic time. In a governance system characterized by supermodularity, shifts from a commitment-based governance system to one that facilitates adaptation to changing conditions will be hard to accomplish. Again,

From Corporate Law to Corporate Governance

Japan's slow progress at reforming the operation of its corporate governance system despite dramatic changes in its formal corporate law stands witness to the problem.

This is an appropriate point to conclude. The move from corporate law to corporate governance, and the resulting increase in complexity, allows us both to understand the problems we need to solve and the difficulty of doing so.

Speaking in broader geographic terms, Manning expanded his point. "Those of us in academic life who have specialized in corporation law face technological unemployment, or at least substantial retooling. There is still a good bit of work to be done to persuade someone to give a decent burial to the shivering skeletons. And there will be plenty of work overseas for a long time to come, for in Latin America, and to a lesser extent on the Continent, the 'corporation' yet thrives and breeds as it did in this country eighty years ago" (id.).

He notes that the term only came into vogue in the 1970s in a single country—the United States. One outcome of this shift was that the "technological unemployment" that Manning feared did not arise. Hostile takeovers, a response to agency costs made broadly

possible by the development of junk bonds, generated enormous amounts of work and profits for fancy law firms. Lincoln Caplan, *Skadden: Power, Money, and the Rise of a Legal Empire* chap. 5 (1993) captures the phenomenon.

(¹²) The term “implicit contract” comes out of the labor economics literature. The critical point is that, from a legal perspective, an implicit contract is not a contract at all: it has neither formal terms nor formal enforcement. Rather, it is a description of patterns of behavior that are enforced by reputation markets. See Sherwin T. Rosen, “Implicit Contracts: A Survey”, 23 *J. Econ. Lit.* 1144 (1985).

(¹³) Ronald J. Gilson, Charles Sabel, & Robert E. Scott, “Braiding: The Interaction of Formal and Informal Contracting in Theory, Practice and Doctrine”, 110 *Colum. L. Rev.* 1377 (2010). The term “braiding” reflects the potential for complementarity between formal law and explicit contracts on the one hand, and implicit contracts on the other. In this account formal law and explicit contracts facilitate the development and maintenance of implicit contracts; in effect, the formal components of the braid endogenize trust, the foundation for sustainable implicit contracts. *Id.* at 1384.

(¹⁴) Like Manning, I have a personal concern about the role of corporate law academics. On this front, the shift from corporate law to corporate governance and to the role of corporate governance in the larger structure of a capitalist economy, has had the desirable result of forcing corporate law academics to become interdisciplinary.

⁽⁵⁸⁾ See, e.g., Romano, *supra* note 55 at 963–971. A flurry of US state statutes that allowed or obligated boards of directors to take stakeholders into account have been largely without substance. Most important, these statutes, as well as corporate charter provisions that mirrored the statutes, were not enforceable by their putative beneficiaries.

⁽⁶²⁾ The converse will also be true. While shareholders can sell their shares if they are treated poorly, the sale price will reflect that treatment, in effect capitalizing the expected reduced returns associated with other stakeholders’ opportunism. The drop in share

price then will reflect the stakeholders' opportunism. The usual reference for the argument to how shareholders can opportunistically shift returns from other stakeholders to themselves is Andrei Shleifer & Lawrence Summers, *Breach of Trust in Hostile Takeovers*, in *Hostile Takeovers: Causes and Consequences* 33 (A. Auerbach ed., 1988). For present purposes I note only that the analysis does not parse. In short form, Shleifer & Summers use post-airline deregulation as an examination of shareholder opportunism. The effect of deregulation was to allow entry of low-cost airlines with the result that the loss of the regulatory rents that had accrued to capital and labor resulted in losses to both. From this perspective, the takeovers that hit the industry were a process of allocating that loss between labor and capital. While Shleifer and Summers argue that the resulting allocation violated an implicit contract between airline and management, they do not explain how one would identify the terms of an implicit contract concerning an event—deregulation—that was not anticipated. They do suggest that the reallocation was only possible because post-takeover management did not value the prior management's reputation and the resulting ability to enter into implicit contracts. However, they do not explain why an asset that is valuable to prior management is not equally valuable to post-takeover management. See Ronald J. Gilson & Bernard S. Black, *The Law and Finance of Corporate Acquisitions* 620–22 (1995).

(⁷¹) Japan may actually illustrate how the stakeholder model, team production, and director primacy can all co-exist in one system (suggesting that they need not be distinct "models" at all). That is, the Japanese firm in its heyday favored employees over shareholders. Those employees engaged in a tournament to become directors, whereupon they would reap the largest rewards (partly through tenure) and play the role of Blair & Stout's (*supra* note 61) mediating hierarchs. Because these senior managers were largely

insulated from capital market pressures, and due to the absence of a lateral market for managerial talent, the system was one of director primacy in the extreme. I am grateful to Curtis Milhaupt for making this connection.

(⁷²) In the 1980s, when hostile takeovers were dismantling the failed conglomerate experiment, firms representing 1–3% of total stock market value underwent leveraged buyouts each year from 1985 to 1988. Bengt Holstrom & Steven Kaplan, “Corporate Governance and Merger Activity in the U.S.: Making Sense of the 1980s and 1990s”, 15 J. Econ. Persp. 121 (2001). This volume of takeovers led to a report by the Council on Competitiveness, headed by Harvard Business School strategy professor Michael Porter, extolling the Japanese governance system: “In general, the U.S. system is geared to optimize short-term returns, the Japanese and German systems optimize long-term returns.” Michael E. Porter, “Capital Choices: Changing the Way America Invests in Industry”, 5 J. Appl. Corp. Fin. 4 (1992). (⁷⁸) As a style of proof that their model is right (and that others are wrong), both Blair & Stout and Bainbridge offer extended arguments that current and historical corporate law is consistent with their respective models. I do not discuss these efforts here for two reasons. First, they necessarily depend on some version of an older argument that the common law, in this case corporate law, is efficient; without needing to rely on Alchian & Demsetz, Holstrom, Coase and Arrow, the process of case selection (and the structure of other lawmaking institutions) will result in efficient rules. This claim, whose intuition was understandable when first made, has not fared well. Absent a mechanism that leads to efficient outcomes based on distributed incentives, the claim devolves into a belief that judges can be expected to get the answer right. My task here is instrumental, intelligent design rather than a blind belief in the operation of the judicial system. Put differently, a claim of survivorship in favor of an observable structure is a weak proof of efficiency. Second, invocation of the consistency of statutory rules and judicial decisions with the professed models is an “inside baseball” argument. The authors discussed in the text (and I)

are, with the exception of one economist whose appointment is in a law school, lawyers. Thus, tying a claim for a particular model back to legal arguments is understandable but backwards: In an intelligent design context, existing legal institutions and rules are a tool, not evidence of efficiency.

(⁷⁹) See Bolton et al., *supra* note 55. Henry Hansmann and Reinier Kraakman point out that even this broad measure of social welfare is contestable. “For many individuals, increasing social stability may be worth sacrificing a meaningful amount of productivity as measured—as it conventionally is—in terms of the net value of market transactions . . . It is not crazy to feel that a leisurely daily walk to a dependable workplace in the well-preserved medieval city of one’s birth is preferable to lower prices on smartphones.” Henry Hansmann & Reinier Kraakman, *Reflections on the End of History for Corporate Law*, in *Convergence of Corporate Governance: Promise and Prospects* (Abdul Rasheed & Toru Yoshikawa eds., 2012). Of course, this trade-off is hardly limited to corporate governance, as a moment’s reflection on the current debate over the desirability of lowering trade barriers reminds. Addressing the broader issue is beyond my ambitions here other than to note that there is nothing in a Kaldor-Hicks analysis that counsels against redistribution of gains and losses.

(⁸¹) I recognize the difficulty of specifying and then operationalizing a fully developed measure of Kaldor-Hicks efficiency. However, I am concerned here with a real corporation’s operating system, where the measure is pragmatic: does it work to manage the stakeholders competing for the corporation’s revenues?

(⁸⁴) Clayton Christensen, *The Innovator’s Dilemma* (2002), focuses on the dangers to market leaders from staying with what seems to work and what they are good at: why industry leaders fail to anticipate an innovation that devalues their skills and products, and as a result dilutes their dominant position—in Christensen’s terms, a “disruptive” technology. The problem is not that the leaders are poorly managed; rather they are attentive to their customers, continually improve the quality of and reduce the prices for their product, and usually anticipate what their customers will want before their customers know it themselves. Instead of merely extending the existing product architecture, a disruptive technology reflects so sharp a break with existing strategies that neither a market leader nor its customers initially see the new technology’s potential. When the disruptive tech-

nology develops so that it is generalized to the industry core, the dominant firms are then displaced because they cannot respond quickly enough to the change in the architecture of production. More recently, the concept has been extended to any change in technology that severely degrades market leaders' capabilities and opens the door to new entrants. Abstract and Keywords

This chapter discusses the question of “convergence or persistence” in corporate law and governance. It first considers efforts to measure convergence directly by focusing on the evolution of law-on-the-books governance provisions before analyzing capital market evidence on convergence, with particular emphasis on capital market indicators such as the decline in “cross-listings” onto US stock exchanges by firms from jurisdictions with weaker investor protection and the increase in initial public offerings (IPOs) on emerging market stock markets. The chapter proceeds by reviewing evidence of divergence, especially “divergence within convergence,” and the failure of the European Union to produce more convergent corporate governance. It also looks at the “End of History” debate over whether corporate governance has converged on a “shareholder value” model and concludes by asking whether “stability” will become a general objective of corporate governance convergence.

Keywords: convergence, persistence, corporate law, cross-listings, initial public offerings, divergence, corporate governance, shareholder value, stability, European Union

1 Introduction

ALMOST 15 years ago Jeff Gordon and Mark Roe co-edited a book, *Convergence and Persistence in Corporate Governance*¹. In their introductory essay, Gordon and Roe (“G&R”) linked the convergence-persistence question to globalization in two distinct senses. The first is whether corporate governance is an element of comparative advantage in global *product* markets, which would imply that the corporate governance norms that tend toward efficient production would disseminate widely. The second sense is whether corporate governance is an element of comparative advantage in global *capital* markets, either because (1) acquirers in cross-border mergers and acquisitions would want to use a standardized “currency” or (2) equity capital suppliers such as institutional investors would push for a standardized corporate governance model. This source of comparative advantage would suggest a convergence toward an international standard of corporate gover-

Convergence and Persistence in Corporate Law and Governance

nance because of its appeal to international capital markets and, generally, a lower cost of equity capital.

G&R also observed that a key feature of corporate governance is its embeddedness in national legal systems and in particular in patterns of ownership, control, and monitoring that have national origin. In consequence, notwithstanding the impact of globalization, the rate and extent of convergence will be constrained by the forces of path-dependency, along two distinct dimensions. First, from an efficiency perspective, a particular national system might well be linked to a set of complementary institutions, so that a governance change to conform to the “international” model might well reduce the value of the firm and, indeed, its global competitiveness. For example, imagine a governance regime dominated by blockholders that included “affiliated” directors placed by the large bank that provided debt (p. 29) finance and the lead underwriters of the company’s public equity. These affiliated directors would have institutional backing for their efforts to check private benefit extraction and the misrepresentation of performance. Adoption of the convergent governance standard in favor of “independent” directors rather than affiliated directors would likely undercut the monitoring capacity of the particular national system. Independent directors would be an efficient substitute only if the domestic court system became robust enough to control private benefit extraction and the domestic securities regulation system became robust enough to protect against fraud. Substitution of the convergent standard without regard for these institutional complements could result in companies that are less efficient and compete less well in global markets.² In consequence, national elites may defend the domestic corporate governance regime.

Second, an existing governance setup will inevitably create rents that incumbents will fight to preserve. Controllers in a blockholder regime may well resist a move toward convergent governance institutions that could impede various sorts of “tunneling”³ (as from genuinely independent directors) or that could facilitate the growth of public capital markets that could finance rivals (as from an increase in minority shareholder protection). Unions may resist convergent measures that “empower” shareholders because of the concern that shareholder pressure could increase the likelihood of employee layoffs. The point is that even if corporate governance convergence was “efficient” in a macro-sense, important local actors might be disadvantaged and use their political tools to resist convergent legal and institutional change.

G&R conjectured that globalization could also affect the pace of convergence through its effect on complementarities. For example, if global competitive pressure forced banks away from a relationship model towards a transactional model, the mutual gains from “delegated monitoring” might well disappear. Alternately, global capital markets might give rise to large institutional investors that pursued a monitoring strategy that exploited different complementarities.

One convergent trend noted by G&R was the decline of state ownership, in light of the privatization waves of the 1990s and 1980s. These privatizations often catalyzed the strengthening of investor protection measures in service of the state’s goal of maximizing

Convergence and Persistence in Corporate Law and Governance

the proceeds on the privatization.⁴ But the consequence was to strengthen public stock markets more generally.

The question is, what is the state of convergence versus persistence as of 2017? The not particularly informative answer is that there has been considerable convergence, and also considerable persistence. There has been convergence in many of the formal governance rules but local applications reveal considerable divergence. Substantial differences in ownership structure persist. Even with improvements in minority shareholder protection, the Anglo-American model of the diffusely-owned firm does not predominate. Instead we see (p. 30) a proliferation of forms of ownership concentration, including family ownership, foundation ownership, and entrepreneur ownership. The rise of China in the post-2000 period has brought prominence to a new form of concentrated ownership, the state-owned enterprise, which has now taken on a pyramidal form.⁵ The success of this organizational form in spearheading China's rapid economic growth has provided counter-evidence to the privatization trend.

G&R, writing in 2003, emphasized the role of global competition in promoting convergence. In 2017, it would also be right to add the role of "global governance," the effort to set standards flowing from supranational public institutions. This has been propelled through three separate channels. First is the World Bank's insistence on corporate governance reform as a condition for receipt of financial assistance, particularly following the East Asian financial crisis but also part of its "development" agenda. Second is the formulation by the OECD of governance "principles" first in 1999 and then in subsequent versions, most recently in 2015 (helpfully available on the OECD website in 10 languages). This in turn has led to the adoption of governance codes by dozens of countries. Third is the push for governance reforms as part of the post-financial crisis agenda of the G-20 group of leading countries, with the Financial Stability Board both shaping the agenda and also providing for follow-up auditing of national adoption of appropriate measures.

From another perspective, it has become hard to separate out the convergence/persistence question from "financial globalization"—the development of worldwide capital markets and a set of complementary actors that make it possible for firms from countries with persistently weak governance institutions to opt into higher governance regimes.⁶ Firms can issue stock in a "global" offering: cross-listing on an exchange with higher governance standards; submitting to a more rigorous, better policed disclosure system of the "borrowed" jurisdiction; making use of an international network of credible investment intermediaries, such as underwriters and accounting firms (applying globally accepted International Accounting Standards)⁷; enlisting high-reputation foreigners as independent directors,⁸ and selling into the portfolios of global asset managers who will bring a certain level of monitoring.⁹ More specifically, careful examination of "what matters" in corporate governance suggests that (p. 31) the quality of the national disclosure regime is a critical variable.¹⁰ High-quality disclosure facilitates better monitoring internally and externally. Yet this is also the governance feature that is most readily borrowed through a global offering. The US disclosure pattern sets the general template because of the desire

Convergence and Persistence in Corporate Law and Governance

to include US institutional investors as offerees. The reputations of global intermediaries as well as legal enforcement play a role in making the disclosure credible.¹¹

Local complementarities may have eroded as cross-holdings unwind (e.g., in Germany¹² and Japan¹³), but global complementarities have become stronger. The pace of strictly national convergence may be slowed by the ability of local issuers to opt into the global governance system.

The “convergence” question also operates on what might be thought of as the teleological level. Have governance systems converged on “shareholder control” and “shareholder value” to the exclusion of stakeholder concerns? The assertion that we had reached the “End of History” in favor of shareholders¹⁴ produced an intense debate. Where are we now?

A final introductory thought: When the G&R book was put together, the questions about “convergence and persistence” related principally to developed market economies. Attention was focused on differences among developed countries: The two-board/codetermination structure of Germany and the main bank/keiretsu structure of Japan were signature preoccupations. More generally, the main difference was framed as between “outsider” and “insider” forms of corporate governance. Were these differences political, relating to the relative power of employees versus shareholders;¹⁵ functional, optimizing for certain forms of production, investment, and adaptability to changing conditions;¹⁶ or rather the result of strong path dependencies?¹⁷

(p. 32) The corporate governance convergence debate today focuses much more on emerging market economies. There are three reasons. First, the East Asian financial crisis of 1997–1998 was taken as showing that the corporate governance failures in such countries could produce financial instability with sharply negative consequences for developed economies. The global externalities of poor corporate governance meant that countries could not be left to internalize costs and benefits. Thus corporate governance reform immediately rose to the top of the global governance agenda through the concerted efforts of the IMF and World Bank. Indeed, a 2016 IMF report reaffirms the financial stability connection, developing the case that emerging market economies with better corporate governance were better positioned to bear the financial shocks of the Global Financial Crisis of 2007–2008.¹⁸

Second, a group of scholars became convinced that better corporate governance would accelerate financial market development and that this in turn would produce faster economic development in emerging market economies.¹⁹ So improved corporate governance became part of the development agenda, also promoted by the World Bank. Third, institutional investors came to believe in both the portfolio value of international diversification and the possibilities in emerging market economies of a higher growth rate than in OECD countries. Corporate governance reform would facilitate pricing, cabin the risks of sudden losses because of insider opportunism, and thus produce superior risk-adjusted returns. Institutional investors became advocates for corporate governance reform,²⁰

Convergence and Persistence in Corporate Law and Governance

operating through private organizations like the International Corporate Governance Network and important quasi-official bodies like the OECD.

The debate about convergence within developed countries is still interesting. For example, given the robust governance of the European Union, why is it that the corporate governance regimes of the EU Member States still exhibit significant divergence? Why isn't there a fully harmonized company law after more than 20 years of trying?

This chapter explores the "convergence or persistence" question as follows: Section 2 explores the efforts to measure convergence directly by observing the evolution of law-on-the-books governance provisions. Section 3 looks at convergence through some capital market indicators: (1) the reduced incidence of "cross-listings" onto US stock exchanges by firms from jurisdictions with weaker investor protection; (2) the increase in IPOs on emerging market stock exchanges; and (3) the increase in cross-border mergers involving a US party in which the survivor is not a US corporation, a so-called "inversion."

Section 4 looks at evidence of divergence, particularly "divergence within convergence," which seems to describe the general state of play. In this regard, a 2017 compilation by the OECD of various national corporate governance provisions, the OECD Corporate Governance Factbook, is a valuable resource. One element that has driven measures of convergence over the past 20 years has been the increasing employment of independent (p. 33) directors across many countries. This section looks at divergent practices regarding the role and selection of the independents. It also looks at the divergent takeup of a governance innovation, shareholder votes on remuneration, "Say on Pay Policy" and "Say on Pay." Metering convergence/divergence is methodologically challenging. Without detailed country analyses, we may be at risk of assuming "convergence" on the basis of formal similarities that mask important functional differences. In this spirit, a recent set of case studies on independent directors in Asia argues for "varieties" of independent directors rather than a unitary institution.²¹ Do we emphasize the divergences, which may fade over time as the convergent features assert themselves, or will the divergences attain their own functional legitimacy?

Section 5 discusses the role of global governance in corporate governance convergence, focusing particularly on the role, post-East Asian financial crisis, of the IMF, World Bank, and OECD, and the additional impact of the global financial crisis in enlisting the G-20 world leaders and the Financial Stability Board in promoting corporate governance convergence. One conclusion is that the convergence push through global governance is motivated by financial stability concerns perhaps at least as much as by efficiency and productivity.

Section 6 asks why the EU, a supranational body empowered with governance authority, has not produced more convergent corporate governance. The asserted answer is not so much the efficiencies of local adaptations and institutions but the desire of the member states to throw sand in the gears of economic and political integration. Divergence makes

it harder to accomplish cross-border merger and acquisition activity, which otherwise would produce much tighter integration.

Section 7 briefly addresses the “End of History” debate: whether corporate governance indeed has converged on a “shareholder value” model. The terms of the debate have shifted, however. It’s not shareholders versus stakeholder in a straightforward sense. We may all be shareholder value proponents now. The current question is, *which* shareholders: the ones who will pursue “efficiency only” or others who may include “stability” within their maximizing function? Stakeholders may fare differently depending on which shareholder objective function is predominant. Family shareholding groups that need political buy-in to protect their economic stakes are likely to see value in stability; large institutional investors that are subject to government regulation, or see themselves as permanent investors locked into the systemic risk of instability, may well have a similar perspective. Global governance institutions, which are accountable to governments, are also likely to have “stability” objectives. One important piece of evidence is the growing movement for “Stewardship Codes” and the concerted campaign against the purported “short-termism” of hedge funds, all designed to add stability to the shareholder maximizing function. The chapter concludes by asking whether “stability” will become a general objective of corporate governance convergence.

(p. 34) 2 The Effort to Measure Convergence Directly

How do we know if corporate governance systems are in fact converging? Can we break a corporate governance regime into discrete elements and measure them, and then sum them up in a reliable way?²² The first effort to do this is associated with the decade-long series of “legal origins” papers of Rafael La Porta et al., which devised various measures of investor protection that were in turn presented as explanatory elements of different ownership patterns and levels of financial development. The project initially focused on an “anti-director rights” index,²³ which was effectively dismantled as a flawed coding exercise by Holger Spamann,²⁴ but then reclaimed through a more accurately coded “self-dealing” index.²⁵ The project was at its core “anti-convergence,” since it was heavily invested in the thesis of transnational “families” of corporate law, locked into their paths through their “legal origins.” But the data that fueled this argument was cross-sectional, not time series, so actually the “legal origins” project was not sufficiently powered to test its most interesting conjecture.

An alternative way to measure a critical dimension of corporate law and governance, “shareholder protection,” has been devised by a group of scholars associated with Mathias Siems, developing “leximetric” measures and evidence.²⁶ The most recent entry states its punchline in the title: “Disappearing Paradigms in Shareholder Protection, 1990–2013.”²⁷ The general strategy is similar to the La Porta et al. approach, devising a “shareholder protection” index with a somewhat different set of variables focused on shareholder powers only. Subjectivity and some arbitrariness are inevitable, as they acknowledge.

Convergence and Persistence in Corporate Law and Governance

Coding requires quantification and an index requires summing, for which there is only questionable theoretical justification.²⁸ With these inevitable caveats, the special contribution of Katelouzou (p. 35) and Siems is the coverage: 10 elements, 30 countries, and 24 years of data; and the use of network analysis to assess country clusters. The authors also divide the variables into “enabling”—those that empower shareholders to take self-protective action—and “paternalistic”—mandatory features.²⁹

Figure 2.1 Katelouzou and Siems, p. 133, fig. 1.

Figure 2.2 Katelouzou and Siems, p. 148, fig. 7.

Their results come through in two charts (see Figures 2.1 and 2.2). Figure 2.1 shows significant convergence across the 30 countries over the period. The average level of shareholder protection as measured by their index advances in every country from the beginning of the period (1990) to the end (2013), and the countries that were lowest at the beginning of the (p. 36) period have made the biggest changes. Further analysis shows that the convergence occurs over roughly the same elements of shareholder protection, consistent with the evolution of a normative model of corporate governance that has international acceptance.³⁰ Figure 2.2 puts paid to the La Porta et al. idea that “origins” are “destiny” by showing great convergence in shareholder protection among the purportedly distinct legal families. More controversially, Katelouzou and Siems seem to think that their results disprove the emergence of a paradigm based on the “American” model, since many of the convergent protections are mandatory rather than enabling.³¹ But the US has adopted many mandatory corporate governance elements over the time period. Indeed, adjustments in mandatory legal rules to reset the accountability of managers and shareholders have constituted an essential part of the American model.³²

There are three important limitations on such direct convergence measures. First, they are based on law-on-the-books coding. Explicit and implicit enforcement mechanisms can vary significantly. For example, the value of the right to bring a shareholder derivative suit for a breach of directors' fiduciary duties will importantly depend upon the functional capacity of the local judicial system.

Second, nominally similar governance elements measures may function quite differently across national regimes, depending on ownership patterns and other complementary institutions. For example, director "independence" in jurisdictions characterized by family and blockholder ownership ought to be defined differently than in the case of jurisdictions characterized principally by diffuse share ownership, in light of the different agency problems to be solved.³³ Directors who are "independent" from management may help constrain managerial agency costs for the typical American firm, but independence from the controlling shareholders is crucial elsewhere for "good governance." Moreover, correctly-framed definitions of "independence" from controllers may be inadequate without public minority shareholders' selection (or veto) rights. To take another example, government ownership presents distinct challenges to the value of "independence." China's state-owned enterprises are populated with "independent directors," but their role presumably is to advance rather than constrain the state's employment of ownership prerogatives. Thus some would argue that a coding methodology is inadequate and even misleading in its capturing (p. 37) of governance features, advocating instead for thick accounts of local governance evolution.³⁴ The convergence picture becomes much more complex through this lens.

Third, direct convergence measures are often incomplete as a measure of a country's corporate governance system. As is explained in Section 3.1, the separate elements of mandatory disclosure found in securities regulation may play a crucial governance role. Yet disclosure regimes and practices can vary widely, quite separate from formal shareholder protection. More generally, even if particular elements of governance are concededly important, such as board structure and disclosure, valid measures of these governance elements may vary significantly across countries.³⁵

3 Capital Market Evidence on Convergence

One important measure of the extent of corporate governance convergence is the behavior of firms seeking to raise equity capital in a globally competitive capital market. Evidence of convergence comes in (1) the decline of cross-listings by firms from purportedly lower investor protection jurisdictions onto US stock exchanges; (2) the increasing capacity of firms in emerging market economies to raise equity capital through IPOs; and (3) an increase in "inversion" transactions in which issuers switch their domicile from the US to a foreign jurisdiction. None of these developments suggest that investor protection is less robust in the US than previously; rather, that the gap between the highest and lowest investor protection regimes has diminished so that countervailing factors might dominate

the listing or domicile choice. This is consistent with the convergence pattern reflected in the Katelouzou and Siems study.

3.1 The Decline in Cross-Listings

A substantial literature documents the existence of a valuation premium for foreign firms that cross-list on US stock markets, and the effect is strongest for firms whose primary listing is in a jurisdiction with weaker investor protection.³⁶ One component of valuation creation (p. 38) is how the listing “bonds” the foreign issuer to the higher quality US regime, in particular the disclosure requirements of the federal securities laws, as enforced by public and private litigation, and the stock exchange listing rules.³⁷ This bonding effect shows the limits of efforts to measure governance convergence through coding corporate law, since a national regime of investor protection can be improved by opting into a more credible disclosure regime.³⁸ The number of cross-listings began to decline in the mid-2000s, and various US business and political leaders claimed that the toughening US regulatory regime, reflected in the Sarbanes–Oxley law that followed the post-Enron/WorldCom scandals, had undercut the value proposition.³⁹ In consequence, the SEC liberalized the “delisting” rules in the hope that easier exit would encourage more firms to cross-list.⁴⁰ Recent papers suggest that the consequence was to reduce the cross-listing premium, especially for firms with weaker corporate governance, because the new rule undercut the credibility of the cross-listing bond.⁴¹ This would reduce the appeal of the US as a “bonding” regime.

But what accounts for the previous decline in cross-listings? It’s not that the US regime is so onerous; rather, the need for bonding has declined. As shown in the prior discussion of “convergence,” corporate governance has leveled up in many jurisdictions. Imperfect coding may still reflect an underlying phenomenon. Firms can also credibly engage in governance self-help through adoption of strong internal governance arrangements (such as credibly independent directors⁴²) and through measures that make disclosure robust and reliable, such as reporting on international accounting standards and retention of high-reputation external accountants. Firms can also hire internationally reputed underwriters in their IPO. Cross-listing may still be valuable for weakly governed firms (even if diminished by the easier US exit), but the decline in cross-listings reflects reduced demand because of reduced need. The willingness of foreign issuers to go public on foreign exchanges rather than the US suggests that the governance-quality advantage of the US has dissipated. Leveling up means (p. 39) that issuers obtain an insufficient cost-of-capital discount for bonding the firm to the US governance regime, given the costs.⁴³

Figure 2.3 OECD Business and Finance Scorecard (2016), fig. 6.

3.2 Increased Emerging-Market IPOs

Another indication of “convergence” is provided by the ability of firms in emerging market economies to access capital markets through IPOs, whether on local exchanges or through cross-listing on an exchange at a global financial center. The OECD Business and Finance 2016 Scoreboard has a graphic, reproduced in Figure 2.3, that shows this, covering the 2000–2015 period.⁴⁴ Firms in emerging markets are able to raise an increasing amount of equity capital over the period, in dollar amount (correcting for the immediate run-up prior to the crisis) and as a percentage of the total amount raised. As shown by the graphic in Figure 2.4 from OECD researchers Mats Isaakson and Serdar Çelik, “advanced economies” dominated the IPO market early in the period; more recently the split with emerging economies has been 50:50.⁴⁵ Moreover, most equity raising by non-OECD firms occurs in non-OECD capital markets. To a significant extent, of course, these changes reflect the economic rise of (p. 40) China,⁴⁶ but such changes do carry evidentiary weight on the governance setup, since public shareholders are directly exposed to frailties in governance.⁴⁷

Figure 2.4 Mats Isaaksson and Serdar Çelik, “Adapting Global Standards to a Changing World”, p. 3, fig. 1.

3.3 “Inversions”

An “inversion” is a merger in which the target is the formal corporate survivor of the transaction, which is so structured to shift the corporate domicile of the ongoing enterprise. Often this is to take advantage of the more desirable governance regime of the new domicile. In the current mergers and acquisition environment, the term most particularly refers to transactions in which a US issuer, typically organized in Delaware, merges into a foreign (p. 41) target, choosing a non-US domicile for the ongoing enterprise. The motivation is tax minimization: US-domiciled firms are subject to US corporate income tax on their worldwide earnings; non-US-domiciliaries are subject to US tax only on their US activities.⁴⁸ Favorite destinations have been Ireland, the Netherlands, and the UK, but Bermuda, Switzerland, and Canada have been chosen as well. The firms retain their US stock-exchange listings and thus remain subject to the US federal securities laws. There are two messages relevant to the convergence debate. First, even though the governance regimes of these particular jurisdictions differ, at least formally, in most respects they are convergent. Or rather, if there is a decrement to governance quality, it is swamped by the immediate tax savings. Second, in considering what “counts” as corporate governance, the content of securities regulation and the exchange’s listing rules also must be included. The “inverted” firms were in the same position as any other cross-listed firm. Their US listing bonded themselves to the disclosure and other regulatory elements of the US federal securities laws and to the exchanges’ own rules, including the implicit and explicit enforcement mechanisms.

4 Evidence of Non-Convergence or Divergence-Within-Convergence

Notwithstanding indications of some convergence, there is also ample evidence of significant divergence. Indeed, the continuing (if reduced) cross-listing premium indicates this. Surveys of institutional investors indicate wariness about foreign firms in countries with relatively weak corporate governance, especially for firms whose ownership structure (such as family control) and internal governance indicate vulnerability.⁴⁹ Empirical evidence on institutional investor investment behavior bears out the reliability of the surveys.⁵⁰

Divergence takes two forms: The first is a non-following of the convergent norm—for example, not requiring independent directors. The second, far more common, is divergence within the convergent norm: “divergent convergence.” Evidence of both forms of divergence is found in the OECD Corporate Governance Factbook (2017), a readily accessible current guide to worldwide corporate law and governance.

For example, the OECD describes a divergent practice on board structure: One-tier boards are most common (19 jurisdictions), two-tier boards are also common (10 jurisdictions), but the optional choice between one-tier or two-tier boards is growing (12 jurisdictions), given the development of the *Societas Europaea* (SE) in the EU. And there are still

Convergence and Persistence in Corporate Law and Governance

other variants in three important jurisdictions: Italy, Japan, and Portugal.⁵¹ The maximum term for board (p. 42) members varies from one year to indefinite terms, though the most common maximum term is three years.⁵²

There is a convergent practice on the presence of independent directors on the board, whether in a two-tier board structure (for the supervisory board) or a one-tier structure.⁵³ Yet the number of independent directors diverges: most common is two or three by law and 50% by voluntary measures (via a “comply or explain” Code). Jurisdictions vary on the numbers and ratios. Moreover, “national approaches on the definition of independence for independent directors vary considerably, particularly with regard to maximum tenure and independence from a significant shareholder.”⁵⁴ These differences would predictably result in divergence on the independence-in-fact of nominally “independent” directors and, indeed, their putative function.

Similarly, there is convergence on “independent” audit committees, formally required for listed companies by 89% of jurisdictions; covered by Code in the rest.⁵⁵ Yet there is divergence on whether this means “majority” independent directors or 100%.⁵⁶ And there appears to be no convergent practice on the relationship between the audit committee and the external auditors.

One fundamental divergence relates to the function of independent directors deriving from the divergent patterns of ownership.⁵⁷ The stylized division is between diffuse ownership (or ownership that is reconcentrated in institutional owners that represent diffuse beneficial owners) and family or blockholder ownership. Independent directors of diffusely owned firms are called to protect the interests of shareholders vis-à-vis the management teams. In family-dominated firms, the controllers monitor management; independent directors are called to protect minority shareholders. This aims to monitor insider dealings of various types. On a count-the-countries basis, family ownership dominates throughout the world.⁵⁸

Nevertheless, in a substantial fraction of jurisdictions (19 jurisdictions of 46), board approval is not required for important related-party transactions, and, where required, independent directors’ review is not necessary (13 jurisdictions), nor is an opinion from an outside specialist (9 jurisdictions).⁵⁹ Moreover, only seven of 46 jurisdictions have special arrangements designed to facilitate minority representation on the board.⁶⁰ Within this group of seven, only Israel gives the public minority the right to veto the reelection of independent directors. How genuinely convergent is the practice of director independence if (p. 43) (1) independent directors will not necessarily review important related-party transactions and (2) formally independent directors are elected by the controllers whose potential self-dealing they are supposed to monitor?⁶¹

Do these divergent elements within a convergent practice matter? The evidence is “yes, they should.” First, the particulars of a reform can determine whether it is “high impact” or not. In the case of the move to independent directors, for example, whether the fraction of independent directors is relatively high or low and whether they are given key governance roles predictably should affect investor protection. The importance of these

variations is borne out in a recent (2017) detailed cross-country analysis of board reforms.⁶² The study finds that “high impact” measures that markedly change the fraction of independent directors, particularly if implemented quickly, will increase the value of the firm (measured by Tobin’s q), as will measures that assure audit committee and auditor independence.⁶³

Second, governance elements commonly have country-specific effects because of country-specific positive and negative complementarities, as well as substitution effects. For example, the level of enforcement resources available to a market regulator will affect the quality of disclosure. The efficiency of a court system will affect the impact of legal rules on investor protection. Independent boards staffed by high-quality directors may substitute for weaknesses in the formal legal system.⁶⁴ The importance of country-specific analysis of “good corporate governance” is argued most forcefully in Bernard Black et al., which builds country-specific corporate governance indices for four emerging market economies covering critical governance variables such as board structure and disclosure.⁶⁵ The index elements that measure “good disclosure” or “better board structure,” for example, vary within each country; the divergences matter.

A good example of partial convergence and divergence-within-convergence is the experience with “Say on Pay,” a shareholder vote on the company’s remuneration practices. The concept has had remarkably quick takeup as an element of global governance best practice since its legislative adoption in the UK in 2002.⁶⁶ Rapid diffusion shows convergence, yet the convergence has been partial. First, jurisdictions have divided on whether to require (p. 44) (or recommend) shareholder votes on remuneration *policy*, a general ex ante view on the company’s pay strategy. As of the OECD’s 2017 survey, 29 of 46 countries (63%) had adopted such “Say on Pay *Policy*.”⁶⁷ Yet a significant number still do not require even *disclosure* of individualized pay and thus are far from empowering shareholders in this way. The division is even sharper on shareholder votes on the level/amount of remuneration, “Say on Pay.” Only 24 countries (52%) require (or recommend) such a shareholder vote. Is the vote binding or advisory? For “Say on Pay *Policy*,” 19 countries (41%) adopt the “binding approval” variant, making that the most widespread. For “Say on Pay,” 17 countries (37%) adopt the binding approval variant (versus seven, advisory only). Takeup of shareholder voting on remuneration policy and practices appears to be far more widespread in the OECD countries, especially the US and the EU member states, than emerging market economies. The EU, for example, promoted shareholder voting on remuneration in the 2017 Shareholder Rights Directive.⁶⁸ As an innovation on a core corporate governance question, there is more convergence on the thesis than on the implementation.

A more radical version of “divergence within convergence” is advanced in a recent volume on independent directors in Asia,⁶⁹ which argues both that (1) independent directors are “ubiquitous” in Asia, found in higher proportion across more firms than in the “West,” and that (2), functionally, there are “varieties” of independent directors in Asia, differing substantially from the US variant and differing even within Asia.⁷⁰ Adoption of a transplant, particularly under pressure of foreign investors or global governance institutions,

does not determine how the new institution will function. That emerges over time, as the transplant is contextualized within the local ecology, and can lead to significant divergence in practice.

5 Global Governance as Promoting Convergence

5.1 Origins

Reform of corporate governance has been on the global development agenda for nearly 25 years. Nearly every country seeking access to external finance has undertaken major reform, as documented by Katelouzou and Siems (30 countries) and also by Fauver et al. (40 countries).⁷¹ This wave of activity is not simply the result of independent action by different countries responding to the imperatives of the global capital market or acceding to letter-writing campaigns by institutional investors. Rather, this widespread adoption of corporate (p. 45) governance reforms has been stimulated through what might be thought of as global governance, in which the main actors have been the IMF, the World Bank, and the OECD. In the aftermath of the global financial crisis of 2007–2009, the G-20 group of national leaders and the Financial Stability Board have joined the project.

Probably the origin of the global corporate governance reform movement was the Cadbury Committee Report issued in 1992.⁷² Although aimed at the governance of UK firms, particularly the “control and reporting functions of boards, and on the role of auditors,” the Report became internationally influential both for the substance of its recommendations and for the form that they took: a “Code of Best Practice” enforced on the “comply or explain” model. The recommendations were not mandatory, but, as a condition of listing on the London Stock Exchange, firms were required to state whether they “complied” with a recommendation, and if not, to “explain” why not. Codes of corporate governance best practice are now a common feature of stock-exchange listing rules or national corporate law, generally following the “comply or explain” pattern, and have provided a channel for convergence.⁷³

5.2 East Asian crisis

The East Asian financial crisis of 1997–1998 propelled corporate governance to the realm of global governance. The Asian “Tigers” flourished in the 1990s, which led to a massive influx of Western finance, generally in the form of dollar-denominated credit to private companies whose earnings were principally in local currencies. This mismatch left these firms seriously exposed to exchange rate risk; depreciation in the value of the local currency would undercut the firms’ ability to repay foreign creditors. Insofar as the entanglement of these firms with the government gave rise to an implicit government credit guarantee, sovereign creditworthiness was also at risk. A devaluation of the Thai baht triggered competitive currency devaluations across many countries in the region and a “run on the bank” by Western lenders who anticipated default. The crisis exploded, threaten-

Convergence and Persistence in Corporate Law and Governance

ing the economic stability of many countries and the region as a whole. Indeed, except for the Great Depression, it was “the crisis of the century.” The IMF stepped in with multi-billion dollar rescue packages.

The IMF imposed many conditions on countries accepting aid (“conditionality”), including corporate governance reform. Financial crises are generally assumed to arise principally from macroeconomic considerations and policy mistakes and have been ubiquitous over time.⁷⁴ The structure of many East Asian enterprises raised problematic governance concerns, however. Family groups owned vast business enterprises through control (p. 46) mechanisms that separated cash flows from control rights, and commonly received preferred access to credit in coordination with the economic growth plans of government elites. This setup provided many opportunities for private benefit extraction at the expense of public shareholders and external creditors. An influential article by Simon Johnson, later the chief economist of the IMF, described the importance of the corporate governance channel as follows:

The theoretical explanation is simple and quite complementary to the usual macroeconomic arguments. If expropriation by managers increases when the expected rate of return on investment falls, then an adverse shock to investor confidence will lead to increased expropriation as well as lower capital inflow and greater attempted capital outflow for a country. These, in turn, will translate into lower stock prices and a depreciated exchange rate. In the case of the Asian crisis, we find that corporate governance provides at least as convincing an explanation for the extent of exchange rate depreciation and stock market decline as any or all of the usual macroeconomic arguments.⁷⁵

Without sufficient protections for public shareholders and creditors:

[M]anagement [in firms that failed] was able to transfer cash and other assets out of company with outside investors, perhaps to pay management’s personal debts, to shore up another company with different shareholders, or to go straight into a foreign bank account. The fact that management in most emerging markets is also the controlling shareholder makes these transfers easier to achieve. The downturns in these countries have been associated with significantly more expropriation of cash and tangible assets by managers.⁷⁶

To elaborate some on the channel: Poor corporate governance enhanced the risks of private benefit extraction. One safeguard was for external credit providers to insist on short maturities. This increased the run risk (from non-rollovers) as creditors would anticipate an increased likelihood of default from (1) the exchange rate mismatch and (2) extra extractions by controllers to protect their positions.

In its report on the crisis, the World Bank concluded that:

The poor system of corporate governance has contributed to the present financial crisis by shielding banks, financial companies, and corporations from market disci-

pline. Rather than ensuring internal oversight and allowing external monitoring, corporate governance has been characterized by ineffective boards of directors, weak internal control, unreliable financial reporting, lack of adequate disclosure, lax enforcement to ensure compliance and poor audit.⁷⁷

Hence significant corporate governance reform became part of the IMF's conditionality program and then, subsequently, associated with lending and more general development activity by the World Bank. Not to demean the development motives, but the impetus for this insistence on corporate governance came from "first world" concerns: In a regime of (p. 47) robust cross-border capital mobility, weak corporate governance in emerging market economies was a threat to global financial stability. A country's corporate governance setup that internalized *local* economic and political costs and benefits could nevertheless produce *global* externalities. Thus corporate governance reform had a new imperative.

5.3 OECD Principles

But what "reforms" exactly? The Asian crisis prompted a call for the OECD to develop "a set of corporate governance standards and guidelines,"⁷⁸ which resulted in the OECD Principles of Corporate Governance, issued in 1999.⁷⁹ The Principles relied heavily upon the work of the business and legal community in the US that had been focusing on corporate governance matters since the 1970s, including the American Law Institute project on corporate governance, as well as the insights and further discussion stirred by the Cadbury Committee Report.⁸⁰ The OECD Principles identified five specific elements: shareholder rights, equitable treatment of shareholders, the role of stakeholders, disclosure and transparency, and the responsibilities of the board. The Principles were somewhat elaborated, both in the text, and in a set of "annotations." The investor protection thesis was supported by the work of economists pursuing the "law and finance" research program,⁸¹ but the Principles had both broader and more specific reach.

5.4 Promoting Governance Reforms

After the East Asian crisis, the World Bank and the IMF established the "Financial Sector Assessment Program," which entailed a country-specific assessment of the soundness of the financial system, the "infrastructure, institutions and markets" needed for development, and the country's adherence to "selected financial sector standards and codes."⁸² The OECD Principles were immediately wrapped into this global governance project of the World Bank and the IMF. The Principles "underpin the corporate governance component of the World Bank/IMF Reports on the Observance of Standards and Codes" (ROSC) and were designated by the Financial Stability Forum (established in 1999, in the crisis aftermath) as "one of the 12 key standards for sound financial systems."⁸³ The Principles were intended to serve as a "reference point," but, between the Principles and the Annotations, there was significant basis for a prescriptive agenda of corporate governance reform and comparative evaluation.

(p. 48) As part of its ROSC program, the World Bank prepares country “assessments” that highlight changes and “improvements,” make policy recommendations, and “provide investors with a benchmark against which to measure corporate governance” in the studied country. In the case of non-OECD countries, the recommendations can be rather detailed.⁸⁴ The corporate governance indicators also became important in the World Bank’s “Doing Business” measures of country-specific business-relevant factors. These indicators, presented in index form, are presumably relevant for foreign director investment and portfolio investment, which becomes the reason that governments may pursue reform. The World Bank also prepares thematic reports arguing for particular “Doing Business” improvements in corporate governance; for example, enhancing investor protection.⁸⁵

In the aftermath of the Asian financial crisis, the World Bank, in cooperation with the Asian Development Bank and the OECD, embarked on a campaign to proselytize for higher corporate governance standards in Asian economies.⁸⁶ Among the tools were “roundtables” of business, government, and academic elites.⁸⁷ Most notable has been the OECD-Asian Roundtable on Corporate Governance, hosting its 18th meeting, October 2017, in Tokyo. Convergence onto an international standard was plainly the agenda. The 2003 Roundtable produced agreement on an “action plan for improving corporate governance,” viz., “The White Paper on Corporate Governance in Asia” (published in English, Chinese, and Japanese). The 2011 Roundtable updated the White Paper with specific reform recommendations; it included an overview of corporate governance frameworks in 13 Asian countries. The OECD Principles were used as the benchmark for developing the ASEAN Corporate Governance Scorecard in 2012, which ranks the top listed companies in six countries.

More generally, the OECD has recently (2017) produced a new OECD Corporate Governance Factbook, a comparative report on 47 jurisdictions “hosting 95% of all publicly traded corporations in the world as measured by market value,” which is presented as “a unique source for monitoring the implementation” of the latest OECD Principles.⁸⁸ The (p. 49) goal of this OECD venture is to promote, through the “soft law” of global governance,⁸⁹ a movement toward a convergent best practice.⁹⁰

5.5 Global Financial Crisis: the Focus on Financial Firms

The global financial crisis of 2007–2009 produced another crisis in corporate governance, in particular the corporate governance of financial institutions. The prevailing governance model was found to encourage excessive risk taking. The deficiencies included misaligned compensation schemes, insufficient board monitoring of the risk taking by the firm, and overly complex organizational structures that made it difficult to manage (or monitor) the business and which greatly complicated resolution planning. This led to revision of the convergent corporate governance prescription for banks, undertaken by the Basel Committee on Banking Supervision. In “Principles for Enhancing Corporate Gover-

nance in 2010” (revised in 2014), the Basel Committee’s additions focused on risk monitoring, including internal controls, compensation, and complexity.

With greater confidence in pursuing a distinctive governance agenda, the Basel Committee revisited bank governance in 2015, with “*Guidelines: Corporate Governance Principles for Banks*” (emphasis added). These “Guidelines/Principles” give considerable specificity to the board’s role in a banking institution, especially the board’s role in risk monitoring and assuring adequate internal controls. Moreover, the board is tasked with additional attention to compliance monitoring in light of other issues that emerged about bank behavior before and after the crisis. The Guidelines/Principles are not meant to be regulatory, but to guide supervisors in assessing corporate governance regimes; nevertheless, the degree of specificity is much greater than in the OECD Principles.

5.6 The G-20 and the FSB

The most important post-crisis global financial governance vehicle was a series of G-20 Leader Summits which brought together presidents and prime ministers of a self-organized group of 20 leading countries to deal with the crisis and its aftermath across a broad range of economic and regulatory items. In turn the G-20 empowered a recharged “Financial Stability Board,” which was tasked with charting out a common regulatory agenda to guard against a crisis recurrence.⁹¹ Obviously neither the G-20 nor the FSB has compulsory authority, but the relevant international organizations have pursued a compliance strategy of “peer assessment” of whether particular countries are pursuing agreed-upon reforms.

(p. 50) Corporate governance made its way to the G-20 agenda in 2015. The OECD examined its Principles in the wake of the financial crisis and decided that the application rather than the Principles themselves were the flaw in the governance of financial firms.⁹² The ongoing second revision of the Principles focused mostly on the expanding significance of institutional investor ownership. The 2015 version of the Principles was submitted to the G-20 Leaders Summit in November 2015 and adopted there. They are now known as the G20/OECD Principles of Corporate Governance. In addition to the additional weight they carry because of the G-20 imprimatur, country-specific compliance with the Principles will now become part of the FSB’s peer assessment process.⁹³ This is important because it will permit the FSB to focus on the country-specific implementation of appropriate governance norms for financial firms.

5.7 Basel Committee and the FSB

Thus it appears that the corporate governance of financial firms will be subject to scrutiny through two elements of the global financial regulatory system: the board focus of the Basel Committee, as transmitted through national supervisors, and the broader governance elements that emanate from the national governance setup, per the FSB’s scrutiny. Yes, the Guidelines/Principles of the Basel Committee admit of diversity, as do the G20/OECD Principles, but convergence pressure seems likely.

The general point is this: To an extent that might surprise academics focused on the political economy of races to the top or bottom driven by local conditions, convergence on a common set of corporate governance principles and practices has been driven by various forms of global governance. One conclusion is that the convergence push through global governance is motivated by financial stability concerns at least as much as by efficiency and productivity. The global governance push has particularly affected less developed countries—“emerging market economies”—that are more sensitive to the certification of the World Bank and other development organizations. But it has affected OECD countries as well, as reflected in the quite common adoption of corporate governance “codes” as well as various elements of prescriptive reform.⁹⁴ Moreover, after the financial crisis of 2007–2009 (p. 51) the corporate governance of large banking organizations has become a particular global governance target.

6 Supranational Governance—the EU

When the G&R book was put together in 2002, the most salient questions of “convergence and persistence” related to the EU countries, Japan, and the United States. The main EU-specific questions were (1) the durability of codetermination in Germany and elsewhere in the EU and (2) the appeal of bank and blockholder monitoring, both elements in opposition to the movement toward the diffuse shareholder-centric model associated with the UK and the United States. As noted in the introduction to this chapter (Section 1), the debate focused, structurally, on “outsider” versus “insider” governance, and whether the governance differences resulted from political stories, functional sorting, or simply strong path dependencies that had perhaps an internal efficiency dimension even if not global efficiency. In any event, the divergent EU countries were member states in a transnational federation with legislative and executive authority, which on many dimensions sought to “harmonize” local regimes. Company law and corporate governance practices seemed a natural target.

So what happened? A recent analysis by Martin Gelter, which reviews the relevant history in some detail, reports that “there is no uniform assessment of company law harmonization in the European Union; views vary between characterizing company law as a ‘success story of European efforts to regulate’ and the claim that EU Company law is ‘trivial’.”⁹⁵ From one perspective, the countries of the EU have converged on a high level of minority shareholder protection and robust disclosure, even if the particulars of such protections are not “harmonized.” Within that convergence, lawmaking on company law in the EU generally has provided significant latitude for national variations, with the rare exception of some prescriptive post-financial crisis limits on executive compensation in banking organizations, which were linked to other financial stability regulation.⁹⁶

An EU path to greater convergence seems stalled for three fundamental reasons. First, “top-down” harmonization applying to all firms in all Member States would produce significant inefficiencies because of diverse initial conditions, particularly diverse ownership patterns that produce different core agency problems. Provisions for shareholder empow-

Convergence and Persistence in Corporate Law and Governance

erment that may be desirable where ownership is diffuse would have negative consequences for minority public shareholders where ownership is concentrated. Moreover, the complex (p. 52) EU politics of lawmaking would also conduce to significant inefficiencies in a top-down approach.⁹⁷

Second, “bottom-up” harmonization in which *companies* could choose the corporate governance model most suited to their objectives would upset national decisions about the balance of power between shareholders and employees. For example, “regulatory competition” on the US model could permit a German firm to shuck codetermination and its two-tiered board via a simple merger with a UK shell set up for purposes of the merger (assuming approval of such a transaction is for shareholders). There is also general concern among EU parties that permitting firms freely to move their “seats” to pursue the optimal company law would lead to a “race to the bottom,” though of course some would claim that Delaware, the winner of the US race, has produced a package of corporate law and judicial machinery that has many positive attributes.

The third factor that has produced corporate governance divergence in the EU is the profound ambivalence about the project of transnational economic and political integration that a convergent system would facilitate. The place where this is clearest is the discord over the 13th Company Law Directive, the Takeover Directive, a debate that raged in the late 1990s and early 2000s.⁹⁸ A key sticking point was the “level playing field”: the need to avoid protectionist national company law that heightened defensive barriers for local firms while permitting acquisition of foreign targets. Firms needed to be mutually contestable to guard against mercantilist behavior.

In the effort to break a deadlock, a representative group of “High Level Company Law Experts” was convened in 2001. The Experts called for a “board neutrality” rule in the face of a hostile bid, a “breakthrough” rule that would permit the holder of at least 75% of the cash flow interest in a target to succeed in the bid, and an overcoming of “Golden Share” vetoes by governments in privatized former state-owned enterprises. The goal of the Experts was to foster the EU’s project of transnational economic integration, which they understood to be advanced by cross-border mergers in order to create companies of EU-wide scale:

An important goal of the European Union is to create an integrated capital market in the Union by 2005. The regulation of takeover bids is a key element of such an integrated market.

...

Many European companies will need to grow to an optimal scale to make effective use of the integrating internal market. The same is true for companies which compete on global markets. Takeover bids are a means to achieve this for those engaged in the business of both bidder and target.

...

In many parts of Europe on the other hand, takeover barriers existing in various Member States more often tend to result in control over listed companies being incontestable. In the view of the Group, this is undesirable in the European context, as an integrated capital market has to be built up in order for business to fully benefit from and make effective use of the integrating internal market in Europe.⁹⁹

(p. 53) There were various technical objections to the Experts' proposal and the proposed follow-on directive from the European Commission, but the rejection came from a deeper source. Strong form convergence, which truly would have brought about free mobility of capital, people, and products—genuine transnational economic integration—was actually not what the Member States wanted, at least not the relevant business and political elites. Too much autonomy and national identity would be sacrificed. The barrier to adoption of the proposed Takeover Directive was not so much the efficiencies of local adaptations and institutions but the desire of the Member States to throw sand in the gears of economic and political integration. Divergence makes it harder to accomplish cross-border merger and acquisition activity, which otherwise would produce much tighter integration. The strength of national identity and the comparative weakness of European identity is the ultimate hindrance to corporate law convergence in the EU.

7 Convergence on “Shareholder Value,” but which Shareholders?

Twenty years (1997) ago Henry Hansmann and Reinier Kraakman wrote an essay for a Columbia Law School conference to address the question, “Are Corporate Systems Converging?” Their answer, “The End of History for Corporate Law,”¹⁰⁰ identified a particular governance modality for large economic enterprises, the “standard shareholder-oriented model,” organized on these principles:

[First, t]he ultimate control over the corporation should rest with the shareholder class; the managers of the corporation should be charged with the obligation to manage the corporation in the interests of its shareholders; [second] other corporate constituencies, such as creditors, employees, suppliers, and customers, should have their interests protected by contractual and regulatory means rather than through participation in corporate governance; [third] noncontrolling shareholders should receive strong protection from exploitation at the hands of controlling shareholders; and [fourth] the market value of the publicly-traded corporation's shares is the principal measure of its shareholders' interests.¹⁰¹

They claimed that this model was superior to a state-oriented model, a labor- (or stakeholder-) oriented model, or a manager-oriented model. Subsequently, they would claim superiority to a model oriented around a powerful family tied to the state and largely free of regulation. The measures for superiority were all of: ideological (normative) appeal, comparative efficiency, and dominance as an empirical matter. The essay spawned a liter-

ature with many interesting objections,¹⁰² some seeing the essay as a polemic and responding in kind.

(p. 54) It seems to me that the current deep question of corporate governance teleology is not “shall the firm be run for the interest of shareholders?” but “which shareholders?” And the end pursued by many shareholders as well as global governance actors (including many governments) is not just “efficiency” but “stability.”

Around the same time as the Hansmann and Kraakman essay, Gordon argued that the linked regimes of trade liberalization, capital market liberalization, and a newly flexible labor market constituted a “new economic order,” and the interaction would produce an unprecedented level of economic adjustment costs.¹⁰³ In particular, the interaction between globalized trade, which heightens product market competition, and liberalized capital markets, which provide additional ways for shareholder insurgents to pressure managements to cut costs, improve margins, and become more efficient, was likely to increase layoffs and flatten wage growth. Finding a new job is costly, and for a meaningful fraction of employees, wage loss after re-employment will be significant.

If adjustment costs are large, widespread, and persistent, social and political stability may be put at risk. “Which shareholders” will affect adjustment costs in important ways. Let us posit that there will be two types of shareholders, overlapping in most respects, but one type that is purely efficiency-minded, and the other, stability-minded as well. First, efficiency-only shareholders may push firms to respond quickly to a changed competitive environment, heedless of adjustment cost issues (to the extent not required by law). A rapid response by one firm in a competitive environment will evoke rapid responses from its competitors, leading to a change in the rate of economic change, an increase in the second derivative, which will much increase the realization rate of adjustment costs. Thus change driven by efficiency-only shareholders will have a redoubling effect on adjustment costs and thereby heighten stability concerns.

Governments are certainly likely to see strong reasons for concern about stability, because of electoral consequences in some countries or simply to retain popular support. But some shareholders will be stability-minded as well, because their interests require attending to stability-preserving objectives. Family shareholding groups that need political buy-in to protect their economic stakes are likely to see value in social and political stability, particularly if their planning horizon is multi-generational. Large institutional investors may well have a similar perspective. First, they are subject to the regulation of stability-preferring governments. But further: a large institutional investor that is diversified across the economy and is a permanent investor will have stability concerns irrespective of implicit government pressure. An efficiency-only investor can opt out of instability by holding cash or gold. A large institutional investor cannot and therefore must internalize instability costs. Global governance institutions, which are accountable to governments, are also likely to have stability objectives. This is demonstrated by the growing global governance movement for “Stewardship Codes” and the concerted campaign against the purported “short-termism” of hedge funds.

(p. 55) The irony, of course, in the “which shareholder” question, is that stakeholder concerns enter through the side door. Worrying about downsizing and depressed wages thus reframed through the stability channel is still about maximizing shareholder value, but for “which shareholder?” To say that we are at “the end of history” only begins the analysis.

8 Conclusion: Convergence and Stability

Corporate governance “convergence” first entered the agenda as a growth and development question. At a time of worry about performance of the US corporate governance model, would “strong monitors” of insider systems prove superior to “weak owners”? The East Asian financial crisis injected corporate governance into the machinery of global financial stability as well as economic development. Perhaps the reconcentration of weak owners in outsider systems into institutional investors will produce another sort of convergence: special attention to the interests of stability-minded shareholders, including the social implications of corporate governance. Stability concerns already exist where family ownership is high. Will stability be added as a first-order element in corporate governance convergence?

China who raised 63% of the total proceeds. China has traditionally been the largest IPO venue among emerging markets. Moreover, in eight out of the last ten years Chinese non-financial companies have also ranked first in the world in terms of the total amount of money raised through IPOs. In this context it may also be noted that IPOs in China were suspended during two periods in the last five years.” “OECD Equity Markets Review: Asia” 2017, www.oecd.org/corporate/OECD-Equity-Markets-Review-Asia-2017.pdf, at 16.

(⁴⁷) An alternative explanation is that shareholders in China companies, many of which have substantial state ownership, are relying on an implicit state guarantee against losses. Evidence for this is provided by the extensive state intervention that halted the sharp Chinese stock market decline in summer 2015, leading to a recovery of prices by year end.

Better corporate governance and investor protection is associated with stronger corporate balance sheets, less reliant on short-term (runnable) funding. These findings, argues the IMF, should lead to further, deeper corporate governance reform, especially on the dimensions of minority shareholder protection and disclosure. Abstract and Keywords

In this chapter, we analyze three instances that illustrate the political economy of corporate governance. First, we examine how the politics of organizing financial institutions affects, and often determines, the flow of capital into the large firm, thereby affecting, and often determining, the power and authority of shareholder-owners. Second, we show how continental European nations have been slow in developing diffusely owned public firms in the years after World War II. The third political economy example deals with management in diffusely owned firms. The chapter also looks at the historical organization of capital ownership in the United States, noting how the country's fragmented financial system limited the institutional blockholders and increased managerial autonomy over the years. Finally, it discusses the power of labor in postwar Europe, political explanations for the continuing power of the American executive and the board in recent decades, other political economy channels for corporate governance, and the limits of a political economy analysis.

1 Introduction

IN this chapter, we analyze three instances that illustrate the political economy of corporate governance. First, we examine how the politics of organizing financial institutions affects, and often determines, the flow of capital into the large firm, thereby affecting, and often determining, the power and authority of shareholder-owners. Second, we show how continental European nations have been slow in developing diffusely owned public firms in the years after World War II. The third political economy example deals with management in diffusely owned firms. The chapter also looks at the historical organization of capital ownership in the United States, noting how the country's fragmented financial system limited the institutional blockholders and increased managerial autonomy over the years. Finally, it discusses the power of labor in postwar Europe, political explana-

tions for the continuing power of the American executive and the board in recent decades, other political economy channels for corporate governance, and the limits of a political economy analysis.

To fully understand the modern corporation's ownership, shape, and distribution of authority, one must attend to politics. Because basic dimensions of corporate organization can affect the interests of voters, because powerful concentrated interest groups seek particular outcomes that deeply affect large corporations, because those deploying corporate and financial resources from within the corporation to buttress their own interests can affect policy outcomes, and because the structure of some democratic governments fits better with some corporate ownership structures than with others, politics can and does determine core structures of the large corporation.

Douglass North captures something close to the idea we use in this chapter: "institutions [for us here, the institutions of corporate governance] are not necessarily or even usually created to be socially efficient, rather they . . . are created to serve the interests of those with (p. 57) the bargaining power to devise [the] new rule."¹ Interest groups often seek to obtain via politics both immediate results and enduring institutions that promote their own current interests and preferences. They do so generally and they do so in ways that can determine corporate governance. The results may be economically efficient, inefficient, or neutral.²

Figures 3.1 and 3.2 illustrate the first generality of our argument here: the firm is embedded in financial, labor, and product markets, each of which affects the shape of the large firm and each of which attracts considerable political attention. The polity shapes the firm directly and, through these three markets, indirectly, as Figure 3.1 illustrates.

Moreover, the principal players inside the firm—corporate owners, executives, and employees—can themselves project power into the polity. Owners seek mechanisms that minimize agency costs, managers seek autonomy and prestige, and workers seek job stability and good wages; each group seeks rules that favor themselves in contested transactions. They are at the three vertices in the triangle in Figure 3.2, with each side of the triangle representing a potential coalition between two of these actors. These three actors interact inside the firm³ and in the economy, and contend or coalesce in the political arena. Corporate governance arrangements inside the firm among these three main corporate actors interact deeply with a nation's politics through party systems, political institutions, political orientations of governments and coalitions, ideologies, and interest groups.⁴

A major part of the differences among corporate governance regimes in advanced industrial countries is determined by policies concerning labor protection, orientation to shareholder value, and product market conditions. How a polity decides to organize capital, labor, and product markets can deeply affect the firm's corporate governance structure.

Corporate Governance and Its Political Economy

Complications abound. A simple map from politics to economics to corporate governance cannot be drawn because causation is bidirectional, as the dotted arrows in Figure 3.2 illustrate. Sometimes causation is circular, with several economic, institutional, and political features determined simultaneously. Sometimes there are multiple equilibria due to path-dependence phenomena, making the original conditions—which may result from chance, contestable events—determinative. Thus, the present corporate governance (p. 58) (p. 59) structure is the consequence of past politics and is also a cause of future politics and economic institutions.* * *

Figure 3.1 The corporate governance environment.

Figure 3.2 The “triangle” of political theory and corporate governance.

Corporate structures around the world⁵ and over time⁶ have been heterogeneous, with the differences seen as most important being “the structure of rights and responsibilities among the parties with a stake in the firm.”⁷ We focus on the large, usually public, firm, partly because the largest firms are the “most politically salient firms in every jurisdiction”⁸ and the institutional differences in corporate governance are more evident in the largest business firms than in medium or small firms. “The different connotations of capi-

Corporate Governance and Its Political Economy

talism that spice political debates in different countries so differently are mainly due to differences in who controls countries' large corporations."⁹

In this chapter, we examine three instances of vital intersections between politics and the organization of the modern corporation. In the first, we look at how the politics of organizing financial institutions affects the flow of capital into the large firm and, hence, the power and authority of shareholder-owners. The channels through which capital flows into the large firm can determine ownership structure and, hence, the distribution of governance authority in the large firm. If financial institutions are barred from owning stock or from operating on a large, national scale, to take an extreme example, then they will be unable to serve as a counterweight to managerial and board authority. Concentrated ownership with institutional blockholding will be difficult or impossible. Its opposite, diffuse ownership with strong managerial control, can readily become the only alternative if the polity prevents financial institutions from growing large or having a role in stock ownership and corporate governance. Powerful financial institutions will produce more of the former—blockholding—than of the latter—diffuse ownership with strong managerial control.¹⁰

(p. 60) Because the flow and organization of capital attracts political attention, corporate structure can be, and often has been, a consequence of politics. The United States historically kept financial institutions small and without authority to own stock and influence large firms, coming close to the extreme instance just mentioned. As a consequence, when American industry went national at the end of the nineteenth century, the continent-spanning industrial firms could not raise capital from a nation-spanning financial market. Capital had to come from disparate institutions and individuals. In other nations tight relationships between large-scale industry and large-scale finance were possible. As a result, in the United States, the large public firm with diffuse ownership and powerful managers became more important, more widespread, and more persistent earlier than in other nations with more concentrated financial institutions and more concentrated ownership. Some of these patterns persisted to the end of the twentieth century. Only in recent years have we seen the rise of stockholding financial firms with noticeable corporate governance authority.

In the second instance, we examine the slowness of continental European nations to develop diffusely-owned public firms in the decades after World War II. While the decades-long persistence of concentrated ownership was surely due in important part to economic forces,¹¹ micro- and macro-politics strongly shaped the structure of the European firm. In particular, during the reconstruction after World War II, powerful labor movements in Western Europe made strong claims on firms' cash flows. Diffuse ownership in a strongly social democratic political environment was dangerous for dispersed shareholders. When labor made these strong claims on firm value, shareholders needed more and stronger mechanisms to keep executives loyal to shareholders. But because the polity would not provide such mechanisms readily, or at all, owners had reason to stay close to the firm to handle managerial agents themselves—either by directly running the firm's day-to-day operations or by keeping a close eye on the managers who did. Shareholders could con-

Corporate Governance and Its Political Economy

tain labor's claims on large firms' cash flows better if stock was in the hands of a close owner than with diffuse owners, which would lead to independent managers and an independent board running a diffusely held firm. Hence, to keep the firm's operating managers more loyal to shareholders, close ownership persisted.¹²

The third example concerns management in diffusely owned firms. Managers wield considerable political influence, which they use to shape the rules governing corporate finance and capital markets. In the 1980s, for example, American capital markets created the hostile takeover, by which an investor or another firm bought enough dispersed stock to control the targeted firm. Managers and directors sought to disrupt those hostile takeovers transactionally and legislatively, with poison pills, staggered boards, anti-takeover legislation, and court rulings, all of which made takeovers harder to accomplish.

The first two instances of the politics of corporate governance have the firm (or players inside the firm) reacting to the political environment. If the polity keeps capital channels fragmented, such as they were in the United States for the nineteenth and much of the twentieth centuries, then the firm learns how to deal with diffuse ownership. In the second instance, when labor (p. 61) makes particularly powerful claims on the firm's value, executives and owners of the firm learn how to create countervailing power inside the firm. In contrast, in the final example that we investigate here, we see players inside the firm—executives and boards—proactively seeking public policies that favor themselves. Those in command of the firm can project power into the polity and will use that power to maintain, and sometimes to obtain, corporate law and other supports that favor them and maintain their authority inside the firm.

In section 2, we examine how the fragmented financial system in the United States historically limited the institutional blockholders and heightened managerial autonomy. In section 3, we analyze the relationships between owners and labor in polities where labor is strong—a corporate governance result well exemplified by German codetermination. In section 4, we examine political explanations for the continuing power of the American executive and the American board during recent decades. In section 5, we briefly look at other political economy channels for corporate governance. And in section 6, we consider the limits of a political economy analysis before we conclude.

We do not assert that these three political channels exhaust all important political channels of corporate governance and, for completeness, we describe at the end of this chapter several other channels, including some that need further research. Nor do we assert that analysis of economics, law, finance, contracts, institutional capacity, and lawmakers' sensibility of what is right and appropriate should be abandoned—i.e., we do not assert that behind each such perspective is a political economy story. Our aim is rather to develop the perspective that corporate governance often reflects political choice and that this channel can complement other efforts to explain the shape of the modern public corporation in the United States and around the world. More sharply, we claim that without political economy analytics, the shape, structure, and extent of the corporation, its ownership, and its place in an economy, cannot be understood.

2 The Historical Organization of Capital Ownership in the United States

When the large firm became technologically possible at the end of the nineteenth century, the types of capital providers were few: banks, insurers, governments, and individuals. There were no institutional investors such as modern-day hedge funds, mutual funds, or pension funds. Individuals were major capital providers to, and owners of, the large firm, but the largest firms in the United States outstripped the financial capacity of even the richest individuals. John D. Rockefeller, the richest person in the United States at the time, owned only a fraction of Standard Oil's stock.

The question to consider here is why deposit-gathering banks (and large life insurers), which were the major financial players of the time, were not then major players in American corporate governance. The answer seems on the surface simple—banks were barred from stock ownership throughout the era (and the insurers were barred eventually as well). Equally or more importantly, American banks were too small to play a role in major firm ownership anyway.¹³

(p. 62) A political economy explanation underlies the organization of American capital markets at the end of the nineteenth century.¹⁴ The United States had its unusual, fragmented financial system largely because the small banks were politically dominant in the United States and made sure that Congress would not disrupt their local monopolies. That history begins with Andrew Jackson's 1830s destruction of the Second Bank of the United States, a large, nation-spanning bank that could have been the model for a continent-spanning financial system. Alexander Hamilton had sought in the 1790s to create a truly national banking system. Several Congresses chartered, at Hamilton's urging at first, and then re-chartered a Bank of the United States, with branches in the major American cities of the time. But the smaller banks found themselves stressed and pressed by the Second Bank's quasi-regulatory efforts.¹⁵ In a Congress that was organized locally, district by district, the small, local bankers could be quite influential and they wanted Congress to rein in the Bank of the United States. Voter sentiment favored the small banks, making it easier for them to prevail. Jackson's famous veto message tapped into populist sentiment that wanted finance small, local, and weak.¹⁶

Those forces—local banker power, American congressional structure, and American anti-big-bank populism—combined to keep the financial system weak (as compared to what was possible and to what emerged in other nations) for well over a century.¹⁷ The United States during the nineteenth century and much of the twentieth had the most unusual banking system in the industrialized world: banking rules barred banks from operating on a national scale—and sometimes even a state-wide scale.¹⁸ Thus, by the end of the nineteenth century, although American industry spanned the continent, banks were small and local. Hence, industry could not gather capital from one or a few large deposit-gathering banks that provided one-stop financing. There was a major mismatch between the scale of American industry and the scale of American banking.

Corporate Governance and Its Political Economy

Insurers sought to fill the financing gap left by fragmented, local banking. And life insurers, whose obligations were long-term, were even better suited structurally for long-term big stockholdings than banks. The life insurers moved to fill the gap that American banking regulation created by taking large stock positions, initially in railroads and utilities. But the then-famous Armstrong investigation (which nearly propelled Charles Evans (p. 63) Hughes, its protagonist, to the presidency) culminated by barring life insurers from stock ownership.¹⁹ The consequence was that the weak and local structure of American banking, combined with barring large life insurers from owning equity, raised the demand and need for securities markets.

Although regulators intermittently sought to permit nation-wide banking, the small local bankers and their allies in Congress blocked their efforts. The National Bank Act, for example, passed to help finance the Civil War, created entities called “national” banks, but they were national only in the sense that Washington provided the charter and legal basis for them to operate. Their operations were largely local, as they were barred from operating from more than a single location. At the end of the nineteenth century, when industry was becoming national, the Treasury Department sought to allow banks to operate more widely geographically. Congress, presumably under the influence of the local bankers (and perhaps with public opinion still moved by an anti-big-bank animus) blocked these changes.²⁰

Banks and insurers were the core financial institutions when industry went national and continued to be core for much of the twentieth century. With banks and insurers restricted in size and from stock ownership, financial institutions could thus not play a strong role in corporate governance. But with money to be made in industry by achieving large-scale economies or sufficient market power to raise prices, firms found ways to raise money from bondholders and stockholders in diffuse securities markets. That result then created groups—small-town bankers with local monopolies—that wanted to preserve that status quo. Consequently, as the founders of nation-spanning industrial firms left their positions, with no blockholder or influential financial institution replacing the founders, diffuse ownership shifted power from capital providers to executives and boards, and these managerial players then also became interests that wished to preserve their authority relative to others inside the firm. With the firm lacking concentrated owners, these managers became freer to act in the policy-making environment than close owners would have allowed them to be.

True, banks’ and insurers’ capacity to improve firm value is limited. Such financial institutions are not entrepreneurs or CEOs. For some industrial firms, financial blockholders may do little of value, and the costs to the financial firm of holding big concentrated blocks may induce even legally authorized, large financial institutions to choose their blocks carefully. Yet, with the rise in recent years of blockholding hedge funds, we know that *some* investors will find blocks to be worth acquiring.²¹ The only question is one of extent. Overall the normative idea is that corporate governance value is probably lost if an organizational form is barred. The normative question then is (1) the size of the value

lost and (2) whether better rules could have channeled institutions to the most value-enhancing results and away from value-diminishing channels.

If the corporate governance consequences here had limited impact on firm value, then the normative story becomes less important but the explanatory story more important. If not (p. 64) much operational value separated the various corporate governance choices, then even small political restraints could sharply shift power inside the firm. That is, if concentrated ownership and diffuse ownership are value-neutral choices for all firms, then political choices are easier for the polity to make, because the economic cost of the choice would be low, or zero. The political choices may be serendipitous or depend on ephemeral political alignments. But if little value is lost from a modest political push, then the explanatory power of politics even more strongly explains the shape of authority inside the firm.²²

The bottom line here in terms of the structural outcome, apart from any normative economic story, is that these interest group and popular configurations left the United States with severe limits to national financial operations: The United States long lacked a national banking system, American banks lacked the power to engage in commerce and, generally, to own any stock at all, and insurance companies lacked the authority to own common stock for most of the twentieth century.

Although other nations have had some of these limits on banks and insurers, few have had them all. Banks and insurers in other countries historically played a role in corporate governance that was more vigorous than the role they played in the United States. Britain, for example, has had powerful insurers that owned or controlled significant stock positions, and continues to have such influential institutional stockholders.²³ Germany has had universal banks with substantial stock ownership and even more powerful control of their brokerage customers' votes.²⁴ Japan has had nation-spanning banks with significant stock ownership.²⁵ The latter two channels of universal banks and main banks have narrowed in importance in the past several decades, although they have not disappeared.

(p. 65) 3 The Power of Labor in Postwar Europe

If labor makes powerful claims on large firms' cash flows, such that how the firms handle these pressures deeply affects shareholder value, then that labor power will affect corporate governance players' choices as to structure, ownership, and power allocations. Moreover, if labor is powerful across the polity, then its power can even more directly determine corporate governance. German codetermination, by which labor gets about half of the seats on public firms' boards, is an explicit instance. And more generally, labor power in Germany and elsewhere in social democratic countries affects ownership structure by making diffuse ownership considerably less valuable for stockholders than close ownership. There is good reason to think that in the immediate postwar decades in Western Europe this impact of labor's power was a large determinant of corporate governance.²⁶

Corporate Governance and Its Political Economy

The general principle here is this: if labor makes strong claims on large firms' cash flows, then shareholders have reason to limit those claims. But executives who are not subject to strong shareholder control can readily "defect" from shareholder value, as the executives' preferred agenda for the firm often overlaps with labor's. Thus, labor and management of a diffusely held firm may have similar agendas in polities with strong labor pressures, and that combined agenda may more sharply differ from that of owners in strong labor environments than in weak labor environments. That difference makes the diffusely owned firm costlier for owners in strong labor environments.

For diffuse stock markets to arise and persist, the diffuse capital owners must see their firms as managed well enough for stockholders, as compared to close ownership's value for stockholders. The public firm provides liquidity and diversification for the original investors and brings in professional managers to run the firm. But for the original dominant shareholders to turn their firm's ownership over to liquid stock markets and, hence, to managerial control, they must expect value from turning over control. If the benefits to stockholders of shareholder liquidity and professional management are exceeded by the costs of turnover due to increased managerial disloyalty because the polity will not support the institutions and rules that facilitate managerial loyalty to shareholders, then fewer dominant stockholders will turn their firms over to managers than otherwise.

3.1 Labor Power and Managerial Agency Costs

Consider the range of agency costs that explained widespread hostile takeovers in the United States in the 1980s: a managerial tendency to expand the firm beyond its efficient boundaries, a managerial tendency to spend the firm's free cash flow instead of returning it to shareholders, a managerial preference for low-risk operations that do not threaten the firm and managers' positions, and a managerial tendency to use up capital in place even when the firm no longer was profitable rather than move the capital elsewhere. Michael Jensen's 1986 analytic is the (p. 66) iconic one of the time.²⁷ These managerial agency costs (if one considers the managers to be working primarily for shareholders) map closely onto the goals of powerful labor: to avoid risky operations that threaten jobs and factories, and to avoid closing down factories even if they are no longer profitable. In such a pro-labor environment, shareholders would have a high demand for the tools that would keep managers pro-shareholder. Their demand for such tools presumably would exceed shareholders' demand for such tools in the United States in the 1980s, as the United States lacked such strong labor pressures. That is, even without such labor pressures, managerial agency costs in diffusely owned firms have been sufficiently important that shareholders sought tools to reduce those costs. Labor pressures like those in Germany would have made those costs even higher in the United States.

For shareholders to count on executives being satisfactorily loyal to shareholder goals, shareholders need institutions and norms that reward that loyalty and that give them means to detect and punish disloyalty. But if a polity will not provide those institutions, or if it denigrates such shareholder-value norms, then dominant stockholders can obtain more shareholder value for themselves by keeping control of the firm. Managerial control

will not ordinarily appear in such a political environment and will be unstable if it does. Stock markets will not be strong in such nations, because managerial agency costs will be too high and too hard to lower to levels that stockholders would find acceptable.²⁸

More texture: A polity in which labor was often the decisive political player would not facilitate managerial shareholder-loyalty mechanisms, such as takeovers, incentive compensation, and corporate transparency for shareholders, as these tools would not be in labor's interest. Without shareholders having those tools, the costs to shareholders of labor power could be large. Consider a firm that contemplates a major expansion into a new market or contemplates whether to take advantage of a new technology to re-orient its production. If the expansion fails or the technology backfires in a weak labor environment, the firm contracts and reverses the expansion. The contraction and reversal are costly, but achievable, limiting the losses to shareholders. Such expansions and, if needed, contractions are common in the United States. But if a pro-labor environment makes contraction and reversal even more costly because it would trigger government inquiry and costs, or if contraction is functionally impossible because the polity and its labor rules will not allow layoffs or make them very costly, then the downside costs to shareholders of misdirected expansion rise.²⁹ Yet, a basic agency managerial cost is posited to be that managers seek larger firms for prestige, power, and often compensation. In a pro-labor environment, shareholders would be especially wary of the firm expanding and would therefore want the upside to be particularly strong and the probability of the downside low. Shareholders with weak corporate governance tools could readily find that the best way to prevent unwarranted expansion is for them to keep a close eye on managers. For them to keep a close eye on managers, they would have to keep close ownership of the firm. And that is approximately what we saw in Western Europe in the immediate postwar decades.

(p. 67) 3.2 German Codetermination

German codetermination, as noted above, provides the most direct labor-oriented corporate governance mechanism here, with German law requiring that half of the seats on the supervisory board be reserved for employees. It resulted from political compromises: Codetermination of labor and shareholders arose just after World War II in the coal and steel industry. In one rendition of the postwar explanation, labor's presence in the boardroom would weaken the wartime industrialists' influence and, hence, the victorious Allies would not need to dismantle the steel and coal industry so as to demilitarize Germany.³⁰ Later political events, such as labor unrest, led to settlements to have the rest of German industry codetermined.³¹

Codetermination is best seen as an amalgam of political objectives, like the goal of industrial and political leaders for labor peace, and the realpolitik that labor had considerable voting power in the polity. Either way—whether by compromise or power play—codetermination directly determines core aspects of German corporate governance, namely the composition of the board of directors, and it is a political economy result. The German supervisory board has a major labor presence and, because the supervisory board appoints

the management board (which runs the firm day to day), there is a major difference in power and governance in the German firm as compared to, say, the American firm. German senior managers typically need some level of labor support, or acquiescence.³²

The logic of the incentives that codetermination creates should foster concentrated ownership as well, in the manner suggested above for pro-labor polities. With employees wielding power in the supervisory board, shareholders would typically do better for themselves overall if they maintained strong countervailing power in the boardroom, as well as having the means to monitor managers directly outside of the boardroom. The obvious way to do both would be to maintain concentrated ownership.

3.3 Data on Correlation of Labor Power and Close Ownership: Bidirectional Causation

Figure 3.3 illustrates the relationship between labor power (quantified by union and job security rules³³) and the degree to which large firms had large blockholders in the year 1995. Greater labor power coincides with greater ownership concentration, weaker labor power (p. 68) with more diffuse ownership.³⁴ Wealthy nations with high employment protection and high labor power lack diffuse stock markets; conversely, nations with high stock market diffusion and fewer large controlled firms do not vigorously protect employees with jobs in place. Essen, Oosterhout, and Heugens bring forward evidence that relational blockholders are better than other owner types at handling powerful labor pressures.³⁵

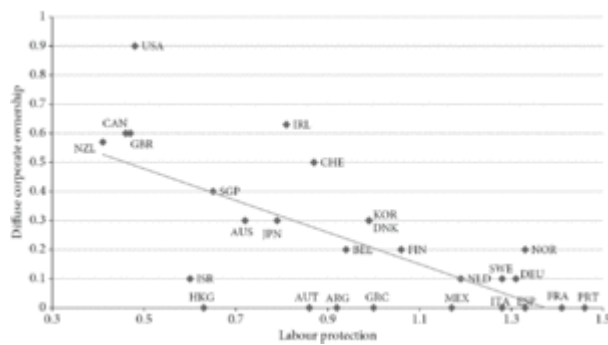

Figure 3.3 Correlation between labor protection and corporate ownership diffusion.

The 27 countries represented are Argentina (ARG), Australia (AUS), Austria (AUT), Belgium (BEL), Canada (CAN), Denmark (DNK), Finland (FIN), France (FRA), Germany (DEU), Greece (GRC), Hong-Kong (HKG), Ireland (IRL), Israel (ISR), Italy (ITA), Japan (JPN), Mexico (MEX), the Netherlands (NLD), New Zealand (NZL), Norway (NOR), Portugal (PRT), South Korea (KOR), Singapore (SGP), Spain (ESP), Sweden (SWE), Switzerland (CHE), the United Kingdom (GBR), and the United States (USA). $y = -0.55x + 0.75$; $R\text{-squared} = 0.47$; $p\text{-value} < .02$; $n = 27$. We include here all nations for which the ownership data is available. One sees that the sample includes a handful of less developed nations, whose inclusion would not change the relationship. Sources and background to the figure can be found in Roe, *Legal Origins*, *supra* note 26, at 497, tbl. 7.

The negative correlation between labor power and shareholder power is striking, making this a good spot to raise the possibility, indeed the likelihood, of bidirectional causation. Thus far, the thesis of this part has been that blockholding persistence is a reaction to labor power. It's of course possible, indeed even likely, that some of labor's power comes from the polity reacting negatively to blockholding.

(p. 69) Concentrated ownership may induce workers to seek employment protection privately via unions and contracting, as well as publicly via employment and anti-layoff rules; that is, ownership concentration may induce employees to call for protection *via* politics:

[E]arly in the twentieth century, the visible power of Germany's large banks, people's envy and resentment of rich industrialists, and the disorientation and anomie induced by Germany's rapid transformation from an agricultural nation into an industrial one helped to call forth codetermination to tame the bankers and industrialists, and to give the workers a voice in the strange new industrial enterprises.³⁶

3.4 Institutional Complementarity

This reverse causation between corporate ownership and labor protection corresponds to the literature on institutional complementarity.³⁷ Briefly, in some economies labor training and skills better complement ownership structures that facilitate labor stability than other ownership systems. Choices in one domain, such as labor protection, act as exogenous parameters in other domains (e.g., the corporate ownership), and vice versa.

Similarly, innovation systems are complementary to ownership systems,³⁸ and determining one economic piece of the corporate governance structure via politics can lock in other elements of the large firm. Corporate governance with large shareholders and highly protected workers supports incremental innovation that requires more cooperation among stakeholders than sharp, radical innovation, as noted above, whereas diffuse ownership and weak employee protection facilitate radical innovation by allowing new production technologies and new products to quickly disrupt labor arrangements.³⁹

Whatever innovation system is in place then interacts with political demands for corporate governance, as noted in section 5. Incremental innovation systems call forth labor (p. 70) protection and, consequently or directly, blockholder ownership. Radical innovation fits best with corporate governance systems with limited commitments to labor and ongoing trading partners.

Overall, as long as institutional complementarities are deep and strong, they can affect, or conceivably determine, the institutional equilibrium, and that system will differ depending on which local complement dominates.

3.5 Coalitions and Rents

Thus far in this section, we have considered the possibility that owners seek to keep managers loyal in high-labor-power environments. This roughly corresponds to the line linking employees and owners in the triangle in Figure 3.2. Next, we consider another such linkage between owners and employees.

Consider first Rajan and Zingales's showing that blockholders will often want to suppress financial market development, particularly if product market competition is weak, because easier access to financing for upstarts would more likely erode blockholders' monopoly rents.⁴⁰ Hence, poor shareholder protection should correlate with trade protectionism.⁴¹

Although this is not *prima facie* a labor-oriented explanation, it could become so. Indeed, since in a functioning democracy the blockholders do not necessarily get their way with the polity if voters do not agree,⁴² labor can play a role in buttressing the incumbent blockholders.⁴³ If labor obtains a portion of the rents that accrue to firms that lacks sharp competition, then this sector of labor also disfavors financial development, which would threaten their rents. They ally with the blockholders, either directly or more likely via coalition voting in parliament to defeat financial liberalization. In this way Rajan and Zingales's blockholder interest explanation can be deepened and extended with labor

Corporate Governance and Its Political Economy

power in the postwar European democracies. In this amendment to the blockholder power theory, labor at established firms allies with incumbent blockholders to influence in the polity to protect their mutual interests.⁴⁴ (p. 71)

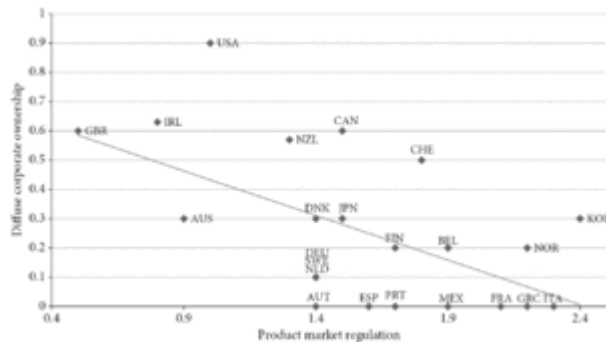

Figure 3.4 Correlation between product market regulation and corporate ownership diffusion.

The 23 countries are Australia (AUS), Austria (AUT), Belgium (BEL), Canada (CAN), Denmark (DNK), Finland (FIN), France (FRA), Germany (DEU), Greece (GRC), Ireland (IRL), Italy (ITA), Japan (JPN), Mexico (MEX), the Netherlands (NLD), New Zealand (NZL), Norway (NOR), Portugal (PRT), South Korea (KOR), Spain (ESP), Sweden (SWE), Switzerland (CHE), the United Kingdom (GBR), and the United States (USA). $y = -0.3047x + 0.7374$; $R\text{-squared} = 0.33$; $p\text{-value} < .02$; $n=23$. Sources: product market regulation comes from Giuseppe Nicoletti, Stefano Scarpetta, & Oliver Boylaud, "Summary Indicators of Product Market Regulation with an Extension to Employment Protection Legislation", OECD Econ. Dep't Working Paper no. 226, at 79, tbl. A3.6 (2000). Nicoletti, Scarpetta and Boylaud measure how deeply product markets are regulated, which presumably causes or is correlated with weaker product market competition. Diffuse ownership is from Rafael La Porta, Florencio Lopez-de-Silanes & Andrei Shleifer, *Corporate Ownership around the World*, 54 J. Fin. 471, 494 tbl. 3 (1999), which tabulates the portion of the 10 firms with a December 1995 stock market capitalization of common equity of just above \$500 million that lack a 20% blockholder.

Blockholders and incumbent workers may ally to create or maintain monopoly rents, which can be split between them; the two can influence the polity to keep trade barriers high and financial competition weak:

[W]ith the monopolies in place in a democracy, the benefited owners have to get other players' political support. Union and employee benefits, instead of being "grabs", could be "pay-offs" from owners, to keep political and internal support strong for hampering competitors. Or, slightly differently, employees and owners can coalesce politically, aiming to weaken competitors, both domestic and foreign, via blocking rules, subsidies, and trade barriers.⁴⁵

Figure 3.4 provides evidence of the negative correlation between product market competition and the diffusion of corporate ownership.

(p. 72)

Weaker product markets and the concomitant monopoly rents can affect corporate governance by loosening constraints on managers and/or by setting up a fertile field where shareholders can cooperatively split rents with incumbent workers.⁴⁶ Large owners and incumbent workers can ally politically in order to frustrate competition policy and its related financial market policy.* * *

Related but differing political economy explanations for corporate governance have emerged, which we discuss further in section 5.

In this section, we have argued that the structure of markets that the large firm faces, the power of labor in the polity overall, and the power of labor vis-à-vis the large firm all deeply affect the large firm. Some ownership structures can do better than others in the face of muscular labor. When labor is powerful, it can determine corporate structures directly, as is the case for German codetermination. The degree of labor power also affects structures pervasively. Managerial agency costs need to be contained, or so shareholder interests demand, and those managerial agency costs in public firms are harder to contain in pro-labor environments. Hence, shareholders have less reason to favor diffuse ownership when labor is powerful. The postwar European evidence suggests that they in fact disfavored diffuse ownership and preferred concentrated ownership.

4 The Continuing Power of the American Corporate Executive

Managers of large diffusely owned firms have reason to disrupt their shareholders' capacity to aggregate their stock ownership in ways that would project more shareholder power into the firm's boardroom. The executives may not own much of the firm's capital themselves, but they control the firm and they seek to maintain their control; powerful stockholders would limit executive autonomy. Managers thus seek laws that impede or bar hostile takeovers and that make large, active shareholder positions costly for shareholders. They oppose voting rules that would make it easier for shareholders to elect directors other than those whom incumbent managers support. Such rules are more likely to arise and persist in countries like the United States, where diffuse ownership prevents blockholders from vetoing managerial influence in lawmaking, because there are fewer blockholders. In countries in which concentrated blockholders tightly control the firm, managers could not readily seek such rules, because the powerful stockholder would be unhappy with such managerial lobbying.

Corporate Governance and Its Political Economy

These managerial efforts to affect the terms of basic corporate and securities law have been significant in the United States historically and continue today. Managers successfully opposed the strongest proposals in this past decade to allow shareholders easy access to the firm's proxy statement, which would allow dissidents to more easily elect directors.⁴⁷ Prior (p. 73) outbreaks of the shareholder voting reform efforts in the United States, starting in the 1940s, also died after managers successfully opposed the proposals. The literature on the spillover of managerial preferences and authority into the political sphere is thinner.⁴⁸

The economic circumstances of the 1980s presented a powerful twin challenge to senior American executives' autonomy. Large manufacturers were challenged by the rise of international competition, mostly from Germany and Japan. Simultaneously, the hostile takeover rose to prominence: a takeover entrepreneur would acquire the funding to buy a target firm's stock and then appeal over the heads of executives and the board to the firm's shareholders. If the shareholders sold their stock to the takeover entrepreneur—often a person, investor group, or another large firm—the takeover entrepreneur would own the company and, often enough, replace the firm's managers.

Managers reacted swiftly and ferociously, building up antitakeover transactional tactics and, when those failed—several were barred by courts in early decisions—the managers sought changes in the law to strengthen their ability to fend off hostile takeovers. The typical antitakeover transactional tool became the poison pill, which would dilute the value of the takeover entrepreneur's stake. The tactic needed validation from courts and legislatures that it was a permitted managerial tool. Eventually, the managers got that authorization and (along with other antitakeover tools) beat back the hostile takeover wave.⁴⁹ As a consequence of the political battles over takeovers, power shifted further to the board of directors in large American firms by the 1990s.⁵⁰

Some of the managers' success in beating back hostile takeovers was due to the strength of their lobbying organizations (such as Chambers of Commerce and the Business Roundtable) in influencing state legislatures to validate antitakeover tools and leave court decisions in place that permitted poison pills. Two political economy aspects ought to be noted. First, the managers' lobbying organizations did well on their own, but acquired even more heft by the fact that employees and voter opinion were mostly on their side in seeking stability and slowing corporate change. This roughly corresponds to an alliance between employees and managers, one side of the Figure 3.2 triangle. Moreover, public opinion was against the hostile takeover, even if it wasn't for the manager.⁵¹

One can see a managerial-labor coalition as decisive in making for some state anti-takeover law.⁵² When a Pennsylvania corporation was targeted for a hostile takeover, it sought strong (p. 74) antitakeover law from the state's legislature. For many Pennsylvania legislators, voting for the legislation was easy, as both the Chamber of Commerce and the AFL-CIO supported the legislation. Consider a contemporary comment: "[The] lobbying effort is the product of teamwork between . . . Pennsylvania labor unions and a coalition

Corporate Governance and Its Political Economy

of over two dozen corporations working for the passage of the bill under the well-organized direction of the Pennsylvania Chamber of Business and Industry.”⁵³

Many states also contemporaneously enacted constituency statutes, which formally authorized boards to weight the impact of hostile takeovers on corporate constituencies, such as employees, when deciding whether to reject or accept an outside bid. In time, boards successfully defeated hostile takeovers when the poison pill was fully validated. When they did, constituency statutes played a limited role thereafter in takeovers.

True, economic circumstances eventually undercut the hostile takeover in that the 1980s hostile takeover was most efficacious for breaking up the conglomerates of the 1960s. Once most were broken up and their separate businesses spun off, there were fewer sweet spots for easy money takeovers. And in time, the takeover machinery monetized incumbent managers’ positional advantage, with hostile takeovers ceasing but “friendly” takeovers proceeding. Nominally, these takeovers were “friendly” and the managers, who often departed, departed very rich.⁵⁴

We can combine this section’s focus on managerial political power with section 2’s focus on the historical weakness of nation-spanning financial institutions in the United States. With managers historically controlling large firms early on in the twentieth century, due to the lack of a strong financial counterweight to managerial authority, they were freer to use political levers to maintain their authority. By weakening proxy fights in the 1950s, by beating back takeovers in the 1980s, and by more generally reducing or reversing reformers’ success in creating rules that would strengthen shareholders and weaken managers, managers maintained their position of authority. If blockholders had been in place, managers could not as readily have lobbied for rules that extend or maintain managerial autonomy and authority.

That is, path dependence affects the corporation and some of that path dependence operates through political channels.⁵⁵ Once there is diffuse ownership and managerial autonomy, for whatever reason, those with power in the firm can project that power into the polity to resist new laws that would reduce their autonomy. That chain of events makes a first- and second-order, path-dependent political economy explanation plausible: autonomy first developed because American politics independently made banks and insurers, the institutional investors of their time, too weak to play a corporate governance role. Diffuse ownership ensued, without controlling institutional shareholders. If there had been controlling shareholders, one assumes they would have looked askance at their CEOs and (p. 75) senior executives seeking to cut back on shareholder power. Managers thus had substantial power to operate in the political arena independently of shareholders, and they used that freedom to act in that political arena (a freedom that came from an absence of controlling shareholders) to bolster their autonomy. As in other path-dependent settings, an early decision and structure affect a later decision, tending to preserve the earlier structure.

Moreover, one can see the ongoing importance of political economy explanations for corporate governance through another political channel. Substantial managerial power may simply originate from the baseline efficiency of separating ownership from control. That separation then gives managers authority in the firm, which they can project into the political sphere, *further enhancing* their authority beyond that which would have prevailed in an efficient, politically neutral setting.

The converse is also true. Once controlling shareholders are dominant across most firms in a given polity, they will tend to use their resulting political power to maintain their controlling positions. For example, in some polities, controlling shareholders can shift value to themselves more easily than in other jurisdictions. Reformers might want to change these rules, lowering the private benefits of control to controllers—by devising rules and processes by which small shareholders can reverse related-party transactions between the firm and the controlling insiders, and restricting the ease with which controlling shareholders can squeeze out minority stockholders at an unfair price. But once a player controls a public firm, it has an interest in maintaining (or expanding) its capacity to shift value to itself.⁵⁶ When many controlling shareholders are in place in an economy, they become influential in the polity. This feature seems to have been important in recent decades in several Western European nations.⁵⁷

5 Further Political Channels

In this section, we examine further interactions between politics and corporate governance in developed countries.

5.1 The Median Voter and the Elites

Politicians seek out the median, pivotal voter, who determines elections in a democracy.⁵⁸ In particular, Perotti and von Thadden show how the preferences of the pivotal voter can depend on the size and form of the returns to human capital relative to the voter's return from financial assets.⁵⁹ If the median voter has substantial financial assets, then she will support financial development and securities markets. But if the median voter has relatively low financial savings and relatively high human capital, then she will prefer low-risk, (p. 76) go-slow economic policies overall and will have little personal interest in supporting securities markets. That preference arises because a financially weakened middle class is largely concerned about the labor income risk associated with freer markets and supports a more corporatist financial system characterized by dominant banks. Banks are dominant because they profit from low-risk loans and their strong presence in corporate governance keeps firms less risky, which is what employees want. In Germany, firms with stronger labor have more bank debt, with the explanation being "that both employees and debt providers have a strong interest in the long-term survival and stability of the firm,"⁶⁰ with other profit-maximizing goals presumably subordinate.

Corporate Governance and Its Political Economy

This median voter thesis relates to the idea that labor, if powerful, prefers block ownership to diffuse ownership.⁶¹ True, workers might well prefer weakened, dispersed shareholders to strong blockholders. Indeed, if the shareholder side becomes weaker, then the corporation is more likely to follow more of labor's preferences. But, workers, particularly if they own only small financial stakes, would prefer risk-reducing banks or large family shareholders to diffused shareholders *if* they believe that the former will typically choose safer, incremental operational strategies. In contrast, a strong equity market would presumably lead to more pro-equity, risky ventures that disrupt workers' lives and jobs. This abstraction largely describes Western Europe in the latter part of the twentieth century.

Culpepper analyses how corporate actors have been able to influence the development of corporate governance law in France, Germany, the Netherlands, and Japan.⁶² When an issue has low political salience to the median voter, then it will likely be decided through "quiet politics," in which corporate actors are preeminent. This is particularly so for those issues that strongly affect corporate actors' interests, such as laws on hostile takeovers. In contrast, where political salience is high, companies are not able to rely on quiet politics, and must instead seek partisan political protection more directly, and try to counter or change public opinion. "Business [elites] frequently lose . . . political battles when the general public pays attention to them [regulatory politics], because when the public pays attention to issues, political parties start paying attention to the opinion of the median voter and stop paying attention to powerful interest groups."⁶³

In this perspective, median voter theory explains the corporate governance outcomes for issues that are salient for the average voter, but fails when the issue is not salient for voters. When it is not salient, the institutions of corporate governance will follow the elite's preferences. Rajan and Zingales argued that controlling shareholders had little reason to (p. 77) support corporate governance reform that would undermine their interests, particularly if the reform would foment better access to funding for upstart competitors of incumbent elites.⁶⁴

5.2 Geopolitics

A related, geopolitical conceptualization may be also in play. The looming presence of the Soviet Union in the second half of the twentieth century was the central geopolitical fact for continental Europe. In the initial postwar elections, the Communist Party did well in France (about 20% of votes from the 1950s to 1970s) and Italy (about 25% of the vote from the 1950s to 1980s), making it important for centrist and conservative parties to co-opt the communist program, which they did. The result was policy that favored incumbent labor and incumbent owners.⁶⁵

5.3 Ideology

We should not ignore the power of ideas and ideologies (or culture in a broad sense). For instance, Aguilera and Jackson report that cross-national differences in managerial behavior depend on differences in managers' world-views, with the differences in world-

Corporate Governance and Its Political Economy

view highly influenced by education. Specifically, managers in the United States are typically well educated in finance and socialized in business schools to have a shareholder-value orientation. In contrast, German managers more typically hold advanced degrees in technical fields such as engineering, and thus tend to adopt a corporatist view of the firm as serving multiple interests and constituents.⁶⁶ Finally, Allen documents that in Japan even junior-high-school textbooks stress that companies should be managed in the interests of all stakeholders.⁶⁷

Ideology can affect corporate governance in ways that go beyond the ideas and training patterns for senior managers, because ideology, whether or not tied tightly to material interests, can affect the organization of finance and the rules that govern the large firm. As we saw above, anti-power populism in the United States favored the fragmentation of the banking system, while in Europe social democratic ideologies⁶⁸ supported empowering employees more and pressured managers to side with employees instead of owners, thereby creating conditions conducive to the concentration of corporate ownership in response.

While ideologies surely often correspond to material interests, we should not discount the possibility that some societies and some polities conceptualize how to handle problems (p. 78) and conflicts and that some of these conceptualizations have a life independent of material interests. For example, the widespread belief in social democracy prevailing in Europe for several decades after World War II was partly due to the shared experience of the world war and the economic devastation it had wrought.⁶⁹

The strength of these European social democratic views has diminished in recent decades. Presumably, underlying interests have changed—basic manufacturing has shifted to a service-oriented economy, reducing the size of the blue-collar vote. Savings have increased, altering the median voter's interests.⁷⁰ Moreover, other influences can affect ideas without necessarily being based only or primarily on narrow self-centered interest. Until the 2008–2009 financial crisis, market-oriented economies performed well; European communism collapsed with the Berlin Wall in 1989, making socialist policies less likely to be seen as successful.

Whatever the underlying explanations, the broad shift in the polity toward a market orientation, at least until the financial crisis, and a weakening of social democratic thinking has been recently measured and documented.⁷¹

That political shift in opinion and interests allows for more complex political configurations in recent years. Left parties that once opposed financial market development came to promote it.⁷² The left of the 1990s did not have the same policy views as the left of the 1960s or 1970s. That shift can be seen in the data of mutating party ideologies⁷³ and can be grasped intuitively by comparing Tony Blair's market-friendly Labour Party to Callaghan's hard-left Labour Party of the 1970s.

Unstated is the possibility that as the economy shifted from basic manufacturing to services, there were simply fewer labor voters for the left parties to appeal to. More generally, when the power of the left subsided, corporate owners and executives could more readily obtain their policy preferences. Culpepper so argues for recent decades.⁷⁴

5.4 The Nature of Political Representation

Pagano and Volpin show that corporate governance regimes may be the result of the political mechanisms of preference aggregation rather than of political preferences.⁷⁵ They suggest (p. 79) that a proportional system predicts weak shareholder protection and strong employment protection, while a majoritarian system predicts the opposite: strong shareholder protection and weak employment protection. The intuition behind these results is that proportional voting pushes political parties to cater more to the preferences of social groups with homogeneous interests such as one party for managers and another for employees, whose party representatives can ally and make deals in the parliament.⁷⁶

Mueller shows further how first-past-the-post electoral systems, such as those in the United States, can affect corporate governance outcomes.⁷⁷ In such political systems, a national interest group, such as labor, needs to persistently recapture a working majority in the legislature, working district by district, legislator by legislator. This process is costly for interest groups. But in a party-list system, the identity of the particular legislator is not vital to the interest group getting that legislator's vote: the legislator follows party discipline, thereby facilitating national deal-making in which national labor institutions can be quite influential. First-past-the-post territorial elections make national coalitions harder to create and maintain. It's thus no accident that Tip O'Neill's famous aphorism—that all politics is local—came from an American national politician, the locally elected leader of the House of Representatives, a legislative body that is a collection of locally elected representatives who make national policy.

Persson and Tabellini have developed an analogous argument.⁷⁸ The state sector will be smaller in majoritarian than in proportional representation systems because competition for votes is in marginal districts rather than nationwide. Politicians accordingly will make smaller commitments in majoritarian systems, because they only need support from voters in the marginal districts. Broader interest groups will therefore get larger support in proportional than majoritarian systems.

5.5 Government Authority

A basic political economy feature is the allocation of authority between the government itself and private sector players who command capital. Government often seeks to obtain for itself capital that it lacks, or seeks to command its use in the private sector, often in ways that favor a dominant governing coalition. In extreme form, a non-democratic, dictatorial government could prefer directly to allocate capital itself, stifling the development of a private sector in general, which might become a counterweight to that dictatorial government, and determining corporate results.

Governmental authority can be a mask for private interests. But we mean something more. Governmental authorities can build, shape, or destroy capital markets and economic institutions for their own reasons and not just as tools of other interests or ideologies. One (p. 80) can recast the concept as a variant of Weingast's dilemma under which a government that is "strong enough to protect property rights . . . is also strong enough to confiscate the wealth of its citizens."⁷⁹ Governmental authorities may denigrate a rival power center.

Moreover, governmental authorities could be susceptible to beliefs that capital markets will not produce social welfare and that government needs to direct and control capital flows to better produce wealth or justice.⁸⁰ In this conceptualization, governmental authorities are themselves an interest, seeking power and enhanced authority.

Finally, governmental authorities may see government action as the vanguard of economic and social development; in pursuing policies to implement their goals, they can crowd out private capital markets and thereby prevent them from developing nicely.⁸¹ As an example, consider the following statement from William O. Douglas, the well-known 1930s chair of the Securities and Exchange Commission (SEC): people who dominate financial markets, he said, have "tremendous power . . . Such [people] become virtual governments in the power at their disposal. [Sometimes it is] the dut[y] of government to police them, at times to break them up."⁸² True, Douglas's view on governmental power may simply reflect that he favored the underlying interests that such a policy would favor. But one should not neglect the possibility that government authorities are themselves an interest group seeking to forward its own interests and ideology, with its own interests distinct from those in the civil, nongovernmental society. Their own direct interests and beliefs can motivate their actions vis-à-vis capital markets. This sub-category may be more vivid in authoritarian nations, but one should not assume its absence in the governments of the rich democracies.

5.6 Cross-Class Coalitions

We have seen conflicts and coalitions among different classes. Here, we describe sectoral and cross-class divisions, which have captured the attention of political scientists who consider corporate and related issues. Hall and Soskice, as well as Iversen and Soskice, emphasize that preferences and interests may follow the production technologies and, hence, can be dissimilar for owners in different sectors and for labor in different sectors.⁸³ Blockholding and employment protection fit well with incremental innovation, they argue, and accordingly owners, managers, and employees in incremental sectors prefer political and corporate institutions that protect employees and facilitate blockholding, each of which supports incremental technical improvement. Owners, workers, and employees are all committed in (p. 81) such sectors to working with specific assets.⁸⁴ The German economy represents an example of this system.

In contrast, corporate governance with dispersed owners and weak employee protection fits well with radical innovation, limited commitments, and flexible assets. Assets are more likely to be general-purpose. The American economy exemplifies this system.

5.7 Democratic versus Aristocratic Roots

Ugo Pagano argues that the diversity of corporate governance systems rests on political conditions existing when “big business” emerged in a country.⁸⁵ If a robust democratic system had already developed when large firms emerged, then democratic politics would likely have challenged the concentration of economic power. With democratic politics limiting the power of large firms and their owners, there was less intensity in the demand from employees for counterbalancing, powerful unions. These democratic roots, hence, supported the public company with diffused corporate ownership, because neither side in the corporate power balance needed to concentrate excessively.

In contrast, if a robust democratic system had not emerged before large firms developed, then social democratic power and unions were more likely to have arisen as a counterbalance to owners’ political and economic power. These non-democratic roots explain a pattern different from the one illustrated for democratic roots.⁸⁶ In this perspective, the United States and Switzerland are two modern economies that had democratic systems at the time of industrialization and, hence, had diffused corporate ownership as a byproduct. Most continental European countries, in contrast, are generally economies that were not democracies when they industrialized and, hence, they did not limit concentrated corporate ownership.

6 The Limits of a Political Analytic

Without a political economy analytic, one can neither fully understand the structure of the modern corporation nor account for international differences. The way capital is organized and how those with authority in the firm project their power into the political sphere to maintain their internal authority are both basic determinants of the modern corporation.

But there are limits to the political economy analytic. First off, while it gives us insight into the broad patterns, it does not give us granularity and precision in understanding (p. 82) specifics. It is not a substitute for the practice of law, for comprehending judicial opinions, and constructing the corporate statutes. It is big picture, not transactional.

Second, even the broad patterns are sometimes applicable only to subsets of nations. The social democratic analytic set forth above broadly explains the situation in the wealthy West in the decades after World War II, but is less good at explaining corporate structures and the (lack of) public markets in less developed and/or more authoritarian polities. But even here, a political economy analytic is needed to fully explain the financial and corporate phenomena. Financial markets and ownership separation cannot and do not develop well in politically unstable environments, with that political instability having

economic inequality as a primary determinant (because the unequal have much to contest). Such politicized explanations have been brought forward and hold promise.⁸⁷

Third, political economy explanations often lack predictability,⁸⁸ because the political process is often dominated by local,⁸⁹ geographic, and historical specifics. Some aspects that seem unpredictable, when properly analyzed, strongly fit with a political theory. For example, some have raised the idea that European social democratic parties, particularly in the 1990s, promoted investor protection, calling this shift a political paradox.⁹⁰ However, the European polity had shifted sharply from the 1950s, moving from polities that were not attuned to markets to polities that grudgingly accepted market-oriented policies. Data is consistent. Again, a comparison illustrates: Tony Blair's Labour Party was much more market-oriented than, say, the 1970s Labour Party of James Callaghan and Harold Wilson. To equate the 1990s Labour Party with that of the 1960s in order to conclude that politics is unpredictable is a comparison that risks conceptual error. Data is broadly consistent: polities moved pro-market as financial markets deepened.⁹¹

Fourth, the political economy analytic lacks strong normative content. It does not tell us what the best corporate policies are, other than perhaps to warn one off policy initiatives that would lack political support.

Lastly, and importantly from an academic perspective, some—perhaps too many—political explanations are susceptible to a narrative but not a test and regression. In (p. 83) econometric terms, political events are often low-frequency occurrences—one nation, one era, one political deal. Some political processes happen once, in one nation, and then become embedded in institutions, politics, and corporations. One cannot readily test how important the one-off decision was and what would have happened if contingent decisions came out differently.

The American history of banking is one such instance. The impact of social democracy on the corporation is more susceptible to testing since multiple nations went through the experience.

7 Conclusion

We have here pushed forward a main thesis with three subsidiary examples. The main thesis is that the shape of the public corporation will attract political attention in wealthy democracies, and democratic politics will accordingly affect the allocation of authority in the large public corporation in a major way. First, politics can determine and indeed has determined the ways in which capital flows into the large firm, shattering financial channels into weak tributaries in the United States for the nineteenth and much of the twentieth century. The consequence of shattered financial channels is that the large public firm could not readily have major and powerful shareholders. Boards and executives had more autonomy than they otherwise would have had. The Berle-Means corporation with diffuse

Corporate Governance and Its Political Economy

ownership and powerful managers was a political construct as much as it was an economic one.

Second, when labor makes powerful claims on a large firm's cash flow, shareholders have reason to keep large offsetting blocks to reduce the strength of those claims. Postwar European polities had such a setting, and one major reason that blockholding by financial institutions like banks and insurers and by stockholding families persisted in the postwar decades seems to have been because they offset labor's claims.

And third, once a corporate governance system is in place, corporate players can project power into the polity and can use that political power to maintain their corporate authority. Managers in the United States fit that example, as they have repeatedly blocked transactions and legal changes that would confine their authority and shift power from themselves to others, typically shareholders, in the large public firm.

A particularly important set of these banking regulations prevented the formation of widespread branching networks. Banking laws prohibited nationally chartered banks from opening branches, and most state-chartered banks faced similar limitations. The result of these restrictions was a nationwide banking system composed mostly of individual unit banks”).

(²²) Bradford J. DeLong, *Did J.P. Morgan’s Men Add Value?*, in *Inside the Business Enterprise* (Peter Temin ed., 1991) provides some of the better-known evidence that the costs of barring financial institutions from substantial governance roles were not small: In end-of-nineteenth-century America, the Morgan firm put its partners on firms’ boards, thereby offering the firm’s own reputation to protect shareholders from scurrilous or incompetent management. Pernicious insider dealings, or undiscovered managerial incompetence, would cost the Morgan firm dearly, so it warranted (albeit weakly) that such nefarious or incompetent results would be unlikely to occur in the firms on whose boards its partners sat. Outside investors might mistrust the firm and its inside managers, but they had more reason to trust the Morgan directors.

(²⁴) A universal bank not only takes demand deposits and makes loans, but can also underwrite, hold, and trade all other securities. Abstract and Keywords

This chapter examines the theoretical and empirical validity of the “contractarian” theory of corporate governance. Beginning with an overview of the contractarian theory and its conceptualization of the relationship between managers and shareholders of a public company, it explains how the theoretical assumptions of the contractarian theory have turned out to be invalid and how the empirical predictions of the theory have not been borne out. The process by which “corporate contracts” develop do not fit the neoclassical model of atomistic competition. As a result, the customization and innovation that the contractarian theory predicts do not occur—either at the IPO stage or at the “midstream” stage when companies are publicly traded.

Keywords: corporate governance, contractarian theory, IPO stage, midstream stage, managers, shareholders, public company, corporate law, corporate charters, corporate contract

1 Introduction

¹LED largely by the work of Frank Easterbrook and Daniel Fischel in the 1980s, a “contractarian” theory of corporate governance and corporate law dominated thinking among US corporate law scholars for many years.² The notion was that a public company’s shareholders and managers enter into a relationship with one another voluntarily on terms that are reflected in the company’s share price, and that managers, as agents in the relationship, have incentives to adopt governance arrangements that minimize agency costs and maximize firm value. The contractarian theory was a positive theory, positing that market forces would lead to optimal governance arrangements in firms. It also had a clear (p. 85) normative implication, which was that there is little, if any, need for law to impose rules on the manager-shareholder relationship.³

Today, the status of the contractarian theory is unclear. Few would deny that when investors buy shares in a public company, they enter into a relationship with management that can reasonably be conceptualized as “contractual.” The key question, however, is whether the “corporate contract” is socially optimal, as the contractarian theory holds?⁴

The “Corporate Contract” Today

Theoretical and empirical doubts have been raised over the years regarding the theory’s validity. We no longer hear the contractarian refrain in opposition to any and all corporate law reform proposals—that any particular proposal cannot possibly be value enhancing, because if it were, firms would have already adopted it in their charters, at least at the IPO stage. We do, however, hear a weaker variant of the contractarian claim, largely from advocates for management opposing legal rules that would shift power to shareholders. This modern-day variant of the contractarian theory is more of a slogan than a theory—that “one size does not fit all.”⁵

This chapter will evaluate the substantive validity of the contractarian theory in light of theoretical and empirical developments since the 1980s. As I explain in the remainder of this chapter, the contractarian theory was really two theories: one of the IPO stage and one of the “mid-stream” stage, when a company is publicly held.

The theory of the IPO stage suffered from a few theoretical flaws, but most fundamentally it assumed that the relationship between shareholders and managers was captured by the neoclassical model of atomistic contracting, with no interdependencies across firms in the terms adopted. This was the basis of the theory that market equilibria must be socially optimal—and therefore the basis of the theory’s non-intervention prescription.⁶ The IPO theory also depended on the validity of the mid-stream theory, since any arrangement put in place at the IPO stage could be undone at the mid-stream stage. With respect to empirical (p. 86) validity, contractarian theorists never attempted to investigate their claims empirically, and when some of us did later on, we discovered that the facts did not fit.⁷

The contractarian theory of the mid-stream stage was recognized from the start as weak. It relied on the existence of market forces to drive managers to adopt and maintain governance arrangements that promote shareholder interests. No proponent of the theory, however, convincingly explained how this would occur, and experience with management resistance of shareholder demands casts serious doubt on the theory as an empirical matter.

Beginning roughly in the mid-2000s, however, legal and nonlegal institutional changes have occurred in the US that one could characterize as a new contract between shareholders and managers. Today’s contract is not an explicit contract written into a corporate charter, as the contractarian theory envisioned. It is instead an implicit contract in the sense that economists use that term—a contract that is not legally enforceable, but that is self-enforcing as a result of carrots and sticks that the parties hold. This new implicit contract reflects a shift in power from managers to shareholders compared to earlier decades. While one can make judgments regarding whether the current balance of power is better or worse than alternatives, there is no analytic basis on which to claim that the current equilibrium is either optimal or suboptimal.

2 The Contractarian Theory

Built on the work of Jensen and Meckling and ultimately that of Ronald Coase, the original contractarian theory of the corporation characterized the relationship between managers and shareholders of a public company as one of contract mediated through the securities market. The implication of conceptualizing the shareholder-manager relationship as contractual was that, in the absence of transaction costs, externalities, or other market imperfections, market forces could be relied upon to create governance arrangements that minimize agency costs and thereby maximize firm value.

The theory was clearest and most promising at the point a company goes public. When a company goes public, its charter is in effect a contract between its management and its public shareholders. The charter confers legally binding rights on shareholders and obligations on managers. It can commit the company to separate the positions of CEO and board chair, to forgo a poison pill, to have a staggered board, to limit directors’ exposure to liability risk, to require managers to hold a certain amount of stock, to compensate management in a certain way, and so on. There are few, if any, legal limits to this freedom.⁸ Pre-IPO managers (p. 87) and shareholders write the firm’s post-IPO charter and sell shares to the public. As public investors purchase those shares, the market sets their price, and that price is expected to reflect the effectiveness of the firm’s governance structure in reducing agency costs. Pre-IPO shareholders—venture capitalists, angel investors, managers, employees, and others—reap the benefit of a high share price and the detriment of a low share price. Hence, the contractarian theory posits, pre-IPO shareholders reap the benefit and detriment of good or bad governance structures. Consequently, the contractarian theory posited that pre-IPO shareholders would design governance mechanisms that maximize the value of their firm, given the particular circumstances of each firm, and that pre-IPO shareholders would make legally enforceable commitments to those mechanisms by drafting them into their charters—the document that reflects the “corporate contract.”⁹ This is the simple, yet compelling, contractarian logic of how governance arrangements formed at the IPO stage.

Once shares of a company are dispersed among public shareholders, the concern became whether management could take advantage of its control to loosen the constraints adopted at the IPO stage or to decline to adopt new contractual constraints in response to agency cost-increasing changes in the business environment.¹⁰ Here, the contractarian theory held that market forces would induce management to maintain and update optimal governance arrangements, proposing charter amendments to shareholders where appropriate.¹¹ The claim was that managers would ultimately reap rewards—through higher compensation or longer-term career success—for increasing firm value by adopting good governance arrangements. This post-IPO or “mid-stream” element of the contractarian theory was viewed as its weakest, even by advocates of the theory.¹²

The contractarian theory’s normative claim followed from its positive claim that market forces would drive firms to adopt optimal, legally enforceable governance arrangements. If this were true, and there were no costs externalized on parties other than a firm’s man-

The “Corporate Contract” Today

agers and shareholders, then it would follow that corporate law should stay out of the way and impose no mandatory legal rules on the shareholder-manager relationship. Advocates of the theory viewed contractual governance as superior to legally imposed governance because firms vary along numerous dimensions, and market forces were expected to induce firms to customize their own governance arrangements in ways that suited their particular circumstances. In addition, market pressure was expected to spur innovation in governance mechanisms over time. In the contractarian view, mandatory legal intervention would prevent customization, and state legislatures (let alone Congress) would be a weak source of innovation compared to the governance ingenuity present in individual firms.¹³

The proper role of corporate law in the original contractarian view was fairly minor. It was to provide default rules that firms could take “off the rack” and incorporate into their (p. 88) governance arrangements, and to enforce whatever terms firms adopted.¹⁴

Furthermore, in the United States, choice of corporate law is itself a matter of contract. When a firm goes public, its pre-IPO managers and shareholders select the state in which to incorporate, and in so doing, opt into that state’s body of corporate law. Once public, the firm can reincorporate with the approval of the firm’s board and its shareholders. Consequently, the contractarian expectation was that firms would initially incorporate, and later re-incorporate, in states whose corporate law best reduce agency costs in each particular firm.¹⁵

The conceptualization of the shareholder-manager relationship as “contractual” is relatively uncontroversial. Shareholders voluntarily enter into the relationship and in doing so they accept the terms of the deal. The securities markets price securities, so it is reasonable to expect that governance terms will be priced—though whether they are or not is an empirical question. But the fact that shareholders and managers come together voluntarily—even if we call the relationship “contractual”—does not mean that the terms of the contract will be socially optimal, as the contractarian theory maintains. There could be a market imperfection that breaks the neoclassical connection between market equilibrium and social optimality.

If the original contractarian theory had been valid, we would expect to see the following:

- firms, at least at the IPO stage, adopting diverse and innovative governance arrangements in their charters;
- governance arrangements tending to maximize firm value; and
- once firms are publicly held, managers proposing value-increasing charter amendments for shareholder approval.

As discussed in the remainder of this chapter, we observe none of the above. In section 3, I explain how the contractarian theory’s claim about the IPO stage are invalid, and in section 4, I address its invalidity with respect to the mid-stream stage—once companies are

publicly held. Finally, in section 5, I discuss what appears to be a newly emergent unwritten implicit contract that reflects a shift in power from managers to shareholders.

3 The Contractarian Theory of the IPO Stage Does Not Hold Up to the Facts

In the discussion below, I first report the results of empirical studies of two questions. First, do firms customize and innovate governance-related charter terms when they go public? Second, do IPO charters appear to maximize firm value? The contractarian theory of the IPO implies a positive answer to both questions. The data, however, answer the questions primarily in the negative. After discussing these empirical findings, I explain how the contractarians went wrong as a theoretical matter.

(p. 89) 3.1 Customization and Innovation, or Plain Vanilla IPO Charters?

The contractarian theory implied that firms would customize and innovate governance arrangements that minimize agency costs to suit their particular business environments, and that firms would make legally binding commitments to those arrangements in their charters. Describing the “corporate contract,” a term they coined, Easterbrook and Fischel stated: “Agreements that have arisen are wonderfully diverse, matching the diversity of economic activity carried on within corporations.”¹⁶ But is this true? Do corporate charters contain customized and innovative governance terms?

In a study published in 2013, I investigated this question by collecting data from a random sample of 373 companies that went public during the period from 2000 through 2012.¹⁷ I searched their charters (and bylaws) for examples of governance customization and innovation.¹⁸ I searched for any nonstandard governance mechanism. In order to structure the search, however, I specifically looked for arrangements that have been the focus of corporate governance debates since the 1980s. Some of these governance arrangements became mandatory under the Sarbanes-Oxley Act or the Dodd-Frank Act: majority independent board, independent board committees, and say on pay. One mechanism, proxy access, was briefly mandated by the SEC and is now explicitly permitted but not mandated. A fifth innovation, majority voting in shareholder elections of directors, has been widely adopted by publicly held firms, and has been shown in some studies to be value enhancing. For each governance innovation that ultimately became legally required, I investigated whether the innovation had previously appeared in IPO charters (or bylaws).¹⁹ For purposes of this chapter, I supplemented these data on these governance innovations with data on a sixth innovation—exclusive forum provisions for shareholder litigation. I obtained these data from Roberta Romano and Sarath Sanga, who have studied the diffusion of these provisions in IPO charters. Exclusive forum provisions require that all corporate-law-related disputes be brought in a single forum—typically the forum of the state in which the company is incorporated, which for companies adopting these provisions is nearly always Delaware. Romano and Sanga found that these **(p. 90) provi-**

The “Corporate Contract” Today

sions appear in IPO charters beginning in 2010, when they were endorsed in an opinion of the Delaware Chancery court.²⁰

A finding that these six innovations commonly appear in IPO charters would support the contractarian theory that the economics of the IPO stage promotes governance innovation and customization. Conversely, a finding that they never or rarely appear in IPO charters would cast substantial doubt on the theory. Although it is possible that the particular innovations for which I searched are not value enhancing for *any* firm, this would be a far-fetched interpretation.²¹

Table 4.1 presents my findings. Of the innovations described above, only exclusive forum provisions were adopted to any significant extent. Of 373 firms sampled, no firm had any of the five other provisions in their charters, and only nine firms had bylaws containing one or more of the five arrangements. Because management could amend these bylaws unilaterally, this handful of provisions are not contractual in the contractarians’ sense of the term.²²

Where do these data leave us regarding the contractarian claim that IPO charters are a locus of innovation and customization in corporate governance? The claim is largely inconsistent with the data. The experience with exclusive forum provisions is unique and, at best, can be generalized only to charter terms that are directly beneficial to management—presumably along with shareholders. Unlike the other provisions that potentially enhance firm value by enhancing shareholder rights, exclusive forum provisions potentially do so by protecting directors and officers from burdensome litigation in multiple jurisdictions. Whether or not they enhance share value, they are attractive to management and could well be adopted for that reason alone. Protecting directors and officers from litigation risk is in the wheelhouse of the lawyers advising management of firms going public. A lawyer (p. 91) would readily understand the provision and how it could benefit management and perhaps increase firm value. This is not necessarily true of innovations that increase firm value by enhancing shareholder rights.

The “Corporate Contract” Today

The lack of governance diversity evident in charters is also evident in firms’ incorporation choices. A large and increasing majority of firms incorporate in Delaware, and nearly all others incorporate in their home states for reasons apparently unrelated to value-maximizing choices of corporate.²³

The most plausible explanation for these findings is that the contractarian claims about the IPO stage are incorrect or at least drastically overstated. But how could the theory be incorrect when it is undeniable that shareholders enter into a relationship with managers voluntarily, and that they do so in a setting that can be reasonably described as contractual? I address that question in section 3.3.

3.2 Are IPO Charters Suboptimal?

The near absence of customization and innovation in IPO charters poses a serious challenge to the contractarian claim that the economics of the IPO stage promotes value-maximizing (p. 92) contracting. Additional evidence weighing against this claim is the presence of staggered boards in the charters of many firms going public. Although some recent studies have found that staggered boards are associated with higher firm value in certain situations,²⁴ the bulk of the research finds that staggered boards are value-reducing mechanisms that management uses to protect itself from the market for corporate control.²⁵ This was certainly the prevailing view when the contractarian theory was developed. The contractarian theory, therefore, implied that staggered boards would not appear in IPO charters. Easterbrook and Fischel expressed this expectation as a statement of fact: “[Takeover defenses] are not included [in IPO charters]. Instead firms go public in easy-to-acquire form: no poison pill securities, no supermajority rules or staggered boards. Defensive measures are added later, a sequence that reveals much.”²⁶

Whether IPO charters contain takeover defenses was an empirical question that was not investigated for another decade. Easterbrook and Fischel apparently made the factual statement above based on theory alone, and for the next decade, no one thought it was worth reading actual charters to validate the theory empirically or even anecdotally.

Three articles published in 2001 and 2002 presented data on the charters of firms going public. Each found that IPO charters commonly contain takeover defenses, including staggered boards.²⁷ The studies covered different sample periods between 1988 and 1999 and found that between 34% and 82% of sample firms had staggered boards, with higher frequencies in later years.

Two of these articles analyzed whether there were efficiency explanations for the presence of staggered boards in IPO charters. Both Laura Field and Jonathan Karpoff and Robert Daines and I analyzed whether the adoption of staggered boards was explained by the need for extra bargaining power in the event of a hostile bid.²⁸ Neither study found support for this explanation. Daines and I also tested whether staggered boards were explained by asymmetric information regarding firm value, which would create the possibility of undervaluation by the market and hence a vulnerability to bids lower than true value. We found no support for this explanation either. In fact, Daines and I found that stag-

The “Corporate Contract” Today

gered boards tended to be present when both these efficiency theories suggested that they would be *least* needed. We concluded that, contrary to the contractarian theory, management entrenchment was the best explanation for staggered boards in IPOs.²⁹

(p. 93) John Coates investigated the influence of lawyers in the adoption of staggered boards. He found that firms that were advised in their IPOs by law firms with extensive M&A transactional or litigation work tended to adopt staggered boards more frequently than did other firms. He inferred that those law firms instill in their lawyers, or in the form charters that their lawyers use, a preference for takeover defenses. As Coates explains, this is hardly evidence of value maximization at work.

There is, however, some recent research supporting the proposition that staggered boards can enhance firm value for a subset of firms under limited circumstances.³⁰ I therefore cannot rule out the possibility that some day we will have a satisfactory efficiency-based explanation for staggered boards in IPO charters. At this point, however, their presence certainly appears to further undermine the contractarian theory of the IPO stage.

3.3 Where Did the Contractarian Theory Go Wrong Regarding the IPO Stage?

The contractarian theory’s application to the IPO stage was its most convincing. Neoclassical theory, coupled with the undeniable fact that shareholders and managers enter into their relationship voluntarily, seemed unequivocally to imply that market forces would produce socially optimal governance arrangements. Yet the facts do not fit the theory. With the exception of exclusive forum provisions, there has been no governance innovation or customization at the IPO stage, and the common use of staggered boards raises serious doubts about the theory’s optimality claims, independent of the lack of customization or innovation. What was the flaw in the logic? Theoretical developments and some further thought have yielded at least two theoretical explanations for the failure of the IPO stage to conform to contractarian expectations. This section provides those explanations.

3.3.1 Customization and Innovation

Two explanations have emerged to explain why the IPO stage does not generate customized or innovative governance arrangements. The first explanation is well grounded in economic theory, but not the neoclassical model on which the contractarian theory was based. Consistent with neoclassical economics, the contractarian theory assumed that each firm’s decision to adopt a particular governance arrangement is independent of other firms’ decisions—that firms were atomistic actors in that one firm’s choice of a governance structure has no effect on another firm’s choice. For at least some corporate governance arrangements, however, this assumption is not valid. There are interdependencies among firms’ choices of governance arrangements. The value of a governance mechanism can be dependent on the number of firms that use the mechanism. If few firms use a governance mechanism, the mechanism will not be as valuable as if many firms use it. The

The “Corporate Contract” Today

underlying dynamic is the same dynamic that is present in product markets with network externalities, such as the market for computer operating systems, word processing and spreadsheet applications, and social network platforms such as Facebook. In each of these markets, the (p. 94) value of a product increases with the volume of use. (Imagine Facebook with one user or even 1,000.)

When network benefits are present, market forces will not necessarily yield socially optimal equilibria. In this type of market, theory shows that there are multiple, socially suboptimal equilibria. In one suboptimal equilibrium, excess uniformity emerges in the products produced. Note that there are very few computer operating systems, word processing and spreadsheet applications, and social network platforms and that each has a large number of users—in contrast, say, to the markets for office supplies, skis, and restaurants. This appears to be the case with respect to corporate governance—there is little variety in the corporate governance arrangements; firms’ governance arrangements are fairly uniform.³¹

Corporate governance arrangements have some of the same qualities as network products. The more firms there are that use a governance mechanism or that operate under the same legal or contractual rule, the more valuable the arrangement becomes. One source of these network benefits stems from judicial precedents that interpret the arrangement in varied settings, thereby reducing legal uncertainty. One can think of each new judicial opinion in a new setting as analogous to a software update for Windows or Word. The more firms there are that operate under, say, a particular state’s fiduciary duty standard, the more precedents there will be—today and into the future. Firms will therefore be attracted to incorporate in that state, and to adopt its default fiduciary duty rule.

Judicial precedents are especially valuable when a governance arrangement entails a legal or contractual rule that is framed as an open-ended legal standard, as opposed to a detailed, specific rule. Open-ended standards are pervasive in corporate law and governance. Fiduciary duties are classic, open-ended legal standards, as are concepts of director disinterestedness and materiality in the disclosure context. They are given content as courts interpret them in a variety of contexts. A firm that adopts, for example, its own unique fiduciary duty, definition of director disinterestedness, or disclosure rule would not have the benefit of ongoing judicial interpretations. The customized arrangement would remain static, unless it is amended (which entails a separate set of problems discussed below). In contrast, a commonly used arrangement will evolve with judicial interpretations. As a result, a firm with a customized arrangement will face greater uncertainty regarding how its own arrangement will apply in unanticipated settings.

Other network benefits associated with corporate governance arrangements are familiarity among lawyers advising firms and familiarity among investors. A lawyer who is familiar with a legal rule can provide advice based on his or her experience, independently of legal precedents. That advice will be more valuable in reducing legal uncertainty than advice regarding a governance arrangement the lawyer has never seen before. Similarly, all other factors being equal, familiarity among investors will be a benefit for a firm. In-

The “Corporate Contract” Today

vestors considering the securities of a firm with a unique governance arrangement will have to figure out what the arrangement means in terms of value to the investor. All other factors being (p. 95) equal, this will deter investment and could drive down the liquidity and value of a company’s securities.

Network benefits associated with corporate governance arrangements tend to make default rules attractive. It is not that default rules are inherently more attractive from the start than alternatives, but rather that they typically are expected to be widely adopted in the future. This may be due to a focal quality that default rules have or to the state legislature’s endorsement. Governance rules and structures provided by statute as menu options—such as staggered boards, voting by written consent, shareholders calling a special meeting, exculpatory charter provisions, and more—have a similar quality. Once statutory terms, whether default or menu, have been used and litigated, their attraction to new firms is even greater.

Delaware corporate law, specifically its default rules and statutory menu options, has benefited from network effects. The large installed base of firms incorporated in Delaware ensures a constant supply of judicial decisions applying Delaware law to many situations. There also is a large supply of lawyers with expertise in Delaware law and an investment community familiar with the workings of key governance arrangements.³² The expertise of Delaware judges is certainly a major attraction as well, but that too is a result of the large number of firms incorporated in Delaware, which produce a large volume of corporate litigation. This volume of litigation has both made the job of the Delaware judge attractive to talented Delaware corporate lawyers and enhanced their expertise while in the job.

Network benefits do not necessarily preclude customization, innovation, or incorporation in a state other than Delaware. If the inherent value of an innovative or customized governance arrangement outweighs the network benefit of a widely used arrangement, a firm could well adopt the former. This would tend to occur with respect to governance arrangements that do not entail open-ended standards, like Delaware fiduciary duties, or a high degree of complexity, like that of disclosure rules under the securities laws. An example of a governance term the attraction of which is not significantly affected by network benefits might be a charter provision that separates the CEO and board chair. This is clear and simple, with no great need for interpretation by courts or expertise in application by lawyers. The network quality of many corporate governance arrangements, however, creates a bias—and apparently a very large bias—in favor of conformity along many dimensions of corporate governance.³³

Accordingly, the theory of network externalities tells us that while a firm going public may maximize its own value by adopting Delaware default rules, all other factors being equal, this does not mean that it is socially optimal for large numbers of firms to adopt Delaware default rules. Accordingly, from a societal point of view, there could well be a suboptimal level of innovation and customization. Moreover, any given default rule may be inherently (p. 96) suboptimal in the sense that an alternative rule might increase ag-

The “Corporate Contract” Today

gregate firm value across all firms *if* it were widely adopted. Similarly, greater heterogeneity in incorporation choices could be socially beneficial. Thus, network externalities inherent in corporate governance arrangements may explain why there is so much uniformity in corporate governance and further explain that, contrary to the contractarian theory, there is no reason to believe this market outcome is socially optimal.

A second explanation for the lack of governance customization or innovation at the IPO stage lies in the acknowledged weakness of the contractarian theory of the mid-stream stage. The dependence of the IPO leg of the theory on the weaker “mid-stream” leg was overlooked by the original contractarians, but there is an important link. Optimal governance arrangements for a firm can change over time. Moreover, as a firm lives with a particular governance arrangement for a period of time, problems may become apparent. If the pre-IPO shareholders and investors can be sure that a suboptimal arrangement will be modified later on, perhaps they would be more inventive at the IPO stage. But if such a change would impair management’s discretion or reduce its perks, there can be no assurance that management will agree to modify the arrangement when it becomes optimal to do so. That is, shareholders cannot count on a midcourse correction. Consequently, an innovative or customized arrangement adopted at the IPO stage could last as long as the firm exists, which could well make it inherently unattractive at the IPO stage.

3.3.2 Staggered Boards at the IPO Stage

Network benefits do not explain why firms adopt staggered boards at the time they go public. Both annually elected and staggered boards are well defined by statute, commonly used, and addressed by a large body of case law ruling on board conduct with each type of board. No-one has come up with a satisfying explanation for the widespread, but not universal, adoption of staggered boards among companies going public, but there are a few candidates.

First, while the bulk of the research suggests that staggered boards tend to reduce firm value, it may be that staggered boards increase shareholder value for some firms. Second, while staggered boards may reduce share value, they could provide more than offsetting private benefits to managers, in which case they could increase the total value of a firm. Perhaps the managers of firms that go public with staggered boards enjoy especially high private benefits and perhaps the cost to shareholders is low.³⁴ Daines and I tested this hypothesis and found no support, but private benefits are not directly observable and proxies for their presence are imperfect. Therefore, we could not exclude this explanation of the data. Either of these explanations, if borne out, would eliminate the inconsistency between the contractarian theory and the common use of staggered boards.

A third potential explanation that would pose a moderate threat to the contractarian theory is that, even if pre-IPO managers and shareholders incur costs by having their firms go public with staggered boards, they can recoup those costs later by having their boards de-stagger before they selling their shares. So long as pre-IPO shareholders can coordinate with (p. 97) one another and control the firm’s board before any wants to sell, a staggered board provides an implicit option on an annually elected board in the future. Public

shareholders will gladly vote to de-stagger a board if the incumbent board gives them the opportunity. On the other hand, an annually elected board is permanent. Public shareholders cannot be expected to adopt a staggered board later on. Thus while this interpretation of staggered boards at the IPO stage is plausible in the abstract, it has no empirical support. Until recent years, firms did not de-stagger their boards after going public, and many firms’ pre-IPO shareholders sold shares not long after their IPO. Moreover, even in recent years, the de-staggering that has occurred has been in response to public shareholder demands, not the interest of insiders who want to sell their shares.

A fourth explanation that does call into question the contractarian theory—indeed one that amounts to heresy among economics-oriented scholars—is that governance arrangements adopted at the IPO stage may not be priced. John Coates raised this possibility in his study of staggered boards at the IPO stage, stating: “A lack of pricing penalty is also consistent with anecdotal reports from IPO participants, including investment bankers, venture capitalists, and lawyers from Wilson Sonsini (among other lawyers), who all uniformly report in conversations that conventional defenses do not affect IPO pricing.”³⁵ A difficulty with this explanation is that since most pre-IPO shareholders, including venture capitalists, continue to own shares after the IPO, the pricing explanation for the presence of takeover defenses would have to extend to pricing in secondary market trading after the IPO as well. This is more difficult to believe, especially in light of studies showing that staggered boards have an impact on price.³⁶

In sum, the weight of the evidence suggests that the widespread adoption of staggered boards at the IPO stage is inconsistent with the contractarian theory. But we still lack a satisfying explanation for why a large number of firms would adopt an apparently suboptimal governance arrangement when they go public.

4 The Contractarian Theory of the Mid-stream Stage also Misses the Mark

In the foreword to a widely read issue of the *Columbia Law Review* in 1989, Lucian Bebchuk stated: “The debate on contractual freedom in corporate law should be viewed as two debates, not one. The questions of contractual freedom in the initial charter and in mid-stream (that is, after the corporation is publicly held) are different and require separate examination.”³⁷ In (p. 98) the same issue, Easterbrook and Fischel acknowledged that “[t]he difference between governance provisions established at the beginning and provisions added later suggests some caution in treating the two categories alike.”³⁸

Once a company goes public, the conceptualization of the manager-shareholder relationship as “contractual” is less accurate than at the IPO stage. The board can make substantial changes to a company’s governance structure unilaterally—for example, it can adopt a poison pill or change executive compensation. It can also decline to accede to a value-enhancing charter amendment that disfavors management.

The “Corporate Contract” Today

Contractarians nonetheless had faith that market forces would yield optimal governance arrangements once a company is publicly held. They supported their position in two ways. First, they expected that IPO charters would contain provisions that constrain management from changing corporate governance arrangements to the disadvantage of shareholders—limits on management’s freedom to adopt a poison pill, for example.³⁹ Second, they believed that market forces would pressure boards to initiate value-increasing governance arrangements. Their logic was that poor governance structures would lead to high costs of capital, which in turn would lead to a lack of competitiveness in the product market, which ultimately would lead to a takeover or bankruptcy and the loss of managers’ jobs.⁴⁰ There was a division in the ranks of the contractarians with respect to mid-stream adoption of governance arrangements related to takeover defenses—for example, a charter provision that disallowed the adoption of poison pills. Easterbrook and Fischel believed that boards should pre-commit to remain passive in response to a takeover bid and allow shareholders to tender their shares. They were doubtful, however, that boards would actually initiate charter amendments imposing such a restriction on themselves, and were thus inclined toward a mandatory legal rule requiring passivity.⁴¹ This sole instance of a lack of faith in their own contractarian logic in such an important area of corporate governance was surprising. David Haddock, Jonathan Macey, and Fred McChesney cried foul. Market forces, they believed, would indeed induce management to adopt value-maximizing charter amendments, including arrangements that limited management’s defense against hostile bids. Although Haddock et al. did not explain what market mechanisms would provide such (p. 99) discipline, and they did not provide any examples of managers whom the market punished for failing to promote shareholder interests in this way, they nonetheless expressed this faith based on “overwhelming [though uncited] empirical evidence from various aspects of corporate governance suggest[ing] that faithful managers are rewarded while the faithless are punished.”⁴²

The contractarian claims for the mid-stream stage raise two empirical questions: First, do IPO charters constrain management-initiated mid-stream governance changes, as the contractarians expected? Second, after a company goes public, do managers tend to initiate value-enhancing charter amendments to improve governance—regarding takeover defenses or otherwise?

Empirical studies of IPO charters address the first question unequivocally: IPO charters do not constrain management’s initiation of mid-stream governance changes.⁴³ Indeed, in contrast to the contractarian expectation, IPO charters commonly restrict *shareholders* from initiating governance changes by requiring supermajority shareholder votes to amend bylaws—particularly bylaw provisions that protect management.⁴⁴

Regarding the second question—whether management initiates value-enhancing charter amendments—there is no evidence of such a contractarian invisible hand driving management to initiate such charter amendments. On the contrary, until recent years, when shareholders have exerted pressure on management to improve governance, management resisted. From the late 1980s to the mid-2000s, shareholders and managers battled over takeover defenses.⁴⁵ Shareholder proposals to redeem poison pills or to subject

them to shareholder approval received substantial and increasing support throughout this period, as did shareholder proposals to destagger boards.⁴⁶ Nonetheless, management declined to accede to either demand.⁴⁷

In sum, the experience of the period from the mid-1980s to the mid-2000s does not support the contractarian expectation that management would initiate agency cost-reducing charter amendments.

(p. 100) 5 Corporate Governance since the Mid-2000s: A New (Implicit) Corporate Contract?

In the wake of the Enron and WorldCom scandals of the early 2000s and the passage of the Sarbanes-Oxley Act in 2002,⁴⁸ dramatic changes occurred in the US that shifted power from management to shareholders. Some of these were changes in the law. Others were nonlegal institutional changes. Still others were norms that directors appear to have adopted.

These changes have created a new *implicit* contract in the economists’ sense of that term—a self-enforcing arrangement in which parties have carrots and sticks that keep their interests aligned. The central weakness of the contractarian theory of the mid-stream stage was that the market mechanisms envisioned as aligning shareholder and management interests were largely just that—envisioned, with little if any theoretical or empirical support. The ultimate connection between weak governance structures and market forces leading to managers being fired was conceivable, but the connection needed to be proved. It wasn’t. Beginning in the mid-2000s, however, new mechanisms emerged that have induced managers of public companies to act in the interest of shareholders. The new implicit contract thus turns the contractarian theory on its head. It works at the mid-stream stage, while the IPO stage remains largely moribund from a contracting perspective.

There is no basis for claiming that the new implicit contract is optimal. To the extent that agency costs were a significant concern in the past, the shift in power toward shareholders could well be a change for the good. On the other hand, critics of the new regime correctly point out that the newly powerful institutional shareholders are run by agents, and that the proxy advisers on which they rely may well offer ungrounded judgments.⁴⁹

5.1 Legal Changes

The Sarbanes-Oxley Act and the stock exchange rules issued in the aftermath of the Enron and WorldCom scandals imposed several requirements on firms regarding the independence and role of outside directors. A majority of directors must satisfy the stock exchanges’ criteria for independence.⁵⁰ Independent directors must meet at least once a year in executive session without members of management present, and they must name

The “Corporate Contract” Today

a director to lead those meetings.⁵¹ In many companies, the result has been the establishment of an ongoing position of lead director.⁵² In addition, Sarbanes–Oxley expanded the role (p. 101) of the audit committee and strengthened its independence requirements.⁵³ The New York Stock Exchange required that boards create compensation, nominating, and governance committees, each comprised entirely of independent directors.⁵⁴ The NASDAQ did not require firms to form those committees, but it required that CEO pay and other executives’ pay be approved by either a majority of independent directors or a compensation committee comprised of independent directors. The NASDAQ imposed a similar requirement for the nomination of directors.⁵⁵ These requirements imposed formal independence on boards. But how independently directors would actually conduct themselves remained to be seen, and of course would necessarily vary across firms.

5.2 Nonlegal Changes

Heading into the mid-2000s, non-legal changes were also developing in the US governance environment. These changes involved executive pay, the composition and attitude of shareholders, and the ability of shareholders to overcome the collective action problem that shareholders had faced in the past. In combination with the legal changes that had occurred, the result appears to be a greater alignment of management interests with shareholder interests.⁵⁶

From the 1980s to the 2000s, executive pay became increasingly stock-based. John Core and Wayne Guay found that, between 2004 and 2008, the median holdings of company stock by CEOs ranged from \$59 to \$79 million (accounting for stock options by converting them into stock equivalents).⁵⁷ This was ten times the amount of stock CEOs held in 1993. CEOs’ increased share ownership is the carrot that is expected to lead them to act in the interests of shareholders.

Institutional shareholdings also increased dramatically from the 1990s to the 2000s. Total institutional stock ownership increased from 37% in 1990 to 50% in 2008.⁵⁸ This increased concentration of shareholdings created an inchoate stick in the new implicit corporate contract. In order for shareholders to wield that stick effectively, however, additional forces would be helpful.

One development that enhanced the power of institutional shareholders was the advent of the proxy advisory services—Institutional Shareholder Services (ISS) and Glass Lewis. ISS and Glass Lewis emerged well before the 2000s, but their power grew as institutional shareholdings grew. These organizations communicate information and substantive judgments to institutional shareholders and, in effect, coordinate voting on everything from board elections to merger approvals to approvals of stock option plans. A second (p. 102) development in the mid-2000s was the emergence of the activist hedge fund. Although the shareholdings of hedge fund activists are relatively small, traditional institutions have supported their challenges of management.⁵⁹ As a result of these developments, the collective action problem long associated with shareholder voting is not an impediment to

The “Corporate Contract” Today

shareholders exerting power over management. Institutions are able to use the stick that their increased shareholdings gave them.

The stick was arguably enhanced further in the mid-2000s by firms’ adoption of majority voting in place of plurality voting. Under majority voting, a director running unopposed needs to garner a majority of votes in order to keep his or her board seat.⁶⁰ From the beginning of 2006 through 2007, the percentage of S&P 500 firms that adopted majority voting rose from 16% to 66%,⁶¹ and from 2003 to 2009, the number of S&P 100 firms that adopted majority voting rose from ten to 90.⁶² This rapid adoption of majority voting both reflected the growing power of shareholders and potentially increased their power. Although few directors have lost their seats by failing to receive a majority of votes,⁶³ majority voting and “just vote no” campaigns seem to augment the power of the shareholders’ stick. A recent study found that majority voting increases firms’ responsiveness to shareholder concerns, and that the adoption of majority voting was associated with an increase in share price.⁶⁴

At least as dramatic as the rapid spread of majority voting was the de-staggering of boards in the mid-2000s—after two decades in which boards refused shareholder demands to de-stagger. According to one study of the period from 2003 to 2010, approximately 60 firms per year de-staggered their boards—compared to an average of four firms per year from 1987 and 2002.⁶⁵ Like majority voting, the de-staggering of a board both reflects increased shareholder power and further adds to their power. Not only does a de-staggered board mean a lower barrier to a takeover, it also exposes all directors every year to the danger of becoming the target of a “just vote no” campaign, especially in combination with majority voting.

(p. 103) Marcel Kahan and Edward Rock, who have reported on these changes in a series of articles,⁶⁶ conclude that the consequence of these legal and institutional developments has been a change in directors’ conception of their role: independent directors became not just nominally independent but “substantively” independent.⁶⁷ As Kahan and Rock explain, this substantive independence is evident in surveys regarding how much time directors devote to their board responsibilities, how directors spend their time, and how they view their roles.⁶⁸

In sum, by roughly the mid-2000s a system of carrots and sticks arose that created what economists would call an implicit contract between management and shareholders. Greater stock-based pay and stock holdings shifted CEOs’ interests more toward shareholder interests, and the potential for collective action among institutional shareholders has kept CEOs’ feet to the fire in terms of satisfying shareholder demands.

Is this the contract the contractarians originally had in mind? No. First, it took two decades to come together, and even then only after key legal changes occurred. Moreover, it happened at the mid-stream stage, which was the weakest leg of the contractarian theory. The IPO stage, which was the core of the contractarian claims and which relied

on legally enforceable commitments, remains largely moribund as a source of innovation or customization.

Moreover, as legal and nonlegal institutional changes in the 2000s have increased shareholder power, there has been a mild resurgence of contractarian-like rhetoric *against* the changes. This opposition has come from advocates for management, most visibly Wachtell, Lipton, Rosen & Katz and the Business Roundtable, and from some academics, with Professor Stephen Bainbridge providing the most sweeping criticism of these changes. The battle cry of these opponents is “one size does not fit all.” They leveled this rhetorical weapon at Sarbanes–Oxley’s requirements concerning independent directors, Dodd–Frank’s requirements regarding executive compensation, the SEC’s proxy access proposal, and ISS’s approach to some governance issues.⁶⁹

With respect to proxy access, the Business Roundtable and Wachtell Lipton took the position that the proposed mandatory rules should instead be default rules, and that *shareholders* should be permitted to vote to have their corporations opt out of them. This is quite different from the approach of the original contractarians, who believed that *management* would have incentives to do right by the shareholders. Bainbridge, however, has maintained the original contractarian line, advocating “board-centric” corporate governance.⁷⁰

(p. 104) 6 Conclusion

This chapter has addressed two questions. The primary question is whether the contractarian theory is a valid positive theory of corporate governance. The answer to that question is no. The theory does not fit the facts uncovered in empirical studies of the content of corporate charters at the IPO stage—the primary focus of the contractarian theory. Corporate charters at the IPO stage are not the fount of innovation and customization that the contractarian theorists imagined them to be, and there is no reason to believe that pre-IPO shareholders customize their charters to maximize firm value. With the exception of the sui generis case of exclusive forum provisions, essentially no innovation or customization occurs in charters. On the contrary, charters are boilerplate documents that overwhelmingly adopt default rules or statutory menu options. Furthermore, the primary menu option that has been adopted is the staggered board, which the weight of evidence suggests reduces firm value. The essentially uniform adoption of default rules and menu options—primarily those of Delaware—is instead consistent with the theory that network economics drive the adoption of corporate governance arrangements. The implication of this alternative theory is that legal rules are important to maintaining effective corporate governance. In contrast to the claims of the contractarian view, decentralized contracting between management and shareholders will not get us there.

The contractarian theory was always viewed as weak with respect to the mid-stream stage. Are managers of public companies truly subject to strong incentives to adopt governance structures that enhance firm value? The contractarians of the 1980s and 1990s did not make a convincing case that they were, and the mid-stream theory was not sup-

The “Corporate Contract” Today

portable. But by the mid-2000s, a set of legal and institutional changes had led management to respond to shareholder interests as never before. Firms have de-staggered their boards, adopted majority voting, faced withhold-the-vote campaigns, responded to activist demands, and increased stock-based pay for management so that management’s financial interests have shifted toward shareholder interests. This is not a result of any sort of charter-based, legally enforceable contract that the contractarians imagined. Nor is it the result of managers simply responding to market forces as the contractarians envisioned. It is instead the result of legal and nonlegal changes that occurred over twenty years. These institutional changes have created a new implicit contract in the economists’ sense of that term—a self-enforcing set of legal and nonlegal carrots and sticks that has emerged to shift managements’ interests toward (but not necessarily into perfect alignment with) shareholders’ interests. Of course, one does not have to use the term “contract” to describe the system of carrots and sticks that shapes corporate governance. I use that term here simply to draw at least a linguistic connection with the original theory of market-driven corporate governance. One could instead describe the relationship simply as one in which legal rules and market forces have engendered a set of institutions and norms that constrain management to be responsive to shareholder interests to an extent that may or may not enhance firm value.

(⁸) The legal limit to the corporate governance commitments a company can include in its charter is that it cannot violate federal law or the law of the state in which the firm is incorporated—which, as discussed below, is itself a matter of contract. For example, the Delaware General Corporation Law provides: “(T)he certificate of incorporation may also contain any or all of the following matters: (1) Any provision for the management of the business and for the conduct of the affairs of the corporation, and any provision creating, defining, limiting and regulating the powers of the corporation, the directors, and the stockholders . . . if such provisions are not contrary to the laws of this State.” Del. Code Ann. tit. 8, § 102(b)(1). Regardless of the state of incorporation, the legal constraint on charter terms is not a strong one.

(¹⁸) Bylaws are not part of a binding contract in the way a charter is. Whereas a charter can be amended only with the approval of the board and the shareholders, bylaws can be amended unilaterally by shareholders, and more importantly for the immediate discussion, by the board so long as the charter allows the board to amend the bylaws, which is universally the case. Nonetheless, I collected data from bylaws as well.

(²¹) This would be the classic (if circular) contractarian inference: If it is not adopted by firms going public, then it is not value enhancing (and should not be legally required). For example, Easterbrook & Fischel argue that if holding an auction among bidders were the value-maximizing response to a hostile offer, then charter terms would require management or the board to hold an auction. Easterbrook & Fischel, *supra* note 2, at 204–05. Haddock et al. similarly argued that, if management passivity in response to a hostile bid were value maximizing, then provisions mandating passivity would be included in IPO charters. Haddock et al., *supra* note 2, at 728.

(²²) The reported results would not change if I were to use the time period 2000 to 2012 for all provisions. That is, outside the restricted periods used in Table 4.1, there were no additional charters or bylaws that contained these provisions.

Abstract and Keywords

This chapter focuses on the competition by states for incorporations. More specifically, it examines three scholarly debates over state competition for incorporations: the “directional” debate, centered around the question of whether firms, if given a choice, will opt for corporate law rules that maximize shareholder value, corporate rules that maximize managerial benefits, something in between, or something else entirely; the “competition” debate, which is concerned with whether, how, and which states compete for incorporations; the “federalism” debate, which deals with the desirability of federal corporate law as an alternative to the present regime, where many corporate law rules are determined by the law of the firm’s state of incorporation. It also analyzes the empirical evidence in relation to all three debates.

1 Introduction

¹THE competition by states for incorporations has long been the subject of extensive scholarship.² Views of this competition differ radically. While some commentators regard it as “the genius of American corporate law,”³ others believe it leads to a “race to the bottom,”⁴ and still others have taken the position that it barely exists.⁵ Despite this lack of consensus among corporate law scholars, scholars in other fields have treated state competition for incorporations as a paradigm case of regulatory competition.⁶

(p. 106) In this chapter, I will try to deconstruct the state competition debates by showing that, in fact, scholars are engaged in three separate debates that are only loosely connected to each other. The first, “directional” debate concerns whether firms, if given a choice, will choose corporate law rules that maximize shareholder value, maximize managerial benefits, something in between,⁷ or something else entirely.⁸ Resolution of this

The State of State Competition for Incorporations

question is relevant regardless of whether states “compete.” All it takes to make this question important is for firms to have a meaningful choice among legal rules.

In the US, a firm can incorporate in any state (or, for that matter, in a foreign country) regardless of where it is headquartered and have its “internal affairs” governed by the laws of its state of incorporation. An existing firm can also change its state of incorporation with the approval of the board and its shareholders without triggering major consequences other than the change in governing law.

As a result, even in the absence of state competition, firms have a choice among legal regimes as long as states offer different legal rules. For that matter, firms can have meaningful choices even if they have no choice of where to incorporate as long as the state’s legal regime offers firms flexibility in devising their governance rules.

The second “competition” debate concerns whether, how, and which states compete for incorporations. Depending on what is meant by “competition,” competition can exist even in a regime where firms have no choice over where they incorporate⁹ and may not exist in a regime where firms have free choice.

The third “federalism” debate concerns the desirability of federal corporate law as an alternative to the present regime, where many corporate law rules are determined by the law of the firm’s state of incorporation. How such a law would stack up in absolute terms along various dimensions—pro-shareholder versus pro-manager, concern for other constituents such as creditors and employees, speed of adopting innovations, and so on—is a question that is entirely separate from the earlier two debates.

(p. 107) 2 The Directional Debate: To the Bottom or to the Top?

The issue in the state competition debate that has been the subject of the fiercest controversy is whether the “race” that state competition supposedly engenders leads to the “bottom”—to laws favoring managers at the expense of shareholders¹⁰—or to the “top”—to laws that maximize firm value.¹¹ That this is the issue most analyzed by commentators is, on the one hand, not surprising: the direction of the “race” is clearly very important from a policy perspective.¹² On the other hand, however, the factors that determine whether the “race” is to the top or to the bottom have virtually nothing to do with state competition. Rather, these factors are internal to the firm.

“Race to the bottom” theorists, in effect, posit that, when given a choice between laws favoring managers that reduce overall value and laws disfavoring managers that increase overall value, firms will choose the former. “Race to the top” theorists posit that firms will choose the latter. Viewed from this perspective, the theoretical debate about direction is more closely connected to the debate about the need for mandatory rules than it is to state competition more generally.¹³

The State of State Competition for Incorporations

As I will discuss here, the positions taken by the partisans, properly understood, are much closer to each other than the literature lets on. At the same time, the theoretical underpinnings make the question of firm choice significantly more complex than the “to the top” and “to the bottom” monikers suggest.

2.1 Extreme versus Nuanced Versions in the Directional Debate

The extreme claim that state competition has resulted in a race to the bottom is clearly false and was probably never seriously asserted. At the very bottom, managers have appropriated all shareholder wealth. The combined market capitalization of stock in US publicly traded companies is (and the returns that investors have earned from stock ownership are) sufficiently high that it is safe to conclude that we have not arrived at the very bottom. Indeed, Lucian Bebchuk, the contemporary scholar most identified with the “race to the bottom” view, argues that firms will choose a law favoring managers which reduces firm value over a (p. 108) law favoring shareholders which increases firm value only if the reduction in firm value, relative to the benefit to the managers, is not excessive.¹⁴

The extreme “race to the top” claim is also difficult to maintain. If firms, when given a choice, always choose the law that maximizes value, it must be either that managers have no power over that decision or that the interests of managers and shareholders regarding the choice coincide perfectly.

A more nuanced version of the “race to the top” claim would admit that firms may sometimes choose a law that reduces firm value and benefits managers. This more nuanced “race to the top” claim differs from Bebchuk’s more nuanced version of the “race to the bottom” claim only in degree (and perhaps not at all). For example, Easterbrook and Fischel, among the most prominent early “to the top” scholars, share Bebchuk’s view¹⁵ that managers regularly choose rules that entrench them against hostile bids even though they lower firm value.¹⁶ So, possibly, the main difference between the two camps has less to do with their views on the directional debate and more to do with their (less well-argued and articulated) views on the federalism debate: how good (or bad) would a federal corporate law be.

2.2 The Multiplicity of Settings for Choice

Firms choose their domicile, and thereby the legal rules that govern them, in a multiplicity of settings. Specifically, firms can make this choice prior to an IPO or mid-stream; they can make it explicitly (by reincorporating) or implicitly (by failing to reincorporate); and managers, at the time of the choice, can hold a small fraction (“outside managers”) or a significant fraction (“large shareholder managers”) of the firm’s voting power. But the direction of firm choice depends on the power and incentives of managers and of shareholders. Because these factors will vary systematically among the settings for choice, there is no a priori reason why the directions of firm choices in different settings should be identical.

2.2.1 The Power to Effect Mid-Stream Incorporation Decisions

To change its state of incorporation, a firm typically merges with a wholly-owned subsidiary incorporated in a different state, with the subsidiary surviving the merger. Mergers generally require a recommendation by the board of directors and the approval of at least a majority of the shares entitled to vote.¹⁷ According to Guhan Subramanian, 373 firms effected mid-stream reincorporations over the 1991 to 2001 period.¹⁸

To effect a mid-stream reincorporation that benefits them at the expense of shareholder value, manager thus need to *both* dominate the board of directors sufficiently to get the board to recommend the merger *and* either own sufficient shares to approve a merger or (p. 109) induce sufficient other shareholders to vote for the merger. To block a reincorporation that benefits shareholders at the expense of managers, managers merely need to dominate the board of director sufficiently to get the board *not to* recommend a reincorporation merger *or* have sufficient shares to block the merger. Obviously, large shareholder managers will have greater power than outside managers to effect or block a reincorporation as they own a greater fraction of shares and as they are more likely to dominate the board.

2.2.1.1 Board Domination

“Race to the bottom” scholars have generally assumed that even outside managers have sufficient influence over board decisions to block a reincorporation that runs counter to their interests and “race to the top” scholars have not directly challenged this assumption.¹⁹ While this assumption may be justified for many companies, the degree to which managers control boards is not uniform and has declined over the years.²⁰ As Ed Rock and I have shown elsewhere, the percentage and the relative power of outside directors on corporate boards have increased substantially over the last 40 years.²¹ Thus, at least in some companies, managers may not have the power to block a reincorporation on the board level.

Whether outside managers in many companies have sufficient sway over their boards to get them to recommend a reincorporation that favors managerial interest at the expense of shareholder interest is questionable. The fact that there is no widespread shareholder opposition to reincorporation recommendations (unlike, say, to board decisions to adopt a poison pill and retain a staggered board) suggests that managerial power in this regard is limited.

2.2.1.2 Shareholder Approval

That shareholders must vote in favor of a reincorporation would seem to indicate that reincorporations ought to benefit shareholders as long as managers do not control the shareholder vote. “To the bottom” theorists have countered that shareholders have imperfect information about the effect of a reincorporation on the value of the firm and may vote in favor of reincorporations that run counter to their interest.²²

The State of State Competition for Incorporations

Whatever the merits of this argument may have been²³ in the past, it has lost much of its currency in light of the increased power of institutional investors. Institutional investors (such as mutual funds and pension funds) hold much larger stakes in specific firms than (p. 110) the individual investors of lore.²⁴ They also hold shares in many more different companies. This generates economies of scope to the extent that they vote on recurring issues that have similar effects on companies (such as decisions to reincorporate). Moreover, institutional investors can pool their resources by hiring proxy advisory firms to give them voting advice.²⁵ It is thus highly doubtful that institutional investors have significantly less information about the effect of a reincorporation than managers do and regularly approve of reincorporations that reduce company value.

A second argument put forth by “to the bottom” scholars is that firms will propose reincorporations that maximize managerial benefits, but subject to the constraint that they do not reduce shareholder value.²⁶ The result of such a process could be characterized as a “crawl upwards,” as firm value increases whenever a firm reincorporates (if only by a little). As discussed in greater detail below, the “crawl upwards” model has significant implication for the optimal competitive strategy of states trying to attract reincorporations.

2.2.2 Conflicts of Interest in Mid-Stream Decisions

Mid-stream, various forces outside of legal rules (e.g., incentive compensation, the managerial labor market, the product market, etc.) align the interests of managers with those of shareholders.²⁷ Some “race to the top” scholars have suggested that these forces are sufficient to induce managers to prefer rules than maximize firm value.²⁸ But since these market forces do not work perfectly, residual conflicts of interest are likely to persist. Indeed, if outside market forces worked to align shareholder and managerial interests perfectly, there would not be much need for corporate law.

Individual managers, however, will have incentives to seek pro-manager rules only to the extent that they themselves profit from these rules. The ability of outside managers to profit from pro-manager rules is a function of their expected tenure. The longer their expected tenure, the larger the benefits they derive, for example, from rules insulating managers from hostile takeovers.²⁹

This has two significant implications. First, since expected managerial tenure is limited,³⁰ incumbent managers will obtain only a fraction of the aggregate managerial benefit of a pro-management rule. Second, because managers differ in their expected remaining tenure, they (p. 111) will differ in their incentives to favor a pro-management rule. Indeed, the incentives of a CEO close to retirement to seek rules that maximize share value (and thereby the value of her stock and stock options) through reincorporations are likely to exceed the incentives to seek pro-management rules.

Large shareholder managers, however, may reasonably expect to sell their shares as a block. If such blocks sell for a higher price as a result of pro-manager legal rules, large shareholder managers can appropriate to themselves the benefits generated by such

The State of State Competition for Incorporations

rules beyond the duration of their managerial tenure.³¹ At the same time, large equity holdings by large shareholder managers reduce conflicts of interests.

2.2.3 The Power over Pre-IPO Incorporation Decisions

Pre-IPO firms generally have few shareholders. It is thus likely that pre-IPO boards will reflect the wishes of the pre-IPO shareholders. Pre-IPO, the power to change (and not to change) the state of incorporation therefore effectively rests with the pre-IPO owners of the firm.

The extent to which the pre-IPO owners are identical to the post-IPO managers of the firm varies from firm to firm. At one extreme, there may be a firm where the founding entrepreneur owns or controls most of the stock and plans to continue managing the firm post-IPO. At the other extreme, the pre-IPO owners may plan not to be involved in the management at all. In between are firms where both the managers and other pre-IPO investors (such as venture capitalists) own substantial shares and jointly exercise the power to make the pre-IPO incorporation decision.

2.2.4 Conflicts of Interest in Pre-IPO Incorporation Decision

In the IPO, the pre-IPO owners will sell a significant fraction of the equity in the firm. The pre-IPO owners—including pre-IPO managers to the extent they are owners—will thus have an incentive to make an incorporation decision that increases the price at which the firm shares can be sold at the IPO. To the extent that the market accurately values the effect of the incorporation state, this gives pre-IPO owners strong incentives to choose a domicile that maximizes firm value.

“Race to the bottom” theorists have made two retorts to this argument. First, they suggest that the market may not value the effect of the incorporation state correctly.³² Second, they argue that, whatever the incentives for pre-IPO incorporation decisions, it will be post-IPO decisions that will drive the direction of state competition.³³ The second retort relates to the competition debate, rather than the directional debate, and will be taken up in the next section.

Whether incorporation decisions are accurately priced in the IPO is essentially a debate about stock market efficiency. Since the firm’s state of incorporation and its laws are public information, believers in market efficiency would argue, their import is reflected in the stock price. “To the bottom” theorists, by contrast, would have to argue that the market (p. 112) systematically undervalues features of the incorporation law that protect shareholders against various forms of entrenchment and overreaching by managers.³⁴

“To the bottom” theorists, however, have failed to present a cogent argument as to why the market would systematically mis-value companies in that fashion.³⁵ Indeed, theoretically, the market should be likely to price standard terms like the incorporation regime reasonably well. While small pricing inaccuracies may persist, it is unlikely that prices would fail to reflect legal rules that had a significant effect on company value.

2.2.5 Summary

Because of these systematic differences related to the multiplicity of settings, and because firms and managers will differ in less systematic ways (e.g., with respect to the degree of influence managers have over the board), it is unlikely that all firm choices follow the same paradigm. Rather, both across settings and, to a lesser extent, within settings, firms may choose different sets of rules.

2.3 Empirical Evidence on the Directional Debate

I now turn to some of the empirical evidence relevant to the directional debate. At the outset, it is important to note that this evidence is almost necessarily inconclusive. It is virtually impossible to distinguish the nuanced versions of the “to the top” and “to the bottom” positions empirically. Heterogeneity among settings and firms further complicates the empirical analysis.

The earliest empirical studies related to the directional debate are event studies that examine the effect of mid-stream decisions to reincorporate on firm value. There have been several such event studies and they generally find a slight (in the range of 1%) statistically significant positive effect on the stock price upon the announcement of a reincorporation.³⁶ “To the top” scholars point to these reincorporation studies as evidence for their hypothesis.³⁷ Alas, these event studies at most show that mid-stream reincorporations tend to benefit shareholders. This result would be consistent with the view by “race to the bottom” scholars that the requirement for shareholder approval constrains managers in this setting and would have no direct implications for pre-IPO incorporation decisions or mid-stream failures to reincorporate. Moreover, the event studies do not distinguish between companies with outside and large shareholder managers.

(p. 113) Another set of studies looks directly at the factors influencing incorporation decisions of firms. In separate studies, Guhan Subramanian³⁸ and Lucian Bebchuk and Alma Cohen³⁹ present evidence that firms are more likely to be incorporated in their home state than in Delaware if their home state has adopted anti-takeover statutes. If these statutes reduce firm value, this result would be consistent with the “to the bottom” view in the directional debate. However, most anti-takeover statutes are rendered redundant by poison pills, so it is unclear why these statutes should matter at all. Indeed, in a different study, I have shown that judicial quality and state law flexibility significantly affect IPO decisions and that, if one controls for these variables, anti-takeover provisions are insignificant.⁴⁰

Another set of studies looks at anti-takeover charter provisions (ATPs) of IPO firms. The selection of charter provisions and the selection of domicile represent similar decisions of firms choosing among legal rules (or sets of legal rules). The first of these studies, by Robert Daines and Michael Klausner,⁴¹ compares IPOs by firms that went public with venture capital backing, firms controlled by LBO specialists, and other firms. Daines and Klausner found that many IPO charters contained ATPs, with about 43% of the firm charters providing for staggered boards and 6% opting for dual-class voting stock. Dual-class

stock was less common in firms with VC or LBO fund backing, but the incidence of staggered boards did not vary significantly between the three groups of companies.

The results found by Daines and Klausner pose questions for both camps. If staggered boards reduce firm value, as believed by several (though not all) “to the top” commentators, IPO charters should not provide for them and should instead (but do not) contain provisions limiting the board’s authority to adopt takeover defenses. But if ATPs reflect managerial self-interest, as “to the bottom” scholars tend to believe, why are they not more universal? In particular, the small percentage of firms with a dual-class share structure is consistent with strong entrenchment provisions being priced at the IPO and being avoided by most firms for that reason. However, the fact that VC and LBO fund backed IPOs are as likely to adopt staggered boards as other firms (even though managers in these firms wield less power),⁴² as well as anecdotal evidence, suggests that these weaker provisions may not affect the IPO price, arguably because their effect on firm value is not clear cut.⁴³

(p. 114) 3 The Competition Debate: Who Competes and How?

The second debate concerns the actions of states: do they in fact compete for incorporations and, if they do, what is their competitive strategy? I refer to this prong as the competition debate.

Until recently, most state competition scholars have regarded the notion that many states compete for incorporations as a premise for their other arguments, without bothering to inquire much into whether this premise is correct.⁴⁴ Starting with Bill Cary, state competition scholars have asserted that states stand to earn substantial franchise taxes by firms incorporated in them, which provides an incentive for many states (especially the smaller ones) to actively seek incorporations.⁴⁵ Other scholars have noted that incorporations generate business for local lawyers, which enhances the incentives provided by the franchise tax.⁴⁶

Whether states in fact compete has only recently become a focus of the academic debate. In two articles from 2001 and 2002, Ehud Kamar and I have argued that only Delaware actively competes for incorporations.⁴⁷ Since our articles, three different positions on whether states compete have emerged. Kamar and I attribute the failure of states other than Delaware to compete to political as well as economic factors. Lucian Bebchuk and Assaf Hamdani basically agree that only Delaware competes for incorporations, but they attribute the failure of other states to do so to other states having realized that competition with Delaware would be futile.⁴⁸ Romano maintains that several states are trying to attract incorporations. Notably, all camps in this debate agree that Delaware competes; the debate only concerns states other than Delaware.

3.1 Do States Compete?

The claim by Kamar and me that states other than Delaware do not actively compete for incorporations rests on two grounds: their lack of meaningful incentives to compete and their failure to take meaningful measures to compete. At the time our article was written, most states either charged a low, flat franchise tax on in-state firms or a tax based on the amount of business conducted in the state that was also charged on firms incorporated in other states. Other than Delaware, no state stood to derive substantial revenues, even if it attracted a large portion of all public companies. Therefore, contrary to the claims in the (p. 115) earlier state competition literature, franchise tax revenues do not drive competition by other states.⁴⁹

Kamar and I further show that the benefits states stand to gain from attracting (or retaining) legal business through incorporations are modest.⁵⁰ These modest benefits may account for the fact that states periodically revise their corporation law or take other low-cost measures.⁵¹ States, however, have not taken any more substantial—and possibly more effective—measures to compete, such as replicating Delaware’s highly regarded Chancery Court which specializes in resolving corporate disputes.⁵² Given the at best modest economic incentives to compete and the at best half-hearted measures to compete, Kamar and I conclude that only Delaware makes significant efforts to attract incorporations.

Consistent with our argument, Rob Daines has shown that most firms incorporate either in Delaware or in their headquarter state.⁵³ If states competed, Daines’s findings would imply that states other than Delaware either do not try, or do not succeed, in attracting firms headquartered elsewhere. It is, however, unclear what competitive strategy other states would follow to produce such a result. It is more likely, as Daines argues, that the pre-existing relationships between managers and (locally-based) lawyers account for the “Delaware or headquarter state” incorporation pattern.

More recently, Michal Barzuza has presented evidence that Nevada competes for, and attracts, some firms who seek extremely lax laws.⁵⁴ Nevada, which had raised its maximum franchise tax from \$85 to \$11,100 in 2003, accounts for about 6–7% of incorporations by firms not incorporated in their home state and could be seen as a niche competitor.⁵⁵ Barzuza’s argument supports our notion, discussed in the next section, that competition (and the lack thereof) is politically contingent, rather than futile, and hence may emerge.

3.2 Why Don’t States Compete?

The prevailing franchise tax structure, which accounts for the fact that only Delaware (and perhaps Nevada) stand to gain substantial revenues from attracting incorporations, is endogenous. States can revise their franchise tax structure, as Nevada did, to give them greater incentives to compete. Why have states not done so?

The State of State Competition for Incorporations

Bebchuk and Hamdani argue that unerodable economic entry barriers account for the lack of competition. Drawing on Michael Klausner's prior work,⁵⁶ they argue that Delaware has competitive advantages over any other state attributable principally to "network benefits" (more on that later) derived from the fact that a large percentage of public companies are incorporated in the state. No competing states could compensate for these advantages because (p. 116) Delaware would quickly copy any "improvement" in the law offered by that state. Other states, understanding this dynamic, have realized that competition would be futile.⁵⁷

For Bebhuk and Hamdani's argument to work, the entry barriers generated by network benefits must be steep. Delaware earns profit margins from the incorporation business that are, in economic terms, of a stupendous magnitude.⁵⁸

As Michael Klausner, on his own and with me, has argued, legal rules in general (and Delaware corporate law in particular) generate possible network benefits since the market is more familiar with Delaware law (making the law easier to price); lawyers are more familiar with Delaware law (and it is therefore easier to obtain legal advice); and there are more judicial precedents (clarifying Delaware law). Importantly, because Delaware is expected to continue to have a large market share, network benefits derive from the expectation that market familiarity and lawyer familiarity will continue in the future and that additional judicial precedents will be generated.⁵⁹ Given their somewhat intangible nature, it is difficult to estimate the magnitude of these benefits with precision. But it seems a stretch to suggest that the entry barriers generated by these benefits are so high as to make competition futile.⁶⁰

Moreover, Bebhuk and Hamdani's argument that competition is futile because Delaware would copy any innovation is premised on the notion that all firms are attracted to the same legal regime. But as discussed before, due to the multiplicity of settings and the heterogeneity of firms, different firms may be attracted to differing regimes. Furthermore, outside managers and large shareholder managers will differ in the kind of legal rules that bestow benefits on them. Outside managers will be interested in rules that entrench them vis-à-vis shareholders (such as rules on takeover defenses), while large shareholder managers will be interested in rules that make it difficult to sue them for breaches of fiduciary duties (e.g., if they engage in self-dealing transactions). Even if Delaware enjoys substantial network benefits, it would thus seem feasible for states to offer a differentiated product attractive to a subset of public corporations, as Nevada does according to Barzuza, and as Maryland does for regulated investment companies.⁶¹

Rather than purely economic factors, Kamar and I argue that political ones account for the lack of more significant competition. For one, states are not firms. Entry is limited (one cannot form a new state) and the notion that existing states will generally try to maximize their profits in designing their corporate law is unsupported. Indeed, both Romano, and (p. 117) Bebhuk and Hamdani acknowledge that economic benefits from attracting incorporations are unlikely to induce larger states to compete. But even most smaller states have probably never given serious thought to competing for incorporations

The State of State Competition for Incorporations

or taken actions like hiring a consultant to explore whether competition would be profitable.

Moreover, seriously competing for incorporations entails substantial *political* costs. For example, in most states, establishing a court modeled after Delaware's Chancery Court would require a constitutional amendment and attract political opposition, e.g., from the plaintiffs' bar worried about undermining the right to a jury trial. If established, the most qualified potential judges would probably not be residents of the state. Small-firm lawyers, who would stand to gain little from attracting public incorporations, may oppose a wholesale change in the state's corporate law. And so on.⁶²

While more costly reform is difficult, states still revise their law. But as Bill Carney has argued, in some states these revisions are driven by the influence of political interest groups—lawyers and management—rather than by a desire to attract incorporations, while other states try to reduce the cost of lawmaking by adopting the Model Business Corporation Act.⁶³

Whether it is just economic or whether it is also political factors that explain the present state of (non-)competition bears on the stability of that state. For Bebchuk and Hamdani, it would take a significant economic upheaval to permit states to compete effectively. For Kamar and me, competition may emerge spontaneously, more states may start pursuing niche strategies, and some niche players may start aiming at a greater market share, as the political dynamics in a state change.

3.3 Competitive Strategy

Though the directional debate and the competition debate are in many ways separate, they are linked with respect to one issue: what competitive strategy should Delaware (and other competing states) adopt?

The discussion of the competitive strategies for Delaware in this section will be somewhat stylized. In reality, it is of course difficult for anyone—and surely for amorphous political entities like states—to devise and implement a strategy. One important aspect of this difficulty is that a significant portion of Delaware corporate law is judge made. And while the judiciary may not be oblivious to a state's goals in attracting incorporations, it is also not the stooge of the state budget and economic development office. Moreover, the interests of lawyers, an important interest group even in Delaware,⁶⁴ may lead to deviations from the profit-maximizing strategy. Thus, whatever a state's maximizing strategy is in theory, in practice it will be implemented imperfectly.

A starting point to the analysis of Delaware's optimal strategy is to determine the forces that shape the law of other states. One possibility is that states will neglect their corporate laws. This is indeed what several very large and very small states seem to be doing. The laws of states like New York, California, Alaska, and West Virginia and the District of Columbia (p. 118) contain, or did until recently, antiquated provisions requiring, for example, a supermajority to approve a merger or cumulative voting for directors. One can

The State of State Competition for Incorporations

speculate that, in these states, corporate laws are not regularly updated either because the corporate bar takes no interest (because it is small or because it is dominated by firms specializing in Delaware law) or because the state legislature has bigger fish to fry.

Another possibility is that managers of in-state public firms will lobby for pro-managerial laws. Bill Carney, among others, has argued that such lobbying accounts for the adoption of anti-takeover laws.⁶⁵ In addition, labor groups may sometimes affect corporate law provisions, as is the case with the notorious section in New York's law imposing personal liability on the ten largest shareholders for unpaid wages.

Third, the local corporate bar may induce states to adopt a relatively decent, and relatively up-to-date, statutory law, either by adopting the Model Business Corporation Act (and updating it regularly) or by devising and updating their own code.⁶⁶ Members of the local bar may do so for a variety of reasons, such as benefiting closely-held companies incorporated in the state or enhancing their reputation. Such updating could also reflect a low-cost attempt to retain and attract incorporations by public firms.

Finally, some states may pursue a niche competition strategy. Such a strategy would not be designed to replicate Delaware's high-quality judiciary and would not significantly erode Delaware's network benefits, but might attract a significant share of firms in a certain market segment.⁶⁷

The resulting laws of states other than Delaware can be mapped along two dimensions. The first dimension concerns the degree to which the law contains pro-management or pro-shareholder rules. The second dimension concerns the overall quality (including the content of rules where shareholder and manager interest do not conflict, judicial quality, and network benefits). The laws of states other than Delaware will differ along both dimensions, because states will differ in their susceptibility to managerial lobbying, in the degree of attention the corporate bar devotes to updating the law, in the influence of the local bar on the political process, in the niche strategy they may pursue, etc.⁶⁸

Delaware's problem then becomes one of positioning its product optimally relative to both the demand by firms and to the products offered by its competitors. If all firms preferred the same position on the pro-management/pro-shareholder dimension, as posited by the more extreme "race to the top" and "race to the bottom" positions, Delaware's strategy would be simple. But if, as argued above, firm choices are heterogeneous, Delaware's positioning choice becomes more complex. To position its law optimally, Delaware would have to take account of the effect on whether existing Delaware corporations migrate out of the state, whether non-Delaware corporations move to Delaware, where companies incorporate at the IPO stage, and how high a franchise tax it could charge.⁶⁹ Moreover, to the extent that it does not reduce network benefits, Delaware would want to provide firms with a choice of rules along the pro-management/pro-shareholder dimension.

The State of State Competition for Incorporations

Return now to the argument that firms will try to maximize shareholder value at the IPO stage (to the extent that the rules of the state of incorporation are priced). “To the bottom” (p. 119) theorists have argued in response that, since the stock of already existing companies is larger than the flow of IPOs, a state trying to compete for incorporations will focus on the latter rather than the former segment of the market.⁷⁰ But if Delaware caters to existing companies (which prefer relatively pro-management rules), why does Delaware attract a high percentage of companies at the IPO stage (which prefer rules that maximize company value)?⁷¹ The answer presumably is that Delaware is superior from the company value perspective, despite its hypothesized pro-management rules.

But such a conclusion raises questions for “race to the bottom” theorists. If states compete, at least some of them should have adopted a niche strategy of catering to IPO firm demand for pro-shareholder rules. And if states do not compete, it must be that, however distorted Delaware law allegedly is by the dynamics of state competition, the product of non-competing states is even worse for shareholders.

Rather, it is more plausible that Delaware positions its law to appeal to both IPO firms and existing companies by pursuing a middle ground on the pro-manager/pro-shareholder dimension and otherwise focusing on maximizing quality (by having an up-to-date law, a good court system, quickly correcting court decisions that reduce firm value, etc.). Since no other state offers a product that is superior for both shareholders and managers, few firms would migrate out of Delaware (and firms from some other states may migrate in). And because the combination of balanced rules and high general quality results in relatively high firm value (possibly higher, or at least not significantly lower, than the rules of any other state), many IPO firms will choose Delaware law.

3.4 Refinements

The preceding discussion of Delaware’s competitive strategy can be refined in several ways. First, whether or not other states are actively competing with Delaware, Delaware has market power. The presence of such market power is suggested by Delaware’s substantial market share and confirmed by the supra-competitive profits Delaware earns from its chartering business.⁷²

Commentators have examined several ways in which market power may affect Delaware’s strategy. Most notably, Ehud Kamar has suggested that Delaware’s use of fact-intensive standards serves to protect its competitive advantages. A competing state can easily copy Delaware’s law. But without an expert judiciary to interpret that law, a law based on fact-intensive standards is less valuable. By using standards, in conjunction with an expert court, it becomes harder for other states to replicate Delaware.⁷³

(p. 120) A relationship between federal lawmaking and Delaware corporate law has given rise to other refinements to the competition debate. Congress has the power, and to some extent has exercised the power, to adopt corporate law rules. Thus, federal law governs issues like insider trading, the right to have shareholder proposals included in the company’s proxy statement, and whether a company can make loans to officers. In theory,

The State of State Competition for Incorporations

federal law could completely supplant the present regime of state-based corporate law. Such a move would be harmful to Delaware, which derives substantial revenues from the franchising business.⁷⁴

Commentators have taken different positions on how the threat of federal intervention affects Delaware law. On one extreme, Mark Roe has argued in a 2003 article that Delaware either mimics the rules favored by federal lawmakers or gets preempted by federal law.⁷⁵ In Roe's world, Delaware is basically a federal implementation agent that enjoys little autonomy. Put in our earlier terms, the threat of federal intervention forces Delaware to place its law at a certain position along the pro-management/pro-shareholder dimension.

On the other extreme, Roberta Romano has argued that states compete largely unimpeded by federal threats because states correlatively exercise power over Congress. As evidence, Romano points out that the key components of state corporate law—fiduciary duties and the allocation of authority between managers and shareholders—are largely governed by state law.⁷⁶

Ed Rock and I have taken an intermediate position.⁷⁷ We argue that the possibility of federal preemption constitutes a threat to Delaware, but that this threat is significant only in times when systemic change can generate a significant populist payoff. At other times, as long as the interest groups representing managers and investors are reasonably satisfied, the built-in inertia of federal legislation makes federal intervention unlikely.⁷⁸

To minimize its exposure to a populist attack, Rock and I argue, Delaware has adopted a classical or nineteenth-century common law model of lawmaking that makes Delaware law less overtly political. Specifically, most important and controversial legal rules are the product of judge-made law. Delaware's judiciary has technocratic expertise on corporate law and is appointed on a non-partisan basis. Its opinions are filled with quasi-deterministic reasoning. Statutory amendments to the corporation law are initially drafted by a bar committee, are adopted without debate or change by the legislature, and address largely technical matters.⁷⁹

(p. 121) 3.5 Empirical Evidence

There is relatively little statistical evidence as to whether states compete. In an early, seminal article on state competition, Roberta Romano found that there is a statistically significant correlation between the percentage of a state's total tax collections derived from franchise taxes and the speed at which the state enacts corporate law innovations.⁸⁰ However, since most states do not stand to gain material franchise tax revenues from attracting incorporations, this correlation does not provide evidence that states adopt innovations to increase revenue.

Another approach in the competition debate is to examine the law of Delaware, the state that is clearly most successful in attracting incorporations. Indeed, several commentators have also tried to resolve the directional debate based on Delaware's actions. For example, Bill Cary, who wrote the first significant modern article on state competition in corpo-

The State of State Competition for Incorporations

rate law, examined several then-recent decisions by the Delaware Supreme Court, found that they were unduly pro-management, and concluded that the race must be heading “to the bottom.”⁸¹ Cary’s conclusion, of course, depends on knowing how the optimal law compares to Delaware law.

A more systematic and elaborate study in a similar vein by Brian Cheffins, Steven Bank, and Harwell Wells (CBW) tracks the development of shareholder rights under Delaware law, Illinois law, and the Model Business Corporations Act (MBCA) from 1899 to the present using three different rights indexes.⁸² CBW reason that, if competition has resulted in an erosion of shareholder rights, the index scores they study should decline. They find a modest downward trend for two of the three indexes and a mixed trend for the third index for each of the three bodies of law.

There are some inherent limitations in the CBW approach: reasonable minds can differ as to what items to include in a rights index and how to score an item. In particular, one may question whether the shareholder rights score should be based on a state’s default rules, the approach taken by CBW, or only on mandatory rules.⁸³

It is also unclear how CBW’s results should be interpreted. For much of the period of analysis, Illinois and the drafters of the MBCA did not compete intensely, if at all, for (p. 122) incorporations. The impact of competition would then be reflected in *differential* trends in the index for Delaware compared to Illinois, and the MBCA. If the Delaware indices show a similar trend to the ones for Illinois and the MBCA, as found by CBW, this could indicate that competition did not drive the index changes.

The most significant statistical analysis of Delaware law is a study by Robert Daines. Daines shows that firms incorporated in Delaware have a higher value (as measured by Tobin’s Q) than similar firms incorporated elsewhere, and argues that this Delaware premium is due to Delaware’s relatively takeover-friendly corporate law.⁸⁴ In a follow-up study employing a different methodology, Guhan Subramanian confirms the results reported by Daines, but finds no statistically significant Delaware premium after 1996.⁸⁵

That Delaware firms have higher value is consistent with the notion that Delaware is competing for incorporations. That Delaware is trying to attract incorporations is, of course, undisputed. So the noteworthy result in Daines is that he was able to show that Delaware law contributes sufficient value to be reflected in a statistically significant difference in Tobin’s Q.

Daines’s results have also become enmeshed in the directional debate. While “to the top” scholars have embraced Daines’s findings as confirmation of their view,⁸⁶ “to the bottom” scholars have pointed to the disappearance of a significant Delaware premium after 1996.⁸⁷ This controversy illustrates once again the conceptual confusion engendered by the failure to separate the various strands within the state competition debate. About half of all firms are *not* incorporated in Delaware. Thus, it is hard to see how a Delaware premium can be proof that *firms* chose a legal regime that maximizes firm value.

Rather, the results by Daines suggest that other states either do not try to compete (or do not compete effectively). In the presence of effective competition, neither the “to the top” nor the “to the bottom” theories would predict a sizeable Delaware premium. If states raced “to the top,” it would be hard to see how Delaware could have earned such a significant lead. And if states raced “to the bottom,” then Delaware would, at most, have to be as good as or slightly better on the shareholder value front than other states. But if other states do not compete and thus offer an inferior product, Delaware becomes able to design its law to appeal to both managers and shareholders.

4 The Federalism Debate: What Would Federal Law Look Like?

Although the arguments are least well worked out, the federalism debate lurks in the background of many disagreements among state competition scholars. If we had a mandatory federal corporate law that replaced the current regime that gives corporations a choice (p. 123) among different bodies of state law, what would it look like and how would it compare to state corporate law?

For adherents to the more extreme positions in the directional debate, it is not necessary to devote much energy to this issue. However, for proponents of the more nuanced versions, the quality they expect federal corporate law to take may be a key determinant of their normative views of the present regime.

But even though one can make some sensible predictions on how federal law would differ from state law, it is hard to arrive at firm conclusions on whether a mandatory federal law, on the whole, would be better or worse than the current regime. This difficulty is compounded by the fact that, in the current regime, only about half of the public companies are incorporated in Delaware, and governed by Delaware law, while the other half are incorporated in other states with a hodge-podge of different laws.

4.1 The Pro-Management/Pro-Shareholder Dimension

As several commentators have noted, federal law would be influenced by political factors, rather than by the desire to attract incorporations.⁸⁸ “Race to the bottom” theorists have acknowledged that federal law may have a pro-management bias as a result of lobbying of managerial interest groups. But they argue that at least such lobbying would be made against a neutral baseline. By contrast, the argument goes, in a state competition regime, pro-management lobbying may also take place, but would occur against a baseline that is already excessively pro-management as a result of states’ interests in attracting incorporations.⁸⁹ Therefore, they claim, federal law would be less pro-management than current state law.

This argument is problematic in two respects. First, unlike federal lawmakers, Delaware lawmakers would have strong incentives to resist lobbying for laws that would reduce

The State of State Competition for Incorporations

Delaware's attractiveness as an incorporation domicile. As a result, in Delaware (and any other state that is actively competing), lobbying would be *less* influential than it would be in a system where attracting incorporations would not be a countervailing objective for lawmakers. If both lobbying and competition introduce a pro-managerial bias, it is a priori unclear when the bias is stronger. At least under some versions of the nuanced "to the bottom" theory (that takes account of the fact that shareholders also have power over incorporation decisions), it is possible that the pro-management bias resulting from lobbying is the stronger one.

Second, not all states actively compete for incorporations. The law of non-competing states, like federal law, would be determined by political factors.⁹⁰ To be sure, the political (p. 124) dynamic on the federal level may work differently than on the state level. In particular, interest groups would have very different incentives to lobby at the federal level, where they would be dealing with a large, monopolistic rulemaker,⁹¹ than they presently do at the state level, where they are dealing with a much smaller lawmaker and may be able to escape any laws by reincorporating.⁹² But it is not evident whether federal law would therefore be more or less pro-management than the laws of non-competing states.

On the other side, commentators have suggested that federal law may impose excessive regulations that are purportedly in the interest of shareholders, but in fact reduce company value. In particular, such overregulation may be the political response to corporate scandals.⁹³ Thus, Roberta Romano has analyzed various corporate governance mandates in the Sarbanes-Oxley Act (SOX) and concluded that the empirical literature does not support the view that they enhance corporate value.⁹⁴

However, many of the studies cited by Romano also do not show that SOX mandates reduce company value. In any case, it would be possible that federal law overreacts to corporate scandals, but at other times provides reasonably efficient regulation. Thus, SOX may not be emblematic of a wholesale federal corporate law. In sum, neither "to the top" nor "to the bottom" scholars have succeeded in establishing that federal law would be, respectively, inferior or superior to state laws on the pro-management/pro-shareholder dimension.

4.2 Other Considerations

4.2.1 Other Interest Groups

Several commentators have argued that groups representing labor, creditor, and similar interests may be more influential on the federal level than they are in Delaware.⁹⁵ To the extent that federal law will cater to such other interest groups, it may result in lower benefits to shareholders or managers (or both). This may, or may not, enhance overall welfare.⁹⁶

One particular interest group—lawyers—requires differentiation. According to Bill Carney, lawyers have a significant effect on the corporate law of states other than

The State of State Competition for Incorporations

Delaware,⁹⁷ and even Delaware law probably caters significantly to the interest of the bar.⁹⁸ Unlike other interest groups, lawyers may thus have less influence in a federal regime than they do presently.

(p. 125) 4.2.2 Judicial Quality and Network Effects

Delaware has an expert corporate law judiciary and, according to many commentators, Delaware law generates network benefits. A federal corporate law would presumably be adjudicated to a large extent by federal courts. Although federal judges are generally highly regarded, they would lack the specialized expertise of Delaware's judiciary. However, companies incorporated in states other than Delaware may see a benefit in a greater opportunity to have corporate law disputes resolved by federal courts rather than state courts.

A uniform federal corporate law is also likely to generate network benefits. However, to the extent that the network benefits generated by Delaware law are dependent on the fact that Delaware corporate law disputes are resolved by Delaware's small judiciary, they may exceed the network benefits arising under federal law.

4.2.3 Innovation

A federal lawmaker would lack incentives to update its law and adopt useful innovations in order to attract incorporations. As a result, the speed of innovation may be lower than it currently is for Delaware.⁹⁹ This is likely true regardless of whether Delaware's market power generates monopoly's slack, as argued by some commentators,¹⁰⁰ or increases its incentives to develop innovations, as argued by others.¹⁰¹ Other states, of course, presently adopt innovations at a lesser pace than Delaware does, and federal law may compare favorably to at least some of such other states.

4.2.4 Rules versus Standards

To the extent that a regulatory agency would have authority to promulgate federal corporate law, federal law may be substantially rule based. Some commentators have suggested that Delaware law relies on open-ended standards more than is optimal.¹⁰² To the extent that this is correct, a more rule-based approach may be superior at the margin. There is, however, no particular reason to believe that federal law would be optimally rule-based or, for that matter, that it would be superior in this respect to the law of Delaware and other states.

4.3 Summary

While the specific parameters of federal law are unclear, there are some weak reasons to believe that federal law would be superior to the laws of non-competing states. Federal law would likely be superior in some respects—like the generation of network benefits and judicial quality—and there are no particular reasons to predict how it would differ in others. (p. 126) Whether federal law would be superior or inferior to Delaware law is not

clear. Moreover, unlike in the present regime, firms would have no alternative to monopolistic federalist regulation if federal law turns out to be substantially suboptimal.¹⁰³

5 A Note on Competition for Incorporations Elsewhere

The notion that jurisdictions may compete for incorporations is not confined to the United States. There is a significant literature and debate about jurisdictional competition in the European Union¹⁰⁴ and, to a lesser extent, in Canada.¹⁰⁵ If there is one take-away point from this chapter, it is that the dynamics of how firms chose rules, whether and how jurisdictions compete, and how the resulting product would compare with a mandatory regime can play out differently, depending not only on the formal requirements for choosing the corporate domicile, but also the institutional and economic context.

As to firm choice, the factors that will affect whether it will trend to the top or the bottom, and by how much, include the extent to which firms have controlling shareholders; whether shareholdings among non-controlling shareholders are highly dispersed or more concentrated; the presence of information intermediaries; the prevalence of non-law-based devices that align the interests of managers and shareholders; and the degree to which legal rules are reflected in the IPO price.

Predicting whether and how jurisdictions will compete is even harder. We do not have a good model that explains when jurisdictions will act as profit maximizers rather than as political actors. Perhaps the only factor one can identify with reasonable confidence is size: smaller jurisdictions are more likely to compete actively than larger ones. The extent to which jurisdictions will face political costs can also not be generalized. Finally, geographic and language barriers may impede competition. Thus, for example, some of the smallest countries in the European Union, such as Cyprus and Estonia, may make unlikely competitors.

Finally, multi-jurisdictional bodies can differ in the power and the political economy of the central government. Even just considering the constitutional structure, there are major differences. Thus, for example, Canada, like the United States, is a federal state; but as a parliamentary democracy with a weak upper house, it is much easier to pass legislation than it is in the US. The European Union is a treaty-based union of sovereign member states, where the governments of member states have much more influence over EU-wide (p. 127) legislation than state or provincial governments have over federal legislation in the US or Canada.

Thus, the main lesson that other jurisdictions should draw from the US experience is that it is difficult to draw any lessons. It is not only that different scholars have come to widely different conclusions regarding the three debates that make up the larger state competition debate. More importantly, however one views the dynamics that evolved in the United States, they may evolve differently elsewhere.

6 Conclusion

Absent clear evidence that federal law would be superior to the current system, one may be inclined not to advocate any major changes. For one, the devil we know may be better than the devil we don't know. Delaware law works at least tolerably well, so why take a chance and replace it with some unknown federal rules. Moreover, the current system has at least the feature that, if the political process for some reason produces a deficient law, companies can opt into a different regime.

This suggests that commentators should focus on how to improve the present regime of state competition, rather than on how to replace it. To the extent that firm choice has features that cause firms to choose suboptimal law, can these features be changed? To the extent that states do not compete (and more competition would be desirable), can more states be induced to compete?

Perhaps the most interesting proposal in this vein has been advanced by Lucian Bebchuk, writing with various co-authors. They suggest that, as a matter of federal law, shareholders should be permitted to initiate and approve a reincorporation from one state to another *without* board approval.¹⁰⁶ Although their premise is that the current system trends to the bottom, their proposal should also appeal to commentators who take a nuanced “to the top” position.

There are various complications and details with Bebchuk et al.'s suggestion that would still need to be worked out. Should large shareholders have a fiduciary duty to minority shareholders in pushing for a reincorporation? Should there be a built-in delay between the time shareholders first vote for a reincorporation and the time the reincorporation becomes effective? What would be the status of charter provisions that are invalid in the state that a company migrates to? Should shareholder power to initiate reincorporations be mandatory or should companies have the ability to opt out?

On the other hand, the proposal has some intriguing elements. The present requirement that boards recommend a reincorporation, together with the possibility that managers at least sometimes use their position on and relationship with the board to advance their personal interest, will bias firm choice at the margin downwards. This, in turn, will induce Delaware to position its law to cater more to managerial interests than it would if managers had less power over incorporation decisions. A shake-up in the rules on reincorporation may (p. 128) also induce other states to enter the competitive fray. Finally, even for “to the top” scholars, it is easy to think of reasons why Delaware would not, on its own, change its law to permit this option.¹⁰⁷ Thus, even though at present it looks as if shareholders would not avail themselves of a power to initiate reincorporations on a regular basis,¹⁰⁸ giving shareholders this power could improve the competitive dynamic and make the present regime more attractive.

(²³) The argument that some shareholders are imperfectly informed is clearly valid. But it does not necessarily follow that they will tend to vote for value-reducing mergers. It may be more rational for rationally uninformed shareholders to abstain, split their votes, vote randomly, or even systematically vote against board proposals (if they believe that most proposals are adverse to shareholder interests). These strategies would be particularly effective if there are other, better informed, shareholders whose votes would become more likely to carry the day. Whether uninformed shareholders ever followed these more sophisticated strategies, however, is unclear.

(²⁷) The extent to which legal rules (e.g., rules on hostile takeover defenses) align interests is not relevant here since these rules can, in principle, be changed through reincorporation. See, e.g., Bebchuk, *supra* note 2, 1467–70.

(²⁹) With respect to other types of rules, for example those permitting blatant forms of self-dealing, even a manager with short tenure may be able to extract the bulk of the value from the company. However, such rules are not really at issue in the state competition debate. See Bebchuk, *supra* note 2; Bebchuk & Ferrell, *supra* note 2.

But innovative rules (like rules permitting poison pills, anti-takeover laws, or the set of legal decisions originally attacked by Cary) may also often be pro-management.

(⁶⁰) There is further reason to doubt that it is network benefits that immunize Delaware from attack. To maximize its profits, Delaware should set its franchise taxes at a level where demand for Delaware incorporations is elastic (i.e., where a change in price will induce a change in the number of firms that decide to incorporate in Delaware). That about half of all public corporations incorporate outside Delaware, and that franchise tax savings are a frequently stated reason for why they do so, is consistent with such a pricing regime. So is the fact that Delaware charges higher franchise taxes to large public firms (which are likely to attribute a greater dollar value to a Delaware incorporation) than to small public firms, but still has a larger market share among large corporations. But if demand for Delaware incorporations is elastic, it follows that a state *could* attract incorporations by improving its products.

(⁷³) Ehud Kamar, “A Regulatory Competition Theory of Indeterminacy in Corporate Law”, 98 Colum. L. Rev. 1908 (1998). Although Kamar, when writing the article, assumed that other states competed with Delaware, his argument requires only that Delaware is concerned about potential competition emerging in the future. In another article, Kamar and I have argued that Delaware engages in price discrimination. In particular, Delaware’s franchise tax effectively discriminates between publicly traded firms (who attribute a greater value to a Delaware incorporation) and closely held firms (who attribute a lower value), as well as, among publicly traded firms, between larger and smaller firms. (⁷⁷) Another intermediate position, taken by Cary, *supra* note 2, and Bratton, *supra* note 8, at 418–25, is that Delaware, in some instances but not always, adjusts its law to ward off federal intervention.

(⁷⁹) Id. at 1590–1615. In a subsequent 2005 article, Roe seems to depart from his earlier claim that the threat of federal intervention is highly constraining and adopts an intermediate position similar to the one taken by Rock and myself. Roe observes that the set of groups that are influential in Delaware (e.g., managers, shareholders, lawyers) is narrower than those that wield power in Washington. As a result, the major state-level players want to minimize federal intervention, at least as long as Delaware does not adopt a lopsided law. This creates space where Delaware has room to maneuver in fashioning its law. Mark J. Roe, “Delaware’s Politics”, 118 Harv. L. Rev. 2493 (2005).

(⁸⁰) Romano, *supra* note 2. Romano, *supra* note 76, at 218, argues that the S-shaped pattern of adoption of innovations and the movement of firms from non-responsive states to responsive states are additional evidence that states compete. An S-shaped adoption pattern, however, does not show that diffusion is due to competition (see Kahan & Kamar, *supra* note 5, at 715–16) and the action of firms relate to the directional debate, not to whether states compete.

(⁸³) The same arguments that “to the bottom” commentators have advanced to argue that firm choice will trend “to the bottom” also imply that default rules do not offer protection. This suggests that erosion of rights could take the form of a state adopting a default rule offering protection (instead of a mandatory rule) with firms opting out of the rule.

Abstract and Keywords

This chapter explores the relationship between culture and law, especially corporate law, and its implications for corporate governance. It begins with an overview of the basic concepts in cultural analysis as well as prevalent theories of cultural dimensions and of social networks as social capital. It then summarizes research findings regarding the consequences of culture for corporate governance on issues ranging from executive compensation to legal transplants and the objectives of the corporation (corporate social responsibility). It also discusses relations with investors and other stakeholders by way of disclosure and dividend distribution, along with the operation, composition, and network structure of the board of directors. Finally, the chapter considers how the relationship between culture and law affects diversity and persistence in corporate governance.

Keywords: culture, corporate law, corporate governance, executive compensation, legal transplants, investors, stakeholders, disclosure, dividend distribution, board of directors

1 Introduction

¹UNDERSTANDING the role of culture in corporate governance has been a subject of growing importance since the latter concept emerged in the late 1980s and even more so since the advent of research on comparative corporate governance during the 1990s.² In the beginning, references to culture—when they were made—tended to be impressionistic. Even those references, however, evinced a newly found awareness of the idea that corporate governance is a complex system whose structure and functioning depend on more than law and economics. Today, no institutional analysis of corporate governance systems would be complete without considering the potential role of the cultural environment in which such systems are embedded. This sea change is largely due to the adoption of dimensional models of culture—an analytical framework developed primarily in social psychology. This chapter provides an overview of the different accounts of how culture in-

teracts with the law (especially corporate law) to shape corporate governance and of how this may help explain diversity and persistence in corporate governance.

To motivate the discussion, consider the People's Republic of China. Better yet, consider China together with its Hong Kong SAR, and then Taiwan, South Korea, Japan, and Vietnam for good measure. These countries, on whose significance in today's world economy one need not elaborate, share a deepseated Confucian tradition which goes back up to twenty-five hundred years ago. With inevitable differences and to various degrees, Confucian values and beliefs—namely, culture—permeate all aspects of life in this region of the world. Notwithstanding past attempts to suppress Confucian traditions in China, Confucianism is (p. 130) on the rise and is taken pride in.³ Numerous questions thus may warrant analysis. First, are Confucian values also liable to affect the working of corporate governance?⁴ Does the all-important concept of *guanxi* ("relationship" is an imprecise translation) entail implications similar to those that director networks have in US and UK firms?⁵ What to make of the fact that both Korea and China have introduced US-inspired "fiduciary duties" of board members into their corporate laws?⁶ Should one expect legally mandated independent directors in these countries to resemble their American counterparts—if not now then after some period of adjustment?⁷

The list of questions could go on. In addressing such issues of culture, law, and corporate governance, two kinds of responses are helpful only to a degree. On the one hand, one may point out that "even Confucian managers respond to incentives," as Bernard Black has noted with regard to Korea.⁸ On the other hand, a common admonition emphasizes "the need to adapt implementation to varying legal economic and cultural circumstances," as the OECD does with regard to its Principles of Corporate Governance.⁹ Both points are well taken, but they do not inform policy- and law-makers how to take culture into account short of ignoring it or just paying it some lip service. What is needed for a meaningful consideration of cultural factors in corporate governance analysis is a tractable framework for comparing cultures. Such an analytical framework could indicate, for instance, whether board members' affiliation with a social network of school alumni may entail similar implications for deeming them independent directors in different countries.¹⁰ Without such a framework, cultural analysis of corporate law and governance runs the risk of being little more than mere hand waving or telling "just-so stories."¹¹

(p. 131) 2 What is Culture and How Do We Know It?

2.1 Basic Concepts

Social scientist Raymond Williams has noted that "[c]ulture is one of the two or three most complicated words in the English language."¹² A definition proposed by the pioneering scholar Geert Hofstede considers culture as "the collective level of mental programming that is shared with some but not all other people" or the "software of the mind."¹³ Another simple yet insightful definition of culture would hold that culture defines "what

goes with what.” This definition reflects the fact that culture refers to implicit knowledge that people have about a wide variety of social practices, ranging from the conduct of leaders and lay people to clothing and food. Only rarely can one find reliable advice on “what goes with what” in guidebooks or in other formal sources.¹⁴ What is “not done” (“faux pas”) belongs in the unwritten and unspoken but still widely known in the society.

These definitions may suggest intuitions about what culture is, yet they do not provide an analytical framework for cross-cultural analysis of law and governance. According to a definition by the preeminent anthropologist Clifford Geertz, culture “denotes an historically transmitted pattern of meaning embodied in symbols, a system of inherited conceptions expressed in symbolic forms by means of which men communicate, perpetuate, and develop their knowledge about and attitudes toward life.”¹⁵ But what are these “symbolic forms”? Social scientists usually mention values, beliefs, and norms as the major components that constitute culture. Shalom Schwartz thus defines culture as “the latent, normative value system, external to the individual, which underlies and justifies the functioning of societal institutions.”¹⁶

With a meaningful definition of culture at hand, the next step is to identify the ways in which culture may influence individual conduct and social structure. The literature has pointed out two major mechanisms: constraints and motivations. The view of culture as a source of constraints is shared by economists and psychologists. The economic approach deserves some elaboration.¹⁷

(p. 132) Culture became an issue of central interest with the advent of New Institutional Economics.¹⁸ In a canonical definition of social institutions, Douglas North states: “Institutions are the rules of the game in a society or, more formally, are the humanly devised constraints that shape human interaction.”¹⁹ Oliver Williamson has elaborated this notion with a model of stratified social institutions.²⁰ The analysis of culture and law deals with the informal institutions (culture) located at Level 1 and their relations with formal institutions (law) at Level 2 in his model. According to Williamson, “Level 1 is taken as given by most institutional economists.” He further postulates that Level 1 informal institutions are “pervasively linked with complementary institutions,” both formal and informal. The resulting institutions “have a lasting grip on the way a society conducts itself.”²¹

In this view, the constraining effect of informal institutions is exogenous. Alternatively, informal institutions are modeled as endogenously appearing self-enforcing rules that are the equilibrium of a repeated game, in which the content of such institutions is common knowledge.²² Social players thus interact with partners assumed to share the same priors (beliefs) and to be guided by a similar set of motivational goals (values). The constraining effect of culture as societal common knowledge in equilibrium stems from the shared conviction that it is in everybody’s self-interest to adhere to these values and beliefs unless and until an exogenous shock upsets the equilibrium.

2.2 Cultural Value Dimensions

The thorniest challenge perhaps in introducing culture into institutional analysis stems from its complexity, which makes it difficult to derive tractable, and testable, hypotheses about its role. Cultures are rich, multi-faceted institutions with protracted histories. On the one hand, this richness enables everyone to find, in a particular culture, something to their liking and to tell a just-so story about it. On the other hand, culture’s complexity may lead an observer to avoid the details and treat culture as a “black box” but such an approach is, at bottom, similar to the former. A meaningful, rigorous analysis of informal institutions requires a methodology for operationalizing culture, i.e., identifying factors with which cultures could be represented and compared.

(p. 133) Cross-cultural psychology has made considerable progress toward developing an analytical framework for comparing cultures. A common postulate in cross-cultural psychology is that all societies confront similar basic issues or problems when they come to regulate human activity. The cultural responses to the basic problems that societies face are reflected, among other things, in prevailing value emphases of individuals.²³ Because values vary in importance, it is possible to characterize societies by the relative importance attributed to these values in society using dimensional models. This yields unique cultural profiles for societies or countries.²⁴

Among the dimensional models for cross-cultural analysis, by far the more important ones are the models advanced by Hofstede and by Schwartz. Hofstede’s pioneering and still influential dimensional framework for characterizing cultures was first published in 1980 using data that were collected from IBM employees around the world during 1968–1973.²⁵ Hofstede identified four, and later five, value dimensions: individualism/collectivism, power distance, uncertainty avoidance, masculinity/femininity,²⁶ and long-term orientation.²⁷ His framework has been used in hundreds of studies; it is widely used in studies on management and accounting and, in recent years, it has gained traction in economics. Table 6.1 provides definitions of the cultural value dimensions distinguished by Hofstede.

Schwartz developed a cultural-level theory during the 1990s and validated it in survey data that covered some 67 nations.²⁸ Schwartz derives three bipolar cultural value dimensions from three basic issues he identifies as confronting all societies: embeddedness/autonomy, hierarchy/egalitarianism, and mastery/harmony. In coping with these issues, societies exhibit greater or lesser emphasis on the values at one or the other pole of each dimension. (p. 134) Seven value orientations on which cultures can be compared derive from the analysis of the bipolar dimensions (due to a distinction between intellectual autonomy and affective autonomy). The theory also specifies the structure of relations among these types of values. Table 6.2 provides definitions of the cultural value dimensions distinguished by Schwartz. Figure 6.1 presents graphically the relations among the value dimensions and orientations as well as values that are prominent in each orientation.

Table 6.1 The Hofstede Cultural Value Dimensions

Culture and Law in Corporate Governance

Individualism/Collectivism	Valuing loosely knit social relations in which individuals are expected to care only for themselves and their immediate families versus tightly knit relations in which they can expect their wider in-group (e.g., extended family, clan) to look after them in exchange for unquestioning loyalty
Power Distance	Accepting an unequal distribution of power in institutions as legitimate or illegitimate
Uncertainty Avoidance	Feeling uncomfortable or comfortable with uncertainty and ambiguity and therefore valuing or devaluing beliefs and institutions that provide certainty and conformity
Masculinity/Femininity	Valuing achievement, heroism, assertiveness, and material success versus relationships, modesty, caring for the weak, and interpersonal harmony
Long-Term Orientation	Having a long-term time orientation; emphasizing traits of Confucian work ethic, such as thrift and persistence

Both the Hofstede and Schwartz models retain their usefulness notwithstanding a generation gap between them. The dimensions of each model bear some conceptual similarity and empirical convergence yet they do not fully overlap. Individualism might exhibit significant relations in a particular study while autonomy would not, whereas in another study egalitarianism may feature highly while power distance would not.²⁹ Each dimension thus likely captures a somewhat different social institutional feature. Between the two models, Schwartz's model is currently considered more advanced for a number of reasons. First, the model is theory-drive; its central elements having been derived from earlier work in the social sciences. Second, and most important, the model uses value measures shown to have cross-culturally equivalent meanings at the individual level to operationalize the cultural dimensions. Finally, validating data for this model were collected more recently.³⁰ In addition to the Hofstede and Schwartz frameworks, a handful of other dimensional models (p. 135) and datasets that share a similar impetus also allow for cross-cultural analysis. Because they are less frequently used and suffer from various limitations that cannot be discussed in the present scope, I abstract from them here.³¹

Table 6.2 The Schwartz Cultural Value Dimensions

Embeddedness/	This dimension concerns the desirable relationship between the individual and the group. Embeddedness represents a cultural emphasis on maintenance of the status quo, propriety, and restraint of actions or inclinations that might disrupt the solidary group or the traditional order. The oppo-

Culture and Law in Corporate Governance

Autonomy	site pole describes cultures in which the person is viewed as an autonomous, bounded entity who finds meaning in his or her own uniqueness.
Hierarchy/ Egalitarianism	This dimension refers to guaranteeing responsible behavior that will preserve the social fabric. Hierarchy represents a cultural emphasis on obeying role obligations within a legitimately unequal distribution of power, roles, and resources. Egalitarianism represents an emphasis on transcendence of selfish interests in favor of voluntary commitment to promoting the welfare of others.
Mastery/ Harmony	This dimension refers to the relation of humankind to the natural and social world. Mastery stands for a cultural emphasis on getting ahead through active self-assertion whereas Harmony represents an emphasis on fitting harmoniously into the environment.

2.2.1 Social Capital

A different vantage point for considering culture and corporate governance draws on social capital theory. While there is no agreed upon definition of social capital, much of the discourse about it is dominated by the views of James Coleman and Robert Putnam.³²

Social (p. 136) capital consists of shared values, beliefs, and norms—hence the conceptual proximity to culture. The most prominent norm is a norm of generalized trust, defined as the shared belief that most others are trustworthy and therefore have benign intentions or, more technically, the probability that two randomly chosen people will trust each other in a one-time interaction. According to Coleman, a group within which there is extensive trustworthiness and extensive trust is able to accomplish much more than a comparable group that lacks them. A social norm of generalized trust entails wide-ranging implications, including implications for corporate governance, as this norm implies lesser concern with, and perhaps lesser incidence of, opportunistic behavior in firms. This, in turn, may be conducive to economic growth and other beneficial effects.³³

Figure 6.1 The Schwartz Model of Relations among Cultural Orientations.

Operationalizing and measuring generalized trust—especially with the “generally speaking question” in Inglehart’s World Values Survey and in similar surveys in Europe and the United States—is not free of issues, however.³⁴ Indeed, the very notion of trust is currently debated and is anything but stable even as a concept.³⁵ Nevertheless, social capital theory goes beyond theories of cultural value dimensions in pointing out the centrality of (p. 137) social networks, in which social relationships and interactions are embedded.³⁶ Ties in social networks function as information channels for observing, monitoring, advising, and consulting with others, etc.

These observations point to various structural features of social networks as factors that may affect their functioning, including in corporate governance. For example, a network’s density, defined as the number of ties between actors in a network, may positively affect the flow of information. Dense networks thus may discourage opportunistic behavior within the network because defection is more likely to be observed due to lower information asymmetry. A separate line of social network scholarship initiated by Ronald Burt emphasizes a structural feature dubbed “structural holes.” A structural hole denotes weaker connections between groups that impede the flow of information between them, while providing those who can bridge a hole with opportunities to derive private benefits from such brokerage.³⁷

2.2.2 Causality

Culture used to have a bad name among economists. It was not particularly popular among lawyers either. One reason probably was that culture is very difficult to observe. One may therefore fear that people would resort to cultural explanations when they run out of good ones, as the former would be impossible to disprove—what was referred to above as “just-so stories.” This problem can be addressed by using data on cultural di-

mensions that derive from rigorous operationalization methodologies. Integrating cultural factors into institutional analyses faces another challenge, however—of showing causality. Because culture comprises values and beliefs and these factors are usually assessed using survey data, one might fear that cultural observations might be either merely epiphenomenal—namely, reflections of more fundamental factors—or endogenous with other institutional factors or policy outcomes. These concerns are well taken.

To argue that “culture matters” one therefore needs to go beyond showing significant correlations to adducing evidence for causal effects of culture. Using panel data that include observations over time may not be informative because, barring major shocks, cultures evolve over very long timespans, ranging from decades to millennia. To assess the causal role of culture on institutions and policy outcomes, scholars in the last decade thus have relied on a different approach that employs instrumental variables, some of them quite imaginative. Briefly, a good instrument should relate to culture in a meaningful way and relate to the dependent factor only through its relation to culture. Luigi Guiso, Paula Sapienza, and Luigi Zingales used historical data on wars and genetic data to gauge the impact of trust on economic exchange.³⁸ In a joint study with Chanan Goldschmidt and Shalom Schwartz, we (p. 138) introduced linguistic variables on grammar of the dominant language to establish an effect of embeddedness/autonomy on the rule of law, corruption, and democratic accountability in nations.³⁹ Another joint study, with Jordan Siegel and Shalom Schwartz, used past war experience, religion, and societal fractionalization to assess the role of egalitarianism on international investment.⁴⁰ Recent studies exploit data on the natural environment such as parasite and pathogen prevalence and on rainfall as instruments for individualism.⁴¹

3 Culture’s Consequences for Corporate Governance

3.1 Relevance

So culture matters. But (how) does it matter for corporate governance? (How) does it interact with corporate laws to affect corporate governance? According to Beugelsdijk & Maseland, “many scholars struggle with the concept of culture. It is unclear whether legal origin is seen as culture (it is, just like culture, an exogenous factor) or whether there is a relationship between legal origin and culture.”⁴²

A key insight here is that culture, as an informal institution, can address the very issues that governance, including corporate governance, calls for regulating. Formal social institutions and formal private arrangements—that is, laws and contracts, respectively—must rely on shared understandings among societal members about persons and property, about interpersonal relations, or about the dynamics of life. I have argued that in a corporate governance setting, cultural orientations regarding these issues would bear on a broad set of questions, including modes of corporate finance, primary approaches to stakeholders, shareholding structures, self-dealing, executive compensation, disclosure,

and so forth.⁴³ The cultural value dimension framework allows for opening the “black box” of culture and forming testable hypotheses about which cultural orientation may be related to a particular corporate governance issue in light of the content meaning of that issue.⁴⁴ Moreover, with an appropriate methodology, causal claims about culture’s consequences for corporate governance can be made and tested.

(p. 139) To get a flavor of how culture might impact corporate governance, consider CEO succession—one of the most significant challenges faced by every company, its board, and its shareholders. Early references to culture in this regard tended to be highly impressionistic.⁴⁵ Granted, the culture of some countries may engender rather idiosyncratic practices for ensuring the quality of controlling persons. For instance, Vikas Mehrotra et al. report that, in Japan, controlling families may adopt a brilliant executive with an average pedigree with a view to handing him (it’s him all right) the family firm.⁴⁶ This is a fascinating example that powerfully drives home the point that culture matters for corporate governance, but from this it is hard to generalize a lesson for other countries. Drawing on Hofstede’s dimensions, these authors propose in a separate study that the spread of marriage for love helps undermine the family firm as a dominant business institution in many countries by depriving those firms of suitable heirs. This tendency is linked to cultural emphases on power distance, collectivism, and uncertainty avoidance.⁴⁷ These authors further find that family firm dominance in the economy interacted with arranged marriage norms and also correlates with lower economic development, suggesting that cultural inertia may also impede convergence to more efficient economic organization.

At the most general level of analysis of the structure of economic systems—sometimes referred to as “varieties of capitalism”⁴⁸—culture has been linked to large-scale variation in such structures. Using the Schwartz dimensions, Frederic Pryor has shown that certain combinations of cultural orientations match the particular economic systems of OECD countries and in fact exert a causal effect on these systems.⁴⁹ Wolfgang Breuer and Astrid Salzmann observe that stronger cultural emphases on embeddedness, egalitarianism, and harmony in the Schwartz model correlate with bank-based corporate governance systems, whereas opposite cultural emphases correlate with market-based systems.⁵⁰ Their results are robust to legal origin, which has separately been linked to varieties of capitalism.⁵¹ Chuck Kwok and Solomon Tadesse have related the prevalence of bank-based versus (p. 140) market-based corporate governance systems to cultural emphases on Hofstede’s uncertainty avoidance.⁵²

3.2 General Relations between Law and Culture

The following sections review the relations between cultural orientations and particular subjects of corporate governance. Prior to that, this section discusses the general relations between culture and law, especially corporate law. As Williamson’s model of social institutions explicates, in a standard setting, culture and law may interact. Culture sets informal constraints and provides motivations for developing the law in a culturally compatible fashion. In tandem, societal patterns of compliance with, or deviance from, cultur-

ally compatible laws inculcate in societal members the value emphases that these laws reflect.

On a deeper level than formal legal rules there lies the institution of legality—the rule of law or, more roughly, property rights, quality of institutions, or simply institutions. A social norm of legality functions as an interface between the informal and formal institutional level. For any law, including corporate law, to operate as designed there must exist a widely shared social norm of law abidingness and law enforcement. Such a norm of legality means that the legal entitlements of societal members are respected—namely, their personal safety, tangible and intangible property (e.g., shares and other cash-flow rights in firms), and other legal interests (e.g., voting rights). Every legal system by definition calls on people to obey the law, yet countries vary greatly in the degree to which laws are followed. A social norm of legality can ensure that formal laws are followed by drawing its injunctive force from its compatibility with certain cultural values—in particular, values that underscore the legitimacy of personal interests and the moral equality of individuals.⁵³

A study with Goldschmidt and Schwartz confirms that cultural emphases primarily on Schwartz's autonomy and on Hofstede's individualism cause countries to have higher levels of legality and lower levels of corruption (which are related).⁵⁴ A follow-up study with Amnon Lehari extends this finding to greater protection of both tangible property and intellectual property in countries.⁵⁵ Claudia Williamson and Carrie Kerekes show that when both formal and informal institutional components are included in the analysis, the impact of formal constraints in explaining the security of property is greatly diminished, while informal constraints are highly significant.⁵⁶

Exogenous shocks may take place at either or both levels of institutions. For example, a major war or conquest experience can affect cultural orientations. Such is the case, for (p. 141) example, with regard to a heritage of state-formation wars during the nineteenth century that promoted an ethos of equality of sacrifice, which today associates positively with egalitarianism.⁵⁷ This is also the case with regard to a communist-rule experience, which is negatively linked to egalitarianism.⁵⁸ The level of egalitarianism in a country in turn may affect, among other things, legally mandated board representation of non-shareholder constituencies as well as other features that are conceptually compatible with egalitarianism. At the formal institutional level, the most well-known exogenous shock in the social institutions and corporate governance literature is British rule, either colonial or in other modes, which nearly invariably entailed the transplantation of a common law legal system; other colonial powers tended to implement a similar transplantation approach with regard to their home legal system. This heritage has affected a massive set of legal rules, including those on investor rights.⁵⁹

In an exploratory study with Goldschmidt and Schwartz, we observe that countries' affiliation with a common-law origin is associated with lower uncertainty avoidance in Hofstede's model, and with lower harmony in Schwartz's model. Moreover, the scores of legal rules of investor protection constructed by La Porta, Lopez-de-Silanes, Shleifer, and

Vishny (LLSV) correlate negatively with these cultural orientations, whereas LLSV's scores of formalism in the court system correlate positively with these orientations.⁶⁰ These results are consistent with the view that a history of British rule has left an impact on both the culture and on the general "legal style," with the result that these nations are more receptive to uncertain and open-ended, even entrepreneurial, mechanisms. Another set of analyses shows that classifications of countries according to legal origin and cultural region correlate with one another, in line with Williamson's theory.

In a joint study with Siegel and Schwartz, we document positive correlations between egalitarianism and a set of legal rules that support the weak in the society, especially employees, the sick, and the elderly, thus reflecting a societal stance against abuse of power.⁶¹ Hao Liang and Luc Renneboog show that an index of country-level regulatory framework in relation to sustainability—a facet of corporate social responsibility (CSR)—correlates robustly with countries' legal origin and also with their scores on some of Hofstede's dimensions.⁶² These findings together indicate that neither legal nor cultural classifications, when considered in isolation, may sufficiently account for variations in (p. 142) countries' legal regimes of corporate governance. Both levels of social institutions should be taken into consideration.⁶³

3.2.1 A Note on Legal Transplants

The idea that formal laws and the functioning of the entire legal system may depend on cultural values in turn implicates the transplantation of legal rules—possibly the most prominent means for policy reform, especially in corporate governance. Legal transplantation is explored in detail in other chapters of this volume. Here, it will suffice to make a brief note on the role of culture.

Legal transplantation may occur through different channels. Transplantation may occur involuntarily, as already noted, consequent to colonial occupation. Japan thus received a version of the Illinois business corporation law because the legal team at the headquarters of General Douglas MacArthur, the Supreme Commander of the Allied Powers after World War II, comprised of lawyers from Chicago.⁶⁴ Legal transplantation often takes place voluntarily through importation of legal mechanisms by legislators—as Korea did with regard to independent directors and US-like fiduciary duties of board members⁶⁵—or by courts—as Israel did with regard to US-like fiduciary duties of controlling shareholders.⁶⁶

Whatever may be the channel of legal transplantation, the cultural environment of the receiving country plays a significant role in determining the manner and extent to which the transplant integrates with the receiving legal system.⁶⁷ People are more likely to comply with the law voluntarily to the extent that a social norm of legality prevails in general and to the extent that the transplant is conceptually compatible with the values that the local law reflects. Young Jeong, in a sober assessment of Korea's corporate governance reform program, thus implicates different facets of Korea's Confucian culture for the limited success with which the US-oriented legal amendments have met.⁶⁸ A similar rejection of a legal transplant could take place even when the graft is synthetic rather than

harvested from a real (p. 143) legal-system donor. Bernard Black, Reinier Kraakman, and Anna Tarassova thus attributed the colossal failure of a corporate law statute for Russia, which was designed to be more immune to the weaknesses of the court system there, to the country's culture of extreme self-dealing and corruption.⁶⁹ One may note that the latter two norms reflect lower autonomy and egalitarianism.

3.3 The Objectives of the Corporation

The debate over the objectives of the business corporation is one of the oldest and probably the most fundamental in corporate law. The proposition that shareholders are the primary beneficiaries of the corporation and hence directors' duties run to them is generally interpreted as calling on corporate fiduciaries to maximize (long-term) shareholder value.⁷⁰ The literature often refers to this proposition in shorthand as the "shareholder primacy norm" or the "shareholder wealth maximization norm." In contrast to shareholder primacy there stands an opposite view—the "stakeholder approach"—which calls on corporate fiduciaries to take into account, in addition to shareholders' interest, also the interests of other constituencies, including employees, creditors, customers, and the community.⁷¹

Legal doctrine regarding the objectives of the corporation varies among jurisdictions. Although common law and civil law jurisdictions often have been characterized as, respectively, shareholder-oriented and stakeholder-oriented,⁷² even a cursory analysis challenges such a clear distinction. Thus, the laws of the state of Delaware and of the United Kingdom endorse the shareholder-oriented approach. In Delaware, the ruling in *Gheewalla*⁷³ underscored shareholder primacy and dispelled any possible ambiguities in the wake of *Credit Lyonnais*.⁷⁴ UK law authorizes board members to consider the interests of non-shareholder constituencies but subordinates the latter to a primary objective of promoting "the success of the company for the benefit of its members [shareholders] as a whole."⁷⁵ In Canada, however, the Supreme Court's ruling in *BCE*⁷⁶ endorsed an approach that balances the interests of different (financial) constituencies. Finally, Indian law is a chimera requiring (p. 144) directors "to promote the objects of the company for the benefit of its members as a whole, and in the best interests of the company, its employees, the shareholders, the community and for the protection of environment."⁷⁷

In the civil law tradition things are not clearer. German law famously vests the managing board with the responsibility "to manage the corporation as the good of the enterprise and its retinue and the common wealth of folk and realm demand."⁷⁸ In China, the 2005 revision of its corporate law requires companies to comply with "social morality" and to "bear social responsibilities."⁷⁹ In Sweden, however, the objective of business corporations is to generate profits for shareholders.⁸⁰

The decades-long debate on this subject shows no sign of abating. Meanwhile, recent research provides several insights with regard to the role of values and culture that shed new light on it. First, whatever the law might say on the objectives of the corporation, board members and top executives may adopt strategies that stray from that injunction. A

joint study with Renée Adams and Lilach Sagiv finds that in Sweden, a social-democratic economy with a shareholder-oriented company law, board members and CEOs vary systematically in their willingness to endorse strategic actions that benefit shareholders at the expense of other stakeholders or balance the interests of several stakeholders.⁸¹ This individual “shareholderism” stance is linked to directors’ personal value profile; the more one endorses entrepreneurial values as guiding principles in one’s life, the more one supports shareholder-oriented strategies, and vice versa. Managers apparently draw on their personal values in deciding what is the right thing for the firm, the law notwithstanding.

This finding at the individual level of analysis points to culture at the societal level of analysis as an institution that, in tandem with the law, can exert substantial influence on corporations’ strategic behavior in shareholder-stakeholder dilemmas. The cultural orientations that prevails in a country may affect the individual value preferences of managers and thus tilt their strategic decisions in a culturally compatible direction. In addition, and regardless of their personal values, managers may also assess the public expectations of the surrounding social environment, what would be considered publicly legitimate, and so forth, and opt for compatible strategies.⁸² Specifically, firms in more egalitarian societies would endorse more stakeholderist strategies, as this cultural orientation expresses a moral equality of all people. Higher harmony may also be related to stakeholderist strategies as it reflects lesser tolerance toward exploitation of the social and natural environment. In the Hofstede model, individualism may relate to shareholderism as the former (p. 145) connotes selfishness at the expense of others, but this conjecture is qualified by the fact that the opposite orientation, collectivism, focuses on the in-group.

Recent empirical studies provide some support for these hypotheses. A study by Siegel and Barbara Larson finds that subsidiaries of a large multinational company adjust their employment practices to the host countries’ egalitarianism levels.⁸³ In a study with Siegel and Schwartz, we show positive correlations between cultural egalitarianism and national averages of a series of firm-level CSR practices such as paying greater firm surplus to employees, voluntary (i.e., non-legally mandated) nonfinancial (CSR) disclosure, and organizational practices that consider human rights in the process of selecting or terminating suppliers or sourcing partners and which take the general community into consideration more generally.⁸⁴ Kurt Desender and Mircea Epure present a more systematic analysis, finding robust relations between egalitarianism and a set of indexes for corporate social performance (CSP).⁸⁵ Although highly suggestive, limitations of current data on CSR, among other things, render these findings tentative at this stage.⁸⁶

3.4 Relations with Investors (and Other Stakeholders)

Defined as the institutional framework that regulates the division and exercise of power in the corporation,⁸⁷ corporate governance addresses the multiple relations among corporate stakeholders, including shareholders, managers, employees, creditors, and others. This section demonstrates the role that culture may play with regard to key issues in the relations with investors and other stakeholder—namely, earnings management, as a facet

of the informational regime that governs public companies, and dividend policy, as a facet of firms' financial relations with its stakeholders.

(p. 146) 3.4.1 Disclosure: Earnings Management

Information asymmetry is pivotal in engendering agency problems. Societies, firms, and individual actors may respond to the challenge posed by agency problems through different measures of disclosure with a view to mitigating these information asymmetries. A disclosure regime regulates the way in which firms communicate with their stakeholders and with market participants more generally. Much of this communication takes place through highly formatted financial statements that are regulated by formal legal rules and accounting standards. Within this formal straitjacket, insiders may still have some wiggle room to massage the financial statements a little bit (short of cooking the books). At the heart of this endeavor lies the financial bottom line—the firm's earnings numbers. Since accounting scholars pioneered the implementation of the cultural value dimension framework, we now have a good deal of research on culture's consequences for various accounting issues,⁸⁸ including earnings management.

Earnings management is the practice of exercising judgment in financial reporting to mislead some stakeholders about firm performance or to influence contractual outcomes.⁸⁹ Corporate insiders may want to manage earnings numbers in order to be eligible to contingent remuneration, or to meet financial covenants in debt instruments, or to meet analysts' expectations to avoid an embarrassment, and so forth. Earnings can be managed to reduce intertemporal variability in reported earning ("smoothing") or to meet certain targets. In a study of earnings management around the world, Christian Leuz, Dhananjay Nanda, and Peter Wysocki have found a significant negative relation between earnings management and two measures of investor protection through the legal system—namely, legal enforcement (rule of law) and outside investor rights, proxied with LLSV's index.⁹⁰ This finding is consistent with the idea that legal systems that better protect investor rights do this also through increasing transparency about "unpleasant" information and reducing insiders' discretion in their communication with the market.

Against this backdrop, Timothy Douppnik has found that Hofstede's uncertainty avoidance correlates positively and individualism correlates negatively with earnings management across a broad cross-section of countries. Culture was found to have greater explanatory power with regard to earnings smoothing and to explain more variation than Leuz et al.'s legal factors.⁹¹ Several subsequent studies corroborate Douppnik's results and also document a negative relation between earnings management and Schwartz's egalitarianism, with some observing that formal legal measures lose significance altogether as predictors for earnings management when culture is entered in the regressions.⁹²

(p. 147) These findings suggest that societies whose culture emphasizes individual initiative and responsibility to one's actions would channel corporate managers to communicate with stakeholders in a way that does not obfuscate information. Importantly, managers exercise this discretion in reporting above and beyond the call of legal duty. The positive correlation with egalitarianism similarly expresses a shared view that all stake-

holders and market participants deserve candor. The findings for uncertainty avoidance suggest that in cultures that perceive uncertainty as threatening, managers may have a stronger inclination to present financial results in a way that conceals actual variability and conveys an image of stability and control. Others in the market tolerate and even expect such behavior as they share the same discomfort with random fluctuations.

When the findings for formal and informal institutions are considered together, the picture that emerges is one of institutional affinities and complementarities, consistent with Williamson's model. Neither law nor culture alone is sufficient for understanding how corporate governance systems function with regard to the informativeness of financial disclosure. Leuz, in another study that uses cultural groupings of countries based on Schwartz dimensions, generalizes this point with regard to investor protection and self-dealing regulation.⁹³ The upshot is that regulatory regimes that appear similar or even identical, such as IFRS accounting standards or EU directives, may nonetheless exert a differential impact depending on the cultural environment.

3.4.2 Distribution: Dividend Policy

Several theories purport to explain dividend policies.⁹⁴ Agency theory holds that dividends may serve to discipline insiders from behaving opportunistically by denying them free funds that could be extracted as private benefits or allow for managerial slack. In this view, discretionary dividend payouts may substitute for legal rights that ensure investor protection. LLSV, however, have documented a positive relation between shareholder rights and dividend payouts around the world.⁹⁵ This finding arguably supports an outcome theory of dividends—namely, that minority shareholder rights support pressures to release free cash (p. 148) to shareholders. Dividend payout increases default risk and might limit future investment such that it affects additional stakeholders like creditors and employees.

Jana Fidrmuc and Marcus Jacob have used empirical specifications similar to LLSV's, which they augmented by entering variables for cultural dimensions from Hofstede and Schwartz in addition to the legal environment variables. These tests revealed strong relations between culture and dividend payouts—specifically, positive for individualism and negative for power distance and uncertainty avoidance, and positive for autonomy and egalitarianism (negative for embeddedness and hierarchy). Among the legal factors, only some exhibited significant relations—namely, public enforcement of securities laws and (weakly) an anti-self-dealing index from Djankov et al.'s study.⁹⁶

Several other studies have looked at the relations between culture and dividend payouts, with some obtaining results in line with Fidrmuc and Jacob and others finding differently. Unfortunately, certain studies raise methodological issues that make it difficult to compare their findings, such that the empirical evidence on this subject is in some disarray. Due to scope limitations, I refer to these studies only briefly. The fuller discussion that they deserve is relegated to another occasion.

Dara Khambata and Wei Liu, indeed pioneering this line of inquiry, have reported that a propensity to pay dividends in the Asia-Pacific region associates negatively with uncertainty avoidance and long-term orientation.⁹⁷ Sung Bae, Kiyoun Chang, and Eun Kang find that dividend payout in general correlates negatively with uncertainty avoidance, masculinity, and long-term orientation, but the signs flip to significantly positive in a subsample of countries with a high anti-self-dealing legal regime (which is significant but unstable).⁹⁸ Liang Shao, Chuck Kwok, and Omrane Guedhami report negative relations with dividend payouts for mastery but, in contrast to other studies, positive relations for embeddedness; shareholder rights, per LLSV's early anti-director rights index, are positively related to dividends only in firm-level tests.⁹⁹ Finally, in an interesting paper, Wolfgang Breuer, Oliver Rieger, and Can Soypak introduce behavioral measures intended to capture patience, loss aversion, and ambiguity aversion to explain dividend policies.¹⁰⁰ For robustness checks, these authors enter some dimensions from Hofstede and Schwartz and various legal protection measures, with uneven results.

The decidedly mixed empirical findings on culture, the legal environment, and dividends, combined with the theoretical puzzle that such policies still pose, defy any coherent (p. 149) interpretation of culture's role in this setting. One thing is clear at this stage: When corporate insiders use their discretion to decide on dividend distributions, they comply with implicit injunctions of informal cultural institutions just as much, and perhaps even more strongly, as they respond to formal legal constraints.

3.5 Executive Compensation

Few issues of corporate governance trigger heated debates and (sometimes frenzied) regulatory intervention in the way that executive compensation does. Executive compensation is a complex issue and corporate governance is only one aspect of it.¹⁰¹ Whether one subscribes to the "managerial power" theory of executive pay or to the "optimal contracting" theory, there is no denying that executive compensation is set by corporate insiders who enjoy discretionary power. This may call for institutional regulation. This section focuses on the role that culture may play in this setting.

In a speech given by the Governor of the Bank of England, Mark Carney, at the World Economic Forum's annual meeting in Davos, stated: "[W]hile regulators . . . can determine the appropriate split of remuneration between fixed and variable elements to limit risks to financial stability, only society, not regulators, can determine whether the absolute and relative levels of compensation are acceptable."¹⁰² Like a good shepherd, Mr. Carney knows his flock. Basing his point on in-depth interviews with UK FTSE100 CEOs, John Hendry observes that these CEOs emphasize values of professional achievement and competitiveness more than the wealth aspects of their pay, which they do not consider as an incentive.¹⁰³ Anna Zalewska has found that in British companies, the greater the pay dispersion within the board, the worse firm performance is, in contrast with findings for the US—a result she relates to British boards being less individualistic and hierarchical than their American counterparts.¹⁰⁴

Separately from asking whether firms pay their top executives for performance, the debate over executive compensation revolves around the question whether managers are paid “too much.” As Carney’s remarks indicate, societal stances may implicate both the level of pay and, perhaps more acutely, the relative level of executive pay in comparison to some benchmark. Cultural orientations may influence executive pay packages through the channels discussed in this chapter: first, through individual value preferences and beliefs about the “right” pay of the people who are parties to the bargain—namely, the executive herself, the board, the board’s compensation committee, and compensation consultants;¹⁰⁵ second, (p. 150) through widely shared beliefs and values about what is acceptable in executive pay, such that straying too far from that consensus would instigate public reaction adverse to the firm;¹⁰⁶ third, indirectly, through culturally consistent legal regulation that affects executive pay.¹⁰⁷ Director networks work to disseminate information (namely, beliefs) about pay practices among connected firms.¹⁰⁸

There is now substantial evidence that cultural orientations are indeed associated with the structure of executive compensation, in line with the hypothesized mechanisms. Henry Tosi and Thomas Greckhamer have found that total CEO pay, the proportion of variable pay to total compensation, and the ratio of CEO pay to the lowest level employee pay correlate positively with power distance. The first two factors also related positively with individualism.¹⁰⁹ Greckhamer later expanded that analysis, observing more nuanced relations between configurations of cultural dimensions from Hofstede and differences in compensation level and compensation inequality.¹¹⁰ Consistently with these findings, in a joint study with Siegel and Schwartz, we document negative correlations between egalitarianism and the ratio between CEO wage and average production worker wage.¹¹¹ Natasha Burns, Kristina Minnick, and Laura Starks find that CEO tournament pay structure—measured by the gap or ratio between CEO pay and the pay of the next highest-paid executives—associates positively with power distance and with measures of a society’s perceived desirability of income inequality and competition from the World Values Survey.¹¹² Stephen Bryan, Robert Nash, and Ajay Patel examine another prominent feature of executive compensation that focuses on incentivizing executives.¹¹³ These authors observe, while controlling for the legal environment, that the relative use of equity-based compensation associates with individualism (positively) and with uncertainty avoidance (negatively)—namely, with a cultural environment that is compatible with shareholders’ interests and entrepreneurship more generally.

(p. 151) 3.6 The Board of Directors

The board of directors is the epicenter of power relations in the corporation. It is therefore a key component in firms’ corporate governance. At first glance, the board is a universal phenomenon. Companies have invariably had boards at least since the East India Company was chartered in 1600. Doctrinally, the board of directors holds the power to manage or direct the management of the company’s business. With various secondary differences, this is the law in virtually all common-law jurisdictions as well as in other legal systems.¹¹⁴ The OECD Principles of Corporate Governance provide a modern rendition of the board’s dual mission—namely, to provide strategic advice and monitor the manage-

ment.¹¹⁵ Although they lack legal force and may not precisely reflect the corporate laws of all countries, the OECD Principles do reflect a universal consensus on the board's responsibilities.¹¹⁶

This image of universality may be misleading, however. When one examines national laws in more detail, numerous differences emerge, especially with regard to the structure of the board (e.g., unitary or two-tiered) and its composition (e.g., worker representation in the board).¹¹⁷ Recent research indicates that formal legal differences, regardless of whether they are consequential or not, may be just the tip of the iceberg. Both the functioning of the board and its structure may also be shaped by informal, cultural orientations. This section reviews current evidence on these issues.

3.6.1 Operation: Board-CEO Relations

Of the two limbs that constitute the board's dual mission, the responsibility to monitor the management has attracted more scholarly attention than has strategic advice. This special interest in monitoring likely stems from the prominence of agency theory, which underscores the need to monitor corporate insiders lest they utilize their discretionary power opportunistically for their personal benefit. Other theories, however, provide different accounts of the relations between the board of directors and the top management team. These theories adopt perspectives beyond agency, including perspectives based on resource dependence, upper echelons, stewardship, social networks, and institutional.¹¹⁸ Among the latter, several theories draw on insights from behavioral science and institutional analysis to highlight the role of values, shared beliefs, social norms, and, at bottom, cultural orientations in (p. 152) molding the interactions between the board and the CEO with regard to both monitoring and strategy setting.¹¹⁹

Craig Crossland and Donald Hambrick have examined the impact that formal and informal institutions exert on discretion at the top management team, particularly by CEOs.¹²⁰ Managerial discretion exists when managers can choose a line of action from a set of viable options. It is a joint product of stakeholder open-mindedness about executive actions and stakeholder inability to block objectionable actions. The scope of discretion thus is affected by what firm stakeholders perceive as possible and acceptable—in other words, on shared beliefs about “what goes with what” or what is “done” or “not done.”

Crossland and Hambrick's results indicate two underlying institutional factors (“themes”) that are positively linked to managerial discretion. One factor consists of individualism and looseness; the other factor combines informal and formal institutions as well as factual circumstances—namely, uncertainty tolerance (reversed uncertainty avoidance), common law legal origin, employer flexibility, and ownership dispersion. These factors reflect the degree to which a country allows individuals to take unilateral, idiosyncratic actions and the degree to which a country tolerates bold, deviant, and risky actions.¹²¹

Drawing on these insights, Crossland and Guoli Chen examine the institutional factors that may lead to greater executive accountability in the form of CEO dismissal in the wake of poor financial performance.¹²² These authors find that CEOs are more likely to

be thus dismissed in countries where managerial discretion is higher, where financial performance measures are more meaningful, for example due to lower earnings management, and also where the legal system has a common-law origin.

These findings weave together several threads that this chapter has already identified. Corporate governance operates differently in different institutional environments in one of its most important tasks. Post-failure CEO dismissal is a particular social norm of accountability that serves to regulate agency problems in firms in a context that is notoriously resilient to formal legal regulation.¹²³ This norm depends on another social norm regarding managerial discretion, on yet another social norm dealing with earnings management, and on the general style of the legal system. The latter institutions in turn draw on fundamental cultural orientations that promote entrepreneurship as they emphasize individual autonomy and tolerance of uncertainty. Thus, we have here a pyramid of norms in which each stratum interacts with and is conceptually compatible with strata above and below it.¹²⁴

(p. 153) 3.6.2 Composition: Board Diversity

Until not too long ago, a typical US board was dominated by white, mid-fifties, wealthy male executives who were predominantly Protestant and Republican.¹²⁵ From a contemporary comparative perspective, however, boards around the world today exhibit at least some diversity in terms of non-executive (independent) members, gender composition, or employee representation, often due to legal requirements. The composition of boards has attracted special attention, and diversity in board composition is subject to heated debates.¹²⁶ Social activists have been calling for even greater gender and ethnic diversity, and policy makers have not been oblivious to these calls, especially in Europe.¹²⁷ To paraphrase von Clausewitz on war, legal regulation of board composition has been and remains the continuation of politics by other means.¹²⁸ The political skirmishes in Europe over board diversity echo a stream in the corporate governance literature that argues that political forces have stood behind many major corporate governance reforms.¹²⁹ Legal reforms in Europe with regard to gender diversity in fact were not confined to boards but have also encompassed political parties.

Culture's role in shaping board composition should be analyzed against this backdrop. Extensive research, both theoretical and empirical, shows that the ways boards fulfill their mission are endogenous. What the board in fact does and how it is structured in a particular firm may be both a cause and an outcome of other factors, including the firm's industry, its stage of development, its financial needs, the individuals in the top management team and on the board itself, and so forth.¹³⁰ Informal institutions would be a potentially important part of this setting—again, functioning both as constraints and as motivators (“isomorphic pressures” in the sociological parlance) for molding board composition to accommodate shared values and beliefs.

From a comparative vantage point, cultural orientations thus stand out as factors that may exert a differential effect on board composition in different countries. For example, a cultural emphasis on egalitarianism likely will buttress social norms on gender equality

that would facilitate a higher female presence on boards as well as in other institutions—e.g., (p. 154) parliaments. Western Europe indeed provides a good example for such an institutional environment, as it scores particularly high on egalitarianism on average and boasts several interventionist pro-gender-diversity initiatives. Similarly, higher egalitarianism may encourage employee representation in boards as a constituency that is also vulnerable to firm performance, in addition to shareholders. Western Europe again comes to mind.¹³¹ In societies that emphasize entrepreneurship more, which would be reflected in higher individualism, lower uncertainty avoidance, and lower harmony, we would expect board composition to be aligned with (outside) shareholder interests—e.g., by having more independent directors.

Plausible as these hypotheses may seem, relatively little research thus far has addressed the role that culture might play in determining board composition. Jiatao Lee and Richard Harrison find that the percentage of outside directors in boards of multinational firms from 15 countries correlates positively with uncertainty avoidance, individualism, femininity, and power distance.¹³² (Except for femininity, similar links were observed for a tendency to consolidate the CEO and Chair positions.) Consistent with the view of boards as endogenous institutions, these findings suggest that the structure of the corporate leadership body also conforms to cultural orientations. These authors did not control for legal requirements, however. That the observed correlations differ from those hypothesized above may suggest that in the sample firms, outside directors do not care solely for outside shareholders but rather for a broader set of stakeholders, who might be less enthusiastic about entrepreneurial strategies.

Johanne Grosvold reports that the percentage of women in the boards of firms from some 50 countries correlates positively with power distance and negatively with uncertainty avoidance, controlling for a set of country- and firm-level factors, though not for legal ones.¹³³ Grosvold and Stephen Brammer separately examine national average percentages of women on boards across regions classified by culture, legal origin, or other institutions.¹³⁴ Although these authors claim that cultural and legal factors appear to play the most significant role in shaping board diversity, their findings do not lend themselves to coherent interpretation.

3.6.3 Structure: Director Networks

In recent years, there has been a flurry of studies on corporate governance and social capital as embodied in social networks. Research thus far has focused on director networks, in which board members also serve as CEOs or as board members in additional companies.¹³⁵ It appears that director networks work as advertised, according to social capital theory, to (p. 155) facilitate information exchange as well as mutual commitment and trust.¹³⁶ In some cases this may prove helpful for attaining strategic resources such as information on growth opportunities or outside managerial talent.¹³⁷ More extensively connected, and hence more powerful, independent directors are economically and statistically positively correlated with shareholder valuations, possibly because more socially powerful independent directors have better information and more influence.¹³⁸

The upshot may also be detrimental to the interest of the company and of its outside shareholders, however. Several studies have associated more extensive director interlocks with higher CEO pay and with less performance-sensitive CEO pay and tenure, indicating reduced monitoring.¹³⁹ Among other things, social acquaintances may engender these adverse effects through compromising the efficacy of formally though not actually independent directors¹⁴⁰ or through propagation of bad practices such as option backdating.¹⁴¹

Assessing the relations between culture and board structure in terms of social network configuration begins with the observation that social networks undergird groups. Social networks constitute one's location in the group and one's linkages with other group members. Social networks, however, are merely a structural concept. They are devoid of content meaning, shorn of any normative implications. In the corporate governance context of board structure, individual board members have power that calls for social regulation. They can follow several lines of action that may sustain multiple equilibriums. This is where (p. 156) culture comes into play. When one is embedded in a particular cultural environment, one takes for granted "what goes with what" in light of the values and beliefs that one shares with other societal members. Holding a position with a high level of centrality in a network of board members or being located in a structural hole of such a social network thus may entail different implications in different cultures. In sum, social capital is also culturally contingent for board members.

The relations between the individual and the group are the primary issue that every society needs to address. Societal stances on this issue constitute the most fundamental social institution. These stances are captured by their location on Hofstede's individualism/collectivism dimension and in Schwartz's autonomy/embeddedness. As noted, the autonomy/embeddedness and individualism/collectivism dimension overlap conceptually to a degree. Both concern relations between the individual and the collective and both contrast an autonomous with an interdependent view of people. However, the dimensions also differ. For instance, individualism implies self-interested pursuit of personal goals while selfishness is not a characteristic of cultural autonomy. Collectivism more than embeddedness highlights ingroup boundaries as delineating the scope of unquestioning loyalty. The correlation between these dimensions is substantial but far from complete.¹⁴²

Research on culture's consequences for social networks is in its infancy at this stage. Scholars have pointed out the importance of individualism versus collectivism for social network analysis, contrasting Western (usually North American) culture with East Asian (usually Chinese) culture. A related concept is the very elaborate set of relational norms known as *guanxi*, which traces its roots to Confucian philosophy and calls on individuals to cultivate the right *guanxi* through extensive, continuing exchanges.¹⁴³ For instance, the scope of people that one might trust seems to be substantially narrower in Confucian countries than in Western countries.¹⁴⁴ This is consistent with a collectivist view of ingroup members only as trustworthy, whereas people in individualistic cultures are less

likely to hold such a bifurcated view of “most others” for purposes of the “generally speaking question” on trust.¹⁴⁵

Business organization scholars are beginning to investigate whether the wisdom of social capital in terms of centrality and structural holes (or similar concepts from the current terminological thicket) applies equally in collectivist cultures.¹⁴⁶ The basic idea, as Zhixing Xiao and Anne Tsui put it, is that “[p]eople who stay at the boundary of two ingroups tend to be distrusted by both groups—both ingroups are likely to regard them as out-group members who do not deserve ingroup treatment . . . Simple and dense networks that represent clear group membership, rather than networks full of structural holes, constitute resources for social actors.”¹⁴⁷

(p. 157) Applying these insights to corporate governance implications of board structure may require careful consideration before extant evidence of the sort mentioned above could be extended to other cultural settings. In doing so, attention should be paid to the dual mission of the board—namely, of strategic advice and of monitoring. The strategy task revolves around board members serving as sources of out-of-firm information and similar resources thanks to external background or linkages. The monitoring task crucially hinges on a certain detachment between directors—especially independent directors—and firm insiders. As the very notion of being “independent” or “external” entails different repercussions in cultures high on collectivism and embeddedness, we should expect such directors to fulfill their tasks differently. Furthermore, since boards are endogenous institutions, we should expect their composition too to reflect the different cultural environment. Outside board members with multiple directorships may not be able to provide valuable information because nobody will supply them with such information, which is reserved for ingroup members. The Japanese family firm practice of adopting adult executives suggests the extent to which societies might go to “familiarize” managers with the firm and its controlling shareholders.¹⁴⁸ On the other hand, such board members might prove to be better monitors if they feel less pressure to socialize within the firm and become part of the ingroup.¹⁴⁹

The above conjectures are preliminary hypotheses that warrant further theoretical development and empirical testing. In tandem, these cultural differences call for careful assessment of legal measures intended to improve corporate governance by imposing “true and tested” fiduciary duties inspired by common-law sources.¹⁵⁰ A standard common-law duty of loyalty requires any fiduciary, directors included, in the strongest of terms, to act in absolute disinterestedness. Practical issues of implementation aside, such a duty is premised on a view of people as autonomous entities, in line with cultural individualism and autonomy. Such a legal duty may not sit well with a social norm of *guanxi* in a board whose members maintain extensive relations with other members in the company.

4 Conclusion

This chapter has surveyed the literature on culture, law, and corporate governance with a view to establishing the importance of considering both formal (legal) and informal (cultural) institutions in the analysis of corporate governance systems. It is hoped that that goal has been met with some success. In an early paper that called for adopting the cultural value dimension framework for such analyses, I referred to culture as “the mother of all path dependencies.”¹⁵¹ The body of scholarship that has since accumulated seems to support the contention made at that time: “At the risk of stretching the mother metaphor a little bit, it can be argued that culture may indeed be perceived as an old mother. It knows a lot, but some of (p. 158) this knowledge might be obsolete today; it is sometimes nagging; it will resist change unless absolutely required. Most importantly, it must not be ignored.”

More work can be done toward revealing additional facets of the relations between corporate governance and culture. Institutional environments in Asia (again, think China) and even in Europe differ markedly from those that prevail in English-speaking countries. Understanding these environments will help policy- and lawmakers to develop corporate governance systems more effectively. To achieve this goal we will need to advance our knowledge beyond observing correlations of the sort that was reviewed here toward a more elaborate understanding of the relations between law and culture. Looking to the road ahead, it is fitting to conclude this chapter with a contemporary quotation from Michael Bond, who together with Hofstede and Schwartz, is among the founders of modern cross-cultural research:

Hypothesizing that this or that Chinese population should be higher (or lower) than mainstream Western norms on this or that construct because this particular Chinese societal context is higher (or lower) than that other comparison context on Hofstede’s, House’s, Schwartz’s, Inglehart’s, or Leung and Bond’s national-level “cultural” dimension of X will not make the cut—there are simply too many ways to challenge such results, even if confirmed. . . This kind of simplistic, straightforward work informed the earlier cataloguing period of diverse phenomena, which was characterized as the “Aristotelean” era of the cross-cultural discipline. . . That was a time for documenting differences in organizational phenomena across cultural groups, a time for establishing the potential of the cross-cultural enterprise. That agenda was met and, in our opinion, that time has now passed.¹⁵²

A Behavioral Perspective on Corporate Law and Corporate Governance

Jaap Winter

The Oxford Handbook of Corporate Law and Governance

Edited by Jeffrey N. Gordon and Wolf-Georg Ringe

Print Publication Date: May 2018 Subject: Law, Company and Commercial Law

Online Publication Date: Jun 2015 DOI: 10.1093/oxfordhb/9780198743682.013.17

Abstract and Keywords

This chapter examines corporate law and governance from a behavioral perspective. It begins with an overview of the growing body of behavioral knowledge and its impact on the core assumptions of the agency theory. It then goes on to consider a number of specific areas of corporate law and governance where behavioral perspectives are particularly relevant, with particular emphasis on rule making. The chapter also explores how the board of directors performs, along with modern executive compensation systems, often in the form of performance-based pay. Finally, the chapter turns to the interaction between executives, non-executives, and (institutional) investors in corporate governance.

Keywords: corporate law, agency theory, rule making, board of directors, executive compensation, performance-based pay, executives, non-executives, investors, corporate governance

1 Introduction

LAW and lawyers traditionally have been rather self-occupied. The study of law focuses on the law as a world in and of itself. To understand it, one must understand key legal concepts that have specific meaning within the law, that generate consequences in law, but also how law and rules are made and applied in specific circumstances, and the fundamental, immovable principles as well as the dependent, context-sensitive principles that govern these processes. Unalienable legal notions such as justice and fairness form part of this understanding of law upon which specific rules and decisions are based and which can even limit the application of specific rules. Lawyers, courts, and legal scholars engage in a constant process of ordering these legal concepts, deducing appropriate rules and decisions, seeking consistency and predictability or criticizing the lack thereof, and sometimes pleading or deciding to change course fundamentally because reality has moved on and requires a new approach. In those latter cases one can see a glimpse of the connection between law and reality that the legal process itself often obscures.

A Behavioral Perspective on Corporate Law and Corporate Governance

In such an inwardly looking legal environment there is little need for lawyers, lawmakers, judges, and legal scholars to have a deep understanding of the reality that is touched by a legal rule or decision. Legal education and legal research as a result also primarily focus on (deepening the) understanding (of) law, legal concepts, and practices from this intrinsic perspective. The economic analysis of law ("Law & Economics") has forced the law to open up to an outside-in perspective. The economic analysis of law questions whether features of the law are economically efficient in terms of maximizing social wealth. Legal rules and case decisions may be consistent, predictable, and even fair, but if they do not facilitate that goods and services end up with those who value them the most, these rules and decisions are not economically efficient and therefore, from an economic perspective, should be changed. (p. 160) This has forced lawyers to rethink what the objectives of the law actually are and how it can be demonstrated that these objectives are met.

The economic analysis of law has been criticized severely by lawyers ("economic efficiency is not the only or most important end of law," "economic analysis of law requires a set of simplifying assumptions that determine the results of the analysis and therefore cannot be applied to real-life situations," "economic analysis cannot value properly such intrinsically legal notions as fairness and justice," and "economic analysis of law reduces law to an instrument to achieve objectives outside law, destroying the built-in integrity of law").¹ Nonetheless it has become the dominant approach to law, particularly in the field of corporate law and corporate governance.

Much of the economic analysis of corporate law and corporate governance that we have seen is methodically mathematical, seeking to establish significant correlations between data. This may blind us from seeing that economics is basically an attempt to understand human behavior. At its core is the presumption that human beings act as rational economic agents acting in their self-interest. Theories are based on this presumption that have had a profound influence on the understanding of corporate law and corporate governance, the most significant of which is the agency theory. This theory positions managers of a company as agents on behalf of shareholders, who, as residual claimants, are the principals. As rational actors, managers will pursue their own interests, which are not necessarily in line with the interests of the principals, and this perspective has created the dominant approach to corporate law and corporate governance. Agency theory suggests that it is the purpose of corporate law and corporate governance to deal with this "agency problem" in order to ensure that the interests of shareholders as principals are sufficiently protected. The focus has been on the rights shareholders should be able to exercise, on the monitoring of executive directors by non-executive directors and by external auditors, on executive remuneration that seeks to align the interests of executive directors with the interests of shareholders, and on takeover bids as a mechanism to discipline executives. These have also become the dominant themes in the legal analysis of the corporate setting. This, in its turn, has determined to a large extent the extensive regulatory agenda in the field of corporate law and corporate governance of the last decade and a half.

A Behavioral Perspective on Corporate Law and Corporate Governance

In more recent years the key assumption of the *homo economicus* acting rationally in his self-interest has been challenged by academics from other behavioral fields and also by economists who have taken on the insights from these other fields to develop the study of behavioral economics. Academics from fields such as psychology, neuropsychology, neurology, evolutionary psychology, sociology, and philosophy have started to challenge the assumptions underlying economic as well as legal theorizing.

The field of behavioral studies is enormous and quickly expanding. In this chapter I will not make an attempt to capture all behavioral insights that potentially are relevant for corporate law and corporate governance. I will first set out how the growing body of behavioral knowledge affects the core assumptions of the agency theory, which renders it at best an incomplete approach to corporate law and corporate governance (section 2). I will then address a number of specific areas of corporate law and corporate governance where (p. 161) behavioral perspectives are particularly relevant. In section 3, I will address behavioral perspectives relevant to rulemaking in corporate law and corporate governance. These are particularly relevant as after the governance crisis and financial crisis we saw a general tendency to increase (mandatory) rules to enforce responsible human behavior in corporate and financial affairs. The regulatory push completely ignores what rulemaking does to people's sense of responsibility for their behavior. In section 4, I take a closer look at how to understand board performance. The agency theory has triggered an expanding field of financial economics, seeking to correlate elements of boards and their composition as regulated in law to company performance. This is one of the core issues of the current corporate governance debate. However, none of this research can truly explain how boards perform. This would require opening the black box of the board and asks for different, behavioral methods of research.

Section 5 will deal with modern executive remuneration systems, typically in the form of performance-based pay. This seeks to align interests of executives with those of shareholders but is based on flawed mechanical assumptions about human performance.

2 Agency Theory and its Defects

The core idea of agency theory, that managers as agents for shareholders as principals do not necessarily have the interests of shareholders at heart when they take decisions as managers of the company, comes across as sensible. It is a relevant insight for anyone who is interested in relationships within the corporation and it poses relevant regulatory questions on how to deal with the principal-agent conflicts in corporations. In fact, corporate law has dealt with agency problems since its incubation and well before anybody framed the potential conflicts of interests between managers and shareholders, or between controlling shareholder and minority shareholders, as agency problems. Economists have sought to understand and calculate the agency costs triggered by these agency relationships, for example the costs of measuring a manager's performance, the costs of monitoring and bonding activities, the costs of receiving information on the manager's behavior, etc. Elements of corporate law are then judged by their tendency to

reduce these agency costs. The more they do, the more efficient in economic terms they are. In order to be able to make those calculations, the theory in an effort to simplify things, takes two crucial starting points: (1) a manager as agent makes rational decisions, and (2) a manager always maximizes his own economic gains.² This is where the economic approach, for the sake of being able to build a model that allows for more or less straightforward calculations, takes an absolute turn that does not reflect how people really behave.

From a behavioral perspective criticism can be raised against the agency theory.

(p. 162) 2.1 Not that Rational

A vast and expanding body of research suggests that we are not the rational decision makers that agency theory assumes. Our rationality is bounded. Our judgment and thinking, based on information that we are aware of, are limited and biased in systemic, predictable ways.³ But our awareness is bounded as well, which prevents people from noticing or focusing on useful, observable, and relevant information. Finally, our ethicality is similarly bounded by psychological processes, leading to questionable behavior by individuals who contradict their own preferred ethics.⁴

People rely on a number of simplifying strategies, or heuristics, when making decisions. Heuristics help us to make sense of complex situations in which we need to make decisions. Most of the time we do this intuitively, without any special thought. Kahneman and others have made the distinction between System 1 and System 2 in the mind.⁵ System 1 operates automatically and quickly, with little or no effort and no sense of voluntary control. System 2 allocates attention to the effortful mental activities that demand it, including complex computations. In most situations our System 1 thinking is quite sufficient. System 1 thinking, among others, allows us to detect that one object is more distant than another, orient the source of a sudden sound, answer $2 + 2 = ?$, and drive a car on an empty road. Errors in our thinking occur frequently in System 1 thinking. These errors are called biases. Numerous cognitive biases have now been identified.⁶ Some of the best known, and also relevant to decision making by managers and boards, are the *overconfidence* bias (the tendency to underestimate risks and overestimate own abilities)⁷; the *escalation of commitment* bias (the tendency to increase investment in a decision based on cumulative prior investment despite evidence that the cost of continuing outweighs its expected benefit)⁸; the *availability* bias (the tendency to believe that events in vivid memory have a higher probability of occurring than they actually have)⁹; the *self-serving* bias (the tendency to attribute success to personal factors and failures to external factors)¹⁰; the *loss-aversion* bias (the tendency to value avoiding losses more than the prospect of gains)¹¹; and the *confirmation* bias (the tendency to search (p. 163) for and accept as valid or true information that confirms prior held beliefs or preferences).¹² Some of the System 1 biases are so strong that they prevent attentive, effortful System 2 thinking to correct them. Kahneman says: “The best we can do is a compromise: learn to recognize situations in which mistakes are likely and try harder to avoid significant mistakes when the stakes

are high. The premise of this book is that it is easier to recognize other people's mistakes than our own."¹³

People are constantly at risk of finding themselves overwhelmed by too much information. To protect themselves against this overload, people consistently engage in information filtering, much of which is carried out unconsciously and automatically. Sometimes this leads to inattention blindness. A popular example is the clip of the "moonwalking bear" passing through two teams of basketball players that goes unnoticed to the vast majority of viewers.¹⁴ Similarly, people have a tendency not to notice change in their physical environments, as is shown by the "colour-changing card trick."¹⁵ Inattention and change blindness are likely also to occur in realms outside visual perception.¹⁶ Focalism or the focusing illusion is the tendency of people to overestimate the degree to which their future thoughts will be occupied by an event on which they focus. Or as Kahneman says it: "Nothing in life is as important as you think it is when you are thinking about it."¹⁷

Our moral judgments are also subject to flaws in our thinking process. People have an innate ability to maintain a belief while acting contrary to it. There is also a tendency to evaluate one's own moral transgressions differently than those of others, applying a self-serving double standard. People tend to focus more on their contribution to a joint effort than on the efforts of others. Organizational practices and language can contribute to ethical fading, framing decisions, for example, as business decisions rather than ethical decisions. Cognitive busy participants in a study were more likely to cheat on a task than less overloaded participants.¹⁸ As long as we cheat by only a little, people also tend to rationalize their behavior so as to benefit from cheating and still maintain a view of themselves as honest people.¹⁹

It is good to note that not only managers as agents are subject to bounded rationality, bounded perception, and bounded ethicality, but also those who take positions as monitors of managers on the basis of the argument of agency theory, such as non-executive directors and external auditors. The same systemic biases and social pressures may cloud the professional judgment of non-executives.²⁰

(p. 164) Cognitive errors may have played a crucial role in governance and financial crises. Ben-David, Harvey, and Graham found that companies with overconfident CFOs apply lower discount rates to value cash flows, use more debt, and are less likely to pay dividends.²¹ Schrand and Zechman found that overconfident executives are more likely to initially overstate earnings which start them on the path to growing intentional misstatements or frauds.²² The availability bias makes us forget after a while that every now and then a big crisis will happen and think that now it is different, which is confirmed by every day and year of good financial performance.²³ The loss aversion bias may have contributed to the collapse of Lehman Brothers. Dick Fuld, CEO of Lehman Brothers, held a capital interest in Lehman Brothers that at one time was valued at \$475 million. In the last year leading up to the collapse of Lehman Brothers, Fuld decided to increase the exposure of Lehman Brothers to toxic mortgage-backed securities, at the same time spend-

ing hundreds of millions on share buybacks, exposing the company and its shareholders to ever more risks.²⁴ Kahneman and Tversky found that people are risk-seeking when all the options are bad. If given the option to choose between getting €900 for sure or having a 90% chance of getting €1,000, most people would choose to get €900 for sure. The subjective value of a gain of €900 is more than 90% of the value of a gain of €1,000. But if given the option to choose between losing €900 for sure or having a 90% chance of losing €1,000 most people choose the 90% chance of losing €1,000. The sure loss is very aversive and this drives us to take the risk.²⁵ *Skin in the game* may be a good thing when all the options are good, but may lead to disaster if the options all become bad.

2.2 Not that Selfish

The assumption that the agent always maximizes his own wealth has also been criticized in behavioral studies. Numerous studies point out that in given situations where a rational self-interested choice would lead to taking a certain decision, the majority of people in fact take the opposite decision. The well-known prisoner's dilemma is a case at hand. Two suspects are put in separate prison cells. Each is told that if neither of them confesses they will both be charged with the crime and be sentenced to one year in jail. Each prisoner is also made an offer: if he decides to confess and to implicate the other, he will go free while the non-confessing partner will be sentenced to 15 years in jail. Finally each of them is told that if they both confess both will be convicted and sentenced to ten years in jail. A rational choice for each of the two prisoners is to defect and get a lower sentence than when not defecting, which is true regardless of whether the other prisoner defects or not. But in reality people often choose to cooperate. This has been demonstrated in hundreds of studies.²⁶ Similarly, (p. 165) in ultimatum games two players need to decide how to divide a sum between the two. The first player makes a proposal to the second player who can either accept or refuse. If the second player rejects, neither receive anything. If the second player accepts, the money is split according to the proposal. If the proposer would be a rational and purely selfish *homo economicus* he would offer the lowest amount possible. If the responder would act as a true *homo economicus* he would accept the lowest amount that can be offered. But in reality the proposer often offers a substantial portion of the stakes, most frequently half. And the responder often rejects the offer when it does not provide him with a substantial portion of the stakes, typically rejecting offers below 30%.²⁷

Many of these and other social dilemma games have been played and studied under a wide variety of conditions. They show that people routinely act unselfishly, sometimes sacrificing their own payoffs to increase others' (altruism), sometimes to hurt others (spite).²⁸ The cooperative behavior of people has been studied at length, by academics from different fields. For example, the volume *Moral Sentiments and Material Interests*, edited by Herbert Gintis and others,²⁹ provides an overview of research in economics, anthropology, evolutionary and human biology, social psychology, and sociology dealing with the theoretical foundations and policy implications of cooperative behavior. It is clear that forms of reciprocity play a crucial role. Weak reciprocity may occur in the case of repeated interactions between people, when factors such as individual reputation and punish-

ment of norm violators play a role. Under those conditions reciprocity may actually be seen as a form of self-interest. But numerous experiments indicate that people also display strong reciprocity in non-repeated sessions: acting kindly to actions that are perceived to be kind and in a hostile way to actions that are perceived to be hostile, both at the cost of personal gain. Many people exhibit strong reciprocity but not everybody. Most studies indicate that a substantial number, but not the majority, of people behave in a purely selfish way.³⁰ The results of these experimental studies are also culturally robust in the sense that in no culture is the canonical model of self-regarding behavior supported. The level of behavioral variability across cultures, however, is considerable. Differences between societies in levels of market integration and cooperation in production may explain about half of this behavioral variation.³¹ These authors dryly note that the Law & Economics analysis, with its abstraction from reciprocity and other non-self-regarding motives, limits its general relevance.

Many economists have now accepted that the assumption of the rational, personal wealth maximizing *homo economicus* may help economic modeling but has at best only limited relevance for understanding human behavior and developing policy decisions.³² Jensen and (p. 166) Meckling themselves have said that “the economic model is, of course, not very interesting as a model behavior. People do not behave this way. In most cases use of this model reflects economists’ desire for simplicity in modeling; the exclusive pursuit of wealth or money income is easier to model than the complexity of actual preferences of individuals”.³³

2.3 Social Context Matters

In yet another aspect, the agency theory is too limited a theory on which to base a full understanding of human interaction in the corporate environment. The agency theory focuses on the pursuit and control of individual agency, not taking into account the social context in which such agency takes place. Individuals operating in that social context form interpretations of the social context, which in turn are socially constructed or constituted. Westphal and others have undertaken extensive research on the social situations in which corporate governance actually takes place, such as social relationships, networks, and institutions that shape individual agency, which becomes contingent on this social context. They note also that an individual’s socialization and cumulative personal experiences define what the individual conceives as situationally possible, thus both enabling and constraining the agency of the individual.³⁴ Westphal, for example, found that increases in a board’s social and structural independence from management motivated CEOs to engage in ingratiating behavior toward independent directors, essentially neutralizing the effects of board independence on a variety of corporate policies ranging from the level and form of executive compensation to corporate diversification strategy.³⁵ Similarly, research has demonstrated that increases of institutional investor ownership prompted CEOs to engage in ingratiation behavior toward institutional fund managers, which in turn alleviated pressure from institutional owners to adopt a variety of corporate governance reforms.³⁶ Others claim that the greater the CEO’s power over the board, the greater the demographic similarity between the CEO and his/her successor, while board power over the

CEO predicted demographic similarity between the CEO's successor and outside directors.³⁷ Westphal and Bednar found a systemic tendency for outside directors to underestimate the extent to which fellow directors shared their concerns about the firm's corporate strategy when firm performance had been relatively poor.³⁸ This pluralistic ignorance would be especially severe when the board was relatively diverse. Likewise, more recent scholarship establishes that security analysts systemically underestimated the extent to which fellow analysts shared their reservations about (p. 167) stock repurchase plans, inhibiting them from responding negatively to the adoption of new plans, despite accumulating evidence that repurchase plans are often not implemented.³⁹ The impact of the gradual acceptance of the agency theory as the dominant theory in corporate governance has also been studied by these researchers. For example, they find that relatively negative appraisals by security analysts in the form of less optimistic earnings forecasts and less positive stock recommendations prompted powerful corporate leaders to symbolically conform to the agency theory prescriptions by increasing the board's formal independence from management without increasing the board's social independence (i.e., appointing directors who lacked formal ties to top managers but who were friends of the CEO).⁴⁰ Another study comes to the same result following negative media coverage.⁴¹

None of these social factors that impact the way executives, non-executives, investors, and analysts interpret the relevant context for their decision making and their actual behavior are taken into account in agency theory based on individual agency of a rational self-regarding agent.

2.4 Groups Matter Too

A specific social context that is key in corporate governance is the context of the group or team within which individuals function. In particular, the board of directors plays a key role in corporate governance and is typically thought of as, and in reality consists of, multiple participants. Also at executive level, although there is a wide variety in size of executive teams and single person (CEO) dominance across countries, to a large extent the executive function is a team effort. Key corporate decisions, therefore, are typically not the result of individual decision making but of group decision making. Agency theory does not shed light on the particularities in decision making by groups.

Cognitive psychologists have long studied the benefits of group decision making versus individual decision making, recognizing that in real life many decisions are taken by groups.⁴² In a number of studies, groups appear to be better decision makers than individuals. Groups have advantages in information processing, by having superior memories for information, by having access to more information, which is then exchanged through discussion, and by processing information more thoroughly through discussion. These advantages of groups over individuals may in particular help to overcome the bounded rationality, bounded perception, and bounded ethicality problems that individuals face. On the other hand, the (p. 168) group context creates its own dynamics as a result of which the quality of decision making can deteriorate. Groups typically spend more time on examining information that two or more members have in common than on examining infor-

A Behavioral Perspective on Corporate Law and Corporate Governance

mation that only one member brings (*shared information bias*). Groups tend to suffer even more than individuals from the confirmation bias, the tendency to search for and accept as valid or true information that confirms prior held beliefs or preferences. Groups often do not urge restraint but polarize; they amplify either riskier or more cautious strategies. Pluralistic ignorance occurs in groups: members believe their own views or concerns deviate from the rest of the group's views and then seek to conform to what they believe to be the group's views. Within groups, conflicts may arise, which prohibits the group from taking the best decision. Finally groupthink may arise where the group values consensus and unanimity more than reaching the best possible decision. Symptoms of groupthink are overestimation of the capabilities of the group, closed-mindedness, and pressure toward uniformity.

Looking at all the evidence of behavioral studies, undermining the absoluteness of the principal elements of agency theory of rational self-interested wealth maximization, and adding the social and group contexts as additional influences on behavior and decision making, it should be clear that agency theory is indeed an incomplete model for the behavior and decision making of key actors in the corporate setting. Agency theory captures an essential but limited part of the complexity of the behavior of corporate actors that corporate law and corporate governance seek to regulate. The conflict of interest that is central to the agency theory is real in the sense that in every corporate setting the agents' behavior may be determined more by their self-interest than the interest of the corporation or its shareholders. That, however, does not mean to say that this is always the case, and that their behavior will always be to the detriment of corporate well-being. Agency theory cannot explain when, under what circumstances, and why it is more or less likely that the inherent conflict of interests indeed leads to the detrimental behavior of the agent. Nor can it explain when, under what circumstances, and why certain corporate regulatory mechanisms that seek to contain this conflict work well or not so well. It should therefore not be the sole theoretical basis for perceiving governance problems and designing regulatory or non-regulatory solutions to those perceived problems. Agency theory is incomplete and should be supplemented, at least, with insights from behavioral studies.

By unconditionally accepting the agency theory and its principal components, lawyers may make the same mistake economists made when they borrowed from physics to shore up the scientific level of their studies. Economists borrowed from nineteenth-century physics notions such as equilibrium and compared value in economics to energy in physics in order to be able to make mathematical predictions of economic behavior. Physics moved on in the twentieth century, challenging equilibrium thinking with complexity notions and complementing Newtonian action-and-reaction concepts with quantum mechanical perceptions of the world. Mainstream economics did not follow the evolution in physics but kept on bending, stretching, and updating its theories to keep them running, and by doing so became ever further removed from real life. Over the last five decades a number of academics from various academic disciplines, such as Herbert Simon, Daniel Kahneman, Amos Tversky, Richard Thaler, Herbert Gintis, George Akerlof, and Dan Ariely, have studied and amended our understanding of human behavior and de-

cision making, developing the field of behavioral economics. However, in the field of corporate law and corporate governance, much of the behavioral insights developed seem to remain unnoticed, with some (p. 169) exceptions.⁴³ Instead, the economic approach to corporate law and corporate governance is based on the traditional, outdated model of man as the rational, self-interested actor. It may be that legal scholars are particularly attracted to applying the agency theory to corporate law and corporate governance because law is often and predominantly concerned with preventing things going wrong and seeking redress (punishment, compensation) when they do. This naturally fits with the agency theory, which presumes that agents are out there acting for themselves, to the detriment of principals. Oliver Wendell Holmes in his famous speech “The Path of the Law” put it like this: “If you want to know the law. . . you must look at it as a bad man, who cares only for the material consequences which such knowledge enables him to predict, not as a good one, who finds his reasons for conduct. . . in the vaguer sanctions of conscience.”⁴⁴ The agency model fits nicely with this bad man presumption. That notion as something that the law particularly is interested in is not the problem in itself. But when corporate law and corporate governance mechanisms are then evaluated or promoted solely on the basis of models applying full rationality and self-interest maximization as assumptions, the analysis becomes flawed. This runs the risk of corporate law and corporate governance regulation that precisely does not strengthen but weakens corporate decision making and responsibility.⁴⁵

3 Rulemaking in Corporate Law and Corporate Governance

The governance crisis of 2001–2003, with a number of high-profile scandals due to governance failures of large listed companies, and the financial crisis of 2007–2009, with financial institutions failing and putting the whole financial system at risk, have led to a surge in regulation in the field of corporate governance, through corporate, securities, and financial regulation. Much of this regulation was promulgated on the basis of the belief that irresponsible behavior in the corporate sector and financial sector had caused these crises and needs to be addressed through regulation in order to prevent another crisis. Much can be said about the forces that push us to respond to every crisis with new regulation seeking to fix the system. A large part can be addressed to our need to have control over our world or at least have the feeling of control. An illusion of control is preferred over a sense of being out of control. Lawmakers feel urged to respond to the outcry of the public, falling victim quickly to the perceived need that “something must be done.” Anything that validly presents itself as such a “something,” therefore, by some logic of action must be done. There is also a strong, often implicit belief that we can indeed cure things, improve matters, prevent future mistakes through new rules and processes that we put in place. And so every crisis leads to new regulation, piled upon previous regulation that apparently was not enough to prevent (p. 170) this crisis from happening. As a result, in many areas of society, whether it be education, academia, health care, legal practice, or the financial-corporate system there is a sense of being overburdened by regulation, of

the primary human practice being overshadowed by the regulations that seek to keep those that practice it in the right place, and that actually things are getting worse instead of better as a result.

There are a number of problems with this belief in social engineering through regulation as the solution to problems in our society.

3.1 Regulatory Crowding Out Effect

Rules have a paradoxical effect on people. More and more rules replace the responsibility we feel for our behavior and for the consequences of our behavior to others by the responsibility to comply with the rules. It generates a sense that anything that is not forbidden or covered by the rules is free territory where anything is permissible and where it is not necessary to ponder the consequences to others of one's behavior. In this way, a regulatory intervention of certain aspects of the financial or corporate reality through more mandatory rules shifts these aspects into a different mental category outside the scope of moral reflection. This perverse effect is similar to the crowding out effect of monetary incentives replacing intrinsic motivation for behavior. This effect was established in the well-known case of day care centers that fined parents for coming late to pick up their children, which had the effect of more parents coming late. The social norm, including feelings of guilt, was replaced by a market norm, the fine became a price to pay so parents could decide for themselves whether or not to be late.⁴⁶ The crowding out effect of incentives has also been established in economic relations⁴⁷ and in relation to legal incentives.⁴⁸ We can speak of a regulatory crowding out effect when new rules and procedures seek to address certain specific forms of problematic behavior that were revealed in the crisis but then lead people to believe that anything not covered by the rules must be ethically permissible.⁴⁹ A consequence of this effect is that the more rules apply to the practice we engage in, the more we experience a sort of outsourcing of our responsibility to those that make the rules. If our behavior in the not-yet-regulated space is challenged, we respond by saying the lawmaker should have made better or more complete rules. The same applies to more and more regulatory supervision by, for example, security regulators seeking to enforce the rules, which may lead us to believe that if the regulator does not intervene, we no longer have to worry about the consequences of our behavior.⁵⁰ The result of the regulatory crowding out effect is that people actually feel less (p. 171) responsible for (the consequences of) their behavior, while the reason for regulatory intervention in the first place was the lack of responsibility by various actors in the field revealed by the crisis.

3.2 Weakening of our Ability to Make Moral Judgments

A related effect of the increase of rules and procedures, particularly after a crisis, is that more and more rules and procedures reduce our ability to make moral judgments. In an environment where what we should and should not do is described in detail by rules and governed by strict procedures, we run the risk of becoming automatons who mindlessly follow the rules and procedures. In doing so we lose the ability to make moral judgments

ourselves about the actions we are about to engage in and their consequences for our own organization, for its clients, customers, shareholders, and others who are affected by these actions. We no longer train our moral muscle, as all we need to know apparently has been described in the applicable rules and procedures. We no longer have to think about the consequences of our actions; what is not filtered out by application of rules and procedures is apparently all right. Thus we lose our practical wisdom.⁵¹ One key element of the notion of practical wisdom that was developed by Aristotle, who referred to this as *φρόνησις*, is sensitivity to context. In most human practices conflicting demands, interests, principles, circumstances, responsibilities, and views are relevant to deciding what action to take. Sound decision taking requires constant balancing of these demands, interests, principles, circumstances, responsibilities, and views. There is no way that any set of rules can predict in advance how decisions should be taken in each and every context that may occur. This requires discretion to balance each of the relevant factors in order to decide what the right outcome is in the particular context. The thrust to regulate extensively after a crisis reduces this discretion. It imposes certain outcomes from the start, typically with only one of the multiple aims or concerns in mind that may be relevant. The discretion required to balance these multiple and sometimes conflicting aims disappears.⁵²

3.3 Another Paradox: We Like the Rules We Say We Hate

Complaints of overregulation abound in many fields of human practice. Our typical response to failures and crises appears to be to try to identify causes and design rules and procedures that seek to ensure that they will not occur again. In the process, we destroy our sense of responsibility, our ability to make moral judgments, and the discretion required to come to balanced decisions. The outcries that the modern regulatory frameworks undermine the professionalism of teachers, academics, doctors, and judges are expressions of these concerns. Yet at the same time, new rules and procedures are designed in all these human practices. Often the request to regulate matters more closely comes from practitioners themselves. I have experienced this once myself in the field of corporate governance. I was (p. 172) a member of the Dutch Corporate Governance Committee that drafted the Dutch corporate governance code in 2003. A first draft was published for consultation in the summer of 2003. I discussed the draft with many executives and non-executives. The general response was that the draft presented an excessively regulatory approach to governance and board practices. It contained no less than 113 best practices and that was seen to be way over the top. At one point, however, the executives in particular took a fully opposite view. In the draft code we had provided that the board of management as a matter of best practice should declare in the Annual Report that the internal risk management and control systems operated effectively. We were criticized heavily for not providing any further rules and processes on the basis of which it would be reasonable for a board of management to make such a statement, as a result of which the provision created an unacceptable level of uncertainty. They demanded more detailed rules before they would accept this provision. The Governance Committee did not yield and the provision was included in the final code as best practice provision II.1.4. The pro-

vision continued to raise concerns, partly because of the potentially broad scope of the statement. In 2008 it was amended to reflect that the statement relates only to financial reporting risks and that only a reasonable measure of certainty was required that the financial report did not contain mistakes of material substance—current best practice II. 1.5.⁵³

A core psychological concept may explain what happened here. In psychology a distinction is made between a real object and the object representation in the mind. Real objects can be observed or understood with day vision; we clearly see or understand them. Real objects are for example a car or an iPad, but also relationships such as marriage or team membership. Object representations are the representations we make in our mind of these real objects, the interpretations and the narratives we generate about them. These interpretations and narratives are generated not only on the basis of what we observe and understand but also on the basis of our past experiences, the beliefs we build on them, and the contexts that we believe to be relevant. These interpretations and narratives act as filters, influencing interpretations of future experiences with these real objects. The interpretations and narratives we generate of the objective world are often unconscious; we are not consciously aware of them. It may take deliberate effort and night vision to become aware of these interpretations and narratives.⁵⁴ The core insight is that it is not the objective world that influences us and determines our behavior but how we represent and interpret the world.⁵⁵

Rules as real objects seen with day vision can be described as guidelines, orders, or prohibitions relating to our behavior: they tell us what to do and what not to do and sometimes how to do it. At a deeper level of understanding, with night vision, we can expose that rules offer certainty and comfort. To the extent they take out our personal judgments and discretion (rules simply tell us what to do), they also take away our responsibility for getting it right when we exercise our judgment and discretion. Rules reduce our fear of responsibility, of having to explain to our peers, those that rely on us, and the public that we got it (p. 173) wrong when we made a judgment. Rules provide safety in a world full of risk. The executives that opposed the in-control best practice provision detected a new responsibility that was imposed on them without the safety of rules and procedures that informed them on what they could rely in making such statements. Clear rules would have reduced their responsibility. This effect may also explain the general and mechanical application of many best practice provisions in corporate governance codes: better to simply (without actually doing anything with the provision beyond formal compliance) apply these provisions, even if they are irritating, than to have to explain why they are not applied and to be challenged on this explanation.⁵⁶ We may like freedom of choice and judgment, but when this also creates risky responsibility we often prefer rules to tell us what to do. By allowing the rules to take over, we effectively hand over our responsibility.

A key notion to grasp from a behavioral perspective is that regulatory intervention itself has behavioral effects that may differ entirely from the effects that the intervention seeks to achieve. This behavioral perspective is not an argument against any regulation per se but should caution us, particularly after a crisis, to analyze carefully whether new rules

and procedures can truly be expected to work before they are launched or whether any positive effect expected of them is outdone by the weakened sense of responsibility, the weakened ability to make moral judgments, and the eroded discretion that also result from the new rules.

4 Understanding Board Performance

Building on the agency theory, economic and finance research has focused on trying to establish a link between the performance of the firm and aspects of the regulation of boards, in particular requirements of independence, expertise, and diversity.⁵⁷ The problem with this research is that it only looks at input variables of board demographics and tries to establish a link between those variables and the outcome variable of firm performance. This assumes a causal relation between board composition and board performance on the one hand and between board performance and firm performance on the other. Both are very difficult to establish. A wealth of research indicates that research into board demographics in relation to firm performance must remain inconclusive if the intermediating process within the board itself is not researched.⁵⁸ Agency-based economic and finance research has so far ignored the black box of the board process and interaction as a key factor in board performance. It typically also focuses solely on the perspective of the non-executive gatekeepers as an indicator of board performance and leaves out the primary contribution of the executives who are being monitored. By ignoring the internal board interaction among (p. 174) non-executives and between non-executives and executives, this research also ignores the human interaction that is the essence of the board process. The board as a combination of executive and non-executive directors⁵⁹ is a social, organizational structure allowing people in different roles to cooperate, debate, and take decisions in order to achieve specific corporate objectives. Both at the level of individual executive and non-executive directors as well as at the level of dynamics of the group as a whole, behavior is driven by factors that cannot be discerned or explained by the agency theory. They can only be investigated and understood by looking into the black box of board interaction, requiring different methodologies, techniques, and concepts. Erik van de Loo and I have developed and described a number of concepts and techniques for this purpose.⁶⁰ I summarize them here.

4.1 Board on Task and Board Interaction

In order to appreciate board performance, one has to have an idea of what the board is supposed to be doing. A *board is on task* when it is doing the right things and doing them right. Precisely on this matter corporate law and non-binding corporate governance regulation, even after a good decade of substantial regulation relating to boards, remain surprisingly vague. The notions described in legislation and governance codes typically use very broad terms, not clarifying what they in fact require of executives and non-executives. In the absence of clear guidance from the law, boards need to develop and define their own role with precision.⁶¹ Many organizational theories distinguish two or three basic roles for the board: control, service, and sometimes as a separate role strategy.⁶²

These theories primarily take the perspective of non-executives to describe the roles of the board. In stewardship theory the role of the board is to facilitate and empower management and the CEO to lead the company, rather than to monitor and control them.⁶³ This theory takes the role of the executives as the primary role with the board consisting primarily of executive directors. A full understanding of board performance requires addressing both the roles of executives and of non-executives and how these roles relate to one another. We have developed a “matrix of board interaction” to discern with more precision in what fields of interaction executives and non-executives can be expected to interact and what types of involvement can be distinguished. Corporate hygiene (internal risk and control, financial statements), strategy (future (p. 175) direction of the company, risks, rewards under uncertainty), performance (current performance monitoring, financial and otherwise), people (role of non-executives as employers toward executives, appointment, dismissal, remuneration), and stakeholders (shareholders, employees, creditors, others) are areas where non-executives interact with executives. The involvement of non-executives may vary from ratifying (non-executives blessing the outcome of the analysis of executives, not supposed to say no), probing (challenging the analysis and outcome, substantively and procedurally), and engaging (contributing beyond probing and challenging, adding specific knowledge or experience to the analysis), to directing (non-executives as owners of the process and the content of the decision). These types of involvement, each requiring different behaviors from both non-executives and executives, can be plotted in a matrix against the fields of interaction. In the field of people, referring to the role of non-executive directors as employers of executives, codes and regulation typically require non-executives to take a directive involvement. In other fields the minimum required involvement of non-executives is probing, while in practice non-executives may still be much more ratifying than probing. In some instances non-executives may have to take a directive role in these fields as well, for example in case of suspicion of financial fraud or when executives are conflicted, as may be the case in takeover bids. Sometimes non-executives can engage beyond probing when they have particular expertise or knowledge that may help the executives. This engaging role typically is for non-executives individually in specific areas rather than as a group.

The matrix of board interaction does not provide a static description of the fields of interaction and the types of involvement of non-executives. On the contrary, the interaction is dynamic by nature from field to field, from time to time, and from company to company.

4.2 Organizational Role Analysis

Distinguishing different fields of interaction and different levels of involvement is a first step to bringing the interaction between executives and non-executives into vision. That in itself, however, does not explain what boards, non-executives, and executives really do. In practice we find that board members may still have different expectations, interpretations, views, and perceptions of what the board, non-executives, and executives do or should be doing. As set out in section 3.3, these personal narratives to a large extent determine how board members act in their roles. A valuable framework to deepen our understanding of these board realities is organizational role analysis (ORA). ORA is a rela-

tively new model, which conceives of the organization as a system of interrelated tasks, roles, and role-holders.⁶⁴ The concept of “role” comprises the “place” or “area” that is the interface between a person and an organization, or between personal and social systems.⁶⁵ It represents a space impacted on the one hand by the organization and its definitions (tasks, other roles, system boundaries, resources, etc.) and on the other by the way this specific person/role holder fills up and shapes this space, fueled by the specific needs, aspirations, values, attitudes, and perceptions of that person. (p. 176) From this perspective the “role” is the place where the formal role (as defined by the organization/system) blends with the informal role (the specific way a specific person takes up his or her role). Crucial in all of this is that the role holder assumes what the role requirements are: what is the primary task and how is it to be fulfilled? Individual role holders construct implicit and explicit task ideas. These task ideas will to a large extent determine how an individual will take up his role. Taking up one’s role represents a complex and interrelated configuration of interpretations: of the system, of the tasks to be fulfilled, of one’s role, of oneself in one’s role, and of others in their roles. For a meaningful explanation of the functioning of a system, it is important to map out how the various role holders interpret their own as well as one another’s roles in it. These can be referred to as *role ideas*. As a consequence, for any group with a joint task or with interrelated tasks it is essential to become aware of both one’s own and of others’ role and task ideas. This requires role awareness and role dialogues.⁶⁶

From the matrix of board interaction we can develop role definitions and distinguish role ideas from both the perspective of non-executives and executives. The probing involvement, for example, requires non-executives to receive information from the executives, to review this information critically, to invest time to understand and prepare for a discussion on the basis of the information received and to engage in that discussion in order to truly understand, to distinguish what is known and what is believed, and to grasp what the risks and opportunities are in light of the inevitable uncertainties. If they in fact are not doing so, their efforts do not go beyond a ratifying involvement. Their actual role idea (of being ratifying) does not fit with the role definition (of being probing). Furthermore, a probing role for non-executives requires executives to provide them with all relevant information. But if executives only bury non-executives with all information available without discerning the key elements, the core questions to address and the essential factors to balance, or if they provide information only at a very late stage, they in fact reduce the role of non-executives to merely ratifying. The actual role idea that executives have of the role of non-executives (only being ratifying) again does not fit with the formal role definition (of being probing). Different fields of interaction also require different role definitions and role ideas. For example, in corporate hygiene a certain critical, strict attitude and healthy suspicion of non-executives is required. If a non-executive feels the need to be seen as nice, this will hinder him in being truly probing. At the same time, executives will need to be able to deal with the critical and robust probing attitude of non-executives. If they perceive criticism as a failure or a sign of distrust and develop a practice of delaying or hiding crucial information from non-executives, they frustrate the probing role of non-executives. In the field of strategy, on the other hand, the nature of the inter-

action is more of a partnering kind, ensuring that best choices are made. Non-executives can improve the thinking process of executives by providing external perspectives and specific expertise. But if executives or non-executives believe that the lack of specific company knowledge on the part of non-executives means that they cannot contribute to the development of strategy in depth, nothing will come of this added value. Again, the role definition requiring a probing involvement is reduced to the role idea of ratifying.

(p. 177) 4.3 Board GPS

In law and in economics the formal system of rights and duties is often taken as a given. A behavioral perspective deepens the scope of the inquiry to what the formal, systemic requirements lead to in the actual behavior of individuals in their roles. The matrix of board interaction seeks to describe the interaction of non-executives and executives in the board at a more granular level, distinguishing fields of interaction and types of involvement. This produces more accurate role definitions. The ORA then provides an approach that helps to identify what role ideas non-executives and executives hold. These internal narratives determine their actual behaviors in their roles as non-executives and executives. In this way the ORA connects the System to the Persons in the board as a Group. If we are to understand board performance in a comprehensive way, we have to apply and combine these three perspectives: Group, Person, and System. This approach, which we call Board GPS, allows us to address behavioral characteristics and factors at personal and group levels, looking into formal and informal leadership in a group, cohesion, conflict resolution, information sharing, reflection, group biases and groupthink,⁶⁷ and personal styles, parrhesia,⁶⁸ empathy, humility, and biases at personal level.

It is clear that reaching into the black box of a board to uncover the reality of the interaction of non-executives and executives requires different techniques and methodologies. Many empirical techniques such as interviews, questionnaires, and observations from various social and behavioral sciences have not yet been applied to boards that often remain closed environments for external academics to research. However, the corporate governance wave that has rolled on for the last two decades has sharpened the focus on board performance. Many boards are moving beyond formal compliance with rules and best practice standards and seek to enhance their performance by internal and externally facilitated board reviews. Researchers in the Netherlands, some of whom are conducting board reviews themselves, are in the process of connecting academic research into board performance with the practice of board reviews in order to make private information on particular boards available for academic research on an anonymous (both individual board members and companies) basis. Erik van de Loo and I have developed a specific questionnaire, the “Board Reality Questionnaire” (BRQ), in order to collect relevant samples of perceived behavioral and emotional interactions in the board. We use the BRQ when we conduct board reviews. The BRQ asks board members and outsiders who can observe (parts of) the board interaction whether they have observed a series of behaviors and events during the last year. These behaviors and events have been formulated in 150 items, based on the concept of Board GPS and asking about the prevalence of behaviors and events relevant from the perspective of the Group, Person, and System. Participants

can indicate whether the behaviors have occurred never, regularly, or consistently, or that they cannot say for the particular behavior or event. The first findings of the BRQ with four boards in 2013 show that non-executives and executives as groups regularly report different and sometimes completely opposing (never versus consistently) scores, and that sometimes the scores also vary strongly within the (p. 178) groups of non-executives and executives. Where these differences occur this indicates that there is no common perception of behaviors and events. This may cause different narratives and interpretations of the reality of the board to exist or continue, weakening the board's performance. By using the BRQ in board reviews we plan to build up a dataset of observations of board realities. This may help us to uncover in what areas it is more likely that differences of perception and interpretation are to occur, potentially weakening board performance.

5 Executive Remuneration Built to Fail

The agency theory postulates that managers of companies as agents have different interests than shareholders as principals and that managers as rational self-interest maximizers seek to further their interests as much as they can, also when this does not serve the interests of shareholders. One strategy that has been designed and enthusiastically applied to deal with this problem is to align the interests of managers with those of shareholders by various remuneration mechanics. The key element of these is that remuneration should not be fixed but should depend on results achieved that are also in the interest of shareholders. Cash bonuses that depend on profits reported are an example. Stock options that give the right to acquire shares in the company for an exercise price equal to the share price of the day of the grant of the options provide an incentive to enhance company performance that should result in a higher stock price, which makes exercising the stock option profitable. Share grants typically vest depending on the position the company holds in a peer group of companies based on total shareholder return (share price increase plus dividends), usually over a period of three years. Shares held after exercise of stock options or vesting of share grants continue to align the interests of managers with the interests of shareholders.

Earlier criticism by scholars indicated that the design and governance of executive remuneration systems are often poor.⁶⁹ Governance regulation, through corporate governance codes and for financial institutions also in EU binding regulation, has attempted to address design and governance problems. But a more fundamental problem remains: modern behavioral research indicates that people cannot handle performance-based variable play, for a number of reasons that I have set extensively elsewhere.⁷⁰ I summarize the gist of the arguments.

5.1 Incentives and Behavior

A growing body of research raises serious questions about the effects of monetary incentives. In section 3.1 I mentioned the crowding out effect of monetary incentives. (p. 179) Monetary incentives have the effect that the intrinsic motivation of people and any social

reasons they may have to perform a certain task well are displaced by the extrinsic monetary incentive, as a result of which the performance may actually become worse. James offers an alternative explanation, holding that an extrinsic incentive may provide intrinsic satisfaction if the incentive indicates competence, but will not do so if it is perceived as controlling.⁷¹ When the size of the incentive is large it will primarily be perceived as controlling as it rationally compels the agent to attribute its efforts to the incentive rather than his own preferences. This latter effect is also demonstrated when the incentive is withdrawn or substantially reduced, leading the agent to question why he would continue to work hard to reach a certain result. This effect was also demonstrated in the case of day care centers where the number of parents that kept coming late did not decrease.⁷² Ariely says: "Once the bloom is off the rose—once a social norm is trumped by a market norm—it will rarely return."⁷³

An even more damaging research result is that monetary incentives appear to have a negative effect on performance when a creative, non-mechanical task needs to be executed.⁷⁴ Amabile and others have shown consistently that extrinsic rewards stifle creativity.⁷⁵ Glucksberg reported that participants who were told they would receive a reward for solving the cognitive complex candle problem faster were actually slower in solving the problem.⁷⁶ Other researchers have found that a higher bonus does lead to better results when the job at hand involved only clicking two keys on a keyboard.⁷⁷ However, once the task required even rudimentary cognitive skills, the higher incentives led to a negative effect on performance.⁷⁸ These results are consistent with the meta-analytical study that Jenkins and co-authors conducted in 1998 on the results of 47 studies known then on the relation between incentive and performance.⁷⁹ They found that financial incentives have a significant relationship to the quantity of work delivered, but not with the quality of the work.⁸⁰ It is clear that the work of executives is not merely to perform mechanical functions. They constantly need to take decisions in uncertainty, gathering information, weighing pros and cons and risks and rewards. Research indicates that large financial incentives are not helping them to make better decisions, but rather the opposite.

(p. 180) 5.2 Target Setting and Cheating

A key element of variable pay systems is that the targets on the achievement of which the incentives depend are set in advance. The payout is then related to the actual achievement of these targets. Jensen refers to this system as a game that pays people to lie twice. "Tell a manager that he or she will get a bonus when targets are realized and two things are sure to happen. First, managers will attempt to set targets that are easily reachable, and once the targets are set, they will do their best to see that the targets are met even if it damages the company to do so."⁸¹ Performance indicators corrupt immediately when they become targets that need to be met in order to receive a certain award. This was illustrated in the case of Chicago public schools, where a change in how schools were held accountable for student learning led to an increase in cheating by teachers.⁸² Target setting in advance for financial incentive purposes was designed on the belief that this would help to base remuneration on objective and measurable factors, thereby limiting the scope for rigging by managers. The opposite is likely to happen. At the same time

most managers will maintain that they are honest. The ability to combine cheating with a view of oneself as honest increases when the manager can categorize his actions and find rationalizations that allow him to reinterpret his actions in a self-serving manner.⁸³

5.3 (Bad) Luck

The self-serving bias also causes us to systematically overestimate our influence on success and to ignore factors that are often more relevant: timing, circumstances, and pure luck.⁸⁴ We tend to create narratives to find meaning in events and we tend to do so in a self-serving way, ignoring that reality is mostly more complex, fuzzy, and messy. As a result we also tend to underestimate our influence on failure and are quick to blame circumstances outside our control. This correlates to an opportunistic shift of perception of what is supposed to be rewarded. When times are good, the creation of value is perceived as the performance that needs to be rewarded, regardless of how much value was actually created by the specific performance of executives. When times are not so good and little or no value has been created, the extraordinary efforts of the executives need to be rewarded. This is confirmed by research indicating that executive pay is most sensitive to industry or market benchmarks when such benchmarks are up, but much less so when they are down. Executives are paid for good luck, but not punished for bad luck.⁸⁵ The basis for this self-serving tendency is (p. 181) the motive to affirm self-worth. People react to negative information about themselves by making more self-serving attributions that affirm their worth.⁸⁶ When performance targets have not been met, the need to affirm our self-worth creates cognitive dissonance. We will look for other reasons outside our own performance to explain the failure to reach targets.

5.4 Benchmarking for Fairness and Status

Another mechanism that seeks to make the system objective and measurable and less subject to rigging by executives is the process of benchmarking remuneration to remuneration received by executives of companies in a peer group. This benchmarking is an expression of the human reality that we perceive the fairness of our income in relative terms, as compared to what others make for similar or different jobs. Benchmarking of executive pay typically is combined with a policy to reward one's own executives above the median or sometimes in the top quartile of the peer group. If all companies in a peer group apply this policy (and they mostly do), the remuneration of all executives of all peer group companies predictably goes up in a race to be in the top 50% or 25% of remuneration, unrelated to the underlying performance of their companies. A German executive once said at a conference I attended: "I know I am being overpaid, but the benchmark shows I am not being overpaid enough!" The cause of this is probably not the desire to receive more remuneration as such. Benchmarking is also an expression of social status. High remuneration signals high social status among peers. Status is a zero-sum game. If my status moves up by receiving more pay, then the status of others comes down.⁸⁷ Research also indicates that the only situation where we may accept a pay cut is when others do so too.⁸⁸

The behavioral research summarized here indicates that substantial executive remuneration through variable pay, target setting in advance, and benchmarking that seeks to solve the agency problem in fact delivers fundamental problems in return which discredit modern executive pay techniques as an effective mechanism to align interests with shareholders.

6 Conclusion

This chapter only addresses a fraction of the behavioral research that could be relevant to aspects of corporate law and corporate governance. It is also only fair to note that much of the behavioral literature cited here does not directly relate to corporate settings but is based on studies of behavior in experimental situations. Some elements of the corporate setting may provide a counter-balance to detrimental behavior that appears to result from these experiments.⁸⁹ Nonetheless, the evidence is more than sufficient to merit at least paying careful attention to it in corporate law and corporate governance. This chapter also only touches upon some elements of corporate law and corporate governance, such as (p. 182) rulemaking, board performance, and executive remuneration. Many other areas could be studied from a behavioral perspective. Shareholders play a key role in corporate law and corporate governance. The role of institutional investors in the corporate governance of listed companies has been debated extensively recently, in particular in relation to the question of whether they should be more engaged in the governance of investee companies and what stops them from doing so. The investment model as such seems to be a key driver for the lack of engagement that we see.⁹⁰ Behavioral sciences also influence the investment model in all aspects of bounded rationality, bounded perception, and bounded ethicality.⁹¹ In addition, the interaction between executives, non-executives, and (institutional) investors in the governance of the company is often difficult. Each of these three players is under scrutiny to contribute to proper governance relations, but what is to be expected of them in this triangle is in practice often unclear.⁹²

Conflicts of interests are a key topic in corporate law and corporate governance. Conflicts may relate to dominating shareholders who may force the company into related party transactions that are detrimental to minority shareholders. Directors may engage in transactions in which they have a personal interest. A typical legal response to conflicts of interest is to require transparency of interest. Research, however, indicates that disclosure may make matters worse. Persons who disclose conflicts may actually feel freer to act selfishly because counterparties have been warned of the risk.⁹³ Another topic where behavioral insights are crucial is director liability. The personal liability of directors to pay damages has been a cornerstone of corporate law since its inception. In some countries criminal liability plays an additional role. Liability for damages is imposed as a sanction in case of improper managerial behavior through which third parties are compensated. However, beyond compensation the function of sanction is that of deterrence. In corporate law debates this deterrence factor is often assumed to be self-evident. Clearly,

A Behavioral Perspective on Corporate Law and Corporate Governance

whether, to what extent, and under what conditions deterrence through personally liability actually works is a behavioral question beyond mere rational calculation.⁹⁴

Corporate law and corporate governance in the end are all about human behavior in corporate roles. We would learn more about how corporate law and corporate governance function in practice by broadening our perspective from the legal intuitions and (p. 183) assumptions behind corporate laws and corporate governance regulations, beyond the economic analysis assuming rational self-regarding behavior into other behavioral disciplines that can explain how we truly behave. We both are rational and make cognitive errors, we can be pro-social but also selfish. Regulating corporate law and corporate governance on the assumption of the one-sided notion of rational self-regarding behavior may actually prove counterproductive.⁹⁵ Opening up to these insights can help us to improve corporate law and corporate governance regulation.

Abstract and Keywords

This chapter examines the empirical literature on corporate law and governance in the United States. Four areas of the US corporate governance literature are discussed: (i) state competition to produce corporate law, (ii) independent boards, (iii) takeover defenses, and (iv) the use of corporate governance indices. The chapter concludes that these areas of research reflect varying degrees of success. The literature on state competition has been a major success. We know much more in this area as a result of empirical analysis in this area than we did on the basis of theory alone. At the other extreme is the literature on takeover defenses and the related literature that uses governance indices as measures of governance quality. Those empirical literatures are plagued by misunderstandings of how takeovers and takeover defenses work, and many results are therefore not as informative as they appear to be. In between is the literature on the impact of an independent board. Here, empiricists faced perhaps insurmountable challenges in proving causation, but nonetheless exposed informative associations.

¹THEORY often does not get us very far in understanding corporate law and governance. Competing plausible theories offer conflicting answers on many questions. For most questions, therefore, we would ideally seek answers based on empirical analysis. But empirical analysis entails its own challenges. Causation is difficult to prove. Reverse causation is often a plausible interpretation of results, as are other endogenous relationships. In addition, unobservable factors are pervasive and the inability to control for them can make results unreliable. Consequently, to address many empirical questions, an exogenous shock would be needed in order to infer causation. But exogenous shocks can be uncooperative in targeting interesting corporate governance questions. Finally, many economists who engage in empirical research on corporate governance lack the knowledge of institutional and legal facts that is needed to carry out empirical analysis of corporate governance questions.

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

Nonetheless, there are certainly areas of corporate law and governance in which we have learned a lot from empirical analysis. Even where imperfect, if econometric analysis reveals a theoretically reasonable correlation between a corporate governance structure and an outcome variable, and the analysis goes as far as one can go toward controlling for extraneous variables and alternative channels of causation, we can learn from the analysis. Over time, other less-than-perfect analyses may confirm the analysis, or fail to confirm it, so that in the aggregate we have a reasonably good answer to the question we are trying to answer.

On the other hand, a finding of a theoretically *implausible* correlation should not be taken seriously. Regrettably, along with the good empirical work that has been done on corporate governance, there have been too many instances of work by economists who (p. 185) do not understand the underlying institutional and legal arrangements. As a result, their hypotheses and tests have generated implausible results. Regrettably, other economists have followed and entire literatures have developed based on an incorrect understanding of the underlying facts. The literature on takeover defenses and state antitakeover statutes is an example—dating back 30 years and continuing today.² The use of governance indices, which I have discussed elsewhere and which I discuss below, is another.³

It is obviously not feasible to survey the entire empirical literature on corporate law and governance in one chapter, so I will adopt two somewhat arbitrary constraints. First, I will only discuss the literature on US corporate law and governance.⁴ Second, I will address just four areas of the US corporate governance literature—state competition to produce corporate law, independent boards, takeover defenses, and the use of corporate governance indices—to illustrate the good and the bad in empirical work on corporate governance.

Studies of state competition have been the most productive. They have taken our knowledge of the world well beyond where it was when legal academics debated this topic on the basis of theory alone. Studies of board independence are more problematic. Econometric challenges are pervasive, but they are generally acknowledged and while few papers can convincingly claim to have identified causal relationships, some have done so, and the literature as a whole is large and collectively informative. The takeover defense topic is the most problematic area of the empirical corporate governance literature. It is here where economists' lack of knowledge of basic institutional and legal facts has resulted in numerous studies that simply cannot tell us anything because the research design is so out of line with the underlying processes being modeled. The design and use of corporate governance indices are a specific and pervasive instance of economists' lack of knowledge in this area. These indices do not measure corporate governance quality, and have been widely employed with no awareness of what they do or do not measure. The E Index, in fact, is a by-product of an article showing that three quarters of the elements included in the G Index are irrelevant. As I explain in section 4 of this chapter, the same is true of three of the six elements retained in what became the E Index.

1 State Competition to Provide Corporate Law

One of the longest running debates regarding corporate law in the US was the question whether there is a “race to the bottom” or a “race to the top” among the 50 states in the enactment of corporate law.⁵ Does the evolution of state corporate law result in improvement or (p. 186) degradation? Plausible competing theories supported each of these propositions. So, if the question can be answered, it would be with empirical analysis.

When a company in the US goes public, its pre-IPO management and shareholders together choose a state in which to incorporate and in doing so, they choose the corporate law of that state to govern the relationship between its post-IPO managers and shareholders. The incorporation decision is thus a choice of corporate law. Once the company is publicly held, its board decides on an ongoing basis whether to remain incorporated in its initial state of incorporation or to reincorporate in another state. Reincorporation requires the approval of both the board and shareholders. But at the time this debate started, public shareholders were viewed as passive followers of management preferences, and boards were seen as controlled by CEOs.

As of the mid-1970s, the prevailing view was that the states were racing to the “bottom” to convince management to choose them as a state of incorporation—meaning that they were viewed as enacting pro-management, anti-shareholder laws that we would characterize today as suboptimal. States enacted these laws, the theory went, in order to bring fees associated with incorporation into state coffers and income into a state’s corporate lawyers’ pockets. The content of the laws then perceived to serve managers’ parochial interests was primarily protection of management from liability risk—for example, the business judgment rule and rules allowing for a wide scope of indemnification.⁶

The competing view, held by most economics-oriented legal scholars beginning in the late 1970s, accepted the premise that states were racing to attract incorporations, but rejected the view that states did so by enacting suboptimal, pro-management laws. In the view of this more economically oriented group of legal academics, managers would gain by maximizing the value of their firms and thereby increasing the value of their shareholdings and compensation. Therefore pre-IPO managers and investors would initially incorporate their firms in states whose corporate law regimes maximized firm value. Then, after going public, firms’ managers would continuously monitor changes in corporate law around the country and reincorporate if a better choice arose.⁷ Advocates of this view theorized that state competition, therefore, must be a race to the “top.”⁸

A third view, which entered the debate later, raised doubts about the competitiveness of the race. Although this view, also adopted by economically oriented scholars, was framed as a challenge to the theory that the race would reach the top, its logic applied as well to the race-to-the-bottom proposition. This challenge was based on the concept that corporate laws have network externality qualities, as discussed in Chapter 4. One would expect the network externalities present in an entire corporate law regime—court decisions, legal expertise, and investor familiarity—to be even more important than those associated

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

with a particular legal rule or a charter or bylaw term, which was the focus of Chapter 4. If, in fact, state corporate law regimes provide network benefits, then once Delaware led the race one would expect its lead to widen and potentially become so dominant that no state would have a chance of gaining significant market share. If this occurred, why would another state run (p. 187) the race at all? The network externality theory implies that once Delaware acquired a substantial lead, as it had well before the “race” debate started in the 1970s, it would maintain that lead. There would be no point in other states challenging Delaware, and there was no reason to believe that Delaware would reach the “top.” The outcome, therefore, would not necessarily be an optimal corporate law regime, as the race-to-the-top theory maintained. This is not to say that Delaware could ignore the care and maintenance of its corporate law; if the law’s inherent quality were to fall too far behind that of other states, the network benefits that Delaware provides could be insufficient to attract additional incorporations or to deter exit to other states. There was a possibility that Delaware could be overtaken in the incorporation market. But Delaware would not have to run very fast to keep its leading position, and it would not have to produce an optimal corporate law, independent of the network benefits it provides.⁹

Roberta Romano provided the first major empirical analysis of state competition in the market for corporate law.¹⁰ In this path-breaking article, she found support for the race-to-the-top theory. She found that Delaware was the most common destination among public corporations that changed their state of incorporation. She further found that reincorporation in Delaware was associated with an increase in share price. This result is consistent with Robert Daines’s later finding that Delaware firms are valued more highly than firms incorporated elsewhere,¹¹ a finding that Guhan Subramanian has contested.¹²

Looking at the supply side of the corporate law market, Romano found that state legislatures adopt legal innovations over time in an S-shaped pattern similar to that of firms adopting product innovations in competitive markets. This suggested a competitive market for the states’ provision of corporate law. Romano further found that a state’s responsiveness to corporate law innovations by other states was correlated with the state’s dependence on corporate franchise fee revenues, again supporting the race-to-the-top theory. Delaware, for which franchise fees comprise a higher proportion of state revenues than they do in any other state, was the quickest to imitate other states’ legal innovations. Importantly, however, Delaware was not an innovator. It maintained its lead by just keeping up with the competition.

Romano concluded that state competition in corporate law does, in fact, exist. She described Delaware’s success as a self-reinforcing “first-mover advantage” stemming from (p. 188) a number of sources: the importance of franchise taxes to Delaware’s budget; a large body of case law; experienced judges; and the familiarity of lawyers nationwide with Delaware law. These findings, however, are somewhat in tension with one another. If Delaware has these first-mover advantages in promoting shareholder interests, and it already held a commanding share of the incorporation market as of the mid-1980s, how much state competition is there likely to be? Why would a state bother to compete with Delaware? Why would any firm incorporate in a state other than Delaware? Does the

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

Delaware legislature have slack with which to respond to the lobbying efforts of managers and others seeking to promote parochial interests that are not consistent with the maximization of firm value? If other states do not compete vigorously head-to-head with Delaware, will Delaware ever get to the “top”?

A series of articles published between 2002 and 2006 addressed the question whether there really is a race of any sort—to the top or the bottom.¹³ One startling finding was that, contrary to the expectations of commentators on both sides of the race debate, there was no nationwide race among the 50 states. Instead, nearly all firms incorporate either in the state in which they are headquartered or in Delaware. Thus, if there is competition among states it would take the form of each state competing with Delaware for the incorporation of firms headquartered in that state. Putting Delaware aside, between 1978 and 2000, the four most successful states at attracting incorporation by out-of-state firms at the IPO stage garnered a total of only 3.5% of firms going public.¹⁴ For firms already public as of 1999, only two states other than Delaware had more than 1% of total out-of-state incorporations. Delaware had 58%.¹⁵ Consequently, there is little out-of-state franchise tax revenue at stake for any state other than Delaware. There may be more potential in-state revenues in large states, but large states are likely to have large budgets in which potential franchise taxes do not make a dent. These findings suggest that states may have no incentive to compete with Delaware.

In an article entitled “The Myth of State Competition in Corporate Law,” Marcel Kahan and Ehud Kamar concluded that the amount of franchise tax revenue at stake for any state other than Delaware is too small to matter. Moreover, they found that no state other than Delaware takes significant steps to attract incorporations or to gain significant revenues from incorporation.¹⁶ They based their conclusions on an analysis of states’ franchise tax structures, their tax receipts, patterns by which laws are adopted across states, and states’ marketing efforts.¹⁷ This paper was not empirical in the sense of compiling statistics and running regressions, but it was deeply empirical in the sense of delving into facts in 50 states in order to determine whether they are participating in any sort of race. Kahan and Kamar’s (p. 189) analysis essentially ended the debate. The states are not racing against one another to attract incorporations—neither by trying to appeal to managers’ parochial interests nor by trying to appeal to their joint interest with shareholders in maximizing firm value.

As Kahan and Kamar’s article was going to press, Nevada was preparing to make a play for incorporation revenue by offering a corporate law that Michal Barzuza has termed “liability-free” for officers and directors. As Barzuza explains and documents, Nevada has targeted a niche of firms whose managers want to be largely free of liability risk in their exercise of fiduciary duty. She and David Smith further find that firms attracted to incorporate in Nevada make good use of the liability-free environment; they are disproportionately more likely than other firms to engage in accounting misstatements.¹⁸ Nevada’s market share, however, is in the single digits. Perhaps Nevada will attract more firms

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

seeking liability-lite. We will see. But Nevada's efforts do not challenge the overall story of the race that never was.

Even if there is no race, however, all states have corporate law, and firms still choose between incorporating in Delaware or in their home state. There is still the demand side of the market for corporate law. What factors influence firms' decisions? Are firms choosing between Delaware and their home state based on differences in corporate law or something else?

The choice of Delaware incorporation provides law and legally-related network benefits—a large and continuously growing body of case law, a specialized judiciary that has a steady flow of corporate law cases with which to maintain its skills and knowledge, a large number of lawyers with expertise, and more. But what about firms choosing to incorporate in their headquarters state? Some states keep more in-state incorporations and some states keep fewer. What drives these differences? The fact that the location of a firm's headquarters plays such an overwhelming role in incorporation decisions suggests that differences in state law are not the primary focus of firms' incorporation decisions. As Robert Daines said in a paper on state competition, Oregon retains almost 70% of IPO firms headquartered there, but in 20 years only three out-of-state firms incorporated in Oregon when they went public.¹⁹ If the attraction of Oregon were its corporate laws, then out-of-state firms would presumably see the attraction and incorporate there. There must be other explanations.

In three articles, Daines, Bebchuk and Cohen, and Kahan offer some other empirically based explanations for in-state incorporation, most of which are not based on the content of a state's corporate law. One is that local lawyers who advise firms on their IPOs have their clients incorporate in-state, perhaps in order to retain their business. A second explanation is that in-state firms want to be in a position to influence the corporate law under which they operate. They may believe that if they incorporate at home they will be able to influence their state legislature to enact laws that favor them. This is consistent with Romano's finding, in 1987, that the enactment of state antitakeover statutes was responsive to domestically incorporated firms.²⁰ Daines finds evidence that firms concerned about future takeovers tend to incorporate in-state and suggests that they may expect to find favor in the state legislature or in the courts when they seek to ward off hostile bidders. Bebchuk and Cohen find that (p. 190) large firms headquartered in small states tend to incorporate in-state, from which they infer that such firms expect to have influence over future changes in corporate law. Kahan, on the other hand, finds some support for the proposition that in-state incorporation is influenced by the quality of state law at the time of incorporation. Specifically, he finds that flexibility to opt out of statutory rules tends to attract more in-state incorporations, and the quality of a state's courts does as well.²¹

In sum, empirical work on state incorporation has moved us well beyond the theory-based "race" debate. We have learned that a race among the states may have occurred at one time, but that by the time the debate got started the race was long over and Delaware

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

dominated the market. We have also learned that while Delaware incorporation may be value-enhancing compared to incorporation elsewhere, Delaware's incentive to reach the "top" is weak as a result of its self-perpetuating lead in the market. A reasonable inference from the empirical work is that much of Delaware's value comes from its network benefits, or what Romano had earlier called "first-mover advantages"—its high volume of case law, expert judiciary, expert bar, and familiarity among investors—and that these benefits unique to Delaware render useless efforts by other states to compete. Nonetheless, Romano found that Delaware is not complacent. Its legislature is quick to follow when other states enact a new law to respond to a new situation.

2 Independent Directors

Another battle that raged at a theoretical level in the corporate governance arena was about independent boards. This was not so much a battle among academics but rather a battle between institutional shareholders and advocates for management. Institutional shareholders viewed boards as monitors of management and therefore in need of independence. Management advocates, on the other hand, viewed boards as part of a cohesive management team that could be disrupted by too much independence. One could imagine either role for a board, and hence reasonably view independence as either a virtue or a vice. One could also imagine some boards performing both roles well. Moreover, one could have different views for different companies, depending on the presence of other monitoring mechanisms. Legal academics took positions on one side or another based on a mix of theory, intuition, and ideology.²²

(p. 191) Congress, the SEC, and the stock exchanges settled this debate by fiat in 2002 and 2003. In 2002, Congress enacted the Sarbanes-Oxley Act (SOX), which imposed independence requirements on audit committees, and in 2003, the SEC approved New York Stock Exchange and NASDAQ rules requiring that a majority of public company board members be independent and that all compensation, nominating, and governance committee members be independent.²³ The stock exchange rules specified criteria by which director independence would be determined. They also required independent directors to meet regularly without management present.

At the time these rules were adopted, there was no basis in empirical research to support the proposition that board independence was value-enhancing as a general matter. For that reason, among others, Roberta Romano referred to the SOX-mandated governance requirements as "quack corporate governance."²⁴

The lack of evidence was not due to a lack of effort. Many empiricists had tried to measure the impact of independent boards on firm conduct and performance. Empirical analysis of whether independent boards were beneficial to corporations was plagued by inherent methodological problems. Even if an association between independent boards and firm value or performance were found, causation was difficult if not impossible to prove.

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

Prior to the stock exchange mandates, a firm's choice to have an independent board was an endogenous choice. There are any number of potential causal relationships between board independence and firm performance. CEOs of firms that performed well might have had greater confidence than those at firms that performed poorly, and might therefore have been more likely to give in to institutional shareholder pressure to nominate more independent directors. Or CEOs of firms that performed well may not have wanted to rock the boat by bringing on more independent directors, and shareholders may not have pressured them to do so because performance was good. Conversely, CEOs of firms that performed poorly might have been more likely to add independent directors to their boards, either in response to shareholder pressure or in order to get more strategic advice. Or CEOs of firms that performed poorly may have opposed nomination of independent directors in order to avoid the pressure and risk to their careers that could ensue. The nature and direction of causation were thus ambiguous. Furthermore, additional problems arise as a result of the inability to observe true independence among directors. A director who meets the legal requirements of independence could well have a relationship with a CEO or a personality that makes him or her an unlikely monitor.²⁵

(p. 192) It is also possible that the benefit of an independent board differs across such factors as industry, firm size, geography, and other less observable factors. The value of an independent board would likely vary as well with the presence of other monitoring mechanisms. Yet another complication is the danger that an independent director, say a CEO from another company, may have conflicts of interest that compromise the contributions he can make to the board. This danger could vary across firms and the fields in which they operate.

In light of these methodological challenges it is not surprising that studies that attempted to uncover a relationship between board independence and firm value or performance failed to yield a clear result. Studies by Bhagat and Black,²⁶ Hermalin and Weisbach,²⁷ and Baysinger and Butler²⁸ all found no correlation. Of course this does not mean there was no relationship. It just means that econometric methods could not be used to reject the null hypothesis that independent boards are unrelated to firm value or performance.

One study, however, used the SOX and stock exchange independence requirements as an exogenous shock in order to analyze the value of board independence for firms that had not voluntarily adopted an independent board before doing so became mandatory. For these firms, the adoption of independent boards was not an endogenous choice; it was imposed on them by the enactment of SOX and the adoption of the related stock exchange rules. This study, by Chhaochharia and Grinstein, found that the board independence mandates had a positive effect on firms that were forced to accept independent boards. Among firms that scored lowest on the authors' measure of board and committee independence prior to SOX and the stock exchange rules, there was a statistically significant and economically substantial increase in abnormal returns when the rules went into effect.²⁹

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

It is difficult to know the extent to which Chhaochharia and Grinstein's results are generalizable to other firms. By the time the stock exchange independence rules went into effect, a large majority of firms already had independent boards. Linck, Netter, and Yang find that as of the end of 2003, when the SEC approved the stock exchange rules, fewer than 10% of boards did not have a majority of independent directors, and those that did not were disproportionately small firms.³⁰ The firms on which the Chhaochharia and Grinstein study is based, therefore, may well have been systematically atypical, and the reasons behind their (p. 193) having non-independent boards prior to SOX could explain why the mandatory imposition of independent boards on them had a positive impact.

Other studies looked at the relationship between board independence and performance of specific tasks. These studies produced some evidence that independent boards were slightly better, for example, at firing poorly performing CEOs than were non-independent boards, but the evidence was not strong.³¹ Studies also found that, among firms that received tender offers and offers of management buyouts, those with independent boards realized higher returns than those with non-independent boards.³² Yet another group of studies looked at returns to bidders in tender offers, and found evidence that bidders with independent boards were less likely to overpay in a tender offer.³³ Each of these studies, however, faced the inevitable methodological difficulties affecting those focused on firm value and performance.³⁴

In sum, empirical studies of independent boards faced what, for the most part, may be insurmountable empirical challenges. Perhaps future studies can test more precise hypotheses regarding where and when independent boards are valuable. It remains to be seen whether one can observe and collect data that reflect the differences relevant to that sort of refinement. Within the limits of what has been done, however, researchers have generated some useful information—hints that independent boards performed some jobs well.

3 Takeover Defenses

Takeover defenses have been a third topic of intense debate in corporate governance since the 1980s. Institutional shareholders have battled management over the adoption of defenses. Management lobbied state legislatures for, and institutional shareholders lobbied against, the adoption antitakeover statutes. Firms continue to litigate management's use of takeover defenses when bidders mount hostile takeovers. And academics continue to debate the value of takeover defenses in law journals and finance journals.

As is true of other corporate governance debates, theory can only go so far. Empirical research has long shown that target shareholders reap substantial gains from hostile acquisitions.³⁵ Takeover defenses, therefore, would reduce target shareholder value to the (p. 194) extent they deter bids or allow management to defeat value-increasing bids. Moreover, if managers feel less pressure from the takeover threat, then all shareholders in the aggregate may be worse off even in the absence of an actual takeover bid. On the other hand, to the extent management uses takeover defenses to reject low bids or to ne-

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

gotiate higher bids, then the presence of the defense could promote shareholder value in firms that receive bids.

Legal academics initially lined up on one side of the debate or the other with only theory to offer, and there were plausible theories on both sides.³⁶ The question whether takeover defenses tend to be value-enhancing or value-decreasing in the hands of management is therefore an empirical question. It is a question as much about the behavior of target management when using defenses, which of course will vary, as it is a question about the mechanical impact of a takeover defense. From an empirical perspective, when we look at the impact of defenses on firm value, the two are combined—the mechanical potential of a defense and management's use of the defense.

Many economists have tried to analyze the empirical relationship between takeover defenses and firm value. Those efforts began in the 1980s and continue today. But the institutional and legal setting of takeovers and takeover defenses is complex, and few economists have mastered the complexity. As a result, much of the empirical literature in this area is fatally flawed.

In a nutshell, the institutional and legal facts one must understand in order to analyze takeover defenses empirically are the following:

- A poison pill, also known as shareholder rights plans, is a complete bar to a takeover so long as a target board keeps it in place.³⁷
- Poison pills were validated by the Delaware Supreme Court in 1985³⁸ and in most other states by 1990.³⁹
- A board can adopt a pill unilaterally at any time, including after a hostile bid has been made.⁴⁰ No shareholder approval is required, and the legal treatment of a pill is the same regardless of when it is adopted.
- (p. 195) A board can withdraw a pill unilaterally at any time, and often announces that it will do so if a bid is high enough.
- A board can keep a pill in place indefinitely in response to bid.⁴¹
- If a bidder cannot convince a target board to withdraw a pill, its only option is to initiate a shareholder vote to replace the board with new directors of its own choosing (who will likely withdraw the pill and allow the takeover to go forward).
- It follows therefore that a takeover defense that could have an impact at the margin, given that all firms have or can have a pill, is one that impedes a shareholder vote to replace a majority of the board of directors with a new board that will withdraw a pill. *This is the key point on which the rest of this discussion hinges.*
- The following defenses can impede that shareholder vote:
 - A staggered board provided for in a firm's charter can delay the replacement of a target board for up to two years.⁴²

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

- A restriction on shareholders' ability to vote in between annual meetings, either by calling a shareholder meeting or voting by written consent in lieu of a meeting, can delay the replacement of a target board for up to one year.⁴³
- A prohibition on the removal of directors without cause can also delay the replacement of a target board for up to one year.⁴⁴

(p. 196) These institutional and legal facts imply certain limitations regarding empirical studies of poison pills, staggered boards, and other defenses—limitations that many studies violate and thus produce results that are uninformative. (I use the term “facts” rather than the more common term, “institutional detail” to make clear that these points are not details and that designing studies inconsistent with these points is not an option.)

3.1 Poison Pill Studies

Between 1986 and 1996, twelve event studies were published on the impact the adoption of a poison pill had on share value.⁴⁵ There is an inherent problem with all of these studies—and with *any* effort to measure the impact of a poison pill. A board of directors can adopt a pill unilaterally at any time. If a firm does not have a pill at the moment, it can have one later today. All that must be done is for the firm's board to adopt one. If a firm does not already have a pill, it certainly will adopt one if and when it receives an unwanted bid. Even if the target management is amenable to a sale, it needs a pill in place in order to negotiate a price if there is any chance that a target will “go hostile” in the lingo of M&A lawyers. One study confirmed that among targets of hostile takeover attempts, every target had adopted a pill either before the bid was made or in response to the bid.⁴⁶ Consequently, while a poison pill is an effective defense against a hostile takeover, the adoption of a pill is a *nonevent*, and an event study will not measure its impact. Coates explained this point in a critique of the empirical corporate governance literature on takeover defenses as of 2000.⁴⁷ As he explained the point, all firms have a “shadow pill” in the sense that all firms can adopt a pill at any time. Consequently, the fact that a pill will be in place whenever it is needed is baked into the price of all shares continuously. As will be evident below, Coates's explanation made little impression on economists writing in this field.

Not surprisingly, the results of pill-adoption event studies ranged from finding no significant abnormal returns to finding statistically significant but economically small returns, both negative and positive.⁴⁸ The studies that found a statistically significant negative effect on share prices were those that used the earliest sample period.⁴⁹ Robert Comment and William Schwert's study, which was the largest at the time, found statistically significant negative effects only in 1984 (when only nine pills were adopted).⁵⁰ As the authors suggested, this may have reflected the market's initial lack of understanding regarding how the pill would work.⁵¹

More recently, there have been additional studies of poison pills. These have been motivated by studies based on corporate governance indices, discussed in section 4, which include poison pills among their scoring elements. In a broad study of takeover defenses,

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

(p. 197) Cremers and Ferrell found that firms that had adopted poison pills had a lower value than those that did not.⁵² For reasons described above, it is doubtful that the direction of causation runs from pill adoption to firm value. Such a relationship would mean the market does not understand that all firms have “shadow pills” despite the fact that the law has been clear on this point for many years. Cremers and Ferrell recognize that the direction of causation could run in the opposite direction, reporting “very modest” support for an inference that firms with low valuation tend to adopt pills.

Emiliano Catan has recently looked more closely at the relationship between poison pills and firm value—cross-sectionally and within-firm over time using quarterly data—in a sample period of 1996 to 2014.⁵³ In order to separate the adoption of a pill from the announcement of a takeover offer, he focuses only on the adoption of “clear-day” pills—pills adopted when there is no publicly known takeover bid in the offing. Catan finds that firms adopt clear-day pills *after* their value has fallen. Moreover, his firm fixed effects results suggest that this dynamic drives cross-sectional differences in value between firms with and without pills. This empirical finding is consistent with the fact that pill adoption is a nonevent and should not affect share value. The inference is further supported by Catan’s second finding—that when firms drop their pills, there is no impact on firm value.

One might still ask why firms adopt poison pills on a clear day rather than waiting until a hostile bid is made. The answer is that there is no harm in doing so, and no harm in waiting. Some firms adopt pills on a clear day and some wait. Since all firms will adopt a pill if it is needed, it does not matter when they adopt it. Catan found that after 2004, when ISS threatened to recommend “withhold” votes for members of boards that adopted clear-day pills (or re-adopted them after they expired), clear-day pill adoptions nearly vanished, even though an ISS threat is highly unlikely to result in a board member losing his or her seat, and even though there was no good reason for ISS to make the threat.⁵⁴ So even a small threat apparently pushed the balance against adopting pills on a clear day.

3.2 Studies of Staggered Boards

Since a poison pill allows a board to resist a takeover bid indefinitely, if it chooses to do so, a bidder’s only response is to give target shareholders an opportunity to remove and replace at least a majority of the target’s directors. In a company with dispersed shareholders and dispersed votes, a staggered board is the strongest impediment to doing so.⁵⁵ With a staggered board in place, two shareholder elections must occur at two consecutive annual meetings in order to replace a majority of the target’s board. This can take two years to occur. It is generally understood that a staggered board is a near bulletproof defense if the target board continues to resist a hostile takeover. In the case of *Air Products and Chemicals, Inc* (p. 198) *v. Airgas, Inc*, William Chandler, former Chancellor of the Delaware Court of Chancery stated, “no bidder to my knowledge has ever successfully stuck around for two years and waged two successful proxy contests to gain control of a classified board in order to remove a pill.”⁵⁶

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

Is a staggered board value-decreasing or value-enhancing? Once again, there is theory on both sides. With a staggered board, directors can prevent a takeover from occurring, even if the takeover would be beneficial for shareholders. Since at least 1990, it has been clear that courts will not interfere.⁵⁷ A staggered board may therefore deter a would-be acquirer from attempting to take over a target in the first place. Furthermore, with this protection from the takeover threat, a company's board and management may feel less pressure to perform and thus may fail to maximize share value on an ongoing basis. On the other hand, if a board is diligent and loyal, and management is motivated to promote shareholder interests, a staggered board can allow a company to make long-term investments without concern that the market will undervalue those investments and thereby expose the company to a takeover at too low a price. In addition, a staggered board might enhance a target's bargaining power in negotiating a sale with an acquirer. So a staggered board could increase *or* decrease firm value, depending on how a firm's board and management are expected to respond to an acquisition offer. One's view on the question in general depends on one's view of how boards and management tend to respond to hostile bids—and of course boards and managers differ, so the empirical question is about averages.

Despite the fact that economists had been studying takeover defenses since the 1980s, the first empirical study of staggered boards was not published until 2002 (by law professors). This study, by Bebchuk, Coates, and Subramanian, found that staggered boards had a negative impact on shareholder value for a sample of firms that received hostile takeover bids between 1996 and 2000.⁵⁸ The authors found that firms with staggered boards were more likely to reject bids and remain independent, and that remaining independent meant lower returns to shareholders as compared with companies that were acquired. They found no evidence of greater bargaining power for targets with staggered boards; when companies with staggered boards were sold, the premiums they commanded were no different from those of firms without staggered boards. The aggregate result of these impacts for firms that received hostile bids meant an average loss of 8% to 10% in share value attributable to a staggered board. In another study, Bebchuk and Cohen directly compared the value of companies with and without staggered boards between the years 1995 and 2002 and confirmed this conclusion, finding that staggered boards were associated with lower Tobin's Q than firms with annually elected boards.⁵⁹

To a large extent, these findings have been confirmed and refined by others. Faleye confirmed that staggered boards are associated with lower firm value and further found that staggered boards are worse at firing poorly performing CEOs than are annually elected (p. 199) boards.⁶⁰ Masulis, Wang, and Xie found that firms with staggered boards make value-destroying acquisitions more than do firms with annually elected boards.⁶¹

In general, staggered boards thus seem to reduce firm value—or more precisely, target boards have used them to reduce firm value, on average, and the market has expected them to do so, at least during the sample periods of these studies. As in other areas of corporate governance research, there are methodological challenges. Each of the studies described above considers the possibility that the choice of a staggered board is endoge-

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

nous—that low value, poorly performing firms may adopt staggered boards to protect management. Each responds to the possibility in reasonable but inevitably imperfect ways. First, they note that shareholders must approve the adoption of staggered boards, and that this is unlikely to happen if a firm is performing poorly. Second, they analyze firms that had had staggered boards at least several years before the years in which value was measured. Another methodological concern is the use of Tobin's Q to measure and compare firm values. Although widely used, this measure is considered by many economists to be an unreliable measure of firm value.⁶²

There are, however, recent studies that find a positive relationship between a staggered board and firm value for certain types of firms. Johnson, Karpoff, and Yi analyze staggered boards adopted at the IPO stage and infer that they are used as commitment devices by firms that have important long-term relationships with suppliers or customers.⁶³ They find that the use of staggered boards by firms that have those relationships enhances value. Cremers, Litov, and Sepe analyze public companies over a 33-year period, from 1978 to 2011, and reach a similar conclusion.⁶⁴ They infer that staggered boards are used by firms to maintain commitments to long-term investments and long-term relationships. Emiliano Catan and I, however, have recently taken a closer look at this result and found that it is spurious.⁶⁵ Daines, Li, and Wang also find that staggered boards have a positive effect on firm value. They focus on smaller firms, using as a natural experiment a 1990 Massachusetts statute that imposed staggered boards on all companies incorporated in that state.⁶⁶ They found that the statute caused an increase in firm value over the next 15 years for small firms and firms with relatively high R&D investment.

(p. 200) All in all, studies of staggered boards have advanced our understanding beyond the realm of theory. As a matter of mechanics, staggered boards give a board the power to thwart value-increasing takeovers. In the 1990s, the market seems to have believed that boards would exercise that power—hence, the negative correlation between staggered boards and firm value. Evidence from the 2000s that Catan and I analyzed suggests (through a null result) that the market no longer believes boards will use the power that a staggered board provides to thwart the interests of shareholders.

3.3 Studies of Other Takeover Defenses

As explained above, a poison pill is freely available to a board facing a takeover threat, and so long as it is in place it is a complete bar to a takeover. To succeed in acquiring a target, a hostile acquirer must either convince a target board to agree to an acquisition, or it must mount a proxy contest to have target shareholders replace their board with one that will agree to be acquired. The only additional takeover defense that is useful, therefore, is one that impedes the ability of the acquirer to have target shareholders replace their board—with a staggered board being the primary example. Any other defense is, at best, redundant with the pill, and in fact other defenses are less effective than a pill.

Due to a lack of understanding regarding how takeover defenses work, however, many economists have published empirical analyses of other apparent defenses that have no

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

impact on shareholders' ability to replace a board at the margin. Once the pill was held to be legally valid, these defenses could have no additional impact on a firm's exposure to a hostile takeover. Some examples are fair price charter provisions and supermajority vote requirements to approve a merger. These studies began in the late 1980s and continue to be published today. Early studies of takeover defenses were problematic in several ways. Some considered only ineffective defenses; some combined ineffective defenses with staggered boards to create a single takeover-defense or "charter amendment" variable; and some considered staggered boards prior to the advent of the pill, when staggered boards did not provide meaningful takeover protection.⁶⁷ Yet others counted up how many defenses a firm had and used that number as a measure of its takeover exposure—more defenses were understood to mean less exposure.⁶⁸ None of these approaches makes substantive sense, and therefore the results of these studies are uninformative. More recent articles continue to refer to the conflicting results of the 1980s and 1990s as a puzzle, as opposed to a reflection of methodological errors.⁶⁹ The confusion thus continues—most rampantly in the use of (p. 201) corporate governance indices, discussed in section 4, which include multiple takeover defenses that have no impact.

There are, however, two other takeover defenses that *can* have an impact at the margin. The first is a combination of two charter provisions that prevent shareholders from voting to replace a board in between annual shareholder meetings: (a) a prohibition on shareholders calling a special meeting and (b) a prohibition on shareholders acting by written consent in lieu of a meeting.⁷⁰ If both these limitations on shareholder voting are present, an acquirer must wait until the target's next annual meeting to mount a proxy contest to replace the target board. The second defense is a charter provision that allows shareholders to replace board members only for cause, which means wrongdoing that goes beyond a difference in judgment regarding whether to allow a takeover to occur. In effect, this provision also requires an acquirer to wait until the next annual meeting to have shareholders replace their board. This delay is not as severe as the delay created by a staggered board, but it could be meaningful. Interestingly, no one has yet studied the actual impact of these restrictions on shareholder voting.

3.4 Studies of State Antitakeover Statutes

Studies of the impact of state antitakeover statutes entail the same types of errors as do studies of firm-level takeover defenses other than staggered boards. Emiliano Catan and Marcel Kahan have recently provided a detailed analysis of this literature, with a focus on the most common and most commonly studied statutes—business combination statutes, fair price statutes, and control share acquisition statutes.⁷¹ As they say, "[c]orporate lawyers and academics generally dismiss these antitakeover statutes as irrelevant."⁷² Regarding empirical studies of antitakeover statutes, they state: "The way financial economists approach takeover defenses results in a highly distorted view of takeover protections supplied by state law."⁷³

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

Catan and Kahan's explanation is the same as that provided here with respect to charter-based takeover defenses. Once the poison pill was validated, the only statutory defense that could have an impact would be one that impeded shareholder votes to replace a target board. With the exception of a few states that mandate staggered boards, state anti-takeover statutes do not do that, and never did. Therefore, after the advent of the pill and the states' validation of the pill, state antitakeover statutes had no impact on a firm's exposure to hostile takeovers.⁷⁴ They were irrelevant. Catan and Kahan explained the point well:

Business combination, fair price, and control share acquisition statutes apply once a raider has become a major shareholder. . . . But if, as a result of the flip-in pill, a raider never acquires a significant stake, any statute that deals with what a raider can do *once it becomes* a major shareholder becomes moot. Similarly, flip-over pills, which make business combinations once a raider has acquired a large stake prohibitively expensive, render business combination and fair (p. 202) price statutes superfluous [because they do the same thing]. Control share acquisition statutes, moreover, do not even purport to offer meaningful protection against hostile bids that are opposed by the board of the target but are favored (as most "hostile" bids are) by a majority of the target's shareholders.⁷⁵

The Delaware Supreme Court held pills to be valid in 1985. For a few years after that, other state courts split on the validity of the pill, but by 1990, 24 states had validated the pill and none had invalidated it. Those states that validated the pill accounted for the vast majority of firms' states of incorporation.⁷⁶ Consequently, even if one assumes that the validity of the pill was still in doubt in the other 26 states, which would be an unrealistic assumption, the window of time and the scope of firms that can be used to study the impact of state antitakeover statutes is very narrow. None of the studies performed to date focuses on state antitakeover statutes within these constraints.

Nonetheless, empirical studies that purport to show impacts of state antitakeover statutes are numerous⁷⁷ and continue to be written today.⁷⁸ These studies are so flawed as to be utterly uninformative. Catan and Kahan use the term "nonsensical."⁷⁹ Catan and Kahan replicated a study by Marianne Bertrand and Sendhil Mullainathan to determine whether the firms they identified as being subject to business combination statutes were also incorporated in states that had validated the poison pill, in which case the business combination statute would have no impact at the margin. They found that this was true of over 50% of the firms whose takeover protection Bertrand and Mullainathan had attributed to business combination statutes.⁸⁰ For this reason and others, Catan and Kahan found that Bertrand and Mullainathan's analysis of the impact of business combination statutes was fatally flawed. This mistake was a result of their misunderstanding of how business combination statutes and poison pills work and how they relate to one another.

In sum, the empirical literature on takeover defenses is a mixed bag. Studies of staggered boards have been relatively well conceived and informative. They face inevitable methodological challenges but these studies have moved us beyond intuition, theory, and ideolo-

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

gy. (p. 203) Other studies of takeover defenses have been fundamentally flawed and uninformative. Beginning with early event studies of the poison pill and extending to studies of state antitakeover statutes today, these studies reflect a regrettable (and avoidable) failure on the part of economists to learn the institutional and legal facts of the takeover context. As discussed in section 4, this problem is present as well in the design and use of corporate governance indices.

4 Corporate Governance Indices

The use—or, as I will explain, misuse—of corporate governance indices has reached epidemic proportions.⁸¹ The “Governance” or “G” Index created by Gompers, Ishii, and Metrick (GIM),⁸² and the “Entrenchment” or “E” Index created by Bebchuk, Cohen, and Ferrell (BCF)⁸³ are used in hundreds of articles covering a wide range of corporate governance topics.⁸⁴ Yet the G and E Indices reflect the same mistakes described above, with some additional mistakes that similarly reflect a failure to understand institutional arrangements and legal rules. For the most part, the elements of the G and E Indices have no impact on entrenchment, or on anything else of importance to corporate governance.

It is doubtful that anyone familiar with the details of corporate charters, bylaws, and state corporate law would have initiated a research program with the hypothesis that the elements contained in the G Index would correlate with firm value or firm performance, let alone the possibility of a causal relationship. The elements of the G Index are a hodgepodge of provisions that range from trivial to important, and from theoretically positive to theoretically negative to theoretically ambiguous in their impact on corporate governance. GIM purposefully did not select the elements of their index based on a substantive judgment regarding their functionality. Instead, as they explained, they took a list of governance provisions that the Investor Responsibility Research Center (IRRC), a nonprofit organization with an interest in corporate governance, tracked for a sample of firms over time, and they combined the provisions that the IRRC tracked into 24 elements that became the G Index. A firm received one point for each IRRC element that it had adopted directly or through operation of state law, and the sum of the firm’s points was its G Index score. GIM then performed an econometric analysis that produced surprising results: Firms with low scores (supposedly better governance) had higher value and higher investment returns than firms with high scores (supposedly worse governance). A few years later, BCF analyzed the (p. 204) GIM results and showed that three quarters of the G Index elements were empirically irrelevant to those results. The fact that 18 elements of the G Index were not correlated with firm value or performance was not surprising to those of us familiar with the Index. But the fact that six elements were correlated *was* surprising. As discussed in detail in section 4.2, there is no functional reason why most of those six elements should have any relationship to firm value or investment performance. BCF nonetheless reported correlations and christened these six elements the “E Index.” From there, the G and E Indices took on lives of their own and became embedded in the empirical corporate governance literature as a measure of governance quality. None of

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

the economists who have used the indices in this way have questioned their validity, nor have they attempted to understand what the indices mean.

Before explaining why the G and E Indices do not measure management entrenchment or any other aspect of governance quality—a discussion that is necessarily detailed and may challenge the attention span of some readers—I will review the empirical findings regarding the relationship between the G and E Indices and firm value, including recent studies that have begun to look for explanations for the GIM and BCF results. While those of us familiar with the IRRC provisions included in these indices would not have headed down this path at the start, now that we are here, GIM and BCF have presented us with a puzzle: What lies behind the GIM and BCF correlations?

4.1 Empirical Findings Regarding the G and E Indices

As a threshold matter, what did the governance indices intend to measure? GIM describe the G Index as measuring the extent to which a firm has “reduce[d] shareholder rights,”⁸⁵ and at another point as measuring “the balance of power between managers and shareholders.”⁸⁶ Neither of these descriptions is very precise, but in setting the context of their study, they explain: “The rise of the junk bond market in the 1980s [. . .] enable[ed] hostile-takeover offers for even the largest public firms. In response, many firms added takeover defenses and other restrictions of shareholder rights.”⁸⁷ So it seems GIM thought they were measuring a firm’s exposure to hostile takeovers. BCF describe their E Index more precisely as containing elements that “*appear to provide incumbents at least nominally* with protection from removal or the consequences of removal”⁸⁸—again, through a hostile takeover or the threat of one. By using the words “appear to” and “at least nominally,” BCF hint at the point I make here.

GIM analyzed the correlation of the G Index with firm value and investor returns. Their results were startling and drew the attention of everyone involved in corporate governance research. If an investor had shorted firms in the worst decile of G Index score and held shares in the best decile, he or she would have reaped a return of 8.5% per year from 1990 to 1999. GIM further found that in each sample year firms with bad scores—a lot of supposed protection—had substantially lower value than those with good scores. For example, in 1999, a one-point increase in a firm’s G Index score (meaning one more supposedly entrenching element), was associated with an 11.4% lower value, as measured by Tobin’s Q. GIM were (p. 205) careful not to attribute a causal explanation to these differences. They investigated alternative explanations and concluded that the evidence was insufficient to draw a conclusion regarding causation. One thing they did not do, however, was to analyze the function of the G Index elements—what do these elements actually do? Doing so would have led them to exclude the possibility of a causal relationship with respect to nearly all G Index elements.

BCF took the first step toward looking more closely at the GIM analysis. They found that out of the 24 elements of the G Index, 18 are empirically irrelevant. Six elements, discussed in section 4.2, account for GIM’s results. Using those six elements, BCF’s long-

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

short strategy would have yielded a 7.4% annual return in equal-weighted portfolios, and a 14.8% return in value-weighted portfolios. Like GIM, BCF also found a strong correlation between the E Index and firm value, measured by Tobin's Q. BCF went a step beyond GIM in analyzing causation by looking at the correlation between E Index scores as of 1990 and firm value between 1998 and 2002, thereby reducing the possibility of reverse causation. They find that the higher a firm's E Index score in 1990 the lower its value between 1998 and 2002 (controlling for value in 1990), from which they suggest a causal relationship between the E Index and firm value.

The literature has gone in two directions with the G and E Indices. A large and growing number of papers blindly add one or both indices to regressions as a measure of good or bad corporate governance. A few, however, have tried to analyze the GIM and BCF results more deeply. The latter path is well worth following. The starting point, as I explain in detail in section 4.2, should be that there can be no causal relationship between the indices and firm value or firm performance—assuming an efficient market and reasonably knowledgeable market participants. The relevant research question, therefore, is: If not causation, what explains the GIM and BCF results? A few papers have shed important light on this question, but the mystery remains unsolved.⁸⁹

A paper that is not directly about the indices but that nonetheless may answer much of the puzzle is Catan's recent paper on poison pills, discussed in section 3.1. He finds that poison pills—an element of both the E and G Indices—tend to be adopted *after* a firm's value declines.⁹⁰ This finding is consistent with the nature of poison pills, discussed in section 3.1. A board can adopt a pill unilaterally at any time. If a firm is performing poorly, its board could decide to adopt a pill just in case it attracts a hostile acquirer. It could of course wait until a hostile acquirer appears, but there is no harm (and no benefit) to doing so in advance. Catan's finding and the inherent nature of pills together dispel any notion that a pill causes a drop in firm value.⁹¹ Thus, to the extent poison pills are driving the empirical correlation between the G and E Indices and firm value, the explanation is not that a change in index score causes a change in firm value.

(p. 206) Cremers and Ferrell have provided further refinement of the GIM and BCF results, also focusing on poison pills.⁹² Their sample period runs from 1978 to 2006, which allows for more within-firm variation and therefore more power in their firm fixed effects models.⁹³ In addition, they cluster standard errors at the firm level, which is a methodological advance that has become standard practice since the time BCF published their article. Cremers and Ferrell find that the presence of a poison pill explains much of the negative correlation between the G and E Index and firm value. They show this in both cross-sectional regressions and time series regressions with firm fixed effects. For firms that have adopted poison pills, no other element of the indices has a significant correlation with firm value. Taking this result together with Catan's, the implication is that for firms that adopted a poison pill, the negative relationship that GIM and BCF find between firm value and the G and E Indices is not causal. (Cremers and Ferrell report some evidence of reverse causation as well.)

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

Cremers and Ferrell, however, also find that for firms that have not (yet) adopted a poison pill, the E Index (minus the pill) is associated with lower firm value—though with statistical significance of only 10%. This warrants further investigation for two reasons. First, since firms that have not adopted a pill can and will do so if they receive a hostile bid, it is not apparent why they should be different with respect to the impact of the G Index elements. Second, in firm fixed effects models Cremers and Ferrell find no statistically significant relationship between firm value and three E Index elements: supermajority vote requirements to amend a charter, to amend bylaws, and to approve a merger. Moreover, they find a *positive* relationship between staggered boards and Q. This leaves only golden parachutes to explain the negative relationship between firm value and the E Index for firms that have not adopted poison pills. More work is needed to untangle these relationships. Nonetheless, Cremers and Ferrell have moved us considerably closer to understanding the GIM and BCF results in a way that is consistent with what we know about how the elements of the E Index work.

Fox, Gilson, and Palia have also weighed in recently with a draft paper that attempts to explain the GIM results for just two years following the Enron scandal in terms of signaling theory.⁹⁴ But the signal Fox et al. see in a firm's index score is not costly to low quality firms—precisely because nearly all elements carry no consequence. Therefore, a good index score sends no signal.

4.2 Why the G and E Indices Fail to Measure Entrenchment or Governance Quality

The G Index comprises firm-level provisions and six provisions of state antitakeover statutes, which are combined into 24 elements.⁹⁵ A firm is scored based on how many of (p. 207) these elements are present in its charter, bylaws, or the law of the state in which the firm is incorporated. The assumption underlying the index is that the more elements a firm has in its charter, bylaws, or elsewhere, the more it is protected from hostile takeovers.

It is implausible that, as a general matter, a firm with a larger number of G Index elements protects management from hostile takeovers more than a firm with a smaller number of G Index elements. Particular elements of the index provide protection (notably, a staggered board), but the vast majority do not. Moreover, the G Index suffers from the flawed conception that *more* elements matter more—that the accumulation of individually entrenching elements layers on more protection at the margin from hostile takeovers or worse governance in some other sense. As explained in section 3, this is simply not true.

The E Index consists of six G Index elements that BCF found to be the underlying empirical drivers of the GIM results.⁹⁶ By omitting 18 G Index elements, which were not only empirically irrelevant to governance but also functionally irrelevant, the E Index is an improvement on the G Index. But the E Index suffers from the same flaws as the G Index on a (p. 208) smaller scale. Five of the six E Index elements are either entirely or nearly irrelevant as measures of entrenchment or governance quality more generally.

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

So what exactly is wrong with the elements of the G and E Indices? Since the E Index is a subset of the G Index, I will answer this question with respect to the broader G Index and in doing so cover the subset of G Index elements that constitute the E Index. For clarity, in the discussion below, each E Index element will be in **bold** type initially. I will also recap with a summary of why the E Index is fundamentally flawed.

The flaws in the G Index fall into the following categories, each of which is explained further below: (1) Some elements can have no impact on management entrenchment; (2) nearly all other elements can have no impact on entrenchment if a firm has a staggered board; (3) some elements can have an impact on entrenchment only under limited and unusual circumstances; and (4) some elements are either of no relevance to entrenchment or they have an affirmatively beneficial impact on governance. Consequently, neither the G Index nor the E Index is a plausible measure of management entrenchment (or any other governance quality).

4.2.1 Takeover-Related Elements with No Takeover-Related Impact

As explained in section 3, the following elements of the G Index have no impact on a firm's exposure to a hostile takeover:

- **Poison pill in advance of an actual bid**
- Coverage by a business combination statute
- Coverage by a fair price statute or charter provision
- Coverage by a control share acquisition statute
- Coverage by a cash-out statute (which is equivalent to a fair price statute).

The presence of a pill at any point in time before a hostile takeover bid is made is of no consequence, as discussed in section 3. What matters is that when a hostile bid occurs, the target firm has a pill. Once a bid is made, the target board has plenty of time to adopt a pill. All it takes is a board resolution. Therefore at any time prior to the point at which a bid is made, a firm without a pill is no more exposed to a takeover threat than a firm with a pill. As explained above, all firms have a "shadow pill." Consequently, inclusion of a poison pill in the G and E Indices is incorrect.

Once a firm adopts a poison pill, the pill provides complete protection from a hostile takeover so long as it is in place. Consequently, the other provisions listed above have no impact on entrenchment (or anything else). Each provides protection that is not only redundant with that of a pill but less powerful than a pill as well.

Because a pill provides complete protection as long as it is in place, the only governance measures that affect a firm's exposure to a hostile takeover are those that impede a shareholder vote to replace a firm's board with a new board that will disable the pill. None of the elements listed above do that.

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

The G Index also includes the following provisions:

- **A supermajority shareholder vote to amend a charter**
- **A supermajority shareholder vote to approve a merger**

(p. 209) The first of these—a supermajority to amend a charter—is of no consequence with respect to takeover exposure. As a matter of law, a charter amendment requires both board approval and shareholder approval. Since board approval is needed, there is no way for shareholders to amend a charter regardless of whether a majority or supermajority vote is needed. If there is anything in the charter that entrenches management—a staggered board, for example—it will stay there unless the board decides to amend the charter to eliminate it, in which case a shareholder vote of approval is sure to follow with or without a supermajority requirement.⁹⁷

A supermajority vote to approve a merger is also of no consequence and does not belong in the indices. A shareholder vote on a merger can come up in the context of a hostile takeover only after a bidder has succeeded in a tender offer for a majority of the target's shares—that is, a majority of the target's shareholders have already sold their shares to an acquirer. (No shareholder vote is needed for this to happen.) If the acquirer wants to buy the remaining shares, which is typically the case, it must conduct a “back-end merger.” This requires a vote of the target shareholders. A majority of the target's votes are already held by the acquirer, and they will obviously be voted in favor of the merger, but if there is a supermajority vote requirement, it is theoretically possible that a large enough minority of shareholders will hold out so that the supermajority threshold (say, 80%) will not be met. But who would hold out? Target insiders, perhaps. But to what end? Their firm is already controlled by the acquirer and they are either out of their jobs or they certainly will be out of jobs if they vote against the merger. Perhaps there is an outside blockholder unrelated to management. But if so, an acquirer will have gotten that blockholder's support in advance. Perhaps a hedge fund could buy up the target's shares after the tender offer in an effort to shake down the acquirer for a higher back-end price. Theoretically, this could happen but it never has. And for a supermajority vote requirement to entrench management, an acquirer must be deterred from the start, which means it must foresee this happening. Not too likely, especially during the period of the GIM and BCF studies.

Neither of these supermajority vote requirements, therefore, belongs in a governance index.

4.2.2 Treatment of Firms with Staggered Boards

As explained above, a **staggered board** in conjunction with a pill is a nearly complete defense to a hostile takeover. It imposes a roughly two-year delay on an acquirer seeking to have target shareholders replace their board with a board that will disable the target's pill. For firms with staggered boards, no other takeover defense can have a protective impact at the margin.⁹⁸ This means that for all firms with staggered boards, the presence of other elements just runs up the score without adding additional protection from hostile

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

takeovers. On the other hand, it would make no sense to give firms a total score of only 1 for having the strongest takeover mechanism in place and none of the remaining ones that provide no (p. 210) protection at the margin anyway. This is just one respect in which the premise of tallying up a score for takeover-related elements that are not additive makes no sense.

4.2.3 Takeover-Related Elements with an Impact Only Under Limited Circumstances

Some takeover-related elements of the G Index can have an impact on management entrenchment, but only under limited circumstances. Two of these elements, discussed in section 3, are those that prevent shareholders from voting to replace board members between annual meetings, and thereby delaying an acquirer for up to one year. These elements are (a) a prohibition on shareholders calling a special meeting and (b) a prohibition on their voting by written consent in lieu of a meeting (or, equivalently, a requirement that such votes be unanimous). These provisions are relevant, however, in only two circumstances. First, they are relevant only for firms without staggered boards. The law governing staggered boards requires that directors be elected *at annual meetings only*.⁹⁹ Second, each is relevant only if the other is present; one alone is useless.¹⁰⁰ Therefore, one point for either provision alone is not appropriate, nor is assigning two points for both.

Another element that is relevant only under certain circumstances is a **supermajority vote requirement for bylaw amendments**. The analysis here is complicated. As a threshold matter, this provision can be relevant only if the combination of the supermajority threshold and inside share ownership is such that it would be difficult to get a sufficient number of outside shareholder votes to amend a firm's bylaws. For example, if an 80% vote is required to amend a firm's bylaws, and management (or outside shareholder allies) hold over 20% of the firm's shares, then management can effectively veto changes to the bylaws. If management holds 15% it would still be difficult to get enough votes to amend. Since inside ownership changes over time and could change specifically in the context of a takeover-related event, this is not a straightforward item of data.

Assuming that the supermajority threshold is high enough to matter, the next condition that must be met for the supermajority to be relevant to entrenchment is that there is something in the bylaws that entrenches management in the first place, or equivalently, that there is something in the relevant state default rules that is entrenching. In either case, to the extent the supermajority provision prevents the shareholders from amending the bylaws to undo (p. 211) the entrenchment, the offending protective mechanism will remain present. A staggered board is the primary example.¹⁰¹ Occasionally, bylaws rather than charters provide for a staggered board. If a firm's bylaws provide for a staggered board and that bylaw provision is protected by a supermajority provision, then the supermajority provision is relevant to management entrenchment. But BCF report both that 5% to 7% of firms in their sample have staggered boards provided for in their bylaws¹⁰² and, separately, that 32% to 40% of firms have supermajority provisions applicable to bylaw amendments.¹⁰³ Unless these additional supermajority provisions protect an entrenching

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

bylaw provision, they should not be included in the index. Moreover, including this supermajority provision in the index means that a firm with both a staggered board provision in its bylaws and a supermajority requirement for amending its bylaws will receive two points, and a firm with a staggered board provided for in its charter will receive only one point, yet the level of entrenchment is the same.¹⁰⁴

Even if there is no entrenching provision in a firm's bylaws at a particular time (or an equivalent provision adopted by default from state law), most firms' charters allow their boards to amend bylaws unilaterally—along with shareholders, who always have a unilateral right as well. Consequently, one might ask whether a supermajority vote requirement for shareholder amendments exposes shareholders to such unilateral amendments by boards with no opportunity for shareholders to undo the damage with their own amendment. This scenario is possible but not with respect to seriously entrenching amendments. In Delaware, a board cannot amend bylaws to create a staggered board, and in states that have adopted the Model Business Corporation Act in its original or revised form, a staggered board must be provided for in the charter, not the bylaws.¹⁰⁵ In addition, any other board-imposed amendment must be in line with the board's fiduciary duty to shareholders and consistent with the corporate statute and the firm's charter.¹⁰⁶ Its impact must also be fully disclosed. If an amendment somehow shields management from a hostile takeover, a court will subject it to serious scrutiny. Consequently, a board's opportunity to amend bylaws this way is not substantial. Therefore if there is nothing in the bylaws (or a state default rule) to protect, a supermajority requirement to amend bylaws should not be given credit in an index as entrenching.

Golden parachutes could well be included in section 4.2.1, among the E Index provisions with no impact on entrenchment. Since 1984, golden parachutes are subject to a tax if they are greater than three times an executive's base compensation.¹⁰⁷

Consequently, most golden parachutes are at this level. Golden parachutes alone, therefore, will not impose a high enough cost to deter a hostile bid. It is possible that, when added to other forms of change-of-control payments, such as accelerated options, golden parachutes happen to become an important deterrent to a takeover at the margin for some firms. It is also true that some golden parachutes are larger than the tax-penalty limit. So it is technically possible that a (p. 212) golden parachute of the right size relative to the gains available to an acquirer could deter an acquirer. But if this were the basis for including golden parachutes in the G or E Index, one would have to include only very large ones—perhaps larger than those that actually exist.

A second potential reason to consider golden parachutes as a negative factor in corporate governance is that they *may* make management indifferent to a takeover at a low price. This seems to be what BCF had in mind. If a golden parachute makes management indifferent to a hostile takeover at a low price and as a result relieves management of pressure to manage the company well, then the golden parachute would be detrimental to shareholders. But will three times base salary have this incentive effect on CEOs and other senior managers? It seems unlikely.

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

Finally, a golden parachute is generally expected to have a *positive* impact on governance because it will reduce management's resistance to a value-increasing takeover bid. That is, it has an anti-entrenchment impact.¹⁰⁸ It therefore does not belong in an index that supposedly measures negative governance quality.

In sum, golden parachutes can be either a positive or negative influence on corporate governance and firm value—and they may have no influence in either direction. Their impact at the margin depends on other factors. To score a golden parachute as entrenching, especially without considering other factors, is incorrect.

4.2.4 Elements that are Unrelated to Takeover-Defense and Affirmatively Good for Corporate Governance

The G Index also contains several elements that are not takeover defenses, that have no bearing on management entrenchment whatsoever, and that are widely understood to be beneficial from a governance standpoint. Three such elements protect board members and managers from litigation and liability risk: (i) director indemnification provided for in bylaws; (ii) director indemnification provided by agreement; and (iii) exculpation of outside directors for monetary liability for violation of the duty of care. All of these protections have exceptions for actions that directors or officers have taken in bad faith.¹⁰⁹ They are not licenses to steal. It is widely agreed that directors and officers should be protected from the expense of shareholder lawsuits, which are often non-meritorious, even if this protection can also extend to individuals who have engaged in misconduct. Indeed, without such protection, it would be difficult to attract outside directors and perhaps even top-level officers to public companies, and those who are attracted would take few risks, regardless of the rewards to shareholders.

4.2.5 The E Index

The E Index contains the following elements of the G Index:

- Staggered board
- Supermajority to amend bylaws
- Golden parachute
- (p. 213) • Supermajority to amend charter
- Supermajority to approve a merger
- Poison pill

Summarizing what has just been explained above, a staggered board is the primary element of the Index with a potential for entrenchment. A supermajority requirement to amend bylaws can, under highly limited circumstances, be entrenching. But treating them as entrenching without taking account of those circumstances is inaccurate. The impact of golden parachutes is even more contingent, and possibly positive. The two other supermajority requirements are not entrenching. And finally, the presence or absence of a

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

poison pill at any point in time is of no consequence and therefore should not be in the index.

So the final tally of E Index elements that can potentially have an impact on entrenchment is three out of six. And of those three, two are highly contingent, and one of those two—golden parachutes—is expected to have positive impact on governance. If researchers want to know whether these three elements have an impact on governance, or if they believe they do *ex ante* in a particular circumstance, there is no reason to combine them into an index. Each can enter a regression separately and each can be refined to capture situations in which they matter.

While a governance index must simplify complex relationships, the simplification must reflect an understanding of how the elements of the index work. This is not the case with the G Index or the E Index. Their elements do not have any justification in terms of how corporate governance works. These problems, coupled with the fact that researchers mechanically use the indices without understanding them, has resulted in widespread and ongoing confusion in the empirical governance literature.

5 Conclusion

Empirical analysis of corporate governance has taken the field beyond the exchange of theoretical assertions and ideological pronouncements that often characterize legal scholarship, and it has the potential to take us farther. There are methodological barriers that warrant modesty with respect to the interpretation of results and even more so to policy prescriptions. But econometricians will continue to develop methods that reduce those barriers.

A greater problem, though one that can (in theory) be corrected, is the fact that many economists working in this area do not understand the institutional and legal context of their research. This is not only a problem with individual economists who write these articles, it is a problem in the finance and economics research infrastructure. The editors and the referees are no better informed than the authors submitting papers for publication, nor are business school and economics department colleagues who are impressed by publications in top journals.

Catan and Kahan described the situation well: “[J]ust like managers suffer from agency costs that distort behavior, academics (in finance, but also in law—ourselves included) have incentives that can distort behavior. And for empiricists, one of the potential distortions is to embrace variables that can be easily employed in an empirical test and to pay little heed to arguments that the variable has no theoretical validity.”¹¹⁰

⁽³⁷⁾ The detailed mechanics of the pill are unimportant, but the basic mechanism is to massively dilute the shares of a would-be acquirer when the acquirer’s shareholding crosses a specified threshold—for example, 20% of outstanding shares. The prospect of dilution stops the acquirer in its tracks until the pill is withdrawn.

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

(⁴²) The staggered board could be provided for in a firm's bylaws so long as shareholders cannot, as a practical matter, amend that provision of the bylaws. Since the law requires firms to allow shareholders to amend bylaws unilaterally, this means the staggered board provision in the bylaws would have to be protected from amendment by a supermajority vote requirement in the charter. The combination of the supermajority vote requirement and inside ownership of the firm's shares (which can change over time) could make the staggered board invulnerable to shareholder action.

In addition, for a staggered board to be effective, shareholders must not have the ability to remove a director without cause, and they must not be able to "pack" the board by enlarging it and electing new members that constitute a majority. Under Delaware law, removal without cause is impermissible for a company with a staggered board, unless provided for in a firm's charter. Del. Code Ann. tit. 8, § 141(k)(1). Under other state laws, removal without cause is permissible unless the charter prohibits it. Model Bus. Corp. Act § 8.08. Shareholders will be unable to pack the board if the charter either (a) sets a maximum board size that is low enough in relation to the board's current size to prevent packing, (b) the charter provides that only the board may set the board size, or (c) the charter does not allow shareholders to fill empty board seats. Sometimes the term "effective staggered board" is used to refer to a staggered board that shareholders cannot unilaterally eliminate in any of these ways. One study showed that about 90% of staggered boards are effective. Bebchuk & Cohen, *supra* note 13, at 419. For simplicity in this chapter, I will use the term "staggered board" to refer to an effective staggered board.

(⁴³) Board elections at annual meetings are mandatory, so shareholders can vote to replace their board at their next annual meeting. Voting by written consent and voting at a special meeting are governed either by the terms of a firm's charter or the default rule of the state in which the firm is incorporated. If the law of a state disallows or restricts either means of voting, it can be overridden in a charter provision. The election of new directors in a vote by written consent requires a majority of shares outstanding to be voted in favor, whereas in a vote at a special or annual meeting, only a majority of shares voted is required.

(⁴⁴) Even if shareholders can call a special meeting or vote by written consent in lieu of a meeting, they must be able to either remove sitting directors or pack the board as explained above in order to elect a majority of the board.

(⁹¹) Some economists will argue that firm value may have declined prior to the adoption of the pill because the market anticipated the pill's adoption, and declined in response. Therefore, they would claim, despite the temporal order between pill adoption and decline in firm value, pills do cause a drop in firm value. This story, however, is implausible in light of the nature of pills. Since every firm can and will adopt a pill by the time it is needed, the adoption of a pill is not an event that market participants need to anticipate. In fact, to the extent pill adoption could signal an imminent hostile bid, it could trigger an *increase* in share value.

- (*) Poison pill
- (*) Staggered board
- (*) Golden parachutes
- (*) Supermajority shareholder vote requirement for bylaw amendments
- (*) Supermajority shareholder vote requirement for charter amendments
- (*) Supermajority shareholder vote requirement for mergers

(⁹⁷) It is possible that the board will want to amend the charter and that a supermajority requirement is so high that the shareholders fail to muster enough votes to carry out the amendment. But this scenario is not a scenario involving management protection.

(⁹⁸) The exception to this statement is dual-class stock, which is rare.

(⁹⁹) Model Bus. Corp. Act § 8.06 (2007); Del. Code Ann. tit. 8, § 141(d) (2013). As discussed in section 4.2.4, these provisions can be useful for a company with an ineffective staggered board, where shareholders might be able to replace the board immediately by passing a bylaw amendment. It is also possible that, for companies with an effective staggered board, one of these provisions could be used for a bylaw amendment that would facilitate an earlier takeover at the margin. This is what shareholders attempted (unsuccessfully) to do in *Airgas, Inc. v. Air Products & Chemicals, Inc.*, 8 A.3d 1182 (Del. 2010), but especially following *Airgas*, such use of these provisions will not have a substantial impact on entrenchment.

(¹⁰⁰) There are relatively minor differences between the two. A vote by written consent requires a majority of outstanding shares, whereas a vote at a special meeting requires only a majority of shares cast. On the other hand, a vote by written consent can be carried out more quickly than a vote at a special meeting. The duration of the delay would

Empirical Studies of Corporate Law and Governance: Some Steps Forward and Some Steps Not

depend on when the takeover bid begins in relation to the target's next annual meeting and the extent to which the state law governing the target allows it to delay its annual meeting.

(¹⁰¹) For firms with annually elected boards, then the two provisions that prevent shareholders from voting outside of annual meetings are the other examples.

(¹⁰²) Bebchuk & Cohen, *supra* note 59, at 419.

(¹⁰³) Bebchuk et al., *supra* note 83, at 797.

(¹⁰⁴) Indeed, the entrenchment of a charter-embedded staggered board is greater because it cannot be undone by a board majority vote. A shareholder vote will always be required, which will add time and uncertainty to a bid.

Abstract and Keywords

This chapter reviews the benefits and costs of using indices, in particular the G- and E-indices, in empirical corporate governance research. As with corporate governance itself, the widespread use of corporate governance indices have both costs and benefits. The literature has identified a number of concerns with the use of these indices including concerns over measurement error, endogeneity, reverse causation, omitted variables and proper identification of the actual mechanisms by which corporate governance might matter. On the other hand, these indices enjoy several important benefits that explain their continued and widespread use. It concludes that event study methodology and the utilization of legal shocks/regulatory discontinuities for identification will likely play an ever greater role in future research.

Keywords: corporate governance, E-index, G-index, corporate governance indices, reverse causation, endogeneity

1 Introduction

INTEREST in corporate governance, whether on the part of academics, governmental agencies, shareholder activists, or market commentators, has never been greater. Shleifer and Vishny define corporate governance as “the ways in which suppliers of finance to corporations assure themselves of getting a return on their investment.”¹ So defined, few issues could be more fundamental to the operation of the capital markets and the financing of corporations.

Given the diversity of differing, and reasonable, views on which aspects of corporate governance should matter to investors, how they matter and when they matter, the resolution of what constitutes good corporate governance practices is ultimately an empirical question. This chapter will focus on the benefits and costs of the empirical literature’s reliance on using corporate governance indices to measure corporate governance in exploring these issues.

2 Measuring Corporate Governance

2.1 Corporate Governance Indices

Measuring firm characteristics related to firm corporate governance for large numbers of firms over substantial periods of time is one of the most important challenges facing (p. 215) corporate governance research. The issues that must be confronted in such an endeavor include whether there are plausible reasons to believe that whatever firm characteristics are being measured could reasonably be expected to matter in the first place, adequate breadth of coverage (both temporally and cross-sectionally), consistency with prior literature, and standardization. Not all these desirable outcomes are always achievable to researchers at the same time, such as the potential trade-off between breadth of coverage and one's preferred measure of corporate governance. As with corporate governance itself, the measurement of corporate governance will also involve debatable trade-offs.

A common approach in measuring corporate governance is to use corporate governance indices. These indices typically sum the number of a particular set of arrangements a firm has and assigns the firm a score based on this summation. Indices therefore ignore weighting particular combinations of arrangements differently from other combinations in the score assigned to a firm. In so doing, the empirical corporate governance literature has followed the approach adopted in other areas such as the use of indices in exploring the effect of country-level legal rules on various outcome measures of interest.² It is therefore not surprising that some of the issues that have arisen with respect to indices measuring the quality of country-level legal rules have also arisen in the context of measuring firm-specific governance arrangements.

Of all the indices, the G-Index measure of corporate governance, first introduced in the seminal paper of Gompers, Ishii, and Metrick,³ has had the most profound impact on empirical corporate governance research. The G-Index is based on how many of 24 possible corporate governance provisions, each of which purportedly restricts shareholder rights in some manner, a firm has at a particular point in time. A higher G-Index therefore indicates fewer shareholder rights. The G-Index provisions include the presence of anti-takeover provisions (such as staggered boards and poison pills), certain types of compensation arrangements that might arguably help insulate management (such as golden parachutes), and various types of supra-majority shareholder voting requirements. Some of these provisions can be found in a corporation's bylaws or corporate charter, some in a firm's contracts with management, and still others are a function of the law of the state the firm is incorporated in.

Building on Gompers, Ishii, and Metrick, another triplet, Bebchuk, Cohen, and Ferrell, construct another widely used corporate governance index, the E-Index, which consists of six of the 24 G-Index provisions.⁴ They argue that these six provisions in particular can matter in furthering managerial entrenchment, particularly that of target management facing a hostile takeover. As with the G-Index, a higher E-Index score is indicative of few-

The Benefits and Costs of Indices in Empirical Corporate Governance Research

er shareholder rights. They document that the negative association of the G-Index with firm value and lower stock returns is accounted for by the E-Index.

To be sure, besides the widely used G- and E-Indices other corporate governance indices have been proposed in the literature, though they are generally used less frequently. For example, Gillan, Hartzell, and Starks construct a board index intended to capture the strength (p. 216) of board monitoring (based on board size, separation of chair and CEO, separate independent board committees).⁵ Brown and Cayler introduced a corporate governance index based on the sum of 51 firm-level provisions.⁶ Cremers and Nair utilize an antitakeover index intended to measure a firm's takeover exposure, which consists of summing whether a firm has a staggered board, blank check preferred stock, and restrictions on shareholders' ability to call a special meeting or act through written consent.⁷ Coates proposes an index carefully constructed to track the legal impact of various provisions on a firm's takeover exposure.⁸ Unlike the typical index approach, his approach considers the interaction of different types of arrangements. In the commercial and advising context, additional corporate governance indices have been used such as the Institutional Shareholder Services' Corporate Governance Quotient Index; the Governance Metrics International's GMI Index; and the Corporate Library's TCL Index, though there are academic concerns regarding these indices' utility.⁹

There are at least three important reasons that can account for the influence of the G- and E-Indices on empirical corporate governance research, at least insofar as the research has focused on the type of provisions tracked by the G- and E-Indices.

First, and perhaps most importantly, these indices are readily calculable from the widely used RiskMetrics database (formerly maintained by the Institutional Responsibility Research Center (IRRC)) covering between 1,400 and 1,800 firms starting in 1990 until 2008 (updated at either two- or three-year intervals). All the firms of the S&P 500 are included as well as a number of others. These firms represent more than 90% of total US stock market capitalization in any given year. As of 2008 and onwards, however, only a subset of the G-Index provisions are covered in the RiskMetrics database rendering it currently impossible to calculate a firm's G- or E-Index scores for more recent years using this database. Given this important and growing gap in the data, and in light of the central role of the G- and E-Indices in empirical corporate governance research, Cremers et al. will be providing this data to researchers for each year starting in 2008 for a large sample of firms while also correcting for some coding issues in the RiskMetrics database.¹⁰ Besides the RiskMetrics database, some of the G-Index provisions are also available from the SharkRepellent database.

Second, readily available indices capturing a range of governance provisions enable researchers to examine the impact of particular corporate governance provisions while accounting for a wider universe of corporate governance provisions. A corporate governance index can readily be broken into its component parts and analyzed in the context of (p. 217) exploring the particular effect of a provision or sub-portion of the index that is of interest. In contrast, much research prior to Gompers, Ishii, and Metrick¹¹ tended to fo-

The Benefits and Costs of Indices in Empirical Corporate Governance Research

cus on just one particular provision or a small set of provisions¹² without accounting for the other provisions tracked by these indices.

Third, despite significant skepticism, particularly in the legal academy, concerning the construction of these indices, it is nevertheless the case that an impressive number of academic papers utilizing the G- and E-Indices in a variety of settings, including a number of papers published in top peer-reviewed finance journals, consistently report finding that these indices are associated with various outcome variables of interest, typically some metric of firm performance. For instance, in an interesting paper, Masulis, Wang, and Xie explore the effect of corporate governance, using the G- and E-Indices, on returns experienced by bidders when making an acquisition announcement.¹³ They hypothesize that bidders with poor corporate governance will experience greater negative stock returns as these firms are likely to engage in poor acquisitions. Consistent with this hypothesis, they report that “bidder returns decrease by 0.290% (0.435%) per one-standard deviation increase in the [G-Index (E-Index)] . . . ”¹⁴ To take another example, Dittmar and Mahrt-Smith investigate whether the market’s valuation of a firm’s cash holdings depends on the quality of corporate governance.¹⁵ They report that whether one uses the G- or E-Index, the “results show that having less entrenched managers (good governance) substantially and significantly increases the value of a dollar of cash, as evidenced by the positive and significant coefficient on the interaction between governance and cash.”¹⁶ As a final example, Giroud and Mueller document that firms with weak corporate governance, using the G- and E-Indices as the measure, have lower labor productivity, make more value-destroying acquisitions, and experience worse operating performance, lower equity returns, and lower firm value when the firm is in a noncompetitive industry.¹⁷ The importance of governance in noncompetitive industries might be the result of firms in these industries facing less pressure from product competition to adopt value-maximizing practices.

While many of these studies focus on the relationship between corporate governance and various metrics for firm performance (typically Tobin’s Q), one of the interesting findings from Gompers, Ishii, and Metrick that has generated its own literature is the association between good corporate governance and positive abnormal stock returns.¹⁸ Economically, (p. 218) the reported results are striking, with a portfolio that buys (sells) firms with strong (weak) shareholder rights having an annualized abnormal return of 8.7% over 1990–1999. This is deeply puzzling as any impact corporate governance has on stock prices would presumably be a one-time event assuming that the firm does not change its corporate governance, and the market salience of corporate governance does not change over time. In other words, the value of the firm might be lower as a result of poor corporate governance, but this firm value effect should not also generate a different return profile going forward over significant periods of time. Various theories have been proposed for the stock return effect, including the market learning of the importance of good corporate governance over long stretches of time, a lack of robustness, and the relationship between takeover exposure (as reflected in the G- or E-Index) and systematic risk.

The Benefits and Costs of Indices in Empirical Corporate Governance Research

Whether all these and similar findings in the literature are due to the direct causal impact of the provisions tracked by the G- and E-Indices (or some subset of these), a correlation of these indices with other more difficult to measure aspects of corporate governance, coding issues, or simply reflect some form of endogeneity inadequately controlled for has been and remains an interesting topic of corporate governance research.

2.2 Measurement Error

While the success of these indices is easy to understand, these indices also have important limitations. I will focus on concerns centered on the construction of the indices in this portion of my discussion.

The theoretical underpinnings of the G-Index, and, in particular, why these 24 provisions in particular might plausibly impact the corporate governance of a firm in a meaningful way, have typically been left at a quite abstract level. For instance, Gompers, Ishii and Metrick themselves argue that the G-Index provisions could create agency costs through “some combination of inefficient investment, reduced operational efficiency, or self-dealing.”¹⁹ These types of managerial agency concerns stated at this level of generality, of course, have a long provenance in the literature beginning with Berle and Means,²⁰ concerns developed by Manne in the corporate control context,²¹ and reflected in the vast agency cost literature beginning with Jensen and Meckling.²² The E-Index has a somewhat more granular justification as it focused on managerial defenses against unwanted changes in corporate control (or at least unwanted by the target’s board). In this context, Bebchuk, Cohen, and Ferrell²³ also point out that the presence of some entrenching provisions, such as poison pills, might provide an informational signal to the market as was pointed out by Coates.²⁴ Managerial (p. 219) entrenchment in the context of a hostile bid has been a prominent concern in the literature since Manne.²⁵

The issue that such an abstract justification for an index, whether it be the G-Index or some other corporate governance index, does not lie in the fact that a researcher could reasonably take the opposite view. For example, managerial entrenchment under certain conditions might result in beneficial effects such as empowering managers to negotiate higher acquisition premiums²⁶ or reducing distortions in incentives to invest in long-term projects.²⁷ After all, this competing view can also be put to the test using these same indices assuming that it is measuring, even if imperfectly, managerial entrenchment.

Rather, the more powerful critiques have focused on the a priori plausibility of a particular index accurately capturing a firm’s corporate governance profile. In short, the claim focuses on whether it is measuring anything at all of importance. For instance, Bebchuk, Cohen, and Ferrell argue that their analysis fails to reveal any basis for viewing 18 of the 24 G-Index provisions as significant.²⁸ To take an important example, antitakeover statutes (such as business combination statutes) were arguably rendered largely irrelevant once target boards had the ability to block unwanted takeovers with a poison pill so long as the directors remained in office. If directors could ward off an unwanted takeover by this means, the additional incremental protections provided to a target board by an an-

The Benefits and Costs of Indices in Empirical Corporate Governance Research

takeover statute are rendered superfluous.²⁹ If correct, this calls into question the numerous corporate governance studies that have focused on the presence of an anti-takeover statute important to the corporate governance of firms incorporated in that state.³⁰ Klausner goes one step further and argues that the only antitakeover provisions that are likely to matter are poison pills and staggered boards (along with dual class shares, which are not one of the 24 G-Index provisions).³¹ Romano, Bolton, and Bhagat argue for the superiority of just one corporate governance variable: the dollar value of the median independent director's stockholding.³²

Indeed, an even further paring back of the firm characteristics that should arguably be included in a measure of corporate governance is possible. As has been clearly recognized since Coates, poison pills can clearly matter a great deal to a firm's corporate governance profile but the extent to which actually having one at any particular point in time should matter is questionable given the unilateral ability of any firm to quickly adopt a poison pill if and when it is desired.³³ In other words, all firms in effect have a "shadow poison pill." Of course, this view is entirely consistent with the fact that a firm's adoption of a pill might well (p. 220) constitute an important signal to the market concerning the firm's management, such as the management's receptivity to a takeover or private information about the likelihood of the firm facing a takeover bid.

Offsetting these objections to the use of corporate governance indices are two considerations. First, while the indices are undoubtedly noisy measures of corporate governance, they are arguably deployed in a manner reflective of this fact. In Gompers, Ishii, and Metrick itself,³⁴ for instance, the empirical analysis focuses on the extreme ends of the G-Index distribution (labeled the "democracy" and "dictatorship" firms). That is to say, even with a noisy proxy for corporate governance, firms at either end of the distribution are more likely to have an acceptable noise/signal ratio, thereby at least somewhat mitigating a concern over mismeasurement. Needless to say, whether this is a satisfying response will depend on the extent of one's concerns over mismeasurement (or non-measurement).

Second, the claim that corporate governance has been substantially mismeasured as a result of the literature's reliance on corporate governance indices does not by itself imply that the typical regressions one sees in the literature are necessarily invalid or uninformative. It is worth noting at the outset that in the literature the corporate governance variable, such as an index, is typically (although not inevitably) on the right-hand side of the regressions, i.e. serves as an explanatory variable. On the left-hand side—the dependent variable—there is very often (although not inevitably) some metric related to firm performance, such as Tobin's Q, return on assets, accounting restatements, cost of equity, and excess stock returns. This reflects the simple fact that researchers are usually interested in investigating the potential association of corporate governance, controlling for other variables, to metrics related to firm performance.

In such a regression framework, as is well understood, any measurement error becomes part of the regression error. Assuming the measurement error is correlated with the corporate governance measure being used as an explanatory variable (or, equivalently, is un-

The Benefits and Costs of Indices in Empirical Corporate Governance Research

correlated with the “true” unobserved corporate governance), this gives rise to a standard errors-in-variables problem with any ordinary least square regressions that are run using this measure. Specifically, any coefficient from a regression using the corporate governance measure, say the G-Index, will suffer from attenuation bias, meaning the coefficient on the index will be biased toward zero.³⁵ As a result, if a positive statistically significant coefficient on corporate governance were in fact found, then a researcher could simply note that even despite this bias working against such a finding they were nevertheless able to find one. There is nothing particularly problematic in any of this. Potentially far more troubling is the further fact that if other explanatory variables (of which there might be a significant number) in a regression besides the corporate governance measure are also measured with error, then the bias on the corporate governance coefficient can go either way, i.e. could be biased away from or toward zero. In such a situation, it may be impossible to draw any inferences from the regression, whether or not the coefficients in the regression are statistically significant.

To the extent the critique of corporate governance indices can be translated into an econometric concern over the impact of measurement error (putting aside the argument that the indices in fact do not measure anything), to what extent is such a critique in fact specific to (p. 221) the use of any particular corporate governance index? After all, it is the potential measurement error in the non-corporate governance right-hand-side variables, regardless of how corporate governance is measured or whether an aggregate index is used, that can rise to the problematic situation discussed earlier where the bias can be away from or toward zero. But this is an issue that can arise for other measures of corporate governance, even assuming a perfect measure for corporate governance (i.e. no measurement error) could be constructed. Presumably, using an accurate measure of corporate governance, whatever this might consist of, would not remove the measurement error in other standard right-hand side variables.

Consider by way of illustration variables that reflect executive compensation that are often used in the corporate governance literature, such as the value of executive compensation,³⁶ or the sensitivity of managerial wealth to stock price.³⁷ To construct these variables, one needs to estimate the value of management’s stock options which usually involves approximation, such as using the Black-Scholes pricing theorem.³⁸ Given these are approximations, these variables will involve measurement error, an issue that would remain even assuming no measurement error in the corporate governance metric. Alternatively, to take another example, variables related to corporate ownership, which are often included on the right-hand side, have known measurement error issues.³⁹

3 Endogeneity

Of course, empirical corporate governance research, as is true for empirical corporate finance more generally, must deal with the endogeneity of corporate governance, irrespective of how it is measured.⁴⁰ One particular endogeneity concern in the literature has been reverse causation: the possibility that low-valued firms tend to adopt poor corporate

The Benefits and Costs of Indices in Empirical Corporate Governance Research

governance with any association between corporate governance and firm valuation thereby not being attributable to the causal impact of corporate governance.⁴¹ More generally, researchers are concerned about the potential for omitted variable bias. This arises when a variable is both correlated with a right-hand-side variable (such as corporate governance) and also correlated with the left-hand-side variable (say some metric of firm performance) but is not included in the regression. Obviously the list of potential omitted variables in the context of studying explanatory variables for firm performance is a daunting one.

(p. 222) I will first focus on the reverse causation issue before turning to the issue of omitted variable bias writ large.

3.1 Reverse Causation

Cremers and Ferrell comprehensively collected G- and E-Index data for panels of firms for the 1978–1989 period, enabling them to study these indices from 1978 to 2007 after combining their data with the standard Riskmetrics/IRRC data that begins as of 1990.⁴² They therefore can directly test the reverse causation hypothesis by examining whether changes in corporate governance (many of these changes occurring in the 1980s) can be attributed to the firm having a low valuation. They find little evidence in support of reverse causation for the G-Index, albeit with an economically modest reverse causation effect with respect to the decision to adopt a poison pill.

On the other hand, with respect to staggered boards, using the same data, Cremers, Litov, and Sepe do report finding reverse causation.⁴³ The latter finding raises the question as to whether the well-documented association between staggered boards and lower firm valuation is due to reverse causation. It is important to emphasize, however, that this finding, by itself, does not establish that for firms with staggered boards adopted long ago causation does not run from staggered boards to lower firm valuation. For instance, the ability to remain a low-valued firm over time could be a function of having adopted a staggered board. Indeed, this could potentially have been the motivation behind the decision to adopt in the first place. Another related issue is whether the mere fact that low-valued firms adopted staggered boards 20 or 30 years earlier can adequately explain the current association between low-valued firms and staggered boards today without attributing some causal role to staggered boards.

The stability of the corporate governance indices for the 1990s and early 2000s has presented both opportunities and challenges in addressing endogeneity concerns. In exploring the reverse causation issue other papers have exploited the stability of corporate governance during this period. For instance, Bebchuk, Cohen, and Ferrell examine whether a firm's E-Index score as of 1990 has a negative association with firm valuation in the 1998–2002 period.⁴⁴ The rationale is that while a firm's 1990 E-Index score is highly correlated with its score in the 1998–2002 period given this stability, a firm's 1990 E-Index score cannot itself be the result of low firm valuation during the 1998–2002 period. To control for the possibility that poor management as of 1990 is responsible for both the ex-

The Benefits and Costs of Indices in Empirical Corporate Governance Research

istence of entrenching provisions in 1990 and the firm's low valuation in the 1998–2002 period, they further control for firm valuation as of 1990 given that poor management would tend to result in low valuation. They find that the E-Index as of 1990 is negatively associated with firm valuation in the 1998–2002 period. Using similar reasoning, Masulis, Wang, and Xie examine whether for firms that went public prior to 1990 there was a negative association between bidder returns (p. 223) and the firm's G- and E-Index scores for bidder acquisitions in the 1990s.⁴⁵ They report that the negative association is even stronger for this subsample of firms.⁴⁶

A second issue that has arisen given the stability of corporate governance is when the dependent variable of interest relates to some metric of the firm's future operating performance. Larcker, Richardson, and Tuna point out that given the persistence of corporate governance combined with the documented persistence of firm operating performance, controlling for a firm's current operating performance in a regression could have the result of simply removing the impact of governance that one is attempting to estimate.⁴⁷

While the persistence of corporate governance for much of the period for which researchers have data can be helpful, it has come at the cost of limiting the ability of investigating the impact of within-firm variation in corporate governance through using fixed effects, as there is relatively little within-firm variation to work off. The Gompers, Ishii, and Metrick regressions, for instance, are cross-sectional in nature, i.e. work off differences across firms. This leads directly to the omitted variable concern of the possibility that there are uncontrolled for differences across these firms with the same G-Index scores. Indeed, Cremers and Ferrell document that firms with the same G-Index scores vary widely in terms of their market betas.⁴⁸ Firm-fixed effects have the benefit of controlling for any unobserved time-invariant firm-specific characteristics and so, to this extent (but only to this extent), can partially address this concern. With this in mind, Cremers and Ferrell examine within-firm variation in their G- and E-Index scores and document that in fact the G- and E-Indices are negatively related to firm valuation with fixed effects.⁴⁹

It is worth pointing out that the critique that corporate governance has been mismeasured has particular salience in the context of firm-fixed-effects regressions given that potentially useful information from across-firm variation is being discarded. This could increase the noise associated with any mismeasurement of corporate governance. Moreover if the mismeasurement of corporate governance is worse in terms of identifying changes in corporate governance at a firm than comparing corporate governance across firms, then the attenuation bias discussed earlier becomes potentially even more severe.⁵⁰

3.2 Omitted Variables

3.2.1 The Problem

Putting aside the specific concern with reverse causation, omitted variable bias remains an important issue given that firms make a decision to change or not change their corporate governance provisions at every point in time in a sense. This firm decision could be (p. 224) influenced by any number of factors, some of which might be difficult or impossible to observe. Moreover, some of these factors might not be constant over time and therefore would not be removed via a fixed effects regression. This is likely to be particularly true over long stretches of time. Without adequately controlling for all these possible factors, the concern is that any association found between corporate governance and some metric of firm performance is in reality driven by these omitted variables. Unlike measurement error in one variable, if there is omitted variable bias, it is often impossible to know in which direction the bias in any estimated coefficient is, such as the coefficient on corporate governance, without having some information about the omitted variables.

One particular omitted variable bias concern is the quality of management. Coles and Li emphasize the importance in some settings of controlling for managerial fixed effects.⁵¹ Perhaps poor management is more likely to adopt poor corporate governance so as to insulate itself. Some papers, following the approach in Morck, Shleifer, and Vishny,⁵² control for this factor using industry-adjusted operating performance as a proxy for the quality of management. While certainly informative, limiting the research question to what is the impact of corporate governance conditional on a given level of managerial quality might be unduly restrictive, as an important effect of poor corporate governance might in fact be poor management and the persistence of poor management. This is the same concern already touched upon in the context of addressing reverse causation by examining within-firm variation in corporate governance.

One standard way to address omitted variable bias (as well mismeasurement of corporate governance and reverse causation) is to find a variable that (i) affects the corporate governance variable but (ii) not the left-hand-side variable except through its effect on corporate governance. While (i) is easily tested, (ii) cannot be directly tested (putting aside over-identification and Hausman tests for reverse causation that must assume that one (or more) of the instruments is in fact valid). Larcker and Rusticus propose some helpful tests to explore whether an IV (instrumental variables) regression is preferable to a simple OLS (ordinary least squares) regression.⁵³

Unfortunately, it is difficult to find plausible instruments in the corporate governance literature. Firm-specific characteristics for these purposes can easily prove problematic. For instance, managerial stock ownership could directly impact firm performance given its effect on managerial incentives (mechanism 1), firm performance could impact decisions concerning managerial stock ownership (mechanism 2), and managerial stock ownership could impact a firm's choices concerning its corporate governance profile, as measured, say by the G- or E-Index, and thereby firm performance (mechanism 3). Mechanisms 1 and 2, which are quite plausible, are problematic from the standpoint of satisfying condition (ii) for instrumental variables.

The Benefits and Costs of Indices in Empirical Corporate Governance Research

Moreover, to further compound the difficulty, there are at least two further generic issues. First is the so-called problem of “weak instruments.” If the instrument is only weakly (p. 225) correlated with the endogenous variable, this can lead to biased and therefore unreliable estimates. This can be a particular problem in the corporate governance context given the difficulty of finding suitable instruments in the first place. A weak instrument might be worse than having no instrument at all.⁵⁴

Second, even assuming a valid instrument with sufficient power, one must be careful in generalizing the results to an overall claim. IV estimates will work off the variation in the endogenous variable that is being instrumented that is correlated with the instrument. As a result, one should keep in mind that IV regression results do not necessarily imply that for other sources of variation in the endogenous variable the same results would necessarily hold.

3.2.2 The Literature and Omitted Variables

Given all this, the most promising approach in the literature has been to focus on exogenous legal shocks or regulatory discontinuities that alter the impact of corporate governance for some firms. Atanasov and Black have a useful survey on the use of shocks, and in particular legal shocks, as a way of tackling endogeneity concerns.⁵⁵

For instance, Cremers and Ferrell use the Delaware Supreme Court’s 1985 decision in *Moran v. Household* which authorized the use of the powerful antitakeover defense of poison pills and indicated judicial acceptance, to some significant extent, of antitakeover defenses more generally.⁵⁶ As a result, any harmful effects of antitakeover provisions on firm valuation should be more pronounced after *Household*. Moreover, for firms for which the *Household* decision is irrelevant, there should be no firm valuation effects associated with the decision (the “control group”). Cremers and Ferrell use the G- and E-Indices as their proxy for antitakeover provisions and dual class share firms as their control group. Dual class share companies already had a powerful antitakeover effect that would render superfluous any additional takeover protection approved in *Household*.⁵⁷ They find that the G- and E-Indices do have a more powerful negative firm valuation effect post-*Household*. The same finding, however, does not hold for dual class shares.

The paper by Cohen and Wang⁵⁸ is particularly interesting in terms of examining legal shocks. They also use Delaware legal decisions as a way of addressing endogeneity but use an event study methodology. They focus on the market’s reaction to the Delaware Chancery Court’s decision in the *Airgas* decision (which casted significant doubt on the antitakeover effectiveness of some companies’ staggered boards) and the Delaware Supreme Court’s reversal of that decision (removing this doubt). Specifically, their event study measures market reactions for firms with staggered boards impacted by these decisions (both the Delaware (p. 226) Chancery Court and the Delaware Supreme Court decisions). Importantly, these decisions were not fully anticipated by the market.

This event study approach is a powerful way of addressing omitted variable bias for three important reasons: (1) firms already incorporated in Delaware were impacted by these

The Benefits and Costs of Indices in Empirical Corporate Governance Research

decisions whether they liked it or not (i.e. no endogenous firm decision); (2) the court decisions had substantially differential impact within the universe of companies with staggered boards thereby enabling them to use as a control group firms with staggered boards but unaffected by the *Airgas* decisions; and (3) observing the immediate market reaction to these decisions provides important evidence as to what the market thought (i.e., provides an unbiased, objective ex ante measure of the expected impact of effective staggered boards). Given all this, this approach provides useful insights beyond simply looking at the effects of a firm deciding to adopt or remove a staggered board (within-firm variation) or the cross-sectional effects associated with staggered boards (firms with versus firms without staggered boards) given the omitted variable bias issue that exists even with firm-fixed effects.

There are two potential criticisms of the event study approach to assessing corporate governance provisions. One is the fact that the market might be reacting to an information signal as well as to any direct causal effects of corporate governance. For instance, an event study of a firm's endogenous decision concerning its corporate governance profile might well carry both negative and positive signals relevant to an assessment of firm value. Such a concern, while often present in the context of event study analysis of firm corporate governance decisions, is absent in the context of a legal shock that applies to a number of firms such as in the Cohen and Wang paper.⁵⁹ Second, some claim that the market is unable to fully evaluate the effect on managerial incentives of the legal shock.⁶⁰ This critique should not be given undue weight, however, without further specific reasons for concluding that the market would somehow be incapable of providing an unbiased estimate of such effects. After all, concerns and market attention over the issue of managerial incentives, and managerial incentives in the context of takeovers, have been actively debated and commented upon for many decades.

4 Corporate Governance Mechanisms

In combination with the search for plausible legal shocks or discontinuities, current research has increasingly focused on identifying the exact mechanisms by which corporate governance impacts the performance of the firm. Consider antitakeover defenses. A number of important questions can be asked that go beyond whether there is an association between an index adding up some provisions and some metric of firm performance. Do antitakeover defenses matter to shareholders in terms of reducing the probability of receiving an attractive bid? Do they matter because it removes the disciplinary effect of hostile takeovers thereby resulting in poor operating performance? Or what is the relationship between the importance of takeover exposure and the size and identity of the firm's shareholders? How does the (p. 227) identity of the shareholders interact with and impact corporate governance and the operation of the firm?

For instance, John and Kadyrzhanova investigate the effect of a staggered board (and G-Index scores) on the probability of a takeover when the firm is in an industry experiencing a merger wave.⁶¹ They find that firms without a staggered board are more than three

times as likely to receive a takeover bid. Given this, they conclude that the relevance of this aspect of corporate governance is time-varying given the time-varying nature of merger waves. Cremers and Nair focus on the interaction of ownership structure and the types of provisions tracked by the G- and E-Index.⁶² They find that public pension fund ownership is important only in the presence of takeover vulnerability and that the market for corporate control is important only in the presence of an active shareholder. Masulis, Wang, and Xie specifically focus on the effect of the G- and E-Index on value-reducing acquisitions.⁶³ Identifying specific mechanisms, and when those mechanisms might be relevant, is a critical step in moving from broad associations to how corporate governance might actually matter and when.

5 Conclusion

Corporate governance indices will undoubtedly continue to play an important role given their ease of use and their acceptance in the literature. That being said, much recent research has moved beyond measuring associations between these indices and some outcome variable of interest. Increasing importance is being placed on generating testable hypotheses where the causal impact of corporate governance arrangements can be inferred. This tends to align with a research focus on the impact of a particular set of corporate governance arrangements in a specific setting. Event study methodology and legal shocks or regulatory discontinuities will likely play an ever greater role in the future.

Abstract and Keywords

This chapter focuses on taxonomies that are commonly applied to corporate law and governance. It begins with an overview of the main rationales for and types of such corporate taxonomies before turning to a discussion of four types of typologies: limited typologies dealing with either legal or non-legal questions, and general typologies having either a legal or a non-legal focus. It then outlines challenges to these taxonomies, with particular emphasis on the criticism against the quantitative research on “legal origins” and how “leximetrics” can be used to address the question of whether or not there are distinct legal families in corporate law. It also presents a cluster analysis of investor protection data of the World Bank’s Doing Business Report.

1 Introduction

¹THE division of the world into distinct legal families is frequently seen to be one of the cornerstones of comparative law.² The corporate law literature also uses taxonomies that divide the world into more or less distinct models, as this chapter will discuss in detail. To set the scene, this introduction will start with an overview of the main rationales for and types of such taxonomies.

One of its main purposes is to understand the complexity of the world. In this respect, “classifying legal systems is similar to reorganizing the books in our library, or the knives in our kitchen.”³ Taxonomies may also help us in describing similarities and differences between countries: to start with, we outline the common features that units of one model share, but subsequently we explain possible complications and overlaps.⁴ Taxonomies can also have a more normative dimension. Such a rationale can derive from the taxonomies themselves. For example, it may be shown that mixing models by way of transplanting legal rules from one model to another leads to inconsistent results.⁵ There may also be more emotional forms of attachment to a particular model: for example, the belonging to

a particular legal family can be a “matter of self-identity” or even an attempt of “insulation” from foreign (p. 229) influence.⁶ Normative statements can also go further. Some of the research discussed in the following claims that the Anglo-American model of corporate law is more conducive to financial development than that of other legal traditions (i.e., it “works better”). But this is not the only possible relationship to be examined. For example, it may also be analyzed how spatial, institutional, cultural, organizational, and relational proximity are related to each other.⁷

These different rationales are reflected in different types of taxonomies. At a general level, one can distinguish between those based on “ideal” and “real” types.⁸ Starting with ideal types may be more typical for the “what works” rationale, whereas research aiming to understand differences may typically focus on real types. However, in practice, these starting points are often less different than they may appear: any ideal types are developed so as to capture actual differences and similarities. Focusing on real types starts with such features but, to avoid the conclusion that all units are unique, it also needs to identify more general “ideal” elements that apply to multiple units.

There is also a link between different rationales and research methods. Research that aims to identify “what works” tends to have a preference for quantitative methods, whereas research aiming to understand differences may prefer qualitative tools. Yet, again, this is not always the case, as quantitative data can also be used for descriptive purposes, and qualitative data too may indicate possible causal relationships. This blurring of different tools can also be seen in the legal scholarship in this field. Since, traditionally, legal scholars did not use quantitative methods, the dominant paradigm was that of understanding similarities and differences in a textual or socio-legal qualitative way. But with the emergence of “leximetrics,” the aim for understanding now also includes quantitative data. Economists, by contrast, have long been more willing to use quantitative methods and, since the 1990s, have also frequently included quantitative legal data in their regressions (e.g., in order to determine what stimulates financial development).⁹

A further distinction is between limited taxonomies (i.e., those being concerned with specific topics) and more general ones. Using this distinction as a starting point, section 2 of this chapter outlines common taxonomies in corporate law and governance. In addition, it distinguishes taxonomies which are mainly focused on the law from those which also incorporate non-legal topics (see the overview in Table 10.1). The subsequent Section 3 discusses challenges to these taxonomies. It presents general counter-arguments but also addresses the more specific criticism directed against the quantitative research on legal origins. This is not meant to reject the possibility of quantifying legal differences. Indeed, Section 4 discusses how “leximetric” tools can contribute to the question of whether there are distinct legal families in corporate law. It outlines research conducted at the Centre for Business Research of the University of Cambridge on this topic. In addition, it presents a new leximetric analysis based on investor protection data of the World Bank’s Doing Business Report. Section 5 concludes. (p. 230)

2 Taxonomies in Corporate Law and Governance

2.1 Limited Classifications: Law-Focused

Some of the limited and law-focused taxonomies differentiate countries according to the relevant sources of corporate law. This often leads to a divide between common and civil law countries similar to the classifications in other areas of law. For example, this distinction may relate to the established view that civil law is based more on statute and common law more on case law.¹⁰ Of course, in corporate law all countries have legislation but it can still be suggested that there are differences: for example, in common law countries the case law on directors' duties tends to be very extensive, with courts often taking account of the case law of other common law jurisdictions. By contrast, the role of case law in the corporate law of civil law countries is more varied; while in bigger jurisdictions such as France and Germany courts have engaged with many questions of corporate law, in smaller jurisdictions statute law is often the sole legal basis.¹¹

A more pronounced difference may be that the corporate law of common law countries is said to be less strict than that of civil law countries. A clear version of a strict law can be found in the German law on public companies which states that the entire Companies Act is mandatory unless explicitly stated otherwise.¹² In substance, French and Chinese corporate (p. 231) law have a similar tendency toward comprehensive regulation, leaving scarcely any room for contractual freedom.¹³ By contrast, in the US, the influential law of Delaware is an example of a "business friendly" law that does not impose many hurdles on companies and their directors. This is often related to the role of regulatory competition in US corporate law,¹⁴ though listed companies also need to comply with the mandatory rules of federal securities law that deal with some topics that in other countries would be seen as rules of corporate law (e.g., proxy voting rules). In the UK, on the one hand, the codified corporate law is more detailed and prescriptive than in Delaware, not

least due to the influence of EU directives.¹⁵ On the other hand, it can be said that the UK relies less on “hard law” than the US since many topics of corporate governance are addressed in a voluntary code of best practice, which has also inspired such codes in other countries.¹⁶

This broad difference between common and civil law countries can also be related to “ideal type” taxonomies. The common law model may be said to be similar to contractual theories of corporate law. In particular, this is the case for the view of the company as a “nexus of contracts” as this is seen to imply only default rules of statute law in order to reduce transaction costs as well as a belief in the efficient forces of capital markets.¹⁷ The civil law model can be associated with counter-views that refer to the statutorily fixed nature of the company, for instance, that the company is an institution, fiction, or real person, and that the articles too constitute not a simple contract but an objective rule.¹⁸

Also related to the sources of law is the question of how many forms of business organizations countries provide. Common law countries typically start with the view of a unitary type of company. Distinctions between closely and publicly held corporations in the US, and between private and public companies in the UK, are therefore seen as two different versions of a single company form. To be sure, there are also some new forms of business organizations, such as limited liability companies and limited liability partnerships, which are addressed in special laws, though often with many references to general corporate law.¹⁹ German law, by contrast, provides two distinct forms of company. The initial form of company, the Aktiengesellschaft, is the equivalent of the public company in other countries. The small company form, the GmbH, was created in 1892 in order to provide smaller and less capital-intensive firms with a more simple legal form that also excludes the personal liability of the shareholders. In the twentieth century, this idea was taken up by a number of (p. 232) other European (and non-European) civil law countries, though not always in two separate companies acts.²⁰

Other taxonomies are more closely focused on specific legal rules. In particular, comparing and classifying those rules is useful as far as they have some relevance beyond the particular problem they are aiming to address.²¹ For example, a frequent distinction exists between countries with one and two boards. The model with just one board of directors (“one-tier model”) was the original one, and this is still the one used in common law countries. When state supervision of companies was reduced in the Germany of the nineteenth century, it was, however, decided that public companies should have two boards: a management board and a supervisory board (“two-tier model”). This German model has spread to some fellow civil law countries, while others, such as France, Italy, and Japan, allow companies to choose between different board models.²²

Many questions of corporate governance depend on the availability and choice between those two models. This topic is also related to the role of employees in corporate law since some of the two-tier countries require employee representatives on the supervisory board.²³ A similar question, often used for taxonomic purposes, is whether directors primarily have to consider the interests of shareholders or whether they can also consider

those of other stakeholders. A typical statement is that in common law countries shareholder interests legally take primacy. The sole or at least primary object of the company is seen as lying in achieving a rise in the share price and high dividends. By contrast, in civil law countries a pluralist, stakeholder approach is often seen as prevailing since it also takes account of the social and financial interests of employees, consumers, and creditors.²⁴

2.2 Limited Classifications: Beyond Law

The main focus of this chapter is on legal taxonomies in corporate law. Yet classifications that go beyond legal questions cannot be ignored, not least since legal and non-legal matters often overlap. The following examples aim to illustrate this point.

(p. 233) The corporate governance literature often makes a major distinction according to the ownership structure of large public companies: in the UK and the US, dispersed shareholder ownership is relatively common, whereas in other parts of the world ownership is more concentrated as other firms, financial institutions, families, or the state hold major blocks of shares.²⁵ A frequent point of discussion is whether these factual differences are the result of legal ones, say differences in shareholder protection.²⁶ Ownership structures can also impact on the way corporate law operates. For example, in companies with concentrated shareholdings it is easier to attain supermajority requirements than in those with dispersed ownership. Thus, it can be suggested that the relatively high majority requirements and the strictness of corporate law in continental Europe compensate for the greater freedom to contract out of statutory corporate law in the UK and the US.²⁷

Related to ownership structures is the distinction between “insider” and “outsider” models.²⁸ As far as companies have concentrated ownership, the dominant shareholders are likely to appoint board members who act on their behalf: e.g., in a family firm, members of that family. Thus, here, the directors are “insiders,” in contrast to firms with dispersed shareholder ownership where newly appointed directors tend to be “outsiders” to the company in question. The link to corporate law is that one would expect that in insider systems the main aim is to protect minority against majority shareholders, whereas in outsider systems it is to protect all shareholders against possible misconduct by directors.²⁹ This corresponds to the distinction that shareholders may be protected by either “voice” or “exit”:³⁰ to some extent this depends on the available legal tools, but the ownership of companies also plays a role, since dispersed owners are more likely than blockholders to be able to be protected by “exit,” i.e. by just selling their shares.

Section 2.1 has already raised the discussion of whether directors’ duties should be targeted toward shareholders only. Yet, the distinction between shareholder and stakeholder models is not primarily a legal one. For example, Japan is usually seen as a stakeholder country, but this is due to cultural and social factors accounting for the role of stakeholder interests, not provisions of its corporate law.³¹ The literature also frequently discusses ideal-type models of the relationship between management, capital, and labor. For example, such ideal-type thinking not only refers to a “stakeholder model” but also to an “or-

ganic” or a “social entity” model putting emphasis on the interests of the corporation as a whole.³²

(p. 234) 2.3 General Classifications: Law-Focused

Going beyond limited classifications, the challenge is that classifying countries means making a decision about some common aspects that matter while disregarding others.³³ With respect to legal taxonomies it may help that comparative lawyers often refer to legal families as relatively coherent “bundles.”³⁴ Thus, it may not be necessary to scrutinize all aspects of the law, but to identify legal rules that are good proxies, at least for a particular area of law.

For corporate law, a group of financial economists has conducted such research, using a quantitative comparative method. The first study by Rafael La Porta et al.³⁵ was based on a small set of variables for shareholder and creditor protection. The core measurement of shareholder protection was an index on anti-director rights, consisting of six variables: proxy by mail allowed, shares not blocked before the meeting, cumulative voting, oppressed minorities mechanism, preemptive rights to new issues, and the right to call a special shareholder meeting. These topics were coded according to a binary scheme (“1” for yes, and “0” for no), and the corresponding numbers were aggregated for 49 countries. The second study by Simeon Djankov et al.³⁶ examined the corporate laws of 72 countries. The index of this study was based on a hypothetical case of a self-dealing transaction: specifically, four variables on ex-ante private control, six on ex-post private control, and four variables on public enforcement. The description of the variables specified that some intermediate score (such as 0.5) could also be awarded, and the main analysis was based on aggregates of the three main categories (i.e., ex-ante/ex-post private control; public control).

In both studies, the authors’ main aim was to establish whether the strength of shareholder protection matters for financial development. Using variables such as ownership dispersion and stock market capitalization as dependent variables, it was confirmed that legal rules on shareholder protection have a quantifiable effect on financial development. A secondary finding—but of major importance for the current chapter—was that the quality of legal rules varied systematically with the “origin” of a country’s legal system, that is, whether it fell into the English “common law” or the French, German, or Scandinavian “civil law” systems. In particular, it was found that countries of English legal origin provided considerably better shareholder protection than those of the other legal origins, in particular French legal origin countries.

Other studies by the La Porta/Djankov et al. group have examined further areas of law.³⁷ Some of those studies cover most countries of the world and some also include a category of socialist legal origin.³⁸ Why exactly a particular country belongs to a particular legal origin (p. 235) is not explained in detail. Rather, to classify countries, the main consideration is whether, according to a book on foreign law,³⁹ the main codes of these legal systems are based on a particular foreign model.

Section 3.3 of this chapter discusses the problems with these studies, but at this stage it is useful to refer to a refinement of the legal origin taxonomy by Daniel Berkowitz et al.⁴⁰ This latter study re-examined the results of the La Porta et al. study, but also distinguished between origin and transplant countries⁴¹ and then identified whether transplant countries had subsequently transplanted laws from either their original or one of the other origin countries. This classification was used to show that “countries that have developed legal orders internally, adapted the transplanted law, and/or had a population that was already familiar with basic principles of the transplanted law have more effective legality than countries that received foreign law without any similar predispositions.”⁴² This finding is particularly important for legal reforms in transition economies, which have also been the subject of further quantitative legal studies.⁴³

2.4 General Classifications: Beyond Law

The corporate governance literature uses categories that, at least for Western countries, mirror those of common and civil law. On one side, one finds the Anglo-Saxon model. This is seen as pursuing a market-based approach according to which the shareholders' individual interests are to the fore. Moreover, in these countries capital markets are seen as more developed, so that interest in shares is broader and shareholder ownership is often dispersed. Markets more generally are also very competitive with firms often pursuing short-term strategies. In continental Europe, by contrast, what counts more are relations within the company than control through the markets. Management cooperates with the dominant shareholders, and the company's banks and employees also hold a strong position. Accordingly, capital markets are less developed and companies rely more on debt finance and support by the state.⁴⁴

(p. 236) But researchers have also suggested further distinctions. A frequent one is between Anglo-Saxon, Germanic, Latin, and Japanese systems of corporate governance. Here, for example, it is said that the Latin and Japanese models are more network-oriented than the Germanic one, that stock markets are more important in the Germanic and Japanese models than in the Latin one, that the government plays a greater role in the Latin model than in the Germanic and Japanese ones, and that ownership concentration is lower in the Japanese model than in the Germanic and Latin ones.⁴⁵

These categories have also been linked to the research in political science on “varieties of capitalism.” The broad distinction is here between liberal and coordinated market economies,⁴⁶ but there are also more refined taxonomies that can then be related to topics of corporate governance. For example, it may be said that there are four categories: liberal-market economies that follow a model of shareholder capitalism (e.g., the UK, the US); business-coordinated market economies with employee inclusion that follow a model of stakeholder capitalism (e.g., Germany, Sweden); government-coordinated market economies that follow a model of state-led capitalism (e.g., France, South Korea); and loosely coordinated market economies with strong employee protection that follow a model of family/state capitalism (e.g., Italy, Spain).⁴⁷ Moreover, the varieties-of-capitalism lit-

erature is helpful in pointing toward “institutional complementarities,” thus justifying the notion of general classifications.⁴⁸

Up to now, this subsection has mainly focused on developed countries, in particular from the West. Of course, this is not the full picture. In terms of economic differences, for example, researchers have often examined the specific problems of transition economies and emerging markets in corporate governance,⁴⁹ but it is also possible to consider on a global scale how corporate governance and categories of economic policy and wealth⁵⁰ are related (p. 237) to each other. In terms of geographic scope, Flores et al. discuss how well regional grouping schemes fit international business research models. They also elaborate on various grouping schemes developed in the literature, some solely based on geographic proximity, others including cultural traits and investment patterns.⁵¹

Cultural and political factors are also of interest for taxonomies in comparative law. The general comparative-law literature sometimes distinguishes between legal systems of professional law, political law, and traditional law—with the latter two categories seen as being more prevalent in non-Western legal systems.⁵² Specifically for the relationship between corporate governance and law, the legal-origin view has been criticized for its disregard of culture, arguing, for example, that the role of the law in the corporate governance of East Asian companies cannot be assessed in isolation from its cultural environment.⁵³ Thus, while some of the “beyond-law” categories support the general legal classifications (see section 2.3), others contest the relevance of Western-based legal origins.

3 Challenging the Value of Taxonomies

3.1 Introduction: Forms of Criticism

The taxonomies discussed in this chapter are relatively diverse. However, it is also possible to present and discuss some common challenges. In particular, classifications are often bound to raise the objection that, on the one hand, they overemphasize differences between categories and, on the other hand, they underemphasize differences within these categories (i.e., in this respect they overemphasize similarities). In the words of Patrick Glenn (writing about legal traditions), it is clear that: “the separation we seek to bring about, for purposes of clarity and recognition, is immediately challenged by information which is inconsistent with the separation we have chosen.”⁵⁴

Section 3.2 discusses the problem of overemphasizing differences and similarities. Section 3.3 turns to the more specific problems with the taxonomies that try to quantify legal information about legal origins (i.e., the La Porta/Djankov et al. studies). Overall, this will lead us to doubt the relevance of many of these categories. In addition, Section 4 presents a “bottom-up” leximetric analysis on whether it is possible to identify distinct legal families in corporate law.

(p. 238) 3.2 Overemphasizing Differences and Similarities

In the general literature on comparative law it is today widely held that the distinction between civil and common law countries is often misleading as it overemphasizes differences. While some legal scholars doubt whether this distinction can be justified from a historical perspective, a more frequent view is that we have seen a recent convergence between civil and common law countries.⁵⁵ For example, this can refer to the sources of law: common law countries are said to have now also reached the “age of statutes,”⁵⁶ and it has been said that it is “fundamentally incorrect” to assume that the civil law judge simply applies a set of complete and self-explanatory rules in a mechanical way.⁵⁷

It can also be objected that there is an overemphasis on the similarities within legal families. For example, the differences between French and German law are said to be “as great, or even greater, than those between French and English, or German and English law,” and England and the US are said to be two legal systems “separated by a common law.”⁵⁸ The established categories are also often seen as misleading due to the frequency of mixed forms of legal systems. This is not only the case for “classical” mixed legal systems such as those of Scotland and South Africa: for example, treating Italy and Portugal as simply part of the Romanist-French legal family ignores the German influence on these legal systems. With respect to Japanese law, treating it as civil law is misleading as it would miss the US influence, but treating it as common law—or Asian law—would also be misleading as it would miss the legal transplant of some of the main German codes.⁵⁹

For corporate law in particular there are good reasons to be even more skeptical. Here, differences tend to be less pronounced than, say, in land and property law. It has even been said that due to the influence of international trade and legal transplants, a strict division between legal families never really fitted with commercial and corporate law.⁶⁰ More specifically, the development of corporate law has been fairly similar across European countries, namely, in its beginnings, the establishment of colonial corporations, then the trend to make the corporate form more widely available, going hand in hand with a codification of corporate law, and subsequently its interpretation and application by courts.⁶¹ It has also been found that by the end of the nineteenth century the most important features of corporate law were already relatively uniform across countries.⁶²

(p. 239) In addition, corporate laws have converged to a significant extent. A research monograph by the author of this chapter examined the convergence of the corporate laws of the UK, the US, France, Germany, Japan, and China.⁶³ Other scholars have also identified various types of convergence in corporate law. Even without formal convergence, there is said to be functional convergence,⁶⁴ for example because incompetent directors may be removed but along different statutory paths. There can also be contractual (or institutional) convergence where private arrangements have a similar effect to statute law.⁶⁵ An example is the distinction between one- and two-tier board models because committees with wholly independent members in a one-tier system make this system akin to a two-tier structure, and an executive committee with a CEO in a two-tier structure makes it akin to a one-tier structure.

Legal family classifications in corporate law may also overemphasize similarities. The EU has harmonized some aspects of corporate law and many related topics of securities law.⁶⁶ This has meant that, for instance, English corporate law has diverged from the corporate law of non-European common law countries such as India and Australia. The partial “Americanization” of some foreign corporate laws has also diluted the legal family classifications. Such US transplants have not led to an “end of history” with just one model of corporate law;⁶⁷ rather, lawmakers typically follow a strategy of “cherry picking,” with different elements of various legal systems being adopted.⁶⁸ As a possible consequence, the group of civil law countries may have diverged in corporate law because some, but not all, of those countries are relatively open toward US influences.⁶⁹

With respect to taxonomies “beyond law,” it is also frequently noted that established categories do not fit reality. For example, Ruth Aguilera and Gregory Jackson refer to many studies showing that the distinction between Anglo-Saxon and continental models “only partially account for governance realities in Japan, East Asia, a wide range of European countries, and the new emerging markets.”⁷⁰ Research by Stephen Letza and colleagues emphasizes the complex, pluralist, and fuzzy nature of corporate governance and recommends that one should stay away from making “permanent, absolute and taken-for-granted” assumptions.⁷¹ For example, this “fuzziness” may challenge the distinction between shareholder and stakeholder models: today, cross-border mergers and investments mean that many larger firms do not simply belong to one of these models but have to accommodate elements of both of them.

(p. 240) Thus, as far as such taxonomies are still used in the corporate governance literature, they are often treated as mere “ideal types.” For example, in an introductory book on comparative corporate governance it may be useful to outline typical features of, say, the German and the Japanese model of corporate governance, but this is not meant to imply that this is how all actual German and Japanese firms are structured. Thus, talking about such models is more akin to the use of words such as “French fries”: the reference to the country in question may have some historical justification but may be of little relevance today.⁷²

3.3 Challenging the Quantitative Research on Legal Origins

The La Porta/Djankov et al. studies on “legal origins” have been highly influential,⁷³ but also highly controversial. Thus, it is worth discussing three main problems of these studies in some detail.

First, these studies assume that the quality of a country’s corporate law can be expressed in numbers. The initial La Porta et al. study mainly used a six-variable index on “anti-director rights” coding 49 countries.⁷⁴ However, subsequent research has identified many coding errors of the legal rules of various countries.⁷⁵ But just correcting these numbers would not be sufficient. Scholars have also raised concerns about the simple aggregation of six variables. Here, one problem is that the same indicator may play a completely different functional role in different countries, or different indicators may play the same

role, with their relative importance varying from one context to another.⁷⁶ The most severe problem is the selection of variables: not only is the number of variables very limited, it also suffers from a US bias (or, more generally, a common law one) since it does not capture important aspects of the corporate law of other countries. Thus, this index cannot be seen as a meaningful tool to compare the strength of shareholder protection across countries.⁷⁷

The more recent Djankov et al. study on self-dealing⁷⁸ may be seen as more advanced:⁷⁹ yet, here too, the precise numbers raise various concerns. This study includes (p. 241) more variables and more care has been taken in the coding of the law. It also identifies the principal components of the sub-indices, thus aiming to address the problem of simply aggregating all variables. Yet the coding of some of the sub-indices can be criticized. For example, the sub-index on public enforcement simply asks whether “jail sentences” and “fines” are available, not considering how severe these may be or whether these sanctions are used at all. A potential advantage of the Djankov et al. study could be that it is based on a hypothetical case, thus potentially addressing the home bias of the La Porta et al. study. However, this method too is problematic as it has to assume that the same type of problem exists in all of the legal systems examined. This is unlikely to be the case since social and economic structures differ widely between countries. Thus, in comparative law a strict functional approach is today widely criticized, given that societies differ from each other in their priorities and preferences.⁸⁰

Second, having coded the legal rules, the La Porta/Djankov et al. studies calculate the average scores of the English, French, German, and Scandinavian legal origins. This is based on the belief that the laws of the origin countries spread to all countries of the world through conquest, colonization, and imitation.⁸¹ However, this disregards the ongoing influence of pre-transplant laws, the mixtures and modifications at the moment when copying of foreign law occurs, and the post-transplant period in which the transplanted laws and institutions may be altered or applied differently. For example, the law and finance literature assumes that the transition economies of Eastern Europe are either German or French legal origin countries, whereas in practice they have been influenced by a number of different traditions. Similarly, it is assumed that Japan, South Korea, and China are of German legal origin, whereas a more nuanced analysis would have to take into account the indigenous legal cultures of these legal systems as well as more recent Anglo-Saxon influence. Furthermore, there is a complete disregard of non-Western legal traditions: thus, the legal origin categories also suffer from a Eurocentric bias.⁸²

The way these studies use legal origins also shows a conceptual misunderstanding. La Porta/Djankov et al. refer to the mainstream literature on comparative law. However, this overlooks the fact that comparative lawyers emphasize that these categories only have a very modest function. For instance, legal traditions are said to be just “a loose conglomeration of data,” and the idea of legal families is said to be “no more than a didactic device” that “merely serve[s] our need to maintain a rough overview.”⁸³ It is therefore doubtful of

whether such (p. 242) deliberately fuzzy and fluid classifications are reconcilable with quantitative research that relies on well-defined data points.⁸⁴

Third, there are good reasons to doubt the claim that the high quality of shareholder protection in common law countries explains their more developed financial markets.⁸⁵ The main problem is whether it can really be said that there is a clear one-way link between law and financial development. It seems more likely that law influences society in multiple ways and with various feedback mechanisms.⁸⁶ There has also been research on the evolution of corporate law in the UK and the US showing that financial market developments preceded legal change as the former precipitated the emergence of interest groups prepared to lobby for changes in the law.⁸⁷ To capture these dynamics, it would be necessary to use legal data that have a time dimension,⁸⁸ as opposed to the mere cross-sectional data of the La Porta/Djankov et al. studies.

Getting these causal relationships right is also crucial for the understanding of legal origins. The La Porta/Djankov et al. research treats these as time-invariant causal variables, i.e. the core of the legal system is seen as immune from economic influence. Yet it does not seem likely that legal systems are locked into particular developmental paths. Thus, here too, it is better to think of a co-evolving, though possibly asynchronic and dynamic interaction between law, politics, and society. This also implies that following the model of another legal origin may not have the desired effect. For example, assuming with La Porta/Djankov et al., that common and civil law countries use distinct legal models, it can be argued that institutions in civil law systems may be well matched to local economic conditions, and that following those of the common law would turn out to be either ineffective or counterproductive.⁸⁹

(p. 243) 4 Leximetrics: Are There Distinct Legal Families?

4.1 Introduction: Calculating Differences without a priori Categories

The general comparative-law literature sometimes complains that the assessment of whether groups of legal systems are similar or different is just too subjective.⁹⁰ A likely response is that one should apply quantitative tools to law ("leximetrics")⁹¹ since those may, in principle, be able to provide a more objective assessment.

Quantitative methods have already been mentioned in previous sections of this chapter. But in the studies mentioned, these quantifications of the law were just a side topic of other research questions, such as whether law matters for financial development. Moreover, studies such as those by La Porta/Djankov et al. just calculate the average of certain aggregate values for particular groups of countries.

By contrast, the research discussed in the following starts without such a priori categories in order to find out whether particular countries seem to belong together. This re-

search is based on legal variables related to topics of corporate law, yet, not simply, for example, the aggregate of shareholder protection, since different variables can lead to the same score at the aggregate level. Rather, to highlight the differences between the countries, the differences between each variable in the law of a particular legal system, and the same variable in the law of the other countries have been calculated; subsequently, the absolute values of these differences were added together. Thus, these numbers provide the differences between each pair of countries,⁹² which can then be analyzed further with tools of network analysis, for instance.

The following uses this “bottom-up” approach with examples from two comparative datasets on corporate and securities law:⁹³ section 4.2 outlines research conducted at the (p. 244) University of Cambridge, and section 4.3 is based on investor protection variables of the World Bank’s Doing Business Report.

4.2 The CBR Research on Differences and Similarities in Corporate Law

Since 2005, researchers at the Centre for Business Research (CBR) of the University of Cambridge have constructed indices for shareholder, creditor, and worker protection. The corresponding datasets are available online, including detailed explanations of the respective legal codings.⁹⁴ With respect to shareholder protection, the dataset comprises two indices. The first one has 60 variables, coding the laws of France, Germany, India, the UK, and the US for the years 1970 to 2005. The second one reduces the number of variables to ten, but codes 25 countries, initially for the years 1995 to 2005, and then for the years 1990 to 2013.

Calculating the differences between the five countries of the first CBR index, it was found that legal families have lost some importance.⁹⁵ In 1970, French law was still relatively similar to German law but more different from UK, US, and Indian law. But this changed in 2005, since here the data show that the French law on shareholder protection is closer to UK law than it is to German law. Throughout the 35 years covered by this study, the US law of shareholder protection has been very different from the other four countries, including the two common law ones—while Indian law has remained relatively close to UK law.

As a general trend, it was found that the five countries of this first index have converged in shareholder protection law. Likewise, the calculations based on the second CBR index, which covers fewer years but more countries, show convergence of the law. Here too, this trend does not involve an Americanization of corporate law since the US was and has remained relatively different from the other countries. Further trends also show that changes have not occurred along legal family lines.⁹⁶

Another paper⁹⁷ focused on the final year of the second dataset with tools of social network analysis (for this technique see section 4.3). The resulting network had some plausible (p. 245) close ties (e.g., China, Germany, and Latvia; Italy, Brazil, and Spain) whereas others were more counter-intuitive (e.g., Pakistan and the Czech Republic; Spain and In-

dia). In addition, this study used more advanced tools to classify the 25 countries of this network. Yet the resulting groups were also not entirely plausible: for example, calculating “factions”⁹⁸ led to one faction with three civil law countries (Argentina, Czech Republic, Netherlands), one with Japan, Russia, and three common law countries (US, India, Canada), one with four transition and developing countries (Pakistan, Chile, Mexico, Latvia), one with South Africa and two Western European countries (Germany, France), and one with ten countries from various legal origins and regions (UK, China, Malaysia, Italy, Spain, Brazil, Switzerland, Slovenia, Sweden, Turkey).

Overall, according to the CBR research, differences and similarities between corporate laws are largely unrelated to alleged differences between legal families. A possible response could be that perhaps there is just something wrong with the CBR indices. The following section therefore applies leximetrics to data of the World Bank’s Doing Business Report which is associated with the La Porta/Djankov et al. research.⁹⁹

4.3 Applying the Leximetric Method to the DBR Data on Investor Protection

The Doing Business Report (DBR) includes an index on “protecting investors,” dealing with three broad topics: disclosure, director liability, and ease of shareholder suits.¹⁰⁰ In total, it has 18 variables.¹⁰¹ The following analysis is based on the first 14 variables of this index since those address topics of company and securities law (the final four variables are entirely about civil procedure).¹⁰² It was the aim to cover the 25 most populous countries of the world; however, Myanmar had to be excluded as it was not included in the DBR. Thus, Figure 10.1 and Table 10.2, below, cover the remaining 24 most populous countries.

Like the research summarized in the previous section, the analysis of this section is based on the paired country differences of each of the investor protection variables. Figure 10.1 shows the closest country pairs, i.e. the most similar legal systems, in a network figure. It was decided to display the closest 37 of the 276 pairs, with the size of the lines determined (p. 246) by the tie strength. The network visualization program (NetDraw) has also shifted the position of countries according to the strength of their relationships, i.e. countries whose shareholder protection is relatively similar are moved closer together. In addition, this program has identified “factions,” based on these 37 pairs.¹⁰³

A benevolent reading of Figure 10.1 may identify some similarities between some of the common law countries: a link between Pakistan and the UK, and a clique between Nigeria, Bangladesh, and South Africa. But many of the other similarities are counter-intuitive, for example the clique of Iran, Italy, Turkey, and Mexico, as well as most of the factions.

The network analysis program (UCINET) can also identify “factions” using the entire information of the network, i.e. all 276 valued country-pairs.¹⁰⁴ Table 10.2 presents the results for two to six factions. Again, these categories challenge conventional views. For example, both of the two factions include civil and common law, as well as developed and developing countries. Interpreting the six factions is not easier; for example, it does not seem intuitive what makes, say, India and France, the UK and Turkey, or Germany and Congo (DR) very similar. (p. 247)

Taxonomies and Leximetrics

(p. 248) As a result, the DBR data on investor protection confirm the skepticism outlined in the previous sections as regards the relevance of legal families in corporate law. Thus, leximetrics has a destructive potential as it may show that established taxonomies do not stand up to scrutiny. However, it may also be constructive as far as it may illuminate unexpected similarities, and thus motivate the conceptualization of new taxonomies.

5 Conclusion

This chapter started with an overview of the different aims that taxonomies can pursue. Given these diverse rationales, it is plausible that there is some variety in the taxonomies used in corporate law and governance. Yet this chapter also explained that some of the classifications have shaped the current debate, notably the “legal origins” research conducted by a group of financial economists.

The idea of “legal origins” is closely related to the discussion in comparative law about “legal families.” Categories such as common and civil law—or English, French, German and Scandinavian legal origin—may initially have had a certain plausibility, but at least today there are also good reasons to be skeptical. In particular, leximetric research has shown that, in reality, differences and similarities between legal systems do not fit with these categories. The use of the legal origin categories is therefore highly problematic as far as they take on a life of their own and become mere stereotypes about country characteristics and alleged group differences.

A possible response could be that, in a similar way to some of the corporate governance taxonomies,¹⁰⁵ we may observe a shift from “real” to “ideal” types. Thus, talking, for example, about, “English legal origin” might not necessarily mean that Anglo-Saxon countries tend to have certain commonalities, but would rather describe certain characteristics that any possible group of countries may have in common.

In addition, this chapter suggests that comparative researchers often do not need such a priori categories. As far as a researcher examines a limited group of countries, such as the UK, the US, Germany, and Japan, it is perfectly possible to explain similarities and differences without the use of potentially misleading categories such as English and German legal origin. But even when more countries are examined, the researcher should resist the temptation to classify too early: here, at best, she may try to identify categories with a “bottom-up” approach,¹⁰⁶ being prepared to find the unexpected.

Abstract and Keywords

This chapter analyzes the economic consequences of external and internal asset partitioning, and it considers implications of this analysis for creditor remedies. External partitioning refers to the legal boundaries between business firms and their equity investors, while internal partitioning refers to the legal boundaries within corporate groups. The chapter begins by cataloguing the benefits and costs of corporate partitioning; it then employs this catalogue to analyze the relative economics of external and internal partitioning. Non-partitioning functions of subsidiaries are also identified. The chapter then considers whether cost-benefit analysis predicts how courts actually apply de-partitioning remedies, with particular emphasis on veil piercing and enterprise liability. The chapter concludes by arguing that courts should employ the distinction between external and internal partitioning when applying creditor remedies that disregard corporate partitions, and it identifies factors—in addition to whether a partition is internal or external—that courts should consider when deciding whether to de-partition.

Keywords: asset partitioning, corporations, subsidiaries, corporate groups, external partitioning, internal partitioning, creditor remedies, veil piercing, enterprise liability

1 Introduction

ASSET partitioning is the use of standard-form legal entities, such as the business corporation, to set boundaries on creditor recovery rights.¹ The corporate form partitions assets in two ways. First, it provides *owner shielding*, meaning that it protects the equityholders' personal assets from the business's creditors. The corporation's particular type of owner shielding is the principle of limited shareholder liability.² Second, the corporation provides *entity shielding*, meaning that it protects the business's assets from the equityholders' personal creditors.³ Entity shielding is not as celebrated as limited liability, but we believe it is the more fundamental type of asset partitioning, because it would be harder to achieve by contract alone, without use of legal entities. By combining entity

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

shielding with owner shielding, the corporation partitions assets from the perspectives of both the business and its owners.⁴

Scholars have identified several economic benefits of corporate asset partitioning. But corporate partitioning also generates costs, and courts have developed equitable remedies (p. 252) that allow unpaid creditors to reach across corporate boundaries to recover. In American law, the most important de-partitioning remedies are veil piercing, enterprise liability, and substantive consolidation, all of which have analogues in the laws of other nations.⁵

Creditors are especially likely to seek a de-partitioning remedy when the debtor is a member of a corporate group, by which we mean a firm organized as a parent entity plus one or more wholly owned subsidiaries. A creditor might ask a court to disregard the boundary separating the parent from its shareholders, which we call an *external* partition. Alternatively, the creditor might seek to cross a boundary that separates one group member from another, which we call an *internal* partition. Several scholars have argued that external partitions provide greater economic benefits than internal partitions and therefore deserve more protection. Most prominently, Frank Easterbrook and Daniel Fischel argued in their 1985 article “Limited Liability and the Corporation” that courts should be more willing to hold a parent entity liable for a subsidiary’s debt than to hold a parent’s shareholder liable for the parent’s debt.⁶

Easterbrook and Fischel’s article is deservedly influential. Its analysis of asset partitioning in corporations is, however, incomplete in two important respects. First, it considers only half the story: it analyzes the benefits of owner shielding (that is, limited liability), but not the benefits of entity shielding. Adding entity shielding to the picture reveals several additional benefits of corporate partitioning that de-partitioning remedies could jeopardize. Second, Easterbrook and Fischel did not consider two important characteristics of most corporate groups: their neglect of subsidiary-level accounting and their heavy reliance on intra-group guarantees, which are contractual arrangements in which group members agree to stand behind each other’s debts to outside creditors. The presence of these characteristics reveals which potential benefits of corporate partitioning a group’s subsidiaries actually provide, and which potential costs they actually generate.

In this chapter, we compare the economic benefits and costs of external and internal corporate partitioning, and we consider our comparison’s implications for de-partitioning remedies. Like previous commentators, we argue that the case for enforcing external partitions is stronger than the case for enforcing internal partitions. We add to the previous literature by identifying factors—other than whether a partition is internal or external—that courts should consider when deciding whether to de-partition. We are able to identify these factors because our fuller list of corporate partitioning’s costs and benefits makes clearer the relevant trade-offs. For example, we argue that a corporate group’s use of intra-group guarantees weighs in favor of disregarding the group’s internal partitions. Intra-group guarantees are both evidence of, and contributors to, the agency costs of debt, which de-partitioning remedies can reduce. Because intra-group guarantees are, in

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

essence, de-partitioning by contract, their use in a particular corporate group indicates that the group's subsidiaries serve functions unrelated to asset partitioning's potential economic advantages.

In section 2, we update the standard catalogue of corporate partitioning's costs and benefits to include those identified since Easterbrook and Fischel's article. In section 3, we use this catalogue to analyze the relative economics of external and internal partitioning. In section 4, we identify non-partitioning functions of subsidiaries, which are functions that (p. 253) de-partitioning remedies do not undermine. Finally, in section 5, we consider whether our cost-benefit analysis predicts how courts actually apply de-partitioning remedies, and we propose general principles for reforming legal doctrine to better reflect the economics of corporate partitioning. In that discussion, we limit our comments to the de-partitioning remedies of veil piercing and enterprise liability, reserving for later work a discussion of substantive consolidation, a remedy that presents unique doctrinal complexities.

2 The Benefits and Costs of Corporate Partitioning

In this section, we review the main benefits and costs of corporate asset partitioning that scholars have identified. We begin with the benefits that are apparent when owner shielding—meaning, in the business corporation, limited shareholder liability—is considered in isolation. We then expand the list to include three benefits that become evident when the other important aspect of corporate partitioning—entity shielding—is considered. Finally, we describe corporate partitioning's two main costs.

Although our aim is to describe the economics of corporate partitioning generally, in the discussion that follows we focus on the economic consequences of an incorporated firm's external partition. We do so because we believe that the benefits of internal partitioning are a subset of those of external partitioning. Put another way, there is no potential benefit of internal partitioning that is not also a benefit of external partitioning. It thus makes sense to begin by listing external partitioning's benefits; in section 3, we consider whether, and to what extent, each benefit can also arise from the partitions within a corporate group.

We define an *external* partition as the legal barrier dividing a corporation from its ultimate owners: its human and institutional equityholders. And we define an *internal* partition as a legal barrier within a corporate group, by which we mean a parent corporation plus all corporations it wholly owns, directly or indirectly. Under these definitions, if a corporate entity has one or more human shareholders, then the partition separating it from its shareholders is external. Conversely, if a corporation has only one shareholder, and that shareholder is another corporation, then the two entities are members of the same corporate group, and the partition separating them is internal. Finally, if a corporation has multiple corporate shareholders and no human shareholders, then the partition

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

separating it from its shareholders is external unless those shareholders are wholly owned, directly or indirectly, by a common corporate parent.

One more note on terminology before we turn to our catalogue of benefits and costs: The act of incorporating a business firm, and thus introducing an asset partition between it and its owners, can shift value from some creditors to others. For example, if the firm has a high debt-equity ratio, then incorporating it could shift risk from the owners' personal creditors to the firm's creditors. When, however, we speak of corporate partitioning's benefits and costs, we do not mean the offsetting consequences of such a zero-sum transfer. Rather, we define a benefit as a source of economic efficiency: something that increases the sum of social wealth. And we define a cost as a consumption of resources or a deadweight loss—something that reduces social wealth.

(p. 254) We begin our list with the benefits of corporate partitioning that are evident when limited liability is considered in isolation. Because these benefits are well described in prior literature, we merely summarize them here.

2.1 Reduced Need for Equityholders to Monitor Each Other

In the general partnership, partners bear joint-and-several liability for partnership debt, and a partner sued by a partnership creditor can seek contribution from her co-partners.⁷ Partners therefore prefer rich co-partners to poor ones, and for this reason might restrict who can become a partner, and also might monitor each other's personal affairs.⁸ However, monitoring is expensive, and restricting membership hinders growth and makes partnership shares less liquid. Limited liability eliminates these costs by permitting equityholders to be indifferent to each other's personal fortunes. Pro rata equityholder liability for the firm's debts—a weaker form of owner shielding—provides the same benefit.⁹

2.2 Facilitating Control Transfers

Without limited liability, investors would, by purchasing equity in a firm, make all of their personal wealth available to its creditors. Therefore, transferring ownership from a poor investor to a rich one would confer a windfall on the firm's creditors, at the rich investor's expense. This surcharge on wealthy investors would discourage transfers of control to parties who might be able to run a firm (or monitor its managers) more effectively.¹⁰ Limited liability eliminates the surcharge by making the value of an equity share independent of its owner's wealth. This benefit is distinct from the previous one—reduced need to monitor other shareholders—because it arises even if a firm has, at any particular time, only one owner.

An alternative way to avoid a windfall for a firm's creditors when the firm is sold to a wealthy investor would be to refinance all of the firm's debt, upon the sale's completion, at lower interest rates. Refinancing would, however, entail transaction costs, especially if the old debt agreements contained prepayment penalties. Limited liability makes refi-

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

ancing unnecessary because it allows ownership to change hands without altering the amount of wealth backing the firm's debts.

2.3 Liquid Shares

Limited liability promotes a liquid market in equity shares, in two ways. First, by making shareholders less concerned about who else owns shares, limited (or pro rata) liability allows (p. 255) firms to relax or eliminate restrictions on share transfers. Second, by making a share's value independent of who owns it, limited liability increases the informational value of market prices.¹¹ An investor can decide whether to buy at the market price without concern that the price results from trading among investors who are poorer than she is.

2.4 Equityholder Diversification

As Henry Manne first observed, limited liability enables shareholders to diversify.¹² In particular, it reduces the volatility of share values by preventing them from dropping below zero. Limited liability therefore makes it easier for investors to reduce the overall riskiness of their portfolios by adding shares of different companies.¹³ Moreover, when a firm's shareholders are diversified, its managers can ignore unsystematic risk when deciding how to invest the firm's funds, widening the range of positive-value projects from which they may select.¹⁴

2.5 Reduced Information Costs for Personal Creditors

Limited liability narrows the factors a prospective creditor must analyze when evaluating a borrower's creditworthiness.¹⁵ The borrower might own shares in a business firm and therefore—without limited liability—be answerable for its debts. The creditor would then have to consider the firm's insolvency risk when analyzing the borrower's credit risk. If, however, the firm is a corporation, then the creditor knows he will not have to compete with its creditors for the borrower's assets. Limited liability thus simplifies lending decisions, which will translate, in a competitive market, into a lower cost of credit.

At first blush, limited liability also seems to reduce information costs for corporate creditors. By denying them access to the shareholders' personal assets, it seems to let corporate creditors ignore those assets when assessing the risk of lending to the corporation. Limited liability is not, however, sufficient to make corporate creditors indifferent to shareholders' personal affairs. Without entity shielding, corporate creditors might be forced to share the corporation's assets with the shareholders' personal creditors. Therefore, corporate creditors will still need to assess the shareholders' personal assets and liabilities when evaluating the corporation's creditworthiness. For this reason, limited liability provides large informational benefits to creditors only when combined with entity shielding—that is, when partitioning is symmetrical rather than asymmetrical.¹⁶

(p. 256) There are three other benefits of corporate partitioning that also depend on entity shielding, which are as follows:

2.6 Bankruptcy Simplification

Just as symmetrical partitioning can reduce creditor information costs, it also can simplify bankruptcy proceedings. A public company's bankruptcy would be unmanageable if the bankruptcy court had to take into account not only the company's balance sheet but also each shareholder's personal assets and debts.¹⁷ The symmetrical partition between the company and its owners—blocking creditors in both directions—divides assets and liabilities into legally tractable bundles. It restricts the bankruptcy estate to the assets and liabilities of the company, excluding those of its shareholder. With fewer assets to value and proofs of claim to validate, the bankruptcy process can determine the ratio of assets to debts more quickly, permitting faster payouts to unsecured creditors.¹⁸ Faster bankruptcy proceedings are more efficient because they redeploy debtor assets to better uses more quickly and generally have lower administrative costs.¹⁹

2.7 Protection of Going-Concern Value

An important component of the type of entity shielding provided by the corporation is liquidation protection.²⁰ Although a shareholder's unpaid personal creditors can seize her shares, they cannot force the corporation to liquidate, a process that in most jurisdictions requires a board resolution followed by shareholder ratification.²¹ Liquidation is therefore unlikely unless in the best interests of shareholders generally, such as when the corporation is solvent but its liquidation value exceeds its going-concern value.²² Without liquidation protection, shareholders could agree to forbid unilateral equity withdrawals, but courts might not enforce such agreements through specific performance, especially against personal creditors who are not parties to the agreements.²³ We see a contrast in the general partnership, whose assets are available for immediate seizure by partners' unpaid personal creditors. For this reason, the traditional rule is that a partner's bankruptcy dissolves the partnership.²⁴

Liquidation protection also promotes share transferability. Without liquidation protection, equityholders would wish to prevent sales of equity shares to indebted investors whose creditors could force liquidation of the firm's assets. Conversely, share transferability (p. 257) complements liquidation protection by giving shareholders an alternative way to convert shares to cash.

2.8 Correcting Debt Overhang

Corporate partitioning makes it easier for indebted entrepreneurs to raise funding to start new businesses. Without the option to form a corporation, an indebted entrepreneur might be unable to borrow to fund a prospective business, even if the business has a positive net present value. If the prospective business were to fail, the lender who funded it might have to share its assets with the entrepreneur's prior creditors. Anticipating this, the lender will demand a higher interest rate, which could make the prospective business unprofitable for the entrepreneur. Entity shielding solves this debt-overhang problem.²⁵ If the entrepreneur commits the new business to a distinct corporate entity that borrows

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

the needed funds, the new lender will have the first claim to the business's assets and therefore will demand less interest, potentially making the undertaking worthwhile for the entrepreneur.²⁶

Corporate partitioning also generates two types of cost:

2.9 Higher Agency Costs of Debt

Debt distorts how managers run a business. A firm with debt can take actions that enrich equityholders not by increasing the firm's total value but by shifting risk onto creditors. Termed from the creditors' perspective, such acts of "debtor misconduct" take a variety of forms, including asset shifting, asset substitution, involuntary subordination, debt dilution (for fixed debt), and correlation seeking (for contingent debt). The anticipation of debtor misconduct induces creditors to incur monitoring costs to prevent it and firms to incur bonding costs to reassure creditors that they will not engage in it. If debtor misconduct is undeterred, the value transfers it brings about induce firms to overinvest in risky projects.²⁷ As defined by Michael Jensen and William Meckling, the direct costs of debtor misconduct, (p. 258) plus the monitoring and bonding costs incurred to prevent such misconduct, constitute the "agency costs of debt."²⁸

Because every debtor is, at some level of debt, judgment-proof, all debtors face an incentive to engage in misconduct. The incentive increases, however, if business owners can incur debt through corporations to which they have committed only a portion of their wealth. Limited liability shifts business risk from equityholders to creditors, which increases the expected benefit to equityholders of debtor misconduct and thus raises the agency costs of debt.²⁹

Incorporating a firm to reduce recoveries for tort creditors can be characterized as a type of debtor misconduct. Whether it actually destroys social wealth depends on the quality of the tort system. If the system is otherwise effective at deterring wealth-destroying torts, then limited shareholder liability leads to underdeterrence. Incorporated firms will overproduce, and they will underinvest in precautions.³⁰ If, however, the tort system overdeters—perhaps because juries are biased against defendants—then corporate partitioning's judgment-proofing effect could be socially beneficial.³¹

2.10 Accounting Costs

A court cannot enforce an asset partition unless it knows which assets and debts belong on each side. When a corporation fails, the proper division of assets and debts among the corporation, its affiliates, and its shareholders may not be obvious, especially if there is a controlling shareholder. The bankruptcy trustee may have to hire an accountant, whose fees will deplete the estate and thus reduce total creditor recoveries. And creditors might challenge the accountant's conclusions, introducing delay and driving up the estate's legal bills.

Accountants also are hired to confirm or demonstrate compliance with loan covenants and statutory creditor-protection measures such as distribution constraints and fraudulent-transfer law. In this way, accounting costs are monitoring or bonding costs and thus components of the agency costs of debt. Even, however, if a firm scrupulously refrained from debtor misconduct, it probably would still pay accountants to prepare financial statements to reduce information costs for its creditors.

(p. 259) 3 Internal Partitioning: Legal Boundaries within the Firm

We now consider whether, and to what extent, each of corporate partitioning's benefits and costs arises from internal partitioning in particular. The economics of internal partitioning are important, as most publicly traded companies are corporate groups with elaborate subsidiary networks.³² In 2010, the 100 largest US public companies by revenues had, on average, 245 major subsidiaries.³³ Corporate groups are also the norm in other developed countries: For example, in 2005, large Japanese public companies averaged 108 subsidiaries,³⁴ and large French firms averaged 68.³⁵

In section 2, we identified eight potential benefits of corporate partitioning. In this section, we argue that internal partitioning cannot generate three of these benefits: reduced need to monitor other equityholders, liquid shares, and protection of going-concern value. Four others—reduced creditor information costs, bankruptcy simplification, shareholder diversification, and the correction of debt overhang—are benefits that internal partitioning can provide, but seems rarely to do so in practice. That leaves efficient control transfers as the only common asset-partitioning benefit of subsidiaries. Moreover, subsidiaries seem to provide this benefit only temporarily, until the debts of the acquired entity are paid off or rolled over.

Besides providing fewer economic benefits than external partitioning, internal partitioning also tends to generate higher costs. Accounting costs are higher because subsidiary boundaries often fail to track the firm's real internal divisions. In addition, internal partitions increase the agency costs of debt by facilitating several types of debtor misconduct, including asset shifting, involuntary subordination, and correlation seeking through intra-group guarantees. The implication, which we develop in section 5, is that courts should be less reluctant to disregard the legal partitions within firms than those surrounding them.

We address first the three benefits of corporate partitioning that internal partitioning cannot provide. These are lower inter-shareholder monitoring costs, liquid shares, and protection of going-concern value. External partitioning generates these benefits by preventing conflicts among shareholders who differ in personal wealth and needs for liquidity. These benefits therefore cannot result from internal partitioning, as shareholder con-

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

flict cannot (p. 260) arise if a corporation—such as a subsidiary in a corporate group—has only one shareholder, or if all its shares are under common control.

There are four other potential benefits of corporate partitioning that internal partitioning could provide in theory but seems rarely to provide in practice. One is bankruptcy simplification. If the members of a bankrupt corporate group operated separately, rarely transacted with each other, and had little overlapping debt, then it might make sense to assign their bankruptcy cases to different judges. Their cases could then proceed in parallel, potentially enabling them to conclude more quickly. In practice, however, we almost never see affiliated debtors assigned to different courts. Instead, when a corporate group fails, its constituent members' cases are administratively consolidated and assigned to a single judge. A collective proceeding makes sense because the affiliated entities often have guaranteed each other's major debts and therefore have common creditors, and because their managers have typically failed to maintain accurate subsidiary-level records, obscuring the proper allocation of assets and debts among them.³⁶ In such a case, there is no procedural advantage to creating a distinct bankruptcy estate for each constituent entity. On the contrary, the lack of reliable entity-level accounting slows down proceedings and consumes administrative resources. For this reason, enforcing the firm's internal partitions will typically complicate the bankruptcy proceeding rather than simplifying it.

A similar story applies to creditor information costs. Like bankruptcy simplification, lower information costs are a benefit that internal partitioning could, in theory, supply.³⁷ Just as external partitioning enables a prospective creditor to disregard shareholders' personal affairs when assessing a firm's creditworthiness, so might internal partitions permit a prospective creditor to focus his credit analysis on the particular entity with which he will transact.³⁸ The cost savings could be considerable if the group's subsidiary boundaries track its real geographical and functional divisions.³⁹ In practice, however, most firms do not maintain informationally relevant internal partitions. Instead of preparing subsidiary-level financial records and sharing them with creditors, firms neglect entity-level accounts and (p. 261) report results only on a consolidated basis.⁴⁰ Indeed, bankruptcy courts cite sloppy or indifferent entity-level accounting and tangled internal affairs as their main reasons for applying the de-partitioning remedy of substantive consolidation.⁴¹

Another practice that undercuts the capacity for subsidiaries to reduce information costs is the widespread use of intra-group guarantees.⁴² To see why, suppose that Subsidiaries A and B are members of a corporate group, that Bank One lends to Subsidiary A, and that Subsidiary B guarantees the loan. The guarantee makes the boundary between the subsidiaries irrelevant to Bank One, as both subsidiaries' assets and liabilities will determine the bank's payout if the group becomes bankrupt. In addition, the guarantee widens the exposure of Subsidiary B's creditors beyond Subsidiary B's own operations. They now bear some of Subsidiary A's credit risk: If A defaults, they will have to share Subsidiary B's assets with Bank One.

It is predictable that a corporate group which relies on intra-group guarantees will not bother to prepare accurate entity-level financial reports. The reports would have little val-

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

ue to the group's shareholders, who care only about consolidated results. The reports' only potential audience would be creditors who have extended credit to particular entities within the group. If, however, the creditors have also received intra-group guarantees that tie their (p. 262) payouts to the performance of the group as a whole, then they too will have little reason to concern themselves with the division of value among entities within the group.⁴³

Shareholder diversification is a third economic benefit that internal partitions provide in theory but not often in practice. In a true conglomerate, each subsidiary is a distinct company, making the group akin to an investment portfolio assembled by the parent entity on behalf of its shareholders. Internal partitioning reduces the portfolio's volatility by preventing one company's insolvency from pulling down the others' equity values. However, true conglomerates are rare, as investors have cheaper and more flexible options for diversifying shareholdings, such as mutual funds. Moreover, a group's subsidiaries will effectively diversify risk only if they refrain from lending to each other and from issuing intra-group guarantees, which is unusual. In fact, the typical corporate group is a single business firm organized as a collection of legal entities.

Finally, corporate subsidiaries could serve to correct debt overhang, but, again, firms seem rarely to use them for this purpose. The debt-overhang problem arises when an indebted firm wishes to invest in a new project. If the project is less risky than the firm's existing projects, it will decrease the firm's overall default risk by reducing the variance of the distribution of the firm's potential net asset values. As a result, the project will confer a windfall on the firm's existing creditors at the expense of equityholders. This value transfer could make the new project unprofitable from the shareholders' perspective even if it has a positive net present value. The firm could overcome this problem by organizing itself as a corporate group that houses each investment project, along with the debt used to fund the project, in a separate subsidiary. In reality, however, most corporate groups do not structure themselves this way. Instead, the parent does most of the borrowing and distributes the proceeds to the subsidiaries, which in return issue upstream guarantees. If debt overhang were a problem, this structure would exacerbate it by giving the parent's creditors a claim on the proceeds from any new projects undertaken by the subsidiaries.⁴⁴

The remaining benefit of corporate partitioning identified in section 2 is the facilitation of efficient control transfers. Unlike the others on our list, this benefit is one that corporate subsidiaries do seem to provide with some frequency. However, the benefit is temporary, lasting only until the acquirer pays off or rolls over the target's preexisting debts. Thus, when two firms combine, they typically engage in a "triangular" merger that makes the target firm a subsidiary in the acquirer's corporate group.⁴⁵ Maintaining the target as a separate entity denies the target's pre-merger creditors recourse to the acquirer's assets. Such recourse would benefit those creditors at the expense of the acquirer's equityholders,⁴⁶ producing a value transfer that would act like a tax on corporate acquisitions, discouraging some wealth-creating combinations.⁴⁷ One commonly offered explanation for subsidiaries is a legacy of (p. 263) mergers and acquisitions,⁴⁸ and we believe that this

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

goal of preventing a windfall for the target firm's preexisting creditors is indeed an important reason that most acquisitions are structured to maintain the target as a distinct entity.

It must be noted, however, that intra-group guarantees undermine this potential benefit of subsidiaries. If a subsidiary results from a merger, and one or more of its creditors subsequently receive downstream or cross-stream guarantees, then those creditors thereby gain access to the acquirer's pre-merger assets, seemingly defeating the purpose of maintaining the target as a distinct legal entity.⁴⁹ How then can we reconcile the widespread use of intra-group guarantees with the practice of triangular mergers? One possibility is that acquirers maintain targets as separate entities for some of the non-partitioning reasons for subsidiaries we will discuss in the next part. A second possibility is that the separate subsidiary is meant to prevent a value transfer to the target's creditors at the time of the acquisition, but not later. Thus, as time passes and the subsidiary rolls over its debts, we can expect its lenders to bargain for cross-stream and downstream guarantees that tie their expected payouts to the performance of the group as a whole. These guarantees will reduce those lenders' information costs given the unlikelihood that the group maintains accurate subsidiary-level records. In addition, the guarantees will protect the lenders against value-shifting within the group. Alternatively, the group will replace the subsidiary's debt with new borrowing at the parent level that the subsidiary guarantees. In either case, the subsidiary will cease to serve its positive asset-partitioning function. The group may nonetheless continue to maintain the subsidiary as a separate entity because it serves non-partitioning functions, or because there is no reason to incur the transaction costs of absorbing it into another entity in the group.

In summary, we find that subsidiaries tend to provide only one of corporate partitioning's eight potential benefits with meaningful frequency: the promotion of efficient control transfers. Moreover, they provide this benefit only temporarily, until the newly acquired subsidiary rolls over its debt, at which point intra-group guarantees are issued that pierce the partitions between the subsidiary and the rest of the group.

Turning to the cost side of the ledger, we find that it too is unfavorable to internal partitioning. A subsidiary network facilitates several types of debtor misconduct, including asset shifting, judgment proofing against tort creditors,⁵⁰ and involuntary structural subordination. As an example of the last, imagine that HoldCo, the parent entity in a corporate group, takes out a loan from Bank One. Shortly afterward, the group's managers shift all of HoldCo's assets into its wholly owned subsidiary, SubCo. SubCo then uses its increased creditworthiness to borrow at a favorable interest rate from Bank Two. This maneuver harms Bank One by subordinating its claim on HoldCo's assets to Bank Two's claim. It also encourages overinvestment by reducing HoldCo's borrowing costs through an asset transfer (p. 264) that, from the perspective of HoldCo's shareholders (as contrasted with its creditors), is costless.⁵¹

Bank One could insist on a debt covenant forbidding such acts of structural subordination. But monitoring for compliance would be costly, especially because the group could

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

shroud asset shifting in sloppy entity-level accounting.⁵² Moreover, the shifting of assets from HoldCo to SubCo would not normally be considered a constructive fraudulent transfer, as a court would probably hold that HoldCo received a reasonable equivalent value through the appreciation in its equity claim in SubCo that the transfer produced.⁵³

A more cost-effective way for Bank One to protect itself against involuntary subordination would be to demand an upstream guarantee from SubCo. The guarantee would leave the bank largely indifferent to the division of assets between the two entities.⁵⁴ In this way, the widespread use of intra-group guarantees evinces that internal partitioning increases the risk of debtor misconduct. It does not follow, however, that intra-group guarantees produce an overall reduction in the agency costs of debt. Although an intra-group guarantee protects its recipient against asset shifting, it also, though correlation seeking, transfers risk onto the guarantor's preexisting unsecured creditors.⁵⁵ Thus, while an upstream guarantee from SubCo would insulate Bank One against asset transfers from HoldCo to SubCo, it simultaneously would take value from SubCo's preexisting general creditors. The value transfer will occur because the probability that the guarantee will be triggered correlates positively with SubCo's insolvency risk,⁵⁶ concentrating the guarantee's burden on SubCo's creditors rather than on the group's equityholders. Those creditors will suffer a net reduction in the expected value of their claims even if Bank One pays SubCo a premium equal to Bank One's (p. 265) full expected recovery on the guarantee.⁵⁷ Therefore, rather than reducing the total agency costs of debt, intra-group guarantees merely shift the impact of debtor misconduct from creditors who receive guarantees to those who do not.

The enforcement of internal partitions also tends to entail high accounting costs. Whereas an external partition can be enforced if a firm prepares only one consolidated set of financial statements, enforcing internal partitions depends on the firm's preparing separate balance sheets and income statements for each of its constituent entities. In addition, internal partitioning encourages disputes over the company's internal accounting and pricing of intra-group transfers and loans. Such disputes are common in bankruptcy because the debtor's managers will have had little incentive to price internal transfers accurately. The managers' duties are to the group's shareholders, whose claims are unaffected by the pricing of intra-group transfers and loans.⁵⁸

Table 11.1 summarizes our comparison of external and internal partitioning. We have italicized three "yes" entries in the external-partitioning column to indicate benefits that (p. 266) external partitioning provides only if a corporation has shareholders who differ in their levels of personal wealth or liquidity requirements. If a corporation has only a single, human shareholder, then its external partition will not provide these benefits, even though it could provide the others in the table.

As Table 11.1 indicates, cost-benefit analysis favors external partitioning. Using a firm's outer boundary to demarcate creditor recovery rights can provide numerous benefits to both creditors and shareholders. By contrast, internal partitioning provides fewer benefits, and its costs are higher, especially if—as is typical—the group neglects subsidiary-level accounting. Such neglect indicates that the group's creditors did not use subsidiary boundaries to economize on credit analysis. It also means that using the internal partitions to delimit creditor recoveries in bankruptcy would require the estate to hire accountants, whose fees would be paid at the expense of the group's general creditors.

4 Non-Partitioning Functions of Subsidiaries

Table 11.1 raises a question. If internal partitioning is costly to enforce and increases the agency costs of debt, and its benefits are either temporary or rare, why do firms have so many subsidiaries? The apparent answer is that subsidiaries serve non-partitioning functions whose benefits outweigh the net costs of internal partitioning, or at least the net costs borne by shareholders. We call these “non-partitioning” functions because, for the most part, de-partitioning remedies such as veil piercing do not compromise them.

One non-partitioning function of a subsidiary is to establish a legal domicile in a particular jurisdiction. For example, a multinational firm might form a corporate entity in a particular country to take advantage of its low tax rate.⁵⁹ Similarly, regulated firms such as banks might be required to maintain distinct entities in each state in which they operate. De-partitioning remedies do not interfere with these jurisdictional functions. If a bankrupt company liquidates, disregarding its internal boundaries when calculating creditor payouts will not nullify the tax and regulatory benefits its subsidiaries provided pre-bankruptcy. If the company instead reorganizes, it can maintain its internal entity structure post-bankruptcy even if that structure was not used in bankruptcy to determine payout entitlements.⁶⁰

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

Another function of subsidiaries is to reduce the transaction costs of spin-offs by preserving transferable bundles of contracts.⁶¹ To see why, suppose that BuyCo acquires TargetCo but wants the option to spin it off cheaply later. During a spin-off, reassigning TargetCo's executory contracts—which might comprise much of TargetCo's real economic value—could be difficult. Most executory contracts contain non-assignment clauses, and (p. 267) non-assignment is the default rule for most employment contracts. These assignment restrictions protect each party to a contract against the risk that the counterparty will transfer its obligations to a third party who will default or otherwise underperform.⁶² Most assignment restrictions do not, however, forbid the sale of the entire counterparty to a new owner. Likewise, the common law rule is that the sale of some or all of a corporation's shares does not constitute an assignment of the corporation's contracts. This rule makes economic sense, because a sale of a corporation's shares does not disrupt complementarities among the corporation's contractual positions and its other assets. In other words, changing a firm's ownership is less risky to its counterparties than individual assignments of their contracts would be. Therefore, by preserving TargetCo as a separate subsidiary, BuyCo can later sell it without having to negotiate for waivers from all of its contractual counterparties, which might create holdout problems.

Once again, de-partitioning remedies do not undermine this function of subsidiaries. If a bankrupt company liquidates, its contracts will be cancelled regardless of how creditor payouts are calculated. If it instead reorganizes, any executory contracts (or leases) it chooses to honor will remain with their original entities after the bankruptcy proceeding,⁶³ preserving the company's contract bundles. Although the subsidiaries might be ignored in the calculation of creditor payouts, including payouts to contractual counterparties whose claims have come due, the subsidiaries can continue to operate as distinct legal persons post-bankruptcy. For this reason, the reorganized company will not be hampered in spinning off any divisions it maintained pre-bankruptcy as separate entities.

5 Legal Implications: Patterns and Presumptions

We now consider our analysis's descriptive and prescriptive implications for creditor remedies that disregard corporate partitions. Descriptively, the distinction between external and internal partitioning corresponds to some, but not all, of the patterns we observe in how courts apply de-partitioning remedies. Prescriptively, our analysis suggests how courts could increase social wealth by bringing doctrine more in line with the economics of corporate partitioning.

The general implications of our analysis are consistent with those of the work of other scholars, beginning with Easterbrook and Fischel. Courts should be less willing to disregard an external partition than an internal one. And they should be especially loath to disregard the external partition of a company with tradable shares, the setting in which

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

shareholders are likely to be most heterogeneous in terms of personal wealth and liquidity needs, and therefore where external partitioning is especially beneficial.

(p. 268) Turning to more specific implications, our analysis suggests that courts should be more willing to disregard an entity's partition when the entity's managers have failed to keep an accurate record of its assets and liabilities. When such records are absent, asset partitioning does not reduce creditor information costs, correct debt overhang, simplify bankruptcy proceedings, promote share trading, facilitate efficient control transfers, or provide liquidation protection. Therefore, a court can apply a de-partitioning remedy without fear that doing so will undermine these various potential benefits of asset partitioning.

Accurate accounting is also essential for asset partitioning to reduce the agency costs of debt. Legislatures have created creditor-protection measures to reduce those costs. In corporations, the most important measures are fraudulent-transfer law and distribution constraints, both of which rely on accurate recordkeeping. Under fraudulent transfer law, relief is typically available only if a creditor (or bankruptcy trustee acting on creditors' behalf) can show that the debtor did not receive "a reasonably equivalent value" when it transferred an asset or incurred an obligation, and that the debtor was insolvent when the transaction occurred.⁶⁴ These are factual showings that require accounting records, including a balance sheet for the time of the transaction. Similarly, distribution constraints presuppose a balance sheet that accurately records the corporation's surplus. Without a balance sheet to cite, creditors cannot prove that a corporation paid dividends out of shareholder capital, which is supposed to remain in the corporation as a cushion against insolvency. Therefore, if managers have failed to keep the accounts necessary for enforcing these boundary-policing measures, courts should be willing to let creditors cross boundaries, especially when equityholders (on whose behalf the managers act) rather than other creditors would bear the consequences.

Our analysis also suggests that courts should be more willing to disregard a corporate partition if the corporation's managers or shareholders have already perforated it by issuing guarantees. A guarantee is voluntary de-partitioning, a waiver of either entity shielding or owner shielding (or both) on behalf of a particular creditor. Therefore, the presence of a guarantee suggests that partitioning's costs outweigh its benefits, at least with respect to the creditor receiving the guarantee.⁶⁵ Moreover, if the cost-benefit analysis of enforcing a corporate partition is unfavorable for one creditor, it is likely to be unfavorable for other creditors, even if—perhaps because they are unsophisticated or have small claims—they did not negotiate for guarantees for themselves.⁶⁶

We have already described how intra-group guarantees undercut several potential benefits of internal partitioning. Besides evincing that the recipient creditor did not rely on subsidiary boundaries to economize on information costs, an intra-group guarantee suggests that a subsidiary is no longer serving to facilitate an efficient control transfer or to correct debt overhang. The former is true if a subsidiary's creditor received a cross-stream or downstream guarantee, while the latter is true if the subsidiary itself issued a

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

guarantee. Courts therefore (p. 269) should treat intra-group guarantee as a factor weighing in favor of de-partitioning remedies within corporate groups.

We anticipate an objection. Courts that selectively ignore corporate partitions could disappoint investor expectations and introduce uncertainty into business affairs. We note, however, that this objection does not argue against de-partitioning remedies per se; rather, it argues against applying remedies unpredictably. If courts made clear the circumstances under which they will allow creditors to cross corporate boundaries, expectations and interest rates would adjust accordingly. As discussed below, we believe that de-partitioning criteria can be adopted that promote economic efficiency and that give parties reasonable notice as to when an asset partition will be disregarded.

With these observations in mind, we now address the particular de-partitioning remedies of veil piercing and enterprise liability. Because our expertise is American law, we focus on doctrine developed by American common-law courts. We do, however, offer a few comparative observations about European and Japanese law.

5.1 Veil Piercing

The remedy of veil piercing suspends the rule of limited liability by allowing a corporate creditor to recover from a controlling shareholder. Under American law, the creditor must satisfy both parts of a two-prong test: He must show (1) that the corporation served as the shareholder's mere "alter ego," and (2) that liability for the shareholder is necessary to avoid some injustice.⁶⁷ The Japanese Supreme Court has adopted a similar test, permitting recovery from a controlling shareholder if the corporation's legal personality is a "mere formality" that has been "abused."⁶⁸ In the United Kingdom, courts occasionally allow a creditor to pierce the veil if the corporation is a "mere façade concealing the true facts."⁶⁹

As these various quoted terms suggest, courts tend to articulate veil-piercing doctrine in vague and conclusory language, making it difficult to evaluate the remedy's economic consequences. If, however, we look at case outcomes, we see that judges—at least in the United States—do often employ the remedy in a manner that protects corporate partitioning's economic benefits and reduces the agency costs of debt. Courts typically consider the first, "alter ego" prong of the veil-piercing test satisfied upon a showing that the corporation failed to follow procedures such as holding board meetings, electing directors, keeping accurate records, and maintaining separate bank accounts.⁷⁰ Several of these procedures—especially the last two—bear directly on the agency costs of debt.⁷¹ As noted above, statutory creditor protections such as fraudulent transfer law and distribution constraints presuppose an accurate corporate balance sheet. Therefore, by emphasizing (p. 270) sound recordkeeping in their alter-ego analyses, courts deter practices that drive up the agency costs of debt.

Regarding the second prong of the American veil-piercing test—the presence of some sort of injustice—studies show that courts are particularly likely to deem it satisfied if the creditor was misled, even if the deception fell short of common-law fraud.⁷² We again see

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

an implicit concern with the agency costs of debt, and also with one of the primary benefits of external partitioning: reducing creditor information costs. Creditors are more vulnerable to debtor misconduct and can rely less on the integrity of entity boundaries, if they cannot count on a debtor's attestations about its financial condition and compliance with loan covenants.

In terms of the specific contexts in which courts pierce the veil, the distinctions we have drawn in this chapter predict some, but not all, of the patterns in case outcomes. Thus, courts never pierce the veil to reach the personal assets of public shareholders,⁷³ which is consistent with our view that corporate partitioning is most beneficial when in the form of an external partition separating a firm from multiple shareholders. On the other hand, there is evidence that, in the context of close corporations, courts are slightly more likely to pierce an external partition (to reach a controlling human shareholder) than an internal partition (to hold a parent liable for the debt of a subsidiary).⁷⁴ This observation is unexpected given that, even in a close corporation, external partitioning can provide greater economic benefits. We hypothesize that confounding variables are at work: Courts are perhaps more likely to find that a creditor was misled by a human shareholder than by a corporate entity, or they might consider it more egregious if a firm as a whole, rather than one entity within a corporate group, has failed to respect corporate formalities.

We now consider doctrinal reforms implied by our analysis. We are not the first commentators to notice that the vague terms in which courts articulate veil-piercing doctrine make it difficult for parties and their attorneys to predict when shareholders will be held liable.⁷⁵ With respect to the American law of veil piercing, we believe that the first prong in particular could usefully be re-conceptualized and re-articulated. As argued above, the corporate formality that is most important to creditors is the maintenance of accurate entity-level accounts. Other formalities, such as enacting bylaws and holding shareholder meetings, are less relevant. The implication is that courts should ground veil piercing's first prong explicitly, and perhaps exclusively, in accurate accounting, with the dispositive question being (p. 271) whether the corporation maintained records adequate to support enforcement of standard creditor-protection measures.

Regarding the distinction between external and internal partitioning, we propose that courts employ it to assign evidentiary burdens. When a creditor of a subsidiary seeks the parent's assets, courts should require the defendant to produce annual balance sheets for the subsidiary that are accurate over the span of the plaintiff's loan. Assigning this burden to the defendant makes sense given that internal partitioning has fewer potential benefits than external partitioning and raises a greater debtor-misconduct risk. If the defendant cannot meet the burden, the plaintiff should recover, even if veil-piercing's traditional second prong is not met. Allowing recovery on such facts would reduce the agency costs of debt by penalizing defendants for failing to maintain the records that underpin statutory creditor-protection measures. If, on the other hand, the defendant can produce accurate accounts, courts should presume that the normal creditor-protection measures

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

were effective. The plaintiff should then prevail only upon a clear showing of misrepresentation or deception.

When, by contrast, a plaintiff seeks to pierce a corporation's *external* partition to reach a controlling shareholder's assets, we suggest that the burden lies initially with the plaintiff. Even when shares are not freely tradable, external partitioning often provides benefits that internal partitioning does not, including shareholder diversification, reduced creditor monitoring costs, bankruptcy simplification, and correction of debt overhang. Therefore, when seeking to pierce an external partition, the plaintiff should have to show that the corporation's records are not complete enough to permit enforcement of statutory remedies. In addition, the plaintiff should have to show either that he was deceived or that the partition did not serve external partitioning's main benefits and therefore should be accorded no more respect than a poorly maintained internal partition.

In support of this last type of showing, a plaintiff should be permitted to cite the defendant's grant of a personal guarantee to one of her corporation's creditors. A personal guarantee reduces the degree to which the external partition diversifies the shareholders' equity portfolio, as it puts the shareholder's personal assets—including her investments in other firms—at risk. The guarantee also suggests that the external partition is no longer serving to preserve the benefits of an efficient control transfer. That benefit arises when limited liability prevents an acquired firm's creditors from reaching the acquirer's personal wealth, and yet such access is exactly what a personal guarantee provides. In addition, a personal guarantee suggests that the external partition did not help creditors economize on their information costs, for reasons discussed in section 3. Therefore, if a controlling shareholder has guaranteed any of her corporation's debts, we propose that the inquiry should be the same as in a case involving an internal partition, with the plaintiff prevailing unless there was no deception and the defendant can show that accurate corporate records were maintained.

Why, one might object, should a contractual creditor who has failed to bargain for a personal guarantee enjoy the same remedy—access to the shareholder's personal assets—as the creditor who did? One response is that this objection proves too much: All creditor-protection measures are substitutes for contractual provisions that creditors could, in theory, bargain for (and pay for, through lower interest rates) themselves. If, however, the goal is economic efficiency, then the relevant question is not whether a creditor could have obtained protection contractually but whether a statutory or equitable remedy would more effectively lower the agency costs of debt. Remedies that lower agency costs increase the surplus from credit arrangements, making both lenders and borrowers better off. We note in this regard (p. 272) that the common practice of giving a personal guarantee to a small firm's most important lender—typically a bank—creates perverse incentives, as banks would otherwise charge higher interest rates to firms with greater tort risk. Moreover, bargaining for guarantees entails transaction costs, which is why shareholders almost never give personal guarantees to trade creditors, who have small claims governed by standard-form contracts. To be clear, our argument is not that the issuing of one personal guarantee should invalidate a firm's external boundary for all creditors.

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

Rather, courts should treat the guarantee as evidence that the boundary does not provide most of corporate partitioning's potential economic benefits. The defendant could still prevail by showing that the corporation maintained accurate records and distinct accounts and by rebutting any claim that the plaintiff was deceived.

5.2 Enterprise Liability

Traditional veil piercing is a vertical de-partitioning remedy: It renders shareholders liable for corporate debt. Sometimes, however, the shareholder has committed most of her wealth to other corporations, which may or may not form a corporate group with the original debtor entity. In that situation, American courts sometimes allow the plaintiff to "reverse pierce" and assert claims against these other corporations.⁷⁶ To reach their assets, however, the plaintiff must first establish the elements of a piercing claim against the defendant shareholder.

Rather than requiring plaintiffs to take this circuitous route through the shareholder's personal estate, some courts have authorized the alternative de-partitioning remedy of enterprise liability. That remedy allows the creditor of one member of a corporate group to pierce horizontally to reach the assets of other members. The remedy does not, however, open the gates to the shareholder's personal assets: It abrogates internal partitions, not external ones.

The factors that courts consider when deciding whether to impose enterprise liability are much like those that govern the first prong—the alter-ego test—of veil-piercing doctrine. However, while the courts of every US state have endorsed some version of veil piercing, courts in only a handful of states have recognized enterprise liability. Moreover, the list became shorter in 2008 when Texas's highest court repudiated the remedy, holding that mere unity of control or function cannot make one corporation liable for the debt of another.⁷⁷ As a result, veil piercing became the only equitable remedy in Texas for abrogating corporate partitioning. Notions of enterprise liability can also be found in British and German company law.⁷⁸

We suspect that enterprise-liability cases are rare in the United States primarily because failed corporate groups typically end up in bankruptcy court, where judges employ a different doctrine—substantive consolidation—to disregard internal partitions.⁷⁹ It (p. 273) therefore is unsurprising that the most prominent judicial opinion to endorse enterprise liability in one state (Louisiana) is from a case involving an insurance company,⁸⁰ as state regulators rather than federal bankruptcy judges oversee insolvency proceedings involving insurers.⁸¹

We recognize the need for a doctrine of enterprise liability in collective insolvency proceedings. Our analysis here, however, suggests that courts should more consciously direct the doctrine toward the goals of reducing administrative costs and the agency costs of debt. It follows that courts should be inclined toward imposing enterprise liability when a corporate group has failed to keep accurate entity-level records, especially if the group has also issued intra-group liabilities. Such doctrinal reform would require courts

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

to amend their lists of relevant factors. Currently, American courts do include shoddy internal accounting among the factors weighing in favor of collective liability within the group.⁸² But they also consider formalities, such as whether the entities had overlapping directors and officers,⁸³ that matter little for creditor protection or for the broader question of whether the benefits of enforcing an internal asset partition exceed the costs. Judges also do not weigh the presence of intra-group guarantees in favor of enterprise liability, perhaps because they may be unaware of how such guarantees, via correlation seeking, contribute to the agency costs of debt.

6 Conclusion

In this chapter, we have introduced what we believe is a useful distinction between two types of corporate asset partitioning: *external* partitioning versus *internal* partitioning. An external partition is the legal boundary that separates a business corporation from its ultimate, real equityholders: its human and institutional shareholders. Internal partitions are the legal boundaries within a corporate group, meaning a parent entity and its network of wholly owned subsidiaries.

We have argued that distinguishing external partitioning from internal partitioning has both descriptive and prescriptive utility. Descriptively, external partitioning provides more benefits than internal partitioning, and it generates lower costs. External partitioning provides at least eight potential benefits: reduced need for equityholders to monitor each other; liquidation protection; liquid shares; shareholder diversification; reduced creditor information costs; bankruptcy simplification; overcoming debt overhang; and efficient control transfers. Internal partitioning, by contrast, cannot provide the first three benefits on this list, and it rarely provides the next four. Conversely, corporate partitioning's two main costs—accounting costs and the agency costs of debt—tend to be higher when partitioning is internal rather than external.

Prescriptively, our analysis suggests that courts should employ the distinction between external and internal partitioning when applying creditor remedies that disregard corporate partitions, such as veil piercing and enterprise liability. To be sure, to some extent they already do. Studies show that courts are especially unlikely to allow a creditor to pierce a (p. 274) public company's external partition, the type of corporate partition with the most favorable cost-benefit analysis. Similarly, courts use the remedy of enterprise liability only to disregard internal partitions, never external ones. The congruence between theory and doctrine is incomplete, however, perhaps because courts often frame de-partitioning doctrine in terms of whether the corporate form has been adequately "respected" rather than whether the economic benefits of partitioning outweigh its costs. We therefore have proposed ways that de-partitioning doctrines could, in light of our analysis, be reformed to increase social wealth.

We are not the first commentators to argue that courts should respect the partition around a firm more than they respect the partitions within it. Thirty years ago, Easterbrook and Fischel argued that courts should be more willing to allow a creditor to pierce

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

the boundary between a corporate subsidiary and the parent than the boundary between the parent and its shareholders. On this point, our conclusions are consistent with theirs. However, the only form of corporate partitioning that Easterbrook and Fischel considered was limited shareholder liability. We have offered a broader analysis that also considers the benefits and costs of entity shielding—the rule that shields a corporation’s assets from the shareholders’ personal debts. And we have factored into our analysis two important observations about corporate groups: their lack of subsidiary-level financial records and their heavy reliance on intra-group guarantees. For these reasons, we have been able to identify a more complete set of considerations that bear on whether a corporate boundary should be disregarded. For example, we have shown how the presence of intra-group guarantees or personal shareholder guarantees—which are forms of voluntary de-partitioning—evinces that a corporate partition is not providing certain economic benefits, and also that enforcing the partition at the expense of creditors without guarantees is likely to increase the agency costs of debt.

By necessity, our reform suggestions have been broad and summary. We have identified factors we think courts should consider, as well as factors they currently consider but should ignore, when deciding whether to grant a de-partitioning remedy. We have also identified presumptions, based on whether a partition is internal or external, that courts could apply in such cases. A more complete treatment of de-partitioning remedies would consider particular areas of doctrinal conflict, such as the tendency for American bankruptcy courts to apply substantive consolidation more often than appellate courts seem to believe is appropriate.⁸⁴ With respect to such issues, we believe that using the economics of asset partitioning generally, and the distinction between internal and external partitioning specifically, to study de-partitioning doctrines is a promising area for future scholarship.

(²⁶) Debt overhang can be a problem even if the indebted entrepreneur plans to finance the new business with her own wealth rather than new debt. Her current creditors, including those who funded her current businesses, will have access to the new business's assets if she is unable to service her prior debt, reducing the new business's expected value to her. Limited liability mitigates this problem if she uses separate corporate entities to house each of her businesses and their associated debt (if any). See Easterbrook & Fischel, *supra* note 6, at 111 (noting that the threat of tort liability would discourage taxicab owners from buying more cabs if they could not incorporate each taxi separately). Strictly speaking, this is not a distinct benefit of limited liability, but rather another way of describing how limited liability makes the value of an equity share independent of its owner's personal wealth. By blocking corporate creditors from seizing shareholder wealth held outside the corporation, limited liability removes a disincentive for the shareholders to increase that wealth.

(³⁹) Anthony Casey has offered a “selective enforcement” variation on the informational theory of subsidiaries. Anthony J. Casey, “The New Corporate Web: Tailored Entity Partitions and Creditors’ Selective Enforcement”, 124 Yale L. J. 2680 (2015). He describes a situation in which a single lender makes loans to two (or more) subsidiaries in a corporate group. The loan agreements include cross-default provisions. If one subsidiary defaults, the lender can use information conveyed by the fact of default to decide whether to accelerate the loans to the other subsidiaries. *Id.* at 2711. The structure thus gives the lender more enforcement options than he would have if the borrowing firm were a single legal entity.

The theory rests on factual assumptions that we find implausible. It presupposes that subsidiaries maintain distinct, accurate financial statements, which—as we discuss—is contrary to the experience of most bankruptcy courts. Without such records, a default by one subsidiary would not convey the information necessary for lenders to make the nuanced enforcement decisions Casey describes. The theory also assumes that a group’s managers would allow one subsidiary to default while another is solvent, rather than using profits or assets from the solvent subsidiary to prop up the insolvent one. Yet, managers face strong incentives to prevent any entity in a group from defaulting, precisely because of the widespread use of cross-default provisions, which make a group’s debts to multiple

External and Internal Asset Partitioning: Corporations and Their Subsidiaries

creditors immediately payable upon a default on any loan. (Fraudulent transfer law does not deter managers from transferring value within the group to prevent defaults; it merely reverses improper transfers if bankruptcy nonetheless ensues.)

Our perception is that major lenders do not typically make distinct loans to multiple entities in a corporate group. Instead, they lend to the parent, who distributes the proceeds to its subsidiaries, in exchange for which the subsidiaries issue upstream guarantees to the lender. See, e.g., *In re Tousey, Inc.*, 680 F.3d 1298, 1301 (11th Cir. 2012); *In re Owens Corning*, 419 F.3d 195, 201 (3d Cir. 2005). Moreover, Casey lumps together cross-default provisions and intra-group guarantees as “cross-liability provisions,” but they have different implications for the possibility of selective enforcement. To forbear enforcing a guarantee from a solvent guarantor when the borrower is insolvent is to forgive a collectible debt, which seems unlikely to be a rational lender strategy.

We believe that intra-group guarantees have a simpler explanation that is more consistent with the observed facts. Lenders seek the guarantees to reduce their information costs and protect themselves against value transfers within the group. And managers issue such guarantees because they reduce the group’s cost of debt on the guaranteed loans, partly by reducing the guaranteed creditors’ information and monitoring costs, and partly by shifting, through correlation seeking, some of the default risk to the guarantors’ general creditors, who are unlikely to charge interest rates that adjust based on whether intra-group guarantees have in fact been issued to other creditors. ⁽⁴²⁾ This objection to the informational theory of internal asset partitioning was first raised by George Triantis. See George G. (⁴⁶) The transfer would not occur if the acquirer's and target's insolvency risks were perfectly positively correlated.

(⁴⁷) To avoid the windfall to the target's creditors, the acquirer could insist on a reduction in the interest rates they are owed, but renegotiating all of the target's debts could require the acquirer to incur significant transaction costs and create holdout problems.

(⁴⁸) See Posner, *supra* note 15, at 510.

(⁴⁹) This is not true if the guarantee is upstream, as such a guarantee merely re-prioritizes creditors, and—unlike a cross-stream or downstream guarantee—does not pledge any shareholder wealth that the lender did not have a claim to already. Squire, *supra* note 32, at 638.

(⁵⁰) See, e.g., Lynn M. LoPucki, "The Death of Liability", 106 Yale L. J. 1, 20 (1996) (arguing that sequestering liability-generating operations in a separate subsidiary prevents tort claimants and other creditors from reaching a firm's most valuable assets).

(⁵¹) Regardless of whether HoldCo or SubCo holds the assets, both entities' creditors must be repaid in full before HoldCo's shareholders can recover. Therefore, the asset shift does not affect the value of the shareholders' residual claims, even though it impairs the claims of HoldCo's creditors.

(⁵²) Discovering the asset shift after the group becomes insolvent and files for bankruptcy is unlikely to be of much help, as Bank One will then be unable to recover the full damages for the breach of the anti-subordination covenant. (⁵⁵) Squire, *supra* note 32, at 623–639 (analyzing correlation seeking through intra-group guarantees). In general terms, correlation seeking occurs when a firm sells a contingent claim against itself that has a positive “internal correlation,” meaning that the claim’s risk of being triggered correlates positively with the firm’s insolvency risk. Richard Squire, “Shareholder Opportunism in a World of Risky Debt”, 123 Harv. L. Rev. 1151, 1159 (2010). Upon issuance, such a contingent claim reduces expected recoveries for the firm’s unsecured creditors. If the firm has priced the contingent claim to capture its full expected value to the claimant, then the consideration the firm receives increases the firm’s equity value by a commensurate amount. *Id.* at 1161.

(⁵⁶) The risks correlate because a group’s entities often make equity and debt investments in each other, and because they typically produce the same goods or services, subjecting them to common supply and demand conditions. *Id.* It therefore is predictable that, when one entity in a group guarantees the debt of another, the guarantor will be insolvent when the borrower triggers liability on the guarantee by defaulting on the debt.

(⁵⁷) It is a straightforward matter to show mathematically that, when the internal correlation is positive, the creditors’ expected loss on account of the contingent liability outweighs their expected benefit from the fee. See Squire, *supra* note 32, at 624–28.

(⁵⁸) The situation would be different if a corporate entity had minority shareholders along with a controlling shareholder and therefore would not be, under the definition we have been using here, a subsidiary within a corporate group. In such a corporation, the minority shareholders care about the pricing of transfers between the corporation and the controller or the controller’s affiliates. For a discussion of how minority shareholders can deter opportunism by the controller in this type of corporation, see Triantis, *supra* note 42, at 1125.

Abstract and Keywords

This chapter explores issues relating to the board of directors. Focusing on the formal model of corporate governance, it considers why corporate decisions are made through the exercise of hierarchical corporate authority instead of consensus. Specifically, it examines the survival advantage that a bureaucratic hierarchy confers on a large corporation and which of its constituencies should elect the board. It first outlines the key functions of the board of directors drawing on the unitary and dual board models. It then asks why corporations are run by boards of directors rather than by shareholders or the chief executive officer. It discusses why ownership and control are separated in the corporate form, with special emphasis on the US experience, along with the economic rationale for vesting control in a group rather than in an individual. Finally, it analyses how boards fail and looks at the reforms that have been implemented to improve their performance.

Keywords: board of directors, corporate governance, corporate authority, unitary board, dual board, corporations, ownership, control, shareholders, chief executive officer

1 Introduction

¹WHEN recognizably modern corporations emerged in Anglo-American law in the early nineteenth century, the board of directors was already deeply embedded in their DNA. New York's 1811 Act Relative to Incorporations for Manufacturing Purposes, for example, vested the power to manage the corporation in a board of directors (albeit using the term trustees).² Likewise, the United Kingdom's Joint Stock Companies Act of 1844 broadly empowered the board of directors to, *inter alia*, "conduct and manage the Affairs of the Company."³ In neither case, moreover, was the statute an innovation. On the contrary, board of directors-like bodies were routine among the modern corporation's antecedents, such as the trading companies created by charters granted by the English crown as far back as the Muscovy Company of 1554.⁴

The Board of Directors

Similar developments were taking place contemporaneously in Europe. Although many large European businesses of the time remained organized as partnerships, with no governing board, there were emerging entity forms such as the Dutch East India Company that were governed by boards.⁵ Interestingly, even though autocratic rule was in its heyday amongst continental governments during much of this period, the antecedents of modern European corporations—like their English counterparts—opted for consensus governance in a board or board-like committee.⁶

(p. 276) Although realworld practice often differs from the statutory ideal, modern corporation statutes still vest ultimate managerial power in neither the corporation's officers (the so-called C-suite) nor its shareholders. Although the differences detail across national boundaries, corporation codes (a.k.a. company laws) establish the board of directors as the key player in the formal decision-making structure. As the influential Delaware code puts it, for example, the corporation's business and affairs "shall be managed by or under the direction of a board of directors."⁷

The formal model of corporate governance thus contemplates a pyramidal hierarchy surmounted neither by a large electorate nor an individual autocrat, but rather by a small collaborative body. This model raises a number of questions: Why are corporate decisions made through the exercise of authority rather than by consensus? Why is corporate authority exercised hierarchically? Put another way, what survival advantage does a large corporation gain by being structured as a bureaucratic hierarchy? Why is the firm's ultimate decision maker a collective rather than an individual? Who, among all the corporation's constituencies, should elect the board?

Section 2 begins the process of answering those questions by looking at the key functions of the board of directors. Although the precise mix of functions varies across national borders, the US unitary board and the German dual board models provide sufficiently useful paradigms that our attention will focus on them. Section 3 turns to the question of why corporations are run by boards of directors rather than, say, by either shareholders or the CEO. It begins by focusing on the separation of ownership and control, discussing how and why the two separated in the corporate form. The focus in this section is mainly on the US experience. Section 3 then turns to developing an economic rationale for vesting control in a group rather than an individual. Section 4 returns to the comparison between the US and German models, exploring the question of which constituencies should be empowered to choose the board of directors. Section 5 discusses the perennial question of whether director independence is to be desired. Finally, while the bulk of this chapter focuses on the theory behind the statutory model, no discussion of the board of directors would be complete without a discussion of how boards so often fail to perform as intended. Section 6 therefore examines how boards fail and the reforms that have been tried to improve their performance.

2 Board Functions

The roles and functions of the board depend in the first instance on the structure given the board by national (or, in the case of the USA, state) legislation. Although the details vary widely among nations, the US unitary board and the German dual board stand as exemplars of the basic statutory options for board governance. Beyond these statutory requirements, of course, best practice norms and other nonlegal considerations further refine the expected functions of the board.

(p. 277) 2.1 The Unitary Board

In the USA's federal system, primary responsibility for creating and regulating corporations is a matter for the states rather than the national government. Among the 50 states, of course, Delaware is far and away the most important. More than half of the corporations listed for trading on the New York Stock Exchange and nearly 60 percent of the Fortune 500 corporations are incorporated in Delaware. Because of the so-called "internal affairs doctrine"—a conflicts of law rule holding that corporate governance matters are controlled by the law of the state of incorporation—Delaware law thus controls the formation and governance of the vast bulk of important public corporations. The most important alternative to Delaware law is the American Bar Association's Model Business Corporation Act (MBCA), which has been adopted in whole by about half the states and in part by many others.

Despite the resulting potential for diversity, there is remarkable uniformity on the basics of board structure. A single board of directors is elected by the shareholders and charged with ultimate decision-making authority within the corporation. Beyond this statutory minimum, there are few housekeeping rules and those are mostly enabling. In most states, for example, there are no rules on board size, term limits, and similar issues.

Instead, the role and functions of the board have been defined mainly by nonlegal norms and expectations. Although the board's functions have therefore varied over time, today they can be sorted into three basic categories. These are management, oversight, and service. Although all three remain important aspects of a board's work, the recent trend has been to elevate the importance of monitoring at the expense of the others.

2.1.1 Management

If one looked solely to corporation statutes for guidance, one would assume that the board of directors plays a very active role in the corporation's management. Besides the general allocation of the conduct of the corporation's business and affairs to the board, corporation statutes include many specific mandates that only the board can fulfill. Approval by the board of directors is a statutory prerequisite, for example, to mergers and related transactions such as sales of all or substantially all corporate assets, the issuance of stock, distribution of dividends, and amendments to the articles of incorporation. Approval by the board of directors of related party transactions involving top managers or board members is a statutory option for substantially insulating such transactions from

The Board of Directors

judicial review for fairness. The board typically has non-exclusive power to amend by-laws. And so on.

In fact, of course, the typical modern public corporation is too big for the board to manage on anything resembling a day-to-day basis. As discussed in Part 6.2, moreover, these days most board members are outsiders who have full-time jobs elsewhere and therefore can devote relatively little time to the running of the business for which they act as directors. As early as 1922, the Delaware Chancery Court therefore acknowledged that the directors' principal role was one of supervision and control, with the detailed conduct of the business being a matter that could properly be delegated to subordinate employees.⁸

(p. 278) The formulation of typical modern corporation statutes reflects this shift. MBCA § 8.01(b), for example, provides that the "business and affairs of the corporation" shall be "managed under the direction of" the board.⁹ This formulation is intended to make clear that the board's role is to formulate broad policy and oversee the subordinates who actually conduct the business day-to-day. In addition, the statute also provides that corporate powers may be exercised "under the [board's] authority."¹⁰ This formulation allows the board to delegate virtually all management functions to senior corporate officers, who in turn of course will delegate most decisions to subordinate employees.

Even so, modern boards typically retain some managerial functions. Indeed, courts have held that some decisions are so important that the board of directors must make them.¹¹ In some states, such basic matters as filing a lawsuit¹² or executing a guarantee of another corporation's debts are viewed as extraordinary decisions reserved to the board.¹³ In recent years, courts also have imposed substantial managerial responsibilities on the board of directors—especially its independent members—in connection with shareholder derivative litigation, conflict of interest transactions, and mergers and acquisitions.

Best practice also assigns important managerial roles to the board. Broad policy making or, at least, review and approval of major policies, for example, are board prerogatives. Boards are also responsible for hiring the top management team, especially the CEO, and setting their compensation.

2.1.2 Service

A diverse board that includes outsiders can provide a number of services to the top management team. Outsiders can provide access to networks to which insiders do not belong, thereby assisting the firm in gathering resources and obtaining business. Outside directors affiliated with financial institutions, for example, facilitate the firm's access to capital. In addition to simply providing a contact between the firm and the lender, the financial institution's representative can use his board membership to protect the lender's interests by more closely monitoring the firm than would be possible for an outsider. In turn, that reduction of risk should result in the lender accepting a lower return on its loans, thereby reducing the firm's cost of capital.

The Board of Directors

Another example is the politically connected board member, whose access to legislators and regulators may aid the firm in dealing with the government. Such board members not only assist with obtaining government contracts, but also with clearing red tape and providing the firm with political cover in times of trouble.

(p. 279) A core service provided by boards of directors, especially its outside members, is providing advice and counsel to the CEO. By virtue of being outsiders, the board members can offer the CEO alternative points of view. In particular, the board can serve as a source of outside expertise. Complex business decisions require knowledge in such areas as accounting, finance, management, and law. Members who possess expertise themselves or have access to credible external experts play an important role in the board's service function.

2.1.3 Monitoring Managers

Modern public corporations are characterized by a separation of ownership and control, which "produces a condition where the interests of owner and of ultimate manager may, and often do, diverge and where many of the checks which formerly operated to limit the use of power disappear."¹⁴ Economists Michael Jensen and William Meckling later formalized this concern by developing the concept of agency costs,¹⁵ which is now widely recognized as "the fundamental concern of corporate law" and governance.¹⁶

Agency costs arise because a firm's agents have incentives to shirk. Specifically, the principal reaps part of the value of hard work by the agent, but the agent receives all of the value of shirking. In a classic article, economists Armen Alchian and Harold Demsetz offered the useful example of two workers who jointly lift heavy boxes into a truck.¹⁷ The marginal productivity of each worker is difficult to measure and their joint output cannot be separated easily into individual components, which makes obtaining information about a team member's productivity and appropriately rewarding or punishing it difficult and costly. In the absence of such information, however, the disutility of labor gives each team member an incentive to shirk because the individual's reward is unlikely to be closely related to conscientiousness.

Although agents have strong incentives to shirk once they enter into a contract with the principal, from an ex ante perspective they have strong incentives to agree to contract terms designed to prevent shirking. Bounded rationality and the potential for renegotiation, however, preclude firms and agents from entering into the complete contract necessary to prevent shirking by the latter. Instead, there must be some system of ex post governance by which firms detect and punish shirking. Accordingly, an essential economic function of management is monitoring the various inputs into the team effort: Management meters the marginal productivity of each team member and then takes steps to reduce shirking.

The process just described, of course, raises a new question, namely, who will monitor the monitors? In any organization, one must have some ultimate monitor who has sufficient incentives to ensure optimal productivity without having to be monitored. Otherwise, one

ends up with a never-ending series of monitors monitoring lower level (p. 280) monitors.¹⁸ Alchian and Demsetz solved this dilemma by consolidating the roles of ultimate monitor and residual claimant.¹⁹ According to Alchian and Demsetz, if the constituent entitled to the firm's residual income is given final monitoring authority, he is encouraged to detect and punish shirking by the firm's other inputs because his reward will vary exactly with his success as a monitor.

Unfortunately, this elegant theory breaks down precisely where it would be most useful. Because of the separation of ownership and control, it simply does not describe the modern publicly held corporation.²⁰ As the corporation's residual claimants, the shareholders should act as the firm's ultimate monitors. But while the law provides shareholders with some enforcement and electoral rights, these are reserved for fairly extraordinary situations.²¹ In general, shareholders of public corporations lack the legal right, the practical ability, and the desire to exercise the kind of control necessary for meaningful monitoring of the corporation's agents.²² As a result, the legal system evolved various adaptive responses to the ineffectiveness of shareholder monitoring, establishing alternative accountability structures to punish and deter wrongdoing by firm agents, most notably the board of directors.²³

2.1.4 Shifting Priorities

The relative balance between these functions has shifted over time. Survey data and other forms of fieldwork in the 1970s suggested that boards had a mainly advisory role. Survey data from the 1990s, by contrast, showed an emphasis on managerial functions in the sense (p. 281) of broad policy making and setting strategy. By the end of the 1990s, survey data showed that boards were becoming active and independent monitors of the top management team.²⁴ What drove this shift?

Although the modern understanding of the board's role and function has no single parent, if one were to insist on finding someone to whom to give the bulk of the credit—or blame—the leading candidate would be Professor Melvin Eisenberg. In *The Structure of the Corporation*,²⁵ “perhaps the most important work on corporate law since Berle and Means's *The Modern Corporation and Private Property*,”²⁶ Eisenberg argued that boards were essentially passive, with most of their functions captured by senior executives. According to Eisenberg, the board's principal remaining function was selection and supervision of the firm's chief executive. Eisenberg contended, moreover, that most boards failed adequately to perform even that residual task.

As a solution, Eisenberg articulated a corporate governance model that explicitly separated the task of managing large publicly held corporations from that of monitoring those who do the managing. In this monitoring model, directors did not undertake decision making or policy making, which were assigned to senior management. Instead, the board's principal function was to monitor the performance of the company's senior executives. Other functions such as advising the CEO, authorizing major corporate actions, and

The Board of Directors

exercising control over decision making were of minor importance or were merely pro forma.

Eisenberg's model proved highly influential. It informed the role set out for boards of directors in the American Law Institute's *Principles of Corporate Governance: Analysis and Recommendations*.²⁷ Aspects of his proposals, such as shifting responsibility for interacting with the auditor from management to the audit committee, have long been incorporated into stock exchange listing standards.²⁸ As early as the late 1970s, guides to corporate governance best practices had widely adopted the monitoring model.²⁹ Indeed, the monitoring model (p. 282) quickly "became conventional wisdom, endorsed by the Chairman of the SEC, the corporate bar, and even the Business Roundtable."³⁰ By 1997, Eisenberg thus was able to declare that "key structural elements of the monitoring model—including a board that has at least a majority of independent directors, and audit, nominating, and compensation committees—[were] already well-established."³¹

The monitoring model of the board's function received further boosts in the major federal corporate governance laws passed in the wake of the Enron scandal and the subsequent financial crisis of 2007–2008. In the wake of the former and the concurrent bursting of the dot-com bubble, Congress passed the Sarbanes-Oxley Act, much of which was intended to require directors to be more effective monitors of corporate management.³² The post-financial crisis Dodd-Frank Act likewise "includes significant governance reforms designed to enhance director oversight of compensation and risk."³³

2.1.5 Critiquing the Monitoring Model

There is an inherent conflict among these roles. Suppose the CEO comes to the board for advice on a proposed project. The board advises the CEO to go forward with the proposal, but the project thereafter fails miserably. The board's role in the original decision inevitably compromises its ability to evaluate and, if necessary, discipline the CEO. The monitoring model seeks to avoid this problem by giving primacy to the board's oversight role.

Yet, in doing so, the monitoring model raises its own set of problems. Do we really want to block boards from playing advisory and service roles? Can we really disentangle those roles from monitoring? Does a focus on monitoring bring its own costs?

2.1.5.1 The Overlap between Monitoring and Management

Eisenberg's somewhat unique theory of corporate law treats it as a species of constitutional law.³⁴ If we pursue the analogy, his monitoring model can be understood as a separation of powers doctrine. The board and management are individual branches of the corporate government, with clearly delineated duties, which must be kept strictly separate in order to maintain the system of checks and balances on which organizational accountability and thus organizational legitimacy depend.

In practice, however, the line between management and monitoring is fuzzy at best. This is so because while monitoring the performance of senior executives is the board's major

The Board of Directors

function, that task necessarily involves activities best described as managing the corporation.

If the board terminates the CEO due to lagging corporate performance, we might call that a pure example of the monitoring function. If the board terminates the CEO because (p. 283) it believes the lagging performance resulted from bad policy decisions by the CEO, that action still fairly could be called monitoring but it also begins to take on managerial aspects. If finding a new CEO whose policy preferences are aligned with those of the board drives the recruitment process, that action takes on an even greater managerial aspect. Providing leadership and guidance to an interim CEO during the interregnum before a new permanent CEO is found also is a common board role, but again is more managerial than oversight in nature.

Not all disciplinary actions rise to the level of termination, of course. In fact, it seems certain that most do not. This is critical because lesser punishments can become almost impossible to distinguish from management. If the board instructs the CEO to change from one policy to another, for example, that order is just as much a management decision as when the CEO instructs a subordinate to do so.

Not only are the two roles almost impossible to untangle, but it also seems clear that performing a management role improves the board's oversight function. On the one hand, the very presence of independent directors who must give their approval to major corporate decisions should go a long way toward encouraging managers to make better and more faithful decisions.

The mere fact that the top executives know they have to make formal presentations about key issues on a regular basis to an audience that may probe and criticize, and that has the power to remove them, elicits a great deal of valuable behavior. Executives gather facts more carefully and completely, make ideas and judgments more explicit, anticipate and deal with competing considerations, and find modes of articulation that can withstand scrutiny outside the inner circle. The consequence of all these efforts to better "explain and sell" the executive viewpoint may well be to clarify strategic thinking and improve decision-making. . . . Similarly, the fact the top executives know they have to present a proposed major financing, business acquisition, or compensation plan to a board that will ask questions and has power to say "yes" or "no" will tend to limit the range of proposals that the executives dare propose and push them somewhat closer and more reliably toward plans that benefit shareholders. The impact is valuable, even if clearly imperfect.³⁵

On the other, managing also makes directors better informed. When the board engages in policy and business strategy decisions, the information the board must gather to make an informed choice inevitably also is relevant to the board's overall evaluation of management's performance.

The Board of Directors

In the real world, management and monitoring thus are inextricably intertwined. As we have seen, both corporation statutes and case law assign a multitude of managerial functions to the board, with best practice assigning even more. Boards are thus involved in a host of basic corporate decisions, including entering and exiting major lines of business, approving securities offerings or major borrowing, mergers and acquisitions, payment of dividends, risk management, disclosure, auditing, and so on. In many of these cases, of course, the board is reviewing proposals made by management. Because the power to review is the power to decide, the board in these cases is effectively deciding whether the proposal has enough merit to go forward. The board's role in these decisions is thus an executive and (p. 284) managerial one, rather than one of mere oversight. As a result, even Eisenberg concedes "the board also has important decision-making functions."³⁶

2.1.5.2 Focusing Solely on Monitoring Undermines Other Board Functions

A slightly different concern arises because the monitoring model contemplates a sort of juridical role for the board, which implies a more formal relationship between the board and management than should or does take place in the real world. Rather than focusing on hiring and firing the CEO, boards typically have a much more richly textured role. Individual directors pass concerns onto the CEO, for example, who in turn bounces ideas off board members. Indeed, even when it comes to discipline, real-world practice likely differs from the formality of the monitoring model. Rather than struggling to overcome the collective action problems that impede firing a CEO, for example, an individual director may try to obtain better performance through a private reprimand. Such seemingly mild sanctions often can be effective without the shaming aspects associated with more formalized disciplinary actions.

2.1.5.3 Monitoring Can Result in Adversarial Relations

Finally, requiring boards to focus almost exclusively on monitoring encourages directors to engage in adversarial forms of oversight. Information is the coin of the realm in the world of corporate boards. The more information boards have, the better they are able to carry out their quasi-managerial functions such as advising senior managers, making major policy decisions, and providing networking services. More and higher quality information, of course, also empowers directors to be more effective in their oversight capacity.

The trouble is that the increasing use of independent directors—as explained in section 6.1 below—means that outsiders dominate modern boards. Because these outsiders lack the sort of informal information networks that employment by or routine business dealing with the firm would provide, there is an inherent information asymmetry between modern boards and the top management team. As we will see, outsiders increasingly can rely on external sources of information for some of what they need, but they still remain dependent on management for much key information.

Because information can be used to management's detriment in the board's oversight capacity, however, management has an incentive to use strategically its position as an informational chokepoint. This inherent incentive for managers to withhold information from the board may force the latter to make the difficult decision of whether their firm's

unique circumstances counsel weaker oversight and better managerial services by board members or stronger oversight and a less effective managerial role on the board's part. By demanding a strong monitoring role by the outside directors, however, the monitoring model impedes boards from making such tradeoffs. Instead, it pushes the board toward an adversarial relationship with management, which further incentivizes the latter to exercise discretion with respect to the information allowed to reach the board. Obviously, managers will be loath to pass on bad news. Even good news, however, will be massaged, phrased, and packaged, not so as to aid the board in making decisions but to cast management in the best possible light. Ironically, the adversarial relations potentially arising from adherence to the monitoring (p. 285) model thus not only make it more difficult for the board to carry out its managerial functions; they also make it harder for the board to serve as an effective monitor.

The aggressive oversight contemplated by the monitoring model may have even more deleterious effects on the management-board relationship than just the perpetuation of information asymmetries. A certain amount of cognitive tension in the board-top management team relationship is beneficial to the extent that it promotes the exercise of critical evaluative judgment by the former. Groups that are too collegial run the risk of submitting to groupthink and various other decision-making errors.³⁷ If aggressive monitoring fosters an adversarial relation between directors and managers, however, this beneficial form of conflict may transform into more harmful forms. At best, rigid adherence to the monitoring model may transform a collaborative and collegial relationship into one that is cold and distant. At worst, it can promote adversarial relations that result in destructive interpersonal conflict. Adversarial relations between two groups tend to encourage each group to circle the wagons and become defensive vis-à-vis the other. They encourage zero sum gamesmanship rather than collaboration. They divert energies into unproductive areas.

2.1.5.4 Summary

In sum, one size does not fit all. The preceding assessment does not deny that the monitoring is a key board function. It does not even deny that monitoring is first among equals. Instead, it simply shows that one size does not fit all.

Firms differ. Every firm has a unique culture, traditions, and competitive environment. A startup with inexperienced entrepreneurs needs an advisory board more than a monitoring one. A company in crisis needs board leadership more than oversight. A well-run, mature corporation staffed by managers with a penchant for hard, faithful work benefits most from a board that provides benevolent oversight and a sympathetic sounding board.

Likewise, different firms have differing arrays of accountability mechanisms. The monitoring board, after all, is not the only mechanism by which management's performance is assessed and rewarded or punished. The capital and product markets within which the firm functions, the internal and external markets for managerial services, the market for corporate control, incentive compensation systems, auditing by outside accountants, are just some of the ways in which management is held accountable for its performance. The

The Board of Directors

importance of the board's monitoring role in a given firm depends in large measure on the extent to which these other forces are allowed to function. For example, managers of a firm with strong takeover defenses are less subject to the constraining influence of the market for corporate control than are those of a firm with no takeover defenses. The former needs a strong monitoring board more than does the latter.

2.1.6 Unitary Boards Elsewhere

In addition to the US, the unitary board is the exclusive form or predominant form in a majority of European Union member states.³⁸ Board functions in EU states following the (p. 286) unitary board model tend to be similar to that of boards in the US. The UK's Corporate Governance Code, for example, provides that:

The board's role is to provide entrepreneurial leadership of the company within a framework of prudent and effective controls which enables risk to be assessed and managed. The board should set the company's strategic aims, ensure that the necessary financial and human resources are in place for the company to meet its objectives and review management performance. The board should set the company's values and standards and ensure that its obligations to its shareholders and others are understood and met.³⁹

Although that description seems to contemplate a more managerial role than is the case in US practice, the Code makes clear that the primary role of outside directors is one of monitoring management:

Non-executive directors should scrutinise the performance of management in meeting agreed goals and objectives and monitor the reporting of performance. They should satisfy themselves on the integrity of financial information and that financial controls and systems of risk management are robust and defensible. They are responsible for determining appropriate levels of remuneration of executive directors and have a prime role in appointing and, where necessary, removing executive directors, and in succession planning.⁴⁰

As is increasingly the case with US boards of directors, moreover, UK boards typically have a number of key committees—such as audit, executive remuneration, and nominating—consisting of non-executive directors.⁴¹ These committees serve to separate the managerial and monitoring functions.

In contrast, Japan also follows a unitary board model, but the functions and composition of Japanese boards differ significantly from the US model. Directors of Japanese corporations typically are insiders, chosen from the ranks of top and middle management.⁴² As one might therefore expect, the board's role is less one of monitoring management and more one of achieving consensus on strategic and managerial planning.⁴³ We have already discussed the advantages and disadvantages of a board focus on monitoring. The advantages and disadvantages of independent-dominated versus insider-dominated boards are discussed *infra* section 5.2.

Many other East Asian economies exhibit high concentrations of corporate control by family groups. In these economies, the controlling shareholder group generally chooses board members.⁴⁴

(p. 287) 2.2 The Dual Board

There are a number of countries whose corporate governance regime departs from the unitary board model, but the best known and most highly developed version is part of the German system known as codetermination. German law in fact has four different statutory models of codetermination, each regulating a different class of corporations.⁴⁵ Although some other member states of the European Union also have some form of employee representation, unless otherwise indicated, discussion of codetermination in this section focuses on the 1976 German codetermination statute, which applies to corporations having more than 2,000 employees.

2.2.1 The German Dual Board

Codetermination actually has two principal components: the dual board and works councils. Only the former is of interest for our purposes.⁴⁶ The dual board structure consists of a supervisory board that appoints a managing board, with the latter actively operating the firm. Workers are represented only on the former.

The supervisory board concept is difficult to translate into terms familiar to those trained exclusively in US forms of corporate governance. Its statutory mandate is primarily concerned with the appointment and supervision of the managing board.⁴⁷ In theory, employees and shareholders are equally represented on the supervisory board. In practice, however, the board is often controlled either by the firm's managers or a dominant shareholder.⁴⁸ One of the employee representatives must be from management, and shareholders are entitled to elect the chairman of the board, who has the power to break tie votes.⁴⁹ If push comes to shove, which it reportedly rarely does, shareholders thus retain a slight but potentially critical edge.⁵⁰

The powers of the supervisory board are limited. It appoints the members of the corporation's management board and its outsider auditors, calls shareholder meetings, and has the right to inspect the company's books and records. It must approve conflict of interest transactions involving members of the management board, but otherwise has no power to make either operational or strategic decisions.⁵¹

(p. 288) Although the dual board structure thus formally separates management and monitoring by assigning these functions to two different boards, there are in fact many commonalities between unitary and dual board systems. Just as the unitary board appoints the top management team, the supervisory board appoints the top managers making up the management board. Just as a unitary board supervises and monitors the top management team, the supervisory board oversees the managerial board. Just as the unitary board is ultimately responsible for the accuracy of the corporation's financial disclosures and oversight of internal controls, so is the supervisory board.⁵² As a result, it has been

The Board of Directors

suggested that “much of the German dual-board structure can be seen as a mere variation on the basic locus of authority in firms, creating management and supervisory boards where American firms create officers and directors.”⁵³ It is for this reason that much of the discussion below of the economics of boards should apply equally well to the dual board structure as to the unitary board model on which the discussion focuses.

2.2.2 Dual Boards Elsewhere

Dual board structures are most common in continental Europe. Besides Germany, Austria, Denmark, and the Netherlands mandate dual boards. A number of other EU member nations, most notably France, allow companies the option of choosing either a unitary or dual board.⁵⁴

2.2.3 Why a Dual Board?

Given the commonalities between unitary and dual board systems, why did dual boards come into existence and why do they persist? At least in the case of Germany, politics appears to be part—if not the complete—answer. Specifically, the German system of codetermination of which the dual board is a key component reflects a political bargain between labor and capital.⁵⁵ This bargain has several dimensions. In an earlier era, when the German economy was capital-poor, codetermination represented a means of encouraging workers to invest in firm-specific human capital despite comparatively low wages. At present, codetermination reflects a political bargain in which employees’ pensions are not well funded, but employees have some voice in corporate governance.

Having said that, however, there may be an economic rationale for the dual board. Renée Adams and Daniel Ferreira argue that while the monitoring and service functions of a unitary board appear to “complement each other, board uses any information the CEO provides both to make better recommendations and to implement better decisions.”⁵⁶ In practice, however, because the CEO is less likely to provide information to actively monitoring boards, “shareholders may optimally elect a less independent or friendlier board that does (p. 289) not monitor the CEO too intensively” so as to promote the board’s other roles.⁵⁷ The dual board structure eliminates the need for boards to make trade-offs between their various roles by limiting the supervisory board’s role to monitoring, while managerial and service functions are assigned to the management board.

Yet, this argument does not justify favoring the dual over the unitary board structure. As Adams and Ferreira note, “the role of the audit committee in the sole board systems of the United States and the United Kingdom may be similar to that of supervisory boards.”⁵⁸ Accordingly, the choice between unitary and dual boards appears to be mainly a function of historical accident, inertia, or political bargaining rather than one of economic advantage.

3 Why a Board?

Ownership and control rights typically go hand in hand. A homeowner may eject trespassers, for example, even using force in appropriate cases. A principal is entitled to control his agent. Each partner is entitled to equal rights in the management of the partnership business.

In the corporation, however, ownership and control are decisively separated. As we have seen, for example, the Delaware General Corporation Law provides that the corporation's "business and affairs . . . shall be managed by or under the direction of the board of directors."⁵⁹ In contrast, the firm's nominal owners—the shareholders—exercise virtually no control over either day-to-day operations or long-term policy. Shareholder voting rights are limited to the election of directors and a few relatively rare matters such as approval of charter or bylaw amendments, mergers, sales of substantially all of the corporation's assets, and voluntary dissolution. As a formal matter, moreover, only the election of directors and amending the bylaws do not require board approval before shareholder action is possible. In practice, of course, even the election of directors (absent a proxy contest) is predetermined by virtue of the existing board's power to nominate the next year's board. The shareholders' limited control rights thus are almost entirely reactive rather than proactive.

These direct restrictions on shareholder power are supplemented by a host of other rules that indirectly prevent shareholders from exercising significant influence over corporate decision making. Three sets of statutes are especially noteworthy: (1) disclosure requirements pertaining to large holders; (2) shareholder voting and communication rules; and (3) insider trading and short swing profits rules. These laws affect shareholders in two respects. First, they discourage the formation of large stock blocks. Second, they discourage communication and coordination among shareholders.⁶⁰

Shareholders not only lack significant managerial rights, they also lack most of the other categories of rights associated with control. Shareholders have no right to use or possess corporate property, for example. As one court explained, "even a sole shareholder has no independent right which is violated by trespass upon or conversion of the corporation's (p. 290) property."⁶¹ Indeed, to the extent that possessory and control rights are the indicia of a property right, the board of directors is a better candidate for identification as the corporation's owner than are the shareholders. As an early New York opinion put it, "the directors in the performance of their duty possess [the corporation's property], and act in every way as if they owned it."⁶²

This raises two distinct questions. First, why do we separate ownership and control in the corporate form? Second, why is control ultimately vested in a board of directors rather than, say, the CEO? Taken together, the answers to those questions help us understand the economic logic of the laws mandating that corporations have boards of directors.

3.1 Why Separate Ownership and Control?

3.1.1 An Historical Perspective

According to the widely accepted Berle and Means's account, ownership and control separated as a consequence of the development of large capital-intensive industrial corporations during the late nineteenth century. These firms required investments far larger than a single entrepreneur or family could provide, which could be obtained only by attracting funds from many investors. Because small investors needed diversification, even very wealthy individuals limited the amount they would put at risk in any particular firm, further fragmenting share ownership. The modern separation of ownership and control was the direct result of these forces, or so the story goes.

Professor Walter Werner aptly referred to Berle and Means's account as the "erosion doctrine." According to their version of history, there was a time when the corporation behaved as it was supposed to:

The shareholders who owned the corporation controlled it. They elected a board of directors to whom they delegated management powers, but they retained residual control, uniting control and ownership. In the nation's early years the states created corporations sparingly and regulated them strictly. The first corporations, run by their proprietors and constrained by law, exercised state-granted privileges to further the public interest. The states then curtailed regulation . . . , and this Eden ended. The corporation expanded into a huge concentrate of resources. Its operation vitally affected society, but it was run by managers who were accountable only to themselves and could blink at obligations to shareholders and society.⁶³

The erosion doctrine, however, rested on a false account of the history of corporations. Werner explained that economic separation of ownership and control in fact was a feature of American corporations almost from the beginning of the nation:

Banks, and the other public-issue corporations of the [antebellum] period, contained the essential elements of big corporations today: a tripartite internal government structure, a share market that dispersed shareholdings and divided ownership and control, and tendencies to (p. 291) centralize management in full-time administrators and to diminish participation of outside directors in management.⁶⁴

In contrast to Berle and Means's account, which rests on technological changes during the nineteenth century, this alternative account rests on the early development of secondary trading markets. Such markets existed in New York and Philadelphia by the beginning of the nineteenth century. The resulting liquidity of corporate stock made it an especially attractive investment, which in turn made selling stock to the public an attractive financing mechanism. Stocks were purchased by a diversified and dispersed clientele,⁶⁵ including both institutions and individuals. The national taste for speculation also played a part in the early growth of the secondary trading markets and, in turn, to dispersal of stock ownership. As a result of these economic forces, ownership and control separated not at the end of the nineteenth century, but at its beginning.

If this version of history is correct, there never was a time in which unity of control and ownership was a central feature of US corporations. To the contrary, it appears that ownership and control separated at a very early date. In turn, this analysis suggests that the separation of ownership and control may be an essential economic characteristic of such corporations.

3.1.2 A Contractarian Rationale for Separating Ownership and Control

The dominant model of the corporation in legal scholarship is the so-called nexus of contracts theory. “Contract,” as used in this context, is not limited to relationships constituting legal contracts. Instead, contractarians use the word contract to refer generally to long-term relationships characterized by asymmetric information, bilateral monopoly, and opportunism. The relationship between shareholders and creditors of a corporation is contractual in this sense, even though there is no single document we could identify as a legally binding contract through which they are in privity.

In a sense, the corporation *is* the nexus of the various contracts among the factors of production comprising the firm. This standard account has a considerable virtue—it emphasizes that the firm is not an entity but rather a set of explicit and implicit contracts establishing rights and obligations among various factors of production. Yet, the standard account fails to capture the more important sense in which the corporation *has* a nexus. Put another way, the standard account understates the role of fiat in corporate governance.

(p. 292) 3.1.2.1 The Corporation Is a Nexus

Corporate constituents contract not with each other but with the corporation. A bond indenture thus is a contract between the corporation and its creditors,⁶⁶ an employment agreement is a contract between the corporation and its workers,⁶⁷ and a collective bargaining agreement is a contract between the corporation and the union representing its workers.⁶⁸ If the contract is breached on the corporate side, it will be the entity that is sued in most cases rather than the individuals who decided not to perform. If the entity loses, damages typically will be paid out of its assets and earnings rather than out of those individuals’ pockets.

One cannot dismiss all of this as mere reification, as some have done. If there were no nexus, employment contracts would cascade—looking rather like a standard hierarchical organization chart—with each employee contracting with his superior. (Debt contracts would be even more complex.) Such a cascade would be costly to assemble, if not impossible.⁶⁹ Indeed, most corporate constituents lack any mechanism for communicating with other constituencies of the firm—let alone contract with one another. Instead, each constituency contracts with a central nexus. Accordingly, constituencies must be (and are) linked to the nexus and not each other.

3.1.2.2 The Corporation Has a Nexus

Alchian and Demsetz famously claimed that the firm “has no power of fiat, no authority, no disciplinary action any different in the slightest degree from ordinary market contracting between any two people.”⁷⁰ Accordingly, they argued, an employer’s control over its

The Board of Directors

employees differs not at all from the power of a consumer over the grocer with whom the consumer does business.

If fiat is not an essential attribute of “firm-ishness,” the firm would be just a legal fiction describing the space within which the set of contracts are worked out. Power exists within firms, however, and it matters. The corporation has a nexus—and that nexus wields a power of fiat different from that of a consumer over a grocer. Indeed, fiat is the chief characteristic that distinguishes firms from markets. As Ronald Coase explained, firms emerge when it is efficient to substitute entrepreneurial fiat for the price mechanisms of the market.⁷¹ One team member is empowered to constantly and, more important, unilaterally rewrite certain terms of the contract between the firm and its various constituents. By creating a central (p. 293) decision maker—a nexus—with the power of fiat, the firm thus substitutes ex post governance for ex ante contract.

Coordination need not imply fiat, as illustrated by the democratic decision-making processes of many partnerships and other small firms. In the public corporation, however, fiat is essential. All organizations must have some mechanism for aggregating the preferences of the organization’s constituencies and converting them into collective decisions. In his important work *The Limits of Organization*,⁷² Kenneth Arrow observed that such mechanisms fall out on a spectrum between “consensus” and “authority.” A consensus-based decision-making process is one that uses “any reasonable and acceptable means of aggregating [the] individual interests” of the organization’s constituents.⁷³ An authority-based decision-making system is one in which the organization creates a central agency to which all relevant information is transmitted and empowers that agency to make decisions binding the organization as a whole.

The choice between consensus and authority is driven by three considerations: access to information, member interests and preferences, and severity of collective action problems. Consensus-based governance systems work best when each decision maker has comparable access to information and shared interests and their decision-making process is unencumbered by serious collective action issues. In contrast, authority-based decision-making structures tend to arise where there are information asymmetries among potential decision makers, those decision makers have different interests, and the group suffers from significant collective action concerns.

With these criteria being specified, it should be self-evident that efficient corporate governance requires an authority-based decision-making structure. Consider the problems faced by shareholders, who are conventionally assumed to be the corporate constituency with the best claim on control of the decision-making apparatus. At the most basic level, the mechanical difficulties of achieving consensus amongst thousands of decision makers impede shareholders from taking an active role. Put another way, in large corporations, authority-based decision-making structures are desirable because of the potential for division and specialization of labor. Bounded rationality and complexity, as well as the practical costs of losing time when one shifts jobs, make it efficient for corporate constituents to specialize. Directors and managers specialize in the efficient coordination of other spe-

The Board of Directors

cialists. In order to reap the benefits of specialization, all other corporate constituents should prefer to specialize in functions unrelated to decision making, such as risk-bearing (shareholders) or labor (employees), delegating decision making to the board and senior management. This natural division of labor, however, requires that the chosen directors and officers be vested with discretion to make binding decisions. Separating ownership and control by vesting decision-making authority in a centralized nexus distinct from the shareholders and all other constituents is what makes the large public corporation feasible.

Even if one could overcome the seemingly intractable collective action problems plaguing shareholder decision making, the shareholders' widely divergent interests and distinctly different levels of information would still preclude active shareholder participation in corporate decision making. Although neoclassical economics assumes that shareholders (p. 294) come to the corporation with wealth maximization as their goal, and most presumably do so, once uncertainty is introduced it would be surprising if shareholder opinions did not differ on which course will maximize share value. More prosaically, shareholder investment time horizons are likely to vary from short-term speculation to long-term buy-and-hold strategies, which in turn is likely to result in disagreements about corporate strategy. Even more prosaically, shareholders in different tax brackets are likely to disagree about such matters as dividend policy, as are shareholders who disagree about the merits of allowing management to invest the firm's free cash flow in new projects.

As to Arrow's information condition, shareholders lack incentives to gather the information necessary to actively participate in decision making. A rational shareholder will expend the effort necessary to make informed decisions only if the expected benefits of doing so outweigh its costs. Given the length and complexity of corporate disclosure documents, the opportunity cost entailed in making informed decisions is both high and apparent. In contrast, the expected benefits of becoming informed are quite low, as most shareholders' holdings are too small to have significant effect on the vote's outcome. Corporate shareholders thus are rationally apathetic. Instead of exercising their voting rights, disgruntled shareholders typically adopt the so-called Wall Street Rule—it's easier to switch than fight—and sell out.⁷⁴

The efficient capital markets hypothesis provides yet another reason for shareholders to eschew active participation in the governance process. If the market is a reliable indicator of performance, as the efficient capital markets hypothesis claims, investors can easily check the performance of companies in which they hold shares and compare their current holdings with alternative investment positions. An occasional glance at the stock market listings in the newspaper is all that is required. Because it is so much easier to switch to a new investment than to fight incumbent managers, a rational shareholder will not even care why a firm's performance is faltering. With the expenditure of much less energy than is needed to read corporate disclosure statements, he will simply sell his holdings in the struggling firm and move on to other investments.⁷⁵

The Board of Directors

Consequently, it is hardly surprising that the modern public corporation's decision-making structure precisely fits Arrow's model of an authority-based decision-making system. Overcoming the collective action problems that prevent meaningful shareholder involvement would be difficult and costly, of course. Even if one could do so, moreover, shareholders lack both the information and the incentives necessary to make sound decisions on either operational or policy questions.⁷⁶ Under these conditions, it is "cheaper and more efficient to transmit all the pieces of information to a central place" and to have (p. 295) the central office "make the collective choice and transmit it rather than retransmit all the information on which the decision is based."⁷⁷ Accordingly, shareholders will prefer to irrevocably delegate decision-making authority to some smaller group.

3.1.2.3 Locating the Nexus

Under conditions of asset specificity, bounded rationality, and opportunism, the ability to adapt becomes the central problem of organization. Contrary to Alchian and Demsetz's argument, in large public corporations, adaptation is effected by fiat.⁷⁸ This is so because, as we have seen, the necessity for a literal nexus—a center of power capable of exercising fiat—within the corporation follows as a matter of course from the asymmetries of information and interests among the corporation's various constituencies.

If the corporation has a nexus, however, where is it located? As we have seen, the Delaware code, like the corporate law of virtually every other state, gives us a clear answer: the corporation's "business and affairs . . . shall be managed by or under the direction of the board of directors."⁷⁹ Put simply, the board is the nexus.

Indeed, we can think of the corporation as a vehicle by which the board of directors hires capital by selling equity and debt securities to risk bearers with varying tastes for risk. The board of directors thus can be seen as a *sui generis* body serving as the nexus for the various contracts making up the corporation and whose powers flow not from shareholders alone but from the complete set of contracts constituting the firm. As an early New York decision put it, the board's powers are "original and undelegated."⁸⁰

3.1.3 Consequences of Separating Ownership and Control

Modern scholars refer to the consequences of separating ownership and control as agency costs,⁸¹ but Berle and Means had identified the basic problem over 40 years before the current terminology was invented: "The separation of ownership from control produces a condition where the interests of owner and of ultimate manager may, and often do, diverge."⁸² To ask the question, "Will the board of directors use its control of the corporation to further the selfish interest of the board members rather than the best interests of the corporation's shareholders and other constituencies?," is to answer it. Given human nature, it would be surprising indeed if directors did not sometimes shirk or self-deal. Consequently, much of corporate law is best understood as a mechanism for constraining agency costs.

The Board of Directors

(p. 296) A narrow focus on agency costs, however, can easily distort one's understanding. In the first instance, corporate managers operate within a pervasive web of accountability mechanisms that substitute for monitoring by residual claimants. The capital and product markets, the internal and external employment markets, and the market for corporate control all constrain shirking by firm agents.

In the second, agency costs are the inescapable result of placing ultimate decision-making authority in the hands of someone other than the residual claimant. Because we could substantially reduce agency costs by eliminating discretion, but do not do so, one infers that discretion has substantial virtues. In a complete theory of the firm, neither discretion nor accountability can be ignored because both promote values essential to the survival of business organizations.⁸³ At the same time, however, the power to hold to account is ultimately the power to decide.⁸⁴ Managers cannot be made more accountable without undermining their discretionary authority. Establishing the proper mix of discretion and accountability thus emerges as the central corporate governance question.

Given the significant virtues of discretion, one ought not lightly interfere with management or the board's decision-making authority in the name of accountability. Because the separation of ownership and control mandated by US corporate law has a substantial insulating effect, by constraining shareholders both from reviewing most board decisions and from substituting their judgment for that of the board, that separation has a strong efficiency justification.

3.2 Why a Board? Why Not a CEO?

At the apex of the corporate hierarchy stands not a single individual but a collective—the board of directors. The legal rules governing the board of directors, moreover, put considerable emphasis on the need for collective rather than individual action.⁸⁵ A director “has no power of his own to act on the corporation's behalf, but only as one of a body of directors acting as a board,”⁸⁶ to cite just one example.

Why this emphasis on collective action? Put another way, why not vest the ultimate power of fiat in an individual autocrat rather than a collegial group?

The commentary to the MBCA's provisions on board meetings provides one answer:

A well-established principle of corporate common law accepted by implication in the Model Act is that directors may act only at a meeting unless otherwise expressly authorized by statute. The underlying theory is that the consultation and exchange of views is an integral part of the functioning of the board.⁸⁷

(p. 297) The drafters' argument runs afoul of the old joke that a camel is a horse designed by a committee, yet their “underlying theory” is pervasively reflected in the statutory rules governing corporate boards.⁸⁸ The implicit preference for group decision making also finds support in two basic economic principles: bounded rationality and agency costs.⁸⁹

3.2.1 The Board as an Adaptive Response to Bounded Rationality

Vesting decision-making authority in a group rather than a single individual is a high value-added adaptive response to the problem of bounded rationality. Decision making requires the use of scarce resources for four purposes: (1) observation, or the gathering of information; (2) memory, or the storage of information; (3) computation, or the manipulation of information; and (4) communication, or the transmission of information.⁹⁰ How do groups minimize these transaction costs vis-à-vis individual decision makers? Multiple (p. 298) sources of information may make it less costly to gather information, but it seems unlikely that directors qua directors do much to facilitate the observation process. Any such savings, moreover, likely are offset by increased communication costs. By decentralizing both access to information and decision-making power, group decision making requires additional resources and imposes additional delays on the decision-making process.

The relevant advantages of group decision making therefore likely arise with respect to either memory and/or computation. As to the former, groups develop a sort of collective memory that consists not only of the sum of individual memories but also an awareness of who knows what. Consequently, institutional memory is superior when the organization is structured as a set of teams rather than as a mere aggregate of individuals. There is some laboratory evidence, moreover, that the collective memory of groups leads to higher quality output.⁹¹ Group members, for example, seem to specialize in memorizing specific aspects of complex repetitive tasks.

As to the relationship between group decision making and computation-based costs, an actor can economize limited cognitive resources in two ways. First, by adopting institutional governance structures designed to promote more efficient decision making. Second, by invoking shortcuts, i.e., heuristic problem-solving decision-making processes. Here we focus on the former approach, positing that group decision making provides a mechanism for aggregating the inputs of multiple individuals with differing knowledge, interests, and skills. Numerous studies suggest that groups benefit from both the pooling of information and from providing opportunities for one member to correct another's errors.⁹² In the corporate context, the board of directors thus may have emerged as an institutional governance mechanism to constrain the deleterious effect of bounded rationality on the organizational decision-making process.

3.2.2 The Board as a Constraint on Agency Costs

Individuals are subject to the temptations to shirk or self-deal. The internal dynamics of group governance, however, constrain self-dealing and shirking by individual team members. In this regard, group decision making has a bi-directional structure. In the vertical dimension, a group may be superior to an individual autocrat as a monitor of subordinates in the corporate hierarchy. In the horizontal dimension, intra-group governance structures help constrain shirking and self-dealing at the apex of the hierarchy.

3.2.2.1 Vertical Monitoring

Suppose an individual autocrat rather than a board of directors capped the corporate hierarchy. Under such circumstances, a bilateral vertical monitoring problem arises. On the one hand, the autocrat must monitor his/her subordinates. On the other hand, someone must monitor the autocrat. In theory, if corporate law vested ultimate decision making authority in individual autocrats, chief executives could be monitored by their subordinates.

(p. 299) Economist Eugene Fama contends, for example, that lower level managers monitor more senior managers.⁹³

It seems unlikely, however, that such upstream monitoring happens often or in a sufficiently systematic way to provide a meaningful constraint on upper management. In any case, this monitoring mechanism does not take full advantage of specialization. Fama and Jensen elsewhere point out that one response to agency costs is to separate “decision management”—initiating and implementing decisions—from “decision control”—ratifying and monitoring decisions.⁹⁴ Such separation is a defining characteristic of the central office typical of M-form corporations. The monitoring mechanisms described herein could be accomplished through a simple pyramidal hierarchy of the sort found in U-form corporations. The M-form corporation adds to this structure a rationalization of decision-making authority in which the central office has certain tasks and the operating units have others, which allows for more effective monitoring through specialization, sharper definition of purpose, and savings in informational costs.⁹⁵ In particular, the central office’s key decision makers—the board of directors and top management—specialize in decision control. Because low- and mid-level managers specialize in decision management, expecting them to monitor more senior managers thus requires them to perform a task for which they are poorly suited.

A different critique of Fama’s hypothesis is suggested by evidence with respect to meeting behavior. In mixed status groups, higher status persons talk more than lower status members. Managers, for example, talk more than subordinates in business meetings.⁹⁶ Such disparities result in higher status group members being more inclined to propound initiatives and wielding greater influence over the group’s ultimate decision. Consequently, a core board function is providing a set of status equals for top managers.⁹⁷ As such, corporate law’s insistence on the formal superiority of the board to management begins to make sense. To the extent law shapes social norms, admittedly a contested proposition,⁹⁸ corporate law empowers the board to more effectively constrain top management by creating a de jure status relationship favoring the board.

3.2.2.2 Horizontal Monitoring

Who watches the watchers? Because all members of the corporate hierarchy—including our hypothetical autocrat—are themselves agents of the firm with incentives to shirk, a mechanism to monitor their productivity and reduce their incentive to shirk must also be created or one ends up with a never-ending series of monitors monitoring lower level monitors. As we have seen, Alchian and Demsetz purported to solve this dilemma by requiring that the (p. 300) monitor be given the residual income left after all other workers

have been paid, but their otherwise quite useful model has limited relevance to the public corporation.⁹⁹

Consequently, corporate law and governance must provide alternatives to monitoring by the residual claimants. A hierarchy of individuals whose governance structures contemplate only vertical monitoring, such as that hypothesized above, cannot resolve the problem of who watches the watchers. By adding the dimension of horizontal monitoring, however, placing a group at the apex of the hierarchy provides a solution to that problem. Where an individual autocrat would have substantial freedom to shirk or self-deal, the internal dynamics of group governance constrain self-dealing and shirking by individual team members and, perhaps, even by the group as a whole. Within a production team, for example, mutual monitoring and peer pressure provide a coercive backstop for a set of interpersonal relationships founded on trust and other noncontractual social norms. Of particular relevance here are effort and cooperation norms.¹⁰⁰

While the old adage opines “familiarity breeds contempt,” personal proximity to others in fact deeply affects behavior. As people become closer, their behavior tends to improve: “something in us makes it all but impossible to justify our acts as mere self-interest whenever those acts are seen by others as violating a moral principle”; rather, “[w]e want our actions to be seen by others—and by ourselves—as arising out of appropriate motives.”¹⁰¹ Small groups strengthen this instinct in several ways. First, they provide a network of reputational and other social sanctions that shape incentives. Because membership in close-knit groups satisfies the human need for belongingness, the threat of expulsion gives the group a strong sanction by which to enforce compliance with group norms. Because close-knit groups involve a continuing relationship, the threat of punishment in future interactions deters the sort of cheating possible in one-time transactions.¹⁰² Second, because people care about how they are perceived by those close to them, communal life provides a cloud of witnesses whose good opinion we value. We hesitate to disappoint those people and thus strive to comport ourselves in accordance with communal norms. Effort norms will thus tend to discourage board members from simply going through the motions, but instead to devote greater cognitive effort to their tasks. Finally, there is a transaction costs economics explanation for the importance of closeness in trust relationships. Close-knit groups know a lot about one another, which reduces monitoring costs and thus further encourages compliance with group norms. Members of close-knit groups therefore tend to internalize group norms.¹⁰³

(p. 301) Taken together, these factors suggest that group decision making is a potentially powerful constraint on agency costs. It creates a set of high-powered incentives to comply with both effort and cooperation norms. This analysis thus goes a long way toward explaining the formalistic rules of state corporate law governing board decision making.¹⁰⁴

4 Who Should Elect the Board?

Is it curious that only shareholders get the vote? What about the corporation's other constituencies, such as employees, creditors, customers, suppliers, etc.? Why do they not get a voice in, say, the election of directors? The traditional answer is that shareholders own the corporation. Ownership typically connotes control, of course. Consequently, despite the separation of ownership and control characteristic of public corporations, shareholders' ownership of the corporation might be deemed to vest them with unique control rights. But the nexus of contracts theory of the firm demonstrates that shareholders do not in fact "own" the corporation in any meaningful sense. By throwing the concept of ownership out of the window, the contractarian model eliminates the obvious answer to our starting question—why are only shareholders given voting rights?¹⁰⁵

(p. 302) Recall that Arrow identified two basic modes of decision making: consensus and authority. Consensus requires that each member of the organization have identical information and interests so that preferences can be aggregated at low cost. In contrast, authority-based decision-making structures arise where group members have different interests and information.

The analysis that follows proceeds in three steps. First, why do corporations not rely on consensus-based decision making? In answering that question, we begin by imagining an employee-owned firm with many thousands of employee shareholders. (Employees are used solely for purposes of illustration—the analysis would extend to any other corporate constituency.) After demonstrating that Arrow's conditions cannot be satisfied in such a firm, we then turn to the more complex public firm in which employees and shareholders constitute separate constituencies to demonstrate that Arrow's conditions are even less likely to be met in this type of firm. Second, why do corporations not permit multiple constituencies to elect directors? Finally, why are shareholders the favored constituency?

4.1 The Necessity of Authority

4.1.1 Information

Assume an employee-owned corporation with 5,000 employee shareholders. Could such a firm function as a participatory democracy? Not if we hoped that each participant would make informed decisions. As a practical matter, of course, our employee shareholders are not going to have access to the same sorts of information. Assuming at least some employees serve in managerial and supervisory roles, they will tend to have broader perspectives, with more general business information, while line workers will tend to have more specific information about particular aspects of the shop floor.

These information asymmetries will prove intractable. A rational decision maker expends effort to make informed decisions only if the expected benefits of doing so outweigh its costs. In a firm of the sort at bar, gathering information will be very costly. Efficient participatory democracy requires all decision makers to have equal information, which requires that each decision maker have a communication channel to every other decision

The Board of Directors

maker. As the number of decision makers increases, the number of communication channels within the firm increases as the square of the number of decision makers.¹⁰⁶

Bounded rationality makes it doubtful that anyone in a firm of any substantial size could process the vast number of resulting information flows. Even if they were willing to try, moreover, members of such a firm could not credibly bind themselves to reveal information accurately and honestly or to follow prescribed decision-making rules. Under such conditions, Arrow's model predicts that the firm will tend toward authority-based decision making. Accordingly, the (p. 303) corporation's employer-owners will prefer to irrevocably delegate decision-making authority to some central agency, such as a board of directors.

Now introduce the complication of separating capital and labor. Nothing about such a change economizes on the decision-making costs outlined above. Instead, as described below, labor and capital can have quite different interests, which increases decision-making costs by introducing the risk of opportunism. In particular, capital and labor may behave strategically by withholding information from one another.

4.1.2 Interests

Again, begin by assuming an employee-owned firm with 5,000 employee shareholders. Is it reasonable to expect the similarity of interest required for consensus to function in such a firm? Surely not. In some cases, employees would differ about the best way in which to achieve a common goal. In others, individual employees will be disparately affected by a proposed course of action. Although the problems created by divergent interests within the employee block are not insurmountable, such differences at least raise the cost of using consensus-based decision-making structures in employee-owned firms.

Empirical evidence confirms the existence of such divergent interests within the employee group. Labor-managed firms tend to remain small, carefully screen members, limit the franchise to relatively homogeneous groups, and use agenda controls to prevent cycling and other public choice problems.¹⁰⁷ All of these characteristics are consistent with an attempt to minimize the likelihood and effect of divergent interests.

Now again complicate the analysis by separating capital and labor. Although employee and shareholder interests are often congruent, they can conflict. Consider, for example, the downsizing phenomenon. Corporate restructurings typically result in substantial reductions in force, reduced job security, longer work weeks, more stress, and diminished morale.¹⁰⁸ From the shareholders' perspective, however, the market typically rewards restructurings with substantial stock price increases. The divergence of interest suggested by this example looms large as a bar to the use of consensus in capitalist firms.

4.2 The Inefficiency of Multiple Constituencies

The analysis to this point merely demonstrates that corporate decision making must be made on a representative rather than on a participatory basis. As yet, nothing in the analysis dictates the US model in which only shareholders elect directors. One could

The Board of Directors

plausibly imagine a board of directors on which multiple constituencies are represented. Indeed, imagination is not required, because the supervisory board component of German codetermination provides a realworld example of just such a board. Empirical evidence, however, suggests that codetermination does not lead to efficiency or productivity gains.¹⁰⁹

(p. 304) Why not? In Arrow's terminology, the board of directors serves as a consensus-based decision-making body at the top of an authority-based structure. Recall that for consensus to function, however, two conditions must be met: equivalent interests and information. Neither condition can be met when employee representatives are on the board.

The two factors are closely related, of course. Indeed, it is the potential divergence of shareholder and employee interests that ensures employee representatives will be deprived of the information necessary for them to function. Because of the board's position at the apex of the corporate hierarchy, employee representatives are inevitably exposed to a far greater amount of information about the firm than is normally provided to employees. As the European experience with codetermination teaches, this can result in corporate information leaking to the workforce as a whole or even to outsiders. In the Netherlands, for example, the obligation of works council representatives to respect the confidentiality of firm information "has not always been kept, causing serious concerns among management which is required . . . to provide extensive 'sensitive' information to the councils."¹¹⁰

Given that providing board level information to employee representatives appears clearly contrary to shareholder interests,¹¹¹ we would expect managers loyal to shareholder interests to withhold information from the board of directors in order to deny it to employee representatives, which would seriously undermine the board's ability to carry out its essential corporate governance roles. This prediction is borne out by the German experience with codetermination. German managers sometimes deprive the supervisory board of information, because they do not want the supervisory board's employee members to learn it.¹¹² Alternatively, the board's real work may be done in committees or de facto rump caucuses from which employee representatives are excluded. As a result, while codetermination raises the costs of decision making, it may not have much effect on substantive decision making.¹¹³

Although Arrow's equality of information criterion is important, in this context the critical element is the divergence of shareholder and employee interests. The interests of shareholders will inevitably differ as amongst themselves, as do those of employees, but individual constituents of the corporation nevertheless are more likely to share interests with members of the same constituency than with members of another constituency. Allowing board representation for employees thus tends only to compound the problem that gives (p. 305) rise to an authority-based hierarchical decision-making structure by bringing the differing interests of employees and shareholders directly into the boardroom.¹¹⁴ The resulting conflicts of interest inevitably impede consensus-based decision making within the

The Board of Directors

board. Worker representatives on corporate boards tend to prefer greater labor advocacy than do traditional directors, no doubt in large part because workers evaluate their representatives on the basis of labor advocacy, which also results in role conflicts.¹¹⁵ The problem with codetermination thus is not only that the conflict of employee and shareholder interests impedes the achievement of consensus, but also that it may result in a substantial increase in agency costs.¹¹⁶

(p. 306) Although it is sometimes asserted that employee representation would benefit the board by promoting “discussion and consideration of alternative perspectives and arguments,”¹¹⁷ the preceding analysis suggests that any such benefits would come at high cost. In addition, there is reason to doubt whether those benefits are very significant. Workers will be indifferent to most corporate decisions that do not bear directly on working conditions and benefits.¹¹⁸ All of which tends to suggest that employee representatives add little except increased labor advocacy to the board.

4.3 Why Only Shareholders?

The analysis thus far demonstrates that public corporation decision making must be conducted on a representative rather than a participatory basis. It further demonstrates that only one constituency should be allowed to elect the board of directors. The remaining question is why shareholders are the chosen constituency, rather than employees. Answering that question is the task of this section.

The standard law and economics explanation for vesting voting rights in shareholders is that shareholders are the only corporate constituent with a residual, unfixed, ex post claim on corporate assets and earnings.¹¹⁹ In contrast, the employees’ claim is prior and largely fixed ex ante through agreed-upon compensation schedules. This distinction has two implications of present import. First, as noted above, employee interests are too parochial to justify board representation. In contrast, shareholders have the strongest economic incentive to care about the size of the residual claim, which means that they have the greatest incentive to elect directors committed to maximizing firm profitability.¹²⁰ Second, the nature (p. 307) of the employees’ claim on the firm creates incentives to shirk. Vesting control rights in the employees would increase their incentive to shirk. In turn, the prospect of employee shirking lowers the value of the shareholders’ residual claim.

At this point, it is useful to once again invoke the hypothetical bargain methodology. If the corporation’s various constituencies could bargain over voting rights, to which constituency would they assign those rights? In light of their status as residual claimants and the adverse effects of employee representation, shareholders doubtless would bargain for control rights, so as to ensure a corporate decision-making system emphasizing monitoring mechanisms designed to prevent shirking by employees, and employees would be willing to concede such rights to shareholders.

The Board of Directors

Granted, collective action problems preclude the shareholders from exercising meaningful day-to-day or even year-to-year control over managerial decisions. Unlike the employees' claim, however, the shareholders' claim on the corporation is freely transferable. As such, if management fails to maximize the shareholders' residual claim, an outsider can profit by purchasing a majority of the shares and voting out the incumbent board of directors. Accordingly, vesting the right to vote solely in the hands of the firm's shareholders is what makes possible the market for corporate control and thus helps to minimize shirking. As the residual claimants, shareholders thus would bargain for sole voting control, in order to ensure that the value of their claim is maximized. In turn, because all corporate constituents have an ex ante interest in minimizing shirking by managers and other agents, the firm's employees have an incentive to agree to such rules.¹²¹ The employees' lack of control rights thus can be seen as a way in which they bond their promise not to shirk. Their lack of control rights not only precludes them from double dipping but also facilitates disciplining employees who shirk. Accordingly, it is not surprising that the default rules of the standard form contract provided by all corporate statutes vest voting rights solely in the hands of common shareholders.

To be sure, the vote allows shareholders to allocate some risk to prior claimants. If a firm is in financial straits, directors and managers faithful to shareholder interests could protect the value of the shareholders' residual claim by, for example, financial and/or workforce restructurings that eliminate prior claimants—all of which raises the question of why employees do not get the vote to protect themselves against this risk. The answer is twofold. First, as we have seen, multiple constituencies are inefficient. Second, as addressed below, employees have significant protections that do not rely on voting.

Suppose a firm behaves opportunistically toward its employees. What protections do the employees have? Some are protected by job mobility. The value of continued dealings with an employer to an employee whose work involves solely general human capital does not depend on the value of the firm because neither the employee nor the firm have an incentive to preserve such employment relationship. If the employee's general human capital suffices for him to do his job at Firm A, it presumably would suffice for him to do a similar job at (p. 308) Firm B. Such an employee resembles an independent contractor who can shift from firm to firm at low cost to either employee or employer.¹²² Mobility thus may be a sufficient defense against opportunistic conduct with respect to such employees, because they can quit and be replaced without productive loss to either employee or employer. Put another way, because there are no appropriable quasi-rents in this category of employment relationships, rent seeking by management is not a concern.

Corporate employees who make firm-specific investments in human capital arguably need greater protection against employer opportunism, but such protections need not include board representation. Indeed, various specialized governance structures have arisen to protect such workers. Among these are severance pay, grievance procedures, promotion ladders, collective bargaining, and the like.¹²³

In contrast, shareholders are poorly positioned to develop the kinds of specialized governance structures that protect employee interests. Unlike employees, whose relationship to the firm is subject to periodic renegotiation, shareholders have an indefinite relationship that is rarely renegotiated, if ever. The dispersed nature of stock ownership also makes bilateral negotiation of specialized safeguards difficult. The board of directors thus is an essential governance mechanism for protecting shareholder interests.

If the foregoing analysis is correct, why do we nevertheless sometimes observe employee representation? An explanation consistent with our analysis lies close at hand. In the United States, employee representation on the board is typically found in firms that have undergone concessionary bargaining with unions. Concessionary bargaining, on average, results in increased share values of 8–10 percent.¹²⁴ The stock market apparently views union concessions as substantially improving the value of the residual claim, presumably by making firm failure less likely. While the firm's employees also benefit from a reduction in the firm's riskiness, they are likely to demand a quid pro quo for their contribution to shareholder wealth. One consideration given by shareholders (through management) may be greater access to information, sometimes through board representation. Put another way, board of director representation is a way of maximizing access to information and bonding its accuracy. The employee representatives will be able to verify that the original information about the firm's precarious financial situation was accurate. Employee representatives on the board also are well positioned to determine whether the firm's prospects have improved sufficiently to justify an attempt to reverse prior concessions through a new round of bargaining.

(p. 309) 5 Should Directors Be Independent?

As the monitoring model came to dominate thinking about the board's role, the board's composition inevitably came to the fore. A board comprised of insiders is poorly positioned to monitor the CEO. Research on group decision making shows that in mixed status groups, higher status persons talk more than lower status members. Managers, for example, talk more than subordinates in business meetings. Such disparities result in higher status group members being more inclined to propound initiatives and having greater influence over the group's ultimate decision. Group dynamics thus help ensure the CEO's dominance over inside directors. As a practical matter, moreover, the CEO typically serves as the chairman of the board, giving him substantial control over both the selection of new directors and the board's agenda. Not surprisingly, director independence therefore is a longstanding goal of corporate reformers, especially those affiliated with the monitoring model school of thought.

5.1 Mandating Director Independence

5.1.1 Director Independence in USA State Law

State corporation statutes are silent on the issue of board composition. Issues such as board size, director qualifications, and independence are left to private ordering. If state statutory law were all that mattered, firms would thus be free to select the board structure and composition optimal to their unique circumstances.

The state common law of corporations does provide some incentives for corporations to include at least some independent directors on the board. It has long been the case, for example, that approval of related party and other conflicted interest transactions by vote of a majority of the disinterested and independent directors effectively immunizes such transactions from judicial review by invoking the defendant-friendly business judgment rule as the standard of review.¹²⁵ In connection with going private transactions initiated by a controlling shareholder, the Delaware Supreme Court called upon boards to create “an independent negotiating committee of its outside directors to deal with [the buyer] at arm’s length.”¹²⁶ Indeed, the Court went on to equate “fairness in this context” to the conduct that might be expected from “a theoretical, wholly independent, board of directors acting upon the matter before them.” Similarly, with respect to antitakeover defenses, the Court has held that the validity of such defenses is “materially enhanced . . . where, as here, a majority of the board favoring the proposal consisted of outside independent directors.”¹²⁷ Taken together with similar decisions in other areas of corporate law, these judicially created safe (p. 310) harbors provide substantial incentives for both boards and managers to favor director independence.

Having said that, however, state law typically is far more concerned with director disinterestedness than independence. Consider, for example, the Delaware law on excusal of demand in shareholder derivative litigation. In *Grimes v. Donald*,¹²⁸ the Delaware Supreme Court identified three reasons for excusing demand: “(1) a majority of the board has a material financial or familial interest; (2) a majority of the board is incapable of acting independently for some other reason such as domination or control; or (3) the underlying transaction is not the product of a valid exercise of business judgment.”¹²⁹ As to the first prong, directors are interested if they have a personal financial stake in the challenged transaction or otherwise would be materially affected by the board’s actions. Consequently, for example, the Delaware Chancery Court excused demand on director interest grounds where five of nine directors approved a stock appreciation rights plan likely to benefit them.¹³⁰

Although the second prong is framed in terms of independence, it is not concerned with whether a director is generically independent of management. While being employed by the corporation would preclude a director from being deemed independent for all purposes under Sarbanes-Oxley and Dodd-Frank, for example, it does not preclude a finding that the director is independent under state law. This is so, in part, because state law views independence from a transactional perspective rather than one of status. The other critical difference is that state law links independence to self-interest in the underlying transaction. Accordingly, demand is not excused simply because the plaintiff has named a majority of the board as defendants.¹³¹ Indeed, it is not enough even to allege that a ma-

jority of the board approved of, acquiesced in, or participated in the challenged transaction.¹³² In other words, merely being named as defendants or participants does not render the board incapable, as a matter of law, of objectively evaluating a pre-suit demand and, accordingly, does not excuse such a demand. Instead, demand typically is excused under this prong only if a majority of the board was dominated or controlled by someone with a personal financial stake in the transaction.¹³³

State law thus fails to satisfy the more exacting standards of independence pursued by reformers like Ralph Nader or Melvin Eisenberg. Instead, the reformers want independence to be defined by status. In general, any material relationship between the director and the corporation or its top management team would be regarded as disabling the director from being deemed independent as they wished it to be defined.

(p. 311) 5.1.2 Director Independence in the Stock Exchange Listing Standards and the Sarbanes-Oxley Act

The Sarbanes-Oxley Act did relatively little to reform boards of directors. Besides some minor tweaking of rules like those governing disclosure of stock transactions by directors and so on, the only substantive changes worked by Sarbanes-Oxley dealt with the audit committee of the board of directors.

Instead, Congress and the SEC left the heavy lifting on board reform to the stock exchanges. All three major exchanges—the NYSE, NASDAQ, and the American Stock Exchange (AMEX)—amended their corporate governance listing requirements to require that a majority of the members of the board of directors of most listed companies must be independent of management. All three also adopted new rules defining independence using very strict, bright-line rules. Finally, all three significantly expanded the duties and powers of independent directors.

The NYSE long required that all listed companies have at least three independent directors.¹³⁴ A director was treated as independent unless, inter alia, (1) the director was employed by the corporation or its affiliates in the past three years; (2) the director had an immediate family member who, during the past three years, was employed by the corporation or its affiliates as an executive officer; (3) the director had a direct business relationship with the company; or (4) the director was a partner, controlling shareholder, or executive officer of an organization that had a business relationship with the corporation, unless the corporation's board determined in its business judgment that the relationship did not interfere with the director's exercise of independent judgment.

The NYSE's pre-SOX listing standards also required that listed companies have an audit committee comprised solely of independent directors. The committee had to have at least three members, all of whom must be "financially literate." At least one committee member had to have expertise in accounting or financial management.

As the Enron crisis was peaking, the NYSE appointed a blue ribbon panel of Wall Street Brahmins to evaluate whether the new environment called for changes in the exchange's corporate governance listing standards. The panel reported back with a number of pro-

The Board of Directors

posed new governance standards, including a mandate that independent directors comprise a majority of any listed corporation's board of directors.¹³⁵ The exchange forwarded the proposals to the SEC for approval. At that point, however, the listing standards proposal was caught up in the larger legislative process surrounding Sarbanes-Oxley and final action on the proposal was deferred until that process was completed.

The Sarbanes-Oxley Act expressly addressed the question of board composition only in § 301, which required the SEC to require that the exchanges adopt new rules for audit committees. The specified duties and powers of that committee will be addressed in Chapter 5. Suffice it for present purposes to note that § 301 requires each member of the audit committee to be independent, which was defined therein to mean that the director could not “(i) accept any consulting, advisory, or other compensatory fee from the issuer; or (ii) be an affiliated person of the issuer or any subsidiary thereof.”

(p. 312) Section 301's focus on the audit committee is broadly consistent with the general thrust of the Sarbanes-Oxley Act, which as a whole is mainly concerned with accounting and auditing issues. Congress was well aware of the pending exchange rulemaking proposals and presumably was content to leave the details to the SEC and the exchanges so long as the final listing standards met the specified minimum requirements regarding the audit committee. In November 2003, the process concluded when the SEC gave final approval to revised exchange listing standards on director independence.¹³⁶

5.1.2.1 The Majority Independent Board

As approved by the SEC, the NYSE listing standards now require that all listed companies “must have a majority of independent directors.”¹³⁷ In addition, as we will see below, the NYSE has mandated the use of several board committees consisting of independent directors. Finally, the NYSE's Listed Company Manual provides that: “To empower non-management directors to serve as a more effective check on management, the non-management directors of each listed company must meet at regularly scheduled executive sessions without management.”¹³⁸ The listed company's Form 10-K must disclose the identity of the independent director who chairs the mandatory executive sessions. Although the rule does not indicate how many times per year the outside directors must meet to satisfy this requirement, emerging best practice suggests that there should be such a meeting held in conjunction with every regularly scheduled meeting of the entire board of directors.

The NASDAQ and AMEX standards are substantially similar. One wrinkle is that NASDAQ expressly states an expectation that executive sessions of the outside directors will be held at least twice a year. Note that all three exchanges exempt controlled companies—those in which a shareholder or group of shareholders acting together control 50 percent or more of the voting power of the company's stock—from the obligation to have a majority independent board.

5.1.2.2 Who Is Independent?

As we saw, Delaware state corporate law asks a very simple question to determine whether a director is independent; to wit, whether “through personal or other relationships the directors are beholden to” management.¹³⁹ In contrast, the exchange listing standards use multipart bright line standards to determine whether a director is independent. The NYSE, for example, has five such standards looking at the relationships between the listed company and a director and his immediate family members. A director will not be independent, for example, if that director “is, or has been within the last three years, an employee of the listed company, or an immediate family member is, or has been within the last three years, an executive officer, of the listed company.”¹⁴⁰ The NASDAQ and AMEX have substantially similar tests.

The trouble with economic tests is that they fail to capture the myriad of other ways in which individuals can be biased toward others. Many nominally independent directors have full-time jobs as executives at other firms or as partners in business service companies such as law firms or financial institutions. Directors tend to be white males, educated at top-20 schools, and share a host of other social ties. When their fellow directors get into trouble, the reaction of these nominally independent directors may be one of leniency, motivated by a “‘there but for the grace of God go I’ empathy.”¹⁴¹

The problem is not just one of undue empathy, however. Social ties have a deterrent effect on director behavior that can be just as important, if not more so, than economic relationships. As Delaware Vice Chancellor Leo Strine observes:

To be direct, corporate directors are generally the sort of people deeply enmeshed in social institutions. Such institutions have norms, expectations that, explicitly and implicitly, influence and channel the behavior of those who participate in their operation. Some things are “just not done,” or only at a cost, which might not be so severe as a loss of position, but may involve a loss of standing in the institution. In being appropriately sensitive to this factor, our law also cannot assume—absent some proof of the point—that corporate directors are, as a general matter, persons of unusual social bravery, who operate heedless to the inhibitions that social norms generate for ordinary folk.¹⁴²

Unfortunately, operationalizing this insight proves quite problematic.

The NYSE definition of independence perhaps seeks to address this problem of structural bias by providing that “[n]o director qualifies as ‘independent’ unless the board of directors affirmatively determines that the director has no material relationship with the listed company.”¹⁴³ The commentary to that section explains that:

It is not possible to anticipate, or explicitly to provide for, all circumstances that might signal potential conflicts of interest, or that might bear on the materiality of a director’s relationship to a listed company . . . Accordingly, it is best that boards making “independence” determinations broadly consider all relevant facts and circumstances. In particular, when assessing the materiality of a director’s relation-

ship with the listed company, the board should consider the issue not merely from the standpoint of the director, but also from that of persons or organizations with which the director has an affiliation. Material relationships can include commercial, industrial, banking, consulting, legal, accounting, charitable and familial relationships, among others.

The commentary thus contemplates an inquiry broad enough to encompass social ties as well as economic relationships (“broadly consider all relevant facts”). Yet, one suspects such inquiries tend to be superficial, at best, and mainly focused on objective factors rather than the sort of soft biases of social ties.

The key problem, of course, is that the board of directors rather than some outside impartial adjudicator is making the independence determination. These directors presumably have at least ties of class, and probably social relations, amongst themselves and with the candidate whose independence is to be determined. The finder of fact is thus structurally biased against making a finding of structural bias. No workable solution to this problem has been forthcoming.

(p. 314) 5.1.2.3 Board Committees

The NYSE Listed Company Manual mandates the establishment of three committees of the board of directors: a Nominating and Corporate Governance Committee (§ 303A.04), a Compensation Committee (§ 303A.05), and an Audit Committee (§ 303A.06). All three must be comprised solely of independent directors. As such, they significantly extend the mandate for a board dominated by directors independent of management.

5.1.3 Director Independence Requirements outside the USA

In dual board jurisdictions, director independence is a natural consequence of the board’s structure. Top managers are limited to the management board and are excluded from the supervisory board.¹⁴⁴ On the other hand, the employee representatives on the supervisory board are typically not independent of the labor sponsors and the shareholder representatives often are beholden to large block holders.¹⁴⁵ Accordingly, the norm of truly independent board members—beholden to no one—is absent.

In EU states in which the unitary board model dominates, the sole pertinent statutory mandate is the EU Audit Directive, which requires that boards include at least one independent director with financial expertise.¹⁴⁶ The question of director independence is otherwise left to national best practice codes.

In the UK, for example, the Corporate Governance Code provides that “at least half the board, excluding the chairman, should comprise non-executive directors determined by the board to be independent.”¹⁴⁷ The Code recommends that the board consist of “an appropriate combination of executive and non-executive directors (and, in particular, independent non-executive directors) such that no individual or small group of individuals can dominate the board’s decision taking.”¹⁴⁸ This recommendation presumably is intended to

curb any tendency toward Imperial CEOs, as is the Code's provision that the board should select a lead independent director.¹⁴⁹

In Asia, a number of key economies have adopted statutory requirements that public companies have at least a specified number of independent directors. In Hong Kong, Singapore, India, and the Philippines, for example, UK-like corporate governance codes recommend that companies have independent directors, although none requires a majority of board members be independent. Korea, Thailand, and China all mandate appointment of (p. 315) independent directors.¹⁵⁰ Whether directors in those countries are actually independent of management, however, is a matter of debate.¹⁵¹ Japan is regarded as the principal outlier in this regard, as neither law nor best practice require director independence to any extent.¹⁵²

5.2 Outsiders on the Board: The Uncertain Case for Director Independence

As we have seen, the board of directors has three basic functions. First, while boards rarely are involved in day-to-day operational decision making, most boards have at least some managerial functions. Second, the board provides networking and other services. Finally, the board monitors and disciplines top management.

Independence is potentially relevant to all three board functions. As to the former two, outside directors provide both their own expertise and interlocks with diverse contact networks. As to the latter, at least according to conventional wisdom, board independence is an important device for constraining agency costs. On close examination, however, neither rationale for board independence justifies the sort of one size fits all mandate adopted by the exchanges at the behest of Congress and the SEC.

5.2.1 Independence, Interlocks, and Decision Making

Putting outside directors on the board can create valuable relationships with a variety of potential strategic partners. This is relevant not only to the board's resource gathering function, but also to its monitoring and service functions. Complex business decisions require knowledge in such areas as accounting, finance, management, and law. Providing access to such knowledge can be seen as part of the board's resource gathering function. Outside board members may either possess such specialized knowledge themselves or have access to credible external sources thereof.

Reliance on outside specialists is a rational response to bounded rationality. The expert in a field makes the most of his limited capacity to absorb and master information by limiting the amount of information that must be processed by limiting the breadth of the field in which the expert specializes. As applied to the corporate context, more diverse boards with strong outsider representation likely contain more specialists, and therefore should get greater benefits from specialization.¹⁵³

(p. 316) Having said that, however, a full-time senior employee has other informational advantages over outsiders who devote but a small portion of their time and effort to the firm. At the minimum, the presence of outsiders on the board increases decision-making costs simply because the process takes longer. Outsiders by definition need more information and are likely to take longer to persuade than are insiders.¹⁵⁴ More subtly, and perhaps more importantly, long-term employees make significant investments in firm-specific human capital. Any employee who advances to senior management levels necessarily invests considerable time and effort in learning how to do his job more effectively. Much of this knowledge will be specific to the firm for which he works, such as when other firms do not do comparable work or his firm has a unique corporate culture. In either case, the longer he works for the firm, the more firm-specific his human capital becomes. Such an employee is likely to make better decisions for the firm than an outsider, even assuming equal levels of information relating to the decision at hand. The insider can put the decision in a broader context, seeing the relationships and connections it has to the firm as whole.

Insider access to information is particularly significant due to the nature of decision making within large corporations. Recall that the corporation is a classic example of an authority-based decision-making structure characterized by the existence of a central agency to which all relevant information is transmitted and which is empowered to make decisions binding on the whole. Unlike many other organizations, the corporation's central agency is not a single autocrat, but rather a multimember body—the board of directors—that usually functions by consensus. Put another way, the board of directors is best understood as a collegial body using consensus-based decision making. Because consensus works best where team members have equal information and comparable interests, insiders may find it easier to reach consensus than would a diverse body of outsiders. Insiders are more likely to have comparable access to information and similar interests than are outsiders. Insiders have many informal contacts within the organization, which both promote team formation and provide them with better access to information. Hence, insofar as efficient decision making is the goal of corporate governance, independence may not be desirable. On the contrary, these factors suggest that an all-insider board might be preferable.

5.2.2 Independence and Agency Costs

Corporate law provides a number of accountability mechanisms designed to constrain agency costs. Chief among them is the board of directors, especially the independent directors. To be sure, outsiders have neither the time nor the information necessary to be involved in the minutiae of day-to-day firm management. What outsiders can do, however, is monitor senior managers and replace those whose performance is sub par. Accordingly, (p. 317) proponents of the monitoring model have always been among the strongest proponents of director independence.

It is not clear, however, why one would expect independent directors to be an effective constraint on shirking or self-dealing by management. Monitoring the performance of the firm's officers and employees is hard, time-consuming work. Moreover, most outside di-

The Board of Directors

rectors have full-time employment elsewhere, which commands the bulk of their attention and provides the bulk of their pecuniary and psychic income. Independent directors therefore may prefer leisure or working on their primary vocation to monitoring management. As Adam Smith observed three centuries ago,

The directors of [joint stock] companies, however, being the managers rather of other people's money than of their own, it cannot well be expected, that they should watch over it with the same anxious vigilance with which the partners in a private co-partnery frequently watch over their own. Like the stewards of a rich man, they are apt to consider attention to small matters as not for their master's honour, and very easily give themselves a dispensation from having it. Negligence and profusion, therefore, must always prevail, more or less, in the management of the affairs of such a company.¹⁵⁵

Other factors impede an independent director from monitoring management, even if he wishes to do so. Although boards meet more often and longer now than they did pre-SOX, board meetings are still few and short relative to the amount of time insiders spend with one another. Moreover, outside directors are generally dependent upon management for information.

Collective action problems also impede the board's ability to effectively monitor and discipline managers. Even though faithful monitoring may be in an individual director's interest, he or she may assume that other directors will do the hard work of identifying sub-par performances, permitting the free rider to shirk. As in any free-riding situation, this will tend to result in suboptimal levels of monitoring. Even in cases of clearly sub-par management performance, moreover, other collective action problems may prevent the board from taking necessary remedial steps. Some director must step forward to begin building a majority in favor of replacing the incumbent managers, which again raises a free-rider problem. Furthermore, if an active director steps forward, he or she must not only overcome the forces of inertia and bias, but also must likely do so in the face of active opposition from the threatened managers who will try to cut off the flow of information to the board, co-opt key board members, and otherwise undermine the disciplinary process. Board members are likely to have developed warm personal relationships with the CEO and other managers, who will in turn have cultivated that type of sentiment. Those relationships make it hard for boards to fire senior managers, especially when personal friendships of long standing are in play. Lastly, some board members will have been responsible for hiring the managers and will need to make the cognitively difficult admission of their error in order to fire the managers.

Finally, the insiders may effectively control nominally independent directors. As we've seen, it has long been common practice for a corporation's outside directors to include lawyers and bankers (of both the investment and commercial varieties) who are currently providing services to the corporation or may wish to provide services in the future.

(p. 318) University faculty or administrators, to take another common example, may be be-

holden to insiders who control corporate donations to their home institutions. None of these outsiders are likely to bite the hand that feeds them.

Even if the independent directors are not actually biased in favor of the insiders, moreover, they often are predisposed to favor the latter. As noted above, outside directors tend to be corporate officers or retirees who share the same views and values as the insiders. Because outside directors are nominated by the incumbent board members and passively elected by the shareholders, structural bias remains one of the key insoluble riddles of corporate governance.

5.2.3 Pre-Crises Empirical Evidence

The logic of the Sarbanes-Oxley Act and the stock exchange board composition rules is that independent directors will be an effective constraint on the agency costs inherent in the corporate separation of ownership and control. As we have just seen, however, theory predicted that independent directors were unlikely to be effective in doing so. Before independent directors can become effective monitors of management, the system must incur costs to remedy the information asymmetry between outsiders and insiders. It also must incur costs to prevent outside board members from shirking. Put another way, hiring agents to watch other agents may compound instead of reducing agency costs.

The empirical evidence on the relationship between board composition and firm performance available when Sarbanes-Oxley was adopted was inconclusive, at best. If independent directors effectively constrain agency costs, one would have expected the evidence to show a correlation between the presence of independent outsiders on the board and firm performance. But it did not.

True, some early studies found positive correlations between independence and performance. Rosenstein and Wyatt, for example, found that shareholder wealth increased when management appointed independent directors.¹⁵⁶ Weisbach studied board decisions to remove a CEO, finding that boards comprised mainly of independent directors were more likely to base the removal decision on poor performance, as well as being more likely to remove an underperforming CEO, than were insider-dominated boards. He also found that CEO removals by outsider-dominated boards added to firm value, while CEO removals by insider-dominated boards did not.¹⁵⁷ Baysinger and Butler found that corporate financial performance tends to increase (up to a point) as the percentage of independent directors increases.¹⁵⁸ Cotter found that boards dominated by outsiders generate higher shareholder gains from tender offers.¹⁵⁹

(p. 319) Other studies, however, such as that by MacAvoy, found that board composition had no effect on profitability.¹⁶⁰ Klein likewise found little evidence of a general association between firm performance and board composition, but found a positive correlation between the presence of insiders on board finance and investment committees and firm performance.¹⁶¹ Rosenstein and Wyatt found that the stock market experienced a significantly positive price reaction to announcements that insiders had been appointed to the board when insiders owned more than 5 percent of the firm's stock.¹⁶²

The Board of Directors

A 1999 meta-analysis of numerous studies in this area concluded that there was no convincing evidence that firms with a majority of independent directors outperform other firms. It further concluded that there was some evidence that a “moderate number” of insiders correlates with higher performance.¹⁶³ A 1998 meta-analysis likewise found no evidence that board composition affects financial performance.¹⁶⁴

A literature review by Wagner et al. further complicated the empirical landscape by effectively splitting the baby.¹⁶⁵ Their meta-analysis of 63 correlations found that, on average, increasing the number of outsiders on the board is positively associated with higher firm performance. On the other hand, increasing the number of insiders on the board had the same effect. In other words, greater board homogeneity was positively associated with higher firm performance, which is not what the Sarbanes-Oxley Act’s proponents would have predicted.

There is some evidence that the post-SOX regulatory changes and the new market forces affecting independent directors have had an impact. Robert Felton’s review of studies of post-SOX boards of directors found that the average number of companies on whose board a director sits has gone down, presumably because boards and committees meet more often and have to process more information. The amount of time required for board service has especially gone up for members of audit committees, who have a host of new duties. Overall, “the average commitment of a director of a U.S. listed company increased from 13 hours a month in 2001 to 19 hours in 2003 (and then fell to 18 hours in 2004).”¹⁶⁶ Whether this strengthens the case for director independence is questionable, however, because many of the factors discussed in the preceding sections likely would have produced similar increases in effort by insider-dominated boards.

(p. 320) Somewhat stronger evidence that the fetish for independence has had at least some beneficial effects is provided by Michael Useem and Andy Zelleke’s survey of governance practices. They found that boards of directors increasingly view delegation of authority to management as properly the subject of careful and self-conscious decision making. The surveyed board members acknowledged that they do not run the company on a day-to-day basis, but rather are seeking to provide stronger oversight and supervision. Increasingly, boards are establishing written protocols to allocate decision-making rights between the board and management, although the protocols vary widely, ranging from detailed and comprehensive to skeletal and limited in scope. Useem and Zelleke conclude that executives still set much by the board’s decision-making agenda. At the same time, they found that boards have been increasingly asserting their sovereignty in recent years and that an emergent norm requires management to be mindful of what information boards want to hear and what decisions boards believe they should make.¹⁶⁷

A critical issue, of course, has always been board access to information. Indirect evidence that independent directors now have good access to information is provided by a study by Enrichetta Ravina and Paola Sapienza of independent directors’ trading results. The authors found that independent directors earn substantial positive abnormal returns when trading in their corporation’s stock. Even more interestingly, the difference between their

results and those of the same firm's executive officers is relatively small, although it widens in firms with weaker governance regimes.¹⁶⁸ It seems reasonable to infer from this evidence that outsiders now have good access to material information about firm performance—indeed, that their access to such information is comparable to that of executive officers.¹⁶⁹

5.3 Does One Size Now Fit All?

The post-SOX regulatory environment rests on the conventional wisdom that board independence is an unalloyed good. As the preceding sections demonstrated, however, the empirical evidence on the merits of board independence is mixed. Accordingly, even though there is some reason to think independent board members are finally becoming properly incentivized and, as a result, more effective, the clearest take-home lesson from the preceding analysis is still that one size does not fit all.

This result should not be surprising. On one side of the equation, firms do not have uniform needs for managerial accountability mechanisms. The need for accountability is determined by the likelihood of shirking, which in turn is determined by management's tastes, which in turn is determined by each firm's unique culture, traditions, and competitive environment. We all know managers whose preferences include a penchant for hard, faithful (p. 321) work. Firms where that sort of manager dominates the corporate culture have less need for outside accountability mechanisms.

On the other side of the equation, firms have a wide range of accountability mechanisms from which to choose. Independent directors are not the sole mechanism by which management's performance is monitored. Rather, a variety of forces work together to constrain management's incentive to shirk: the capital and product markets within which the firm functions; the internal and external markets for managerial services; the market for corporate control; incentive compensation systems; auditing by outside accountants; and many others. The importance of the independent directors' monitoring role in a given firm depends in large measure on the extent to which these other forces are allowed to function. For example, managers of a firm with strong takeover defenses are less subject to the constraining influence of the market for corporate control than are those of a firm with no takeover defenses. The former needs a strong independent board more than the latter does.

The critical mass of independent directors needed to provide optimal levels of accountability also will vary depending upon the types of outsiders chosen. Strong, active independent directors with little tolerance for negligence or culpable conduct do exist. A board with a few such directors is more likely to act as a faithful monitor than a board that has many nominally independent directors who shirk their monitoring obligations.

The post-SOX standards, however, strap all listed companies into a single model of corporate governance. By establishing a highly restrictive definition of director independence and mandating that such directors dominate both the board and its required committees, the new rules fail to take into account the diversity and variance among firms. The new

rules thus satisfy our definition of quack corporate governance. The one size fits all model, they mandate, should be scrapped in favor of allowing each firm to develop the particular mix of monitoring and management that best suits its individual needs. This conclusion becomes even stronger when one considers the adverse albeit unintended consequences of the movement for director independence, as discussed in the next Part.

5.4 A Note on CEO/Chairman Duality

The exchange listing standards require appointment of an independent lead director if the listed company's CEO serves as the chairman of the board of directors. The lead director presumably chairs the executive sessions of the independent board members. Because the lead director's identity and contact information must be disclosed, he also acts as a point person for shareholder relations. The lead director should have a voice in setting the board's agenda, as a check on the CEO/Chairman's control of board meetings. The lead director should serve as a rallying point for the other independent directors in times of crisis, especially those involving CEO termination or succession.

The lead director position was a compromise with those commentators who wanted the exchanges to mandate a non-executive chairman of the board of directors. The proponents of splitting the CEO and board chairman role, however, continued to press the idea and sought to use Dodd-Frank as a vehicle for doing so. In the end, however, Dodd-Frank Section 973 merely directed the SEC to adopt a new rule requiring reporting (p. 322) companies to disclose whether the same person or different persons hold the positions of CEO and Chairman of the Board.¹⁷⁰ In either case, the company must disclose its reasons for doing so.

The legislative history expressly states that the Act "does not endorse or prohibit either method."¹⁷¹ This is just as well, because neither method has compelling support in the empirical literature. To be sure, an independent chairman of the board is becoming more common:

Approximately 16 percent of S&P 500 companies now have an independent chair; among S&P Mid and Small Cap companies the figure is higher (23 percent and 27 percent, respectively). In 2008, 95 percent of S&P 500 boards had an independent lead or presiding director, compared with only 36 percent in 2003.¹⁷²

The latter figure represents the impact of exchange listing standards, of course, and thus should not be taken as evidence in favor of a non-executive chairman. The real question is whether the relatively modest number of companies with such an independent chair is due to market failure or reflects optimal board design.

A study by Olubunmi Faleye finds support for the hypothesis that firms actively weigh the costs and benefits of alternative leadership structures in their unique circumstances and concludes that requiring a one size fits all model separating the CEO and chairman positions may be counterproductive.¹⁷³ A study by James Brickley, Jeffrey Coles, and Gregg A. Jarrell found little evidence that combining or separating the two titles affected corporate

performance.¹⁷⁴ A subsequent study by the same authors found “preliminary support for the hypothesis that the costs of separation are larger than the benefits for most firms.”¹⁷⁵

As John Coates summarizes the field, the evidence is mixed, at best:

At least 34 separate studies of the differences in the performance of companies with split vs. unified chair/CEO positions have been conducted over the last 20 years, including two “meta-studies.” . . . The only clear lesson from these studies is that there has been no long-term trend or convergence on a split chair/CEO structure, and that variation in board leadership structure has persisted for decades, even in the UK, where a split chair/CEO structure is the norm.¹⁷⁶

(p. 323) Although Coates concludes that splitting the CEO and chairman positions by legislation “may well be a good idea for larger companies,” he further concludes that mandating such a split “is not clearly a good idea for all public companies.”¹⁷⁷

Proponents of a mandatory non-executive Chairman of the Board have overstated the benefits of splitting the positions, while understating or even ignoring the costs of doing so. Michael Jensen identified the potential benefits in his 1993 Presidential Address to the American Finance Association, arguing: “The function of the chairman is to run the board meetings and oversee the process of hiring, firing, evaluation, and compensating the CEO. . . . Therefore, for the board to be effective, it is important to separate the CEO and Chairman positions.”¹⁷⁸ In fact, however, overseeing the “hiring, firing, evaluation, and compensating the CEO” is the job of the board of directors as a whole, not just the Chairman of the Board.

To be sure, in many corporations, the Chairman of the Board is given unique powers to call special meetings, set the board agenda, and the like.¹⁷⁹ In such companies, a dual CEO-Chairman does wield powers that may impede board oversight of his or her performance. Yet, in such companies, the problem is not that one person holds both posts; the problem is that the independent members of the board of directors have delegated too much power to the Chairman. The solution is to adopt bylaws that allow the independent board members to call special meetings, require them to meet periodically outside the presence of managers, and the like.

Indeed, the influence of an executive chairman may not even be a problem. Brickley, Coles, and Jarrell concluded that the separation and combination of titles is part of the natural succession process. A successful CEO receives a variety of rewards from the company, one of which may be a fancier title. If the power that comes with the combined title came as a reward for sustained high performance, that power may actually redound to the company’s benefit.

Turning from the benefit side to the cost side of the equation, even if splitting the posts makes it easier for the board to monitor the CEO, the board now has the new problem of monitoring a powerful non-executive chairman. The board now must expend effort to ensure that such a chairman does not use the position to extract rents from the company

and, moreover, that the chairman expends the effort necessary to carry out the post's duties effectively. The board also must ensure that a dysfunctional rivalry does not arise between the chairman and the CEO, both of whom presumably will be ambitious and highly capable individuals. In other words, if the problem is "who watches the watchers?," splitting the two posts simply creates a second watcher who also must be watched.

In addition, a non-executive chairman inevitably will be less well informed than a CEO. Such a chairman therefore will be less able to lead the board in performing its advisory and networking roles. Likewise, such a chairman will be less effective in leading the board (p. 324) in monitoring top managers below the CEO, because the chairman will not know those managers as intimately as the CEO.

6 How and Why Boards Fail

Boards of directors have long had bad press. In the eighteenth century, Adam Smith famously complained that one could not expect that the directors of a joint stock company, "being the managers rather of other people's money than of their own, . . . should watch over it with the same anxious vigilance with which the partners in a private copartnery frequently watch over their own."¹⁸⁰ Almost two centuries later, William O. Douglas complained that there were too many boards whose members did "not direct"¹⁸¹ and dismissed directors as "business colonels of the honorary type—honorary colonels who are ornamental in parade but fairly useless in battle."¹⁸²

More recently, the SEC in 2009 complained that the financial crisis had "led many to raise serious concerns about the accountability and responsiveness of some companies and boards of directors."¹⁸³ In the same time frame, prominent Canadian corporate governance commentator Stephen Jarislowsky argued that corporate "boards 'have enormous responsibility for' " the financial crisis of 2007–2008.¹⁸⁴

Despite this long history of complaints about board performance, there seems little doubt that the rise of the monitoring model has been accompanied by important improvements in board behavior. In 1995, only one in eight CEOs was fired or resigned under board pressure; by 2006, almost a third of CEOs were terminated involuntarily.¹⁸⁵ Over the last several decades, the average CEO tenure has decreased, which also has been attributed to more active board oversight.¹⁸⁶ In sum, boards of directors, "which once served largely as rubber stamps for powerful CEOs, have become more independent, more powerful, and under more pressure to dump leaders who perform poorly."¹⁸⁷

In addition to the evidence from CEO terminations, other studies confirm a general improvement in board performance. Studies of post-SOX boards of directors find that average board size has increased, presumably because companies are adding more independent directors rather than replacing incumbent insiders.¹⁸⁸ Conversely, the average number of (p. 325) companies on whose boards a director sits has gone down, presumably because boards and committees meet more often and have to process more information.¹⁸⁹

The Board of Directors

Michael Useem and Andy Zelleke's survey of governance practices provides additional evidence for improved board performance.¹⁹⁰ They found that boards of directors increasingly view delegation of authority to management as properly the subject of careful and self-conscious decision making.¹⁹¹ The surveyed board members acknowledged that they do not run the company on a day-to-day basis, but rather are seeking to provide stronger oversight and supervision.¹⁹² Increasingly, boards are establishing written protocols to allocate decision-making rights between the board and management, although the protocols vary widely, ranging from detailed and comprehensive to skeletal and limited in scope.¹⁹³ Useem and Zelleke conclude that executives still set much of the board's decision-making agenda.¹⁹⁴ At the same time, they found that boards are increasingly asserting their sovereignty in recent years and that a norm is emerging among managers that, at the very least, they must be mindful of what information boards want to hear and what decisions directors believe the board should make.¹⁹⁵

6.1 Room for Improvement

While many modern boards demonstrably outperform their predecessors, it would be Pollyannaish to deny that there is still much room for improvement. The financial crisis of 2007–2008, for example, revealed widespread board failures in areas such as enterprise risk management. According to a 2002 survey of corporate directors, 43 percent said that their boards had either an ineffective risk management process or no process for identifying and managing risk at all.¹⁹⁶ According to the same survey, 36 percent of directors felt they had an incomplete understanding of the risks faced by their companies.¹⁹⁷

A 2008 Towers Perrin survey of CFOs suggests that risk management remained underdeveloped when the financial crisis hit. Seventy-two percent of the respondents, for example, "expressed concern about their own companies' risk management practices and ability to meet strategic plans."¹⁹⁸ Instructively, 42 percent "foresaw more energized involvement by boards of directors in risk management policies, processes and systems,"¹⁹⁹ which implies that (p. 326) pre-crisis boards were inadequately engaged with risk management. This inference finds support in a 2006 observation that risk management was still "a work in progress at many boards."²⁰⁰

Respondents to the Towers Perrin survey pointed to these failures as a root cause of the financial crisis. Sixty two percent of respondents blamed "poor or lax risk management at financial institutions as a major contributor to the current financial mess."²⁰¹ Instructively, surveyed CFOs were more likely to point to risk management failures by boards as a reason for the financial crisis than either the complexity of financial instruments or speculation (55 percent and 57 percent, respectively).²⁰²

Still another widely asserted criticism is that boards have failed to rein in allegedly runaway executive compensation. In an influential critique, for example, Lucian Bebchuk and Jesse Fried argued that "directors have been influenced by management, sympathetic to executives, insufficiently motivated to bargain over compensation, or simply ineffectual in overseeing compensation."²⁰³ As a result, they claim, executive pay has greatly exceeded

the levels that would prevail if directors loyal to shareholder interests actually bargained with managers at arm's-length.²⁰⁴ Many other commentators have leveled similar criticisms at boards.²⁰⁵

6.2 Why Boards Fail

The reasons boards continue to struggle include the outsider status of most directors, inadequate time, misspent time, inadequate information, improper skill sets, and insufficient incentives. Ironically, while many of these concerns are longstanding, they have almost all been compounded by recent reforms, especially those focusing on increasing director independence.

As a result of the repeated reforms increasing the number of independent directors, boards today are dominated by part-timers, the vast majority of whom have full-time employment elsewhere, which commands the bulk of their attention and provides the bulk of their pecuniary and psychic income.²⁰⁶ This has had a number of unintended adverse consequences.

(p. 327) 6.2.1 Time Constraints

Historically, moreover, directors did not spend much time together working as a group.²⁰⁷ Board meetings were few and short. According to one survey, for example, during the 1980s directors in large manufacturing companies averaged a total of 14 board and committee meetings per year, with the average board meeting lasting only three hours.²⁰⁸

To be sure, as we have seen, the legislative and regulatory fallout from the financial crises of the last decade resulted in directors devoting greater time to board service. Yet, independent directors by their very nature remain part-timers, which has very real costs:

Independent directors are part time participants in a corporation's affairs. By definition they are outsiders. However intelligent, hardworking or strong minded they may be they do not have the time or the mandate to challenge management's judgments except as to a discrete number of issues. If they spend all of their time trying to audit the auditors and assure that executive compensation is reasonable, they will have no time for focusing on important business and strategy matters.²⁰⁹

It appears, moreover, that much of the time directors do spend directing is misspent. Given that time is a scarce resource—especially for the sort of successful individuals likely to be tapped for board memberships—this is a potentially serious problem with contemporary board governance.

Much of the additional time appears to be devoted to oversight activities, which is hardly surprising given that both the Sarbanes-Oxley and Dodd-Frank Acts reinforced the monitoring model's influence.²¹⁰ If so, the additional time and effort being expended by directors may have important costs. The rise of the monitoring model long has threatened to generate unproductive adversarial conflict between boards and management. A certain amount of cognitive tension in the board-top management team relationship is beneficial

to the extent that it promotes the exercise of critical evaluative judgment by the former.²¹¹ Groups that are too collegial run the risk of submitting to groupthink and various other decision-making errors.²¹² If aggressive monitoring fosters an adversarial relation between directors and managers, however, this beneficial form of conflict may transform into more harmful forms. At best, rigid adherence to the monitoring model may transform a collaborative and collegial relationship into one that is cold and distant.²¹³ At worst, it can promote (p. 328) adversarial relations that result in destructive interpersonal conflict.²¹⁴ As noted above, adversarial relations promote conflict rather than collaboration and divert energies into unproductive areas.²¹⁵ Unfortunately, as Peter Wallison observes, the “congressional imprimatur” Sarbanes-Oxley put on the monitoring model has compounded the problem by encouraging “an adversarial relationship between managements and boards that will, over time, impair corporate risk-taking and thus economic growth.”²¹⁶

Even if a firm’s board and management maintain an appropriately balanced relationship, the additional time and effort elicited by the Sarbanes-Oxley Act may not be directed productively. Boards today “are more focused on compliance with standards and regulations than they are on obtaining a competitive advantage.”²¹⁷ This leaves boards with less time to devote to their traditional functions, including management oversight.

6.2.2 Compounding the Board’s Inherent Information Disadvantage

At the minimum, the presence of outsiders on the board increases decision-making costs simply because the process takes longer. Part-time outsiders by definition need more information and are likely to take longer to persuade than are full-time insiders.²¹⁸ In addition to having greater access to formal intra-firm information flows by virtue of being full-timers, insiders have lots of informal contacts within the firm, which provide even better access to information than are available to outsiders whose interactions with firm employees is limited.²¹⁹ More subtly, and perhaps more importantly, long-term employees make significant investments in firm-specific human capital.²²⁰ Any employee who advances to senior management levels necessarily invests considerable time and effort in learning how to do his job more effectively. Much of this knowledge will be specific to the firm for which he works, such as when other firms do not do comparable work or his firm has a unique corporate culture.²²¹ An employee who has made significant investments in firm-specific human capital is likely to make better decisions for the firm than an outsider, even assuming equal levels of information relating to the decision at hand. The insider can put the decision in a broader context, seeing the relationships and connections it has to the firm as whole.

(p. 329) 6.2.3 Compounding the Generalist Problem

In contrast to insiders, independent directors have little incentive to invest in firm-specific human capital. As noted, they typically have full-time jobs elsewhere and often serve on multiple boards simultaneously. As a result, they tend to be generalists with little firm-specific knowledge, skills, or expertise.²²² Modern boards thus tend to be “composed of

The Board of Directors

individuals who are not qualified to assess the strategic viability of the corporations they direct.”²²³

Corporate casualties in the most recent crisis represent instances of board members lacking expertise. In years past, some of Merrill Lynch’s board members were leaders of prestigious colleges and universities. However, nothing would indicate that these individuals had meaningful accounting or financial expertise. Their backgrounds and lack of corresponding expertise raise concerns as to their ability to effectively monitor an investment bank such as Merrill. Similarly, Citigroup has been criticized for a board that had a dearth of independent directors with a financial background. Critics have attributed the independent board members’ lack of financial skill as a major contributing factor to the company’s problems.²²⁴

Unfortunately, the rules mandating director independence virtually ensure that this problem will remain insoluble. The standards defining what constitutes independence effectively rule out “just about anybody who has firsthand knowledge of the company and its industry.”²²⁵ While independent directors can develop such knowledge over time, doing so can be a very lengthy process.²²⁶ Many independent directors thus never develop more than a “rudimentary understanding of their companies’ workings.”²²⁷

While at least some long-serving directors may develop a reasonable knowledge of the company’s inner workings, long service can give rise to close friendships between nominally independent directors and the managers with whom they serve.²²⁸ This can compromise the director’s ability to take strong action when management falters. In some cases, but not all, long-serving directors “may find it difficult to be truly independent in deciding what’s in the shareholders’ best interests.”²²⁹

6.2.4 Compounding the Improper Incentives of Independent Directors

The most basic way of incentivizing people to do a good job is to pay them for doing so.²³⁰ Oddly, however, it long was against the law for corporations to compensate directors at all.²³¹ Because boards at that time consisted mainly of people associated with the firm, such as founding entrepreneurs, insiders, or representatives of major shareholders, their stake in the (p. 330) company provided alternative incentives for good performance.²³² As independent directors with no such stake in the company became more common, however, legislatures and courts recognized that compensation now was a necessary incentive and changed the law to allow it.²³³ By the mid-1970s, almost all public corporations paid their directors, and the amount of director compensation grew rapidly in the following years.²³⁴

Unfortunately, the combination of growing cash compensation and management’s control of the board nomination process acted “to align the interests of the outside directors with current management rather than with the shareholders. . . . Directors whose remuneration is unrelated to corporate performance have little personal incentive to challenge

The Board of Directors

their management benefactors.”²³⁵ In response, Charles Elson proposed a radical change in the form of director compensation:

To ensure that directors will examine executive initiatives in the best interest of the business, the outside directors must become substantial shareholders. To facilitate this, directors’ fees should be paid primarily in company stock that is restricted as to resale during their term in office. No other form of compensation, which serves to compromise their independence from management, should be permitted. The goal is to create within each director a personally based motivation to actively monitor management in the best interest of corporate productivity and to counteract the oversight-inhibiting environment that management appointment and cash-based/benefit-laden fees create.²³⁶

In 1996, a NACD blue ribbon panel adopted many of Elson’s ideas, recommending the use of stock-based compensation and further opining that directors should personally invest an amount in company stock sufficiently large so as to decouple the director’s financial interests from those of management.²³⁷ The core idea rapidly caught on, although few firms went so far as to eliminate all cash compensation and benefits. According to a 2007 report by the Conference Board, 90 percent of surveyed companies made some form of stock-based compensation to directors, with 38 percent paying all or part of the basic retainer in stock.²³⁸

In theory, this change in board compensation practices should align director incentives with the interests of shareholders. If directors have skin in the game, their interests will be more closely aligned with those of the shareholders. The problem is that the practice of paying directors in stock occurred simultaneously with a dramatic increase in the use of (p. 331) stock options to pay management.²³⁹ There’s some evidence that stock-based compensation is associated with an increase in managerial manipulation of financial results.²⁴⁰

The incentives of directors with substantial stock holdings or in-the-money options are more closely aligned with managers than those of shareholders.²⁴¹ As a result, if managers inflate the company’s stock prices by manipulating financial data or otherwise cooking the books, “directors may go along because they also stand to benefit.”²⁴² There is thus an inherent tension between the competing goals of ensuring director independence and incentivizing them to perform at a high quality level. The more stock a director owns, the less independent the director becomes.²⁴³

6.2.5 The Lost Benefits of Insider Representation

Oliver Williamson suggests that one of the board’s functions is to “safeguard the contractual relation between the firm and its management.”²⁴⁴ Insider board representation may be necessary to carry out that function. Many adverse firm outcomes are beyond management’s control. If the board is limited to monitoring management, and especially if it is limited to objective measures of performance, however, the board may be unable to differentiate between acts of god, bad luck, ineptitude, and self-dealing. As a result, risk-

The Board of Directors

averse managers may demand a higher return to compensate them for the risk that the board will be unable to make such distinctions. Alternatively, managers may reduce the extent of their investments in firm-specific human capital, so as to minimize non-diversifiable employment risk. Insider representation on the board may avoid those problems by providing better information and insight into the causes of adverse outcomes.

Insider representation on the board also will encourage learned trust between insiders and outsiders. Insider representation on the board thus provides the board with a credible source of information necessary to accurate subjective assessment of managerial performance. In addition, however, it also serves as a bond between the firm and the top management team. Insider directors presumably will look out for their own interests and those of their fellow managers. Board representation thus offers some protection against dismissal for adverse outcomes outside management's control.

(p. 332) Such considerations likely explain the finding by Klein of a positive correlation between the presence of insiders on board committees and firm performance.²⁴⁵ They also help explain the finding by Wagner et al. that increasing the number of insiders on the board is positively correlated with firm performance.²⁴⁶

6.3 Boards-R-Us: A New Direction for Reform

As the preceding discussion confirms, the myriad of reforms of the last decade have for the most part simply compounded the problems that lead to board failure. Accordingly, Todd Henderson and this author recently proposed a new direction for board reforms.²⁴⁷

Bainbridge and Henderson propose permitting independent firms (e.g., partnerships, corporations, etc.) to provide board services. They call these businesses "board service providers" (BSPs). The idea would be for a corporation, such as Microsoft or ExxonMobil, to hire another entity, call it Boards-R-Us, to provide director services, instead of the group of unrelated individuals it currently hires to provide these services.

Companies provide almost all the goods and services in our economy, including such professional services as accounting or law, because they offer some well-known advantages compared with sole proprietorships. For instance, providing director services as a group would allow directors to decrease individual risk in ways that are more efficient than third-party insurance. It would also allow directors to deploy experts as needed to address particular problems as they arise, just as consultancies and law firms do.

Board members currently have to get expertise from outsiders hired typically by the CEO, which creates conflict-of-interest problems. (Conflict problems arising from BSPs could be handled through rules limiting cross-selling of services, just as Sarbanes-Oxley did for accounting and consultancy services.) Allowing these experts to be under the same roof would reduce this problem, as well as transaction costs. Finally, service firms have reputations that exceed those of individual members, meaning the potential for slack or oppor-

The Board of Directors

tunism is reduced. When an individual acts alone, only one reputation is at stake, but when a firm acts, it is effectively betting the reputation of the firm each time.

Hiring a BSP to provide board services instead of a loose group of sole proprietorships will increase board accountability, both from markets and judicial supervision. For instance, BSPs traded in public markets will be disciplined to provide quality services at competitive prices, and courts may be more willing to enforce fiduciary duties against companies than against individuals.

There currently is no market for directors. They find their way onto boards largely through personal connections, often with the CEO, or the opaque headhunter process, and because (p. 333) votes are private and decisions are made collectively, the accountability to shareholders is greatly diminished. Although it is possible for any individual to run for a board seat on any company, the publicity and voting costs are prohibitive. A BSP with a national reputation and the ability to provide all director functions would be able to reduce the cost of winning board seats. For instance, BSPs can use their brand and economies of scale to lower the costs of communicating with and persuading shareholders to hire them.

Bainbridge and Henderson do not argue that all public companies should hire BSPs to provide their board services. Companies should merely have the choice to use BSPs—and to understand their potential benefits—just as they do for all other services they require.

The Board of Directors

model. In 1978, for example, the American Bar Association's Section of Business Law promulgated a Corporate Director's Guidebook that embraced an Eisenberg-like model in which the management and monitoring of management roles were separated, with the latter task being assigned to a board comprised mainly of outside directors. ABA Section of Corporation, "Banking and Business Law, Corporate Director's Guidebook", 33 Bus. Law. 1591, 1619-28 (1978). (⁶⁵) A slightly different version of this story is told by Herbert Hovenkamp, who argues that separation of ownership and control is less a function of firm size than of firm complexity. Under this model, neither technological change nor corporate financing was the dispositive factor. Rather, ownership and control separated when, because of a high degree of vertical integration, firms became sufficiently complex to require professional managers. Herbert Hovenkamp, *Enterprise and American Law: 1836-1937* 357-60 (1991). Notice the close fit between this interpretation and the economic model advanced in this chapter. Under both, the unique attribute of modern public corporations is the hierarchical decision-making structure adopted as an adaptive response to organizational complexity.

(⁶⁶) See, e.g., *Lorenz v. CSX Corp.*, 1 F.3d 1406, 1417 (3d Cir. 1993) (“It is well-established that a corporation does not have a fiduciary relationship with its debt security holders, as with its shareholders. The relationship between a corporation and its debentureholders is contractual in nature.”); *Simons v. Cogan*, 549 A.2d 300, 303 (Del. 1988) (holding that “a convertible debenture represents a contractual entitlement to the repayment of a debt”).

(⁶⁷) See, e.g., *Berman v. Physical Med. Assocs.*, 225 F.3d 429, 433 (4th Cir. 2000) (holding that, “as to Berman’s claims under the employment agreement and severance benefit agreement, only the corporation owed Berman a contractual duty”).

(⁷⁴) Again, the extent to which the growth of shareholder activism challenges this framework is beyond the scope of this chapter, but has been addressed in the works cited *supra* note 22.

(⁷⁵) Finally, portfolio theory offers yet another justification for separating ownership and control. By virtue of their non-diversified investment in firm-specific human capital, managers bear part of the risk of firm failure. As the firm’s residual claimants, however, shareholders also bear a portion of the risk associated with firm failure. Portfolio theory tells us that individual shareholders can minimize that risk through diversification, which managers cannot do with respect to their human capital. Separating ownership and control thus unbundles the risks associated with the firm and allocates each of those risks to the party who can bear it at the lowest cost. We regard this explanation as somewhat problematic, however, due to its managerialist overtones.

(⁷⁶) Similar analyses apply to other corporate constituents on whose behalf claims to control of the decision-making apparatus might be made, such as employees or creditors.

(⁷⁷) Arrow, *supra* note 72, at 68–69.

(⁷⁸) Obviously, fiat within firms has limits. Some choices are barred by contract, such as negative pledge covenants in bond indentures. Other choices may be barred by regulation or statute. Still other choices may be unattractive for business reasons, such as those with potentially adverse reputational consequences. Within such bounds, however, adaptation effected through fiat is the distinguishing characteristic of the firm.

(⁸⁶) Restatement (Second) of Agency § 14 C cmt (1958).

⁽⁸⁷⁾ MBCA § 8.20 cmt. An alternative explanation is suggested by Jeffrey Gordon's persuasive demonstration that voting within a corporation is subject to Arrow's impossibility theorem, in the sense that voting on most matters of day-to-day policy would result in cyclical majorities. Although we will rely more heavily on information and incentive-based arguments for the board's authority than does Gordon, he does present a convincing argument that corporate law's authority-based board of directors system is explicable in very large measure as a device for avoiding the cycling problem by restricting owner voice. Jeffrey N. Gordon, "Shareholder Initiative: A Social Choice and Game Theoretic Approach to Corporate Law", 60 U. Cin. L. Rev. 347 (1991).

⁽⁸⁸⁾ Many of these housekeeping rules doubtless seem formalistic or even a little silly, but the requirement that the board act only after meeting as a collective body actually has a sound economic basis. Work by experimental psychologists has found that group decision making, under certain circumstances, can be superior to decision making by individuals. Where evaluation of complex problems requiring the exercise of critical judgment is concerned, the evidence is clear that the performance of a group will be superior to that of the group's average member. This result has been confirmed by experiments requiring performance of a wide variety of tasks. See, e.g., Larry K. Michaelsen et al., "A Realistic Test of Individual versus Group Consensus Decision Making", 74 J. App. Psych. 834 (1989) (test taking in team learning settings); Marjorie E. Shaw, "A Comparison of Individuals and Small Groups in the Rational Solution of Complex Problems", 44 Am. J. Psych. 491 (1932) (puzzle solving); see generally Gayle W. Hill, "Group versus Individual Performance: Are N + 1 Heads Better than One?", 91 Psych. Bull. 517 (1982). For a detailed review of the evidence on group decision making, with applications to corporate law, see Bainbridge, *supra* note 37.

⁽⁸⁹⁾ There may also be a behavioral explanation for the board. Research in behavioral economics has identified a number of pervasive cognitive errors that bias decision making. Several of the identified decision-making biases seem especially pertinent to managerial decision making, especially the so-called overconfidence bias. The old joke about the camel being a horse designed by a committee captures the valid empirical observation that individuals are often superior to groups when it comes to matters requiring creativity. Research on brainstorming as a decision-making process, for example, confirms that individuals working alone generate a greater number of ideas than do groups, especially when the assigned task is "fanciful" rather than "realistic." Hill, *supra* note 88, at 527. Individuals often become wedded to their ideas, however, and fail to recognize flaws that others might identify. Peter M. Blau & W. Richard Scott, *Formal Organizations* 116-21 (1962). In contrast, there is a widely shared view that groups are superior at evaluative tasks. Group decision making presumably checks individual overconfidence by providing critical assessment and alternative viewpoints, which is consistent with the standard account of the board's function. Recall that our taxonomy identified three basic board roles: monitoring, service, and resource gathering. At the core of the board's service role is providing advice and counsel to the senior management team, especially the CEO. At the intersection of the board's service and monitoring roles is the provision of alternative points of view. Put another way, most of what boards do requires the exercise of critical

The Board of Directors

evaluative judgment, but not creativity. Even the board's policy making role entails judgment more than creativity, as the board is usually selecting between a range of options presented by subordinates. The board serves to constrain subordinates who have become wedded to their plans and ideas, rather than developing such plans in the first instance.

⁽¹⁰⁰⁾ Social norms are relevant to other aspects of decision making besides agency costs. Group norms of reciprocity, for example, facilitate the process of achieving consensus within groups.

⁽¹⁰¹⁾ James Q. Wilson, "What Is Moral and How Do We Know It?", *Commentary*, June 1993, at 37, 39. See also Kenneth L. Bettenhausen, "Five Years of Groups Research: What We Have Learned and What Needs to Be Addressed", 17 *J. Mgmt.* 345, 348 (1991).

⁽¹⁰²⁾ See generally Williamson, *supra* note 23, at 48 ("Informal peer group pressures can be mobilized to check malingering The most casual involves cajoling or ribbing. If this fails, rational appeals to persuade the deviant to conform are employed. The group then resorts to penalties by withdrawing the social benefits that affiliation affords. Finally, overt coercion and ostracism are resorted to.").

(¹⁰³) The case should not be overstated. Cohesive groups are subject to inherent cognitive biases that limit their effectiveness. A widely cited example is the so-called risky shift phenomenon. There seems to be a polarizing effect in group decision making, so that post-discussion consensus is more extreme than the individual pre-test results. See Norbert L. Kerr, "Group Decision Making at a Multialternative Task: Extremity, Interaction Distance, Pluralities, and Issue Importance", 52 *Org. Behav. and Human Decision Processes* 64 (1992). The most significant group bias for our purposes, however, is the "groupthink" phenomenon. Highly cohesive groups with strong civility and cooperation norms value consensus more greatly than they do a realistic appraisal of alternatives. Irving Janis, *Victims of Groupthink* (1972). In such groups, groupthink is an adaptive response to the stresses generated by challenges to group solidarity. To avoid those stresses, groups may strive for unanimity even at the expense of quality decision making. To the extent groupthink promotes the development of social norms, it facilitates the board's monitoring function. It may also be relevant to other board functions, such as resource acquisition, to the extent that it promotes a sort of esprit de corps. Yet, the downside is an erosion in the quality of decision making. The desire to maintain group cohesion trumps the exercise of critical judgment. Adverse consequences of groupthink thus include not examining alternatives, being selective in gathering information, and failing to be either self-critical or evaluative of others. Studies of meeting behavior, for example, conclude that people tend to prefer options that have obvious popularity. Kiesler & Sproull, *supra* note 96. In the corporate setting, board culture often encourages groupthink. Boards emphasize politeness and courtesy at the expense of oversight. CEOs can foster and channel groupthink through their power to control information flows, reward consensus, and discourage the reelection of troublemakers. The groupthink phenomenon therefore demands close attention with respect to a variety of corporate governance issues, but is most directly relevant to the board composition debate discussed below.

(¹⁰⁴) Noting that most corporations—especially outside the USA and UK—have highly concentrated ownership, Morten Bennedsen suggests that a major function of boards is to mediate conflicts between controlling and non-controlling shareholders. Morten Bennedsen, *Why Do Firms Have Boards?* (March 2002 (copy on file with author)). Of course, this is also an agency cost story, focusing on a different potential set of conflicts.

(¹⁰⁵) The extent to which the increasingly important phenomenon of shareholder activism requires us to rethink the issues discussed in this section is beyond the scope of this chapter. As already mentioned *supra* note 22, however, the author has discussed that phenomenon at length elsewhere.

(¹⁰⁶) Oliver E. Williamson, *Markets and Hierarchies: Analysis and Antitrust Implications* 46 (1975). In addition to the transaction costs associated with making an informed decision, which by themselves are doubtless preclusive of participatory democracy in the large firm setting, the opportunity cost entailed in making informed decisions is also high and, even more importantly, readily apparent. In contrast, the expected benefits of becoming informed are quite low, as an individual decision maker's vote will not have a sig-

nificant effect on the vote's outcome. Our employee owners thus will be rationally apathetic.

(¹¹¹) One sure result of lost confidentiality will be worker demands for higher wages. This prediction is supported by an empirical study finding that provision of financial and other business information to employees of non-unionized firms had a negative effect on firm profitability, which was attributed to higher wages demanded by the informed employees. Morris M. Kleiner & Marvin L. Bouillon, "Providing Business Information to Production Workers: Correlates of Compensation and Productivity", 41 Indus. & Lab. Rel. Rev. 605, 614-15 (1988). See also Stuart Ogden, "The Limits of Employee Involvement: Profit Sharing and Disclosure of Information", 29 J. Mgmt Stud. 229 (1992) (stating that UK employers are reluctant to provide disclosure of financial information for fear of stimulating workers to make demands respecting pay and working conditions). In a unionized firm, moreover, management will be especially reluctant to inform union members on the board of information that might aid the union in collective bargaining.

(¹¹²) Hopt, *supra* note 45, at 206.

(¹¹³) Tove H. Hammer et al., "Worker Representation on Boards of Directors: A Study of Competing Roles", 44 Indus. & Lab. Rel. Rev. 661, 663 (1991) (Scandinavian experience with codetermination shows it has little substantive effect on corporate decision making).

(¹¹⁴) The difficulty, of course, is not merely that the interests of employees and shareholders diverge, but also that different classes of employees have divergent interests. As we have seen, this seriously compounds the problem of aggregating constituency preferences.

(¹¹⁵) Cotton, *supra* note 46, at 128 (1993). This conflict is exacerbated in heavily unionized industries, as representatives of a single union might sit on the boards of multiple firms within the industry. In the extreme case, the demise of one firm might redound to the greater good of the greatest number by benefiting union members who work at competing corporations. This creates the potential for perverse incentives on the part of union representatives on the board.

⁽¹¹⁶⁾ The most obvious problem is the possibility that employee representation will permit management to pursue its own self-interest at the expense of both shareholders and employees by playing worker and shareholder representatives off against each other. Legal and market accountability mechanisms constrain this tendency, but because they are not perfect there remains the possibility that self-interested managers may throw their support behind the side of the board whose interests happen to coincide with those of management in the issue at hand. See William J. Carney, "Does Defining Constituencies Matter?", 59 U. Cin. L. Rev. 385, 420-24 (1990).

This conflict is well-known, of course, but there is a more subtle problem that is often overlooked. Corporate employees have an incentive to shirk so long as their compensation does not perfectly align their incentives with those of the firm's shareholders. In turn, knowing of this phenomenon, the firm's shareholders should expect management to reduce the compensation of the firm's employees by the amount necessary to offset the expected degree of employee shirking. Because *ex ante* wage adjustments rarely are fully compensatory, due to bounded rationality and the resulting use of incomplete contracts, the firm's shareholders should expect management to monitor the employees and punish *ex post* those who shirk. Benjamin Klein, "Contracting Costs and Residual Claims: The Separation of Ownership and Control", 26 J. L. & Econ. 367, 368 n.2 (1983). Would it not seem odd that those who are to be monitored should be allowed to choose the monitors? One of the accountability mechanisms that aligns managerial and shareholder interests is monitoring by the board of directors. Allowing employee representation on the board necessarily reduces the likelihood that the board will be an effective monitoring device. Because shareholders "could seek profits by getting highly motivated managers who sweat the labor force," workers have an interest in supporting rules that free management from accountability to shareholders. Roe, *supra* note 55, at 44. Managerial shirking of its monitoring responsibilities thus will often redound to the workers' benefit, which suggests that employee representatives on the board of directors are less likely to insist on disciplining lax managers than are shareholder representatives. If employees are entitled to voting representation on the board of directors, monitoring by the board and its subordinate managers will be less effective, which will cause agency costs to rise.

The validity of this prediction is confirmed by the German experience with codetermination. Conflicts of interest faced by employee representatives on the supervisory board remain a serious but unresolved concern. Employee representation slows the finding of a consensus on the supervisory board and creates a built-in polarization problem. Not surprisingly, it is standard practice for employee and shareholder representatives to have separate pre-meeting caucuses. Hopt, *supra* note 45, at 206-08.

ed., 1983) (opining: "As to the majority of managerial policies concerning, for example, dividend and investment policies, product development, and the like, the typical employee has as much interest and as much to offer as the typical purchaser of light bulbs").

(¹¹⁹) See, e.g., Frank H. Easterbrook and Daniel R. Fischel, *The Economic Structure of Corporate Law* 66–72 (1991). An alternative answer based on the model used herein returns to the divergence of interests within constituency groups. Although investors have somewhat different preferences on issues such as dividends and the like, they are generally united by a desire to maximize share value. Board consensus therefore will be more easily achieved if directors are beholden solely to shareholder interests, rather than to the more diverse set of interests represented by employees.

A related but perhaps more telling point is the problem of apportioning the vote. Financial capital is fungible, transferable, and quantifiable. Control rights based on financial capital are thus subject to low-cost allocation and valuation. In contrast, the human capital of workers meets none of these criteria. While one-person/one-vote would be a low-cost solution to the allocation problem, it appears highly inefficient given the unequal distribution of reasoning power and education. If the most competent people and/or those with the most at stake should have the most votes, some more costly allocation device will be necessary.

(¹²⁰) The superiority of shareholder incentives is a relative matter. Shareholders may have better incentives than other constituencies, but the phenomenon of rational apathy nevertheless limits the extent to which shareholders can be expected to act on those incentives.

(¹²¹) According to the Coase Theorem, rights will be acquired by those who value them most highly, which creates an incentive to discover and implement transaction cost minimizing governance forms. See Ronald H. Coase, "The Problem of Social Cost", 3 *J. L. & Econ.* 1 (1960). Although shareholders and employees obviously do not bargain, a basic premise of the law and economics account is that corporate law provides them with a set of default rules reflecting the bargain they would strike if they were able to do so.

(¹²²) See generally Oliver Williamson, "Corporate Governance", 93 *Yale L. J.* 1197 (1984). This is not to say that exit is costless for either employees or firms. All employees are partially locked into their firm. Indeed, it must be so, or monitoring could not prevent shirking because disciplinary efforts would have no teeth. The question is one of relative costs.

(¹²³) As private sector unions have declined, the federal government has intervened to provide through general welfare legislation many of the same protections for which unions might have bargained. The Family & Medical Leave Act grants unpaid leave for medical and other family problems. OSHA mandates safe working conditions. Plant closing laws require notice of layoffs. Civil rights laws protect against discrimination of various sorts. Even such matters as offensive horseplay have come within the purview of federal sexual harassment law.

(¹⁵³) Conversely, however, note that, because their decisions are publicly observable, board members have a strong incentive to defer to expert opinion. Because even a good decision maker is subject to the proverbial “act of God,” the market for reputation evaluates decision makers by looking at both the outcome and the action before forming a judgment. If a bad outcome occurs, but the action was consistent with approved expert opinion, the hit to the decision maker’s reputation is reduced. In effect, by deferring to specialists, a decision maker operating under conditions of bounded rationality is buying insurance against a bad outcome. In a collegial, multi-actor setting, the potential for log rolling further encourages deference. A specialist in a given field is far more likely to have strong feelings about the outcome of a particular case than a non-expert. By deferring to the specialist, the non-expert may win the specialist’s vote in other cases in relation to which the non-expert has a stronger stake. Such log rolling need not be explicit, although it doubtless is at least sometimes, but rather can be a form of the tit-for-tat cooperative game. In board decision making, deference thus invokes a norm of reciprocity that allows the non-expert to count on the specialist’s vote on other matters.

Abstract and Keywords

This chapter examines current trends in the regulation and practice of executive remuneration, particularly emphasizing incentives like stock options and long-term pay. It first outlines the main problems of executive pay from the perspective of agency costs theory, banking theory, and corporate social responsibility. It then discusses the main policy issues relating to executive pay, from design problems and remuneration governance to disclosure of pay policies and amounts, and prudential regulation of pay structure at banks. It considers the regulation of pay governance and disclosure, with special reference to EU law, comparative law, and international practice. It explores the rise of shareholder engagement in listed companies across the Atlantic and the impact of say on pay rules on shareholder activism. Finally, it analyzes the implications of international principles and standards, the Dodd-Frank Act, and CRD IV for the regulation of the pay structure at banks and other financial institutions.

1 Introduction

EXECUTIVE pay lies at the heart of current discussion on corporate governance reform. Increased disclosure, monitoring by the media, and institutional investor activism often suggest that the levels and structures of executive remuneration are divorced from corporate performance, and represent a sharp conflict of interest between management and shareholder interests. Moreover, “excessive” compensation at banks and other financial institutions is widely believed to have contributed to the financial crisis by incentivizing managers to take excessive risks. In the present chapter we consider executive remuneration from a transatlantic perspective, looking at corporate practices, regulation, and investor behavior both in Europe and the US. The remainder of this introductory section introduces the main problems of executive pay from the perspective of agency costs theory, banking theory, and corporate social responsibility. In section 2, we analyze the main policy issues concerning executive pay, such as design problems, remuneration governance,

disclosure of pay policies and amounts, and prudential regulation of pay structure at banks. In section 3 we examine the regulation of pay governance and disclosure, focusing on EU law, comparative law, and international practice. In section 4 we analyze the regulation of pay structure at financial institutions (banks in particular) focusing on the international principles and standards, on the Dodd-Frank Act, and CRD IV. Section 5 concludes.

1.1 Agency Costs

The principal-agent model has generated two competing views of executive pay.¹ Under the first view, executive pay remedies the agency costs generated by the misalignment of management and shareholder interests in the dispersed ownership company. Shareholders (p. 335) in dispersed ownership systems have only a fractional interest in firm profits, are not fully incentivized to discipline, and have limited opportunities to monitor management.² Management's unobserved actions, particularly where personal costly decisions (e.g., laying off employees) and private beneficial activities (e.g., consuming perquisites) are involved, can reduce shareholder wealth and give rise to agency costs. Whether, and the extent to which, a manager will fully pursue the shareholders' agenda depends on how she is incentivized. Agency theory suggests that the performance-based pay contract, which links pay to shareholder wealth via performance indicators such as share prices or accounting-based targets, is a powerful way of attracting, retaining, and motivating managers to pursue the shareholders' agenda.³ In the dispersed ownership context, this approach has dominated the pay debate and pay practices since the early 1990s and still enjoys considerable support as making management more sensitive to shareholders' interests.⁴

According to a second view, executive pay can also be regarded as an agency cost in itself in that it provides a powerful and opaque device for self-dealing by conflicted managers.⁵ In practice, pay is not set by shareholders; instead, it is set on their behalf by the board of directors, which is expected to align shareholder and managerial incentives.⁶ Nonetheless, a conflicted board may use the pay-setting process to influence pay and extract rents in the form of pay in excess of that would be optimal for shareholders, given weaknesses in the design of pay contracts and in their supporting governance structures.⁷ In other words, executive pay raises an additional agency problem: How can the effectiveness of the executive pay contract as a remedy for manager/shareholder agency costs be protected from conflicts between the board, as pay-setter, and the shareholders?⁸ The equity-based incentive contract may, as post-Enron scholarship argues, deepen conflicts of interest between shareholders and managers by generating perverse management incentives to manipulate financial disclosure, particularly earnings, and distort share prices, which can lead to catastrophic (p. 336) corporate failures. The consequences of such a cycle of ever higher share prices, and their impact on pay, have been examined as "the agency costs of overvalued equity."⁹

Executive Remuneration

The relationship between agency problems and the executive pay incentive contract takes on an additional complexity in continental European firms, characterized by concentrated shareholdings and long-term shareholder commitment.¹⁰ Here, incentives and conflicts change, as concentration of control (possibly intensified by cross shareholdings, pyramidal ownership structures, proxy voting by financial institutions connected to the company, and voting pacts) recasts the agency problem which executive pay is designed to resolve. The agency costs which trouble the dispersed ownership company are reduced, as block-holding shareholders have both incentives and resources to monitor managers effectively. As a result, there is less need for an incentive contract to control the conflict between management and shareholder interests that is remedied by executive pay. There is also less probability of the agency problem which derives from executive pay arising. However, other concerns may emerge with regards to concentrated shareholdings regarding also executive pay.

1.2 Financial Stability

The traditional agency approach does not fully explain the problems of bankers' pay and their possible impact on financial stability. No doubt, a widespread post-crisis view holds that the failure of banks both in Europe and the US may have been at least partially caused by flawed remuneration structures, including short-term incentives that may have led bank managers to take risks which in the long run appeared to be excessive. Nonetheless, empirical research has shown that banks that failed in the crisis somehow complied with best practices as to corporate governance and executive remuneration.¹¹ A paper by Rüdiger Fahlenbrach and René Stulz analyzes a sample of 98 large banks across the world and finds "no evidence that banks with a better alignment of CEOs' interests with those of their shareholders had higher returns during the crisis."¹² The authors rather identify "some evidence that banks led by CEOs whose interests were better aligned with those of their shareholders had worse stock returns and a worse return on equity." According to their study, CEOs had substantial wealth invested in their banks, with the median CEO portfolio including stocks and options in the relevant bank worth more than eight times the value of the CEO's total compensation in 2006. Similar equity holdings should have led CEOs to focus on the long term, avoiding too much risk and excessive leverage for their banks. Instead, the study shows that a bank's stock return performance in 2007–2008 was negatively related to the dollar value of its CEO's (p. 337) holdings of shares in 2006, and that a bank's return on equity in 2008 was negatively related to its CEO's holdings in shares in 2006.

However, another stream of literature highlights possible agency costs in banks caused by inadequate remuneration structures. A paper by Lucian Bebchuk, Alma Cohen, and Holger Spamann on executive compensation at Bear Stearns and Lehman Brothers focuses on the link between substantial short-term incentives and excessive risk taking.¹³ The authors argue that the large losses on shares that the top financiers suffered when their firms melted down do not offer a full picture of their payoffs, which should include what the same executives cashed out in the 2000–2008 period and what they owned initially. In the observed timeframe, the relevant executives received large amounts of cash bonus

Executive Remuneration

compensation and “regularly took large amounts of money off the table by unloading shares and options.” Indeed, performance-based compensation paid to top executives at Bear Stearns and Lehman Brothers substantially exceeded the value of their holdings at the beginning of the period. Bebchuk et al. argue that this provides a basis for concern about the incentives of the two banks’ executives. Rather than producing a “tight alignment” of their interests with long-term shareholder value, the design of performance-based compensation provided executives of the relevant firms with substantial opportunities “to take large amounts of compensation based on short-term gains off the table and retain it even after the drastic reversal of the two companies’ fortunes.”

In order to get the full picture, the remuneration of other bank employees (such as traders) should also be taken into account, particularly that of high earners who contribute to risk taking by the firm.¹⁴ Even though precise empirical data are lacking, it is well known that many of these employees were paid short-term incentives before the crisis in amounts much greater than that of their fixed salaries. As explained by Diamond and Rajan (2009):

Given the competition for talent, traders have to be paid generously based on performance. But many of the compensation schemes paid for short-term risk-adjusted performance. This gave traders an incentive to take risks that were not recognized by the system, so they could generate income that appeared to stem from their superior abilities, even though it was in fact only a market-risk premium.¹⁵

No doubt, assuming that CEOs and other top managers were awarded the right incentive schemes—i.e., not only short-term, but also long-term incentives—the fact that other employees had mainly short-term incentives should not be a source of great concern, provided that sound risk management systems were in place and an effective oversight was exercised on risk takers by their superiors. However, as widely acknowledged in the aftermath of the crisis, this was not always the case at large banks, where risk management systems were often deficient, and CEOs and top managers frequently did not have proper controls over the financial operations. Moreover, the problems were exacerbated by the huge (p. 338) amounts promised by banks to their employees. As colorfully described by Professor Alan Blinder, traders and other employees were often offered:

the following sort of go-for-broke incentives when they place financial bets: Heads, you become richer than Croesus; tails, you get no bonus, receive instead about four times the national average salary, and may (or may not) have to look for another job . . . Faced with such skewed incentives, they place lots of big bets. If heads come up, they acquire dynastic wealth. If tails come up, OPM [other people money] absorbs almost all losses.¹⁶

1.3 Social Issues

The criticism of excessive pay also concerns non-financial firms and, across sectors, portrays a social perspective. Indeed, populist and political resentment against income disparity is on the rise, particularly in the present context of economic uncertainty, leading to a lack of confidence in the integrity and fairness of large corporations. The US was the first to officially address the social implications of high executive pay.¹⁷ In September 2013 the SEC proposed new rules on disclosure by public companies of the ratio of CEO pay to median employee pay, as required under Section 953(b) of the Dodd-Frank Act.¹⁸ This approach has been the subject of intense debate and has garnered significant media attention.¹⁹ Its supporters, including pension funds and other socially-minded investors, argue that the ratio represents material information for investors and that looking at the overall compensation framework of a single company can help rein in excessive executive pay.²⁰ In contrast, business organizations, major law firms, and other market constituencies argue that the pay ratio would provide little or no insight for investors, who are rather interested in the correlation between CEO pay and the company's financial performance, also in comparison with pay practices at other public companies.²¹

The reported ratio is expected to be very high, even for CEOs whose compensation is relatively modest. Whilst the US is attempting to deter excessive executive pay by holding boards (p. 339) accountable both to shareholders and society through mandated disclosure, some European countries target similar goals through different measures.²² For example, France uses taxation as a means to rebalance pay differences between corporate executives (and high earners in general) and other employees, through a 75 percent “super tax” payable by employers on compensation over €1m.²³ In Germany, changes to the Corporate Governance Code were effected requiring supervisory boards (1) to set maximum payout levels on the total and individual pay of executive board members and (2) to consider the relationship between executive board members' remuneration and that of staff generally.²⁴ In Switzerland, following a public referendum against excessive salaries in March 2013 (the “fat cat initiative”), the voters' majority called for new constitutional rules to control executive pay and improve the corporate governance of listed companies.²⁵ As the referendum's outcome was not directly enforceable, the Federal Council adopted an interim ordinance,²⁶ which intends to improve the corporate governance of Swiss listed companies and empowers shareholders to express a binding vote on executive compensation. The new ordinance is particularly striking as it includes penal provisions for breaches of its rules and for executives being granted or accepting excessive compensation.

2 Policy Issues

2.1 Design Problems

Performance pay may suffer from a number of inherent design defects which damage the performance link at the heart of the incentive contract's effectiveness as an interest-alignment device, and which provoke conflicts between management and shareholders or, potentially, between management/controlling shareholders and minority shareholders (according to the particular shareholder/management profile in blockholding companies). These defects heighten the need for an effective governance and disclosure matrix for pay setting if the alignment process is to work. We highlight three main design challenges: proxies for firm performance, stock options, and long-term pay.²⁷

(p. 340) 2.1.1 Proxies for Firm Performance

Share price is ordinarily the best available proxy for shareholder wealth and reflects overall corporate performance more effectively than business-line linked, target-specific bonuses. But the danger arises when generating incentives to inflate earnings and manage disclosure to generate short-term share-price increases. Equity-based compensation also risks over-compensation of executives who preside over a period of market growth and under-compensation of those caught in a period of overall poor market performance. It is, however, difficult to construct a better alternative for shareholder wealth, given that it does reflect the market's perception of the company's current and future cash flows, and so its perceptions of management performance and investment opportunities.²⁸ The risk of management inflating the share price, however, demands that the governance matrix, which monitors management and supports pay setting, whether it be independent directors, institutional investors, or controlling shareholders, is robust and establishes risk-adjustment mechanisms in the remuneration policy.

2.1.2 Share Options

Share options pose a second major design problem. They can create potentially powerful incentives by linking pay to shareholder returns expressed via the share price. They can incentivize executives to take efficient but personally stressful decisions and promote greater efforts to increase the global value of the company and the share price.²⁹ They have an attractively asymmetrical pay structure in that they reward success but do not appear to penalize failure: Executives are not likely to equate the failure to make a gain with an actual loss. Options can also act as a powerful inducement to attract talent and can incentivize executives to stay. At the same time, share options also display a number of inherent inefficiencies and possible risks,³⁰ such as the following:

1 Relative performance. Fixed price options, where vesting is independent of performance, can deliver very large gains for executives whenever the market is rising, even if the company is under-performing its competitors.³¹ This problem can be avoided by linking the option's exercise price to a market or peer-group index such that executives are rewarded only when they outperform the competition, or linking exercise to the achievement of performance conditions.

(p. 341) **2** Repricing. The capacity for share options to be re-priced when the share price falls on poor corporate performance (rather than on sector-wide movements)

further weakens the incentive justification and damages the alignment mechanism.³² This was a common practice in the US prior to changes in accounting regulations.³³

3 Impact on dividend policy. If share options appropriately align shareholder and management incentives, management should be incentivized to allocate cash flow to shareholders in the form of dividends. Share options can distort this alignment as the value of options drops with dividend payment, incentivizing management to reduce dividends.³⁴

4 Dilution. Share options carry the risk of dilution and, therefore, of a reduction in earnings per share and entrenchment of management voting power.³⁵ Dilution also raises difficulties in blockholding companies, where controllers may see their dominant position weakened.

Option grants can, however, be structured to avoid incentive alignment weaknesses. The share option problem then becomes one of how to ensure good supporting governance in, and disclosure of, pay setting, rather than a difficulty with the option as a tool of executive pay per se. Design problems are in the hands of the board, as pay setter, and its allied monitoring structures. If the board strategy is aligned with shareholder interests, structure problems can be mitigated. Although the connection between bad governance and suboptimal pay structures is not entirely clear,³⁶ the link between optimal shareholder interest alignment and good governance drives regulatory responses to remuneration.

2.1.3 Long-Term Pay

One of the concerns in the discussion regarding executive pay design has been that it is insufficiently focused on the long term, leading to reckless, short-term decision-making by executives and to financial bubbles.³⁷ However, combating short-termism appears to be high on the post-crisis agenda, as shown by the Kay Review in the UK, suggesting that “companies should structure directors’ remuneration to relate incentives to sustainable long-term business performance. Long-term performance incentives should be provided (p. 342) only in the form of company shares to be held at least until after the executive has retired from the business.”³⁸ In addition, corporate governance scholars suggest that executives should be encouraged to focus on the long term by holding a large fraction of their equity after it vests. Bhagat and Romano, in particular, recommend that incentive compensation should consist only of restricted stock and restricted stock options—restricted in the sense that the executive cannot sell the shares or exercise the options for two to four years after his or her last day in office. They contend that such an incentive compensation package will focus management’s attention on the long-run and discourage investment in high-risk, value-destroying projects.³⁹ Bebchuk and Fried also focus on equity-based compensation as a way for tying incentives to long-term results.⁴⁰ They particularly analyze the optimal design of limitations on unwinding, arguing that an executive receiving an equity-based grant should not be free to unwind the received equity incentives for a specified period of time after vesting, after which she should be permitted to unwind the equity only gradually. Moreover, they advocate that firms adopt arrangements designed to ensure that executives cannot easily evade both the prescriptions that require executives to hold equity for the long term and those that prevent gaming.

2.2 Governance Mechanisms

The effectiveness of the incentive contract largely depends on the management of agency problems between the board and shareholders and on adequate monitoring by, inter alia, independent directors and, ultimately, shareholders.

2.2.1 Boards

A board may become passive or captured by management, and hence poorly incentivized to bargain for optimal incentive pay in shareholder interests. The addition of independent directors to the board (or board remuneration committee) may provide a solution and is a dominant theme of regulatory responses to remuneration, albeit adjusted, in blockholding systems, to reflect the influence of controlling shareholders.⁴¹ Independent, well-resourced, informed, and competent directors should be able to withstand any overbearing influence of senior management and be more likely to judge performance in the shareholders' interests and with respect to the company's performance.⁴²

(p. 343) There are, however, certain impediments to optimizing the presence of independent directors. Independent directors in given circumstances may be reluctant to disturb the status quo, or may be incentivized to set pay in a manner beneficial to them where they are serving executive directors. They may lack expertise on pay or have insufficient time to become expert. Disclosure flows to independent directors on corporate performance may be unreliable. Reputational factors, which may result in an independent director who is regarded as "tough on pay" being blacklisted from other boards may arise. The empirical evidence on the effectiveness of independent directors is equivocal.⁴³ It has also been suggested that independent directors have not always controlled executive pay but rather presided over its explosion.⁴⁴

One way out of this impasse is to impose rigorous controls on the independence of nominally independent directors, which can only be achieved to a limited degree in blockholding systems. Composed primarily of independent directors and exercising pay-setting functions delegated from the board, the remuneration committee can act as an objective control on the pay-setting process. However, the remuneration committee may be particularly ineffectual in blockholding companies playing, in effect, a fictional role as pay is set by the controlling shareholders directly, although it has a potentially important role in minority shareholder protection.

While external remuneration consultants provide expertise in the complex area of pay design and improve disclosure flows to the remuneration committee, they are also vulnerable to capture by the board and may exacerbate problems by acting as a camouflage mechanism to legitimize suboptimal pay decisions, unless selected by and accountable to the remuneration committee.⁴⁵

2.2.2 Shareholders

The effectiveness of back-stop shareholder monitoring of the incentive contract and the pay-setting process lies at the core of the pay-setting problem in the dispersed-ownership

context. As effective monitors, whether via direct shareholder voice mechanisms, such as votes on pay, or via indirect lobbying, shareholders suffer from the collective action problem and from lack of information. Collective action problems are exacerbated in the case of executive pay as shareholders are unlikely to see substantial individual gains from a potential reduction in executive pay, and may suffer if management incentives are damaged. An examination of the optimality of pay decisions requires careful case-by-case analysis of disclosure which, even where it is made available, can be difficult for shareholders. Institutional investors are, albeit controversially, often regarded as potentially strong corporate monitors. The extent to which institutional investors can bear on the pay process is, however, doubtful.⁴⁶

(p. 344) The collective action problem arises and is aggravated by the need for institutions to have diversified holdings,⁴⁷ which dilutes the ability of institutional investors to focus on company-specific issues. Institutions may not communicate effectively as a group and so fail to influence the board. Agency problems can also arise within an institutional investor, where, for example, an investor's corporate governance team faces pressure from other internal groups which provide services to a company's management.⁴⁸ Institutional investors may also be prone to short-termism and ill-equipped to undertake successful long-term monitoring of executive pay strategies. However, there is some US evidence that large shareholders (5 percent and over) can act as an effective governance mechanism with respect to remuneration.⁴⁹ Law, and particularly mandatory disclosure, appears to matter in this context, as the changes to UK company law in 2002 requiring a shareholder vote on the Director's Remuneration Report, appeared to galvanize institutional investors into action, as we argue below.

However, a significant development in the last few years has been the rise of shareholder engagement. This mainly depends on the re-concentration of ownership in the hands of institutional investors and on the willingness of many of these to behave as active investors.⁵⁰ While there are also other issues to debate (such as corporate social responsibility), remuneration stands out in particular as a topic on which investors have significant interest.⁵¹ Generally, companies engage with shareholders on executive compensation well ahead of the annual general meeting. While initially engagement occurred primarily in cases in which a "no" recommendation had been issued by proxy advisors on a company's pay policy or other negative feedback had come from significant shareholders, it is accepted today that dialogue with shareholders should take place in all circumstances.⁵² Indeed, not only pay practices but also corporate performance drive proxy advisors' recommendations and voting by institutional investors.⁵³ Therefore, a negative recommendation or vote could be issued simply on the basis of a perceived disconnect between between pay and corporate performance or shareholder return, regardless of how carefully remuneration structures comply with best practices.

(p. 345) 2.3 Disclosure

Disclosure may provide the least costly way to manage the range of potential agency costs by ensuring that shareholders have sufficient information on remuneration as well as on any potential conflicts in the remuneration-setting process. It is also a more limited form of intervention in governance, which would allow flexibility and increase transparency in remuneration-setting in dispersed and blockholding ownership companies.⁵⁴

Disclosure requirements prompt the board to justify pay choices and the pay-setting process, and can also enhance the accountability and visibility of the remuneration committee. They can also sharpen shareholder monitoring, particularly by inducing institutional shareholders to play a more active role. Disclosure of pay lowers the cost of monitoring by raising the reputation of institutional investor monitors by signalling or publicizing the results of their active approach and generating greater deterrence effects. It also facilitates communication between institutional investors and with company management.

While disclosure is traditionally associated with minimal regulatory intervention, there are costs involved. The benefits of potentially greater shareholder activism must be weighed against popular and political reaction to enhanced disclosure of executive pay. With enhanced disclosure, pay questions are played out in the media, influenced by labour, captured by private interests (such as those of political activists and union personnel), and politically infused. Remuneration committees may be vulnerable to responding to political and workforce pressures and adopting suboptimal remuneration structures which are not sufficiently sensitive to performance.⁵⁵ Disclosure which focuses on headline pay levels invites popular hostility and does not assist shareholders in assessing remuneration structures, and the pay-setting process is destabilizing.⁵⁶ By contrast, disclosure which makes it easier to assess the pay-performance relation/incentive structure and the effectiveness of governance can remedy some of the structural and process weaknesses of executive remuneration. Among other possible drawbacks of excessive disclosure, there is the risk that disclosure may result in an increase in pay due to a ratcheting effect.

2.4 Mandatory Pay Structure

In a previous paper we argued that the case for regulating the structure of bankers' pay appears to be rather weak.⁵⁷ First, it is far from proven that pay structures generally contributed to excessive risk taking before the recent crisis. According to some of the studies cited above, corporate governance and compensation structures of CEOs at banks that failed were not necessarily flawed. Second, even assuming that compensation structures were flawed—in particular, those of traders and other middle-managers taking excessive risks for banks—the need for their regulation would not be automatically established. In fact, excessive risk taking could be curbed directly through prudential regulation of banking activities, rather than by modelling the incentives of bank employees, also given that regulators (p. 346) may not be professionally qualified for designing pay structure.⁵⁸ Thirdly, mandating pay structures hampers the flexibility of compensation arrangements,

which need tailoring to individual firms and managers, also in light of the latter's portfolios of their own bank securities. Moreover, in this context, bank boards may lose one of their key governance functions, finding it more difficult to align executives' incentives to corporate strategy and risk profile. This may also create problems in keeping and attracting managerial talent, particularly from countries that adopt a more liberal stance or from firms that are not subject to regulatory constraints (such as hedge funds or private equities).

Nonetheless, competent authorities should supervise bankers' compensation from the perspective of bank safety and soundness. Rather than designing compensation structures *ex ante*, which is a matter for institutions and their boards, they should analyze the impact of actual remuneration structures on risk taking and conduct their surveillance activities accordingly, for instance by imposing higher capital requirements to institutions adopting "aggressive" or inappropriate remuneration mechanisms. Moreover, supervisors should check bank compliance with compensation governance requirements and with the disclosure requirements concerning remuneration policies. Rather than interfering with pay structures, this type of regulation aims to ensure that organizational structures and procedures are in place for the setting of pay in compliance with safety and soundness requirements.

3 Regulating Pay Governance and Disclosure

3.1 EU Law

Disclosure, shareholder voice, and the independent director all appear in the EU's strategy for executive pay. The EU's initial approach, set out in the 2004 and 2005 Recommendations, was based on pay governance.⁵⁹ A number of directives adopted under the Financial Services Action Plan also form part of the EU's pay matrix by improving disclosure, both generally and with respect to pay, and by addressing insider dealing risks.⁶⁰

3.1.1 The 2004-2005 Recommendations

To achieve its objectives, the Commission employed a non-binding Recommendation, avoiding a "one-size-fits-all" solution at the firm and Member State levels. The 2004 Recommendation was the EU's first attempt to address best practice with respect to pay governance. It uses disclosure and shareholder voice mechanisms to support efficient pay and recommends: disclosure of company pay policy, either in a distinct remuneration report or in the annual report; detailed disclosure concerning individual directors' pay; a (p. 347) shareholders' vote on company pay policy, which can be either binding or advisory; and a priori approval of share-based schemes. The Recommendation does not engage with pay design, although support for performance-based pay is implicit across the Recommendation.

Executive Remuneration

The role of the board in pay setting is addressed by the parallel 2005 Recommendation on the role of non-executive directors, which highlights remuneration as an area in which the “potential for conflict of interest is particularly high” and recommends that boards should have an “appropriate balance” of executive and non-executive directors such that no individual or group of individuals can dominate decision-making and there is a “sufficient” number of “independent” non-executive directors; board committees should be created for issues particularly vulnerable to conflict of interest (including remuneration); and the remuneration committee (its functions are delineated in some detail) should be composed exclusively of non-executive or supervisory directors, a majority of whom should be independent. The Recommendation also provides guidelines on the notion of “independence.”

Member States were free to adopt the Recommendations (implementation was not mandatory) either through legislation or, as has been the dominant method, through soft law, typically based on the local Corporate Governance Code and, for many Member States though not all, on the related “comply or explain” principle.⁶¹ Poor compliance need not necessarily follow from soft law implementation; companies that voluntarily adopt more rigorous corporate governance structures can be rewarded by a positive effect on firm value.⁶²

3.1.2 The 2009 Recommendation

Executive pay in non-financial firms was pulled into the Commission’s wider financial crisis reform agenda with the adoption of a 2009 Recommendation on Directors’ Remuneration, which had to be implemented by the Member States by the end of 2009. Through it the Commission moved closer to the problematic, but politically appealing, design sphere. Noting that remuneration structures have become increasingly complex, too focused on the short term and leading, in some cases, to “excessive” remuneration not justified by performance,⁶³ the Commission adopted a series of voluntary principles concerning the structure of remuneration. The 2009 Recommendation focuses in particular on the pay/performance link, on long-term sustainability and on restricting “excessive” variable pay.

(p. 348) The Recommendation addresses remuneration policy disclosure, suggesting that the remuneration policy be clear and easily understandable, that an explanation be provided concerning how performance criteria relate to firms’ long-term interests and with respect to whether those criteria were fulfilled, and that “sufficient information” be provided concerning termination payments, vesting, and other restrictions, and concerning the peer groups on which the remuneration policy is based. The Recommendation touches upon the remuneration committee, buttressing its independence and suggesting that one member have knowledge and experience concerning remuneration. The Recommendation also considers design issues, suggesting that performance criteria promote long-term sustainability and include relevant non-financial criteria, that variable pay be withheld when performance criteria are not met, and that arrangements be made to claw back variable pay awarded on the basis of data which proves to be misstated. Moreover,

Executive Remuneration

termination payments should not exceed a fixed amount and, in general, not be higher than two years of non-variable pay.

However, the Recommendation goes further and appears imbued with a concern to reduce pay levels. The suggestion that undefined “limits” should be placed on variable pay is particularly troubling, given the benefits of incentive alignment, and represents an undue incursion into corporate autonomy.⁶⁴ The Recommendation similarly suggests that remuneration committees should ensure that executive director remuneration is “proportionate” to that of other executive directors and other staff members. While efforts have been made by some Member States to address proportionality concerns, this is not widespread and there is little evidence that intervention in support of “reasonable” pay works.⁶⁵

The Recommendation’s suggestions with respect to the deferral of pay are similarly intrusive. It suggests: that the “major part” of variable pay should be deferred for a “minimum period” of time; that restrictions on share-based pay and that the vesting of shares and the exercise of share options be subject to predetermined and measurable performance criteria; that shares should not vest for at least three years after their award and that share options or similar rights should not be exercisable for three years. The Commission has also suggested that a certain number of shares be retained by directors until the end of their mandate. Performance share plans, particularly linked with director shareholding periods, have proved to be a very useful mechanism for aligning director interests more effectively with long-term performance and are already a feature of several European Codes.⁶⁶

3.1.3 Recent Proposals

In 2014 the European Commission proposed a revision of the Shareholder Rights Directive (SRD), including measures to improve the corporate governance of listed companies in an effort to increase the transparency and long-term sustainability of these companies. The new (p. 349) Directive, which was adopted in 2017, aims to encourage shareholders to engage more with the companies they invest in and to take a longer-term perspective on their investments.⁶⁷

The amended SRD strengthens shareholder rights to exercise proper control over management, including a binding “say on pay.” This comes as a reaction to the insufficient link between management pay and performance, which has determined harmful short-term tendencies. In addition, the new directive enhances transparency on remuneration policy and the actual remuneration of individual directors, and improves shareholder oversight of directors’ remuneration. Each listed company in the EU will be required to put its remuneration policy to a binding shareholder vote at the general meeting. However, Member States may provide for the vote on remuneration policy to be advisory. Shareholders will also vote on a company’s remuneration report, which describes how the remuneration policy has been applied in the last year, but their vote would be advisory only. Where the shareholders vote against the remuneration report, boards will need to explain

Executive Remuneration

in their next remuneration report how the vote of the shareholders has been taken in account.

Companies will have to provide a clear, understandable remuneration policy, in line with the business strategy, long-term interests, and sustainability of the firm. The policy will set clear criteria and explanations for the award of fixed and variable remuneration; explain how the pay and employment conditions of employees of the company were taken into account when establishing the remuneration policy; indicate the main terms of the contracts of directors and the decision-making process leading to their determination. The remuneration report also will need to be clear and understandable, including information on the total remuneration split out by component; the relative proportion of fixed and variable remuneration; how the total remuneration complies with the adopted remuneration policy; and how the performance criteria were applied. Once the shareholders have approved the remuneration policy, a company will not be permitted to pay remuneration to directors other than in accordance with that policy.

The Directive does not regulate the level of remuneration and leaves decisions on this to companies and their shareholders. The transparency and voting requirements are similar to those already in place for UK quoted companies. However, there are no detailed requirements for disclosure. Other Commission proposals also have an impact on the approach to remuneration policies by the companies. Notably, the Recommendation on the quality of corporate governance reporting (“comply or explain” principle) provides guidance to listed companies, investors, and other interested parties so as to improve the overall quality of corporate governance statements.⁶⁸

3.2 Comparative Regulation

The EU regulatory framework based on non-binding recommendations proved unsuccessful in embedding good practices with respect to remuneration governance across Europe’s largest companies.⁶⁹ Significant differences continued to persist across Member States’ regulatory regimes and in pay governance practices.⁷⁰ Institutional investors were not persuasive in demanding better practices either, which may reflect the difficulties they faced in assessing industry-wide practices given generally poor disclosure.

3.2.1 From Soft to Mandatory Regulation

Either anticipating or following the Commission’s proposals, Belgium, Portugal, Spain, Italy, and the UK were the first jurisdictions to consider moving remuneration governance and disclosure into law. Belgium adopted a law aimed primarily at reinforcing boards in listed companies,⁷¹ which lifted a number of the national Corporate Governance Code provisions to the legislative level. As a result, the creation of a remuneration committee became mandatory and the publication of a corporate governance statement including a remuneration report was required. The Portuguese market regulator issued a 2010 Regulation on Corporate Governance, which provides for mandatory description of the remuneration policy and disclosure of individual director remuneration.⁷² The regulation also

requires firms to report on the composition of the remuneration committee and the fact that at least one of its members has knowledge and experience in remuneration policy issues. In Spain, the Law on Sustainable Economy, in effect since March 2011, delegated the Ministry of Economy and Finance and the market supervisor (CNMV) to determine the structure and content of companies' remuneration report.⁷³ The CNMV issued a regulation requiring disclosure of remuneration in a standard annual report format.⁷⁴ Similarly, in 2011 in Italy the Securities Commission (CONSOB) adopted new rules on transparency of remuneration,⁷⁵ requiring uniform and detailed disclosure of compensation practices and setting standards characteristics to be included in the remuneration report. The regulation also makes provisions for shareholder vote on both the previous year's policy and the proposed future policy.

The UK has traditionally had the most extensive set of governance requirements in force with respect to executive compensation in Europe. Listed companies have been required to prepare a Directors' Remuneration Report since 2002 and submit it to the advisory (p. 351) vote of shareholders.⁷⁶ Despite similar regulatory measures, during the recent crisis, UK companies—banks in particular—raised serious concerns for what many observers considered as “excessive executive pay.”⁷⁷ This led the government in 2011 and 2012 to announce a reform directed to curb executive pay through greater remuneration transparency, more shareholder powers, and more diverse board and remuneration committees.⁷⁸

3.2.2 Say on Pay

Pressure over dealing with “inappropriate” executive compensation, be it understood as either “excessive” or misaligned with shareholder value, has led to initiatives giving investors greater influence over executive pay through a vote on companies' remuneration policies and packages, i.e., through the “say-on-pay” process.

In the US, votes on pay are mandatory under the 2010 Dodd-Frank Wall Street Reform and Consumer Protection Act, but the voting result is not binding. Most European jurisdictions, in their governance codes, introduced an advisory vote on the remuneration policy and a binding vote on equity-based incentive schemes. Few regulators went further, introducing binding votes on pay policy, in the hope that such votes would determine corporations to be more conservative with respect to the total amount paid to their executives and that this would be more driven by corporate performance. The Netherlands, Sweden, and Norway, however, had already required binding say on pay before the crisis.⁷⁹

Post-crisis reforms not only regard the nature of the vote (binding or advisory), but also the possible shift of voting requirements from best practice principles to legislation. Spain and Italy were among the first countries to introduce a similar rule in their corporate laws, while France has extensively debated the issue at government level.⁸⁰ For a long time, in the UK the shareholder advisory vote on executive compensation has been non-binding on companies and their boards. Since spring 2012, however, the government moved toward a binding regime through a range of proposals, including: an annual binding vote on future remuneration policy; an annual advisory vote on how the company's

Executive Remuneration

pay policy was implemented in the previous year; and a binding vote on “exit payments” of more than one year’s salary.

The effects of say on pay started to be felt soon after the launch of these reforms. The case of UK companies failing to receive majority support for their pay policies in 2011 could be considered representative for the history of “say on pay.”⁸¹ In the US, by comparison, the (p. 352) impact of the recent reform introducing say on pay may be seen as modest. Amongst the Russell 3000 companies with say-on-pay votes occurring between September 2011 and June 2012, 2.4 percent failed to achieve shareholder support levels of 50 percent or higher. These results point to a slight rise in say-on-pay failure rates compared to 2011, when 1.6 percent of Russell 3000 companies failed over the same timeframe.⁸²

No doubt, “say-on-pay” has increased the power of proxy advisory firms, especially the two largest, Institutional Shareholder Services (ISS) and Glass Lewis and Co. Similar to rating agencies prior to the financial crisis, these firms have implicitly been granted by regulators significant power as to the shaping of corporate governance policies in US public companies and their influence has spread over to Europe and Asia as well.⁸³ Research has consistently shown a strong correlation between recommendations of proxy advisors and proxy voting by institutional shareholders.⁸⁴ The influence of these firms is enhanced by the fact that investors may find it less costly to pay a fee for the advisory firms’ reports and rely on their recommendations especially in highly technical, if not arcane, matters like incentives structure for top executives and the link between incentives and corporate performance. However, large institutional investors such as Fidelity, Vanguard, BlackRock, and T. Rowe Price still assign analysts to study executive compensation at their portfolio companies, develop internal policies, and make voting determinations.

Studies show that, historically, a negative recommendation from ISS will, on average, influence between 13.6 percent and 20.6 percent of votes cast on management-sponsored proposals.⁸⁵ Companies that receive a negative recommendation from ISS almost always fail their say-on-pay vote, whereas no company that receives a positive ISS recommendation fails its say-on-pay vote. The policies that advisory firms prefer also influence decisions by the non-executive directors of public companies. However, there is evidence that such influence may not be for the better in terms of shareholder value enhancement. For example, research found that, when public companies implement certain principles defined by proxy advisers as “best practices” (in this case with regard to stock option exchange programs), gains in shareholder value are on average 50 percent to 100 percent less than at other firms.⁸⁶ Conflicts of interest (p. 353) of proxy advisory firms have also become an issue, so that regulators from Europe and the US have proposed to regulate these firms; and the policy debate continues.⁸⁷

As a result of the ambiguous benefits of proxy advisors and of increased shareholder activism, several investors have reduced their reliance on advisors’ recommendations. In 2013 Blackrock (the world’s largest asset manager) announced that they were no longer following ISS recommendations and released their comprehensive voting policies for each

Executive Remuneration

main jurisdiction.⁸⁸ These policies sometimes go against practices which, in a given jurisdiction, are generally accepted, such as performance based remuneration for non-executive directors in German companies; poor disclosure of remuneration policies in Greek companies; excessive severance payments in Italian companies. They also emphasize the importance of aligning the performance metrics of variable pay to the execution of strategy at UK companies, where long-term compensation plans are known to be rather complex.

Several investors and representative associations have put forward principles with regard to remuneration, setting out their own views on the role of shareholders and directors in relation to remuneration and the manner in which remuneration should be determined and structured. For example, the National Association of Pension Funds (NAPF) in the UK updated its remuneration guidelines and published a “Remuneration Principles” document. The Guidelines track the Principles of the UK Corporate Governance Code, and give guidance on how each principle should be applied and what investors might look for in particular, followed by a voting recommendation. The revisions of the NAPF’s remuneration guidelines include a new list of practices that are likely to cause investor concern and may even trigger a vote against Directors’ Remuneration Reports and/or new share plans.⁸⁹ Investors often act in concert when addressing governance issues of investee companies, with the aim of building a meaningful voice, as in the case of the GC100 and Investor Group (Group formed by GC100 representing FTSE100 companies and the Corporate Governance Forum, a network of leading institutional investors) who issued their own Directors’ Remuneration Reporting Guidance.⁹⁰ The guidelines substantially change the requirements for the contents of the directors’ remuneration report and include some significant new disclosures, expecting companies not to adopt a “boilerplate” approach and be innovative in order to meet their specific needs.

Other large investors—including Fidelity, Legal & General, and Vanguard—went as far as sending alerts to the CEOs of large companies, communicating changes in their voting policy on remuneration and conditioning a positive vote on specific provisions, which largely go beyond the current regulatory and governance requirements, and trying to ensure a better alignment between executive compensation and the longer-term performance of the company. In 2013 Fidelity sent a letter to Europe’s 350 largest companies requiring them (and anticipating otherwise a negative vote) to lengthen the required term of the LTIP by (p. 354) distinguishing between “vesting periods” and “holding periods” of the incentive, requiring a holding period of minimum five years and a minimum three-year vesting period. Legal & General sent a letter to FTSE 250 companies calling them to provide certain enhancements in their remuneration disclosure, warning them in regard to unclear explanations on the performance measures behind incentive schemes; making significant “golden hello” payments; providing matching schemes to new recruits; not considering the experience of the individual when recruiting external candidates. L&G specifically anticipates voting against remuneration in companies that do not provide sufficient information on performance measures, unless full explanation on the lack of transparency is provided. In anticipation of the 2014 proxy season, Vanguard sent letters to approximately US 350 companies to proactively engage with them on governance issues.

The letters are tailored to the individual companies and identify governance practices at the companies that Vanguard believes are not in line with what the asset manager views as best practices.

Clearly, we have entered into a new chapter of executive pay governance and the ways in which companies respond to shareholder engagement have evolved significantly: “[T]he process has become less defensive and more proactive.”⁹¹

3.3 Some Empirical Data

In this section, we summarize the outcomes of our previous paper on firms’ remuneration practices before and after the crisis, with particular emphasis on the governance process and the quality of disclosure.⁹² Our original paper compared the data collected for the years 2007 and 2010, thus providing evidence on the evolution of pay practices in response to the recent financial crisis and to the remuneration reforms adopted by European policy makers.

3.3.1 Statistics on Governance

Following the 2005 Recommendation, most EU corporate governance codes endorsed the setting up of a remuneration committee with a majority of independent directors. Only the German Corporate Governance Code did not specifically recommend the formation of a remuneration committee. Moreover, the 2009 German Act on the Appropriateness of Management Board Remuneration marked a departure from European corporate law and practice by requiring that the full supervisory board decide on individual management board pay (including salary and incentive-based pay).⁹³ Reflecting this regulatory framework, our analysis found a widespread recourse to the remuneration committee, both before and after the crises, in all countries except Germany, where only about half of the companies in our sample established this committee, with a slight increase in 2010. Again with the exception of German firms, the independence requirement (i.e., the committee should only include non-executive members, with a majority of independent directors) was fulfilled by (p. 355) most of the companies having a remuneration committee (about 80 percent of the sample, with a small increase from 2007). However, several compensation committees still did not fulfil the composition criteria established by either best practice or regulation.

Requirements concerning the presence and role of compensation consultants in continental European countries are weak compared to the UK.⁹⁴ In the UK, the Directors’ Remuneration Report Regulations of 2002 require that firms disclose consultant information. Although the Commission supports the presence and independence of remuneration consultants in its 2004 and 2009 Recommendations, strong disclosure requirements are not found in continental Europe, where the relevant provisions are rather patchy. Our analysis showed that all UK companies used a third-party consultant to advise them on compensation levels and design since before the crisis. Furthermore, all UK firms in our sample make a statement regarding their independence, i.e., non-engagement in other consulting services for the management. In the other jurisdictions, the presence of an exter-

nal consultant is usually not disclosed. Similar disclosure gaps bar an accurate review of the remuneration governance process.

3.3.2 Statistics on Disclosure

Current disclosure criteria require remuneration statements to be clear and easily understandable, to provide detail on the alignment between pay and performance, and to be transparent about the individual directors' compensation packages. However, significant differences existed amongst national jurisdictions as to pay disclosure before the financial crisis. In our paper, we found that disclosure of remuneration generally improved post-crisis in all jurisdictions, even though the levels of compliance vary greatly across countries. We showed that compliance with the remuneration statement requirement was quite strong across jurisdictions before the crisis and improved post-crisis at the few non-compliant firms. All of the remaining variables for the remuneration policy showed a significant increase in compliance for the whole sample, with the exception of performance criteria for bonuses.

As to individual disclosure, increased compliance (even though not statistically significant) was observed for the two variables capturing disclosure of the annual compensation components for executive and non-executive directors. On average, disclosure of individual share schemes is lower, although some countries (in particular the UK, Italy, and France) show significant improvements. However, the jurisdictions where remuneration disclosure and governance standards were lower prior to the crisis (Greece and Portugal in particular) did not show substantial improvements post-crisis.

These findings show that the firms' approach to compliance is strongly dependent on their home country's approach to regulation and governance culture. Firms generally tend to reflect the way in which EU regulations are implemented at the national level—either through mandatory legislative requirements or best practice guidelines—and the level of detail in the formulation of the relevant standards.

(p. 356) 4 Regulating Pay Structure

4.1 Long-Term Remuneration

Investor initiatives and political developments continue to exert pressure over executive compensation, especially on the design and structure of long-term incentives.⁹⁵ The public debate and regulatory initiatives have resulted in heightened scrutiny of executive pay by the shareholders and shareholder advisory groups, particularly focusing on the relationship between executive pay and firm performance. A related theme for investors is that a greater portion of incentive pay should relate to long-term performance, as it is widely believed that anything less than three-year performance periods would carry the risk of significant compensation being paid for performance that is not truly sustainable.⁹⁶

Executive Remuneration

The combination of these forces has accelerated the adoption of performance-linked long-term incentive programs. A decade ago, plain-vanilla stock options filled up the compensation packages of executives, while terms such as restricted stock, full-value awards, or performance shares were almost unheard of.⁹⁷ Research has shown that a majority of individuals view stock options as a “gift.”⁹⁸ As a result, they significantly discount the value of stock options and view them as something that is a “nice to have” rather than an essential element of their compensation plan. Today, plain-vanilla options are on the decline, while restricted stock and performance shares are a regular part of the long-term incentive lexicon, especially in public companies.⁹⁹ In a pay-for-performance world, equity compensation is increasingly becoming a reward for achievement of success. The problem with paying for upside potential is not only reflected in cash bonuses but also in short-term gains through stock options.¹⁰⁰ Initial values mean far less than what is finally delivered (or not) to the employee. Performance criteria add another layer of complexity to a compensation program, but performance may also add the secret ingredient of direct alignment that allows for a compelling discussion between the company and its stakeholders on current and potential value.

The key condition to any reward is making sure that the linkage between achievement and payout is reasonable and comprehensible. Investors pay more attention to changes in (p. 357) the proportion of shares issued and shares conveyed to employees; they scrutinize time-based stock plans (i.e., restricted stock, time-vested stock) and performance share plans with a lower than three-year performance period.¹⁰¹ They value stock ownership and retention requirements, which are considered to reinforce executives’ “shareholder mindset.” Similar concerns have led to legal changes and governance codes reviews in major markets over the last few years, either requiring or recommending deferral of annual incentives and/or longer vesting periods for long-term incentives for senior executives in all listed companies (not just financial services). As we move into the era of “say-on-pay,” performance hurdles are also being added to these awards.¹⁰²

As a result, companies are working to balance their compensation philosophy and executive pay programs have come under closer scrutiny. Equity compensation has become more volatile and complex during the past two decades, requiring more planning, expertise, and pragmatism.¹⁰³ The growing focus on aligning pay with long-term performance has driven many companies to grant performance-vested long-term incentives,¹⁰⁴ apply not lower than three-year performance measurement periods, align plans with two or more performance measures, make executive directors maintain a substantial ownership interest for the duration of their employment, and establish stock ownership plans for directors. Several companies are moving away from full vesting and toward pro-rata vesting of equity, toward more disciplined target setting and greater consideration of strategic, non-financial performance measures in annual and long-term incentives.¹⁰⁵

4.2 FSB Principles

Compensation structures at banks are considered by the FSB principles along lines that reflect, to a large extent, general best practices already adopted before the crisis.¹⁰⁶ However, pre-crisis practices mainly emphasized the alignment of managers' incentives with shareholder wealth maximization. The principles break new grounds by requiring financial institutions to align compensation with prudent risk taking. Accordingly, compensation should be adjusted for all types of risk, including those considered difficult to measure, such as liquidity risk, reputation risk, and capital cost. Compensation outcomes should be symmetric with risk outcomes. Deferral of compensation, traditionally used as a retention mechanism (on the basis that a "bad leaver" would generally lose unpaid deferrals), should (p. 358) make compensation payout schedules sensitive to the time horizon of risks. In particular, a substantial portion of variable compensation (i.e., 40–60 percent) should be payable under deferral arrangements over a period of not less than three years, provided that this period is correctly aligned with the nature of the business, its risks, and the activities of the employee in question. Furthermore, a substantial portion (i.e., more than 50 percent) of variable compensation should be awarded in shares or share-linked instruments, as long as the same create incentives aligned with long-term value creation and the time horizons of risk. In any event, awards in shares or share-linked instruments should be subject to an appropriate retention policy.

The principles also tackle concerns relative to bonuses, which famously emerged during the recent crisis. They require "malus" and "clawback" mechanisms, which enable boards to reduce or reclaim bonuses paid on the basis of results that are unrepresentative of the company's performance over the long term or later prove to have been misstated. They consider "guaranteed" bonuses (i.e., contracts guaranteeing variable pay for several years) as conflicting with sound risk management and the pay-for-performance principle. Severance packages need to be related to performance achieved over time and designed in a way that does not reward failure.

The FSB principles represent a political compromise between the various interests at stake in the area of compensation, incorporating traditional criteria and adapting them to new circumstances by focusing on long-term incentives, in order to counter the role allegedly played in the crisis by short-term incentives; tracking already existing practices, but extending the same to a greater number of bank employees; and widening the powers of supervisors by explicitly making pay at financial institutions subject to prudential supervision. Similar to other international financial standards, the principles remain at a sufficient level of generality and allow for flexibility in implementation; in several instances, financial institutions are permitted to depart from a given principle or standard, if application of the same would lead to unsound consequences.

4.3 Dodd-Frank

The FSB principles were implemented along different models.¹⁰⁷ Some jurisdictions follow a primarily supervisory approach to implementation, involving principles and guid-

Executive Remuneration

ance and the associated supervisory reviews. In other jurisdictions the model includes a mix of regulation and supervisory oversight, with new regulations often supported by supervisory guidance that illustrates how the rules can be met. The US initially followed the supervisory model of implementation. However, with the enactment of the Dodd-Frank Wall Street Reform and Consumer Protection Act on July 21, 2010,¹⁰⁸ a mixed model of implementation was adopted. The Act includes two sets of provisions on executive compensation. On the one side, there are those applicable to all listed companies,¹⁰⁹ touching upon issues like say on (p. 359) pay; independence of compensation committees; enhanced proxy disclosure; “clawbacks” of incentive compensation; and disclosure of employee and director hedging. On the other, Section 956 of the Act (headed “Enhanced Compensation Structure Reporting”) requires Federal regulators of financial institutions to issue new rules in two areas.¹¹⁰ First, they must jointly prescribe regulations or guidelines requiring each covered financial institution to disclose to the appropriate federal regulator the structure of all incentive-based compensation arrangements in a manner sufficient to determine whether the same provide an executive officer, employee, director, or principal shareholder of the covered financial institution with excessive compensation or could lead to material loss to the covered institution. Second, they must prescribe regulations or guidelines that prohibit any type of incentive-based payment arrangements that encourage inappropriate risks by covered financial institutions by providing an executive officer, employee, director, or principal shareholder with excessive compensation or that could lead to material financial loss to the covered financial institution.

In February 2011 the federal agencies jointly exercised their mandate by approving a proposal on incentive-based compensation arrangements for “covered financial institutions.”¹¹¹ These are institutions under the supervision of the respective federal regulator, with total consolidated assets of \$1 billion or more.¹¹² The Rule supplements existing rules and guidance adopted by the relevant agencies regarding compensation, including the Interagency Guidance on Sound Incentive Compensation Policies referred to above.

The use of “standards” rather than “rules” analytically defining the compensation structure not only reflects the international Principles, but also the federal regulators’ willingness to avoid a “one-size-fits-all” approach and keep the needed flexibility in compensation arrangements. Under the proposed standards of “reasonable” (as opposed to “excessive”) compensation, “balanced” arrangements, and “appropriate” risk taking, the institutions concerned have to tailor their remuneration policies to their businesses and risks, assuming responsibility for the relevant arrangements through good corporate governance and internal control mechanisms. At the same time, the regulators will be in a condition to influence the supervised institutions’ compensation practices through general guidance and individual inspections. To this effect, the proposed Rule also requires the covered financial institutions to submit an annual report to regulators describing the structure of incentive-based compensation arrangements.

Executive Remuneration

Specific rules apply to “larger covered financial institutions,”¹¹³ such as bank holding companies with consolidated assets of more than \$50 billion. In addition to mandating wider disclosure to the Federal regulators, the proposed Rule requires similar institutions to defer at least 50 percent of the incentive-based compensation payments to executive officers over (p. 360) a period of a minimum three years, with the release of the deferred amount to occur no faster than on a pro-rata basis.¹¹⁴ A “malus” mechanism also applies, in that the deferred amount should be adjusted for actual losses incurred by the institution or other measures of performance during the deferral period. Moreover, if the covered financial institution has consolidated assets of \$50 billion or more, the board of directors (or a board committee) shall identify those covered persons (other than executive officers) who individually have the ability to expose the institution to possible “substantial” losses. These covered persons may include, for example, traders with large position limits and other individuals who have the authority to place at risk a substantial part of the capital of the covered financial institution. The board of directors (or a board committee) must approve the incentive-based compensation arrangements for covered persons after determining that the same effectively balance the financial rewards and the range and time horizon of risks associated with the covered person’s activities.

4.4 CRD IV

The European regulation in this area was deeply overhauled by CRD IV. The new regime applies on a consolidated basis, i.e., to “institutions at group, parent company and subsidiary levels, including those established in offshore financial centres” (Article 92(1)). The ratio for an EU-wide scope of application is “to protect and foster financial stability within the Union and to address any possible avoidance of the requirements laid down in this Directive” (67th considerandum). The new regime applies to different categories of staff including senior management, risk takers, staff engaged in control functions, and any employee receiving total remuneration that takes them into the same remuneration bracket as senior management and risk takers, whose professional activities have a material impact on their risk profile (Article 92(2)). In this regard, the Commission has recently adopted a delegated Regulation including regulatory technical standards on the identification of risk takers.¹¹⁵

Article 92(2) requires inter alia that the remuneration policy should be consistent with sound and effective risk management and should not encourage risk taking in excess of the tolerated risk level of the institution. Moreover, the remuneration policy should be in line with the business strategy, objectives, values, and long-term interests of the institution, and incorporate measures to avoid conflicts of interest.

Article 94, para. 1 provides several requirements for the variable elements of remuneration. Some of them are rather generic, such as the one requiring performance pay to be based on a combination of the assessment of the performance of the individual and of the business unit concerned and of the overall results of the institution. In addition, performance should be assessed in a multi-year framework in order to ensure that the assessment process is based on longer-term performance and that the actual payment of perfor-

Executive Remuneration

mance-based components of remuneration is spread over a period which takes account of the underlying (p. 361) business cycle of the credit institution and its business risks. Moreover, the total variable remuneration should not limit the ability of the institution to strengthen its capital base. Furthermore, the fixed and variable components of total remuneration should be appropriately balanced and the fixed component should represent a sufficiently high proportion of the total remuneration to allow the operation of a fully flexible policy on variable remuneration components, including the possibility to pay no variable remuneration component.

Other requirements in Article 94, para. 1 are more specific, particularly regarding the “bonus cap” that the European Parliament asked to include in CRD IV. Under Article 94(1)(g), the variable component should not exceed 100 percent of the fixed component of the total remuneration for each individual. However, Member States may set a lower maximum percentage (as Belgium and the Netherlands did, by setting 50 percent and 20 percent respectively). Moreover, Member States may allow shareholders of the institution concerned to approve a higher maximum level of the ratio between fixed and variable remuneration provided the overall level of the variable component shall not exceed 200 percent of the fixed component of the total remuneration for each individual. Member States may also set a lower percentage. In any case, approval of a higher percentage should occur through a special procedure that is described in detail by Article 94(1)(g)(ii).

The official justification for this bonus cap is to avoid excessive risk taking (65th consideration). However, the provision has generated some debate, particularly on whether the bonus cap is suitable to prevent excessive risk taking by bank managers and traders. As stated by Kevin Murphy, several arguments show that neither the objective to reduce excessive risk taking nor the one to reduce perceived excesses in the level of banking remuneration will be achieved by capping variable remuneration.¹¹⁶

First, the bonus cap may lead to an increase in the level of fixed remuneration, making banks more vulnerable to business cycles and therefore increasing the risk of bank failure. Anecdotal evidence already shows that fixed pay at large European banks is on the rise¹¹⁷. Secondly, the traditional bonus system at investment banks, which is characterised by below-market salaries and high bonus opportunities, provides strong incentives to avoid “bad” risks and to take “good” ones. On the contrary, the new system—which will be characterized by above-market salaries and “capped” bonuses—provides incentives to take “bad” risks and avoid “good” ones. In fact, if bad risks materialize, the bank manager will not suffer, for her remuneration is to a large extent fixed. But, if the bank shuns good risks and the relevant profits, the responsible manager will not be worse off given that his bonus is capped. Indeed, the bonus cap reduces incentives to create value, which is the main purpose of variable pay. Third, executive remuneration is largely set by the markets, so that a bonus cap could also have unintended consequences on the firms’ ability to hire people of adequate standing in the international market for managers. In the end, remuneration “will reflect a less-talented workforce as the top producers leave for better-paying opportunities in financial firms not subject to the pay restrictions.” In other words, the cap “will not lead to lower levels of overall remuneration after

adjusting for ability and the risk of the remuneration package.”¹¹⁸ Furthermore, the cap on variable pay may reduce the competitiveness of the EU (p. 362) banking sector relative to non-EU banks and other nonbank financial intermediaries which are not subject to similar restrictions. Fourth, the mandatory cap also reflects a “one-size-fits-all” approach, which is clearly too rigid for different types of credit institutions that are presented with different levels of risk exposure, so that an incentive structure which is appropriate for one firm is not necessarily suited to another. Moreover, the EU bonus-cap applies to all credit institutions, without regard to their size and therefore to systemic risk considerations.

5 Conclusions

In this chapter, we have analyzed the current trends in the regulation and practice of executive remuneration. No doubt, the role of regulation is on the rise, particularly after the recent financial crisis, and the standards as to pay governance and structures are spreading from the financial sector to the non-financial one. As a consequence, today’s remuneration practices are shaped not only by the need to reduce managerial agency costs at listed companies through appropriate incentives, but also by the hard and soft laws tackling corporate governance and remuneration structures. While the governance prescriptions (such as those on remuneration committees and say on pay) are intended to reduce the agency costs relative to incentive pay, the regulation of pay structures has an impact on incentives and the quantum of remuneration. Moreover, this type of regulation also responds to social issues and political pressures, thus reflecting concerns about inequality in the distribution of wealth and incentives to undertake “excessive” risks in the financial sector.

We then examined the main policy questions concerning incentive pay, including the optimal design of stock options, their impact on dividends and dilution, and the importance of long-term pay. Amongst the governance mechanisms, we have considered both the role of boards and independent directors, and that of shareholders under say on pay rules, taking into account the rise of shareholder engagement in listed companies across the Atlantic. As to the structure of pay, we have highlighted the special problems of banks and the main policy issues concerning regulation of pay at financial institutions.

We have subsequently analyzed regulatory developments in Europe in the last ten years and most recent proposals by the Commission, comparing the same with developments at Member State level and in the US. In particular, we have highlighted the impact of say on pay rules on shareholder activism, expanding on the role of proxy advisors and the behaviour of the largest institutional investors, who have shown an autonomous and active stance on executive remuneration issues at large listed companies. We lastly focused on the regulation of pay structures, showing that long-term incentives are clearly favored for both financial and non-financial companies by either regulators or institutional investors. However, financial institutions are the main target of post-crisis reforms, first at the international level through soft-law initiatives like the FSB principles and standards, and sec-

Executive Remuneration

ond at US and EU levels, where the FSB principles have been implemented along partially diverging routes. CRD IV, in particular, has marked a new trend in the regulation of bankers' pay, by imposing a bonus cap that we have criticized from an economic perspective and which clearly goes beyond what is required by the international principles.

Abstract and Keywords

This chapter examines the role of institutional investors in corporate governance and whether regulation is likely to encourage them to become active stewards. It considers the lessons that can be learned from the US experience for the EU's 2014 proposed amendments to the Shareholder Rights Directive. After reviewing how institutional investors fit within the historical evolution of finance, the chapter documents the growth in institutions equity holdings over time. It explains how institutional investors are governed and organize share voting before turning to two competing hypotheses to account for the relative passivity of institutional investors: the excessive regulation and the inadequate incentives hypotheses. In evaluating these hypotheses, it reviews the results of the SEC's attempt to incentivize mutual funds to vote their shares. The chapter concludes by highlighting the role of hedge funds in catalyzing institutional shareholders, along with some of the risks associated with such highly incentivized actors.

Keywords: institutional investors, corporate governance, regulation, EU, Shareholder Rights Directive, share voting, incentives, Securities and Exchange Commission, mutual funds, hedge funds

1 Introduction

Effective and sustainable shareholder engagement is one of the cornerstones of the corporate governance model of listed companies, which depends on checks and balances between the different organs and different stakeholders. Greater involvement of shareholders in corporate governance is one of the levers that can help improve the financial and non-financial performance of companies, including as regards environmental, social, and governance factors, in particular . . .

Institutional investors and asset managers are often important shareholders of listed companies in the European Union and can therefore play an important role in the corporate governance of those companies, but also more generally with re-

gard to their strategy and long-term performance. However, the experience of the last years has shown that institutional investors and asset managers often do not engage with companies in which they hold shares and evidence shows that capital markets often exert pressure on companies to perform in the short term, which may jeopardise the long-term financial and non-financial performance of companies and may, among other negative consequences, lead to a suboptimal level of investments, for example in research and development, to the detriment of the long-term performance of both the companies and the investors.²

LIKE poets and revolutionaries, corporate law scholars and policy makers dream. If only we could find the silver bullet, the wonder drug, we could solve the manager-shareholder (p. 364) agency cost problem that is the focus of much of corporate law. For a while in the 1980s, some thought that the hostile tender offer was that magic potion. Then, beginning in the late 1980s, attention shifted to institutional investors, where it has stayed, on and off, ever since. Noting that shares of publicly held corporations are largely held by institutions, and that shareholding among institutions is concentrated, some have viewed institutional investors as having the potential to act as the responsible owners that corporate law seems to presume: shareholders that, by virtue of their holdings, will have the skills and incentives to keep an eye on managers and check departures from maximizing firm value, to prevent “short termism,” and to do whatever else one wants responsible owners to do.

As with other utopian dreams, reality has proved to be less exciting and less transformative. In this chapter, I try to synthesize what we have learned about institutional investors in corporate governance over the last 30 years or so.

2 Who and What are “Institutional Investors”?

Robert Clark provides a basic framework for understanding how institutional investors fit within the historical evolution of finance.³ The first stage, characteristic of the nineteenth century, was the age of the promoter-investor-manager, exemplified by Rockefeller or Carnegie. The second stage, characteristic of the first part of the twentieth century, was the age of the professional business manager who took on the management of the corporation, while leaving the financial claims to the owners of shares. This stage was exemplified by managerial giants such as Alfred Sloan who led the way in creating the modern, publicly held business corporation. The third stage, characteristic of the late twentieth century, was the age of the portfolio manager in which the selection of the financial claims (stock, bonds, etc.) was professionalized, while leaving the beneficial ownership to the capital supplier. This age of financial intermediaries is the age of the institutional investors, with great stock pickers like Peter Lynch as representative heroes.

In this age of intermediated finance, the investment function—where to invest money that is being saved—is separated from the savings decision and given to professionals, the “money managers.” By professionalizing the investment function, which had been bundled with the savings decision, the third stage parallels the professionalization of the

Institutional Investors in Corporate Governance

management function that characterized the second stage of capitalism. The most prominent “traditional” intermediaries are public and private pension funds, mutual funds, insurance companies, and endowments (collectively referred to as “institutional investors”). More recently, as will become apparent later, activist hedge funds have emerged as a distinct category of specialized professional investors.

Clark’s description, and the above taxonomy, is most applicable to economies with corporations with dispersed public ownership, most prominently the US and the UK. In (p. 365) economies dominated by publicly held firms with concentrated ownership, such as the countries of continental Europe, this description is less accurate but the trend lines point in the same direction. In this chapter, I primarily focus on the US experience, with secondary attention to drawing lessons for the UK and continental Europe.⁴

As is now widely recognized, institutional ownership of equities has been transformed over the last 60 years. In 1950, institutions held \$8.7 billion in equities (6.1% of total); in 1980, institutions held \$436.2 billion in equity (18% of total); in 2009, they held \$10.239 trillion (40.4% of total).⁵ In this growth, mutual funds have been especially prominent, going from owning \$70 billion in 1980 to \$7.2 trillion in 2009.⁶

The effect of this growth has been to concentrate ownership of publicly held firms in institutional hands. Between 1987 and 2009, the institutional ownership in the top 1000 US corporations grew from 46.6% to 73%.⁷ In 2009, the 25 largest corporations by market value had an average institutional ownership of over 60%.⁸

The concentration of ownership within these firms is impressive as well. Table 14.1, drawn from data in the 2010 Conference Board report, shows institutional ownership in the 25 largest corporations, and the ownership of the top five, ten, 20, and 25 institutions in each. As this table makes clear, both the level and the concentration of institutional ownership in even the largest companies is high.

Institutional Investors in Corporate Governance

Two factors seem to have driven the trends over time: regulation and market forces. The extraordinary growth of institutional investors in the US owes much to the 1974 enactment of ERISA which mandated that pension commitments be fully funded by segregated pools of assets.⁹ This led to the creation of independent corporate pension funds to fund “defined benefit” plans (in which employees’ pensions were a certain percentage of final salary). It also eventually pushed corporations to shift to “defined contribution” plans in which the employer and employee each contribute to a tax-advantaged retirement account (almost invariably managed by a mutual fund) to support the employee after retirement. From an employer’s perspective, the great virtue of a “defined contribution” plan is that it is fully funded from the beginning and all investment risk falls on the employee. From an employee’s perspective, the benefit of a defined contribution plan is complete portability, a significant advantage for a mobile workforce. (p. 366)

(p. 367) At the same time, the growth of institutional investors has made them remarkably efficient managers of capital. Vanguard's 500 Index fund allows investors to invest in a basket of securities that tracks the S & P 500 stock index for as low as five basis points (i.e., 0.05% per year).¹⁰ This extraordinarily low price reflects, among other things, massive economies of scale.

When all these factors are brought together, the critical fact that must ground any analysis of corporate governance is the “de-retailization” of the capital markets.¹¹ Any sensible discussion must begin from the fact that between 60% and 70% of the shares of medium and large public corporations are held by institutional investors, and that even in the largest corporations, a significant percentage of the shares are held by a handful of investors.

3 The Governance of Money Managers

The governance of money managers themselves is quite varied. There are four or five different models, as illustrated by some of the leading firms. First, there are for-profit asset managers, some of which are publicly held (e.g., BlackRock and State Street are both NYSE companies), while others are privately held (e.g., Fidelity Management & Research Company, which acts as the investment advisor to Fidelity's family of mutual funds).¹² Included in this group are (for-profit) insurance companies and savings institutions.

Second, there are “mutual” and nonprofit management companies. For example, Vanguard's management company is owned by the Vanguard funds, and thus indirectly by Vanguard participants,¹³ while CREF, the College Retirement Equity Fund, is a nonprofit corporation whose trustees are directly elected by participants, with votes weighted by dollar amount in an account.¹⁴

Third, there are public-employee pension funds in which the governing managers or boards are appointed by politicians or directly elected by voters. At CalPERS, the board includes six elected members, three appointed members, and four ex officio state officials.¹⁵ The NYCERS board “consists of eleven members: the Mayor's Representative, the City Comptroller, the Public Advocate, the heads of the three unions with the largest number of participating employees, and the five Borough Presidents.”¹⁶ By contrast, the NY State & Local Retirement System is headed by the elected NY State Comptroller.¹⁷

(p. 368) Finally, there are the union-related funds that have been prominent governance activists. With respect to shareholder proposals, which require minimal investments, the AFL-CIO has filed proposals using its \$28 million “Reserve Fund.”¹⁸ The joint union-employer pension funds (known as “Taft-Hartley Plans” after the key regulation) collectively hold approximately \$400 billion in assets (of which \$100 billion is in common stock), but have not been active, largely because discretion is delegated to outside money managers in order to avoid the risk of liability under ERISA.

Governance structure affects activism in predictable ways. The union funds pursue a labor agenda. The public pension funds respond to political pressure.¹⁹ For-profit money managers such as BlackRock rarely engage in aggressive activism, although increasingly they engage with companies and support dissident shareholders.²⁰

4 The Organization of Share Voting by Institutional Investors

With the thousands of public companies held by institutional investors, each with an annual meeting and a variety of matters to vote on, voting shares is a huge task. Major institutional investors establish dedicated proxy voting departments that are responsible for developing voting guidelines and voting proxies.

To get a sense of how proxy voting is organized at major institutional investors, and what sort of people are involved, consider Exxon Mobil's three largest shareholders: BlackRock, State Street, and Vanguard, each of which owns more than 3% of the company.²¹ At BlackRock, for example, there is a "Corporate Governance and Responsible Investment" (CGRI) team that acts as a central clearinghouse across its various portfolios.²² The CGRI team has 20 professionals working out of six offices around the world,²³ has responsibility for voting proxies, and has developed general Proxy Voting Guidelines.²⁴ Since 2009, the group has been headed by Michelle Edkins, who has made a career of corporate governance analysis, previously as managing director at Governance for Owners and, earlier, as Corporate (p. 369) Governance Director at Hermes in London.²⁵ Daniel Oh, VP for the Americas on the CGRI team, was previously part of the corporate governance team at State Street, and still earlier was a corporate governance advisor at ISS.²⁶

At State Street, the:

Corporate Governance Team is responsible for implementing the Proxy Voting and Engagement Guidelines (the "Guidelines"), case-by-case voting items, issuer engagement activities, and research and analysis of governance-related issues. The implementation of the Guidelines is overseen by the SSgA Global Proxy Review Committee ("SSgA PRC"), a committee of investment, compliance and legal professionals, who provide guidance on proxy issues as described in greater detail below. Oversight of the proxy voting process is ultimately the responsibility of the SSgA Investment Committee.²⁷

Rakhi Kumar leads the group as the head of Corporate Governance.²⁸ A Yale MBA, she spent time earlier in her career at Proxy Governance Inc.

At Vanguard, proxy voting is delegated to the "Proxy Voting Group," which, in turn, is overseen by the "Proxy Oversight Committee" made up of senior officers and reporting to

Institutional Investors in Corporate Governance

the board.²⁹ The Proxy Voting Group applies the general proxy voting guidelines to specific instances, and is responsible for:

(1) managing proxy voting vendors; (2) reconciling share positions; (3) analyzing proxy proposals using factors described in the guidelines; (4) determining and addressing potential or actual conflicts of interest that may be presented by a particular proxy; and (5) voting proxies. The Proxy Voting Group also prepares periodic and special reports to the Board and any proposed amendments to the procedures and guidelines.³⁰

The Proxy Voting Group is led by Glen Booraem, who joined Vanguard in 1989 and has spent his entire career in fund accounting and administration roles.³¹ In addition to leading (p. 370) Vanguard's corporate governance program, he is also responsible for fund accounting, administration, and compliance services.³²

Other major institutional investors organize the proxy voting/corporate governance functions the same way. At Fidelity, Mark Lundvall is the Vice President of Investment Proxy Research, having earlier worked on corporate governance and compliance at Vanguard.³³ Gwen Le Berre, Director of Proxy & Governance at Charles Schwab, is responsible for the development of Schwab's corporate governance policies and oversees the implementation of its proxy voting guidelines.³⁴ She came to Schwab from BlackRock's Corporate Governance and Responsible Investment group, with similar functions at Barclays.³⁵ Not surprisingly, some corporate governance professionals have spent time at a proxy advisory firm such as ISS, Proxy Governance Inc., or IIRC.³⁶ Public pension funds, such as CalPERS and CalSTRS, approach corporate governance and proxy voting in the same way.³⁷

Given the number of companies in the portfolio, and the legal pressures to vote shares, the role inevitably includes a compliance function. Simply voting the shares, without even considering *how* to vote them, is an enormous task. In addition, especially in recent years and especially at the largest institutional investors, these groups have become increasingly active in corporate governance. From an incentive perspective, however, these activities are not treated as an investment function: unlike with portfolio managers, the compensation of governance professionals is not typically linked to the performance of the portfolios.

Proxy voting groups at institutional investors invariably subscribe to the major proxy advisory firms ISS and Glass Lewis. From what one can tell from the outside, there is a significant difference in the use made of the information and recommendations of those services.³⁸ At institutions with large in-house proxy voting groups, ISS and Glass Lewis are mainly (p. 371) useful as information aggregators.³⁹ Smaller institutions seem to rely more heavily on the proxy advisory firms' recommendations.⁴⁰

On high-value, high-profile issues such as contested mergers, proxy voting groups consult with the managers of the portfolios that hold the relevant shares. Otherwise, portfolio managers are typically less involved. Indeed, some report that portfolio managers some-

times oppose governance activism for fear that it may make it more difficult to arrange meetings with management.

5 The Promise of Institutional Shareholder Activism

The 2017 amendments to the EU's Shareholder Rights Directive, quoted above, accurately express the conventional view that "effective and sustainable shareholder engagement is one of the cornerstones of the corporate governance model of listed companies, which depends on checks and balances between the different organs and different stakeholders."⁴¹ The frustration, going back at least as far as Berle and Means (1932), is that shareholders in public corporations with dispersed ownership do not perform that function. Much corporate law scholarship and policy making has focused on how to remedy or adapt to this failing.⁴² The move towards ensuring that the board of directors is dominated by independent directors can best be understood as one type of solution to the lack of shareholder engagement: Because shareholders themselves do not monitor managers, we need a new player in the boardroom to play that role for the benefit of passive shareholders. Likewise, for some, hostile (p. 372) tender offers can provide a lever of managerial accountability that passive shareholders do not supply.

In the late 1980s, with the decline of the hostile tender offer, attention shifted to the rise of institutional investors as a potential solution to the separation of ownership and control. Institutional investors combined large stakes with professional management, at a time when the increased concentration of shareholdings reduced the costs of collective action. Perhaps, optimists thought, institutional investors would emerge from their historic lassitude that was summarized by the phrase "Wall Street Walk": Shareholders dissatisfied with management would (or should) sell their shares rather than engage in corporate governance activism. With the increased institutional holdings, perhaps institutional investors would emerge to provide the missing lever of corporate governance, to hold the management to account for its performance.

6 How Best to Explain Institutional Investor Passivity? Two Competing Hypotheses

Given the traditional passivity of institutional investors, policy makers needed to understand why they had played so minor a role in corporate governance. Two explanations were offered: excessive regulation and inadequate incentives.

6.1 The "Excessive Regulation" Hypothesis

In the late 1980s, Mark Roe and Bernard Black separately catalogued the dizzying array of regulatory barriers to activism found in state corporate law, federal securities law, federal regulation of investment companies (mutual funds), state insurance company regula-

tion, and pension regulation.⁴³ Moreover, as Roe demonstrated, many of these barriers were erected as part of a political decision to *prevent* institutional investors from playing an active role in corporate governance.

Together, these analyses implicitly proposed “excessive regulation” as the explanation for why institutional investors, despite their size and expertise, were not more active in corporate governance. If only these largely unnecessary regulations were reduced or eliminated, they seemed to suggest, we could expect institutions to take a more prominent role.

(p. 373) 6.2 The Inadequate Incentives Hypothesis

During this same period, other scholars argued that the source of institutional investor passivity was to be found in their lack of or misaligned incentives.⁴⁴ Institutional investors are intermediaries, competing against each other for investors’ funds. Many of the largest institutions offer low-cost diversification, by tracking stock indices or the equivalent.

This industry structure has a variety of implications, almost all of which point away from serious engagement with corporate governance. First, the market for money managers is highly competitive, with money flowing to funds offering higher returns. To the extent that competing funds track indices, superior returns can *only* come from lowering costs, leaving little money for activism. Outside of the hedge fund sector, discussed below, even “active managers” will typically only depart slightly from an indexing strategy.⁴⁵

Second, the costs of activism are borne by the activist while the benefits are enjoyed by all the shareholders, potentially leading to both “rational apathy” (when the private costs exceed the private benefits) and the “free rider problem” (when shareholders refuse to incur costs, hoping to benefit from other shareholders’ activism). As shareholding becomes more concentrated, and the costs of coordination among shareholders drops, both of which have occurred in the last 20 years, shareholders can capture more of the gains, allowing them to move beyond rational apathy.

Third, institutional investors’ revenue model is typically a percentage of assets under management. In such a system, the dominant incentive is to increase fund or fund complex size. This can be done via a variety of avenues, including both marketing and performance. There is thus a link with fund performance, but it will be indirect.

Fourth, money managers may have perverse incentives with regard to activism: To the extent that funds depart from an index, but still compete with managers of similar funds, a fund’s *relative* performance improves when “underweighted” companies in their portfolio perform *badly*.⁴⁶ If Fund A has 4% of X Corp and 2% of Y Corp, and competes with Fund B, with 4% of X Corp and 4% of Y Corp, the worse that Y Corp performs, the better Fund A’s relative performance vis-à-vis Fund B. Indeed, to the extent that relative performance

is determinative, Fund A would have a financial incentive to vote against a merger that would benefit Y Corp or elect incompetent directors.

Fifth, consistent with the old “Wall Street Rule,” noted above, portfolio managers still believe that involvement in everyday corporate governance is a tough way to make money and would prefer to devote their efforts to selecting better investments. Moreover, corporate governance activism can make it difficult for portfolio managers to gain access to the management of portfolio companies, making their jobs more difficult.

(p. 374) Finally, asset managers face a variety of conflicts of interests. It is difficult to compete for corporate pension business while criticizing the company. When the asset manager is part of a larger group including an investment bank, the bankers may pressure asset managers not to antagonize current or prospective clients by, for example, voting against the CEO’s pay.⁴⁷

6.3 A Natural Experiment: Partial Deregulation of Institutional Investors

In the years since 1990, concentration of ownership has continued to increase and many of the regulations that Black and Roe identified have been relaxed. Thus, the 1992 reform of the proxy rules allows institutions to talk with other institutions about the performance of the management without fear of liability for improper solicitation of proxies.⁴⁸

Regulation Fair Disclosure, effective in 2000, prevents corporate managers from punishing active investors by providing selective disclosure of important information only to friendly portfolio managers, thereby protecting active shareholders from at least one form of retribution.⁴⁹

Yet institutional investors have not emerged as shareholders’ champion. While not conclusive, the evidence strongly suggests that the primary explanation for institutional investor passivity is inadequate incentives, rather than excessive regulation.

7 Can We Fix the Incentive Problems?

7.1 The European Commission’s 2017 Amendments to the Shareholder Rights Directive

The European Commission, as reflected in the 2011 Green Paper, has been frustrated by the same shareholder passivity that has frustrated US observers.⁵⁰ In its proposal to amend the Shareholder Rights Directive,⁵¹ it observed that:

The financial crisis has revealed that shareholders in many cases supported managers’ excessive short-term risk taking. Moreover, there is clear evidence that the current level of (p. 375) “monitoring” of investee companies and engagement by institutional investors and asset managers is sub-optimal. Institutional investors and their asset managers do not sufficiently focus on the real (long-term) performance

of companies, but often on share-price movements and the structure of capital market indexes, which leads to suboptimal return for the end beneficiaries of institutional investors and puts short-term pressure on companies.

Short-termism appears to be rooted in a misalignment of interests between asset owners and asset managers. Even though large asset owners tend to have long-term interests as their liabilities are long-term, for the selection and evaluation of asset managers they often rely on benchmarks, such as market indexes. Moreover, the performance of the asset manager is often evaluated on a quarterly basis. As a result many asset managers' main concern has become their short-term performance relative to a benchmark or to other asset managers. Short-term incentives turn focus and resources away from making investments based on the fundamentals (strategy, performance and governance) and longer-term perspectives, from evaluating the real value and longer-term value creative capacity of companies and increasing the value of the equity investments through shareholder engagement.⁵²

In its 2017 Amendments to the Shareholder Rights Directive, in an effort to address this lack of engagement, the EU adopted a variety of measures, including the requirement that institutional investors and asset managers develop and disclose (on a “comply or explain basis”) a policy on shareholder engagement: “Institutional investors and asset managers shall develop and publicly disclose an engagement policy that describes how they integrate shareholder engagement in their investment strategy. The policy shall describe how they monitor investee companies on relevant matters, including strategy, financial and non-financial performance and risk, capital structure, social and environmental impact and corporate governance, conduct dialogues with investee companies, exercise voting rights and other rights attached to shares, cooperate with other shareholders, communicate with relevant stakeholders of the investee companies and manage actual and potential conflicts of interests in relation to their engagement.”⁵³ In addition, institutional investors are expected to disclose the results of their policies, how they vote in general meetings, and an explanation for how they vote.⁵⁴ The Amendments also seek to encourage institutional investors to incentivize asset managers to manage for the medium- to long-term performance of assets.⁵⁵

Are these attempts to encourage or force institutional investors to play a more significant and productive role in corporate governance likely to succeed? In this regard, it is worth reviewing the US experience with a very similar set of reforms.

7.2 The 1988-2013 Mutual Fund “Experiment”: Imposing Obligations on Mutual Funds

In 1988, the Department of Labor issued the legendary “Avon Letter” which declared that proxy voting rights are plan assets subject to the same fiduciary standards as other plan (p. 376) assets.⁵⁶ In subsequent letters, the DOL amplified on this responsibility.⁵⁷ Since then, the SEC has repeatedly made clear that, under the Investment Company Act and In-

Institutional Investors in Corporate Governance

vestment Advisors Act, the voting of proxies is a matter of money managers' fiduciary duties.

The SEC raised the stakes in 2003 when it promulgated two related releases that together imposed an obligation to disclose proxy voting policies and proxy votes on registered investment management companies (the managers of mutual funds) and investment advisors (the individuals who work for the managers of mutual funds).⁵⁸ In promulgating these new rules, the SEC focused on (1) mutual funds' large holdings; (2) advisors' and investment management companies' fiduciary obligations to their investors to vote proxies responsibly and in the interests of the investors; (3) mutual funds' historic passivity; and (4) the potential for conflicts of interest between mutual funds' duties to their investors and their commercial interests. One can almost feel the SEC's frustration that, despite 15 years of emphasizing money managers' fiduciary responsibility to vote proxies, nothing much had changed.

The SEC justified imposing new obligations on mutual funds on two grounds: (1) investors' "fundamental right" to information on how mutual funds vote and (2) the ways in which transparency will allow investors to hold mutual funds accountable for how they vote, thereby controlling conflicts of interest and inducing more responsible "stewardship":

Proxy voting decisions by funds can play an important role in maximizing the value of the funds' investments, thereby having an enormous impact on the financial livelihood of millions of Americans. Further, shedding light on mutual fund proxy voting could illuminate potential conflicts of interest and discourage voting that is inconsistent with fund shareholders' best interests. Finally, requiring greater transparency of proxy voting by funds may encourage funds to become more engaged in corporate governance of issuers held in their portfolios, which may benefit all investors and not just fund shareholders.⁵⁹

Further, the SEC seemed to expect that disclosure of mutual fund proxy voting would lead investors to choose funds based on how active they are in corporate governance:

A number of commenters, including an overwhelming number of individual investors, strongly supported the Commission's proposal to require a fund to disclose its complete proxy voting record. Many of these commenters stated that this disclosure would improve (p. 377) shareholders' ability to monitor funds' voting decisions on their behalf and that it would allow investors to make more informed decisions when choosing among funds . . .

After careful consideration of these comments, we continue to believe that requiring funds to disclose their complete proxy voting records will benefit investors by improving transparency and enabling fund shareholders to monitor their funds' involvement in the governance activities of portfolio companies.⁶⁰

Institutional Investors in Corporate Governance

In addition, the SEC expected that “more conscientious” mutual fund voting would lead to increases in firm value:

A third significant benefit of the amendments comes from providing stronger incentives to fund managers to vote their proxies conscientiously. The amendments could increase the incentives for fund managers to vote their proxies carefully, and thereby improve corporate performance and enhance shareholder value. The improved corporate performance that could result from better decisionmaking in corporate governance matters may benefit fund investors. In addition, other equity holders may benefit from the improvement to corporate governance that results from more conscientious proxy voting by fund managers. We note that assets held in equity funds account for approximately 18% of the \$11 trillion market capitalization of all publicly traded US corporations, and therefore funds exercise a considerable amount of influence in proxy votes affecting the value of these corporations.⁶¹

Further, the release provided guidance on what sort of proxy voting policies mutual funds should have:

We do expect, however, that funds’ disclosure of their policies and procedures will include general policies and procedures, as well as policies with respect to voting on specific types of issues. The following are examples of general policies and procedures that some funds include (p. 378) in their proxy voting policies and procedures and with respect to which disclosure would be appropriate:

- The extent to which the fund delegates its proxy voting decisions to its investment adviser or another third party, or relies on the recommendations of a third party;
- Policies and procedures relating to matters that may affect substantially the rights or privileges of the holders of securities to be voted; and
- Policies regarding the extent to which the fund will support or give weight to the views of management of a portfolio company.

The following are examples of specific types of issues that are covered by some funds’ proxy voting policies and procedures and with respect to which disclosure would be appropriate:

- Corporate governance matters, including changes in the state of incorporation, mergers and other corporate restructurings, and anti-takeover provisions such as staggered boards, poison pills, and supermajority provisions;
- Changes to capital structure, including increases and decreases of capital and preferred stock issuance;
- Stock option plans and other management compensation issues; and
- Social and corporate responsibility issues.⁶²

Finally, the SEC gave advice on how funds might handle conflicts of interest:

Advisers today use various means of ensuring that proxy votes are voted in their clients' best interest and not affected by the advisers' conflicts of interest. An adviser that votes securities based on a pre-determined voting policy could demonstrate that its vote was not a product of a conflict of interest if the application of the policy to the matter presented to shareholders involved little discretion on the part of the adviser. Similarly, an adviser could demonstrate that the vote was not a product of a conflict of interest if it voted client securities, in accordance with a pre-determined policy, based upon the recommendations of an independent third party. An adviser could also suggest that the client engage another party to determine how the proxies should be voted, which would relieve the adviser of the responsibility to vote the proxies.⁶³

7.3 The Effects of the SEC Release

Mutual funds complied with the requirements of the release. They now have proxy voting guidelines⁶⁴ and disclose their proxy voting.⁶⁵ Not surprisingly, funds have adopted voting guidelines that rather closely follow the SEC guidelines for what such guidelines should look like. Thus, guidelines typically take positions on general governance matters like classified boards, independent directors, anti-takeover provisions, and compensation.

Note how the SEC's release shaped the *substance* of mutual funds' engagement. By describing "best practices" for proxy voting guidelines, the SEC effectively mandated a (p. 379) particular "guidelines" approach to shareholder engagement, and rejected the perfectly respectable view that governance is endogenous to firms. It would take an unusually assertive and brave mutual fund to announce the following (entirely fictional) approach:

We believe that there are no general principles or best practices in corporate governance. Rather, we believe that optimal governance depends on firm specific factors and that market pressures, even in the absence of regulation, drive most firms to adopt optimal governance arrangements. In addition, we believe that most shareholder voting is irrelevant to firm value, a distraction to corporate management, and does not contribute (and can interfere with) maximizing the financial performance of your fund. Therefore, we will routinely vote with management unless we become aware of a specific problem at a particular company. In those cases, we will decide how to vote on a case by case basis, taking into account all factors and discussing issues with management and other shareholders.

I am not aware of any funds that have announced this approach, even though such an approach, many believe, would be optimal for investors in widely diversified funds.

The SEC, in emphasizing money managers' fiduciary duties, and the extent to which conflicts of interest may breach those duties, created a compliance challenge. By then indicating reliance on guidelines or a predetermined policy of voting based on "the recommendations of an independent third party," the SEC gave a boost to "guideline based

Institutional Investors in Corporate Governance

voting” (noted above), as well as to the proxy advisory industry. A subscription to ISS and Glass Lewis can be viewed as a kind of “ERISA insurance.”⁶⁶

So the SEC achieved its immediate goal, namely the routine disclosure of proxy voting policies and proxy votes. But has this disclosure led investors to choose funds based on those policies or votes? And has this new disclosure mandate increased firm value?

I have not found any evidence that investors seeking to maximize returns pay *any* attention to either the policies or the votes. In particular, I cannot find any evidence that investors *choose* funds based on how the fund voted its proxies. There is, however, evidence that labor and environmental groups use the voting reports to determine whether mutual funds comply with the groups’ guidelines, and to criticize those that do not.⁶⁷

Further evidence of compliance with the SEC requirements, and of the transformation of proxy voting into a “compliance function,” is the creation of “proxy voting groups” at large mutual fund complexes, described above, staffed with people whose compensation does not depend on the performance of the companies or funds for which they vote proxies. The very existence of these groups indicates portfolio managers’ *lack* of interest in voting routine proxies (although they clearly do weigh in on major decisions like mergers). Given that portfolio managers select investments and are judged based on the performance of the investments they select, this itself is strong evidence that an individual fund’s routine proxy voting does not have any measurable effect on performance. The lack of incentive compensation for proxy voting groups eliminates any straightforward “pay for performance” penalty for votes that reduce firm value. Although mutual funds reliably support “performance (p. 380) compensation” for portfolio companies because of the incentive effects, proxy voting groups are not, themselves, compensated in this way.

With ten years of experience with the SEC’s mutual fund release, we can begin to measure the effect of these mandates on firm value. The preliminary results are not encouraging. In an important paper, Larcker, McCall, and Ormazabal (2015) use the Dodd-Frank mandated “say on pay” votes to study the impact of proxy advisory firms on shareholder voting and firm value.⁶⁸ Their key findings are:

proxy advisory firm recommendations have a substantive impact on say-on-pay voting outcomes, a substantial number of firms change their compensation programs in the time period before formal shareholder votes in a manner consistent with the features known to be favored by proxy advisory firms in an effort to avoid negative voting recommendations, and the stock market reaction to these compensation program changes is statistically negative.⁶⁹

The first two findings support the conventional wisdom. Consistent with other research, the recommendations by ISS and Glass-Lewis have a significant effect on how mutual funds vote. The second finding confirms that, when proxy advisory recommendations matter, portfolio firms will tailor their conduct to comply and thereby avoid a negative recommendation.

The most important, and intriguing, finding is the third; namely, that complying with ISS guidelines to avoid a negative recommendation is correlated with a *decline* in firm value. Larcker et al. interpret this result as suggesting that “outsourcing voting to proxy advisory firms appears to have the unintended economic consequence that boards of directors are induced to make choices that decrease shareholder value.”⁷⁰ An alternative explanation for the results is that firms identify themselves as out of compliance with proxy advisory firm recommendations by disclosing these changes, and that “lack of compliance” is evidence that firms are badly governed, leading to a fall in stock price. If, however, this were the explanation, then one would predict that *future* performance of these firms would decline; Larcker et al., however, show that this is not the case. As interesting and suggestive as these results are, more research is clearly needed to determine whether and to what extent proxy advisory firms’ recommendations are value increasing or decreasing.

What can we learn from the last 25 years during which the US has experimented with using fiduciary duties and disclosure to induce mutual funds, an important subset of institutional investors, to be more active in corporate governance? The most immediate lessons are discouraging. While regulation clearly changes behavior—it led mutual funds to adopt proxy voting guidelines, to disclose their proxy voting, and to subscribe to proxy advisory services—it failed to achieve its core goal, namely, transforming mutual funds into shareholders’ champions that assume a role in corporate governance commensurate with their shareholdings. Indeed, in an example of the law of unintended consequences, the effects of the effort may well be negative on the core measure of firm value. Not surprisingly, the fundamental incentive structure outlined above—in which institutional investors, as intermediaries, have minimal incentives to become active in corporate governance—seems to undermine even the best-intended regulatory intervention. It is very difficult to force anyone to be free.

(p. 381) There is little reason to believe that the European Commission’s reforms will fare any better. Now that the amendments to the Shareholder Rights Directive have been adopted, one can predict that institutional investors and asset managers will reliably comply (rather than explain why they did not), will dutifully create and disclose policies for engagement, and will disclose their votes at general meetings. Likewise, one can predict that institutional investors will turn to proxy advisors for assistance. Finally, one suspects that this greater engagement will not increase firm or portfolio value.

8 The New Reality: Institutional Investors and Activist Hedge Funds

But these negative assessments may be too quick. Although traditional institutional investors have not emerged as active “stewards,” there has been a more modest, although still important, change in institutional investor behavior: Institutional investors are engaging with management in a much more active way than ever before; and, rather than always supporting management, institutional investors are now willing to support hedge

Institutional Investors in Corporate Governance

funds and other corporate governance activists when they are convinced that doing so will increase firm value.⁷¹ As one hedge fund manager explains, “The brute force of ownership is not required anymore because the big institutional players listen to both sides and are willing to back the activist fund if they believe in them . . . You can win with persuasion and ideas.”⁷²

Hedge fund activists include some familiar names from the 1980s like Carl Icahn and Nelson Peltz, as well as newer players like Bill Ackman, Daniel Loeb, and Jana Partners. Although exact figures are hard to come by, Icahn is said to have \$20 billion available,⁷³ while Ackman has around \$12 billion.⁷⁴ Overall, corporate activist hedge funds are estimated to have a total of around \$100 billion.⁷⁵ While these are very large sums, they are small relative to the amounts managed by the largest institutional investors. As of 2017, the largest included: BlackRock (\$5.1 trillion), State Street (\$2.5 trillion), Vanguard (\$4 trillion), and (p. 382) Fidelity (\$2.1 trillion). They are also small relative to the market capitalization of the largest companies. As of September 29, 2017, the median market cap for the S & P 500 was \$20 billion; the smallest market cap was \$2.7 billion; the largest \$796 billion.⁷⁶

Hedge funds, in contrast to traditional institutional investors, engage with particular companies over firm-specific issues. Their activities can usefully be divided into corporate governance activism (e.g., pressuring management over business issues such as asking management to spin off a division, nominating a “short slate” of directors, and pushing for changes in corporate financing such as buying back stock or paying a dividend), and corporate control activism (e.g., blocking acquirers from completing a merger, blocking targets from agreeing to a merger, pushing the board to sell the company, and even making bids for the company).

The biggest difference between hedge funds and traditional institutional investors is hedge funds’ business model. For traditional institutions, activism, when it occurs, is a response to unexpected and undesired problems that emerge in portfolio companies. Once problems arise, institutional investors must decide whether to sell the position (the “Wall Street Walk”), to intervene to improve it, or to do nothing. As we saw above, institutional investors’ incentives to intervene are very weak.

By contrast, for activist hedge funds, activism is ex ante and strategic.⁷⁷ Activists first identify a problematic company, then decide whether intervention can improve matters. If activists conclude that an intervention is warranted, they buy a stake in order to intervene. When combined with high-powered performance-based incentives (typically between 1% and 2% of money under management plus between 15% and 20% of gains), hedge funds, unlike traditional institutions, have strong financial incentives to get involved. When an engagement is effective, the gains to the hedge fund can be huge. Moreover, activist hedge funds typically do not have the same conflicts of interest as institutional investors, as they do not sell money management services to portfolio companies.

Institutional Investors in Corporate Governance

The links between activist hedge funds and traditional institutional investors are critical to understanding hedge funds' influence and institutional investors' contemporary roles in corporate governance. First, because activist hedge funds do not have sufficiently large positions to prevail in medium or large cap companies, they must convince the other shareholders—mainly the traditional institutional investors—to support them. Hedge funds play an important “catalyst” role in facilitating shareholder action.

Second, the border between the “investor” side and the “issuer” side has become increasingly permeable, with increasing mobility of corporate governance professionals between the investor and issuer “sides” of the table. Stephen Brown, Director of Corporate Governance at TIAA-CREF, became the CEO of the Society of Corporate Secretaries and Governance Professionals and then joined KPMG's “board leadership” group.⁷⁸ Bess Joffe, by contrast, left Goldman Sachs to become Managing Director of Corporate Governance at TIAA-CREF.⁷⁹ Linda Scott, managing director at Governance for Owners and, before that, Director of Corporate Governance at TIAA-CREF, is now SVP and Associate Corporate Secretary at JPMorgan Chase.⁸⁰ Abe Friedman, founder and managing partner of CamberView Partners, a boutique advisory firm that advises issuers, came from BlackRock. Chris Young, after six years as Director of M & A and Proxy Fight Research at ISS, is now managing director and head of contested situations at Credit Suisse where he advises issuers.⁸¹ And, of course, John Wilcox, after a long career at the leading proxy solicitor Georgeson, became SVP and head of corporate governance at TIAA-CREF, and is now chairman of Morrow Sodali, which works with issuers in developing institutional investor relationships.⁸²

Third, and critically, a significant (but undisclosed) amount of activist hedge fund capital is raised from traditional institutions. According to the 2010 Conference Board report, hedge fund and other alternative investment assets have grown from under \$2 billion in 1990 to around \$1.5 trillion in 2009.⁸³ This growth has been fueled by institutional investment. As of 2009, the largest 200 defined benefit plans had invested around \$70 billion in hedge funds alone.⁸⁴

Institutional investor investment in activist hedge funds potentially align interests in a variety of interesting ways. First, it insulates institutional investors from criticism by those opposed to the activists' agenda, and avoids antagonizing portfolio companies and incurring the wrath of portfolio managers. Second, encouraging activism through hedge funds allows for much higher-powered financial incentives than would be politically acceptable within institutional investors. Third, the arrangement allows for a division of labor, with the hedge funds developing expertise in pressuring management. Having induced activism through investments in hedge funds, institutional investors quite reasonably may choose to take a more passive reactive role. Fourth, the investments partially align the financial interests of the institutional investor and the hedge fund. Finally, major institutional investors only invest in hedge funds after significant due diligence. The process associated with institutional investors' *investment* in hedge funds provides some assurance to the general investing public of the activists' bona fides. Institutional investors are now

Institutional Investors in Corporate Governance

far more willing to consider proposals for change made by the activist hedge funds than they used to be.

At the same time, hedge funds' high-powered financial incentives create grounds for concern. Hedge funds exist to make money, and will likely attempt to do so, whether or not it benefits shareholders as a group. Thus, for example, hedge funds have sought to acquire companies and, of course, sought to do so at the lowest possible cost. Hedge funds have also (p. 384) used tactics such as "empty voting" that serve the hedge funds' interest at the expense of the other shareholders.⁸⁵

The potential constraints induced by the need to form a coalition can be usefully illustrated by the Air Products/Air Gas battle.⁸⁶ In 2012, Air Products, an industrial gas producer, launched a hostile bid for Air Gas, a supplier of gas delivered in canisters. Air Gas, which had a staggered board and a poison pill, resisted Air Products's above market bid on the grounds that it undervalued the company. Eventually, Air Products launched a proxy fight to elect a short slate of directors. Air Products nominated three independent directors who were committed to taking a "second look." After prevailing in a hard-fought contest, with support of ISS, hedge funds, and traditional institutions, the newly elected directors, with separate counsel and investment banking advice, surprised many by concluding that the Air Products' offer, though a premium above market value, substantially undervalued Air Gas, and became the most vociferous proponents of resisting the Air Products offer. Air Products ultimately refused to raise its offer, and the bid failed. Air Gas's stock price has remained above the offer price and, in fact, has increased nearly 50%. The newly elected outside directors seem to have been right.

From a corporate governance perspective, one of the most interesting features of the battle was that Air Products did, in fact, identify and elect genuinely independent directors and not a slate committed to selling the company.⁸⁷ The best explanation one heard for this "unusual" tactic is that the institutions and the hedge funds that held Air Gas shares were genuinely unsure of the value of Air Gas, and would not have supported a more partisan slate.

The world has changed when F. William McNabb, III, chairman and CEO of Vanguard, publicly salutes certain interventions by activist hedge funds:

The nature of activist investing has changed significantly since the 1980s. Today, we're seeing a greater trend toward constructive activists rather than destructive activists. Activists are not inherently good or bad. They often raise legitimate questions.

And when they raise legitimate questions and tie their business cases to long-term shareholder value—that gets our attention. There have been a number of cases where a board wasn't asking the right questions and eventually lost touch with how the company was being run, and how it was being perceived by investors. I'll

share two instances where Vanguard has sided with activist campaigns in recent years.

- **Canadian Pacific Railway:** In 2012, activist Bill Ackman went in and identified some vulnerabilities in Canadian Pacific Railway. We agreed—as did many other large investors—that the company had been poorly run and governed. Ackman brought in an experienced CEO and a number of directors they thought could make a difference. It’s been an activist success story—by and large.

- **Commonwealth REIT:** Another example of us supporting an activist: Earlier this year, Corvex and Related Companies waged a successful campaign to replace the (p. 385) entire board of Commonwealth REIT. This was a company with a track record of poor performance and poor governance, and they were ultimately held accountable. Commonwealth was using a third-party management firm, RMR, that was run by family members of Commonwealth leadership. RMR extracted value from the public company. They didn’t operate it well, but they were paid well nonetheless. We supported wiping the slate clean. In the case of Commonwealth, we were the largest shareholder. We were important to Corvex’s case, but at the end of the day, I don’t think they needed us. 81% of Commonwealth shareholders voted to remove the company’s board.⁸⁸

The constraining effects of coalition building have some interesting implications. We should be more worried about cases in which hedge funds can act on their own than when a coalition with other shareholders is required. Thus, for example, the squeeze-out threshold in the EU for completing a takeover under the Takeover Directive (95% in Belgium, Germany, France, Italy, and the Netherlands; 90% in Spain, Sweden, and the UK)⁸⁹ is an invitation to hedge funds to acquire a blocking position. Especially at the 95% level, it would seem close to “hedge fund malpractice” not to buy a blocking position, especially in private equity deals in which the sponsor’s financing requires owning 100%. Some worry that similar hold-out problems can be created by “majority of the minority” provisions, whether in a controlling shareholder context or a management-sponsored LBO. This suggests that such provisions should be used sparingly. It also raises the possibility that the doctrinal effect of such provisions should be revisited.⁹⁰

9 Conclusion

The preceding discussion suggests that, try as we might, we are unlikely to transform institutional investors into “stewards” of portfolio companies. The emergence of activist hedge funds raises an even more fundamental question that applies equally to institutional investors: Do we, as a society, actually *want* shareholders to act like owners? Highly incentivized, focused actors can be and often are socially disruptive. In the US during the 1980s, the disruption accompanying hostile tender offers resulted in anti-takeover (p. 386) legislation, as well as judicial decisions that limited shareholders’ ability to proceed unilaterally.⁹¹ Mark Roe’s political history of US corporate finance provides numerous examples of regulatory pacification of active or potentially active shareholders.⁹² Whenever hedge funds have emerged as activists, they have produced a backlash as their

single-minded, incentive-driven focus—whether on shareholder value maximization or blocking a transaction or exploiting ambiguities in bond contracts—has made people nervous. The rise of hedge funds in Europe has led to calls to constrain them.⁹³

When one reads the EU's 2017 Amendments to the Shareholder Rights Directive, and the discussions leading up to it, one gets the distinct impression that shareholders who act too much like shareholders, with single-minded focus on maximizing shareholder value today, are *not* what is sought. Too often, it seems, with a focus on maximizing profits, they push for unpleasant things like closing plants, moving work to China, firing employees, or putting competitors out of business. Rather, the EU seems to be searching for a very different sort of shareholder, a shareholder more like a rich uncle who, while demanding, is ultimately focused on doing what is best for the family as a whole, one who “can be encouraged to take an interest in sustainable returns and longer term performance” even at the cost of lower returns. The US experience makes clear that traditional institutions and hedge funds are not this sort of investor and it is unlikely that regulation can transform them into this sort of “patient capital.”

Too often, shareholders are only interested in the highest possible dividends. That is understandable but it fuels short-termism. We have spoken for years about shareholders rights. It is time to also talk about shareholders’ obligations. All these measures put together will make a difference and lead to better corporate governance in companies, to more responsibility and more accountability. We still need to debate how we put these measures in place—but I am clear we will not be able to rely only on voluntary codes.”

The amendments to the registration statement and reporting forms that we are adopting will benefit fund investors, by providing them with access to information about how funds vote their proxies.

First, the amendments will provide better information to investors who wish to determine:

- (•) to which fund managers they should allocate their capital, and
- (•) whether their existing fund managers are adequately maximizing the value of their shares.

The investment adviser to a mutual fund is a fiduciary that owes the fund a duty of "utmost good faith, and full and fair disclosure." This fiduciary duty extends to all functions undertaken on the fund's behalf, including the voting of proxies relating to the fund's portfolio securities. An investment adviser voting proxies on behalf of a fund, therefore, must do so in a manner consistent with the best interests of the fund and its shareholders. The increased transparency resulting from proxy voting disclosure may increase investors' confidence that their fund managers are voting proxies in accordance with their fiduciary duties. Without disclosure about how the fund votes proxies, fund shareholders cannot evaluate this aspect of their managers' performance. To the extent that investors choose among funds based on their proxy voting policies and records, in addition to other factors such as expenses, performance, and investment policies, investors will be better able to select funds that suit their preferences. Further, insofar as investors may over-emphasize certain of these factors, e.g., past performance, in selecting funds, it may be beneficial to provide additional information to use in selecting funds. On a related point, we anticipate that over time, commercial third-party information providers will offer services

that will enable investors to better analyze proxy voting by funds. These developments will further facilitate the benefits to fund investors from proxy vote disclosure (Id. at *72–74; footnotes omitted).

Abstract and Keywords

This chapter examines the phenomenon of shareholder activism within the context of corporate governance and its place in today's debate on shareholders and shareholder empowerment. It first reviews the concept of shareholder activism and emphasizes the importance of the shareholder structure under which it operates before turning to the historical developments of shareholder activism, with particular emphasis on the U.K., US, and continental Europe. It then describes the various methods employed by activist shareholders and the corresponding regulatory constraints. It also discusses the impact of the global financial crisis of 2007–2011 on shareholder activism. The chapter suggests that shareholder activism has been enjoying something of a renaissance lately, with hedge fund activism becoming more refined, as well as a surge in success following the global financial crisis.

Keywords: shareholder activism, corporate governance, shareholder empowerment, shareholder structure, UK, United States, Europe, activist shareholders, financial crisis, hedge fund activism

1 Introduction

¹WHEN considering shareholder activism, the likes of Chris Hohn, Carl Icahn, Bill Ackman, Nelson Peltz, T. Boone Pickens, CalPERS, and Atticus are commonly at the forefront of people's minds. As minority shareholders they commonly use their equity stakes in targeted corporations to sway management, arguably towards short-term value enhancement.² This can occur via proxy battles or voting contests, negotiations behind closed doors with management boards, publicity, litigation, and so forth. In recent years, activist investors seem to have honed their tactics.³ However, in relation to a concept that not only encompasses various strategies for intervention but also applies to a multitude of minority shareholder profiles, care must be taken not to overgeneralize.⁴

Shareholder activism has become an important and integral part of our corporate governance reality. This chapter takes stock of the phenomenon of shareholder activism and evaluates its importance for the shape of today's debate on shareholders and shareholder

empowerment. My main focus will be on the evolution of activist shareholder structures in the UK, the US, and continental Europe as well as historical developments, the guises and traits (p. 388) of shareholder activism, regulatory constraints, and finally the perspectives for shareholder activism following the financial crisis that plagued the global economy from 2007 to 2011.⁵

My main arguments are as follows: first, the seemingly straightforward term “shareholder activism” may cover a range of different activities, and may be exercised by a broad variety of activist investor types. Second, the importance and the effect of shareholder activism will very much depend on the prevailing shareholder structure under which it operates; and the economic benefits that we attach to shareholder activism may likewise vary depending on the environment in which it occurs. Third, I document that shareholder activism has seen something of a renaissance lately, with hedge fund activism becoming more refined, and also popular following the 2007–2009 global financial crisis.

I proceed as follows. Section 2 explores the concept of shareholder activism and emphasizes the importance of the shareholder structure under which it operates. Section 3 then looks back in time and seeks to explain the historical developments of shareholder activism, mostly in the US, UK, and continental Europe. This allows us to discuss the various methods of activist shareholders in section 4 and the corresponding regulatory constraints (section 5). Finally, section 6 demonstrates that activist shareholders suffered badly during the global financial crisis, but that more recent years seem to suggest that they are experiencing a “comeback.” Section 7 concludes.

2 Shareholder Activism in Context

A share in a company may afford the owning shareholder a range of rights and liabilities under the prevailing jurisdiction, but it is the way in which these rights are utilized in conjuncture with investment strategies of profit maximization that define shareholder activism.⁶ In parallel, the legal protection given to a share as an asset not only plays a crucial role in stimulating economic activity in equity markets but also enables the modern syndicate to prosper.⁷

In its most general form, shareholder activism means nothing more than an active, engaging shareholder who does not simply consider the investment made as purely financial, but as strategic. The most obvious way in which shareholders may voice their demands is to exercise the voting rights associated with share ownership. One of the main problems of shareholder voting is that small shareholders generally have weak incentives to exercise their voting rights. This is the well-known phenomenon of “rational apathy” of (dispersed) shareholders.⁸ The relationship between vote and benefit is usually so unfavorable for (p. 389) retail investors that the rational investor will not seriously engage in the business strategy in order to make an informed decision or to vote. Activist shareholders, by contrast, overcome this passivity—for various reasons—and actively monitor the company’s strategy and management’s decisions. Activism comes in many different shapes. During the 1980s, it appeared in the form of corporate raiders dictating company

Shareholder Activism: A Renaissance

policies, or as leveraged buyout funds taking public companies private in order to change corporate policy. More recently, some pension funds have exerted pressure on management in publicly listed companies, often in the form of behind-the-scene negotiations. The latest activist trend can be seen in hedge funds which have discovered corporate activism as their business model. In any case, it is important to bear in mind that each shareholder activist will pursue their own style of trading and methods for engaging with management boards, within the relevant legal and regulatory environments.⁹ Without doubt these varying facets accord a degree of complexity to the meaning of shareholder activism.

In general terms, early forms of shareholder activism encompassed all forms by which shareholders engaged with targeted corporations on matters of company policy. This broad meaning was subsequently broken down into formal and informal activism.¹⁰ Shareholder activism of a formal nature takes place in the public domain, for example at annual general meetings. Gillan and Starks consider there to be three residual categories to formal shareholder activism: namely, “transacting” shareholders, whereby shareholders voice their views on the performance of the targeted corporation by purchasing or selling shares; “activist blockholders” who focus on influencing decision making by gaining a minority control in the targeted corporation and voicing their views; and finally shareholders who seek to implement their changes by gaining control of the company, availing themselves of a (hostile) takeover.¹¹ Informal shareholder activism, in contrast, occurs in private, behind closed doors, and away from the prying eyes of the public. It therefore rarely attracts any media attention, rendering it near impossible to prove unless one has access to an activist’s private database.¹² Although the above goes some way in defining the generalist traits of shareholder activists, the evolution of shareholder structures, regulatory regimes, and stock markets in the UK, US, and continental Europe has played a crucial role in influencing activist engagements. Shareholder activism in other parts of the world has been less pertinent, and is beyond the scope of this chapter.¹³

(p. 390) 2.1 Shareholder Activism: UK/US

Despite diversified shareholder structures being present in both the UK and US they have evolved into their current forms for differing reasons. The diversified shareholder structure seen in the UK has to a greater extent been developed by responding and adapting to the regulatory changes that have taken place over the past century and the globalization of stock markets.¹⁴ Whilst the shareholder structures of corporations were historically comprised of “local” regional owners, the diversification of stock ownership in the UK only really commenced from the offset of the 1990s as UK insurance companies and pension funds began to emerge on stock markets. In parallel, foreign investors materialized as equity investment strategies became globalized due to the growing internationalization of corporate activities.¹⁵ Akin to the UK, the shareholder structures of large US listed corporations are also dispersed in nature, but arguably for different reasons. To start with, dispersed ownership arrived in the United States much earlier: scholars disagree on the precise background, but, most commonly, the early twentieth century is named as the decisive period, though the developments that paved the way for equity dispersion had begun in the last quarter of the nineteenth century.¹⁶ According to Mark Roe, an impor-

Shareholder Activism: A Renaissance

tant feature was legislation enacted in 1940, which, by restricting the power of large financial conglomerates, inadvertently constrained the control of large blockholders in American corporations.¹⁷ By restraining the operations of large blockholders it became possible to not only protect minority shareholders but to facilitate the diversification of US corporate shareholder structures. Influential in the diversification of both UK and US corporate shareholder structures was the mergers-and-acquisitions wave in the first half of the twentieth century. Equity exchanges during mergers and acquisitions furthermore dispersed the ownership of stock in both the UK and the US as the shareholdings of existing investors became diluted.¹⁸

In such a shareholder environment, activist shareholders are seen as those amongst the vast, anonymous shareholder body who actually take an interest in the company's affairs and in monitoring the management, contrary to what an ordinary shareholder would do. Activist shareholders are largely associated with a positive contribution to the business of the company, since they invest time and resources to make informed decisions and to engage in corporate strategy. Mostly, the realization of their plans will depend on the support of larger (p. 391) institutional investors.¹⁹ Recent evidence supports the view that this is indeed happening increasingly. A concrete example is Jana Partners, an activist hedge fund, teaming up with the Ontario Teachers' Pension Plan to bring about change at McGraw-Hill, the education and data company.²⁰ In this case, activist shareholders act as governance intermediaries, actively monitoring company performance and then presenting to companies and institutional investors concrete visions for business strategy. In this scenario, activists can serve to reduce the market's undervaluation of voting rights to the advantage of all shareholders.²¹

2.2 Shareholder Activism: Continental Europe

In contrast, the shareholder structures of continental European corporations (and many other countries of the world) have historically been dominated by blockholders and arguably continue to be so despite an increase in foreign investors. As recently as 2001 it was reported that the shareholder structures of more than 50% of European corporations consisted of a single majority blockholder.²² This contrasted greatly with the shareholder structures of UK and US corporations as they were comprised of less than 3% of blockholders.²³ Today prominent families and large financial institutions remain the majority shareholders of corporations in continental Europe.²⁴ For example, it has been reported that a family blockholder is present on circa 66% of all listed companies in Italy whilst circa 10% of the Borsa Italiana is controlled by a sole Italian family.²⁵ This phenomenon is not only seen in Italy as other countries in continental Europe and beyond are experiencing a similar degree of domination by blockholders in national corporations and stock markets. Take Sweden as an illustration: about 50% of the market capitalization on the Stockholm Stock Exchange is controlled by a single Swedish family—the Wallenbergs—due to their shareholdings in listed companies.²⁶ A small number of very wealthy families are commonly able to exert a high degree of control over corporations in several continental European countries via pyramids, dual class shares, cross shareholdings, and differential voting shares.²⁷ For example, a (p. 392) pyramidal structure can enable a family

Shareholder Activism: A Renaissance

to gain control of a corporation via a small outlay that enables them to establish a chain of ownership relations.²⁸ As an illustration, if a family directly owns 50% of a corporation, which itself has a 50% stake in another corporation the family will indirectly gain a 25% controlling interest in the latter corporation from their initial outlay.²⁹ In the alternative, the industrial success experienced in Germany was attributed in part to a system of cross-shareholdings and interlocking directorates between banks, insurance companies, and institutional firms. This web of mutual participations appears to be eroding in recent years.³⁰ Historically, however, these cross-shareholdings were credited for having protected German companies from hostile takeovers due to the stability of ownership and continuity that they provided.³¹ After the end of World War II, only one out of three relevant public takeovers had succeeded until the trend was broken by the Mannesmann-Vodafone takeover in 1999/2000.³²

It has been argued that this concentration of block ownership of corporations in many countries outside of the US and the UK is directly attributable to a country's corporate governance regime; namely, the notion that a lack of minority shareholder protection leads to a concentration of ownership structures.³³ With a lack of regulatory protection shareholders are often forced to protect their investments by directly exercising control via the ownership of large blocks of shares.³⁴ In summary, it could be argued that the degree of minority shareholder protection given by the prevailing regulatory systems played an instrumental role in the evolution of shareholder structures of corporations in the UK and US vis-à-vis those in continental Europe and beyond.³⁵ The causality aspect of this account is, however, not certain.

In such a business environment of concentrated ownership, shareholder activism necessarily has an entirely different role and meaning than in a dispersed, US/UK style system. One aspect is that other stakeholders carry out the monitoring duties in such countries—typically blockholders, families, or banks (depending on the country). In a stable and solid corporate environment, the symbiotic relationship between company and controller can continue for a long time. Activists are then smaller shareholders who rebel against the controlling shareholder and attempt to bring about change, usually acting or purporting to act on behalf of all other shareholders.³⁶ This differs from the UK/US context, where activists (p. 393) typically understand themselves as advocates of shareholders generally, and the opponent would be the corporate management.

Where a dominant or even controlling shareholder is present, the strategies and tactics pursued by activist shareholders need to be fundamentally different from their US/UK counterparts, and their situation is probably more difficult. They might nevertheless be successful, as the French example shows.³⁷ In other countries like Brazil they are also gaining ground.³⁸ In this context of corporate governance conflict between dominant blockholders and minority shareholders, institutional investors are considered to usefully exploit shareholder activism techniques in order to build an opposition and a counterbalance to controlling shareholders. They thereby strengthen and support the voice and the position of minority shareholders.³⁹

Shareholder Activism: A Renaissance

To illustrate, consider the example of the merger between VW and Porsche, which was proposed in 2009. Both companies were dominated by family and state ownership, and Porsche already owned 53% of VW at the time. Minority shareholder Norges Bank Investment Management was the only investor to voice early concerns, stating that the proposed transactions were “unacceptable” as they “leave the impression of being designed to suit the needs of the Porsche controlling families.”⁴⁰ They also accused VW chairman and Porsche co-owner Ferdinand Piëch of being exposed to heavy conflicts of interest and of violating principles of good corporate governance.⁴¹ Even though the merger was eventually consummated, the example illustrates that “activism” in this context does not simply mean shareholder engagement—rather, it may be understood as a rebellion of minority shareholders against an unrestrained reign by the controllers.

It is important to understand the fundamental differences between types of shareholder activism depending on the shareholder structure and environment. Critics may argue against this distinction, claiming that “shareholder activism” in all situations has a similar structure: the common element is always an initiative against the “controller”—whether the controller is the board (as in the US/UK context) or a dominant shareholder (as in Europe), or both. This perspective overlooks, however, that activism in a controlling shareholder world differs on a number of fundamental points. It is, first of all, more difficult to push (p. 394) through activist initiatives for minority shareholders in a controlled firm, since the “controller” normally has the voting power to sanction the incriminated act or behavior. Second, the minority activist will usually find it more difficult to argue their case, and to show that their own ideas will benefit all shareholders, not just the majority.

2.3 Jurisdictional Influences on Shareholder Activism

By investing in the stock of a corporation, a shareholder risks losing potential returns on their investment should the targeted corporation underperform. Thus, shareholders generally have an interest in ensuring that the economic performance of the company within which they own a share is sustained or, alternatively, improved.⁴² Shareholder activists will often engage in a proactive manner with their targeted companies in order to ensure that strategies are adopted that will generate abnormal returns on their investments.⁴³ However, the extent to which a shareholder activist can exert influence on their targeted corporation is often constrained by the prevailing laws, regulations, and realities of the country within which they are operating. This naturally adds to the complexity of comparing shareholder activism between nations. For example, it has been argued that the right to vote is often one of the most effective modes of activism for shareholders. However with fluctuating threshold requirements at general meetings, the scope for activism by voice is often inherently facilitated or hindered when acting in one nation or another. For example, whilst the UK’s typical voting block lies at circa 10%, this is almost double that required in the US. Continental European countries, on the other hand, require considerably higher thresholds: in France circa 20%, and in Germany up to 57% in certain cases.⁴⁴

The combination of a low voting threshold, recourse to proxy voting by a dispersed shareholder structure, and certain regulatory requirements has unquestionably facilitated shareholder activism in the US and enabled the emergence of adversarial voting against the boards of targeted corporations in comparison to the preference for informal activism in the UK.⁴⁵ In relation to continental Europe it becomes evident that voting patterns of shareholder activists fluctuate greatly from one nation to another. This is predominately due to the governing laws and regulations of European nations. It appears that shareholder activism is more adversarial in nature in nations that offer minority shareholder protection against managerial and controlling shareholder influences.⁴⁶ This is the case in France, Greece, Belgium, and Sweden, where the voting patterns of activists are decidedly confrontational in nature.⁴⁷ In contrast, shareholder activists in Italy and Germany often opt for more subdued activist strategies.⁴⁸ This is particularly so in Germany where shareholder activists have limited room for maneuver due to the historical existence of cross-shareholdings and (p. 395) the presence of employee representatives on supervisory boards irrespective of the trend towards a market-orientated system.⁴⁹ With ownership patterns in Germany shifting, however, hedge-fund activism may find new investment opportunities in Germany too.⁵⁰

In summary, it can be argued that the voting patterns of shareholder activists in continental Europe are influenced by national laws and regulations, shareholder structures, and the existence of control enhancing mechanisms (CEMs).⁵¹ In contrast, whilst the UK's legal and cultural environment supposedly fosters shareholder activism there is relatively little evidence of actual shareholder activism. This could in part be due to the fact that the vast majority of shareholder influence is exerted behind closed doors in the UK.⁵² Informal talks between institutional investors and management are common, supported by a low removal threshold of corporate directors.⁵³ The US market, however, remains at the forefront of activist engagement and has experienced the greatest volume of successful shareholder activism to date.

3 Historical Development of Shareholder Activism

A close nexus between stock-market trading and corporate ownership was originally established during the Gilded Age and the takeover wave of the 1980s in the US.⁵⁴ In considering the historical development of shareholder activism, it is beneficial to take into consideration the impact that regulation and ownership structures had on the development of shareholder activism, in addition to the evolution of shareholder activism from its origins in the US stock market to subsequent developments seen elsewhere.

(p. 396) 3.1 Impact of Regulation on the Development of Shareholder Activism

The enactment of regulation by lawmakers and market conditions have often had a twofold impact on shareholder activism; namely either acting as a deterrent, by, for example, erecting obstacles with the purpose of hindering investors from gaining majority holdings in companies, or alternatively facilitating shareholder activism, by for example deregulating fixed commission rates and thus increasing the incentives for fund managers to maximize returns for investors. If one takes the US as an illustration, it becomes evident that regulations have often been enacted in response to developments on the stock market.⁵⁵ For example, the Buttonwood Agreement of 1792⁵⁶ was a response to a market crash at the time and the virtual cessation of credit, trading, and liquidity. The agreement itself set minimum stockbroking commissions and was in force until the 1970s upon which commission rates became fully negotiable as fixed commission rates were abolished completely.⁵⁷ It has been argued that a combination of the deregulation and the technological advances at the time, such as the arrival of the personal computer, facilitated the ease in which stocks were traded on the stock market for the first time.⁵⁸

The enactment of the Glass-Steagall Act in 1933⁵⁹ was furthermore a response to market events and in this particular case a direct response to the 1929 stock market crash, a nationwide commercial bank failure, and the Great Depression. The Act itself led to a clear demarcation between the activities of investment and commercial banking as it was considered that the overzealous investment strategies of commercial banks were directly responsible for the 1929 stock market crash. In particular, it has been argued that the Glass-Steagall Act contributed towards a rapid decline in shareholder activism.⁶⁰ However, subsequent legislation such as codification of shareholder entitlement by the Securities and Exchange Commission (SEC) in 1942 yet again facilitated shareholder activism. This instance marked the advent of the first shareholder proposal rule.⁶¹ The rule enabled shareholders to submit proposals for vote at (annual) general meetings and facilitated the predominant means by which shareholders could actively participate in postwar company life. The rationale behind the rule, as stated by Commissioner O'Brian in 1943, was to reincarnate the widely attended meetings that were characteristic of the times when companies were geographically limited and locally owned.⁶² The rule arguably paved the way for shareholder engagement and (p. 397) activism, which is illustrated by the fact that a mere 50 proposals were recorded annually in the 1940s whilst an average of 220 proposals were recorded by 1969, and circa 650 proposals were recorded annually by 1979.⁶³

The abolition of the Glass-Steagall Act in 1999 and subsequent deregulations played a prolific role in fuelling competition in the American financial landscape and arguably triggered an increase in the exploitation of investment banking opportunities by, inter alia, engaging in risk-averse investment strategies during mergers and acquisitions.⁶⁴ However, the Bull Market of the late 1980s and early 1990s saw a downturn in shareholder activism as investors took a step back and relied on the gadflies to uphold shareholder rights.⁶⁵ Nevertheless, subsequent financial disasters, such as those seen at Enron and

Shareholder Activism: A Renaissance

Tyco, in addition to the credit bubble of the mid-2000s, presented the ideal platform for a re-emergence of shareholder activism as hedge funds took center stage.⁶⁶ With an availability of cheap debt, market conditions were ripe for activists to lobby their targeted corporations for the distribution of cash to shareholders or for the sale of the corporation itself.⁶⁷ Paradoxically, the financial crisis that plagued the recent global economy from 2007 to 2011 marked the most recent downturn in shareholder activism.

3.2 Impact of Ownership Structures on the Development of Shareholder Activism

As mentioned above, the shareholder structures of most corporations in the UK and the US are widely dispersed, whilst those of continental European corporations are dominated mostly by blockholders. If one takes the UK as an illustration, it becomes apparent that a dispersed ownership structure and an emergence of shareholder activism were in essence driven by policy. In contrast, when considering Germany and the structure of the “Germany Inc.” it becomes evident that the domination of blockholders on the shareholder structures of corporations fuelled shareholder activism as minority shareholders rebelled against their controlling influence.

In the first instance, as opined by Brian Cheffins, the dispersion of ownership in England only emerged after World War II as families began to unwind their controlling stakes in companies to benefit, inter alia, from tax incentives that favored diversification and the managerial revolution.⁶⁸ Furthermore, it was the legal reforms that were enshrined in the Companies Act of 1948⁶⁹ that gave minority shareholders a voice for the first time in the (p. 398) UK. However, despite being relatively groundbreaking in nature as they represented the first statutory remedy for shareholders in England, they proved relatively inadequate in reality.⁷⁰ Lord Hoffman shed further light on the matter by stating that it was not until 1980 that Parliament gave the unfairly treated minority shareholder the power to “slay the dragon” by passing into law the “unfair prejudice” remedy, which is now found in section 994 of the Companies Act 2006.⁷¹ Thus, despite reforms occurring in 1948 it was only in 1980 that minority shareholders finally gained a voice in the UK stock market. For various reasons, however, they did not take up the legal instruments that were available to them. The “unfair prejudice” remedy ultimately only really applies to small, quasi-partnership companies, and is unsuitable for large public companies.⁷² The other minority shareholder activism tool, the derivative claim, suffered a setback in the famous case of *Prudential Assurance v. Newman Industries Ltd*, the only reported case where a UK institutional investor brought a derivative suit against directors of a portfolio company.⁷³ Despite the recent codification and extension of this remedy in the 2006 Act,⁷⁴ it has not gained great prominence for activist investors to date.

So in sum, although shareholder rights became enforceable by law, many investors, and especially institutional investors, were cautious about engaging in activism. This was also due to fears of either being found guilty of market abuse because of potentially being privy to insider information or being considered to be acting in concert within the definition of the City Code on Takeovers and Mergers.⁷⁵ As such, activism per se did not really

Shareholder Activism: A Renaissance

materialize in full until the UK's 2008 banking crisis led to a call on institutional investors to take a more proactive approach in the enforcement of corporate governance. Consequently, shareholder activists began to gain a reputation for overcoming apathy and actively engaging in the strategies of their targeted corporations.

In the second instance, the ownership structure of the "Germany AG," which was characterized by a concentration of ownership due to extensive cross-shareholding networks, and long-term relational financial ties between banks, insurance companies, and (p. 399) institutional firms, guaranteed not only ownership stability and continuity but also acted as a shield against hostile takeovers.⁷⁶ With blockholders dominating the shareholder community and, to a degree, the supervisory board, minority shareholders were left with no other option but to engage in activism in order to maximize the returns on their investments. In any case, the abolishment of the capital gains tax on the sale of cross-shareholdings in early 2002 marked a pivotal change in Germany's former low-liquidity insider market.⁷⁷ The removal of capital gains tax on the sale of cross-shareholdings opened the floodgates to foreign investors who had previously only held circa 18% of German stocks.⁷⁸ As foreign investors arrived on the German market so too did shareholder activists. This pivotal change undermined the ownership networks that had shielded German corporations from takeovers for decades. Out of the three relevant public takeovers that had taken place after the end of World War II only one was a success until Vodafone's acquisition of Mannesmann.⁷⁹

In summary, it becomes evident that regulatory changes have not only been influential on the extent of shareholder activism but that developments in global markets and ownership structures have played an equally influential role on the commonality of shareholder activism.

3.3 Origins and Evolution of Shareholder Activists

As mentioned above, a close nexus between corporate ownership and stock-market trading was first established during the Gilded Age and the takeover wave of the 1980s in the US. The Gilded Age and the 1980s became synonymous with corporate raiders buying shares to gain control of their targeted corporations. However, the primary goal of gaining control of their targeted corporations was not in pursuit of making returns from the corporation's operational profits but to raise the firm's listed value to maximize the returns as shares were subsequently sold at peak prices.⁸⁰ Buying or selling businesses, or threatening to do so, became more lucrative than actually running a company, and consequently led to the takeover wave of the 1980s.

(p. 400) 3.3.1 Corporate Raiders and the Takeover Wave of the 1980s

The takeover wave of the 1980s was characterized by daring takeover bids that were engineered by corporate raiders on the basis of aggressive and innovative financial techniques.⁸¹ An activist cohort subsequently established itself in the US which specifically targeted underperforming corporations in the hope of improving operational performance before exiting. Amongst others, the operating performance of a targeted corporation was

Shareholder Activism: A Renaissance

often improved by initiating changes to the firm's strategy. The cohort included renowned raiders such as Carl Icahn, the Bass Brothers, and Coniston Partners. However, despite their apparent success, it remains undisputed that the purchase of these shareholdings was financed predominately out of debt with limited equity which generated short-term gains and left no company safe from a hostile bid.⁸² In consequence of their aggressive strategies, opposition to corporate raiders soon mounted, not only on the part of the targeted corporations themselves via the implementation of defense strategies but also on the part of the government, which took action to protect the interests of targeted corporations. Although takeover defense strategies became plentiful the most successful was colloquially known as the "poison pill" defense. The "poison pill" defense was developed by Martin Lipton, a New York attorney, in order to help El Paso Co. fend off a hostile takeover bid.⁸³ The "poison pill" as a takeover defense strategy can either come in the form of a flip-in or flip-over but fundamentally consists of a strategy whereby the target corporation attempts to reduce the value of or dilute its stock in order to ward off a hostile bid.⁸⁴

The 1980s also marked the re-emergence of institutional shareholder activism as pension funds, mutual funds, insurance companies, and managed trust funds submitted proposals and forced management boards to reform, inter alia, executive remuneration packages and defense strategies against threats of takeover.⁸⁵ These strategies were dramatic in nature and a far cry from previous engagements which had consisted of the strategy of "voting with their feet."

3.3.2 Institutional Investors

The rapid growth of institutional investors in the 1980s was primarily in response to an increased proportion of household savings being invested directly in equity and corporate bonds via private-funded pension schemes and life-insurance policies as the longevity of the aging population increased.⁸⁶ Larger portfolios meant that many institutional investors (p. 401) could no longer dispose of large blocks of stock on the market at any one time and were thus forced to alter their strategies from one centered on exit to one that advocated activist engagement in pursuit of profit maximization.⁸⁷ Additionally, the disposal of large stocks on the market at any one time was no longer an option as it risked triggering sharp falls in stock valuation, a market crash, and a probable reduction in the value of portfolios.⁸⁸

Although the rapid growth and subsequent increase in institutional investor portfolios forced investment strategies to be altered, the rise of institutional shareholder activism in the UK was predominantly driven by policy. Policy makers in the UK were the driving force in advocating that institutional shareholders engage in activism in response to wider corporate governance concerns and the social good.⁸⁹ The policy-led drive for activism in the UK was more in keeping with a shareholder's responsibility and accountability to the market at large as opposed to promoting investment strategies tailored towards profit maximization. Scholars such as Christoph van der Elst further argue that this policy-led drive for activism in pursuit of greater corporate governance was also widespread in continental Europe and was subsequently embodied in regulations and corporate gov-

Shareholder Activism: A Renaissance

ernance codes.⁹⁰ It is argued that institutional investors are best placed to enforce corporate governance as, unlike individual investors, they are operating within a professional capacity and thus have the necessary expertise to manage the investment funds within their portfolios.⁹¹ Irrespective of the origins in the surge of activist engagements, it should be noted that institutional investors are often constrained in their ability to partake in shareholder activism due to their own conflicts of interests.

Conflicts of interests usually derive from the business relationships between the target corporation and the institutional investor, which often compels the latter to concur with management even if this were to conflict with their fiduciary duties.⁹² As an illustration, a US mutual fund that is associated with a financial institution may err on the side of caution when engaging in shareholder activism so as not to jeopardize the business relationships between present or future clients of their parent company.⁹³ In other words, it has been argued that conflicts of interests arise between banks and insurance companies due to their day-to-day business dealings with corporate management, between private pension funds and their governing corporate managers, and with public pension funds due to external political influences.⁹⁴

In summary, the extent to which institutional investors engage in shareholder activism, and thus utilize the power granted to them by laws and regulations, is constrained by the (p. 402) eventual occurrence of conflicts of interests.⁹⁵ Nevertheless, despite the affect a potential conflict of interest may have on the degree of activist engagement, institutional investors still represent one of the largest forms of shareholders in the US, having increased their shareholdings in US equities from a mere 10% in 1953 to over 70% in 2006.⁹⁶ In comparison, the size of institutional shareholdings in European corporations tends to fluctuate from circa 80% in the UK to 20% in Italy, with Germany and France experiencing shareholdings of up to 30% and 60% respectively.⁹⁷

3.3.3 Hedge Funds

Nearly two decades after corporate raiders dominated stock markets, hedge funds began to re-emerge, filling the gap that had been left by institutional investors due to their concerns over conflicts of interests and regulatory constraints.⁹⁸ Despite re-emerging in the 1990s it was only in the twenty-first century that hedge funds took center stage as shareholder activists.⁹⁹ Their ability to take the stock market by storm with over \$1 trillion under management, a cutting-edge investment strategy which centered on corporate activism, and a cut-throat “do what it takes” mentality were arguably in part a result of their organizational structure and the subsequent lack of regulation governing their operations.¹⁰⁰

By comparing hedge funds with institutional investors it is possible to shed some light on their unique business structure that has enabled them to pursue a strategy of corporate activism away from the prying eyes of the public and policy makers. Although hedge funds are commonly managed from the US or the UK, they are typically incorporated in offshore jurisdictions and are thus subjected to a minimal degree of public oversight and regulation.¹⁰¹ An intrinsic lack of regulation and public oversight has enabled hedge

Shareholder Activism: A Renaissance

funds to increase their market power whilst diversifying their risks by benefiting, *inter alia*, from derivatives and high levels of leverage.¹⁰² Furthermore, unlike institutional investors, hedge funds are not constrained by potential and/or actual conflicts of interests in pursuing their investment strategies. This is predominately due to the fact that they avoid investing in large entities where wider interests can often conflict with a duty towards their investors.¹⁰³ By (p. 403) rather opting to invest in corporations that enable them to make trading-induced profits with a quick turnaround, hedge funds do not run the risk of being confronted with potential conflicts of interest.¹⁰⁴ Targeted corporations are subsequently undervalued, presenting the ideal opportunity for profit maximization via shareholder activism.

Their often aggressive tactics in the pursuit of profit maximization in the short term can be attributed to the performance-based compensation schemes for hedge fund managers which contrast greatly with the fixed compensation fees earned by institutional investors.¹⁰⁵ This compensation scheme typically comprises of an annual fixed fee that ranges from 1–2% of portfolio assets in addition to a performance-based fee ranging from 15–25% of the profits earned annually.¹⁰⁶ This arguably aligns the interests of fund managers and investors in generating maximum returns on investments. Thus, shareholder activism is purely an element of a hedge fund's investment strategy as opposed to the concurrent enforcement of corporate governance that is pursued by many other institutional investors today.¹⁰⁷

As such, markets fully anticipate that the engagement by a hedge fund in a targeted corporation will undoubtedly lead to an improvement in the target's operational performance.¹⁰⁸ It is therefore common to witness steep increases in stock prices as hedge funds make their initial stock purchase in the target. New empirical data from the US and Europe illustrate that hedge fund engagement mostly involves advantages for other shareholders. According to these studies, the initial investment decision by an activist hedge fund is usually related to a substantial increase in their returns.¹⁰⁹ These increased returns are apparently a consequence of real improvements and reliable profits, and not a mere redistribution to the detriment of debtholders and other stakeholders.¹¹⁰ Further, the holding periods of hedge funds are much longer than previously anticipated.¹¹¹

These positive effects for the shareholders of a company in which a hedge fund invests need to be distinguished from the question of whether a hedge fund brings profit for its own (p. 404) investors.¹¹² However, empirical evidence from 2007 indicated that hedge funds make absolute returns from circa 5–7% on the initial share price after commencing activism in the US, whilst further empirical evidence from 2008 indicated that hedge funds make absolute returns of circa 12% for the duration of a two-to-three-year period following activist engagement.¹¹³ Of interest here is that these empirical studies did not have access to the private databases of their sample and relied solely on publically available information in reaching their conclusions.¹¹⁴ By contrast, another empirical study from 2008 was conducted with full access to the sample hedge fund's private database, including the fund's trades and asset values, and concluded that a dependence on public information alone would have omitted approximately 12 out of a total of 30 engagement

cases.¹¹⁵ This is a clear illustration of the intrinsic lack of publicly available information on activist engagements by hedge funds and the secretive manner in which they protect their engagements. However, having been accountable for up to half of the daily activity on the New York Stock Exchange (NYSE) and the London Stock Exchange (LSE) in 2005 alone, it is likely that they will remain an important and controversial feature in stock markets for some time to come.¹¹⁶

Regulatory strategies following the financial crisis target hedge funds in particular.¹¹⁷ It is notable, however, that none of these new regulatory instruments target the implications of hedge fund activity for the functioning of traditional corporate governance mechanisms. It is clear that hedge funds' sophistication in exploiting the traditional categories and tools of corporate governance poses significant challenges for regulators and lawmakers.¹¹⁸ For example, the European AIFM Directive and the US Dodd-Frank Act limit themselves to certain rules on the supervision of hedge fund managers, and do not pursue an activities-based approach.¹¹⁹

3.3.4 Private Equity Funds

The twenty-first century also marked the emergence of private equity funds which have frequently been compared with hedge funds due to their innate similarities. Nevertheless, despite their concurrent reputations for activist engagement and similar remuneration structures for fund managers, they arguably deploy different investment strategies. As opposed to the short-term investment strategies of hedge funds, private equity funds will typically focus on long-term investments which are innate to closed-end funds. Investments (p. 405) of a closed-end fund in targeted corporations will usually last five years, at which point in time the fund will exit passing the proceeds to their investors.¹²⁰ Adopting a long-term investment strategy with a corporation arguably implies that a private equity fund will be inclined to adopt a "hands-on approach" with the board as they are of the opinion that this method is the most effective in generating value before the firm is either sold or rejoins the market.¹²¹ This contrasts greatly with the strategies deployed by hedge funds as they typically avoid majority or sole ownership, preferring to reap rewards as minority shareholders.¹²² With a long-term outlook, it is more common for private equity funds to actively engage in the strategy and management of their targets; an engagement policy which is argued to be pivotal in generating shareholder wealth and enabling a fund to exit with profit.¹²³ A study conducted by Acharya and co-authors revealed that private equity funds play an active role in the strategy of the targeted firm, with 89% of interviewees citing value creation and 56% of interviewees citing exit as their principal priorities.¹²⁴

4 Methods of Shareholder Activism

From the offset of the 1980s shareholder activists have been playing the market instead of carefully protecting the value of their holdings.¹²⁵ By operating under a common set of assumptions, namely public information and commercial consensus, investors are able to strike bargains by purchasing undervalued shares which they subsequently sell at abnor-

mal prices after having improved the operational performance of their targeted corporation.¹²⁶

It was traditionally viewed that shareholders turned to activism when they were dissatisfied with the management or the operational performance of the targeted corporation by commonly opting to vote with their feet by exit. However, the modern-day approach witnesses the purchase of shares in the hope of generating short-term gains via activist engagement.¹²⁷

But what techniques do activists use? Empirical evidence in the US suggests that activism (in particular by hedge funds) encompasses a wide range of activities, from the subtle pressure on the incumbents through letters, other communications, and meetings to the requisition of a shareholder meeting, possibly involving the drama of a management change, or the commencement of litigation or a takeover bid from the activist.¹²⁸ Practitioners report (p. 406) an even more diverse set of tactics.¹²⁹ Recognizing that activism involves an evolutionary decision-making behavior, researchers have provided empirical evidence on activism in the US by modelling activism as involving four distinct phases: demand negotiations, board representation, threat of proxy fight, and proxy contest.¹³⁰

4.1 “Voting with the Feet”

“Voting with the feet” or the “Wall Street Rule” is a traditional form of shareholder activism whereby activists opt to sell their stock rather than partaking in often costly and futile efforts of reform in pursuit of increasing the value of their investments.¹³¹ It is worth bearing in mind that this passive approach to activism used to be rooted in the respect of traditional values as opined by Brian Cheffins. Cheffins argues that this traditional method of activism was nestled in the Chandelarian exhortation which first and foremost respects the managerial revolution and thus leads to the unquestionable acceptance of managerial power on the boards of companies.¹³² However, in today’s economy this method of exit can be both complex and costly for an activist. An increase in the size of shareholdings, especially in relation to those held by institutional investors, has rendered this form of activism more hazardous due to the risks posed by disposing of large volumes of stock on the equity markets at any one time. The risks can be threefold in nature, triggering a sharp fall in the valuation of the stock, a stock market crash, or a reduction in the overall value of the investor’s portfolio.¹³³ However, institutional investors aside, it can be argued that modern-day activists generally acquire small quantities of stock in a targeted corporation to minimize their risk exposure and remain anonymous to management boards by not exceeding the thresholds that trigger disclosure obligations.¹³⁴

4.2 Purchase of Stock

The present trend to purchase small quantities of stock enables shareholder activists to seek not only the most opportune moment for action but also support from other activist investors before striking with an element of surprise to gain the upper hand in communi-

cations with the targeted corporation. This strategy often improves the success rate of their (p. 407) interventions as, on the one hand, targeted corporations are by default left with a limited time period within which to prepare defense strategies. On the other hand, the shareholder activist can carefully select support from fellow activist investors whilst mitigating the likelihood of freeriding. A case in point was Knight Vinke's target of HSBC in 2007. Knight Vinke was able to target HSBC with a shareholding of less than 1% via the use of informal methods of activism. In the first instance, Knight Vinke wrote to HSBC in 2007 asking the board for, inter alia, an independent non-executive Chairman and an in-depth review of its strategy and management structure. These demands were reiterated in 2008 in a letter signed by not only Knight Vinke but also six of the world's largest institutional investors that had by then amassed shareholdings in HSBC. HSBC responded publically to the second letter stating that the majority of demands had already been met and took further steps to, inter alia, replace almost a third of the non-executive board members whilst selling part of their non-core banking network. This was arguably a success for an activist with a minority holding that deployed informal methods of activism, but it is worth bearing in mind that little evidence is commonly available on private negotiations between shareholders and companies as and when they actually occur.¹³⁵ An exception to this is the clinical study¹³⁶ of the Hermes UK Focus Fund where the authors were granted access to the fund's private databases and were able to ascertain that focused engagements with the support of other institutional investors, on private meetings and letters, etc., generated substantial returns on investments and especially so when changes to the structure of the board and the target's strategy were demanded.¹³⁷ Had the authors relied on public information alone they would have been unaware of at least 12 out of the 30 reported engagement cases.¹³⁸ A further study,¹³⁹ which compared positive abnormal returns between public and private interventions, concluded that private interventions generated higher returns than those conducted in the public domain but were also more expensive to run.¹⁴⁰ Accordingly, "voice" and participation at annual general meetings are often a popular strategy for activist engagement.

4.3 "Voice"

"Voice" is arguably one of the most common methods of shareholder activism and as such has often been cited as a distinguishing feature of shareholder activism. Shareholder activists are commonly referred to as investors who via voice aim to alter the status quo of a targeted corporation without altering the manner in which the firm is controlled.¹⁴¹ The activist method of "voice" itself encompasses a broad spectrum of activities including shareholder proposals, proxy contests, influencing the strategy of targeted corporations, and voting at shareholder (p. 408) meetings. A shareholder activist will attempt to persuade the management board of their targeted corporation to pursue certain strategies via the private communication of information in the hope that this will enable returns on investments to be maximized.¹⁴² However, the effectiveness of the use of "voice" as a method of shareholder activism is dependent on the degree of publicity used and the credibility of the actual message.¹⁴³ For example, Apple recently bowed to renewed pressure from CalPERS for shareholders to have a greater say on the election of directors.¹⁴⁴

Shareholder Activism: A Renaissance

It is interesting to note that in pursuit of a drive to hold management boards to account for their actions CalPERS has convinced a total of 77 large US corporations to implement majority voting in the last two years alone, and is currently targeting a total of 17 corporations that are holding out.¹⁴⁵ This clearly highlights the effectiveness of a credible and public message in instigating desired changes in a targeted corporation. However, it is also worth bearing in mind that the legal environment within which a shareholder activist operates can also play a pivotal role in facilitating or restraining their recourse to “voice.” This is particularly so in relation to their ability to vote on certain matters at the general meeting.

The participation of shareholder activists at annual and other general meetings is historically low in Europe and highly dependent on regulatory constraints pertaining, *inter alia*, to conflicts of interest, national and cross-border proxy voting, and the separation of ownership.¹⁴⁶ In contrast, the US has always experienced a considerably higher degree of participation despite the existence of legal barriers. For example, although shareholder engagement at general meetings was facilitated in the UK under the Companies Act of 2006, investors continued to refrain from intervening in the management of large corporations as they believed that it was neither their role nor their duty to do so.¹⁴⁷ It was only following the call on investors to take a more active role in enforcing corporate governance after the 2008 banking crisis that shareholders began to actively engage with management in the UK. In contrast, the legal environment in the US established numerous barriers for shareholder activists that sought to actively influence the management board of targeted corporations by “voice.”¹⁴⁸ For example, despite the fact that the former proxy regulation Rule 14a-8 enabled a selection of shareholder proposals, it neither allowed director nominations nor objections to be made against management’s proposals—arguably impeding the influence of shareholder activists.¹⁴⁹ Nevertheless, despite the presence of these former barriers, activist engagements still became an inherent part of corporate governance in the US.¹⁵⁰ This is illustrated by the fact that attendance at annual general meetings reached 87% in 2006 and 79% in 2010, considerably higher than that seen in Germany, or the UK for that matter (respectively 60% and 68% in 2010).¹⁵¹ Many have argued that the rationale behind the higher turnout at shareholder meetings in the US in comparison with that experienced (p. 409) in Europe hinges on the widespread recourse to proxy voting by the dispersed shareholder base in the US.¹⁵²

4.4 Litigation

Litigation is often considered to be the last resort for a shareholder activist due to its unpredictable nature and the fact that it rarely leads to immediate results. Not only does its use hinge on the substantive laws and regulations of the jurisdiction within which a shareholder activist is operating, but a shareholder activist will also have recourse to different forms of litigation dependent on where they are operating. For example, litigation can include the pursuit of damages against the directors of targeted corporations, injunctive relief for the enforcement of inquiry requests, the contestation of resolutions passed at general meetings, or derivative actions whereby the shareholder activist brings an action on behalf of the targeted corporation in order to uphold the firm’s rights if the direc-

tors cannot or will not enforce them.¹⁵³ As an illustration, in contesting resolutions made at general meetings, actions are often brought in the name of the actual shareholder in Germany, whereas shareholder activists have typically used legal loopholes to sue in France.¹⁵⁴ Nevertheless, although shareholders have the ability to bring a civil action on behalf of the company against a director (or against a third party) in the UK, shareholders rarely do so and the courts have the ultimate right to refuse the claim in any case. For example, the abandoned Equitable Life litigation is illustrative of the hurdles that are faced in reality when seeking legal redress for acts that amount to a director's legal breach of their duties in the UK.¹⁵⁵ Despite the varying use of litigation in Europe, full proxy fights and threats to litigate are commonly used by shareholder activists in the US. This is particularly true of hedge funds operating in the US, as they commonly have the financial means to pursue the matter to the end should they wish to do so. In light of this, corporations in the US will more often than not concede to the demands of hedge funds before class actions and less common derivative actions are even made.¹⁵⁶

In summary, it is clear that shareholder activists engage in various methods of activism in pursuit of realizing their ultimate goal of profit maximization. However, the prevailing regulatory regimes can often facilitate or hinder their activist strategies. It is common for targeted corporations opting to ignore activist demands to receive negative press. These firms are often relegated on governance ratings whilst their directors diminish their chances for re-election.¹⁵⁷

(p. 410) 5 Regulatory Constraints

The announcement by BNP Paribas in August 2007 that it would cease the activities of three hedge funds specializing in US mortgage debt and the subsequent bankruptcy of Lehman Brothers in September 2008 not only marked the commencement of the most far-reaching crisis to hit the global economy since the Great Depression but also saw calls for greater regulation and government intervention.¹⁵⁸

However, it has been argued that no single entity can collate all the requisite information in order to draft rules that would be adequately binding for all.¹⁵⁹ If one takes the UK as an illustrative example, it becomes evident that it is a combination of both legal obligations which are derived from, amongst others, the Companies Act 2006,¹⁶⁰ the Criminal Justice Act 1993,¹⁶¹ the Financial Service and Markets Act 2000,¹⁶² and industry benchmarks for best practices which are embodied in the UK Corporate Governance Code¹⁶³ and the Stewardship Code,¹⁶⁴ that govern the activities of investors today. As the current most prominent regulatory constraints on shareholder activism concern proxy access, acting in concert, and insider dealing, these will form the focus of this section of the chapter.

5.1 Proxy Access

Shareholder activism through the proxy process has always been subject to considerable debate amongst regulators and academics. On the one hand, it is argued that proxy access is an inherent right of shareholders and places them in a better position to monitor the performance of corporations and corporate governance. On the other hand, it is argued that by giving shareholders greater access to the boards of corporations they will pursue changes for personal benefit at the cost of the firm's long-term future. Additionally, the laws and regulations that govern proxy access by shareholders vary considerably from one nation to another often constraining their use by activists.

Although the majority of European jurisdictions recognize the benefits of affording minority shareholders rights to protect their interests, the laws and regulations governing proxy access remain stringent when compared to those that are currently in place in the US.¹⁶⁵ For example, in the UK, under the Companies Act 2006, shareholders may submit proposals (p. 411) for vote at general meetings provided they own at least 5% of the corporation's issued stock, whilst ownership of 5% of the corporation's stock also enables shareholders to requisition an extraordinary shareholder meeting and propose their own nominees to the board.¹⁶⁶ The situation is similar in Germany where the German Stock Corporation Act¹⁶⁷ decrees that new agenda items and extraordinary meetings can be demanded by shareholders that own at least 5% of the corporation's voting capital.¹⁶⁸ Therefore, it would appear that shareholders in the UK and Germany, amongst other European nations, are in a strong position to engage in activism if they are of the opinion that the boards of their targeted corporations are not addressing their concerns in an adequate manner.¹⁶⁹ Nevertheless, the logistics of national and cross-border proxy voting and the ability to meet quorum requirements have often acted as a barrier to the use of the proxy process by activists in Europe. According to Manifest, with the increased dispersion of ownership in Europe and an unduly cumbersome system of proxy voting due to the need for cross-border chains of intermediaries, the ability to vote and satisfy quorum requirements became both time-consuming and prone to errors.¹⁷⁰ The July 2007 Shareholder Rights Directive was designed to remove these hurdles to the proxy process for shareholders by facilitating the exercise of basic shareholders' rights and enabling national and cross-border proxy voting.¹⁷¹ The Directive, in essence, provides shareholders with the tools needed to not only monitor management boards but also to facilitate their involvement in the corporation's activities via, inter alia, advanced access to information ahead of general meetings.¹⁷²

By comparison, the current situation in the US is arguably more conducive to the submission of proxy proposals by shareholders at general or annual general meetings. However, this has not always been the case as significant barriers used to exist for shareholders seeking proxy access, for example, to monitor the performance of the board of a company in the US. In particular, as mentioned, the former proxy regulation Rule 14a-8 on the submission of proxy proposals by shareholders excluded areas of fundamental importance such as the ability to make director nominations.¹⁷³ The recent economic crisis and subsequent calls for (p. 412) greater accountability of corporate boards by, for example, the

Shareholder Activism: A Renaissance

Dodd-Frank Act¹⁷⁴ led to the SEC's proposal of rules that would enable shareholders with access to the proxy statements of companies to nominate directors. The proposals were subsequently enacted under Rule 14a-11 permitting shareholders, satisfying certain requirements, to include director nominees on the proxy materials of a corporation that are distributed to shareholders.¹⁷⁵ Further amendments were also made to Rule 14a-8(i)(8) in narrowing the types of shareholder proposals that could be excluded under the "election exclusion." The rationale behind the amendments lay in the need to empower shareholders to hold boards to account for their actions by, inter alia, facilitating communication between shareholders in the proxy process and improving corporate suffrage.¹⁷⁶

A study on shareholder activism through the proxy process found that proxy proposals were generally targeted at underperforming corporations and/or those with a poor governance structure.¹⁷⁷ Specifically, the authors ascertained that it was more likely for proposals to be submitted against corporations that have ineffective and entrenched CEOs and management that lacks the incentive to act in the best interests of the firm.¹⁷⁸ This conclusion was supported by the fact that out of their sample the majority of proposals made were in relation to takeovers, the removal of the management board, and poison pills.¹⁷⁹ However, it is worth noting that the sample period ranged from 1996 to 2005 and thus occurred during the time when greater regulatory constraints existed on proxy access.

5.2 Acting in Concert

Cooperation between shareholders is not uncommon if one considers that a shareholder activist will usually hold a minority shareholding and will thus commonly hold insufficient stock to realize their goals.¹⁸⁰ However, a greater degree of strategic care is currently required not to fall foul of the laws and regulations that govern acting in concert, which could in certain jurisdictions even risk triggering a mandatory bid for the targeted corporation.

In Europe, the Directive on Takeover Bids defines acting in concert as cooperating under the guise of an agreement with the offeror or the offeree corporation to either acquire control of the offeree corporation or hinder the bid that has been made.¹⁸¹ Under the rules of the Directive, those found to be acting in concert are required to make a mandatory offer to the (p. 413) other shareholders of the targeted corporation if together they surpass a "control" threshold, usually fixed at about 30% of the voting rights.¹⁸² The same concept of acting in concert is also relevant for the block disclosure rules under the EU Transparency Directive.¹⁸³ Depending on the context and depending on the jurisdiction, the precise definition of "acting in concert" has been implemented in different ways.¹⁸⁴ The resulting legal uncertainty has prompted the European Securities and Markets Authority (ESMA), on the request of the European Commission, to publish a White List of "innocent" activities.¹⁸⁵ The concept of "acting in concert" and its divergent interpretations may chill shareholder activism, a development which policy makers may or may not welcome.¹⁸⁶

Shareholder Activism: A Renaissance

The situation is slightly more complex in the US where there are numerous barriers to prevent acting in concert.¹⁸⁷ For example, section 13(d) of the Exchange Act¹⁸⁸ requires a shareholder or group owning more than 5% of a listed company's shares to file a "Schedule 13D" publicly. A "Schedule 13D" discloses all parties involved in addition to their intended aims in relation to the targeted corporation. However, it was recently clarified that shareholders are able to communicate, plan, and even act together to effect policy changes without disclosing their affiliation under section 13(d) of the Exchange Act.¹⁸⁹ It is only on the grounds of acquiring, holding, voting, or disposing of their shareholdings that they must disclose their group arrangement in a Schedule 13D filing.¹⁹⁰

The above clearly outlines the complexity of acting in concert and the restricting effect it can have on activist engagement. It should, however, be noted that the fundamental aim behind the laws and regulations on acting in concert is to protect the interests of minority shareholders by granting them the right to exit on fair terms when the controlling shareholders change.¹⁹¹

5.3 Market Abuse and Insider Dealing

Many of the activities that activists are pursuing touch on the limits of legally permissible market behavior. For example, in circumstances in which the activist shareholder has engaged in previous communication with the target company's board, it is possible that inside (p. 414) information has been divulged, which would restrict the shareholder from being able to deal in the company's shares. Moreover, in some instances it is possible that the actual strategy being pursued by the activist shareholder is itself inside information, thus requiring disclosure to the market as a whole.

Insider dealing not only risks undermining the shareholder voting process but also has negative repercussions on timing paramount for the proper functioning of the stock markets.¹⁹² By trading on inside information, investors are selling and buying at the most opportune moment in time but are breaching their fiduciary duty or other relationship of trust and confidence whilst they are in possession of stock information that is not publicly available. These actions ultimately undermine confidence in the integrity and fairness of stock markets.¹⁹³

In establishing the cause of the 1929 financial crash, US Congress ascertained that widespread insider dealing had played a pivotal role and so enacted the Securities Exchange Act of 1934 with the principle aim of deterring unfair transactions.¹⁹⁴ With an increase in corporate takeovers and coincidental abuses of cash tender offers, the Williams Act of 1968 was passed to make full and fair disclosure a mandatory requirement. This legislation ultimately enabled the SEC to fine and prosecute offenders like the corporate raider Ivan Boesky. Ivan Boesky was fined \$100 million in 1986 for having launched takeover bids on the basis of information that was obtained illegally. By acting on inside information, Ivan Boesky was able to purchase stock in his targeted corporations before his takeover bid went public.¹⁹⁵ This enabled him to reap rewards as the stock's value subsequently rose. The proactive approach taken to tackle insider dealing in the US was not

mirrored by legislators in the UK, as it was only in 1980 that insider dealing became a criminal offence there.

In the UK, dealing on insider information was considered legitimate and widespread until the late 1950s when it began to be considered an unethical practice. Nevertheless, the practice was as widespread as ever in the 1960s and 1970s and was even being depicted as the crime of being something in the City by the Financial Editor of The Sunday Times in 1973.¹⁹⁶ It was only in 1980 that insider trading became a criminal offence in the UK and is currently enforceable under the Criminal Justice Act 1993.¹⁹⁷ However, as cases are rarely prosecuted (p. 415) under this Act, the Financial Service and Markets Act 2000¹⁹⁸ subsequently came into force, giving the FSA wide-ranging powers to prosecute offenders for insider dealing.¹⁹⁹ Insider dealing has been subject to European regulation since the 2003 Market Abuse Directive.²⁰⁰

With the identities of shareholder activists constantly evolving, hedge funds have recently become a focal point for regulators in many jurisdictions as the inherent nature of their operations often makes them vulnerable to involvement in market abuse, advertently or inadvertently.²⁰¹ As pointed out by a former Chairman of the SEC, William H. Donaldson, hedge funds present a unique challenge as the vast majority are not registered with the SEC, which limits the SEC's ability to detect matters such as fraud before stock markets or investors are affected.²⁰² Inherently, this would arguably also be applicable to other regulators and governing bodies due to the tendency for hedge funds to register offshore in order to benefit from lighter regulatory oversight and weaker control environments.²⁰³ However, as market dynamics and investor strategies continue to evolve, regulators and governing bodies have to constantly respond and adapt in order to maintain the fairness and integrity of the equity markets.

6 Shareholder Activism during the Financial Crisis and in the Future

Allen Boyer argues that the market has never altered the role of a shareholder activist but has always defined that role.²⁰⁴ It is therefore tenable that the abundance of world trade agreements since the 1960s facilitated the liberalization of worldwide capital flows and contributed to the denationalization of the corporate and financial landscape.²⁰⁵ The free flow of financial capital within and across national borders not only altered the power dynamics between governments, shareholders, and corporations but also facilitated the realization of abnormal returns on investments by shareholder activists. This was particularly the case for hedge funds that were able to reap returns by deploying activist strategies. Nevertheless, as the market facilitated the realization of activist strategies it also restricted their reach as illustrated by the recent financial crisis and the initial demise of private equity (p. 416) and hedge fund activity. In short, research has documented that activist hedge funds are thus heavily pro-cyclical.²⁰⁶

6.1 Initial Demise of Private Equity and Hedge Funds

During the financial crisis, the outlook for activists, in particular hedge funds and private equity firms, was bleak. A reduction in available liquidity, private companies seeking a quick exit from their private equity shareholders, and potential targets shying away from listing on the main markets due to costs and regulatory obligations seemed to create the advent of a “buyer’s strike” or the end of the locust era.²⁰⁷ Faced with higher startup costs and an increasingly competitive market, private equity and hedge funds were perceived to be finding it ever more difficult to amass sufficient returns to remain profitable.²⁰⁸ Some scholars even heralded the near “eclipse” of private equity.²⁰⁹

However, it is now evident that that shareholder activism has not just survived but dramatically prospered over the past years since the crisis. During crisis times, falling profits and dividends will force management boards to be more responsive to demands for disposals by shareholders.²¹⁰ For example, Chris Hohn, the founder of The Children’s Investment Fund Management (TCI), gained notoriety in 2005 after having succeeded in removing Rolf Breuer and Werner Seifert from the board of Deutsche Börse and in stopping attempts to acquire control of the London Stock Exchange.²¹¹ Following heavy losses of 43% in 2008, and the departure of various founding partners, little was heard of the fund on the market. However, recent filings with the SEC indicate that activity is once again well under way: as per the quarterly 13-F reports The Children’s Investment Fund Management (UK) LLP increased its portfolio of US shares to levels equal to those seen at the fund’s peak in 2008.²¹² More recently, TCI seems to have fully regained its pre-crisis strength.²¹³ Additionally, recent figures on the hedge fund industry indicate that activist hedge funds alone now have a total of \$66 billion under management after recent years have seen strong capital inflows and record (p. 417) profits in 2013.²¹⁴ As a note of caution, however, the future success of shareholder activism looks likely to be constrained with new regulations coming into force over the next few years and a growing concern over the implementation of short-term investment strategies.

6.2 Activism post the Financial Crisis

The 2008/2009 global financial crisis has intensified the debate about the role that investors play or should play in corporate governance. To some, increasing shareholder influence and facilitating shareholder intervention when necessary is part of the essential reforms; activism in particular is often hailed as the solution for effectively monitoring management. To others, activism by shareholders who potentially have short-term interests is part of the problem, not a solution. Lawmakers are still undecided to what extent (and when) shareholder activism can improve firm value and performance or to what extent (and when) shareholder activism can produce distortions that make matters worse. Research by financial economists that seeks further light on these questions will provide valuable input to the questions with which decision makers are struggling.

In any case, following the struggle of hedge funds and private equity funds during the crisis, the ensuing recession and more recent years have undoubtedly played a role in the

Shareholder Activism: A Renaissance

rise of more targeted and more focused shareholder activism.²¹⁵ For many investors, voting their shares has become a legitimate method to express dissatisfaction with the performance of a specific board member. In addition, the weak stock market performance since 2007 has increased the clout of activist investors, and low interest rates have given hedge funds record investment volumes. At the same time, the slight economic recovery since 2009 has given companies time to reduce debt and to build cash piles which make them interesting targets for activists.²¹⁶ This may help explain why shareholder activists in recent times have also begun targeting larger and blue-chip companies such as Apple, Procter & Gamble, and Sony, generating a profound echo in the corporate world and in the media.²¹⁷ It is said that activism has outpaced any other hedge fund strategy performance over the past years.²¹⁸

Advances in technology have surely helped foster this development. The rise of the Internet, along with greater disclosure obligations, has made it easier to access information about target companies, board members, and financial data.²¹⁹ It has further encouraged (p. 418) greater shareholder collaboration. Shareholder activism can therefore be said to have become more targeted in character.²²⁰

6.3 The “Teaming Up” Strategy

Finally, the techniques of shareholder activism seem to have changed. Along with new technological advantages come broader alliances that activists are seeking to build with traditionally passive institutional investors. In most cases, the realization of activists’ plans (in particular in large target companies) will depend on the support they get from larger institutional investors.²²¹ As a consequence, hedge funds may seek to form coalitions with these institutions, sometimes even before they invest. Scholars such as Ronald Gilson and Jeffrey Gordon have argued that the ultimate solution to shareholder passivity may be a new breed of activist shareholder—those who do not bring about change themselves, due to the small stakes they hold, but who can pressure for change by teaming up with normally rather passive institutions such as pension funds and mutual funds.²²² According to this view, such activist investors, in particular hedge funds, fill a vacuum that is created by the increased remoteness of investment and shareholder apathy.²²³

Practitioners confirm this trend. According to reports from the law practice, activists are now receiving greater support from traditional institutional investors, including those that might not themselves agitate for change.²²⁴ This development goes hand in hand with the feeling that supporting activists has largely lost the stigma that it used to have among traditional investors, which once may have viewed activists as a disruptive influence acting contrary to the long-term interests of the company.²²⁵ One recent example of this phenomenon actually happening is Jana Partners, an activist hedge fund, teaming up with the Ontario Teachers’ Pension Plan to bring about change at McGraw-Hill, the education and data company.²²⁶ Another example is the 2014 alliance between activist fund Legion Partners Asset Management LLC and pension fund California State Teachers’ Retirement System (CalSTRS) to press retailer Perry Ellis International Inc. into considering strategic (p. 419) alternatives.²²⁷ CalPERS, the largest pension fund in the US, is also re-

Shareholder Activism: A Renaissance

ported to be toying with the idea.²²⁸ A recent report by business consultancy FTI found that 76% of the institutional investors they interviewed in December 2014 were backing shareholder activism by supporting the actions of traditional activists as well as using their own tactics.²²⁹

Related strategies for activists include the possibility of convincing proxy advisors such as ISS to support their campaigns²³⁰ or to team up with other activists, building a “wolf pack.”²³¹ According to some, institutional shareholders are even reportedly encouraging activists to agitate at underperforming companies in their portfolio.²³²

Apart from these few sketchy examples, the “teaming up” phenomenon seems to be developing into a broader market trend, and a positive one, since the support by conventional investors serves as an additional check on the validity and long-term viability of the activists’ plans.²³³ Activists are viewed as suitable governance intermediaries, actively monitoring company performance and then presenting to companies and institutional investors concrete visions for business strategy. The pension fund’s support gives them additional credibility, both in relation to the target company and to the wider market, and may discredit the common complaint about activists’ short-term perspectives.²³⁴ The collaboration between a passive investment fund and an activist investor can thus be understood as a win-win scenario in three ways: It bolsters the position of the activist, giving them more influence and credibility. At the same time, activist influence is welcome support for large institutional investors who do not need to invest their own resources in detecting strategic investment possibilities. Finally, such joint initiatives may serve as a “screening” process to give other investors, or the wider, market an indication of which activist projects are legitimate for the shareholder body as a whole, since the support by the traditional investor promises an increased likelihood of long-term orientation and value creation. Taking all of these points together, the teaming-up strategy holds great promise—and activists can effectively serve to reduce the market’s undervaluation of voting rights to the advantage of all shareholders.²³⁵ It should be noted that the “teaming-up” concept needs to be seen within the respective regulatory framework, and existing legal barriers—for example, as discussed, on “acting in concert”—should be reconsidered in the light of these positive market trends.²³⁶

(p. 420) Modern hedge fund activism can thus be said to be an improved, more sophisticated version of its predecessors. The “teaming-up” concept has a double advantage: hedge funds cannot do it alone; they must convince fellow shareholders that their ideas are beneficial for the entirety of the shareholders, including the typically long-term oriented pension funds. But this step additionally amounts to a de facto “vetting process,” whereby checks and balances are created: if and insofar as activists need to convince other funds that their strategic plans are beneficial for the company as such (and do not create idiosyncratic benefits for the hedge fund), this process mitigates the potential extraction of short-term private benefits and ensures that activism is channeled into mutually beneficial activities.

6.4 New Regulatory Constraints

It is apparent that the width and depth of the recent financial crisis has reignited the regulatory debate on shareholder activism, when previously many seemed content to leave control to the mechanisms of the market as a whole.²³⁷ The new regulatory reforms that look set to constrain the activities of hedge funds in particular over the coming years are the US Dodd-Frank Act of 2010 and the European Directive on Alternative Investment Fund Managers.²³⁸

6.4.1 US Dodd-Frank Act of 2010

The Dodd-Frank Act is the main US regulatory response to the global financial crisis. It arguably represents one of the most significant changes to the US financial regulatory system since the Great Depression.²³⁹ The fundamental aim of the Act is to prevent another financial crisis by reining in the activities of Wall Street and abolishing the bailout of institutions that are argued to be too large to fail. The principal changes that will affect the scope of shareholder activism are those that are related directly to hedge funds, the SEC, and the strengthening of shareholder rights.

As part of the “shadow banking system,” hedge funds have traditionally been largely exempt from the scope of regulators. This exemption from regulatory oversight has enabled hedge funds to operate freely, transferring vast volumes of capital and risk on equity markets in the pursuit of maximizing their investments. This operational freedom has often risked the stability of financial markets or damaged trade execution and settlement processes.²⁴⁰ (p. 421) Thus, Title IV of the Act (or the “Private Fund Investment Advisers Registration Act” of 2010) requires hedge funds managing over \$100 million to register as investment advisors with the SEC and disclose the requisite financial data required for monitoring risk and protecting investors.²⁴¹ It is hoped, on the one hand, that the disclosure of financial information will mark an end to the “shadow” financial system within which hedge funds previously operated. On the other, it is hoped that the requirement to register with the SEC will enable the assessment of systemic risk and thus help maintain the stability of the financial market.

In parallel, by strengthening a shareholder’s ability to influence matters such as executive pay and the enforcement of greater accountability, it is hoped that the current system supporting the realization of short-term gains will be reversed.²⁴² This should in theory give board members the incentive to minimize taking risks with excess leverage which inherently had a detrimental effect on the long-term performance of their firms and negatively affected the stability of the economy as a whole.²⁴³ Whether the Act does indeed transform the stability of the US economy remains to be seen, as it does not appear to have the same farreaching consequences as the Glass-Steagall Act did.

6.4.2 European Directive on Alternative Investment Fund Managers

The European Directive on Alternative Investment Fund Managers (the “AIFM Directive”), which came into force on July 21, 2011, has the aim of rectifying the regulatory gaps and inconsistencies that previously governed the operations of collective investment

undertakings over the value of €100 million, such as hedge funds and private equity funds.²⁴⁴

The Directive not only applies to the worldwide activities of alternative investment fund managers based in the European Union but also the activities conducted inside the EU by alternative investment fund managers that are based in third countries. By stipulating that an alternative investment fund manager will need to obtain prior authorization from national authorities in order to operate, the Directive is creating a “passport system” under which alternative investment fund managers will have the authority to market alternative investment funds in the EU.²⁴⁵ Once a “passport” has been obtained, the alternative investment fund manager will need to satisfy additional requirements, namely the preparation of an annual report which is to be made available to investors, the disclosure of specific information such as a description of their investment strategy, and reporting to regulatory authorities on a regular basis on matters such as liquidity, risk management arrangements, (p. 422) and leverage. Furthermore, the Directive will also exert a degree of influence on the pay and bonus schemes of an alternative investment fund’s personnel by, for example, stipulating that 40% of bonuses must be deferred for at least three to five years with the potential for earlier recovery should relevant investments perform badly.

Despite its purported aim, the Directive has come under heavy criticism since the first draft was published in April 2009. Many have urged that the Directive is not a proportionate response to the 2007–2009 financial crisis, having targeted hedge funds despite major reports, such as the de Larosi re Report²⁴⁶ and the Turner Review,²⁴⁷ concluding that hedge funds did not play a significant role in the crisis.²⁴⁸ Furthermore, it appears that the Directive in part goes against the advice set out in the G20’s 2009 Global Plan for Recovery and Reform. The G20’s Global Plan not only advocated a supervisory and regulatory framework that was more globally in sync but also encouraged regulators and supervisors to reduce the capacity for regulatory arbitrage and resist protectionism in pursuit of promoting global trade and investment.²⁴⁹ As such, it will be a matter of time for the full effectiveness of the Directive to be determined.

6.4.3 Assessment

Despite these concerns, it is submitted that regulatory efforts overall have been relatively modest, and for good reason.

Both the AIFM Directive and the Dodd–Frank Act limit themselves to certain rules on the supervision of hedge fund managers, and do not pursue an activities-based approach that would address specific corporate governance methods used by activists.²⁵⁰ Given that potential pathologies of corporate governance—such as empty voting, for example—can be pursued by any investor (and not just hedge funds), it would appear pointless to regulate such behavior on an individual, hedge fund basis. Insofar as these tactics pose governance problems, these problems are best dealt with by general corporate law.

Broader hedge fund market regulation can be meaningful, instead, in addressing market concerns such as market stability and integrity, that is, a more macroprudential-oriented

approach. In this context, the newly introduced regulatory framework can contribute to a smooth functioning of the market and strengthen market oversight powers for regulators.

(p. 423) 6.5 Short Termism

The rationale behind equity markets is twofold: namely, that investors can reap the benefits generated from linking their savings to business profits and that the operational performance of corporations can be improved by the efficient allocation of capital.²⁵¹ The efficiency of the market, in other words the smooth functioning of a market whereby investors have recourse to liquidity and transparency, is thus dependent on long-term strategies that do not take into consideration day-to-day stock fluctuations.²⁵² The reality of the equity markets, however, could not be further from this definition as the regulatory framework has a tendency to support liquidity and trading activity over a period of long-term ownership.²⁵³ It is argued that this short termism could not only be having a detrimental effect on market efficiency but could also be jeopardizing the long-term growth and success of corporations.²⁵⁴

Arguably, it is shareholder engagement, and thus shareholder activism, which has encouraged corporations to focus on short-term financial gains at the cost of a corporation's growth and development in order to generate abnormal returns on investments.²⁵⁵ If one takes hedge funds as an illustration, it becomes evident that long-term investment strategies would risk excessive leverage and exposure to fluctuations in a sector or the market as a whole. The hedge fund manager is therefore pursuing short-term strategies to satisfy the demands of investors who at times of uncertainty, as is presently the case, have a preference for immediate cash flows and dividends as opposed to growth over the long term.²⁵⁶ Private equity funds have also been criticized despite typically engaging in longer-term strategies. It has been argued that the boards of corporations owned by private equity funds are under increasing pressure to refrain from investing in the business for its long-term future and instead ensure that earnings are increased so that a speedy refinancing or early exit can be achieved by the private equity manager.²⁵⁷ Boards of takeover targets are also often forced to concede to shareholder activism, as was the case in the takeover of Cadbury by Kraft. Sir Roger Carr, who was the Chairman of Cadbury at the time of the takeover, is quoted as having stated that the board did not feel it an option to reject a high bid even if they were of the opinion that it was not in the corporation's long-term interests.²⁵⁸

This chapter does not purport to seriously address these complaints, let alone the question of whether short-term perspective is really detrimental to value creation.²⁵⁹ It suffices to point out that the "teaming-up" strategy discussed above may serve as an effective check on too much alleged short termism.²⁶⁰ In summary, it has become evident from the above that market conditions have been the driving force in defining the role of shareholder activists. Accordingly, whether shareholder activists will opt to engage in long-term investment strategies for the benefit of a corporation as a whole not only depends on the demands of (p. 424) their investors but also on market conditions and the knock-on

effects of the new regulatory constraints that are currently coming into force in the US and the EU.

7 Conclusion

This chapter paints a largely positive picture of activist investors' engagement in corporate governance. Exploring the historical roots and the methods of shareholder activists, I argue that shareholder structure is an important variable to determine the shape and the importance of activist engagement. In all environments, however, the key question to address is how to constrain self-serving activist behavior while harnessing its positive effects. Regulation has only a modest share in this context. The recent trend of forming coalitions between activists and conventional institutional investors may however be seen as a promising strategy that serves as a screening test on legitimate agendas while giving activists more credibility.

Shareholder activists have rebounded strongly after the financial crisis. Even though policy makers seized the opportunity of introducing more regulation to contain hedge funds, for example, in both the US and the EU, regulation is and should play a modest role in this field. A market supervision approach, monitoring systemic concerns, coupled with individual steps to address specific corporate governance problems appears to be the right way forward.

In sum, there's life in the old dog yet. Whilst some predicted the end of hedge funds and private equity a few years ago, they have emerged from the financial crisis stronger than ever. Having honed their tactics and enhanced their credibility, they are here to stay—constantly updating their strategies.

⁽⁸⁴⁾ A flip-in poison pill is the more frequently used out of the two and enables existing shareholders to purchase further stock at a discount when the poison pill is activated by a hostile bidder. This has the effect of diluting the would-be acquirer's stock in the target and thus deters a hostile acquisition. In contrast, a flip-over enables shareholders to purchase the acquirer's shares at a discounted price but only after the merger has taken place. In the last 15 years the poison pill has only been triggered intentionally twice. *Id.*

Corporate Short-Termism: In the Boardroom and in the Courtroom

Abstract and Keywords

In this chapter I examine whether short-termism in stock markets justifies using corporate law to further shield managers and boards from shareholder influence, to allow boards and managers to pursue their view of sensible long-term strategies in their investment and management policies even more freely. First, the evidence that on stock market short-termism is mixed and inconclusive, with managerial mechanisms under-rated sources of short-term distortions, including managerial compensation packages whose duration often is shorter than that of institutional stockholding; further insulating boards from markets would exacerbate these managerial short-term-favoring mechanisms. Nor are courts well positioned to make this kind of basic economic policy, which if serious is better addressed with policy tools unavailable to courts.

Keywords: corporate decision-making, short-termism, stock markets, corporate governance, corporate law, boards of directors, compensation packages, courts, short-term trading, managerial agency costs

1 Introduction

THE belief that short-term stock market trading undermines corporate decision making at the top has long been part of the corporate governance discourse and policy making, and in recent years has picked up articulate judicial adherents. One of the most vivid and effective classic attacks on financial market short-termism came as the takeover wars of the 1980s opened up, via Martin Lipton's well-known justification to further empower managers to defeat hostile takeovers: "It would not be unfair," he wrote, "to pose the policy issue as: Whether the long-term interests of the nation's corporate system and economy should be jeopardized in order to benefit speculators interested . . . only in a quick profit . . . ?"¹ Over the years the chairs of the Securities and Exchange Commission, Congress,² business analysts,³ and the business media have regularly excoriated trading markets as perniciously shortening corporate time horizons, justifying corporate law rules that insulate boards from markets. And more recently, leading Delaware corporate law judges have indicated in off-the-bench analyses that the short-termist issue is something

Corporate Short-Termism: In the Boardroom and in the Courtroom

they take seriously as people with deep experience in corporate lawmaking and policy. This all leads us to the question posed here: Should short-termism weigh heavily, or at all, in corporate lawmaking today?

Management's attention to quarterly earnings is well known, inducing dubious, perhaps misleadingly illegal, shifts in sales and profits.⁴ The question I pose here, though, is whether (p. 426) such earnings management systemically degrades real investment and real economic activity, and, most pointedly, whether the policy tools available to courts making corporate law are appropriate for remedying the purported problem.

The short-termist argument is afflicted with five substantial debilities. First, one must evaluate the American economy from a system-wide perspective. The American economy is replete with venture capital markets, private equity markets, and many privately held firms. As long as venture capital markets, private equity markets, privately held firms, and similar conduits mitigate or reverse enough of any short-term tendencies in the public securities market, then the purported problem is not a systemic economic issue. We would have no corporate law reason to reorient the system to pick up one type of slack.

Second, the evidence that the stock market is, net, short-termist is inconclusive. There is indeed much evidence supporting the conclusion that it undervalues long-term value. But there is also much evidence that stock market sectors often overvalue the long term, most obviously in the intermittent bubbles in technology and other new industries. The lofty price-earnings multiples long accorded Amazon, Apple, and Google are suggestive of a market that appreciates the long term; the dot.com bubble of a decade ago suggests that the markets can over-value the long term. Hence, we cannot focus solely on evidence of short-termism in our evaluation, but must evaluate excessive long-termism as well. Intermittent over-valuation in the stock market is not a virtue, but its frequent occurrence tells us that the market is not uniformly short term. This over-under problem is what one would expect from an imperfect institution: sometimes it overshoots, sometimes it undershoots, and sometimes it is on target.

Third, mechanisms inside the corporation may well be important sources of short-term distortions and these internal distortions can be, and would be, exacerbated by insulating boards further from external financial markets. The CEO is still the most important decision maker inside the firm, and human psychology suggests that CEOs will typically want good results to occur on their watch, and prefer that poor results be pushed into the future, beyond their tenure. With average overall tenure for CEOs now at seven years, the typical CEO can expect about three more years at the top. Moreover, senior managers not yet at the top but with an eye on their future job prospects in the labor market want strong results before the next headhunter calls them. There is considerable evidence consistent with managerial distortions being a major source of short-term focus. Boards and managers may well have leeway in setting the horizon for compensation and that horizon may be shorter than it needs to be: the time duration for executive pay packages appears to be shorter than the duration of institutional investor holdings.

Fourth, courts are not well equipped to evaluate this kind of economic policy and should leave this task to other regulatory institutions that have better remedies available than courts do. Some, like the Federal Reserve and the US Treasury, are better positioned than courts to assess the extent, location, and capacity for lawmaking to ameliorate the purported problem. For reasons similar to those that underpin the business judgment rule, courts should be as reluctant to make economic policy decisions as they are to second-guess unconflicted board business decisions.

Fifth, the widely held view that short-term trading has increased dramatically in recent decades is unquestioned but may well misinterpret the data. The duration for holdings of the country's major stockholders, such as mutual funds at Fidelity and Vanguard, and major pension funds, has not shortened. Rather, a high-velocity trading fringe is moving stock (p. 427) rapidly through their computer systems. But these new high-velocity trading patterns do not affect the major stockholding institutions and, hence, should not yet affect corporate law thinking.

Each of these five problems with the short-termist view for corporate lawmaking is largely independent of the other four. Each could alone justify the view that courts and corporate lawmakers should not allow short-termism to join the considerations that go into the lawmaking balance. It is at least possible that the arguments proxy for a view that stakeholders should be better attended to, or that managers should have more autonomy generally. Regardless, the five together make the standard corporate governance case based on the view of excessive short-termism untenable.

2 The Influence of the Short-Termist Argument

In this section, I recount the persistent influence of the short-termist argument on corporate law policy thinking, particularly its implication that managers should be isolated from financial markets so that they may be free to pursue longer-term horizons. Of course, the long term is not to be preferred, just for its own sake, if it yields poorer returns and wastes resources. The short-termist view is rather that financial mechanisms induce corporate directors and managers to favor immediate but lower-value results over more profitable long-term results.

2.1 Takeovers in the Boardroom

Rapid trading in stock markets, with a diminishing breed of long-term holders, is thought to be the primary culprit in inducing too strong a focus on short-term results inside the corporation. Quarterly results trump long-term investment, particularly long-term technological development.⁵ These pernicious effects of securities markets are then emphasized by those seeking to influence policy-making that would insulate managers and boards from markets. Thus, Martin Lipton, the corporate world's most prominent and persistent promoter of board autonomy over the decades, offered short-termism as a primary reason why hostile takeovers needed to be stopped. "It would not be unfair," he wrote in the well-known *Business Lawyer* article quoted above, "to pose the policy issue as: Whether

Corporate Short-Termism: In the Boardroom and in the Courtroom

the long-term interests of the nation's corporate system and economy should be jeopardized in order to (p. 428) benefit speculators interested . . . only in a quick profit . . . ?"⁶ Shareholder-induced corporate short-termism, he argued, threatened the overall health of the economy.⁷ And he indicated that it still does: the first key issue facing boards in 2013 was that money managers "are wildly skewed to short-term results."⁸

And those views on shareholder short-termism, as reasons for managerial and boardroom autonomy, were rebroadcast in the 1980s, the 1990s, and the last decade,⁹ justifying board insulation from leveraged buyout pressures, from hedge fund activism, and from capital markets generally. The view justifies board autonomy from more market influence via five-year board terms. Overall, it is perhaps corporate law's longest-running modern refrain: financial short-termism demands that managers and boards be further insulated from financial markets, with enhanced autonomy to resist market pressure for performance, for fear that the pressure will over-emphasize short-term results.

The issue has persisted in media and corporate discourse. Arthur Levitt and William Donaldson, chairs of the Securities and Exchange Commission, saw the securities markets' propensity to induce corporate short-termism as a problem needing public attention.¹⁰ Prominent executives and corporate analysts have pushed forward parallel points.¹¹ Media attention to short-termism has further delegitimized the securities markets' influence on corporate decision making.

2.2 Current Views from the Delaware Judiciary

Today, the state corporate judiciary decides corporate election rules, the ease of insurgent proxy contests, and the rules governing the occasional takeover offers. Influential thinkers and decision makers in the Delaware corporate lawmaking structure have come to see the short-termist argument as important and as one that should influence corporate law election rules and electoral frequency. None has articulated this broad view in judicial decisions, but they have offered the power of the short-termist view in off-the-bench writings, with the judicial attention to short-term horizons narrower and more transactional.¹² The thesis here is that although the subject is ripe for out-of-court consideration, it is not one that should (p. 429) influence on-the-bench thinking for election rules, proxy rules, and the rules governing takeovers.

Thus, Justice Jacobs of the Delaware Supreme Court seeks means by which Delaware's corporate law can bolster long-term investment capital,¹³ justifying three-year board terms.¹⁴ Leo Strine, as vice-chancellor of the Delaware Court of Chancery, viewed the short-termism problem as a "substantial policy dilemma."¹⁵ "It is jejune," he said, "to demand that CEOs and boards manage for the long term when the stockholders who can replace them buy and sell based on short-term stock price movements, rather than the long-term prospects of firms."¹⁶ And vice chancellor Laster recently argued that time horizon differences between blockholders and other shareholders could create serious conflicts of interest inside the boardroom.¹⁷

With important judges thinking in their extra-judicial analytics that short-termism is a problem and wondering whether corporate law could help combat the problem, we must consider whether the issue should affect corporate lawmaking more directly. I conclude here that it should not.¹⁸

(p. 430) 3 The Short-Termist View

3.1 The Argument

The core short-termist concept is that because securities traders hold their stock for such a short duration, they look for strong corporate results only during the period they hold the corporation's stock so that they can sell profitably.¹⁹ Many institutional investors, such as mutual funds, are afflicted with this short horizon because they seek to show strong short-run results so that they can attract new investors to their funds.²⁰ Pension fund managers seek good short-term results so that they can renew their management contracts and obtain new ones,²¹ while hedge fund managers are often compensated on immediate results.²² And because they cannot evaluate complex, long-term, technologically sophisticated information well, they rely on simple signals to evaluate the value of the corporate stock in their portfolio. Quarterly earnings results accordingly loom larger than they would otherwise because of their relative simplicity.²³

For the trading argument to have traction, these stock market trading structures need a transmission mechanism into the corporation to affect corporate time horizons. That is, even if the short-term traders furiously moved a company's stock every nanosecond, managers could still be fully free to decide on corporate investments and time horizons, as the furious traders would typically pay no attention to the firm's horizons and would be incapable of intervening in corporate-governance decision making even if they paid attention. So more is needed—a transmission mechanism from the market to the boardroom.

In an earlier era, the transmission mechanism from short-term holding to corporate action was thought to be the hostile takeover. In the current era it would be shareholder activism and executive compensation, with boards more willing to fire CEOs if short-term financial results are poor, partly because directors fear for their own jobs or reputations. If senior management is compensated based on stock market returns, then management will tend to replicate the time horizons of the market. The end result would then be that boards and senior managers would forgo long-term value maximization for short-term results, all toward the end of pleasing the stock market.

By breaking the transmission mechanism (via longer election periods for directors or via greater managerial and board autonomy from the market), corporate leaders have sought to foster sensible long-term corporate behavior. Is this action wise?

(p. 431) 3.2 The Evidence in Favor

There is indeed hard evidence supporting the short-termist argument. Matched samples of privately held and publicly held firms show that the privately held firms invest more in their firm's operations than the publicly held half of the sample.²⁴ Matched samples of firms that went public and similar firms that did not show key personnel leaving the public firm shortly after the offering, which suggests an inability of the relevant firm to manage and create for the long term.²⁵ Corporate managers attuned to short-term thinking (as evidenced by their persistent reference to the short term in their communications with investors) had a short-term investor base with higher turnover than average. (Whether the first fact is caused by the second is not shown, but the possibility that causation runs from shareholder horizons to managerial orientation cannot be dismissed.²⁶) Private equity funds with shorter time horizons invest in firms at a later development stage than those with a longer horizon.²⁷

In addition, there is evidence that markets underestimate long-term corporate cash flows.²⁸ And there is evidence that mispriced public firms invest in line with the time horizons of their major investors.²⁹ Earnings management and earnings manipulation are regularly evidenced.³⁰ Initial public offers often use dual class stock, with insiders obtaining higher voting rights that insulate them from stock market pressure. More generally, corporate managers regularly bemoan the pressure from shareholders to produce strong quarterly results³¹ and report in a prominent study that they would give up shareholder value to report better earnings.³²

Thus we have the basic corporate argument for pernicious stock market short-termism and the evidence in its favor.

(p. 432) 4 Difficulties with the Basic Argument: Concept

But the short-termist argument faces counter-arguments that largely neutralize the idea that fears of short-termism should bear weight in corporate lawmaking. One class of counter-arguments is primarily theoretical, the other primarily factual. As far as I can tell, several of these theoretical arguments that I present here are new to the discourse.³³

4.1 Market Correctives

If short-term stock market pressures are inducing firms to give up value over the long run, then firms and markets would have incentives to develop institutions and mechanisms to facilitate that long-run profitability. Those that do will over the long run make more money. For example, if short-term trading reduced firms' time horizons perniciously, then some investors could profit by trading for the long term, by placing longer-term bets, and by developing credible mechanisms so that they will hold onto profitable long-term ventures. Such efforts may be incomplete in inducing the system to improve,³⁴ but

the market system would have incentives to push in that direction. If small stockholders find it not to be worthwhile to evaluate long-term, complex information, then the market has incentives to produce mechanisms that facilitate larger block holdings for longer time periods. Persistent rules and politics stymieing such efforts are plausible, particularly in the United States, which has had a long history until recently of cutting finance down and keeping blockholders small, intermittent, and ineffective; I previously analyzed these rules as likely to hinder blockholder efforts to overcome the information transmission breakdowns.³⁵ But market incentives to counterbalance have arisen, even if restrained and insufficient.

Private equity could correct some short-termism. If the public markets are inducing a publicly held firm to be excessively short-term oriented, then private equity holders, often with time horizons of years, sometimes stretching toward a decade, could buy the company, take it off the public market, and reorient its business model toward the longer term. If a firm produced poor profits because it overly focused on quarterly results, the marketplace incentives would be to move the firm into private equity's hands, where the horizons are longer. For transactional examples that were widely reported in the business press, one can (p. 433) look to the private equity investments in Dollar General, a mass-market retailer, and Seagate Technologies.³⁶

Aggregate data is consistent with private equity providing a longer-term alternative to public markets, when that alternative is useful. Firms that private equity takes private have increased patenting efforts in the target firms' core areas of strength.³⁷ An older study finds increased spending on research after firms are taken private.³⁸ These suggest a shorter-than-optimal public market; but they also point to an existing cure to the problem. And other studies find that higher inside block ownership is associated with more long-term investment.³⁹ A recent study shows that hedge fund ownership is associated with "better quality, higher impact innovations" than those in firms lacking hedge fund ownership.⁴⁰ Shareholder value holds up over the long term after activist hedge fund intervention.⁴¹

More generally, product market competition can partially correct short-term financial markets. For some excessive short-termism, the firm will find itself behind the curve technologically or otherwise at a later date. When it finds itself lagging, it will have the incentive to catch up.

4.2 Trade-Offs

If stock markets are indeed excessively inducing corporate short-termism, and if board and managerial isolation from financial markets is a partial solution, then unintended costs need to be accounted for in any cost-benefit analysis of a policy of insulating boards and managers from stock market influence, as there are obvious costs that come from further insulating them. If managers drift away from efficient, competitive behavior, financial markets can sting them into returning to a better corporate strategy. If boards and managers can freely dismiss market signals as the misguided views of short-term

traders, if corporate policy makers bless that view, and if their blessing of that view leads to further isolation of boards and managers from markets, then the corrective could (1) go too far and (2) facilitate (p. 434) managerial drift. These managerial agency costs are well known. The point here is that there is a trade-off of costs and benefits, even if the market turned out to be, net, short-term oriented.

4.3 Short-Termism in the Courtroom: Limits to Judicial Correctives

Is the courtroom an appropriate venue to consider short-termism? Proponents of board autonomy may well wish that short-termism be part of the judicial decision-making mix and could hope that, if the short-termist view proved to be persuasive in the courtroom, it would affect the atmospherics of corporate judicial decision making. Litigants have pressed that view on the Delaware Chancery Court.⁴² However, although astute judges have sympathized with the short-termist view in off-the-bench analyses, the record does not indicate that the short-termist view is yet regularly being explicitly weighed in the corporate lawmaking. Still, with the off-the-bench statements common and clear, one has to assess whether off-the-bench thinking affects judicial courtroom perspectives that are not fully articulated.

Consider the recent *Airgas* takeover opinion, which was a major decision. It does display courtroom viability for the short-termism argument—rejected at first in the opinion and then seen to be relevant in the decisional mix.

The target firm defendants asserted in *Airgas* that the target's short-term stockholder base justified strong defensive antitakeover measures. Said Chancellor Chandler:

Defendants' argument . . . [is] based on the particular composition of Airgas's stockholders (namely, its large "short-term" base). In essence, Airgas's argument is that "the substantial ownership of Airgas stock by these short-term, deal-driven investors poses a threat to the company and its shareholders."⁴³

And

[The defendants assert that the board should have more defensive room because of a] risk . . . that a majority of Airgas's [excessively short-term focused] stockholders . . . will tender into Air Products' offer despite its inadequate price tag, leaving the [longer-term] minority "coerced" into taking \$70 as well.⁴⁴

The Chancellor rejected this short-termist argument, at first: "The defendants do not appear to have come to grips with the fact that the [short-term] arbs bought their shares from long-term stockholders who viewed the increased market price generated by Air Products' offer as a good time to sell."⁴⁵

The Chancellor's strong rejection of the time horizons argument, however, did not persist to the opinion's conclusion. He ultimately ruled for the defendants and, with time horizons in mind, he turned the defendants' assertion into a question: Were enough stockholders "so 'focused on the short-term' that they would 'take a smaller harvest in the

swelter of (p. 435) August over a larger one in Indian Summer?’ ” he asked, quoting the defendants.⁴⁶ Yes, he concluded: Both sides’ experts testified that the short-term arbitrageurs would tender “regardless of whether the price is inadequate,” even if it failed to reflect the company’s long-term value.⁴⁷ The rhetoric of short-termism was in play in *Airgas*, in the context of a takeover.

Courts are not the right institution to do this kind of economic policy making. Consider that the judicial deference embedded in the business judgment rule is based largely on the presumption that judges are poorly positioned to make, or to second-guess, boardroom business decisions. The corporate judiciary ought to be even more reluctant to assess whether the corporate economy is too short term, too long term, or just right. Even a state legislature, with its parochial funding concerns, is ill-placed to make such judgments beyond firms operating primarily within the state’s own borders. To allow short-termism issues into the courtroom is to facilitate a type of business and economic engineering that the best business judges rightly decline to do in more compelling situations, such as that of a single mistaken business decision for a firm.⁴⁸

Other institutions and other policy makers are better suited to assess how well the economy is handling time horizons. Moreover, other policy avenues beyond corporate lawmaking, such as tax policy or policy on ownership structure, are better suited to handle any short-termism, if policy makers conclude that stunted horizons are real and pernicious.

On ownership structure and short-termism, a long-standing view has seen impediments to large blockholding as inducing more short-termism than is optimal, particularly because some information travels badly from inside the firm to diffuse public markets. Blockholders, I have previously argued, could better handle complex, technological, and subtle information than diffuse stock markets. They could signal to public stock markets the blockholder’s view that a managerial long-term decision was good for shareholder value.⁴⁹ Says the global managerial director of McKinsey & Company in discussing the problems of short-termism, “[t]he most effective ownership structure tends to combine some exposure in the public markets (for the discipline and capital access that exposure helps provide) with a significant, committed, long-term owner.”⁵⁰

(p. 436) 4.4 Regulatory Correctives

Consider, moreover, that the other remedy that has often been prominently touted over the years has been a Tobin tax on rapid trading. When policy thinkers such as Joseph Stiglitz, Lawrence Summers, or the blue-ribbon Aspen Institute have considered short-term stock markets a problem, they have turned to a Tobin tax as the appropriate mechanism to reduce short-termism, not to using corporate law to increase board and managerial insulation.⁵¹

Thus, three of the most prominent policy measures to reduce unwarranted short-termism have been a Tobin tax on securities trading, a sliding-scale capital gains tax tied to the length of the holding period, and facilitating more and larger blockholders. The corporate judiciary and state legislatures constructing corporate law cannot implement most such

measures, and cannot well assess whether such measures would be the best means to mitigate any securities market short-termism.

5 Difficulties with the Basic Short-Termist Argument: Facts

The short-termist theory faces offsetting facts, which make it unwise to place much weight on the theory for corporate policy making. First, even if the stock market is excessively short-run focused and even if there are transmission mechanisms that bring excessively short-term financial markets' time horizons into corporate decision making, policy makers need to see the American economic system as a whole, where there are counter-measures. Second, there is considerable evidence of stock market long-termism. Third, substantial, albeit unheralded, sources of excessive short-termism come from inside the corporation. The average duration for executive compensation appears to be shorter than the average duration of institutional-investor stock-market holdings, for example. Fourth, the purported shortening of investor holding periods during recent decades may be exaggerated. Fifth, the new short-termism, if it exists, may be an appropriate reaction to changes in the economic environment: more rapid technological change, increased globalization, and government short-term policies. If the facts of the firm's basic business surroundings are changing more quickly than ever, the firm's business horizons should indeed change and become shorter.

I take each of these in turn.

5.1 The Economic System

Alternatives to public ownership can be structured to plan for the long term: venture capital markets and private equity markets; privately held firms; and government financing of (p. 437) long-term research, to name the basics.⁵² If these alternative economic institutions provide much of the long-term orientation that securities markets purportedly do not, and if securities markets provide substantial other benefits—in diversification, liquidity, and aggregation of capital from disparate investors—then the system's complementarity may make the short-termism problem a problem for one firm or another, but not a problem for the American economy overall.

True, these sectors may not be big enough. Or they may not be long-term enough—venture capital and private equity often have horizons of five to ten years. Perhaps that is not long enough. Privately held firms may weaken as their founders age. Governments make mistakes. The point is not that these institutions are fail-safe but that they are offsets, and often substantial offsets.

5.2 Stock Market Long-Termism

The substantial evidence of financial market long-termism tends to be ignored in this debate, although public firms are often overinvesting compared to their private counterparts.⁵³ Financial economists return results that are inconsistent with institutional investors causing corporate short-termism. “Indeed,” say two prominent researchers, “we document a positive relation between industry-adjusted expenditures for [property, plant, and equipment] and R&D and the fraction of shares owned by institutional investors.”⁵⁴ After analyzing “corporate expenditures for property, plant and equipment (PP&E) and research and development (R&D) for over 2500 US firms,” they conclude that “[w]e find no support for the contention that institutional investors cause corporate managers to behave myopically.”⁵⁵ In industries dependent on outside capital, public firms “generate patents of higher quantity, quality, and novelty compared to their private counterparts.”⁵⁶ And again, “[c]ontrary to the view that institutional ownership induces a short-term focus in managers, we find that their presence boosts innovation.”⁵⁷ Particularly when managers are less entrenched, the authors find, institutions induce the firm to innovate more effectively.

(p. 438) Companies whose managers’ compensation is tied to volatile stock prices overinvest in R&D, compared to companies whose managers’ compensation is not so closely linked.⁵⁸ The bulk of the studies show institutional ownership to be associated with higher R&D intensity;⁵⁹ firms that become more insulated from financial markets reduce long-term R&D investments.⁶⁰ Takeover protection has been one of the most prominent policy prescriptions induced by those who see stock-market-induced short-termism as a serious problem. If the prescription were on average correct, then isolating boards and management from takeovers would lead to higher R&D and other results. But, although two studies are consistent with this view,⁶¹ as many or more studies do not find such increases following takeover protection.⁶² The most recent extensive studies on the issue find that patents and innovation (p. 439) decrease “for firms incorporated in states that pass anti-takeover laws relative to firms incorporated in states that do not.”⁶³

Consider the regular, but intermittent high valuations accorded to one sector or another of the financial market. At the very beginning of the twenty-first century, there was a boom, many now say bubble, in internet stocks.⁶⁴ New companies arose, went public, and were accorded high—sometimes astronomical—valuations.⁶⁵ These high valuations can be, and should be, interpreted as stock market long-termism. The market was valuing firms with no immediate earnings as very good investment prospects. Indeed, analysts concluded that many high-tech, dot.com firms would have needed to grow at unprecedented rates for the high prices of the late 1990s to be accurately predicting long-term prices.⁶⁶ Stock market beneficiaries of the concomitant rising equity prices invested more in capital—i.e., more in the long term—than they otherwise would have.⁶⁷ The “run-up in equity prices allowed for new projects to be undertaken by these [high-priced] firms—projects that otherwise would likely be underfunded.”⁶⁸

Nor were the dot.com bubble and its concomitant market overvaluation unique. Railroads, automobiles, the telephone, and plastics have at various times been overvalued.⁶⁹ Of course, these bubbles and their manifestation of excessive long-termism are not testimonials to our having an efficacious stock market. They are themselves problems. The point is not that markets are therefore efficient, or even that they are good. The point of overvaluation is that it fits better with a market that is giving excessive weight to the long term. It is not short-term.⁷⁰

More prosaically, analysts sympathetic to the short-termist viewpoint should focus on the planning horizons for firms that must focus on returns over decades. Oil production companies, for example, invest in oil fields that will produce for multiple decades, often over a good fraction of a century.⁷¹ These firms are disproportionately public firms with scattered, (p. 440) trading stockholders. At the same time, the bond market has historically had little problem in making long-term financing commitments to much of the American economy.⁷²

5.3 Short-Termism Inside the Corporation

Short-termism can arise inside the corporation and can do so in ways that would be exacerbated by insulating boards further from markets.

The first intuition is simple: The CEO is still the most influential corporate decision maker in most large public firms. It is basic human nature that the CEO will want good results to come to fruition during his or her tenure. With the average CEO's tenure at about seven years,⁷³ many CEOs could well think that there are only a few years left to their time as CEO. They have personal reasons to emphasize projects that will have good results during those few years, as a matter of personal pride.⁷⁴ Older CEOs put their firms on a low-risk path when their firms become more insulated from shareholder influence (while younger CEOs do the opposite).⁷⁵ Older CEOs reduce research and development as well as their firm's overall riskiness by diversifying more.⁷⁶ While some of these CEOs may worry that they will be replaced by powerful shareholders, an equally logical hypothesis is that they favor short-term results because they want results to be good before they retire. A "one standard deviation increase in CEO age decreases [a measure of R&D intensity] by almost 20%."⁷⁷

(p. 441) Several empirical studies show entrenched, older CEOs investing less than younger ones.⁷⁸ These results suggest that enhancing CEO autonomy from financial markets will lead to more short-termism, not less. One study, for example, finds that CEOs increase their firms' research and development spending during their first year as CEO, and reduce it in their final years as CEO.⁷⁹ Managers not at the top of the firm but who are mobile want to show good short-term results to managerial labor markets.⁸⁰ This is short-termism, and potentially pernicious short-termism, but it originates in managerial labor markets, not stock markets. And internal organizational metrics can overemphasize immediate results.⁸¹ Lastly here, overconfident managers, who abound at the top, sug-

gest several authors, “are likely to delay recognition of losses . . . , [perceiving] poorly performing negative NPV projects . . . as positive NPV projects.”⁸²

Overall, there is considerable evidence that the internal organizational structure of the large firm is a source of significant short-term impulses. More prosaically, boards and executives do have capacity to design longer-term compensation contracts to mitigate market features they see as deleteriously short-term, if they wish to.⁸³

A commonly cited short-termist mechanism is that corporate managers are unable to communicate complex or technological information to a diffusely held market of nonexperts. But if this is a primary problem, a significant improvement could come from rules that facilitated blockholders in the large American corporation instead of impeding these blocks from forming, persisting, and participating in corporate governance. Such blockholders would have incentives to process the more complex information that distant, smaller stockholders cannot readily process and understand.⁸⁴ That the core cure that is promoted is often to insulate boards from stockholders, by according boards greater autonomy, and not to facilitate more blockholding⁸⁵ or lengthen the duration of executive (p. 442) compensation, makes it plausible that for some adherents the excessive short-termist theory is proxying for a more general managerialist view of what makes the corporation run well.

5.4 Interpretive Error?

It is a widely held view that the holding duration of equity has dramatically shortened in recent decades. Trading volume is up and traders’ average holding periods are down. Those developments make even the limited shareholder attention span of the 1970s flicker as shareholders buy and sell, in this view. Program traders can move much stock through the system in microseconds.

For example, Delaware’s judicial leader, Leo Strine, when chief of the chancery court, where the country’s major corporate litigation usually transpires, bemoans stock churning and the rapid turnover of a typical public company’s stockholder base.⁸⁶ Short-termism and stock turnover are being taken as serious corporate issues by important corporate policy makers.

As we have seen, however, churning would not in itself be dispositive for a short-termist view for corporate lawmaking, if (1) short-term trading did not much affect corporate decision making because, say, no transmission mechanism brought those trading horizons into the firm’s decision-making process, (2) there were sufficient market correctives if it did affect corporate decision making, or (3) the costs of correction were too high. The prior three sections discuss these three possibilities. This section discusses a fourth reason for continued reticence in corporate lawmaking here—that interpreting the market turnover data as showing a shortening duration for America’s core stockholders may well be erroneous. Its duration may not even be shortening.

Corporate Short-Termism: In the Boardroom and in the Courtroom

Consider this possibility: Starting in 1985, 100 shareholders each hold 100 shares of the XYZ Corporation for three years. They sell their shares, after holding onto them for three years, to other investors, who in turn hold their shares for three years and then resell them. The average, median holding duration for each 100-share shareholder is three years.

Thereafter, by 2013, 10 of those 100 shareholders become active traders. These active traders sell their shares every four months to a new set of shareholders. For this group we have 10 holders every four months, 30 holders every year, and 90 holders every three years. For 90 holders, the average duration of ownership is four months. For another 90 holders, the average duration is still three years. One might be tempted then to say that for the entire stock of 180 holders of XYZ stock during the past year, the average duration for holding was only 20 months, while in the good old days it was 36 months. Holding duration has nearly halved.

These statements would be accurate counts, but the question is whether they are the best way to interpret the changing holding duration for policy-making purposes. For 90% of the shareholder mass, their turnover period and their holding duration are just as they always have been. For 90% of the shareholders, nothing has changed and their holding period has not shortened.

(p. 443) This analytical problem is hardly unique to short-termism. When a distribution is skewed and not symmetrical, the average—the mean—can fail to describe properly the population and its change over time.

Emerging evidence suggests that this interpretive consideration is in play for the duration of stock ownership in the United States. For example, two of America's primary shareholders—Fidelity and Vanguard—have holding durations that have not budged since 1985.⁸⁷ The overall holding duration for mutual funds and pension funds—America's core stockholder class—increased during the quarter century from 1985 to 2010.⁸⁸ These institutional investor holding durations seem to exceed the managers' time-to-realization—the duration—for executive pay.⁸⁹

The authors of the stock holding duration study report that they investigated "institutional investors' holding durations since 1985 and find that holding durations have been stable and, if anything, slightly lengthened over time." In 1985, the average duration for stock holding in the United States was 1.2 years; in 2010 it had increased to 1.5 years.⁹⁰ This data erodes the typical short-termist factual foundation on directionality.

True, even if this reinterpretation of the data trends comes to be seen as accurate, the short-termist view can persist, but it would have to be recast. The typical holding duration has not shortened, short-termists would concede, but they could contend that it is still too short-term now, just as it was too short before. So, as a policy matter, shareholders must be neutered from corporate governance influence. And, even if shareholders' typical holding duration is somewhat less short-term today than in the 1980s, they might argue, their corporate strength and influence have changed. Proponents of the short-termist view must be prepared to defend their position against this new evidence.

mist view would argue that shareholders have become more powerful—staggered boards are largely gone, many firms have majority voting, SEC rules favor shareholder voice, and hedge funds allow some shareholders influence that disaggregated holdings do not. Others would argue the contrary—that the central governance event of the past quarter century was the hostile takeover’s demise, with offsetting shareholder gains in strength being pale, weak substitutes for the lost takeover.⁹¹

(p. 444) People could disagree here on the overall direction of shareholder power, but the point is that this disagreement is a very different argument from one that says that shareholders have been becoming more short-term over the past quarter century and that corporate America needs a remedy for the shortening of that duration. The most recent data analysis suggests the contrary.

5.5 More Powerful Core Causes? Speeding Technology, Increasing Globalization, and Unstable Government Policy

Whether or not stock markets are moving faster, the world is moving faster in the twenty-first century than it moved in the twentieth. Technological change is faster, the Internet is destroying old distribution systems, computers change how business is done, and modern telecommunications make global markets local. International trade more quickly hits local businesses that were once isolated from world markets. Government policies—whether it is the American fiscal cliff or the European potential for an imploding euro—make it hard for businesses to plan for the long term.

Keep in mind again that conventional long-term production requiring massive investment does happen in large public firms: shale oil and gas are being produced for the long term,⁹² as are oil and gas from conventional fields that must be developed with infrastructure investment requiring 30- or 40-year horizons. These investments do not support the idea that the stock market cannot handle the very long term.

But other investments do not have the same long-term luxury. Consider the speed of technological change. Earlier we noted that financial markets have not deterred major technological firms from their tasks. Amazon, Apple, and Google come to mind as public companies with a focus on innovation and the long term.

Amazon’s CEO is aggressive on the issue. In 1997, the year Amazon.com went public, its chief executive, Jeff Bezos, issued a manifesto: “It’s all about the long term,” he said. He warned shareholders “we may make decisions and weigh trade-offs differently than some companies” and urged them to make sure that a long-term approach “is consistent with your investment policy.” Amazon’s management and employees “are working to build something important, something that matters to our customers, something that we can tell our grandchildren about,” he added.⁹³

There is also a reverse side to the disruption wrought by rapid technological change, such as that which Amazon has pursued. Critics might look at bricks-and-mortar bookstores that fail to expand, invest, and discover new means to market their business. If the companies are public, critics might blame public markets for that unwillingness to invest. But the underlying problem may well be simpler, in that technological changes are eroding the viability of such firms' business models.

(p. 445) Finally here, consider the reported corporate reaction to the risks emanating from uncertainty about government policy and from the deepening inability of Washington to effectively address economic issues.⁹⁴ "At Vanguard, [the large mutual fund complex,] we estimate that policy uncertainty has created a \$261 billion drag on the U.S. economy."⁹⁵ To observers looking at ownership structure, stock market trading of these firms' equity may seem to be the root cause of the drop-off in investment spending—a basic indicator of a preference for the short term over the long term. But identification of misshapen markets rather than policy as the more fundamental cause may be mistaken here.

Consider former Federal Reserve Chair Ben Bernanke's PhD thesis:

When Ben S. Bernanke wrote his doctoral thesis in 1979, he could have been channeling the quandary that C.E.O.'s face today. "Uncertainty about the long-run environment which is potentially resolvable over time thus exerts a depressing effect on current levels of investment," he wrote at the Massachusetts Institute of Technology. "Uncertainty provides an incentive to defer such investments in order to wait for new information."⁹⁶

The corporation may indeed now need to plan more for the short run than for the long run. But this explanation for the shortened planning horizon lies more in the nature of shortening technological life cycles, globalization, and changing government policy than in the financial markets external to, or the structures internal to, the large public firm.

6 The Short-Termist Argument as Proxy

The short-termist argument is closely associated with two views of corporate governance and may proxy for, or be used to bolster, these views. These views, though, must stand on their own. They get no extra weight and no extra persuasive power by using the short-termist argument.

6.1 As Proxy for the Need for Managerial Insulation

Shareholders, it has been said, are best served by managers with enormous discretion and autonomy. It is asserted that shareholders will not be well informed generally, will disagree with one another on corporate strategy, and will disrupt boardroom decision making if given too much authority to affect corporate decision making directly.⁹⁷

Corporate Short-Termism: In the Boardroom and in the Courtroom

The short-termist view may proxy here for the managerialist view, in that managerialists see shareholders as afflicted by a wide range of debilities, and see boards as needing to be (p. 446) separated from shareholders' influence in order to coherently lead the corporation and keep it competitive.

Here I make no claim on the appropriateness of this view, positively or negatively. I do assert, however, that this view gains no added persuasive power from the short-termist argument, which is insufficiently strong, empirically and theoretically, to affect corporate rulemaking. Perhaps boards need to be left largely unaffected by shareholders, but the short-termism argument is not one of the reasons for it. The board insulation view must stand or fall on its own, without reference to short-termism. But one way to see the short-termist argument is that managerialists can offer it to policy makers as "cover" from public criticism. Short-termism justifies protecting managers; it resonates with public and popular prejudices on the functioning of financial markets. Even better for the managers if legislative and judicial decision makers with authority over the structure of power in the corporation believe short-termism to be pernicious and needing correction.

6.2 As Proxy for the Need to Attend to Stakeholders

Similarly, the view is widely but not universally held that short-term-oriented shareholders induce firms to be less attentive to the firm's other stakeholders, to government regulation, and to societal values generally. The firm that is excessively solicitous of short-term shareholders will in this view treat labor badly, will sell defective products, will take excessive risks with public funds in the financial sector, and will degrade the environment, all in ways that make our society worse off.⁹⁸ Shareholder voice degrades each of these stakeholders in the corporation, many think. Short-termism is the catch-all term to embody these negatives.

But this is an incorrect use of the short-termist view. We ought not to conflate corporate bad behavior with short-termism. Bad behavior could be long-term or short-term.⁹⁹

Many perceive these negatives as serious faults of the large public corporation, warranting public policy attention. I do not evaluate this view here. But the purported tendency of shareholders to shorten the corporate time horizon must not figure into the balance. The stakeholder view, like the managerialist view, must stand or fall on its own.

7 Conclusion: No More than Watchful Waiting

We have here evaluated the long-standing short-termist argument in corporate law, using modern thinking and data on markets and the economy, and have found it wanting. It (p. 447) should be given no weight in corporate lawmaking. The short-termist argument suffers from five substantial weaknesses.

First, policy makers must evaluate the American economy from a system-wide perspective. System-wide, the American economy is replete with venture capital markets, private

Corporate Short-Termism: In the Boardroom and in the Courtroom

equity markets, and many privately held firms, all of which are capable of the longer-term planning that the public firm is thought in some circles to be capable of. As long as venture capital markets, private equity markets, and other conduits mitigate or reverse enough of any short-term tendencies in the public securities market, then the purported problem is less systemic. While these institutions are themselves imperfect, they must still be considered when evaluating whether stock market short-termism, if it is excessive, is a system-wide problem.

Second, the evidence that financial markets are excessively short-term is widely believed but not proven, and there is much evidence pointing in the other direction. We have seen bubbles and overvalued companies with little more than a business plan, strongly suggestive that financial markets can be excessively long-term. Markets undershoot and overshoot, as one should expect. We see technology companies and prosaic natural resources companies making major long-term investments that far exceed stock market holding periods and CEO job tenure.

Third, mechanisms inside the corporation may well be important sources of short-term distortions and these internal distortions can be, and would be, exacerbated by further insulation of boards from external financial markets. It seems obvious (but underexamined) that CEOs will prefer that good results occur on their watch, and that poor results be pushed off into the future, beyond their tenure. There is considerable evidence consistent with this likelihood that a major source of short-term focus originates inside the corporation and not outside in financial markets. Senior managers with an eye on a new position want good results and they want them soon.

It is not impossible that the short-termist view captures a rhetorical high ground in the case for board autonomy by contrasting the positive connotation of patient long-term capital against short-term frenzy. But it is at least possible that some of the phenomenon is better captured by contrasting dynamic firms that change and adapt quickly, i.e., in the short run and sometimes due to shareholder pressure, with lackluster, encrusted organizations that do not move as nimbly.

Fourth, if proponents of the short-termist view are seeking to influence courts and state legislatures that make corporate law, their view should be rejected. Courts are poor places to make this kind of basic economic policy. They may even find it difficult to assess accurately whether the economy is too short term, too long term, or just right. If such considerations are to make their way into economic policy, these should be national policies, coordinated with tax policy, and perhaps implemented via the tax code, securities laws, and the rules that influence the size of stockholdings, not via parochial corporate law.

Fifth, the widely held view that short-term trading has increased dramatically in recent decades is unquestioned but should be examined, as that view may misinterpret the data. The best recent evidence indicates that the duration for holdings of the country's major stockholders, such as mutual funds at Fidelity and Vanguard, and major pension funds, has not shortened. Instead, a high-velocity trading fringe is moving stock rapidly through

their computer systems. Their holdings, when averaged into market-wide data, make the duration appear to be shortening across the entire financial market. But these new trading patterns (p. 448) do not affect the major stockholding institutions and, hence, should not affect corporate law thinking.

Any one of these features should induce substantial caution among corporate law policy makers before using the short-termist view to buttress law that would further insulate managers from markets. It is at least possible that the arguments proxy for a view that stakeholders should be better attended to, or that managers should have more autonomy generally. Regardless, in combination, they tell us that corporate law courts and corporate lawmaking legislators should view the short-termist argument for further board and CEO insulation as one that should be accorded no weight today.

The influence of the stock market here may well be pernicious, by inducing managers to overinvest in less-than-profitable R&D, so as to falsely signal good corporate prospects. But the point is that the stock market is not facilitating R&D cuts—the usual short-termist *bête noir*—but inducing greater R&D, contrary to the short-termist prediction.

A noticeable part of the finance literature on short-termism depends on the firm sensitivity to state-based takeover rules and charter terms. There is

good reason to find this literature even more indeterminate than the text argues, as using state antitakeover legislation as a variable is questionable. Emiliano M. Catan & Marcel Kahan, “The Law and Finance of Anti-Takeover Statutes”, 68 *Stan. L. Rev.* 629 (2016). It’s questionable because since the early 1990s, all American firms have a “shadow poison pill,” in that they, even if there is no antitakeover legislation and even if the firm has not put antitakeover tactics in place in advance, ward off most takeovers by putting in a poison pill at the last minute. They find that debt markets have become less willing to finance long-term operations than previously. They link the shortening debt maturity largely to the increasing number of new, smaller, riskier firms accessing the bond market. This suggests an issue that is not one for corporate law courts but is one that arises from the changing nature of the economy.

(⁷⁴) *Id.* at 67. The problem is more complex and causation need not be one way. Financial markets could press firms to produce results, which in turn could press boards to fire CEOs more frequently, which in turn could press CEOs to emphasize immediate firm performance. But the fact that older CEOs seem more susceptible to under-investment suggests that some of the cause emanates from the CEO, in that older CEOs are more likely to expect their current position to be their last.

But, if this is so, then the short-term problems lie inside the firm, as compensation could be tied to other measures or to longer-term stock price averages.

Abstract and Keywords

This chapter examines legal issues concerning majority control and minority protection in firms with concentrated ownership governance structures, with particular emphasis on the tradeoff between the goals of protecting minority shareholders and allowing controllers to pursue their vision and how corporate law should balance these conflicting goals. Focusing primarily on Delaware corporate law, it suggests that holding a control block allows majority shareholders to pursue their idiosyncratic vision in the manner they see fit, even against minority investors' objections. Idiosyncratic vision refers to the subjective value that entrepreneurs attach to their business idea or vision, and this chapter considers its role in the value of control. It also discusses the perils of asymmetric information and differences of opinion, as well as the risk of agency costs for minority investors.

Keywords: majority shareholders, minority shareholders, idiosyncratic vision, Delaware corporate law, asymmetric information, investors, entrepreneurs, agency costs, controlling shareholders, governance structure

1 Introduction

MINORITY protection is a central issue for legal systems that regulate firms with a controlling shareholder. Concentrated ownership is the predominant ownership structure of public companies around the world, and even in the United States and the United Kingdom, where dispersed ownership is the norm, firms with concentrated ownership make up a substantial portion of publicly held companies. In this organizational structure, a person or entity—the controlling shareholder—holds an effective majority of the firm's voting and equity rights.¹

Despite the costs of illiquidity and suboptimal diversification associated with being a controlling shareholder, concentrated ownership remains prevalent throughout the world. Several theories attempt to make sense of this apparent anomaly. These theories identify justifications for the presence of controlling shareholders and offer explanations for

Majority Control and Minority Protection

cross-jurisdictional differences in the prevalence of the concentrated ownership structures.

The prevailing view posits that controllers are drawn to what corporate lawyers and economists call “private benefits of control.”² These benefits can be both pecuniary, where controlling shareholders may be able to engage in self-dealing transactions or tunnel funds, and nonpecuniary, such as enhanced social status and ego.³

(p. 450) In this chapter, we provide a brief summary of our new explanation of the value of corporate control for controllers-entrepreneurs and the prevalence of concentrated ownership.⁴ We then use our new framework to offer a blueprint for the corporate law regime governing firms with controlling shareholders. In our view, holding a control block allows the entrepreneur-controlling shareholder to pursue her business idea (i.e., any concept that she genuinely believes could produce an above-market rate of return) under conditions of asymmetric information and differences of opinion in the manner she sees fit, even against minority investors’ objections. We call the subjective value entrepreneurs attach to their business idea or vision the entrepreneur’s *idiosyncratic vision*.

Both our novel explanation and the existing ones for the prevalence of controlling ownership have a foundation in reality, and indeed, both may be at play in a single firm. While pecuniary and nonpecuniary private benefits of control may be a strong motive for many controlling shareholders, the pursuit of their idiosyncratic vision notwithstanding investors’ objection may motivate others to hold a control block. Moreover, our theory can explain the prevalence of concentrated ownership even in countries with strong investor protection and offers important implications for corporate law governing firms with controlling shareholders.

Corporate control matters in our framework because business ideas take time to implement. The successful implementation of a business idea requires many decisions, ranging from day-to-day management issues to major strategic choices. Perhaps the most important decision is whether to continue a project notwithstanding some setbacks. Due to either asymmetric information or differences of opinion between entrepreneurs and investors, there may be substantial disagreements over whether the project should be continued and in what fashion. The entrepreneur will therefore want to retain control over a wide range of management decisions to successfully pursue her vision. In short, control enables controlling shareholders to capture the value that they attach to the execution of *their* vision.⁵

Henry Ford’s story is the best illustration of the importance of control for entrepreneurs-controlling shareholders in pursuing their idiosyncratic vision. Ford did not invent the automobile, nor did he own any valuable intellectual property in the technology. Therefore, he had to compete with hundreds of other entrepreneurs who were attempting to create a “horseless carriage.” Ford had a unique vision regarding car production, however. In the first firm that Ford founded, the Detroit Automobile Company, investors retaining control resulted in tensions over the automobile production timeline. While Ford’s investors demanded that cars be immediately produced and sold, Ford insisted on perfecting the de-

Majority Control and Minority Protection

sign prior to production. This difference of opinion led to delays, frustration on both sides, and the eventual shutdown of the firm by its investors.⁶ Ford's second attempt, the Henry (p. 451) Ford Company, was also controlled by investors. Again, after designing a car, Ford resisted the investors' pressure and did not move swiftly into production. Eventually, his obstinacy led to the investors replacing Ford with Henry Leland, changing the company name to the Cadillac Automobile Company and producing the car designed by Ford with great success.⁷ Finally, on his third attempt—the Ford Motor Company—Ford insisted on retaining control. This time, with no outside investor interference, Ford transformed his ideas of car design and production (i.e., his idiosyncratic vision) into one of the greatest corporate success stories of all time.⁸

While Henry Ford's story demonstrates the perils of asymmetric beliefs and investor control from the entrepreneur's perspective, asymmetric information also introduces the risk of agency costs for investors. Entrepreneurs are not always right. For Henry Ford's investors, it was difficult to know whether Ford was pursuing a viable vision or simply wasting valuable money and time on an unattainable project. More importantly, entrepreneurs might behave opportunistically. An entrepreneur may continue a failing project out of personal interest, or, in the type of concentrated ownership structure discussed in this chapter, exploit her dominant position to consume private benefits at the expense of minority shareholders. She can, for example, pursue pecuniary benefits by entering into self-dealing transactions,⁹ engaging in tunneling,¹⁰ or employing family members. In addition, she can also capture nonpecuniary benefits such as boosting her ego and social or political status through her influence on corporate decisions.¹¹ These risks, called agency costs, arise when the interests of agents and their principals are not perfectly aligned.

Protecting investors against agency costs is in an unavoidable conflict with allowing entrepreneurs to pursue their idiosyncratic vision. The more freedom an entrepreneur has to pursue her business vision, the more exposed the investors are to agency costs, and vice versa. Entrepreneurs and investors allocate control and cash-flow rights to resolve the inevitable trade-off between agency costs and idiosyncratic vision. In a firm with concentrated ownership, the entrepreneur must hold a substantial fraction of cash-flow rights to secure the ability to pursue her vision. This allows the controller to pursue her vision while reducing (due to the controller's considerable share of cash-flow rights) minority shareholders' exposure to management agency costs. The controlling shareholder is willing to bear the costs of holding a large block of shares in exchange for gaining uncontested control, which enables her, through the pursuit of her idiosyncratic vision, to generate an appropriate return on her investment and effort while simultaneously generating pro-rata benefits for investors. (p. 452) But, although controlling shareholders hold control primarily in order to *increase the size of the pie* (via the pursuit of vision), there is a risk that they might attempt to dictate the *pie's distribution* (via the consumption of private benefits). Minimizing this risk, i.e., the risk of control-agency cost, is at the center of minority protection.

On the policy level, our theory of the value of control for entrepreneurs offers important lessons for the regulation of firms with controlling shareholders. The existing corporate law literature associating control with consumption of private benefits solely focuses on minority protection from agency costs. However, within our framework of the concentrated ownership structure, controlling shareholders' right to pursue their idiosyncratic vision also plays, and should play, a critical role in corporate law. Specifically, any legal regime governing firms with controlling shareholders encounters an inevitable trade-off between the goals of protecting minorities and allowing controllers to pursue their idiosyncratic vision. Corporate law must balance these conflicting goals instead of pushing for only one of them. Our analysis in the remainder of this chapter focuses mostly on Delaware, the jurisdiction with the most developed corporate case law and jurisprudence.

2 The Trade-off between Minority Protection and Controller Rights

As delineated above, corporate law should recognize the controller's right to pursue her vision while simultaneously protecting investors from expropriation through self-dealing and other methods of value diversion. Finding the appropriate doctrinal balance is challenging because of the inevitable conflict between minority protection and controller rights, especially since distinguishing between legitimate corporate decisions that enhance business vision and those that lead to unequal distributions can be difficult. The same asymmetric information and diverging beliefs that make the contracting process between investors and entrepreneurs challenging makes the enforcement of the rules against self-dealing challenging as well. Minority-protecting measures may lead to costly errors, and efforts to police the prohibition on non-pro-rata distributions may require legal or governance measures that would undermine the controller's management rights.

To illustrate the interplay between minority protection and controller rights, assume that the entrepreneur owns 60% of a firm. The entrepreneur genuinely believes that a specific component produced only by one particular company is necessary for the development of a new product. It so happens, however, that the company producing the component is 100% owned by the entrepreneur. Accordingly, the entrepreneur wishes for her 60%-owned firm to buy the components from her wholly owned company. If the entrepreneur were the sole owner of both firms, she could simply buy the component under whatever terms she desired. But, with investors owning 40% of the firm's shares, there is an understandable suspicion that the entrepreneur is abusing this transaction to divert value from minority shareholders to her wholly owned corporation, and ultimately, to herself.

This illustration underscores the at-times opaque line between unfair self-dealing and business decisions that are necessary for implementing the controller's vision to the (p. 453) benefit of the controlling and minority shareholders alike. Protecting the minority against inappropriate value diversion requires some constraints on the entrepreneur's ability to exercise control. These constraints can take the form of ex post review by courts with regards to the fairness of the transaction, or an ex ante requirement to secure ap-

Majority Control and Minority Protection

proval by a majority of the minority shareholders.¹² Thus, the need to provide the minority with protection against agency costs will necessarily require curtailing some of the controller's freedom to pursue her idiosyncratic vision that she would have otherwise enjoyed as a single owner.¹³

One might argue that constraining self-dealing need not interfere with the controller's ability to pursue her vision. After all, the argument goes, if the controller does not intend to expropriate the minority, why would she care about the extra supervision? If the transaction is on arm's length terms, the court will find it to be fair ex post,¹⁴ or minority shareholders will grant their approval ex ante. This argument would be correct in an ideal world without transaction costs. In the real world, however, plaintiffs sometimes bring suits without merit¹⁵ and courts make mistakes.¹⁶ Likewise, under a rule that requires a majority-of-minority vote, minority shareholders might strategically attempt to hold out or simply err in evaluating the proposed transactions.¹⁷ This conclusion also applies to other prophylactic measures required for creating an effective minority-protection regime.¹⁸ Accordingly, protecting minority shareholders against agency costs inevitably interferes with the controller's right to pursue her business vision.

The trade-off between minority protection and controller rights has obvious implications for the design of corporate law. It requires lawmakers and courts to seek an optimal balance between minority protection and controlling shareholder freedom to make managerial decisions. More practically, the nature of minority protection should depend on enforcement considerations. Enforcing a given protection may be too costly not only because of the direct compliance costs incurred by corporations or courts but also due to the unavoidable cost of interfering with the entrepreneur's pursuit of her idiosyncratic vision.

(p. 454) 3 Controller Rights

Analysis of the controlling shareholder's side of the corporate contract focuses on the scope of the controller's rights vis-à-vis the scope of minority protection. The division of cash-flow rights and control rights is a zero-sum game between entrepreneurs (controlling shareholders) and investors (minority shareholders), such that any freedom granted to the controller to pursue her vision will increase minority exposure to agency costs, and vice versa.

3.1 Property Rule Protection: Preserving Control

To preserve the entrepreneur's incontestable control and the ability to pursue her idiosyncratic vision, her right to make management decisions should be afforded property rule protection.¹⁹ In this context, property rule protection means that the market (i.e., minority shareholders) or courts cannot unilaterally take control rights away from the controller in exchange for an objectively determined compensation. Instead, the controller can prevent a non-consensual change of control from ever taking place at all.²⁰

Majority Control and Minority Protection

Property rule protection of controller rights has clear implications analogous to standard private property protections. For example, controllers cannot be forced to sell their control block even when doing so would clearly benefit the corporation or its minority shareholders.²¹ Furthermore, the controller is generally free to exit her investment by selling her control block whenever she wants and for whatever price she sees fit.²²

Property rule protection for controlling shareholder management rights extends further to a broad range of corporate actions. Controllers can lose control not only when they sell their shares, but also when the company takes action—such as issuing shares—that dilutes (p. 455) their holdings. Companies with controlling shareholders cannot take actions that would cause the controller to lose her control, even when doing so would benefit the corporation or minority investors.

Consider the following hypothetical. A bank must increase its capital to meet new capital adequacy requirements. The bank has two options: issuing new shares or selling one of its subsidiaries. The bank's controlling shareholder, who owns 51% of the shares, has her own liquidity problems that prevent her from buying additional shares of the bank. Issuing new shares would therefore dilute the controller and may cause her to lose her controlling position. How should the board decide between the two options? At first glance, directors' fiduciary duties seem to require them to choose the option that best serves the company's interests while disregarding the controller's interest in preserving control. Under Delaware case law, however, the board might be prohibited from taking steps that would make the controller lose corporate control "in the absence of a threatened serious breach of fiduciary duty by the controlling stockholder."²³ Therefore, the board may decide to sell a subsidiary merely because issuing new shares would force the controller to lose control.²⁴

This outcome runs against the traditional notions of shareholder value maximization because it allows value-reducing actions in light of a need to protect the controller's rights. Yet a regime under which minority shareholders, the board, or courts could compel the controller to lose control—whether by a forced sale, dilution, or any other action—is inconsistent with the need to provide controllers with a property rule protection for their right to make managerial decisions and pursue their business vision. It is important to note that this outcome is not justified by the need to provide controllers with private benefits to reward them for their willingness to monitor management. Instead, it is based on the parties' mutual consent ex ante on an arrangement that would enable entrepreneurs to pursue their idiosyncratic vision to the benefit of both minority investors and the entrepreneur.

3.2 Management Rights: Business Judgment Rule and Board Composition

Application of the business judgment rule strengthens the controlling shareholder's control over management decisions in pursuit of her idiosyncratic vision. The business judgment rule embodies the principle that courts should generally refrain from interfering

Majority Control and Minority Protection

with business decisions made by controllers or their representatives. The entrepreneur-controller (p. 456) is willing to make a significant equity investment in exchange for the right to pursue her business vision. The allocation of control particularly matters in light of the asymmetric information and differences of opinion between the entrepreneur and the investors/market. Some of the greatest breakthroughs in business ideas were “crazy” before they became “visionary.” These ideas would have never come to pass in the absence of control. What then should be the nature of protection of idiosyncratic vision?

Application of the business judgment rule recognizes the controlling entrepreneur’s right to exercise control over any issue that could affect the firm’s value. Controlling shareholders should be free to set the firm’s direction and make all management decisions. This includes the right to assume a managerial role (if the controller is an individual) as well as the right to appoint and fire managers. This has two implications for corporate law doctrine and policy. First, courts should generally refrain from interfering with business decisions that controllers or their representatives make—in other words, follow the business judgment rule.²⁵ The controller-entrepreneur retains control because of her expectation that asymmetric information or differences of opinion would induce investors to make decisions that would destroy her vision. The existence of asymmetric information and differences of opinion, moreover, should give courts pause before they attempt to intervene in business decisions. Like investors, courts may make decisions or take actions that, from the entrepreneur’s perspective, would destroy her vision.

The business judgment rule is often justified on the grounds that judicial review of non-conflicted transactions is unnecessary in a concentrated ownership environment where the controlling shareholder’s significant equity stake provides sufficient incentive to maximize value for all investors.²⁶ The need to allow the entrepreneur-controller to pursue her idiosyncratic vision, however, provides another explanation for the business judgment rule. The entrepreneur should have the freedom to implement her business plan even when investors and courts believe that such a plan is not value-enhancing.

Moreover, controllers’ management rights have significant implications for corporate governance reforms designed to enhance board independence at firms with controlling shareholders. Traditionally, the controllers’ voting power enables them to appoint any candidate they wish to the board. Recent corporate governance reforms, however, constrain the controllers’ power to appoint directors. Listing requirements, for example, require boards or board committees to maintain a certain percentage of directors who are independent, not only from the company, but also from the controller.²⁷ Some legal systems go even further and empower minority shareholders to influence board composition by, for example, appointing their own representatives to the board.²⁸

(p. 457) These measures may be necessary to enforce the rule against self-dealing.²⁹ Board reforms aim to make the board more effective in monitoring those with power—the CEO or the controlling shareholder. However, asymmetric information and differences of opinion could prevent the controller-entrepreneur from credibly communicating her beliefs regarding her business vision not only to investors but also to skeptical independent

Majority Control and Minority Protection

board members. Thus, the need to balance controller rights and minority protection should also shape board reforms at firms with controlling shareholders. Since the presence of minority representatives, or even just fully independent board members, could interfere with the controller's ability to manage, the controller should at least have the power to appoint a majority of the board (which in turn should have the power to appoint the CEO and other managers). Presently, this necessity to balance those conflicting goals in firms with concentrated ownership is reflected in exceptions to the NASDAQ and NYSE listing rules for controlled companies.³⁰

3.3 Right to Sell Control for a Premium

Whether controlling shareholders can sell their shares for a premium is one of the most important and controversial questions for firms with controlling shareholders.³¹ Delaware recognizes the right of controlling shareholders to sell at a premium, subject to the restriction on selling control to a looter (the "market rule").³² As explained above, the controller's right to sell at any time is the essence of her property right. But what about the right to sell for a premium not shared by minority shareholders?

The right to sell for a premium that is not shared by minority shareholders seems to contradict the idea of pro-rata value distribution. Nevertheless, the property rule protection counsels in favor of allowing controllers to sell their stake at a premium without sharing it (p. 458) with the minority shareholders. A key premise underlying the objection to controllers' right to sell for a premium is that a control premium serves as a proxy for private benefits and thus for minority expropriation. Under this view, imposing constraints on controllers' ability to sell for a premium would decrease the risk of inefficient sales motivated by the prospect of consuming private benefits at the expense of minority shareholders.³³

As demonstrated above, however, a control premium is not necessarily a proxy for private benefits of control or the magnitude of minority expropriation. Instead, it could also reflect the value of the entrepreneur's idiosyncratic vision from either the buyer's or the seller's perspective. A seller who believes that she could earn above-market return on her shares would insist on a premium for selling her stake even if, had she stayed in control, she would have shared the profits from her realized idiosyncratic vision on a pro-rata basis with minority shareholders. In this sense, the seller is only taking a premium that is reflecting her pro-rata share of what she expects to receive. Consequently, a buyer that believes she could make an even greater above-market return on the new investment would be willing to pay such a premium. Thus, under our framework, the new controller's willingness to pay a premium for buying control does not suggest that she intends to exploit minority investors.³⁴

However, corporate law in many jurisdictions appears to not subscribe to this rationale, instead imposing the so-called equal-opportunity rule that requires the buyer of more than a certain percentage of a firm's shares (usually around 30%) to make a tender offer that would take the shareholder to at least 50% share ownership.³⁵ To be sure, the equal-

opportunity rule could protect the minority against a sale to a looter. (After all, we do not rule out the possibility that a control premium can reflect private benefits of control.) Moreover, it does not prevent the controller from selling her shares for a premium. Rather, it requires the buyer to offer the same premium to all shareholders. Yet, forcing the buyer to pay a premium to all shareholders raises the acquisition's total costs, thereby effectively barring a range of control-motivated transactions in which the buyer's expected increase in corporate value is insufficient to justify paying the premium demanded by the current controller to all shareholders. Thus, to the extent that a control premium is a proxy for business vision instead of private benefits, the costs imposed by the equal opportunity rule—in terms of discouraging efficient transactions—are expected to be higher.³⁶

(p. 459) 4 Minority Rights

An analysis of the minority shareholder's side of the corporate contract focuses on the threats facing minority shareholders in corporate structures with a controlling shareholder and the type of protection that should be provided to enforce minority rights.

4.1 Type of Protection

Just as the protection of controllers' rights can exist as a property or a liability rule, minority shareholders can receive either property or liability rule protection against the possible exploitation by a controlling shareholder.³⁷ Under a liability rule, the controller can engage in self-dealing transactions without minority shareholders' consent, subject to her duty to pay an objectively fair price. This pecuniary commitment is supervised by courts. On the other hand, under a property rule, the controller cannot engage in self-dealing without securing the minority's consent, typically by a majority-of-the-minority vote.

Indeed, legal regimes could also leave protection against the controlling owner's self-dealings up to the unconstrained forces of the market, allowing for individualized solutions.³⁸ Shareholders would consider the risk of possible self-dealing as a threat to their investments when deciding on share ownership, leading the market to offer protections that mitigate this risk and assuage investor fears. However, markets are not perfectly efficient, and information costs undermine the efficacy of market-based solutions to the point of relatively diminishing standards.³⁹ Therefore, property- and liability-based protections are more efficient than a non-interventionist approach.

The need to balance controller and minority rights dictates the desirable form of minority protection. A property rule provides the minority with consent-based protection that is vulnerable to holdouts and other problems that can prevent the controller from getting minority approval even for a value-enhancing transaction, risking interference with the controller's management right. In contrast, a liability rule provides the minority with fair-

Majority Control and Minority Protection

compensation-based protection. This form of protection is vulnerable to judicial error, but it is less likely to interfere with the controller's management rights.⁴⁰

Given the nature of these tradeoffs, a liability rule theoretically strikes the optimal balance between protecting the minority against agency costs and preserving idiosyncratic vision.⁴¹ (p. 460) However, the actual effect of protections based on property or liability rules depends on the judicial system, market efficiency, and institutional investors of a given jurisdiction.⁴²

In the presence of transaction costs, which include negotiation and adjudication costs, the choice between a liability rule and a property rule depends on which rule encourages and facilitates efficient transactions and discourages inefficient ones. In other words, a rule that facilitates the pursuit of idiosyncratic vision and the curtailment of agency cost should be implemented. A property rule, requiring approval by a majority of the minority of shareholders, involves high negotiation costs. These costs stem from dissemination of information and administration of the voting process, including the risk of strategic voting and hold-outs during the vote. On the other hand, although a liability rule does not rely on negotiations and thus does not entail high negotiation costs, negotiations do take place in the "shadow of the law."

Adjudication costs are relatively low in the presence of a property rule, where the courts need to only determine the procedural integrity of the shareholder approval process. Under a liability rule, the courts are called upon to examine the merits of a deal and opine as to its overall "fairness," which can require significant financial modeling by economic experts and has to rely upon a judicial system competent enough to navigate such complex cases. Costs of erroneous rulings are another type of adjudication cost. In the context of valuation, it is often the case that no "objective" market-based value exists, so the court must rely on a compilation of subjective assessments. In addition to increasing direct adjudication costs, this also increases the risks of mistakes, leading to high indirect adjudication costs as well.

Therefore, where negotiation costs are high due to a lack of sophisticated investors, and only a minimal level of judicial efficacy exists, the balance of negotiation and adjudication costs may weigh in favor of a liability rule. The opposite holds true where adjudication costs caused by judicial inefficiency outweigh negotiation costs. In some circumstances, negotiation and adjudication costs will point to the same direction, where either both will be high or both will be low. When both types of costs are high, a property rule is desirable because the risk of minority exploitation is sufficiently high that the private sector is better suited to respond. It is more likely that markets will react and improve minority protection than it is that governments will overcome path-dependency and improve courts' efficacy. Conversely, when both types of costs are low, a liability rule is desirable because the risks to investors are likely lower and liability protection provides greater ability to contract for alternative protections. An assessment of the relative weights of these two categorical transaction costs can indicate which rule is appropriate in a given context.

Majority Control and Minority Protection

As demonstrated, there is no single efficient mechanism for the protection of the minority from corporate self-dealing. Rather, the choice between a property rule requiring majority-of-the-minority approval before every conflicted transaction and a liability rule allowing controller discretion subject to the court's objective evaluation of a transaction's fairness depends on the unique characteristics of each jurisdiction and how those characteristics impact the balance of the transaction costs. Ultimately, the rule that achieves the lowest (p. 461) transaction costs, thereby encouraging efficient transactions and discouraging inefficient ones, should be chosen.

4.2 Pro-Rata Share: Identifying Self-Dealing

The principal form of minority protection is the strong regulation prohibiting non-pro-rata distributions of a firm's assets. Minority shareholders' main concern is that the entrepreneur-controller will engage in self-dealing, tunneling, or other methods of capturing more than her pro-rata share of cash-flow rights. Therefore, in exchange for the controller's freedom to pursue her idiosyncratic vision by executing her business idea as she sees fit, the controller commits to share proportionally with the minority any cash flows that the project will produce. If she seeks any preference over the minority, she should negotiate with the minority investors and obtain their approval—either before entering the joint investment or before obtaining the preference. Otherwise, any non-pro-rata distribution will be subject to strict judicial scrutiny.⁴³

A legal regime governing companies with controlling shareholders thus should accomplish two important tasks: first, create a workable distinction between neutral business decisions and self-dealing; and second, implement adequate mechanisms to govern self-dealing transactions. The distinction between self-dealing and other transactions has considerable judicial consequences. Under Delaware law, for example, this distinction determines whether a lawsuit challenging a transaction will be carefully reviewed under the plaintiff-friendly entire fairness standard or quickly dismissed under the defendant-friendly business judgment rule.⁴⁴ However, drawing the line between cases that deserve close scrutiny and those that do not is often difficult. Only rarely are cases straightforward; for example, when the controller sells her privately owned asset to the publicly traded firm that she controls, this would most likely constitute self-dealing. In many cases, however, it is unclear whether the mere fact that the controller's interests with respect to certain corporate actions are not fully aligned with those of the minority justifies close scrutiny.⁴⁵

In considering the difficulty of characterizing a transaction as conflicted or non-conflicted, the *dividend distribution* question underlying the *Sinclair* case is instructive.⁴⁶ Should courts protect the minority against the risk that a controlling shareholder will use a pro-rata dividend distribution to advance her own interests? The *Sinclair* court answered this question with a clear answer: "No." Rather, it held that pro-rata dividend distributions do not amount to self-dealing and should thus be reviewed only under the business judgment rule.⁴⁷ Is this the most desirable outcome?

Majority Control and Minority Protection

(p. 462) For purposes of our discussion, assume that a pro-rata distribution could be used to satisfy the controller's own liquidity needs while denying the corporation highly profitable growth opportunities. In other words, assume that a pro-rata dividend distribution could be harmful to minority shareholders. Nevertheless, a legal rule that would aspire to supervise the controller and prevent such "abusive" distributions would be too costly.

Any rule that tries to scrutinize pro-rata dividend distributions would necessarily interfere with the controller's management rights and her ability to pursue her idiosyncratic vision. First, control over the firm's capital structure—the amount of capital that is required and how to finance the firm's operations—might be an integral part of implementing an entrepreneur's vision.⁴⁸ External intervention would therefore significantly interfere with the controllers' ability to make management decisions concerning their vision. Second, distinguishing "legitimate" dividend distributions from illegitimate ones is prone to errors because of asymmetric information and differences of opinion.⁴⁹ A court required to implement this distinction will have to assess the decision to pay dividends in light of its alternative, i.e., a decision to retain the dividend amount and invest it in potential projects. But, how will the court determine that the business opportunity abandoned by the corporation in order to facilitate the dividend distribution was indeed a good business opportunity? Will the court assume responsibility for the investment forced upon the controlling owner when it rules that the dividend is illegal? Lastly, even if courts were to accurately determine that a certain dividend is illegal, effective enforcement would itself require excessive intervention.

A disgruntled controller prohibited from paying a dividend may decide, for example, to avoid investments and instead deposit the dividend amount in the firm's bank account in order to distribute the same amount in the near future. Clearly, courts would not take away the controller's rights to make management decisions by forcing the controller to put the money to other, more profitable uses. In other words, effectively enforcing the (p. 463) non-distribution of dividends would ultimately require courts to abandon the business judgment rule.

Our discussion of *Sinclair* thus shows that the omnipresent tension between controller management rights and minority protection should shape the legal distinction between self-dealing and other transactions. The interests of controlling shareholders, to be sure, are not always fully aligned with those of minority investors. Yet not every conflict of interest justifies legal intervention to protect the minority.

4.3 Mid-Stream Changes

The preceding analysis provides support for Delaware's approach to self-dealing transactions. In this section, however, we explain that the same approach fails to protect minority shareholders against unilateral mid-stream changes to the firm's governance. Controlling shareholders can enjoy more than their pro-rata share of cash-flow rights by using their control to change the firm's governance arrangements mid-stream either directly—through changes in the charter or bylaws—or indirectly through a business combination,

Majority Control and Minority Protection

such as a merger. These changes could be inconsistent with the initial contract between the entrepreneur and investors.⁵⁰

Consider, for example, the link between control and cash-flow rights. Under the one-share-one-vote rule, the controller's willingness to make a significant equity investment in order to secure his controlling position alleviates management agency costs and asymmetric information concerns. Once he raises funds from investors, however, the controller might be tempted to unravel this arrangement and find ways to preserve incontestable control without having to incur the costs associated with holding a large equity block.⁵¹ A necessary element in any minority-protection scheme is, therefore, a protection against the unilateral, mid-stream changes to the firm's governance arrangement.

Indeed, on several occasions, minority shareholders did attempt to challenge such changes in Delaware courts, but without success. Courts refused to review these changes under the entire fairness standard, holding that the disparate *economic* impact of such changes on the controller did not amount to self-dealing as long as the *legal* effect was equal.⁵²

This legal approach assumes that absent a clear restriction in the charter the controller has the right to change the allocation of control rights, thereby exposing the minority shareholders to agency costs. This approach may stem from the fact that Delaware courts use a single test for two distinct tasks—identifying self-dealing transactions and coping with mid-stream changes. However, mid-stream governance changes by controlling shareholders require a separate legal framework that first identifies cases of mid-stream changes, and second, makes a decision on the nature of protection that minority shareholders should enjoy.

(p. 464) 5 “Difficult Cases”

In this section, we consider two examples of transactions that have occupied courts and scholars alike and are not easily classified as dealing with either minority protection or controller rights. We first address freezeout transactions. Transactions of this type raise an inevitable and difficult tension between minority protection and controller rights. Second, we consider Delaware's indeterminate approach concerning transactions in which both the controller and the minority sell, for equal consideration, 100% of the firm to a third party. In these cases, the need for minority protection is substantially weaker than in a freezeout transaction. At the same time, however, subjecting these transactions to closer scrutiny is unlikely to interfere with the controller's right to secure her business vision.

5.1 Freezeout Transactions

In a freezeout transaction, the controlling shareholder of a publicly traded company buys out minority shareholders in order to take the company private. Although freezeouts have

Majority Control and Minority Protection

been subject to extensive analysis by legal scholars,⁵³ courts continue to struggle with the proper approach to regulating these transactions.⁵⁴

Let us start with controller rights. Reviewing freezeout transactions through the lens of the inevitable conflict between minority protection and controller rights calls for providing controllers with an option to discontinue their partnership with the minority by taking the firm private. Buying out the minority may be required when keeping the firm public interferes with the realization of idiosyncratic vision,⁵⁵ or when a minority-protection regime proves too costly. Additionally, bolstering minority protection increases the likelihood that minority-protection measures will interfere with the controller's freedom to pursue her vision, thereby creating an increased need to make it possible for controllers to take the corporation private.⁵⁶ Furthermore, there is an obvious difficulty in forcing an (p. 465) entrepreneur to "work" for others—minority investors—for as long as the investors wish or demand.⁵⁷ As a matter of legal doctrine, the need to provide the controller with an option to buy out the minority explains why Delaware courts have abandoned the requirement that freezeout transactions satisfy a business purpose test.⁵⁸

For minority shareholders, however, freezeout transactions present a substantial risk of expropriation on a large scale. Controlling shareholders might opportunistically use the option to buy out the minority at unfair prices while taking advantage of their superior access to information concerning the firm's true value.⁵⁹ The risk of expropriation calls for effective measures to protect minority shareholders in freezeout transactions.

However, a property rule protection—requiring a freezeout transaction to be conditional on a majority-of-the-minority vote—might undermine the controller's ability to take the firm private in order to preserve her idiosyncratic vision.⁶⁰ Providing minority shareholders with the power to veto a freezeout may inhibit the goal of preserving the controller's idiosyncratic vision in two respects. First, asymmetric information or strategic voting considerations might lead minority shareholders to vote against going-private proposals that are fair to the minority, thereby preventing the controller from an exit that could be vital for securing her business vision. Second, forcing the controller to keep the firm public has the same practical consequence as preventing dividend distribution. The court would have to interfere with management decisions, normally protected by the business judgment rule, to make sure the controller continues to work efficiently for the minority. Therefore, despite the high risk of expropriation, protection for minority shareholders in freezeout transactions should tilt toward a liability rule protection.⁶¹

A narrow reading of the Delaware Chancery Court's decisions in *CNX Gas* is consistent with favoring liability rule protection for minority shareholders in the context of a freezeout. It is possible to read the decision as requiring controlling shareholders to allow the board to use a poison pill to prevent a freezeout.⁶² However, in a subsequent decision, the court (p. 466) seems to suggest that a poison pill is required only if the controller wishes to avoid judicial review of the transaction under the entire fairness standard.⁶³ In other words, the court allowed controllers to choose between a liability rule (judicial review) and a property rule (majority-of-the-minority vote and board veto). Allowing controllers to

Majority Control and Minority Protection

choose the legal regime that would apply to their going-private transaction seems consistent with the pursuit of idiosyncratic vision.⁶⁴ However, a regime that would compel controllers to subject their going-private transaction to a board's deployment of a poison pill would unnecessarily delay the freezeout by forcing the controller to replace the directors before merging.

5.2 Sale to Third Party

The last example we consider is a transaction in which a third party, unrelated to the controller, buys all the company's shares from both the controller and the minority shareholders. In a transaction of this type, the controller—with a majority of the votes—can effectively force the minority to sell their shares (an implied drag-along option). Delaware courts have reviewed such transactions under different levels of scrutiny, depending on whether the controller and the minority received equal consideration. A sale to a third party raises genuine minority protection concerns when the consideration for the controller differs from that payable to the minority. Cases of this type create a conflict between the controller and the minority over the allocation of the sale proceeds. The controller might abuse her control over the target by bargaining with the third party buyer for a transaction that would benefit the controller at the expense of the minority. Not surprisingly, courts have subjected these transactions to the searching entire fairness test.⁶⁵

In contrast, when a third party buyer offers equal consideration to all shareholders, minority shareholders should not need any protection. After all, with the largest equity stake and no apparent conflict, the controller could be relied on to work diligently to achieve the best feasible bargain. Yet Delaware case law on this issue is in remarkable disarray. While some decisions hold that these transactions do not require close scrutiny,⁶⁶ others have allowed minority shareholders to proceed with claims that the controller's need for (p. 467) cash—liquidity—created a conflict of interest that justified the court's review of the transaction.⁶⁷ Delaware courts' willingness to treat the controller's liquidity needs as creating a conflict that justifies judicial review is especially puzzling given their reluctance to treat the controller's liquidity needs as justifying judicial review in other contexts, such as pro-rata dividends.⁶⁸ Despite this seemingly inconsistent approach, the answer to the courts' treatment may lie, not in the nature of the conflict, but rather in the absence of business vision concerns.

To begin, the controller can sell her block at a premium, thereby taking her share of the idiosyncratic vision, while enabling the minority to stay and share in the expected profits arising from the buyer's idiosyncratic vision. Alternatively, the controller can freeze the minority out to pursue her idiosyncratic vision in a wholly owned corporation, subject only to minority shareholders' right to receive an appraisal and entire fairness protection.⁶⁹ However, in contrast to these situations, the right to drag-along the minority does not protect the controller's idiosyncratic vision: The controller sells the corporation and ends her pursuit of the vision. Why, then, does the controller receive the right to force the minority to sell their shares along with her?

Majority Control and Minority Protection

The answer is to allow the *buyer* to pursue her business vision in a wholly owned corporation. Instead of buying just the control block and then freezing out the minority subject to appraisal rights and entire fairness review, the buyer is willing to pay an equal premium to the minority to avoid the costs of a freezeout (i.e., time, effort, uncertainty, and litigation). In this scenario, the controlling seller who forces the minority to sell together with her assumes the role of an auctioneer. However, the controller has substantial holdings that normally induce her to maximize sale price. Thus, unlike the board of directors of a widely held firm that assumes the role of an auctioneer subject to both duty of loyalty and a heightened duty of care (i.e., *Revlon* duties),⁷⁰ the controller is only subject to the duty of loyalty.

Of course, the controller can avoid the role of an auctioneer by selling only her block. Obviously, she will simply do just that unless selling with the minority will result in a higher price. Put differently, the seller needs the minority to sell with her not because doing so will allow her to get the right price for her business vision, but because it will allow her to extract a higher share of the *buyer's* idiosyncratic vision. Accordingly, a controller cannot, for example, decide to take a cash offer over a higher valued bid while dragging along the minority to satisfy her liquidity needs, as this would be a breach of her duties as an auctioneer.

(p. 468) Our framework thus calls for a different treatment of controllers' liquidity needs across transactions. A regime that imposes stricter scrutiny on dividend distributions would inevitably interfere with the controllers' management rights and might undermine their ability to preserve their idiosyncratic vision. These concerns cease to apply when the controller decides to sell the whole corporation to a third party. By putting her management rights up for sale, and also forcing the minority to sell, the controller signals that she is no longer concerned with the firm's implementing *her* idiosyncratic vision. Moreover, a sale to the highest bidder also means that asymmetric information is no longer an issue. In other words, employing judicial review is less likely to be costly here. Thus, even a relatively small risk of a conflict of interest may call for judicial scrutiny.

6 Summary

In publicly held companies with concentrated ownership, minority protection is a central concern of firm regulation. The presence of a controlling shareholder who owns only a fraction (albeit a majority) of cash-flow rights leads to potential agency costs for minority shareholders. In our framework, however, the need to protect minority shareholders from these inevitable agency costs must be balanced against preserving controlling shareholders' ability to pursue their idiosyncratic vision. This tension determines the type of protection that should apply to both the controllers' rights to make management decisions and the minority's rights to receive a pro-rata share of the firm's cash flows.

The value of control lies at least partially in the freedom for an entrepreneur to pursue her idiosyncratic vision associated with her business idea. This pursuit commonly takes place under the conditions of asymmetric information and differences of opinions. Conse-

Majority Control and Minority Protection

quently, this chapter discussed the need for property rule protection of the controlling owner's right to control. Property rule protection guarantees that minority shareholders or courts cannot unilaterally take control rights away from the controller, even for objectively fair compensation. The deferential business judgment rule further strengthens the controlling shareholder's ability to manage the company in pursuit of her idiosyncratic vision. Property rule protection extends to a broad range of corporate actions by the board, such as preserving the controlling shareholder's control even when it is not value-maximizing and protecting the ability of controllers to sell their control block for a premium.

On the other hand, the form of minority protection is also an important question for any legal regime. Minority protection can take two primary forms. Liability rule protection guarantees the minority shareholders that they will receive objective compensation for any unfair self-dealing by a controlling owner after an ex post entire fairness review by the courts. Property rule protection requires a majority-of-the-minority vote ex ante before any self-dealing transaction can be consummated in the first place, essentially guaranteeing the minority the subjective value of their consent. Transaction costs inform which rule should be utilized. Differences in the relative size of negotiation and adjudication costs based on the efficacy of judicial systems, efficiency of markets, and presence of institutional investors suggest a liability rule in some jurisdictions and a property rule in others.

Minority protection is characterized fundamentally by the principle of equal, or pro-rata, distribution. Under this imperative, controlling shareholders have agreed to allow (p. 469) minority shareholders to share equally the proceeds arising from the controller's freedom to pursue her idiosyncratic vision. However, the application of this principle can be difficult in reality because of the frequently unclear division between conflicted and non-conflicted transactions. Finally, certain kinds of transactions, such as freezeouts and sales of 100% of a controlled company to a third party, present unique problems in achieving an optimal balance between securing the controller's ability to pursue her business vision and protecting the minority shareholders against agency costs and exploitation.

Notes:

(¹) Our definition of concentrated ownership structure sets it apart from dual class firms and pyramidal structures. In the United States, Delaware courts have declined to quantify the precise percentage of stock necessary to constitute an "effective majority," choosing instead to engage in a factual inquiry of the exercise of actual control in each case. See, e.g., *Kahn v. Lynch Comm'ns Systems*, 638 A.2d 1110 (Del. 1994).

Majority Control and Minority Protection

⁽³⁾ Another perspective takes a more positive view of concentrated ownership, emphasizing the governance role of controlling owners. This view argues that an investor's significant equity stake in a firm leads to more effective monitoring of management, and considers the private benefits associated with controlling ownership to be a reward or compensation for this monitoring. See, Ronald J. Gilson, "Controlling Shareholders and Corporate Governance: Complicating the Comparative Taxonomy", 119 Harv. L. Rev. 1641, 1663-64 (2006).

⁽⁴⁾ Our theory is fully developed elsewhere. See, Zohar Goshen and Assaf Hamdani, "Corporate Control and Idiosyncratic Vision", 125 Yale L. J. 560 (2016).

⁽⁵⁾ It is important not to confuse business vision with nonpecuniary benefits of control. Non-pecuniary benefits of control refer to the value (e.g., personal satisfaction, pride, fame, political power) that only the entrepreneur derives from the execution of her business idea. In contrast, the pursuit of business vision—if properly harnessed—will equally benefit all shareholders in the corporation.

⁽⁹⁾ See Djankov et al., *supra* note 2. Based on their study of 72 countries, the authors suggest that regulation of self-dealing transactions is best done by disclosure and ratification by disinterested shareholders. The analysis of the relative efficiency of rules regulating self-dealing was developed several years earlier. See Zohar Goshen, "The Efficiency of Controlling Corporate Self-Dealing: Theory Meets Reality", 91 Cal. L. Rev. 393 (2003) [hereinafter Goshen, Controlling Self-Dealing] (introducing and applying the property rule/liability rule analysis to minority-shareholders' protection) [hereinafter Goshen, Controlling Self-Dealing].

(¹⁴) For a case in which the court concluded that a controlling shareholder had a strong idiosyncratic vision (without using this term, of course), and therefore approved a series of long-term self-dealing transactions as fair, see *Cookies Food Products, Inc. v. Lakes Warehouse Distributing, Inc.*, 430 N.W. 2d 447 (Sup. Iowa 1988).

(¹⁶) See Goshen, Controlling Self-Dealing, *supra* note 9 (explaining the inefficiencies associated with a fairness test).

(¹⁷) See *id.* (reviewing opportunism and inefficiencies associated with majority-of-minority voting).

(¹⁸) Modern corporate governance relies on a variety of gatekeepers and enforcement measures to constrain agency costs. These include, for example, financial reporting and other disclosure duties, requiring outside auditors and setting standards for their work, and requirements for outside independent directors. These measures could interfere with the controller’s ability to manage the firm in a way that limits her ability to capture the full value of her idiosyncratic vision.

(¹⁹) See generally Guido Calabresi & A. Douglas Melamed, “Property Rules, Liability Rules, and Inalienability: One View of the Cathedral”, 85 Harv. L. Rev. 1089 (1972).

(²⁰) The need for property rule protection arises from the fundamental justification for allocating control and management rights to the entrepreneur. The controller-entrepreneur is the one who has the unique vision or subjective assessment concerning the project’s value (idiosyncratic vision). Any objectively determined compensation for a non-consensual taking will rarely be fair to the entrepreneur. The extensive academic literature on property and liability rules suggests that a property rule protection is appropriate when business vision is present. See Henry E. Smith, “Property and Property Rules”, 79 N.Y.U. L. Rev. 1719, 1722–31, 1755–56 (2004).

(²¹) See *Bershad v. Curtiss-Wright*, 535 A.2d 840 (Del. 1987). But see generally Jens Dammann, “Corporate Ostracism: Freezing Out Controlling Shareholders”, 33 J. Corp. L. 681, 694 (2007) (explaining an innovative proposal for a regime under which minority investors could force the controller out).

(²²) Some limits are imposed, however, on the identity of the buyer. See *Harris v. Carter*, 582 A.2d 222 (Del. Ch. 1990) (prohibiting sale of control to a known looter and imposing limited duties of investigation on controlling shareholders). In *Hollinger*, Delaware’s Chancery Court allowed the board to use a poison pill to prevent a controlling shareholder from selling his control block. We believe, however, that this holding applies only when the sale of the block is in clear violation of the controller’s fiduciary duties. See *Hollinger Int’l., Inc., v. Black*, 844 A.2d 1022, 1085–86 (Del. Ch. 2004) (allowing the board to deploy

Majority Control and Minority Protection

a poison pill when sale of control was the culmination of an improper course of conduct by the controller and in violation of his contractual obligations).

(²³) See *Mendel v. Carroll*, 651 A.2d 297, 306 (Del. Ch. 1994). For an analysis of this decision and its implications, see John C. Coffee, Jr., “Transfers of Control and the Quest for Efficiency: Can Delaware Law Encourage Efficient Transactions While Chilling Inefficient Ones?”, 21 Del. J. Corp. L. 359, 390–96 (1996).

(²⁴) Note that this treatment of the controller differs from that of minority shareholders (or investors at widely held firms). We normally allow management to use rights offerings even when that might coerce investors into a choice between dilution and increasing their investment. For evidence that a controller’s need to preserve control affects firm decisions concerning capital structure, see, e.g., Thomas Schmid, “Control Considerations, Creditor Monitoring, and the Capital Structure of Family Firms”, 37 J. Banking & Fin. 257 (2013) (finding evidence consistent with the hypothesis that family firms in Germany use firms’ capital structure to optimize control over the firm).

(2009) (finding corporate value is consistently higher in controlled firms with independent directors).

⁽³⁰⁾ Indeed, under NASDAQ Rule 4350(c)(5) a controlled company is exempt from the requirement of Rule 4350(c) of the NASDAQ Marketplace Rule requiring a majority of independent directors on the board. A similar exemption exists under Section 303A of the NYSE's Listed Company Manual.

⁽³¹⁾ The common-law norm to sell control for a premium is explained clearly in *Zeitlin v. Hanson Holdings, Inc.*, 397 N.E.2d 387, 388–89 (N.Y. 1979) (“It has long been settled law that, absent looting of corporate assets, conversion of a corporate opportunity, fraud or other acts of bad faith, a controlling stockholder is free to sell, and a purchaser is free to buy, that controlling interest at a premium price.”). But see William D. Andrews, “The Stockholder’s Right to Equal Opportunity in the Sale of Shares”, 78 Harv. L. Rev 505 (1965) (arguing for a sharing of control premium with minority shareholders).

⁽³²⁾ See *Abraham v. Emerson Radio Corp.*, 901 A.2d 751, 758 (Del. Ch. 2006); *Harris v. Carter*, 582 A.2d 222, 234 (Del. Ch. 1990).

⁽³³⁾ See Lucian A. Bebchuk, “Efficient and Inefficient Sales of Corporate Control”, 109 Q. J. Econ. 957 (1994).

⁽³⁴⁾ At the same time, our framework could lend support to the equal-opportunity rule. After all, investors in our framework allow the controller to preserve control in order to enable the controller to pursue idiosyncratic vision that would then be shared with investors. When the controller exits the joint investment she takes her pro-rata part of her business vision from the buyer, leaving minority shareholders to wait until the new buyer realizes his idiosyncratic vision. The claim could thus be that the seller must first perform her contractual commitment to the minority (pay the promised share of idiosyncratic vision) before she can ask the minority to enter a new contract with the buyer.

⁽³⁵⁾ See, e.g., U.K. City Code on Takeovers and Mergers, Rule 36 (stating a purchaser crossing 30% triggers a mandatory offer for over 50% of the company); EU Takeover Directive (Directive 2004/25/EC [adoption: codecision COD/2002/0240]) (mandating that “Member States must ensure that [a controller] is required to make a bid as a means of protecting the minority shareholders of that company. Such a bid must be addressed at the earliest opportunity to all the holders of those securities for all their holdings at the equitable price”).

Majority Control and Minority Protection

(³⁹) See Goshen, Controlling Self-Dealing, *supra* note 9, at 405.

(⁴⁰) To be sure, as Delaware's case law demonstrates, majority-of-the-minority votes may play an important role in scrutinizing self-dealing transactions even under a liability rule. Yet it authorizes courts to approve self-dealing transactions notwithstanding the minority objection, thereby reducing the risk of errors resulting from hold-outs or differences of opinion between the controller and investors.

(⁴¹) Note that specialized courts would not only enhance minority protection, but also reduce the risk of excessive interference with controlling shareholders' rights. Specialized courts are less likely to err. This in turn would decrease the cost—in terms of undermining controller rights—of rules designed to protect minority shareholders. See, e.g., Luca Enriques, Off the Books, But on the Record: Evidence from Italy on the Relevance of Judges to the Quality of Corporate Law, in *Global Markets and Domestic Institutions: Corporate Law in a New Era of Cross Border Deals* (Curtis Milhaupt ed., 2003).

(⁴⁸) In a world with no transaction costs the firm's capital structure (i.e., its debt to equity ratio) can be determined using any combination of dividends, leverage, and share issuance, with the same effect on corporate value. Similarly, buying a risky investment with no leverage is the same as buying a solid investment with leverage. See Merton Miller, "The Modigliani-Miller Propositions after Thirty Years", 2 J. Econ. Persp. 99 (1988) (discussing Modigliani and Miller's theorems about the irrelevance of capital structure and dividend policy for corporate value). But, in a world with transaction costs, vision as to a business idea is no different than vision as to capital structure. A controlling shareholder decision to issue new shares and invest in a project should be treated in the same manner as her decision to avoid a project and distribute the money.

Majority Control and Minority Protection

(⁴⁹) Any investment offers a combination of risk and expected returns that are calculated based on estimates of future events or consequences. An investment with an expected return that equals the market pricing of a similar risk offers a zero net present value (NPV). In efficient markets all investments are zero NPV, but to make our point it is sufficient to assume that most of them are. If the expected return on the investment is lower (higher) than the market pricing of the risk that it carries, then it offers a negative (positive) NPV and should be avoided (is a bargain). A controller decision to forego an investment in order to distribute dividends will harm minority shareholders only if the avoided investment was positive NPV (negative NPV should be avoided, and zero NPV leaves shareholders with many alternatives for reinvesting the dividend). Deciding about an investment's NPV would require courts to decide whether the investment is good or bad. Courts cannot make such a decision. Indeed, avoiding such decisions is a major justification for the business judgment rule.

(⁵⁵) For example, an entrepreneur may believe it is no longer possible to implement her vision while complying with the extensive disclosure duties imposed on public companies. (⁵⁶) Assume a liability rule protection against self-dealing under which courts make errors in 20% of the cases: in half of them they approve unfair transactions and in the other half they block fair transactions. When the court approves an unfair transaction, the direct damage is the given transfer of wealth from the minority to the controller (i.e., zero sum transfer), while the indirect damage of under-deterrence is limited due to the small percentage of such mistakes. However, when the court erroneously blocks a fair transaction the damage is not limited to over-deterrence and zero sum transfer, as it also includes the frustration of business vision. The last damage might in some cases be too high to tolerate. Thus, due to the potential incidence of such cases the legal system should contain a safety valve when minority shareholder protections are involved—the ability to take the company private.

Abstract and Keywords

This chapter focuses on the evolving role of debt as a tool of corporate governance, or debt governance, within the context of developments in the private credit market. It first discusses debt's traditional function, with particular emphasis on illiquid loans and the lenders' reliance on monitoring and covenants in order to manage a borrower's credit risk. It then considers how loans and lending relationships have evolved over time in light of the increased liquidity of traditionally private instruments. One outcome for debt governance may be a shift from the traditional dependence on covenants and monitoring to a greater reliance on the disciplining effect of liquid credit instruments.

Keywords: debt, corporate governance, debt governance, private credit, illiquid loans, lenders, credit risk, lending, liquidity, private instruments

1 Introduction

¹WITHIN the traditional framing,² lenders rely on loan covenants and monitoring to minimize agency costs, restrain borrower misbehavior, and manage credit risk.³ A borrower's commitment to making principal and interest payments may also reduce the agency costs of free cash flow.⁴ Debt, however, can be a clunky governance device.⁵ Financial contracts are incomplete and covenants are imprecise—reflecting, among other things, the difficulty of predicting a borrower's future actions and circumstances when first agreeing on a (p. 471) loan's terms.⁶ If the terms are too flexible, the borrower may pursue projects that benefit its shareholders, potentially at the lender's expense.⁷ If the terms are too strict, the borrower may forgo projects that are valuable to the firm and, potentially, its creditors.⁸ Over time, as new information arises, lenders can renegotiate the loan's terms—including modifying outdated covenants and waiving events of default—but only to the extent the original agreement was broad enough in the first place to capture the borrower's future actions or circumstances.⁹

As Oliver Williamson has described, the way a firm is governed is closely related to how it raises capital.¹⁰ A corollary to Williamson's insight is that change in the capital markets can also result in change in corporate governance.¹¹ This chapter traces debt's evolving role as a corporate governance device (sometimes referred to as "debt governance") in light of developments in the private credit market. It starts by reviewing debt as it was traditionally structured—illiquid and largely reliant on covenants and monitoring, with contract providing creditors a long-term say in how borrowers were managed. The chapter then explains how the relationship between creditors and borrowers has evolved over time as traditionally private instruments have become more liquid. Today, lenders can manage credit risk through purchases and sales of loans and other credit risk,¹² potentially lowering capital costs,¹³ but (p. 472) also weakening their incentives to monitor and enforce covenant protections.¹⁴ Loans and lending relationships have evolved in response to those changes, providing new means for debt to influence corporate governance.¹⁵ In particular, actions affecting a borrower's credit quality are more likely to be reflected in the price at which its loans and other credit instruments trade in the secondary market.¹⁶ Those changes can affect the borrower's cost of capital, providing managers with a real-time incentive to minimize risky behavior—an emerging discipline that may complement the traditional protections provided by covenants and monitoring.¹⁷

2 Debt's Traditional Role

Most public company debt is private, and most private loans are made or arranged by commercial banks (although increasingly they involve nonbank lenders).¹⁸ Even among public firms, which typically have access to larger pools of capital,¹⁹ roughly 80% maintain private credit arrangements.²⁰

Loans are illiquid within the traditional framing of the firm. The difficulty in trading loans reinforced the lenders' (often banks') reliance on monitoring and covenants in order to manage a borrower's credit risk.²¹ Portfolio theory suggested there were less costly means for lenders to do so,²² but they required a liquid market for the purchase and sale of credit, which (p. 473) did not exist at the time.²³ Diversification's benefits, therefore, applied principally to public common stock, with lenders instead relying on contractual protections to manage loan-related risks. As described below, other characteristics affecting debt governance included borrower reputation,²⁴ the reduction in free cash flow,²⁵ and loan maturity.²⁶ Together, they provided creditors with tools to oversee a borrower's business and operations.

2.1 Low-Cost Monitoring

Within the standard construct of the firm, lenders rely on long-term relationships in order to monitor borrowers and their credit quality.²⁷ Banks can access quasi-public information about borrowers in the ordinary course of business—for example, through deposit taking and providing financial advice.²⁸ Doing so permits banks to monitor borrowers in more detail and at lower cost than other creditors.²⁹ It also allows banks to detect and de-

ter managerial slack at an early stage, minimizing potential losses and providing shareholders and other investors with a credible signal of the borrower's performance.³⁰ The resulting benefits can be tangible—the borrower's capital costs may decline as other investors, including shareholders, freeride on the enhanced oversight provided by self-interested bank monitors.³¹ That reliance, however, can increase a bank's bargaining power over the borrower. The bank's presumptive knowledge of a borrower's credit quality can create a hold-up problem if the bank demands a greater return as a condition to making (or rolling over) a loan. In response, the borrower may look to diversify its funding sources, relying on other lenders in order to dilute the bank's ability to appropriate rents.³² Weighing against those benefits, however, is the (p. 474) likelihood that less-informed creditors will seek stricter covenants in order to more closely control a borrower's actions in light of the higher cost of monitoring.³³

2.2 Covenants

In a perfect world, creditors would be as familiar as a borrower's managers with projects that require new financing. In the real world, with costly monitoring,³⁴ lenders have only limited information, which potentially allows managers to invest in less profitable projects that may benefit them personally or favor one class of investors over another.³⁵

In order to attract new lending at low cost, managers must credibly commit to behave in a manner consistent with the creditors' interests. That commitment is particularly important to debt holders, since shareholders (who benefit from directors' fiduciary duties, and who may exercise voting control over the board³⁶) are interested in increasing the firm's risk-taking once debt is in place. Doing so may enhance shareholder returns without raising the limit on their losses. Lenders typically do not share (or share less) in any incremental returns.

Covenants provide one solution by contractually limiting how managers operate the borrower's business. By protecting lenders, tighter covenants can improve the firm's borrowing capacity, decrease costs, and increase share price through the debt capital available to fund new projects and the positive signal provided by new lending.³⁷ Covenants also act as early warning "trip wires,"³⁸ when breached, that enable lenders to reassess a borrower's credit quality and mitigate loss by renegotiating a loan's terms.³⁹

Covenants, however, are imperfect predictors of management behavior. Lenders may not be able to anticipate a borrower's future actions or circumstances at the time the loan is made.⁴⁰ Consequently, covenant violations are not uncommon, but they typically do (p. 475) not result in lenders accelerating repayment of the loan or taking control of the borrower.⁴¹ Instead, the violations are often waived by the lenders, but can be costly to a borrower because renegotiations may prompt closer scrutiny of the borrower's credit quality and tighter covenant restrictions in both the renegotiated and future loans.⁴² Managers, therefore, have a strong incentive to ensure the firm complies with the loan's original terms.⁴³

Debt and Corporate Governance

A loan's terms may also adjust in response to changes in a borrower's circumstances.⁴⁴ A pricing grid is one example. Normally, a decline in cash flow would cause the borrower, in light of its riskier position, to be better off under the loan's original terms than if it entered into a new loan, creating a strong incentive for it to avoid renegotiation. A pricing grid can adjust the amount of interest that is payable based on changes in a borrower's riskiness, as measured by its financial ratios or credit rating. By increasing interest payments, the pricing grid shifts the relative bargaining power to the lender, which can restructure the loan to reflect the borrower's new circumstances. Conversely, improved performance can cause a drop in the interest the borrower must pay, reflecting its better credit quality.⁴⁵ Together, the grid establishes minimum performance standards for the borrower and rewards actions that minimize risk to the lender.⁴⁶

A creditor can also use covenants to limit a borrower's use of funds that are available to repay its loan.⁴⁷ The effect of the limit is likely to depend on the borrower's characteristics. A start-up firm with high growth opportunities, for example, is likely to benefit if management's hands are relatively untied, permitting them to allocate capital to the most profitable projects. Such a firm, however, often has fewer tangible assets against which a loan can be made. The lender may then rely on shorter maturities⁴⁸ or more costly loan restrictions in order to manage its exposure to the borrower.⁴⁹ A slower-growing firm, by contrast, faces the possibility of managers making unprofitable investments. In that case, covenants restricting overinvestment or a borrower's ability to incur debt may benefit the lender. Explicitly limiting capital expenditures, particularly after a decline in the firm's credit quality, is likely to enhance operating performance and cause a rise in stock price.⁵⁰ Although there is a risk that some covenants will limit profitable activity, that cost can be (p. 476) offset by the ability, among a small group of lenders, to inexpensively renegotiate covenants that become too restrictive.⁵¹

2.3 Reputation

A borrower's reputation can affect the covenant types that lenders demand and, in turn, the means by which lenders oversee corporate governance.⁵² A firm that repeatedly accesses the credit market has an economic interest in developing a reputation as a "good" borrower, acting in a manner consistent with lender expectations. Lenders may begin to relax their reliance on covenants and monitoring for borrowers with established reputations.⁵³ Nevertheless, as Michael Jensen and William Meckling famously noted, even "sainthood" cannot drive agency costs to zero.⁵⁴ Lenders and borrowers have short-term memories, so the incentives that make reputation valuable in the near-term can shift with changes in the marketplace. Actions that prompt a poor reputation may be forgotten over time.⁵⁵

2.4 Free Cash Flow

Debt can help curb excessive management spending, in large part through contractual provisions, like loan covenants, that require the debtor to make specified payments (principal and interest), meet minimum financial criteria, report periodically, and operate with-

in bounds specified by the creditors.⁵⁶ Loans, therefore, can reduce the (p. 477) agency costs of free cash flow, making less cash available to be spent at the managers' discretion.⁵⁷

The board typically has discretion to suspend dividend payments, but suspending interest payments usually is a breach of the firm's debt obligations. Thus, debt financing increases the risk of bankruptcy, and greater leverage increases a firm's risk of incurring the real costs of financial distress—the actual costs of bankruptcy, as well as a rise in risk premiums demanded by customers, suppliers, and employees.⁵⁸ In order to reduce those risks, managers are motivated to maximize profitability, including by reducing business expenses, working harder, and investing more carefully.⁵⁹ Incurring greater debt may signal a manager's confidence in the company's future by requiring a commitment to making profitable investments (in order to pay amounts owing under the indebtedness) and a willingness to be monitored by outsiders.⁶⁰ Furthermore, greater leverage permits superior managers to signal their quality, separating them from managers who potentially suffer a greater risk of bankruptcy.⁶¹ Managers have a direct, personal stake in avoiding bankruptcy, since directors and officers of bankrupt firms tend to do poorly in the labor market.⁶²

On balance, entrenched managers⁶³ are more likely to prefer lower levels of borrowing in order to reduce monitoring and minimize the limitations imposed by (p. 478) creditors.⁶⁴ Less debt reduces the risk of financial distress and, in turn, the risk to managers of losing the private perks of their position.⁶⁵ Nevertheless, in some cases, entrenched managers may incur higher levels of indebtedness. A manager whose interests are aligned with the shareholders (e.g., where compensation is tied to the firm's stock price) may prefer riskier policy choices that are more likely to benefit shareholders at the creditors' expense.⁶⁶ Entrenched managers may be less risky—more willing to adopt conservative investment policies⁶⁷—and, therefore, lenders may be more willing to provide those managers with lower-cost financing.⁶⁸ In that case, a greater reliance on debt may reflect weaker corporate governance rather than signal an improvement in managerial performance.⁶⁹

2.5 Maturity

Loan maturities can also affect corporate governance. Debt with a short-term maturity motivates managers to invest in profitable projects or risk the loss of future, near-term financing. Before rolling over an existing loan or extending a new one, lenders must be convinced of management's ability to operate the firm profitably; any doubts may be reflected in increased capital costs.⁷⁰ Likewise, if funding is short term, successful management can be (p. 479) reflected in a lower cost of refinancing, resulting in a decline in the firm's capital costs that benefits shareholders as well as creditors.⁷¹

Longer-term debt postpones a borrower's need for refinancing. The longer maturity may reflect less need for creditor oversight, or it may reflect concerns over the borrower's near-term capacity to repay the loan.⁷² Repayment, however, depends on the borrower's

future earnings, so longer maturities may also help motivate managers to pursue longer-term, value-additive projects.⁷³

3 Private Credit Market Liquidity

Within the traditional framing of the firm, a bank's familiarity with a borrower made it less costly for it to extend loans than a more arm's-length creditor.⁷⁴ That same advantage also made it more difficult for the bank to resell loans to less knowledgeable purchasers, a classic "lemons problem" that impeded the creation of a liquid credit market.⁷⁵ The lending business, however, began to transform in the 1970s and 1980s, driven by increasing competition (both for depositors and borrowers), innovation in the marketplace, and changes in financial regulation.⁷⁶ Developments in technology also eroded the banks' informational advantage over nonbanks, making it easier for new market participants to assess a borrower's (p. 480) credit quality.⁷⁷ Banks, as a result, began to reassess corporate lending and loan trading, with many adopting new strategies to minimize costs.⁷⁸

Among the new approaches, banks began to diversify their exposure to credit risk, which required a liquid market to buy and sell loans and other credit instruments. New technologies could measure risk and diversification across loan portfolios, enabling banks to decide which assets to buy and sell, and at what price, in order to optimize a portfolio's return-to-risk relationship.⁷⁹ The costs traditionally associated with loan resales were offset by the real benefits of managing credit risk, among them more profitable loan portfolios.⁸⁰ The lending business evolved as banks originated loans for sale to others and bought and sold credit risk in order to better manage their exposure.⁸¹ A portion of the gains could be (p. 481) passed on to borrowers, potentially enhancing a bank's competitiveness and lowering the borrowers' real cost of capital.⁸²

The result was greater liquidity in the private credit market, in part through loan syndication, collateralized loan obligations (CLOs), and credit default swaps (CDS). Within loan syndications, one or more "lead banks" (or "arrangers") negotiates the terms of a loan and invites other lenders to participate at origination. Interests in a loan, whether or not syndicated, can also be sold in the secondary market, which riskier borrowers and non-bank investors tend to dominate.⁸³ Through CLOs, a portfolio of loans can be sold to a special purpose vehicle that, in turn, issues multiple tranches of CLO securities in order to fund the purchase. Converting loan assets to securities, and then transferring interests through the capital markets, enhances their liquidity.⁸⁴ Finally, credit derivatives enable lenders to transfer credit risk to other investors. Using CDS,⁸⁵ for example, a lender can sell all or a portion of a borrower's credit risk without transferring the loan itself. In effect, CDS permit lenders to outsource credit risk to CDS investors who can assume (and manage) a borrower's credit risk without funding the working capital component of the loan.⁸⁶ Doing so enables (p. 482) lenders to manage credit exposure more efficiently, providing value-maximizing managers with an incentive to continue to grow the private credit market.⁸⁷

Balanced against liquidity's benefits is the risk that by "decoupling" economic and control rights—for example, through CLOs or CDS—a lender may have less interest in monitoring the borrower or acting for those who own economic interests in the loan. Purchasers of credit risk may be better able to manage that risk through diversification, but they may also be less able to oversee borrowers as effectively as the originator, resulting in increased agency costs and an overall decline in corporate governance.⁸⁸

Those costs are similar to agency costs that arise in the public market, but with a critical difference: Unlike firms that issue public bonds, information regarding private borrowers is often less accessible.⁸⁹ Some portion of the cost is offset by the creditors' ability to buy and sell credit risk more efficiently.⁹⁰ Nevertheless, investors may demand higher returns to compensate for the greater risk—a result that is unlikely to be sustained if there are less-costly means to mitigate the agency costs. Designing resale arrangements to address the problems of limited information can reduce the lemons problem, increasing a bank's ability to transfer loans at lower cost and enhancing profitability.⁹¹ Market participants, therefore, have looked to change how loans are structured and, by extension, they have shaped new forms of debt governance.⁹² As discussed below, a key to that change has been the response of the private credit market to shifts in the source of capital, as providers have moved from bank lenders (within the traditional framing) to bank and non-bank investors in an increasingly liquid credit market.

(p. 483) 3.1 Syndication

A loan is more likely to be syndicated as information about the borrower becomes more accessible (e.g., through reliance on a credit rating or based on public information).⁹³ For less well known borrowers, the number of lenders may be capped and resales restricted in order to encourage direct monitoring and renegotiation if a covenant is breached.⁹⁴ Participants in the original syndicate are more likely than later purchasers to have long-term relationships with the borrower, enabling them to monitor the borrower at lower cost and facilitating coordination.⁹⁵ Thus, a lead bank's traditional governance role in overseeing a borrower may be replaced by the collective oversight of the syndicate's members.

As a condition of sale, a purchaser can also require the lead bank to continue to hold a portion of the loan until it matures.⁹⁶ By retaining economic risk, the bank can credibly commit to continued monitoring and, as necessary, enforcing a loan's covenants.⁹⁷ A lender can also commit to monitoring if, as is often the case, other relationships with the borrower continue to motivate oversight. Those relationships, however, may be of questionable value **(p. 484)** to the extent they result in a conflict between the economic interests of syndicate members and the originating lender.⁹⁸

3.2 Changes in Covenants

Covenant levels may drop if creditors are unable at low cost to monitor a borrower's compliance with its obligations or to renegotiate the terms following breach. Public bonds

typically contain less restrictive covenants than loans,⁹⁹ in part due to the public availability of information, the higher cost to directly monitor and enforce compliance, and a decline in the ability (or, for higher-quality borrowers, the need) to mitigate credit risk through contract.¹⁰⁰ For private borrowers, covenants levels may increase as one means to offset the greater monitoring costs that arise with more opaque firms.¹⁰¹ Thus, non-syndicated loans structured for resale (typically leveraged, risky loans to nonbank, institutional investors) may contain higher covenant levels tied to observable public information. In addition, by tightening covenants, lenders can more quickly discover changes in a borrower's financial position. And by tying covenants to observable data, purchasers can mitigate the increased cost of direct monitoring.¹⁰²

Transferring credit risk may also enable a creditor to enforce its covenant protections more effectively. The decline in exposure can enhance the lender's relative bargaining power, enabling it to more easily refuse to renegotiate a loan unless the terms are attractive. In the extreme, a creditor who transferred its economic risk may have less incentive to renegotiate or restructure a loan altogether, potentially reducing the value of the borrower's outstanding debt or even pushing the borrower into bankruptcy.¹⁰³

Consequently, growing liquidity has (p. 485) prompted the rise of specialist investors (sometimes referred to as "vultures") who look to influence a firm's management through its debt covenants. Loans purchased by those investors are often distressed, with the discount in purchase price (and potential for substantial return) offsetting the greater cost of monitoring.¹⁰⁴ Investors use the borrower's breach of its covenants to force a change in policies or a change in control. This provides another pair of eyes over distressed borrowers, where the potential for management opportunism can be greatest.¹⁰⁵

3.3 Reputation

Reputation can also mitigate agency costs, although as noted earlier,¹⁰⁶ its influence may not be significant or long lasting. A reputable borrower is more likely to be able to obtain loans with fewer restrictions than a borrower with a less well known or reputable credit history. The potential benefits can incentivize a borrower to act in a manner consistent with its lenders' interests.¹⁰⁷ For example, prior to the 2008 financial crisis, private equity sponsors saw a substantial rise in "covenant-lite" (or "cov-lite") loans, which, as the name suggests, have fewer covenants (typically, fewer maintenance covenants) than most commercial loans. Competition among bankers for new business is likely to have contributed to the climb. Reputation may have also played a role. The private equity market is comprised of a limited group of participants that interact frequently, suggesting that a reputation as a "good" borrower may have had substantial and positive economic consequences.¹⁰⁸

Bank reputation can also be important.¹⁰⁹ The manner in which a bank structures a loan or monitors a borrower may not be apparent to investors at the time the loan is sold. The purchaser, instead, must rely on the lender's reputation based on prior sales. Structuring a bad loan or failing to monitor a borrower can hurt that reputation. Consequently, so long as loan sales are a significant part of its business, concerns over reputation may in-

duce an originating bank to continue to monitor a borrower, even after its credit risk has been transferred.¹¹⁰

(p. 486) 4 Debt's Evolution

Lending has changed in response to greater liquidity in the private credit market. Syndicate structure, covenant levels, and reputation are all means to reduce the resulting agency costs and balance the potential decline in debt governance.

A further change has resulted from greater liquidity in the credit market itself. For public debt, secondary trading prices inform managers of how the market assesses a borrower's credit quality.¹¹¹ Likewise, as the private credit market becomes more liquid, one would expect actions that affect a firm's credit quality increasingly to be reflected in changes in the price at which a firm's loans and other credit instruments trade. Those changes may affect a borrower's cost of capital, providing a discipline through the feedback furnished by market participants that complements the traditional protections provided by contract.¹¹²

Loan agreements already include features, like pricing grids,¹¹³ that adjust the real cost of capital based on pre-agreed changes in a borrower's financial condition or credit rating. Going forward, lenders can also rely on the secondary pricing of credit instruments in order to assess a firm's credit quality and, if necessary, determine the cost of hedging their credit exposure. A borrower's actions that change the price at which its existing loans or other credit instruments trade can influence the price and non-price terms on which lenders are prepared to make subsequent loans. Since most loan pricing is tied to default risk, actions that increase credit risk will result in a corresponding increase in a borrower's cost of capital.¹¹⁴

As a result, growth in secondary trading may begin to overtake the role of covenants and monitoring in corporate governance. Covenants can be over- or under-inclusive, reflecting the difficulty of anticipating future events and drafting terms that properly reflect them. By contrast, since firms access the credit market on a regular basis,¹¹⁵ changes in credit pricing that directly affect a firm's cost of capital may provide a more efficient and timely alternative.¹¹⁶ More costly debt can affect a firm shortly after a change in its credit risk, either through a higher interest rate on an existing loan or the greater cost of a new loan. That cost, in turn, may lower the firm's share price and, like public equity, discipline managers by affecting compensation, retention decisions based on share price performance, and the possibility of a hostile takeover.

To be clear, covenants and monitoring are likely to continue to play an important role in corporate governance, but some portion of the traditional reliance may be offset by the feedback provided by an increasingly liquid credit market. The trick, as the markets become (p. 487) more complete, will be to balance that new discipline against the traditional role played by covenants and monitoring.

5 Conclusion

Traditional debt governance is premised on debt's relative illiquidity. Banks with access to private information were able to extend loans at lower cost than other lenders, but looked to covenants and monitoring as a principal means to manage credit risk. The last four decades have witnessed the transformation of the traditional bank-borrower relationship, resulting in growth in the private credit market. Over time, with greater liquidity, changes in a firm's credit quality may increasingly be reflected in the pricing of its credit instruments. This may create a more efficient "real-time" alternative that supplements a lender's traditional reliance on covenants and monitoring. In short, as noted at the outset of this chapter, changes in the capital markets have affected capital structure, and changes in how a firm raises capital have also affected corporate governance.¹¹⁷

Those changes prompt a question: To what extent should new financial regulation—beyond its focus on market integrity, customer protection, and systemic risk—take into account its effect on corporate governance? Consider, for example, the new federal regulation of credit derivatives. In a frictionless world, a firm's equity and debt prices should move in tandem when new information is discovered.¹¹⁸ In practice, CDS often have reacted first to new credit information—with prices moving ahead of changes in equity and debt,¹¹⁹ as well as preceding the public announcement of a negative change in a firm's credit rating.¹²⁰ A change in CDS pricing, therefore, often mirrored an increase or decrease in a firm's credit quality before a change in its debt or equity price. The result was more timely (and potentially more accurate) feedback on changes in a firm's riskiness,¹²¹ particularly in light of recent (p. 488) concern over LIBOR and the credit-rating process.¹²² That feedback, in turn, affected new credit extended to the firm, providing the borrower with a real-time incentive to manage its risky projects and activities.¹²³

Part of the difference in responsiveness reflected the special access of banks that traded CDS to quasi-public information about borrowers.¹²⁴ With the passage of the Dodd-Frank Act, however, CDS have become subject to the federal securities laws. As a result, trading in CDS based on material non-public information is prohibited, and those instruments are likely to become less informative.¹²⁵ Prohibiting insider trading in CDS may not be a bad outcome. But to what extent should the impact of CDS on corporate governance be part of the analysis around the new regulation? Should that effect, and the weakening of a debt governance tool, inform part of the policy makers' deliberations? These questions mirror the evolving nature of debt and debt governance described in this chapter. They also suggest a need to take a more expansive view of the effect of new financial regulation on how corporations are governed.

Whitehead, *Evolution of Debt*]. I appreciate the valuable research assistance provided by Eric DiMuzio and Shandy Pinkowski.

(²) I mark the traditional framing as the agency-cost model published in Michael C. Jensen & William H. Meckling, “Theory of the Firm: Managerial Behavior, Agency Costs and Ownership Structure”, 3 *J. Fin. Econ.* 305, 308–10 (1976).

(³) See *id.* at 337–38. Empirical work suggests that public debt covenants, which are typically less restrictive than bank covenants, see Greg Nini et al., “Creditor Control Rights and Firm Investment Policy”, 92 *J. Fin. Econ.* 400, 401 (2009), also reduce agency costs. See, e.g., Matthew T. Billett et al., “Growth Opportunities and the Choice of Leverage, Debt Maturity, and Covenants”, 62 *J. Fin.* 697, 729 (2007).

(⁴) See Michael C. Jensen, “Agency Costs of Free Cash Flow, Corporate Finance, and Takeovers”, 76 *Am. Econ. Rev.* 323, 324 (1986) (noting that debt contracts bind managers, while promises to pay dividends do not); see also René M. Stulz, “Managerial Discretion and Optimal Financing Policies”, 26 *J. Fin. Econ.* 3, 4 (1990) (suggesting that debt, which reduces investment in all states, addresses the agency costs of overinvestment).

(⁵) References to “governance” and “corporate governance” in this chapter are to mechanisms to reduce or deter agency costs arising from management incentives or actions that impede the maximization of firm value.

(⁷) See, e.g., Jensen & Meckling, *supra* note 2, at 335 (“[I]f the owner has the opportunity to first issue debt, then to decide which investments to take, . . . he can transfer wealth from the (naïve) bondholders to himself as equity holder.”); see also George Triantis, “Exploring the Limits of Contract Design in Debt Financing”, 161 *U. Pa. L. Rev.* 2041, 2043 (2013) [hereinafter Triantis, *Limits of Contract Design*] (citing studies that indicate that lenders price covenants).

(⁸) See, e.g., Jensen & Meckling, *supra* note 2, at 338 (“[C]ovenants occasionally limit management’s ability to take optimal actions on certain issues.”).

(⁹) A classic example of activities that fall outside an agreement’s terms is Marriott’s 1992 spin-off of Marriott International (containing Marriott’s most profitable operations) to its shareholders, causing a substantial decline in the value of Marriott’s bonds. The spin-off was not prohibited by the bond indenture’s terms. See F. John Stark, III et al., “‘Marriott Risk’: A New Model Covenant to Restrict Transfers of Wealth from Bondholders to Stockholders”, 1994 *Colum. Bus. L. Rev.* 503, 516–19 (1994). Lenders, accordingly, have an incentive to over-regulate a firm’s risk taking in an effort to protect their own investments. See Kose John et al., “Corporate Governance and Risk Taking”, 63 *J. Fin.* 1679,

1681 (2008) (finding that corporate risk taking positively correlates with shareholder protection and that growth correlates with risk taking); see also George G. Triantis, “Financial Contract Design in the World of Venture Capital”, 68 U. Chi. L. Rev. 305, 315 (2001) (noting that renegotiation “lies at the heart” of banks’ relational lending).

(¹³) There is substantial literature on why firms choose to fund with varying amounts of debt, beginning with the Modigliani–Miller claim that, absent frictions, capital structure is irrelevant to firm value. See, e.g., Franco Modigliani & Merton H. Miller, “The Cost of Capital, Corporation Finance and the Theory of Investment”, 48 Am. Econ. Rev. 261, 268–69 (1958). Scholarship regarding tax and other real-world frictions demonstrate that firm value may be enhanced through a capital structure that includes both debt and equity. See Franco Modigliani & Merton H. Miller, “Corporate Income Taxes and the Cost of Capital: A Correction”, 53 Am. Econ. Rev. 433, 442–43 (1963). But see Merton H. Miller, “Debt and Taxes”, 32 J. Fin. 261, 267 (1977) (suggesting that the inclusion of income taxes at the personal level nullifies the advantages of debt). I do not address that scholarship in this chapter, except to the extent it relates to our principal focus on debt governance.

(¹⁴) See Whitehead, *Evolution of Debt*, *supra* note 1, at 646–47. New credit instruments have been blamed for the 2008 financial crisis, calling into question the viability of a corporate governance mechanism that relies, in part, on an increasingly liquid credit market. From the perspective of debt governance there are important differences between those instruments—primarily tied to subprime mortgages—and unsecured corporate debt. By their nature, subprime mortgage instruments rely principally on collateral to manage credit risk. Unsecured loans, however, are much more dependent on covenants and monitoring, without offsetting protection. See *id.* at 647–48.

(³²) See Raghuram Rajan, “Insiders and Outsiders: The Choice between Informed and Arm’s-Length Debt”, 47 *J. Fin.* 1367, 1392 (1992). Of course, the bank-borrower relationship can change after a loan is made. As J. Paul Getty is said to have observed, “If you owe the bank \$100, that’s your problem. If you owe the bank \$100 million, that’s the

bank's problem." See Simon Johnson & James Kwak, 13 Bankers: The Wall Street Takeover and the Next Financial Meltdown 184 (2011). A later, unexpected downturn in the borrower's affairs may force the bank to make additional loans or forestall a default rather than risk a write-down of the value of its original investment. See Arnoud W.A. Boot, "Relationship Banking: What Do We Know?", 9 J. Fin. Intermediation 7, 16 (2000). New financial instruments, however, may permit a lender to transfer all or a portion of a borrower's credit risk to others, raising the lender's relative bargaining power and enabling it to more effectively enforce its covenant protections. ⁽⁶³⁾ In this chapter, a manager is considered entrenched when it is difficult for the shareholders to remove her and, consequently, she is able to use the firm to further her own interests rather than those of the shareholders. Pathe Communications Corp.*, 1991 WL 277613 (1991). There, Chancellor Allen posed a hypothetical where a firm’s sole asset was a judgment (\$51 million) against a solvent debtor. The case was on appeal, with the firm receiving offers to settle for an amount that would satisfy both shareholders and debt holders. Diversified shareholders, nevertheless, would be likely to reject the settlement offers and appeal, since the additional upside if the firm won would be theirs, whereas the downside of losing would be borne by both shareholders and debt holders.

For example, from the mid-1970s, the asset-backed securities market was fueled by the drive toward lower-cost financing. See Lowell L. Bryan, *Breaking Up the Bank: Rethinking an Industry Under Siege* 76, 82–83 (1988). Banks reportedly moved subprime mortgage assets off their balance sheets due to the greater capital requirements to which they were subject on the banks’ balance sheets compared to securities firms. See Charles W. Calomiris, “The Subprime Turmoil: What’s Old, What’s New, and What’s Next” 47–48 (Oct. 2, 2008), available at <https://www.imf.org/external/np/res/seminars/2008/arc/pdf/cwc.pdf>. Assets that were traditionally held by banks moved to a “shadow” banking system comprised of structured investment vehicles and other financing conduits set up to minimize the effect of regulatory capital requirements. As former Citigroup Chairman and CEO, Charles Prince, told Rep. Barney Frank, off-balance sheet financing was necessary because on-balance sheet financing “would have put Citigroup at a disadvantage with Wall Street investment banks that were more loosely regulated and were allowed to take far greater risks.” Nelson D. Schwartz & Julie Creswell, *What Created This Monster?* N.Y. Times, Mar. 23, 2008, at BU1. Those vehicles raised funds primarily by selling short-term commercial paper and medium-term notes to money market funds and other investors. The proceeds of those sales were then used to purchase longer-term mortgage loans (or, in some cases, mortgage-backed securities). See Gretchen Morgenson, *Debts Coming Due At Just the Wrong Time*, N.Y. Times, June 14, 2009, at B1. Assets owned by the conduits were used to make payments on the outstanding securities, as well as provide collateral in the event of default. See Markus K. (⁸⁵) A CDS permits a counterparty to a swap contract to buy or sell all or a portion of the credit risk tied to a credit instrument, such as a loan or bond. See, e.g., Morton Glantz, Managing Bank Risk: An Introduction to Broad-Base Credit Engineering 531 (2003). The CDS customer pays the “writer” of the swap a periodic fee in exchange for a contingent payment in the event of a credit default. See *id.* at 540; see also Blythe Masters & Kelly Bryson, Credit Derivatives and Loan Portfolio Management, in Handbook of Credit Derivatives 47–48 (Jack Clark Francis et al. eds., 1999) (noting that credit events often also include “bankruptcy, cross acceleration, restructuring, repudiation” and, if measurable, significant price decreases “in a specified reference obligation issued or guaranteed by the reference entity”). If a credit event occurs, typically involving default by the borrower, the CDS writer typically pays the counterparty an amount sufficient to make it whole, see Glantz, *supra*, at 540; accord Masters & Bryson, *supra*, at 48, or purchases the referenced loan or bond at par, see Masters & Bryson, *supra*, at 49. Although there are important differences, a CDS in substance is economically similar to a term insurance policy written against the credit downgrade of the referenced borrower. See, e.g., Adam B. Ashcraft & João A.C. Santos, “Has the CDS Market Lowered the Cost of Corporate Debt?”, 56 J. Monetary Econ. 514, 515 n.5 (2007) (noting that CDS, unlike insurance, do not require trading in the underlying asset).

(⁸⁹) Much of the new credit market has been concentrated among large banks. See, e.g., Bernadette A. Minton et al., "How Much Do Banks Use Credit Derivatives to Hedge Loans?", 35 J. Fin. Serv. Res. 1, 2-3 (2009); Wilmarth, *supra* note 76, at 334-35. Part of the reason may be the informational asymmetry that historically has given banks a competitive edge over nonbank lenders. See Viral V. Acharya & Timothy C. Johnson, "Insider Trading in Credit Derivatives", 84 J. Fin. Econ. 110, 111 (2007). Trading among a small group of informed investors, however, can still result in the public release of a substantial amount of private information through competitive pricing. Others can rely on that information to make their own investment decisions, resulting in an overall increase in market size. See Craig W. ⁽⁹⁶⁾ That condition is now mandatory for most securitizations, even though not a legal requirement for loan syndication. Section 941 of the Dodd-Frank Act added new Section 15G to the U.S. Securities Exchange Act of 1934 (Exchange Act), which generally requires securitizers to retain at least five percent of the credit risk of any asset included in a securitization. See Dodd-Frank Wall Street Reform and Consumer Protection Act, Pub. L. No. 111-203, § 15G, 124 Stat. 1376, 1891–1896 (2010) (codified at 15 U.S.C. § 78o-11 (2012)). The requirement generally does not apply to asset-backed securities comprised of “qualified residential mortgage[s]” (no credit risk retention required) or that otherwise meet underwriting standards established by regulation (less than five percent credit risk retention required). See 15 U.S.C. § 78o-11(c)(1)(B). Securitizers are prohibited from directly or indirectly hedging or transferring the credit risk they are required to retain, unless permitted by regulation. See 15 U.S.C. § 78o-11(c)(1)(A). Final rules implementing the section 941 requirements subsequently were adopted in a flurry of regulatory actions intended to require securitizers to maintain some risk exposure to securitized loans and other assets. ⁽¹¹⁸⁾ A loan, in that world, is economically equivalent to the lender owning a riskless claim on the borrower and also issuing a put option on the borrower to the borrower’s shareholders. If the value of the borrower’s assets falls below the face value of the loan, then the borrower defaults—with the shareholders, in effect, exercising their right to “put” the firm to the lender in satisfaction of its claims. The implication is that there is a correlation between the value of a firm’s debt (including credit derivatives tied to that debt) and equity, so that market prices should adjust at the same time and to the same information. Accounting and Financial Reporting: Global Aspirations, Local Realities

Abstract and Keywords

This chapter examines the functions of corporate accounting and financial reporting around the world, with particular emphasis on how local realities that explain persistent diversity often pose a barrier to aspirations for a universal system. It first charts the history and progress of contemporary efforts to move accounting from its diverse local roots to a unified global stage before turning to a discussion of the varying functions of accounting and reporting laws around the world. It then looks at aspects of accounting that are affected by national variation, including securities regulation, corporate governance, and corporate finance. Finally, the chapter explains how related forces contribute to persistent divergence in financial reporting.

Keywords: accounting, financial reporting, diversity, laws, securities, corporate governance, corporate finance

1 Introduction

¹“YOU manage what you measure,” the late Louis Lowenstein noted when explaining the importance of accounting in corporate governance, and the insight remains durable. Highlighting the functions of corporate accounting and financial reporting worldwide, this chapter explores how aspirations for a universal system are often disappointed by local realities that explain persistent diversity. Section II provides context and background by summarizing the history and progress of contemporary efforts to move accounting from its diverse local roots to a unified global stage. Section III identifies the varying functions of accounting and reporting laws around the world and reflects on how related forces contribute to persistent divergence in financial reporting.

Despite a gloomy assessment of the prospects for achieving a universal system of accounting, a more profound and happier truth should be stressed at the outset. The goal of international accounting is instrumental in promoting cross-border economic exchange, not an artistic aspiration for pure uniformity of financial reporting. Although pure accounting harmony appears to be an impossible dream, its pursuit has helped to facilitate

the expansion of global capitalism, a substantial accomplishment. There is work ahead to promote prosperous convergence, but progress is significant in absolute terms and probably in relation to what might be attained by continued investment in international standards.

(p. 490) 2 Accounting Contributes to Globalization

Through the late twentieth century, accounting systems in most countries developed within the traditions of each country and varied considerably across them. But, as globalization took hold in the century's final decades, an appetite for a universal system emerged. After numerous fits and starts, beginning from 1973, international standards ripened in the twenty-first century into a comprehensive system achieving international recognition. But the struggle continues.

2.1 Struggle

The quest for international accounting standards is motivated by increased cross-border capital flows manifested in worldwide stock market listings, foreign ownership of domestic securities, and an expansion of transnational business combinations. Unsurprisingly, differences in national accounting standards and their application interfered with expanding these desirable activities. Accountants produced different reports of income and equity for identical underlying transactions, a phenomenon famously illustrated the German automaker Daimler-Benz's traditional German accounting results differed radically from the US accounting standards it applied when it first listed in the United States.²

Internationalization of accounting standards has historically centered in London. There, in 1973, a group of accountants began a process of articulating global standards.³ The organization, originally called the International Accounting Standards Committee (IASC), was formed by agreement among professional accountancy organizations in Australia, Canada, France, Germany, Ireland, Japan, Mexico, the Netherlands, the United Kingdom, and the United States.⁴ By 1983, IASC included all professional accountancy bodies that were also members of the International Federation of Accountants.⁵

Between 1973 and 1987, IASC issued twenty-six accounting standards (and by 2000 had issued a total of forty-one standards).⁶ However, IASC lacked an effective governance structure and the political clout to attract adherents.⁷ Its standards were too vague and contained numerous optional approaches to reporting identical transactions. The products were usefully adopted by developing countries that lacked accounting standards.⁸ But IASC's founding countries largely ignored the standards, preferring to use their own.

(p. 491) Efforts to strengthen IASC were redoubled in 1988 with backing from the International Organization of Securities Commissions (IOSCO).⁹ IASC began to review its standards, omit optional treatments, enhance disclosure, and "specify in greater detail how each standard was to be interpreted."¹⁰ The result was a formal 1995 agreement between IASC and IOSCO on a joint program to develop standards comprehensively.¹¹ This project

led IOSCO, in 2000, to endorse IASC revisions while letting national regulators add requirements such as disclosure, specificity, and reconciliation.¹²

During the 1990s, the US Securities and Exchange Commission (the SEC) emphasized that, to achieve requisite stature, IASC needed to develop a comprehensive, high-quality, generally accepted basis of accounting.¹³ It would be characterized by transparency, comparability, and full disclosure and would be susceptible to rigorous interpretation and enforcement. On process, the SEC prescribed modeling IASC's governance structure after that of the US accounting standard-setting body, the Financial Accounting Standards Board (FASB).

The SEC was able to exert this power over IASC because of how, along with US GAAP, it had consolidated a position as the gold standard in financial reporting. Beginning in 1983, non-US companies interested in accessing US capital markets were required to use US GAAP, at least by reconciling their home-country statements to it.¹⁴ Adding to its influence, some multinational enterprises adopted US GAAP completely, including Daimler-Benz, which switched from German GAAP to US GAAP in 1993 to gain its US listing.¹⁵

US GAAP's leadership paralleled US leadership in capital markets, which New York had dominated throughout the second half of the twentieth century. Traditionally, the United Kingdom was a strong competitor in capital market advancement, where London long rivaled New York. In the early 1990s, after the collapse of the Soviet Union and the end of the Cold War, world trade expanded and capital flows began to move more freely and rapidly across more national borders.

The existence of multiple, alternative accounting systems can increase the costs of cross-border deals. Multinational enterprises based in various countries moved from domestic accounting regimes toward internationally useful and recognized systems. Most often, this meant a shift from national accounting systems to US GAAP, although interest grew in the standards that IASC offered. The appetite for a universal accounting system increased during the late 1990s and early 2000s as market integration accelerated.

Signaling belief in the possibility of moving from country-specific accounting standards to an international approach, the SEC issued a concept release in 2000 outlining essential elements of international standards.¹⁶ The SEC did not pursue this concept, however, as (p. 492) accounting scandals at Enron and other companies diverted its attention. Instead, it entered a period of domestic regulatory activity that produced and implemented the Sarbanes-Oxley Act of 2002.

Meanwhile, the IASC, boasting more than one hundred professional accountancy bodies by 2000, revised its governance along the lines that the SEC had recommended.¹⁷ It modeled itself closely after FASB, renamed itself the International Accounting Standards Board (IASB), and renamed its standards as International Financial Reporting Standards (IFRS). IASB propounded new and revised international accounting provisions that were destined to set a new gold standard in financial reporting.

IASB also began a vigorous marketing campaign with numerous countries and blocs to gain recognition.¹⁸ This led the European Union to pass legislation in 2002 requiring all EU-listed companies to use IFRS beginning in 2005 (subject to the European Union's endorsement of each new standard as it was produced).¹⁹ Additionally, IASB's campaign led scores of other countries, from Australia to Singapore, to embrace its standards (subject, in most cases, to the same endorsement mechanism).²⁰ Others, including Japan and the United States, agreed with IASB to work to converge national standards and IFRS.²¹

During this period, coordination accelerated between the United States and European Union. In 2004, the SEC and the Committee of European Securities Regulators (CESR)²² agreed to increase collaboration on accounting convergence, including a commitment to concentrate on the consistent application, interpretation, and enforcement of IFRS.²³ Within one year, the SEC unveiled a "roadmap" to convergence (including ending the US reconciliation requirement for non-US issuers by 2009 or sooner),²⁴ and CESR declared that US GAAP was substantially equivalent to the European Union's IFRS.²⁵ In both Europe and the US, as elsewhere, IFRS required making significant cultural adjustments from historical traditions.²⁶

(p. 493) In 2006, the SEC and CESR reaffirmed and deepened their earlier commitment in a formal work plan to intensify joint investment in IFRS.²⁷ Meeting the roadmap commitment, the SEC ended the reconciliation requirement in 2007 and broached letting US issuers choose to adopt IFRS instead of US GAAP.²⁸ In 2008, however, the financial crisis sidetracked the SEC, much as the Enron-period scandals had earlier; this time under the weight of the Dodd-Frank Act of 2010. In 2012, the SEC staff issued its final report on the work plan. It might have endorsed IFRS and recommended that the Commission do so, but it did neither, putting its fate in the United States in limbo.

2.2 Standstill

IASB's impressive showing was reinforced by enthusiasm for the notion that IFRS largely took the form of principles as opposed to rules. This enthusiasm was a stunning turn-about since IASC standards set from 1973 to 1987 and into the late 1990s were criticized and did not catch on because they were too loose.²⁹ Earlier objections to IASC's relatively vague standards were based on the requirement that an accounting system must provide definiteness.

Specifically, an accounting system must enable preparing financial statements that meet basic criteria that are recognized worldwide for reliability and usefulness. Such a system is reliable when it is capable of transparently capturing, aggregating, and summarizing vast quantities of transactions with varying qualities, which is possible only if standards are sufficiently comprehensive to address most transaction types and categories.

To be useful, an accounting system must facilitate comparability across enterprises. Thus, one risk of principles that are too generic is that the role of subjective judgment diminishes the comparability of resulting statements. Yet that risk of excessive generality was off-

Accounting and Financial Reporting: Global Aspirations, Local Realities

set by several forces, which together made a global turnabout from criticizing to applauding IASC's standards, which came to be called "principles-based."

Foremost among these forces, in the earlier period, there was less pressure for countries supporting IASC to adopt its standards. For example, countries like Australia, Britain, Germany, and France had respected systems; therefore, IASC standards were generally only taken up by less developed countries that lacked accounting traditions, such as countries in Eastern Europe and former members of the Soviet Union. The pressure equation changed as the value of international standards increased to developed countries amid post-Cold War globalization.

Moreover, to command acceptance among far-flung participants, from the European Union to the United States and scores of other countries, it is helpful for accounting standards to be written at a relatively high level of generality. If too detailed or overly tailored (p. 494) to specific attributes of particular nations, the standards appeal only to those nations and not to others.

In addition, literal and functional translation costs are proportional to the relative generality or specificity of the original text. Because of language differences, it is necessary to translate the standards from their original language, English, into other languages. More general language is easier to translate into other languages and easier for readers of the translated texts to comprehend.

Finally, the relative generality of IFRS was more appealing in the early 2000s than before because of events in the United States that reverberated worldwide. It was tempting to attribute the Enron debacle to how US GAAP were highly detailed and dense with rules. Enron's managers—and managers at other companies in the heady period—appeared to manipulate US GAAP's rules by designing transactions that could opaquely avoid triggering adverse accounting results and enable reporting beneficial ones.³⁰ Critics of US GAAP, and foes of using rules in regulation generally, offered such examples as evidence that rules are costly and that it is better to regulate and design accounting systems using principles.³¹

The force of globalization and related harmonization efforts led to substantial but incomplete convergence in accounting standards worldwide. IFRS has many followers. Its standard-setters have worked closely with FASB to evolve US GAAP in harmony. However, there are still significant differences in the content of IFRS versus US GAAP on many topics.³² Centrally promulgated IFRS are often adopted in a slightly different form by given countries or companies, which prepare statements to comply with country-specific variations.³³ Related auditing opinions tend to attest to the country-specific versions of IFRS rather than to the IASB version.³⁴ There is also a wide variety of applications of given IFRS standards.³⁵ Variety extends to the form of presentation,³⁶ (p. 495) bottom-line income statement figures,³⁷ cash flow statements,³⁸ and a variety of transactional matters.

Despite powerful forces of globalization, then, the project of establishing a single-set of high-quality accounting standards has proven to be monumentally elusive. Some of the reasons may be found in the local character of traditional accounting, which produces significant counter-pressures, as discussed next.

3 Accounting Still Remains a Local Language

The following discussion uses familiar classifications from legal scholarship to highlight aspects of accounting that are affected by national variation. Underlying cultural and legal features shape the development of accounting standards. Those features explain the variability of traditional accounting standards from nation to nation, as well as the continuing differences between IFRS and US GAAP. The pressure of these features, which tend to be sticky, also explains sustained variation in the application of uniform international accounting standards.³⁹

3.1 Legal Origins

National accounting systems are connected to local legal traditions. A broad contrast among legal traditions distinguishes common law and civil law.⁴⁰ Accounting standards in common law countries, such as the United States and United Kingdom, traditionally obtained authority through general acceptance by the profession;⁴¹ accounting systems in civil law countries, including most continental European countries (the Netherlands is the major exception), obtain legitimacy by enactment as law.⁴² Japanese accounting exhibited a blending of these traditions.⁴³

These origins play out in different views on how to apply identical accounting requirements. A salient manifestation of how legal origins influence the application of identical accounting requirements concerns the principle that financial statements should present a true and fair view of the business and financial condition of an enterprise.

(p. 496) This edict, perhaps the most famously flexible and contingent notion in all of accounting, can mean different things in different cultures and contexts. For example, in England, “fair” denotes that reports are within a range of fidelity to business records and economic reality; “true” negates its opposite—false.⁴⁴ But, until the United Kingdom joined the European Union, the concept of “true and fair” was alien to non-Dutch Europe; the European Union’s 1978 Fourth Directive introduced the requirement.⁴⁵

The Italian translation of “true and fair” is “true and correct” (*rappresentare in modo veritiero e corretto*),⁴⁶ which is then equated with Italian civil law requiring “straightforwardness and truth” (*evidenza a verita*).⁴⁷ Many translations replace the compound phrase with a single word. In Greece, this is the equivalent of “real”; in Belgium, France, Luxembourg, the Netherlands, and Spain, it is the equivalent of “faithful.”⁴⁸ In the United States, the concept is embedded in the requirement that financial statements “fairly present” an enterprise’s financial condition and results of operations.⁴⁹

Substantive disagreements exist concerning the relationship between the principle and other accounting standards. Conflicts arise when applying the standards could impair the objective. There are at least three alternative approaches to resolving such a conflict.⁵⁰ In the United Kingdom, an override is called for so that the true and fair view is privileged and conflicting standards are subordinated; in Europe, overriding the written rules is repugnant, despite the “true and fair” view concept; and in the United States, overrides have generally not been used because litigation risks induce people to comply with rules.⁵¹

These legal origins explain some of the observed and persistent divergence among companies purporting to use IFRS.⁵² Across the European Union, differences are (p. 497) significantly influenced by the legal origin of the firm’s home country (i.e., common law or civil law traditions).⁵³ It appears unlikely that any international standard will be capable of reconciling these disagreements. After all, local cultural influences will retain a role in how any principle is applied.

3.2 Securities Regulation

Legal traditions continue to influence the shape of securities regulation in different countries. Securities regulation, in turn, influences accounting standards. The most forceful examples of these relationships appear in the contexts of investor protection and enforcement intensity.⁵⁴ In the United States, investor protection is among the chief purposes of securities regulation, and accounting principles are designed to bolster investor protection.⁵⁵ In many other countries, interests of constituencies other than investors matter, and investor protection is one among several competing goals of securities regulation.⁵⁶

Enforcement intensity refers to the relative strength of legal institutions equipped to police adherence to securities regulations, including accounting provisions.⁵⁷ The United States employs an intense enforcement apparatus, one that includes the SEC, private litigation, and various other state and federal authorities.⁵⁸ Few countries match this level of enforcement intensity, and many exhibit a weak enforcement program.

These differences pose implications for a range of accounting issues. A general example concerns the preferred form that standards assume, ranging from detailed rules to vague principles. Indeed, it is possible to understand the relative rules-density of US GAAP as a product of an intensive enforcement environment.⁵⁹ Thus, litigation threats may lead preparers and auditors to value clarity in accounting standards, leading to extensive provision of detailed guidance.⁶⁰ Unlike US companies, European and Asian companies and constituents may be able to accept relatively more generic accounting standards, in part because of the comparatively lower level of private and public enforcement of securities laws through regulation, prosecution, and litigation.

Predicting the effects of cultural variance on the future of IFRS is not easy. It is conceivable that relative enforcement intensity and the value of investor protection can converge worldwide. That would mean making legal changes to US regulations in order to reduce the role of liability risk and litigation threats on preparers and auditors. These changes

would curtail (p. 498) demand for detail or increase those levels in other nations. Both prospects entail momentous changes with uncertain prospects and payoffs. Even substantial reductions in the scope of legal liability for accounting violations are unlikely to eliminate litigation as a dispute resolution mechanism in the United States.⁶¹ Intensifying enforcement activity in other countries is possible but is by no means certain or desirable.

3.3 Corporate Governance

Corporate governance, referring to the combination of corporate purpose and organizational arrangements designed to achieve it, varies worldwide. Broadly defined, corporate purposes range from a shareholder profit maximization philosophy to a pluralistic conception of corporate constituencies that includes shareholders, creditors, employees, suppliers, communities, and the state.⁶² Organizational arrangements reflect these purposes through devices such as the design, composition, and duties of boards of directors.

Boards may have one or two tiers, members may be elected by shareholders only or by other groups, and duties may range from maximizing profits to assuring the corporation's long-term sustainability. Accounting in systems characterized by shareholder profit maximization may naturally emphasize the measurement of profit from period to period, whereas more pluralistic systems may emphasize net worth and consistent levels of profit over time.

In addition, the role of employees, at both the senior executive levels and the broader level of laborers, can have significant effects on accounting philosophy. Labor plays an active role in corporate governance in many countries, a role rarely held in the United States.⁶³ For example, employees are formally represented on boards of directors in Germany.⁶⁴

For senior executives, the most pronounced global difference concerns levels and forms of compensation. US corporations pay executives considerably greater compensation than elsewhere, often by staggering multiples and often in the form of stock options and other compensation that is contingent on varying measures of corporate performance.⁶⁵ Thus, setting the benchmarks of corporate performance and calculating compensation levels play a more important role in accounting systems such as those in the United States than in some other systems. However, such benchmarks assume less or no importance where executive compensation packages are more modest.

(p. 499) In the most general terms, the varying corporate purposes and organizational designs around the world reflect varying forms of capitalism.⁶⁶ National accounting traditionally reflects competing conceptions of capitalism. Although these and other distinctive traditions are converging, enduring diversity in views on capitalism are likely to continue to exert influence at national levels, posing challenges to the formulation, acceptance, application, and enforcement of international standards.⁶⁷

3.4 Corporate Finance

Even within corporate governance systems that exhibit family resemblance, there may be differences in corporate finance that lead to sharply different conceptions of accounting's purpose and audience. Corporate finance refers to the sources of capital employed to fund a business organization and the entity's resulting capital structure. The chief categories of capital are equity and debt securities. The combination, identity, and role that the two forms of investment play influence the audience for whom accounting is designed.⁶⁸

Needs and interests of debt and equity investors differ. For equity investors, accounting standards and statements should be useful to form judgments concerning business value.⁶⁹ Standards quality is evaluated in terms of the relationship between reported accounting figures and resulting stock market prices or returns. On the other hand, for debt investors, accounting standards should make contract negotiation more efficient. Standards quality is evaluated in terms of whether they translate into financial statements that are useful for establishing covenants and other contractual provisions that regulate the rights and duties of lenders and borrowers.

Corporate finance characteristics also influence the relative importance of transparency that accounting can provide. Anglo-American finance is oriented toward equity and open capital markets, often attracting dispersed and uninvolved equity owners, making transparency in financial reporting vital.⁷⁰ Traditionally, Euro-Japanese finance relies on banks, which exercise considerable power within corporations.⁷¹ This reduces the importance of reporting transparency for external users.

The relative needs of equity or debt investors also bear on how accounting standards and statements address uncertainty. The traditional US approach to uncertainty is conservatism, meaning asymmetric recognition of losses compared to gains.⁷² However, investors and (p. 500) other constituencies may have different demands for relative conservatism. In general, debt demands greater conservatism than equity.⁷³ Managers compensated heavily using stock options or other devices based on reported accounting results will demand a different level of conservatism than managers not so compensated. Managerial demand for conservatism relative to that demanded of equity or debt investors will differ accordingly.

Corporate finance also can influence the relative weight assigned to the income statement or balance sheet. This sometimes follows from the traditional forms of capital structure that prevail. To the extent that debt capital dominates, the balance sheet assumes greater importance to provide a basis for estimating solvency; where equity capital dominates, the income statement warrants a more central role in evaluating business performance. It is also possible for the relationship between financial and tax reporting (and the role of the state) to influence the relative importance of, and the relationship between, the income statement and the balance sheet. Accounting for inventory illustrates both points.

It is conceptually defensible to assume that goods in inventory are sold either in the direct order that they are produced (first-in-first-out, or FIFO) or in reverse order of production (last-in-first-out, or LIFO). In a period of rising prices, FIFO is more faithful to economic reality in the balance sheet, because it lists the inventory assets at more current values; conversely, LIFO is more faithful to economic reality in the income statement, because it records the costs of goods sold at more current costs. US GAAP permits choosing between these measurements, allowing enterprises to determine whether balance sheet or income statement fidelity is more important; IFRS requires using FIFO, suggesting balance sheet primacy.

Concerning taxation, the US Internal Revenue Code, requires conformity between inventory accounting for financial and tax reporting purposes.⁷⁴ Specifically, a company must use LIFO for both or FIFO for both. The rationale is simple. In a period of rising prices, FIFO results in reporting higher income compared to LIFO. Thus, managers may prefer FIFO for financial accounting to show investors higher income but prefer LIFO for tax accounting to pay lower taxes. The Internal Revenue Code's conformity requirement reflects how US culture generally considers tax and financial accounting separate subjects with generally different standards, whereas in many countries the two subjects are substantially co-extensive.⁷⁵

A broader point about the cultural contingency of giving greater weight to the income statement or balance sheet is the question of which emphasis is more susceptible to manipulation (sometimes referred to as "tunneling").⁷⁶ In countries with dispersed equity ownership, such as the United States, controlling persons have greater incentives to manipulate the income statement, as their payoffs are a function of earnings per share.⁷⁷ In countries with (p. 501) concentrated ownership, such as in Europe and Japan, the incentives are to manipulate the balance sheet, as controlling person payoffs come from allocating corporate assets to themselves rather than serving as stewards for other claimants.

It is not obvious whether IFRS provisions are designed to influence managerial propensity to manipulate the income statement or the balance sheet. It is likewise uncertain whether accounting standards could eliminate those propensities by proper design. Still, the cultural differences that lead to these alternative incentives matter in assessing universal accounting standards, both in production and application. Currently, it is more important for investors in US companies to constrain discretion over the income statement and for investors in European companies to constrain discretion over the balance sheet.⁷⁸

Time horizons, referring to the distinction between the long-term and short-term, can be of great significance in conceiving appropriate accounting standards. Consider the case of traditional German accounting, which permitted and sometimes required the recognition of revenue or expense through hidden reserves across multiple time periods.⁷⁹ Although relevant in some countries, these have little to do with recognition concepts in US or UK accounting, which reflect more immediate time periods.

The use of hidden reserves, also followed in other European countries, including Austria, Denmark, Finland, and Switzerland, and to lesser degrees in Spain, would constitute earnings management in the United States and United Kingdom and would be a violation of both accounting standards and securities laws.⁸⁰ Even if these principles were abandoned for enterprises using IFRS, traditional knowledge and associated sensibilities would likely play a part in applications. The effect of this is that preparers in different countries could, in good faith, apply identical standards in different ways.

3.5 The Market

The relative role of markets in corporate activity covered by accounting reports can influence the character of accounting standards and the attitudes of those applying them. An example appears in the fundamental accounting issue of measuring assets. In general, there are two choices: measuring assets based on observed transactions (known as historical cost accounting) and measuring assets based on prevailing market conditions (known as fair value accounting).

National accounting systems take differing stances on whether to prefer historical cost or fair value accounting in general and in specific circumstances. Many are dual-attribute models, in which some items are measured using historical cost and others are measured using fair value. The choice is determined according to trade-offs between accounting's goal of relevance and that of reliability.

(p. 502) The appeal of historical cost accounting is that measurements arise from observed transactions, such as the purchase price of an asset, which leads to reliable figures. Judgments are required to allocate that cost over the asset's life. As time passes, the historical cost figure becomes less relevant in the context of prevailing conditions.

The virtue of fair value accounting is that measurements are based on prevailing conditions, such as market prices of an asset, which leads to relevant figures.⁸¹ But, cost allocations may require adjustment; a limitation occurs when exact market prices are inaccessible (either because the asset does not trade on a market, the asset trades infrequently, or the asset has few substitutes), making it less reliable than historical cost figures.

US GAAP traditionally preferred historical cost accounting, subject to a "lower of cost or market principle" that used market values when these were lower.⁸² A US trend toward favoring fair value accounting began in the late twentieth century.⁸³ For its part, IFRS favors fair value accounting, in part as a product of the projects designed to converge IFRS and US GAAP.⁸⁴ Other national accounting systems vary in their relative preference for historical cost and fair value accounting. Thus, any choice IFRS makes will entail cultural adjustment in some countries.

Further, a putative advantage of fair value accounting is its use of markets as a basis for asset measurement. Yet a limitation arises if markets are imperfect or unavailable to mea-

sure particular assets. When that occurs, preparers and auditors must estimate fair value using judgments based on hypothetical valuation modeling tools.

This activity raises a broad question of how much deference these actors should receive when making such judgments compared to how much power investors and other users of financial statements should have to challenge those judgments. The national significance of this question will vary according to local investor demographics, including the mix of debt and equity in a capital structure and the degree of ownership concentration or dispersion.

3.6 The State

The role of the state varies across nations, even within capitalist societies. In comparative terms, the social democrat traditions prevalent in many continental European nations demand a state role consciously committed to protecting its citizens, including in the context of economic policy. The European practice of designating some corporations as “national champions” illustrates this sensibility as does assigning a special status to some constituent groups, such as labor unions. In contrast, US sensibilities, certainly among conservatives and even among many centrists and liberals, evince a more individualistic proclivity that (p. 503) reduces the role of the state in economic life (and other spheres). Thus, there are no or few national corporate champions in the United States, and constituents vie for shifting political and economic power.

The consequence of these sensibilities is illustrated by differences between traditional French accounting compared to US (and UK) accounting. French accounting is heavily linked to, and co-extensive with, state fiscal policies,⁸⁵ while in the United States, tax accounting and financial accounting are distinct. Also, the US/UK income statement is designed to present information in forms useful to decision making by equity owners, whereas traditional French income statements were organized according to a statutory scheme that reflected an orientation toward the French state.⁸⁶ Similarly, US/UK balance sheets conceptualize assets in economic terms, while traditional French accounting conceives of them in a “patrimonial sense” of interests in tangible property.⁸⁷

The state’s role also bears on relative accounting conservatism. States may prefer a level of conservatism designed to generate desired tax revenue from corporations subject to tax within their jurisdiction. The exact appetite various states have for relative accounting conservatism may depend on population demographics, the manner of raising fiscal revenue, and the influence of economic theories on national policy, such as views on what supply-side effects have on production and total tax revenue. Whatever a state’s appetite is, it may differ from those of the state’s constituents and from those prevalent in other countries.

A state’s net appetite for relative accounting conservatism may also be influenced by the demands of corporations and their constituents domiciled within the country. In countries that tend to identify national champions among their corporate elite, a national solicitude toward their interests is likely to interact with fiscal policy making. The net appetite also

likely will be influenced by the historical relationship between financial and tax accounting. In the United States, because these accounting systems have been distinct, financial accounting can generally be evaluated independently of fiscal policy. For countries in which financial and tax accounting are co-extensive, the state's interest will continue to influence desired choices within financial accounting.⁸⁸

The state interest manifests in many matters of international affairs. Even when political blocs endorse IFRS, it does not mean that all member countries follow suit or companies within them do. Some members of the European Union, for example, are notorious for ignoring EU directives, especially the Czech Republic, Greece, Italy, Luxembourg, and Portugal.⁸⁹ Many members, including such diverse countries as Cyprus, Germany, Hungary, and Spain, have altered IFRS to reflect local needs.⁹⁰ Beyond the European Union, IFRS (p. 504) endorsers include such assorted countries as Armenia, Iraq, and Kuwait.⁹¹ Considering this diversity, it may be naïve to believe that accounting standards will be enforced uniformly in all these places.

It may be highly unlikely for countries to do so when national interest warrants non-compliance. An example is the experience of Japan in the late 1990s. When accounting rules required Japanese banks to record big losses on large loans in the 1990s, Japan's government intervened against doing so to avert a national financial crisis.⁹² For another, after IASB adopted rules for financial instruments, the French government lobbied the European Union to obtain an exception to reduce volatility in reports of French banks.⁹³ Steps like these will continue and, depending on frequency, could stealthily destroy global uniformity.

4 Conclusion

Pressure of global capitalism has induced the drive toward universal accounting standards, and it can be difficult for any centralized authority to control that journey. It may be possible to bridge diversity using a universal set of accounting standards that concentrates on points of congruence while appreciating the consequences of difference. After all, inchoate but real convergence has occurred in important aspects of modern culture. These aspects include melding of legal traditions, coalescing around some forms of capitalism, and expanding global coordination and governance in many spheres of human activity. Yet diversity endures in many of those spheres, including those that affect accounting, especially law, economics, politics, and language.

Other cultural phenomena have proven more or less susceptible to such transcendence. Consider the metric system—a standardized, uniform method of measurement. This innovation was important to expanding international trade. It was begun by France in the late eighteenth century and was gradually adopted by all countries except the United States and two smaller ones.⁹⁴ Even in the United States, however, people are familiar with the metric system, and its use is widespread in everything from consumer goods to industrial production.

Accounting and Financial Reporting: Global Aspirations, Local Realities

Although accounting is more complex and involves more than just measurement, measurement is an important aspect of accounting. Accounting's more complex attributes explain the hackneyed adage that accounting is the language of business.

Thousands of languages exist in the world, and hundreds are in use in the United States alone. Still, English has emerged as a widely spoken, nearly universal language, at least among active participants in international matters. On the other hand, conscious efforts to create a universal language have failed. The infamous example is Esperanto. This was a (p. 505) high-quality language, grammatically sound and coherent, with a sizable vocabulary capable of extensive expression. Yet it never caught on and is not widely used anywhere.

Today's accounting is more like the metric system than Esperanto. It is widely recognized if not universally embraced or uniformly implemented and has contributed substantially to the proliferation of global capitalism and related prosperity. That is quite an achievement, though the quest for a truly uniform system of accounting is elusive. It was shrewd or lucky that proponents set their sights on the bold vision of universal accounting, as such an outsized target equipped participants and followers to achieve the more realistic and practical objective.

In the nineteenth century, Max Weber explained how capital accounting was a pre-condition to the flourishing of capitalism.⁹⁵ The spread of reliable systems of accounting contributed to the flourishing of capitalism even though those systems were imperfect, incomplete, and incompatible across countries. Today, a global financial reporting system may be seen as a pre-condition to globalization, and one that has already substantially been achieved despite inherent imperfections and persistent shortfalls from pure comparability.⁹⁶ IFRS has helped to draw more countries into capitalist traditions. Its limits may simply reflect the different forms of capitalism and the different conceptions of corporate purpose and constituencies in the world.

The initial inspiration for international standards was to promote global capitalism, to facilitate cross-border capital flows, deals, and listings, an instrumental value, rather than the intrinsic beauty or Platonic value of an elegant universal ideal system. It has succeeded to a very large degree. We can accept both that the pure idea of universal accounting is a dream and that the practical efforts people took in its name have been valuable.

Abstract and Keywords

This chapter examines the legal and policy implications of transactions between a corporation and a “related party.” It begins by spelling out the reasons why related party transactions (RPTs) are a common phenomenon worldwide before discussing RPTs as an instrument for tunneling and why many jurisdictions provide for specific regulations on RPTs in addition to general rules or standards against dominant shareholders’ abuse. It then looks at the legal tools that can prevent the use of RPTs for tunneling purposes, namely: prohibitions, procedural safeguards such as majority of the minority shareholder approval and independent directors’ involvement, mandatory disclosure, external fairness opinions, and ex post standard-based judicial review. Finally, the chapter discusses the challenges of enacting reforms that would make regulation of RPTs (or tunneling) more effective in preventing (minority) shareholder expropriation, and suggests the importance of sophisticated enforcement actors such as experienced courts and/or active, committed securities regulators in battling tunneling as a business practice.

Keywords: tunneling, related party transactions, dominant shareholders majority of the minority approval, independent directors, mandatory disclosure, fairness opinions, corporate law enforcement

1 Introduction

¹THIS chapter covers transactions between a corporation and a “related party,” a term of art that usually comprises counterparties who, thanks to their influence over corporate decision makers, may secure better terms for themselves than they would get following arm’s-length bargaining.

First of all, it highlights the reasons why related party transactions (“RPTs”) are so common around the world (section 2). Next, it better identifies the phenomenon as a specific class of potentially value-diverting behavior by dominant shareholders and managers, i.e., as an instrument for tunneling,² and asks why many jurisdictions provide for specific regulations on RPTs in addition to general rules or standards against controllers’ abuse (section 3). Then, it describes the legal tools that policy makers and legal scholars commonly

or increasingly consider as useful to tackle tunneling via RPTs:³ prohibitions, procedural safeguards, mandatory disclosure, external independent advice, and ex post standard-based judicial review (section 4). Because of the focus on RPTs, this section does not include non-transaction-based, structural measures to prevent tunneling and dominant shareholders' (p. 507) abuse, like limits on deviations from one-share-one-vote,⁴ board composition requirements, or measures affecting the company's ownership (including the mandatory bid rule or oppression remedies); such tools' operation is not, whether by design or necessarily, dependent on abuse involving RPTs.

Finally, this chapter concludes that no regulation of RPTs (or tunneling) can succeed in preventing (minority) shareholder expropriation in the absence of sophisticated enforcement actors, i.e., experienced courts and/or active, committed securities regulators, operating in a social context that rejects tunneling as a business practice (section 5).

2 Welcome to Tunnelland

You are the founder and sole owner of a flourishing incorporated firm in Tunnelland, a notoriously business-unfriendly country: its punitive and inefficient tax system imposes unbearable tax rates, but leaves tax collection in the hands of unsophisticated, or selectively sophisticated (corrupt), tax officials.⁵ Its politicians are strongly inclined to grabbing value from businesses by seizing corporate assets or allocating them to third parties, whether via legitimate enforcement of existing business-unfriendly laws or by exercising "raw power."⁶ In addition, Tunnelland's courts are slow, unpredictable, and corrupt. Finally, its bankruptcy law is pro-creditors and liquidation-oriented and its banking system prone to liquidity crises: in the event of a credit crunch, firms face the risk of a value-destroying bankruptcy procedure due to illiquidity problems that are beyond firm owners' control.

If you are successful, you will soon experience how difficult it is, given the weakness of the institutional framework, to have satisfactory long-term, complex contractual relationships with business partners. You will then find it convenient to expand into adjacent industries, such as the production of materials or the supply of services you need for your initial business⁷: by governing these supply relationships by fiat within your firm, you will reduce the transactions costs thereof.

In such a setting, a constant worry of yours will be how to minimize the risk of government expropriation and of value destruction due to creditor rights enforcement. How much wealth should you leave within your corporation? The easy answer is: as little as is strictly (p. 508) sufficient to keep the firm viable. How will you transfer wealth that is not strictly necessary for the corporation's viability into safer pockets? Again, there is an easy answer: in the way that makes it hardest for creditors, including the state as tax collector, and enforcement agents (public prosecutors, securities regulators, and courts) to detect and prove that you have transferred value out of the firm for nothing. The best way to do that is via transactions with yourself and/or entities you control. You will have made sure that there are plenty of these entities: in fact, your legal and tax advisors will have easily

Related Party Transactions

persuaded you to grant formal ownership rights over as many of the company's assets as possible to "third" parties connected to yourself, such as wholly owned companies, possibly even better if operating from a foreign jurisdiction. By doing so, you will have reduced the risk that those assets end up in the hands of tax authorities and/or creditors if things go wrong.

Your advisors will have more generally recommended that you structure your whole business as a web of connected, but formally separate, entities, each involved in a different production phase, typically with a holding company in charge of financing operations, one or more operating companies producing the goods or providing the services (the core firm(s)), and other satellite companies in charge of supplying the core firm(s) with components and other goods or services, like real estate or distribution. Once such a corporate group is in place,⁸ RPTs will become routine and, correspondingly, it will be harder to find them suspicious, especially if businesses structured as corporate groups are a common organizational form within the economy. If RPT terms are such that the operating corporation receives less than it gives away, you can routinely transfer wealth from its coffers to your (affiliates') pockets.

Unfortunately, there are still countries around the world displaying at least some of the business-unfriendly features of Tunnelland.⁹ In such countries, tunneling via RPTs is, in a way, a physiological, and possibly even social welfare enhancing, reaction to badly functioning institutions. It may be the case that, in their absence, the cost of running a business would be even higher for entrepreneurs, fewer firms would exist and those countries would be even less prosperous.¹⁰

An even higher number of countries have proved as business-unfriendly as Tunnelland until fairly recently.¹¹ There, tunneling via RPTs, or possibly RPTs without tunneling, may still be common because of path dependence, i.e., because in the past the institutional environment made it convenient for businessmen to adopt business structures (practices) that may now be costly (for tax reasons or for the rents the dominant shareholders still extract through them) to disentangle (abandon).¹²

Of course, the point here is not to justify business practices that are almost universally viewed as harmful to investors and financial markets. Rather, as anticipated, it is to illustrate why RPTs are so common in many countries around the globe. The fictitious example of Tunnelland also shows what the minimal quality of property rights institutions must be in (p. 509) any given system for RPTs to be rather a key issue for reform-minded policy makers aiming to boost domestic capital markets than a "second-worst" solution to a dysfunctional institutional environment. Finally, the example highlights how, in bad institutional environments, RPTs may be frequent also in closely held corporations with no distinction between controlling and non-controlling shareholders. Once corporations plan for a listing and try to raise outside capital, the controlling shareholders' private costs (including the tax implications) of disentangling complex organizational structures and the related web of RPTs may be higher than the increase in the IPO price they may secure by doing so. That is especially the case if credibly committing not to engage in tunneling is

Related Party Transactions

costly or even impossible, for example because the legal regime is too lax to serve as a credible commitment device.

Eventually, in countries with better functioning institutions, RPTs are not just the remnants of darker ages. Whenever an agency relationship exists, as is the case between shareholders as a class and creditors, between controlling and minority shareholders, and between managers and shareholders in dispersed ownership companies, the party with de facto residual rights of control over corporate assets, i.e., the agents, will appropriate as much value as they can expect to get away with, after factoring in the probability of detection and punishment.¹³ RPTs are, again, an effective technology to appropriate value, because of the same attractive features highlighted above: first, they are easier to disguise as legitimate business transactions; second, thus disguised, they are not taxed as corporate distributions.¹⁴

At the same time, no one denies that RPTs exist that create value for all parties involved.¹⁵ That may more easily be the case in closely held companies incurring higher transaction (p. 510) costs when dealing with unconnected market participants, due to higher information costs on both sides.¹⁶ But listed companies may enter into entirely fair RPTs as well.

For instance, a company's labs may start developing a new product, but the finance department may later find that it is impossible to bring it to market, e.g. due to financial constraints and the need to concentrate R&D investment in other, more promising areas. The dominant shareholder may be in the best position to buy the project from the company and have a company wholly owned by himself work on it. Selling to a third party may be worse as an alternative, if the project is better developed with the dominant shareholder's unique entrepreneurial input and/or if it is hard for any third party to understand the project's chances of success: any offer from such third party will discount the higher perceived risk of failure. If the dominant shareholder buys the project for more than its net present value to the company, then the transaction is both fair and efficient.

This stylized example also shows how difficult it will be for third parties, be they minority shareholders, financial analysts, the company's audit firm, enforcement agents, or the public at large, to understand whether a RPT is in the best interests of the company: to do so, they would not only need to gauge what the right value of the project to the company would be if it realized it internally, but also assess whether it would be possible to find a third party willing to offer a price higher than the sum of (1) the price offered by the controlling shareholder and (2) the transaction costs that finding another buyer and negotiating with him would involve.

More debatable is whether even RPTs harmful to the company and/or its minority shareholders, and tunneling more broadly, may be efficiency-justified as the quid pro quo for the "public" (or shared) benefits minority shareholders enjoy as a consequence of the monitoring/entrepreneurial effort undertaken by dominant shareholders.¹⁷ Note that there is no reason why minority shareholders themselves should a priori dislike a system thus designed. Provided ways are found for the dominant shareholder to pre-commit to a

Related Party Transactions

given level of private benefits extraction, minority shareholders may in fact understand the virtues of a regime that maximizes the sum of their (direct and indirect) losses from private benefits of control and of their gains from public benefits of control. In other words, they may be ready to tolerate private benefits extraction, so long as the contribution to the company's value by the dominant shareholder compensates for that.

(p. 511) The problem with this idea is, again, that private benefits extraction is hard to verify by a third party like a court or even an arbitrator. Even a comprehensive system of mandatory disclosure may be insufficient for the purpose: no disclosure regime can be expected to succeed in forcing dominant shareholders to confess how much they are stealing from their controlled company.¹⁸

No legal regime explicitly subscribes to the “quid pro quo” view of private benefits extraction.¹⁹ But laxity in regulation and enforcement of anti-tunneling provisions has traditionally been common around the world.²⁰ That is tantamount to an implicit legalization of pecuniary private benefits extraction;²¹ it also provides a strong incentive for parties to devise contractual or, better, non-legal (and especially reputation-based) constraints on tunneling. A credible device to commit to moderate tunneling is family ownership itself: so long as the dominant family member has descendants who may be at the company's helm some day, he can be expected to stop short of subtracting so much value as to make the company no longer profitable in the long run.²²

Finally, tunneling not only raises distributional concerns in the relationship between insiders (managers or controlling shareholders) and (minority) shareholders,²³ but has an intuitively negative effect on capital markets as a whole and their dynamic efficiency. First, pervasive tunneling may have chilling effects on the IPO market: if a prospective listed company is unable to signal its controllers' intention not to engage in tunneling and/or to credibly commit to higher standards, it may desert the IPO market, leaving it to tunneling-prone issuers.²⁴ Second, a high level of tunneling (actually, of private benefits of control more generally) may lead to distortions in the market for corporate control (the highest-value user may be unable to buy control from the incumbent controlling shareholder, if the former is unable to extract as high private benefits)²⁵ and in ownership structures more generally (no one will relinquish control to the market if the private benefits of control to be extracted are high).²⁶ Finally, tunneling may well lead to distortion in managerial and strategic (p. 512) choices within individual companies, as controlling shareholders will choose transactions and strategies allowing them to extract more value via tunneling than those that maximize overall firm value.²⁷

3 Related Party Transactions versus Tunneling versus Conflicted Transactions

Because RPTs are a usual suspect as a vehicle for tunneling, a number of jurisdictions provide for specific provisions addressing RPTs as such. For instance, accounting standards, including the US GAAP and the International Financial Reporting Standards

Related Party Transactions

(IFRS), provide for disclosures on (material) related party (relationships and) transactions.²⁸ Similarly, the UK has since long provided for procedural safeguards and immediate disclosure of larger RPTs.²⁹ Italy has followed the UK example in 2010.³⁰ Under the influence of international economic organizations such as the OECD and the World Bank,³¹ many Asian countries,³² including India,³³ have recently broadened the scope of RPT rules and tightened their content.

If RPTs do not necessarily involve tunneling and tunneling itself can be the outcome of behavior not involving RPTs, why do those jurisdictions single out RPTs for specific regulation (p. 513) rather than dealing, more broadly, with conflict-of-interest transactions or, even better, any kind of tunneling?

To answer this question, let us first identify RPTs by reference to their accounting definition, taking the one in the International Financial Reporting Standards as an example. According to International Accounting Standard 24,³⁴ “[a] related party transaction is a transfer of resources, services or obligations between a [corporation] and a related party, regardless of whether a price is charged.”³⁵ Who qualifies as a related party is, in turn, defined very analytically in the same Standard so as to include all entities and persons, such as directors and controlling shareholders, that may presumptively have a significant influence on a corporation’s decision on whether to enter into a transaction and under what terms, together with their (again broadly and analytically identified) affiliates.³⁶

A key component of the RPT definition is in the preposition “between:” technically, no RPT exists if the transaction does not have the corporation (or an affiliate of its) on one side and a related party on the other. Hence, various transactions with tunneling potential entered into directly between the controller and shareholders do not qualify as RPTs because the company is not a party to the transaction. Such is, for example, the case of: (1) “internal tender offers,” by which a controlling shareholder aims to take the company private via a bid for all of the shares he does not already own; (2) sales of the controlling block at a premium incorporating the present value of future private benefits; and (3) share purchases other than from the company itself on the basis of inside information.³⁷

Other tunneling transactions do not qualify as RPTs because the counterparty to the corporation is not a related party, although the dominant shareholder may indirectly gain from the transaction to the detriment of (some of the) minority shareholders.³⁸ Such may be the case when a side deal exists between the controller and the company’s counterparty. For example, the latter pays a kickback to the former in exchange for an above-market discount from the controlled entity: these transactions would clearly qualify as conflict-of-interest transactions, but they are not between the company and a related party.

No RPT is entered into in the following case either: suppose a company is controlled by a parent also active in the same business. For antitrust or regulatory reasons, the latter has to divest part of its business. Instead of selling its own assets, it may force the subsidiary to sell its own and even to select a buyer that will not challenge the parent’s dominant position in the market, when possibly another competitor would have done so and paid more for the assets (assuming the subsidiary will no longer be active in that market after the

Related Party Transactions

sale, selling (p. 514) to an aggressive competitor would have harmed the parent's profitability, but not necessarily the subsidiary's).

Another example may be that of a secondary offering at a discount over the market price, but the price of which is still inflated because of negative information that has not yet been disclosed or because of false or misleading statements that keep market prices artificially high. If (some of the) minority shareholders subscribe to the newly issued shares and the controller does not, the former, together with any other new shareholder, will lose and the controller will correspondingly gain (to be sure, together with other non-subscribing shareholders).³⁹

Transactions by which minority shareholders are forced to sell their shares to the company or the controlling shareholder, when executed outside the framework of a merger with a related party (as can be the case in Europe following a takeover bid,⁴⁰ where they are known as squeeze-outs) are also transactions in which the interest of the controller is clear, equity tunneling may take place, but no transaction between the company and a related party would occur.

Finally, according to its accounting notion, a RPT involves a transfer of resources. When value is transferred between the company and the related party that does not qualify as a resource, no RPT is involved. Such is for example the case where the controller appropriates a mere business idea (or a corporate opportunity).⁴¹

Of course, the fact that RPTs are subject to specific rules not applying to other tunneling techniques, and vice versa, can be fully justified. There might be tunneling transactions falling under a category of transactions normally displaying no potential for abuse, which yet happen to transfer value to the related party due to some idiosyncratic features of theirs. As an example, consider the case of an undercapitalized two-layer pyramidal group which operates at both layers in an industry (e.g., banking) where capital ratios are required at a consolidated level. Suppose that the higher-layer company is undercapitalized while the lower-layer company is well capitalized. The dominant shareholder at the top of the group will have an interest in raising new capital at the lower level of the pyramid, so as to minimize his burden in the recapitalization. That may, however, come at the expense of the lower-layer (p. 515) company's profitability. Yet applying the special rules on RPTs to all new share issues to prevent idiosyncratic tunneling transactions such as the one just described may lead to burdensome, over-inclusive regulation: other things being equal, in such a case ex post judicial review would sound like a better solution.

At the same time, when the law treats differently two tunneling techniques allowing a controller to reach exactly the same expropriation outcome, the controller may engage in "tunneling arbitrage" and choose the more loosely regulated technique.⁴² For instance, should a legal system provide that the procedural safeguards for RPTs have to be followed in the case of parent-subsidiary mergers, while much looser rules apply to tender offers initiated by the dominant shareholder and followed by a squeeze-out (again execut-

ed other than via a merger), the latter will be the preferred avenue to freeze out minorities.⁴³

So why do reform efforts in various jurisdictions in recent years focus on RPTs as opposed to, for example, the broader (and, in many jurisdictions, more traditional) category of conflict-of-interest transactions?⁴⁴ One plausible explanation (in addition to the more prosaic one that the international policy debate is framed in terms of RPTs and domestic policy makers are just receptive of that language) is that rules applying to RPTs are more easily complied with and enforced than rules on conflicts of interest. Intuitively, the question of whether a “conflict of interest” exists in a given transaction is much more subjective and uncertain than the question of whether someone is a related party (although there is room for discretion in that respect as well). More precisely, it would be harder for companies as well as for regulators to set up, respectively, an effective compliance program or supervisory policies for conflict of interest transactions than for RPTs, especially if the special procedure has to apply (and enforcement powers are to be used) as soon as negotiations of an RPT start. Detecting a RPT is easier than deciding on a case-by-case basis whether on a given issue a director or a dominant shareholder may have a direct or indirect interest (in some jurisdictions: that conflicts with that of the corporation). In the case of the former, a “map” of related parties is relatively easy to draw and update, of course with the collaboration of “direct” related parties such as directors and dominant shareholders. Identifying “interests,” especially indirect ones, equally implies the collaboration of directors and dominant shareholders, but, first, their discretion will be wider because of the subjective call (p. 516) that is needed to decide whether an interest has arisen with regard to a specific transaction (and whether it may conflict with the corporation’s interest); second, the identification exercise would have to be undertaken for each and any individual transaction, which makes a properly formalized procedure or supervisory policy necessarily over-inclusive, and therefore burdensome. For the company, it would in fact imply asking directors and dominant shareholders to self-scrutinize each corporate transaction as opposed to providing an updated list of their affiliated persons and entities. True, this issue is less serious when the applicable rules provide for no special safeguards already to be complied with ahead of a formal resolution, for example, by the board. And yet, even when legal rules only pertain to the final stages of a transaction (e.g., requiring the additional approval by the shareholder meeting and detailed disclosure over the transaction), the risk remains higher of failing to apply the relevant rules to a conflicted transaction than to a RPT.

4 Legal Tools Against Tunneling via RPTs

Turning to the question of how legal systems can prevent RPTs from being used for tunneling purposes, the key issue is how to minimize that risk (i.e., to have rules that are effective enough to give rise to few “false negatives”) without stifling value-creating transactions (i.e., avoiding “false positives” as much as possible) and more generally without imposing higher costs.⁴⁵ Because a number of context-specific factors and variables will determine what the best solution is for any given jurisdiction,⁴⁶ no attempt is made here

Related Party Transactions

to rank the legal tools described below, let alone recommend any of them as suitable. Rather, the conditions for them to be effective and their limits will be sketched out in very general terms.

4.1 Prohibitions

The seemingly most draconian way to address tunneling via RPTs is a simple prohibition of RPTs as such. Straightforward as it may seem, that strategy has two main drawbacks: it would also rule out value-creating RPTs that insiders may otherwise have entered into on fair terms for the corporation and, more importantly, it “may not [even] accomplish much”:⁴⁷ unless an equally well enforced prohibition on any form of tunneling is in place,⁴⁸ insiders would just avoid RPTs as an expropriation technique and use functionally equivalent substitutes. In other words, a prohibition on RPTs is only effective if the enforcement system can tackle tunneling more broadly. That requires enforcement actors to use open-ended standards to respond to insiders’ ingenuity in devising seemingly legitimate (p. 517) value-diverting transactions. However, if an enforcement system is so sophisticated as to be capable of dealing with tunneling in all its forms, then there is no reason for using such a raw technique as a per se prohibition to prevent corporate theft. Conversely, and for the same reasons, a prohibition on RPTs would ineffectively tackle tunneling exactly where, on its face, it would be most justified to protect minority shareholders, i.e., in countries with bad enforcement institutions.

One may counter that a prohibition will be better than nothing and that, however little, it will raise the costs of tunneling, making it less profitable. Yet it remains true that if enforcement institutions are bad enough, the costs of evading the prohibition on RPTs will still be low: for instance, a counterparty will be related to the corporation if it is in turn controlled by a related party. Assessing whether a *control* relationship exists inevitably leaves much room for discretion and for clever lawyers’ tricks to disguise it.

True, it might be the case that in countries which have neither excessively bad nor particularly good enforcement institutions, a RPT prohibition may indeed lower the amount of tunneling in the economy. But even there, prohibitions may be self-defeating in the long-term: because individual RPTs can be entirely fair for the company, and sometimes even necessary (as in crisis situations in which outsiders may be unwilling to do business with the company), value-creating transactions may be entered into in violation of the prohibition. As it happens, one of the parties to the RPT may ex post find it convenient to renege on it. It may then opportunistically use the prohibition to free itself from its obligations. In those cases, the pressure for judges to come up with doctrines or interpretations eroding the automatism of RPT prohibitions will be strong. With time, prohibitions “in action” may end up looking ever more similar to ex post standards.⁴⁹

Prohibitions selectively targeting a specific category of RPTs, i.e., loans to related parties such as directors and executives, have traditionally been more common in Europe⁵⁰ and gained traction in the US and China in the first half of the 2000s. In the US, Congress banned loans to officers and directors⁵¹ after WorldCom and other corporate scandals

Related Party Transactions

highlighted both the magnitude of the phenomenon and how loans could be used to circumvent executive compensation disclosure rules or delay compliance therewith.⁵² In the wake of widespread abuse, China banned debt guarantees to shareholders from companies and their affiliates.⁵³

(p. 518) 4.2 Procedural Safeguards

Most jurisdictions provide for rules on how to enter into RPTs. Procedural rules may apply to RPTs as such (as is the case in India and Italy), to a broader set of transactions that include some or all RPTs (as is the case in France, where procedural rules apply to all transactions in which a director has a direct or indirect interest⁵⁴), or to a subset of RPTs (as is the case in Germany, with its very narrow rules applying to transactions in which the director is the counterparty or acts in the counterparty's name⁵⁵). Often jurisdictions provide for different procedural rules depending on whether the related party is a director or a controlling shareholder (e.g., Belgium). Sometimes, quantitative thresholds or qualitative features are used to define the scope of procedural rules (e.g., in the UK and Italy).

In general, procedural rules can be defined as more or less strict, depending on how effectively insulated corporate decision makers are from the dominant insiders and on the extent to which they put such “independent” decision makers in control over the negotiating process. Relatedly, a crucial element for rules' effectiveness is decision makers' access to relevant information and their ability to process it as disinterested executives would.

The focus here is on two of the main procedural safeguards that at least some jurisdictions currently deploy: approval by a majority of independent shareholders and approval by disinterested/independent directors.

4.2.1 MOM Approval

A popular idea in academia as well as among policy makers is that the most effective procedural safeguard against tunneling is a veto power over RPTs for a majority of the shareholders other than the related party itself (a majority of the minority, or MOM, in companies with a dominant shareholder).⁵⁶ An increasing number of countries (including the UK, Israel, and all major East Asian countries, with the notable exceptions of Japan and South Korea⁵⁷) provide for such a requirement with respect to larger, non-routine transactions.

A MOM requirement does ensure that only fair RPTs are entered into, provided at least four conditions are met:

- (a) Minority shareholders have a real opportunity to cast their vote.
- (b) Voting shareholders do so sincerely, for example being truly unrelated themselves to the related party and having been paid no bribe to vote in favor.

(p. 519) (c) The MOM approval is the outcome of a well-informed decision-making process, following full disclosure of all material information about the RPT.

Related Party Transactions

(d) Shareholder voting takes place at a moment in time when vetoing the RPT is still a viable choice for the corporation.

Condition (a) would seem to always apply and hence not be even worth mentioning. However, the Russian experience in the 1990s reminds us that where enforcement institutions are dysfunctional enough, even MOM clauses are deprived of their “self-enforcing” appeal.⁵⁸ A famous account of asset stripping after privatization in Russia includes an anecdote of how Mikhail Khodorkovski, then the dominant shareholder at Yukos, managed to obtain the legally required shareholder vote for a number of tunneling transactions involving its subsidiaries:

Yukos owned only 51% of the shares in the subsidiaries, and needed 75% of the votes of the shareholders who participated in a shareholder meeting to authorize the share issuance (plus a majority of the votes of noninterested shareholders). Khodorkovski’s solution was bold, if not exactly legal: The day before the subsidiaries’ shareholder meetings, Yukos arranged for a compliant judge to declare that the minority shareholders were acting in concert, in violation of the Antimonopoly Law. The judge disqualified everyone but Yukos and its affiliated shareholders from voting. When minority shareholders arrived at the meetings, they were greeted by armed guards; most were barred from voting or attending on the basis of this court order. Yukos’ shares were voted and were counted as noninterested; the proposals all passed.⁵⁹

That was also a case in which condition (b) (sincere voting) was not met. In the absence of broad-scope rules on who is disqualified from voting, MOM approval may just pay lip service to minority shareholder protection. In countries where families often control listed companies, like Hong Kong, excluding the related party but counting votes from “relatives, such as cousins, nephews, and uncles, as well as friends and other members of the board of directors”⁶⁰ may easily lead to routine general meeting approval of RPTs.⁶¹

Less blatant cases of conflicted voting are those where shareholders are (controlled by) current or potential providers of financial services to the company (and/or its dominant shareholder):⁶² in countries with smaller capital markets and a small presence of international institutional investors and/or independent asset managers, shareholders of that kind may well ensure that RPTs are routinely passed.⁶³

(p. 520) Condition (c) presupposes rules ensuring that full disclosure is made of information shareholders need in order to make an informed decision about the transaction.⁶⁴ In addition, it presupposes that shareholders are able to make good decisions on individual business transactions as opposed to decisions on how to invest.⁶⁵

To be sure, a disinterested, albeit less well-informed, decision maker may generally be preferable to one with the relevant knowledge but a clear conflict of interest: that MOM approval may also lead to false negatives does not mean that shareholders would be better off without it.

Related Party Transactions

Finally, disinterested shareholders may well approve a RPT which appears not to be the best deal for the company, when the alternative unconnected transaction would now be less convenient to the company after taking prospective transaction costs into account. Suppose the shareholder meeting is convened to approve the sale of an asset to a related party for a (fair) price of \$100. Once the proposed transaction is disclosed, an unrelated party credibly declares that it would buy the same asset for \$102, subject to due diligence etc. If the company has to spend more than \$2 in transaction costs to negotiate with the unrelated party, disinterested shareholders will vote for the RPT even if, by now, they are aware that the company would have gained more by searching for another buyer on the market.⁶⁶

Of course, a MOM requirement also makes it more likely that a fair RPT (i.e., a transaction in the best interests of the company) will not be entered into. That may be the case when:

- 1 Shareholders are ill-informed about the real value to their corporation of the asset to be bought (sold), thinking it is worth less (more) than the related party offers.
- 2 One or more shareholders have the power to hold out and no agreement is (or may be) reached on the side payment that they request to vote in favor of the transaction.⁶⁷
- 3 The marginal transaction costs of obtaining MOM approval, including the longer time and the publicity needed to finalize it, are such as to make the transaction no longer worth entering into or practicable.

(p. 521) The transaction cost issue is the reason why jurisdictions that provide for MOM approval (e.g., the UK, Hong Kong, Singapore) do so only for RPTs above a given size, typically when their value is above 5% of the company's market capitalization. France is an exception, because the exemption is only for routine self-interested transactions (i.e., those the company itself assesses to be entered into in the ordinary course of business and at market conditions). However, MOM approval in France is only ex post, at the annual meeting, and denial of approval of a properly board-approved transaction has very little practical impact, if any.⁶⁸

4.2.2 Disinterested or Independent Directors' Approval

Jurisdictions may require involvement of independent directors in the approval process, as is the case in Belgium (for intra-group transactions specifically⁶⁹) and Italy,⁷⁰ or make it strongly advisable, as under Delaware case law with regard to some transactions with controlling shareholders.⁷¹ Within or across jurisdictions, however, approval merely by disinterested directors is sometimes sufficient: such is the case in Belgium and Delaware for transactions with directors and in France generally for transactions in which a director or a substantial shareholder have an interest.

For independent directors (and a fortiori for merely disinterested ones) to play an effective role in the protection of minority shareholders, the key issue is of course how truly independently from controllers one can expect them to act. In part, that will depend on

Related Party Transactions

how “independence” is defined and, primarily, on whether being nominated by the controlling shareholder precludes that qualification. Even when a director is nominated and appointed with the involvement of minority shareholders (like in Israel, Italy, and Spain⁷²) substantial independence is not guaranteed, as that is mainly a function of an individual’s assertiveness, ability not to succumb to boardroom biases,⁷³ and reputational and career concerns.⁷⁴

Even assuming that an independent director has such personal qualities and concerns, a handicap she still faces is her inferior knowledge of a company’s business.⁷⁵ The presence of what are to her unknown unknowns may well allow insiders opportunistically to filter the pieces of information based upon which her decision will be made.

(p. 522) Independent director involvement may also vary in intensity. The weakest involvement requirement is for independent directors to give non-binding advice on RPTs, like in Belgium and, limited to smaller transactions, in Italy. Such a requirement does not prevent the dominant shareholder, or at least non-independent directors, from being part of the internal decision-making process. Yet, provided that the negative advice is to be disclosed and private enforcement tools are available to shareholders, non-binding negative advice can serve shareholder interests by giving them a persuasive piece of circumstantial evidence of tunneling before the court. Further, the market may use it as a signal of the dominant shareholder’s inclination for tunneling, although that will be of little consequence if control is incontestable and the company has no prospect of raising more equity. Finally, especially when the negative advice is to become public, boards will tend not to deviate from the independent directors’ advice.⁷⁶

Involvement is stronger with a requirement that the transaction be approved not only by the board as a whole but also by a majority of the independent directors. Here, it makes a difference whether their decision is made in the same room and at the same time as the board’s decision, and whether interested directors, and especially the CEO or the dominant shareholder, are present.

Still stronger is an independent directors’ binding advice, in which case they do have a veto power over the RPT. Whether that power is effective (will be exercised as often as necessary to protect shareholders’ interests) depends not only on the directors’ substantial independence and on whether they have full access to information, but also on whether they can be assisted by experts (lawyers, investment bankers, etc.) of their own choice at the company’s expense (like in Italy⁷⁷), and on how late in the negotiation process they are involved: the later they are to express themselves on the RPT, the more likely that a number of alternatives will no longer be practically available, so that the RPT may have become the only viable way ahead for the corporation and favorable advice a forgone conclusion.

The strongest form of involvement is finally the “independent negotiating committee” (or “special committee”) Delaware courts have since long nudged boards into using when a parent-subsidiary merger or an MBO is on the agenda:⁷⁸ the board delegates a small number of independent directors to conduct negotiations on the transaction and to decide

Related Party Transactions

upon it, usually having freedom to search for alternative counterparties. Because of their total control over the process, special committees have various advantages over shareholder MOM approval: their involvement is more timely, their (access to) information better, no serious holdout risk exists,⁷⁹ and the procedural costs should be lower. The crucial point is always whether one can expect independent directors to make decisions in the best interests of the company rather than in the related party's.⁸⁰

(p. 523) 4.2.3 Independent Directors and MOM Approval?

All in all, neither MOM approval nor the independent directors' role ensures that tunneling via RPTs will not occur. To lower that risk, a jurisdiction may think of combining the two procedural safeguards discussed above. There are obvious synergies between the two: as (then) Vice-Chancellor Strine put it, the independent directors' role "is important because the directors have the capability to act as effective and active bargaining agents, which disaggregated stockholders do not."⁸¹ They may thus screen RPTs and ensure that their terms are better for the shareholders: the risk that shareholders approve unfair transactions because it is too late for alternative solutions to be considered⁸² should go down considerably. But, again in Chancellor Strine's words, "because bargaining agents are not always effective or faithful, [MOM approval] is critical, because it gives the minority stockholders the opportunity to reject their agents' work."⁸³ Ex ante, it will prompt independent directors to negotiate harder.⁸⁴

Net of the higher direct transaction costs, compared to MOM approval alone, the combination of independent directors and MOM approval may also lower the risk that value-creating transactions will not be entered into. In fact, approval by well-reputed independent directors may act as a credible signal of a transaction's fairness to minority shareholders. These, in turn, may be more inclined to vote for the proposed RPT rather than siding with opportunistic activist investors who, by holding out, may aim to extract value from the company.

No main jurisdiction has so far addressed RPTs by combining independent directors and MOM approval. The one which has come closest is Delaware: for endgame transactions such as MBOs and freeze-outs, its courts have held that combining both a special committee and MOM approval grants a company and its dominant shareholder the protection of the business judgment rule, and therefore virtually insulates the transaction from judicial review.⁸⁵

4.3 Disclosure

One of the core functions of mandatory disclosure has traditionally been to cast light on self-interested transactions.⁸⁶ Mandatory disclosure is still today a widely used technique to (p. 524) address RPTs. In isolation, mandatory disclosure may be insufficient to prevent tunneling, which is well documented even via transactions that are publicly disclosed.⁸⁷ Its importance is more in supporting internal decision makers' independence (they will

Related Party Transactions

act more assertively if they know the RPT under consideration will be subject to public scrutiny) and in facilitating private and public enforcement against tunneling.

Financial reporting standards nowadays require disclosure (and therefore the audit)⁸⁸ of information relating to material RPTs almost everywhere.⁸⁹ In addition to accounting standards' requirement for periodic information about RPTs, the US SEC requires companies to annually disclose RPTs above \$120,000 so long as the related party has a material interest in the transaction.⁹⁰ In Europe, as elsewhere, companies going public have to provide detailed information of material transactions with related parties in their prospectuses.⁹¹

All of these rules and standards rely on a company's necessarily discretionary assessment of whether a transaction (or a related party's interest) is material for disclosure purposes. Especially if that assessment is not itself made by independent directors, embarrassing RPTs may well remain hidden from the public's view.⁹² And even independent directors may not always be in the best position to make that call: if they approve the transaction themselves, given a choice on whether their judgment should be subject to public scrutiny, they will naturally tend to favor opacity.

Some jurisdictions also provide for ad hoc, immediate disclosure of larger RPTs, whether as a step in the process leading to MOM approval (UK) or as an independent requirement once the transaction has been entered into (Italy; the UK for "smaller transactions"). In the former case, because disclosure is made well in advance of the shareholder meeting where MOM approval is scheduled, there is the additional advantage that attention from the media, financial analysts, and activist investors may pressure the company into obtaining better terms for (minority) shareholders or even into abandoning the transaction altogether.⁹³

Even when ex post, ad hoc disclosure has an additional advantage over periodic disclosure in IFRS-compiled financial statements: while in the former case details about the individual (p. 525) transaction are normally to be provided, according to International Financial Reporting Standards, RPTs "of a similar nature may be disclosed in aggregate except when separate disclosure is necessary for an understanding of the effects of related party transactions on the financial statements of the entity."⁹⁴ The wording, again, grants a company (its audit firm) discretion in the choice of whether to aggregate RPTs (in objecting to that choice).

Finally, given the discretion in disclosing RPTs, rules requiring public disclosure as to who is in the position to engage in RPTs with the corporation can also help detect tunneling. Ownership disclosure rules allow the market to have updated information about who has or may have an influence over the company's management.⁹⁵

4.4 Third Party Advice and Fairness Opinions

To tackle the issue of insufficient (independent director and/or) shareholder information, some jurisdictions require that companies make an independent financial advisor's opinion available to shareholders,⁹⁶ whether in anticipation of their vote on the transaction or as a supplement to information on the transaction itself. Voluntary use of independent third parties as advisors in the negotiation process, be they lawyers or investment banks, is also common practice.⁹⁷ Such advice usually includes (when it is not confined to) a fairness opinion, which the law may then require to disclose.⁹⁸

Because fairness valuations imply a high degree of discretion,⁹⁹ the value of the independent experts' fairness opinions ultimately rests upon the experts' reputation. Their effectiveness as a tool to protect investors is thus as doubtful as that of gatekeepers more generally,¹⁰⁰ the main concern being, as usual, that outside experts, even when chosen by (p. 526) independent directors, may be less independent than they look, as they usually stand to gain much more from other advisory and investment banking roles than from providing fairness opinions.¹⁰¹

In addition, as a piece of information instrumental to shareholder voting on the transaction, the fairness assessment per se is not particularly informative.¹⁰² What can be helpful is information the fairness opinion is based upon, like management's projections of future cash flows, and the assumptions and methods the advisor has used.¹⁰³ Delaware is the only main jurisdiction that has developed a wide body of case law on the scope of required disclosure on fairness opinions,¹⁰⁴ while Italy's CONSOB Regulation on RPTs requires information about fairness opinion contents roughly equivalent to Delaware case law.¹⁰⁵ Other countries appear to be less detailed in their requirement for fairness opinion disclosure.

4.5 Ex Post Standard-Based Review

Jurisdictions often rely also on ex post judicial enforcement of one form or another of a "don't tunnel" standard to tackle RPTs. Generally, what the various manifestations of ex post standard-based review have in common is that courts look into the merits of a RPT to find out whether its terms were "fair" to the corporation, i.e., whether it suffered any prejudice (broadly or strictly identified) therefrom.¹⁰⁶

Different standards of review may apply to different RPTs within the same jurisdiction. Notably, corporate law in many countries, including France and Italy, provide for more lenient standards when RPTs also qualify as intra-group transactions.¹⁰⁷

(p. 527) Ex post standard review can be an alternative to the legal safeguards analyzed so far, in which case a jurisdiction comes closest to a pure liability rule on RPTs.¹⁰⁸ The country which is closest to a pure liability rule model among the main ones is Germany: leaving aside a very specific provision on purchases from some related parties in the two years following the company's formation¹⁰⁹ and non-binding corporate governance code recommendations enacted in 2015,¹¹⁰ its procedural rules only apply to RPTs in which the

Related Party Transactions

director is formally on both sides of the transaction.¹¹¹ Ex post enforcement relies on the prohibition of concealed distributions,¹¹² on directors' duty of loyalty, and on the very broad domain of the criminal provision on breach of trust (Untreue).¹¹³

In form, Delaware is similar to Germany, because no remedy can be successfully obtained if the RPT is judged to have been entered into on fair terms. However, as a matter of practice if not of substance, Delaware case law nudges corporations into subjecting RPTs to procedural safeguards: the more rigorously these safeguards are complied with, in form as well as in substance, the less the judges will be inclined to rule for the plaintiffs by finding that its terms themselves are substantially unfair.

When ex post standard-based review goes together with procedural (ex ante) safeguards, the two legal tools can interact in at least three ways. First, ex post review may strengthen (minority) shareholder protection by working as an additional safeguard to procedural ones. That is the case if a remedy (such as damages and/or nullification) is available if the transaction is judged to be unfair, proof of compliance with ex ante safeguards having no bearing on the outcome of the case. Examples of standard-based remedies that help police tunneling via RPTs are often found in criminal, bankruptcy, and tax law. In France prosecution for abuse of corporate assets (*abus de biens sociaux*) complements procedural safeguards relying on shareholder meeting ratification of RPTs, while in Italy criminal penalties for tunneling are only relevant, for practical purposes, in the event of bankruptcy, on a count of "fraudulent bankruptcy."¹¹⁴ In bankruptcy, actions to recover assets for the benefit of creditors, such as the *actio pauliana*, can also be used to tackle tunneling.¹¹⁵ Ex post review is finally the technique tax laws use to deal with RPTs aimed to minimize a company's tax burden (so-called transfer pricing).¹¹⁶

(p. 528) The opposite occurs when a remedy for violations of ex ante safeguards is only available if the transaction is also judged to be unfair, in which case ex post standard-based review effectively weakens ex ante safeguards.¹¹⁷ Even MOM approval, on its face a property rule (i.e., a rule that requires consent of the relevant party, in our case—minority—shareholders), proves to be very much akin to a liability rule if defendants may prove that a RPT that has not been MOM-approved is still valid because it has caused no damage to the corporation.¹¹⁸

Finally, procedural safeguards may trump ex post standard-based review: such is the case when compliance with ex ante safeguards immunizes the transaction, i.e., prevents judges from declaring a transaction void or even from finding for the plaintiff in a liability suit despite evidence that the transaction is, in fact, harmful to the corporation.¹¹⁹

5 The Challenges of Enacting Effective and Enduring Reforms

Reform-minded policy makers aiming to improve domestic capital markets' attractiveness have recently singled out RPTs among tunneling techniques and designed special prophylactic rules, relying mainly on procedural and disclosure requirements.

For such reforms to be effective in the long run two elements are crucial: first, the law in action has to follow through on the reformed law on the books; second, the new legal environment must be either supported by relevant market players or in tune with social perceptions about tunneling.

Good enforcement institutions are key because, first, in this area there is no such thing as an effective bright line rule,¹²⁰ and even self-enforcing provisions prove illusory.¹²¹ Second, substantial fairness is intuitively hard to evaluate, as the convenience of a transaction to a corporation is known only, at most, to corporate insiders.¹²² Third, even procedural rules will require difficult judgment calls on the part of enforcers (be they prosecutors, lawyers, judges, or supervisory authorities officials). Such rules may indeed better screen tunneling (as they do introduce a filter). But when, for whatever reason, the filter does not work, ex post enforcement will often be not much easier than when substantial fairness review is required. Enforcers will have to resolve questions such as whether a control relationship exists (a key component of the notion of related party), disclosure has been complete, pivotal votes were (p. 529) sincere, and/or independence (disinterestedness) was just formal (ostensible) or substantial (real) as well. Most of the times, none of these questions will have a straightforward answer.

Only by seeing more and more cases can enforcers develop the "smell"¹²³ that is needed to discern bad RPTs from good. This is why the ease by which private and public enforcement actors can start a case and collect evidence is not only key to assessing a jurisdiction's anti-tunneling regime,¹²⁴ but also relevant to predicting how likely it is that the law in action will evolve in the right direction.

The problem is that even reform-minded policy makers will hesitate to unleash incompetent judges by easing shareholder access to justice. Unpredictability of outcomes and outright wrong decisions, no matter whether in favor of plaintiff shareholders or defendant insiders, may well harm an equity market's reputation no less than the absence of avenues for judicial redress.

That may explain why in countries with traditionally weak enforcement institutions (think, for example, of Italy or Brazil) it is often securities regulators who have taken the lead in enforcing anti-tunneling rules. Not only can securities regulators hire experienced professionals from the market, but, given their investor protection mission, they may also perform their enforcement tasks zealously.

Related Party Transactions

But even fervent enforcement by a committed securities regulator, backed, as it may, by law reforms tightening RPT rules, can reveal itself to be no more than a flash in the pan in countries where either no social norm against tunneling exists (i.e., where “don’t engage in tunneling” is not a specification of the prohibition on theft)¹²⁵ or market players do not themselves effectively demand high compliance rates and strict enforcement.

Unless social norms evolve in unison with the new stricter rules and thus make tunneling socially unacceptable,¹²⁶ the social perception may soon become one of overzealous bureaucrats harassing successful entrepreneurs/employers for the benefit of anonymous and often foreign investors, at which point it will be easy for the powerful business elite to obtain laxer enforcement and/or a “reparation law.”¹²⁷

(p. 530) Social norms can switch to anti-tunneling mode in two ways. The easier one is when “obey the law” is a social norm itself: anti-tunneling rules will almost automatically convert into social norms. Unfortunately, the “obey the law” norm is far from universal.¹²⁸

When no such norm exists, a “tunneling shock” will be necessary¹²⁹ (and perhaps not even sufficient). Think of spectacular instances of tunneling at an individual company (e.g. at Italy’s Parmalat) or across the market (e.g. in Russia or the Czech Republic after privatization or in East Asian countries in the run-up to the 1990s East Asian crisis) affecting one or more large firms’ viability and therefore harming wider constituencies than investors, such as employees, suppliers, and entire communities. When that happens, a backlash may ensue and tolerance for tunneling may fall. That will be fertile ground for effective corporate governance reforms, so long as, of course, intolerance for tunneling stabilizes as well, i.e., it is not just an ephemeral outbreak of moralism with no roots in deeply felt social convictions about loyalty bonds.¹³⁰

Finally, there might be situations in which market players themselves may not only pressure politicians to enact stricter anti-tunneling provisions, but also keep the pressure high on enforcement agents and the government, so that there are no second thoughts. Large international institutional investors and independent financial media are the best candidates for that job, while global law firms and leading issuers may set the right tone at the top of the legal and business elites.¹³¹ But that kind of dynamics is rarely observed: independent institutional investors may have too little at stake in an individual jurisdiction’s equity market to keep the pressure high. Further, in many jurisdictions independent financial media, when they exist, find it hard to retain their independence for long.

6 Summary

This chapter has given an overview of related party transaction regulation from a comparative perspective. It has first shown how RPTs are a common phenomenon in many jurisdictions, whether as a political risk management tool in countries with bad quality institutions, as a more elegant way than outright theft to misappropriate corporate value by dominant shareholders, or as a tool to create synergies or better allocate resources be-

Related Party Transactions

tween connected businesses. Next, it clarified the distinction between tunneling and RPTs and showed why it can make sense to have specific rules on the latter. Subsequently, it analyzed (p. 531) some of the most common legal tools to regulate RPTs: prohibitions, procedural safeguards (independent director and majority-of-the-minority approval), disclosure, external independent advice, and ex post standard-based review. As a conclusion, it sketched out the conditions for anti-tunneling law reforms to be effective.

(¹⁰) Yet, it goes without saying that one cannot expect capital markets to develop so long as “defensive” tunneling is pervasive. See *infra* notes 13 and 23–27 and accompanying text.

(¹¹) One may think of Italy or South Korea.

(¹²) See generally Lucian A. Bebchuk & Mark J. Roe, “A Theory of Path Dependence in Corporate Ownership and Governance”, 55 *Stan. L. Rev.* 127 (1999).

(¹³) Scholars tend to associate RPT-based tunneling more with dominant shareholders than with managers, who are said to appropriate private benefits via excessive compensation (see Lucian A. Bebchuk & Assaf Hamdani, “The Elusive Quest for Global Governance Standards”, 157 *U. Pa. L. Rev.* 1263, 1304–05 (2009)). However, there is no reason why, other things being equal, managers should prefer excessive compensation to RPTs as a tunneling technique. As a matter of fact, in jurisdictions where tunneling is widespread and unchecked for by legal and non-legal institutions, not only do manager-controlled companies often enter into RPTs (see, e.g., Merritt B. Fox & Michael A. Heller, *What Is Good Corporate Governance?*, in *Corporate Governance Lessons from Transition Economy Reforms* 3, 18 (Merritt B. Fox & Michael Heller eds., 2006)), but it is also the case that such companies soon become shareholder-controlled, whether because managers themselves succeed in securing a controlling ownership stake (usually via “equity tunneling:” see Atanasov et al., *Unbundling*, *supra* note 2, at 110–111) or because someone else acquires control in their stead. Control is simply too valuable to remain “up for grabs” for long. See Lucian A. Bebchuk, “A Rent-Protection Theory of Corporate Ownership and Control” (1999), National Bureau of Economic Research Working Paper No. w7203, available at <http://www.nber.org/papers/w7203>. Hence, even in such jurisdictions we observe no managerial tunneling in equilibrium: dominant shareholders themselves will keep managers on a tight leash. It is where institutions effectively address tunneling that one can observe dispersed ownership in equilibrium and, possibly, excessive managerial compensation. This form of tunneling is more common than others in such an environment, because it is hard to detect: executive pay is inevitable and determining what is reasonable compensation highly subjective.

(¹⁴) Of course, the same is usually true of excessive compensation. See note 13. Hwang and Kim report that in Korea RPTs are also used to transfer wealth to heirs so as to avoid estate and gift taxes. See Sunwoo Hwang & Woochan Kim, “When Heirs Become Major Shareholders. Evidence on Pyramiding Financed by Related-Party Sales”, 41 *J. Corp. Fin.* 23 (2016).

(¹⁵) RPTs may even be entered into at favorable terms for the corporation and correspondingly unfavorable ones for the related party, whenever the latter has an interest in supporting the former (so-called propping), if only to keep extracting private benefits of control from it in the future. See Atanasov et al., *Unbundling*, *supra* note 2, at 108.

Related Party Transactions

(¹⁶) See, e.g., Luca Enriques et al., Related Party Transactions, in Reinier Kraakman et al., *The Anatomy of Corporate Law* 145, 146 (3d ed. 2017). Savings in transaction costs may be such that a below-market rate or price for a given RPT may be justified (i.e., involve no harm to the corporation). See, e.g., David Kershaw, *Company Law in Context* 478 (2d ed. 2012).

(¹⁷) For this proposition see María Gutiérrez Urtiaga & Maria I. Sáez Lacave, “A Carrot and Stick Approach to Discipline Self-Dealing by Controlling Shareholders” 7, ECGI—Law Working Paper No. 138 (2010), available at <http://ssrn.com/abstract=1549403>; Ronald J. Gilson & Alan Schwartz, “Constraints on Private Benefits of Control: Ex Ante Control Mechanisms Versus Ex Post Transaction Review”, 169 *J. Institutional & Theoretical Econ.* 160, 162 (2013). Both models crucially rely on the verifiability of tunneling levels whether by markets via disclosure (Gutiérrez Urtiaga and Sáez Lacave) or courts (Gilson and Schwartz). See also Jens Dammann, “Corporate Ostracism: Freezing Out Controlling Shareholders”, 33 *J. Corp. L.* 681, 705–25 (2008) (a system allowing for unfair related party transactions coupled with a structural ex post remedy may be more efficient for some companies than a transaction-based approach to tunneling control). But see contra Alessio M. Paccès, *Rethinking Corporate Governance* 96–97, 151–52 (2012): “[s]tealing is always inefficient ex ante.”

(¹⁸) Cf. Alessio M. Paccès, “Controlling the Corporate Controller’s Misbehaviour”, 11 *J. Corp. L. Stud.* 177, 193 (2011) (highlighting the unattainable conditions for ex post mandatory disclosure to work effectively in this area).

(¹⁹) What comes closest to that are rules allowing for individual unfair transactions to go through in the context of corporate groups. See *infra* note 107 and accompanying text.

(²⁰) See, e.g., Sang Y. Kang, “‘Generous Thieves’: The Puzzle of Controlling Shareholder Arrangements in Bad-Law Jurisdictions”, 21 *Stan. J.L. Bus. & Fin.* 57, 85–95 (2015).

(²¹) See Gutiérrez Urtiaga & Sáez Lacave, *supra* note 17, at 14; Gilson & Schwartz, *supra* note 17, at 162.

(²²) See Kang, *supra* note 20.

(²³) The ability of relatively efficient markets to discount tunneling risk makes distributional concerns less troublesome anyway: a company’s share price should reflect information about known (uncompensated for) past tunneling and expectations about (uncompensated for) tunneling yet to come (or to detect). Thus, shareholders buy shares at a price that discounts the predictable harm resulting from tunneling. They may miscalculate the amount of undetected and future tunneling, but that is no different from miscalculating future earnings. Incidentally, the tunneling discount makes tunneling more socially acceptable even when detected: minority shareholders deserve no particular sympathy if the price they paid compensated them ex ante for taking that risk. But see *infra* notes 24–27 and accompanying text for the various inefficiencies arising from tunneling.

Related Party Transactions

⁽³⁴⁾ International Financial Reporting Standards were previously known as International Accounting Standards. Confusingly, standards adopted prior to renaming, like the one dealing with related party transactions, have kept their previous name of International Accounting Standards (IAS) followed by the relevant number.

⁽³⁵⁾ See International Accounting Standard 24, *supra* note 28.

⁽³⁶⁾ *Id.* at 2–4 (using 857 words to define related parties).

⁽³⁷⁾ See Vladimir Atanasov, Bernard S. Black & Conrad S. Ciccotello, “Law and Tunneling”, 37 J. Corp. L. 1, 16 (share sales on the basis of inside information are at the expense of prospective shareholders. *Id.* at 23).

⁽³⁸⁾ To be sure, under the UK Listing Authority Listing Rules for Premium listed companies RPTs are defined more broadly to include also transactions (other than in the ordinary course of business) “between a listed company and any person the purpose and effect of which is to benefit a related party” (UK Listing Authority Listing Rules, LR 11.1.5.R(3)).

⁽³⁹⁾ See Jesse M. Fried, “The Uneasy Case for Favoring Long-Term Shareholders”, 124 Yale L. J. 1554, 1604–06 (2015). For empirical evidence from Chile on this form of tunneling see Borja Larrain & Francisco Urzúa, “I. Controlling Shareholders and Market Timing in Share Issuance”, 109 J. Fin. Econ. 661 (2013).

⁽⁴⁰⁾ See, e.g., Edward Rock et al., Fundamental Changes, in Kraakman et al., *supra* note 16, at 171, 190–91.

⁽⁴¹⁾ The point is tricky, however, because there is no doubt that a RPT is entered into if the controller indeed pays a price for the business idea. In the absence of a formal deal, there is a transfer of value between the company and the controller, but what is transferred would arguably not qualify as a “resource,” because there is no evidence thereof in the company’s books. This makes sense from an accounting perspective, because in the absence of a resource (i.e., asset), there can be no entry for the tacit transaction in the company’s accounts. It makes much less sense if RPTs are the subject of procedural rules or other mandatory disclosure rules. This example shows how the automatic transplant of accounting concepts into regimes aimed to substantially or procedurally regulate behavior may be problematic. Examples of regulations transplanting the accounting definitions of RPTs to define the scope of procedural safeguards include Italy’s CONSOB Regulation on RPTs (*supra* note 30) and the European Union’s new regulatory framework for RPTs (see Directive (EU) 2017/828 of the European Parliament and of the Council of 17 May 2017 amending Directive 2007/36/EC as regards the encouragement of long-term shareholder engagement, O.J. L132, May 20, 2017, 1, and more precisely Art. 1(4) thereof, which inserts a new Article 9c in Directive 2007/36/EC).

Related Party Transactions

(⁴³) This was the case in Delaware with reference to parent-subsidary mergers, on the one hand, and tender offers launched by an already dominant shareholder, on the other: courts treated internal tender offers more leniently than mergers, until they recognized that the two transaction forms are functionally equivalent. See, e.g., Suneela Jain et al., “Examining Data Points in Minority Buy-Outs: A Practitioners’ Report”, 36 Del. J. Corp. L. 939, 941–48 (2011). Legal scholars’ criticism of Delaware’s bifurcated approach to such pairs of transactions was instrumental to the Court’s acknowledgment of their functional equivalence. See especially Ronald J. Gilson & Jeffrey N. Gordon, “Controlling Controlling Shareholders”, 152 U. Pa. L. Rev. 785 (2003); Guhan Subramanian, “Fixing Freezeouts”, 115 Yale L. J. 2 (2005). The role legal academics had in such evolution in Delaware case law illustrates how sophisticated, functionally minded legal scholars may sometimes be as important as sophisticated courts in ensuring that the law in action works effectively to protect minority shareholders.

(⁴⁴) Conflict-of-interest (or self-interested) transactions are a traditional focus of corporate law rules in many jurisdictions and are still the target of anti-tunneling provisions in some of them. Such is the case in France (special rules for transactions in which either directors or controlling shareholders have a direct or indirect interest: Code de Commerce (C. Com.) Art. L225-38) and in Belgium (for transactions in which directors have a conflicting interest: Code des Sociétés Art. 523).

⁽⁶²⁾ The Delaware case *Hewlett v. Hewlett Packard Co.*, 2002 Del. Ch. LEXIS 35, while not dealing with a tunneling transaction, aptly shows how difficult it is for a plaintiff to prove that an institutional investor’s vote may have been tainted by conflict of interest.

⁽⁶³⁾ For Israeli evidence of that see Hamdani & Yafeh, *supra* note 56, at 706-08, 711-13 (analyzing Israeli companies’ shareholder votes on RPTs in 2006). The most blatant example of “friendly” institutional investor voting on a RPT comes from South Korea: in August 2017, Samsung’s CEO, Lee Jae-yong, was convicted for making payments to foundations close to South Korea’s president in exchange for state pension funds’ favorable vote in a merger between two Samsung affiliates that cemented the CEO’s control over the *chaebol*. Related Party Transactions

(⁶⁵) See Rock et al., *supra* note 40, at 174.

(⁶⁶) Assuming that the transaction costs of dealing with the related party were half those of dealing with an outsider (say, \$1.5 versus \$3), the company would originally have been better off selling to the outsider for 102. Note, incidentally, that the stylized example in the text is unlikely. Similarly, a scenario in which the company starts negotiations both with an outsider and a related party will be infrequent. Even assuming that the negotiation process itself can be shaped in such a way as to rule out favoritism and hence persuade the outsider to compete with the related party, the outsider should know that the related party will have better information about the value of the asset than the outsider, so that either the related party will outbid the outsider or the outsider will have paid too much for the asset. Ex ante, this is likely to discourage the outsider from starting negotiations. (I am grateful to Luigi Zingales for this insight.)

⁽⁹³⁾ For the same reason, disclosure as an independent requirement would be more effective if it were to be made before the transaction is finalized. Notice, however, that even with disclosure to the market prior to MOM approval, renegotiation is highly unlikely if, like in the UK, the applicable rules allow for the transaction to be finalized before it, with the only proviso that it must be approved by shareholders.

Rev. 713, 720 & 735 (2010) (describing ownership disclosure as “mainly a tool for ensuring better corporate governance by guaranteeing that the market knows who has an influence over management”).

⁽⁹⁶⁾ Such is for example the case in Belgium (for intra-group transactions: Code des Sociétés Art. 524(2)) and Singapore (see Rule 921, Singapore Exchange Mainboard Rules).

(¹⁰⁵) See CONSOB Regulation, *supra* note 30, Annex 4.

(¹⁰⁶) Matters are more complicated in the US, where *ex post* review looks not only into a transaction’s substantial fairness, but also its procedural fairness. See, e.g., Melvin A. Eisenberg, “The Divergence of Standards of Conduct and Standards of Review in Corporate Law”, 62 Fordham L. Rev. 437, 451–57 (1993).

(¹⁰⁷) See Hopt, *supra* note 8. The justification for a looser approach on such transactions is that these are routine, repeat transactions, the individual review of which by courts would be practically incompatible with the very group business form; in addition, no matter whether the individual transaction is fair to the individual group entity, synergies arising from repeated intra-group RPTs or lower transaction costs may make both the parent and its subsidiaries better off in the longer run. Abstract and Keywords

This chapter examines the regulatory issues that arise when there is an offer to acquire shares directly from one or more shareholders of a company such that control of that company shifts to the acquirer. It begins with a comparison between control shifts implemented by contract and corporate transactions which produce the same result. It identifies three principal areas where contract may need to be supplemented by takeover-specific rules arising out of the coordination costs of target shareholders, powers of target management, and agency costs of non-controlling shareholders. It then considers how takeover regulation could be fashioned so as to promote efficient and discourage inefficient transfers of control. The chapter concludes by focusing on the choices actually made in four countries: Japan, Germany, UK, and the United States.

Keywords: shares, shareholders, control shifts, coordination costs, centralized management, agency costs, regulation, wealth transfers, corporate law, takeovers

1 Introduction

¹THIS chapter analyzes the regulatory issues which arise when a person, typically a company (the “acquirer”), makes an offer to one or more shareholders of a “target” company to acquire their shares in sufficient quantities to give it control of the target. The mechanism discussed in this chapter is a technique for shifting control of a company which is capable of embracing a wide variety of types of control shift. Through the share acquisition, control may move from an existing controlling shareholder (or controlling shareholder group) to the acquirer or, in a dispersed shareholding structure, from the management of the target company to the acquirer (which itself may be management or shareholder controlled). The shareholders of the target company may exit entirely from their interest in the target (as in a cash bid) or they may replace that interest with an interest in the combined entity (as where the acquirer offers its own equity as consideration in the offer). In the latter case it is even possible that the shareholders of the target will end up with the dominant economic interest in the combined group, where the target has a larg-

er market capitalization than the acquirer (sometimes referred to as a “reverse takeover”). For this reason the US term for the subject matter of this chapter—“tender offer”—is perhaps more appropriate than the UK term—“takeover bid” or “takeover offer.” The former term focuses on the mechanism—the invitation to offer shares to the acquirer—whilst the latter hints at a substantive outcome.² Insofar as the share acquisition process can be used to effect a “merger of equals” (the shareholders of the acquirer and (p. 533) target having a roughly equal economic interest in the combined entity), the characterization of this as a “takeover” is somewhat misleading. Nevertheless, we will use the term “takeover” as a shorthand way of referring to a shift in control through an offer to acquire shares directly from the target shareholders, on the grounds that, in global usage, this term seems to have the edge.³

Section 2 seeks to identify the “corporate law” issues involved in the regulation of takeovers; section 3 considers how those issues could be resolved in the light of an overarching criterion of increasing the productive efficiency of companies. Section 4 analyzes the choices actually made in four jurisdictions: UK, US, Germany, and Japan.

2 Control Shifts via Share Acquisitions and Corporate Transactions

The legal technique at the heart of the takeover could hardly be simpler or more familiar. Typically, shareholders may contract to sell their shares, on or off-market, at any time to someone who is willing to purchase them for a consideration which the seller finds acceptable.⁴ In most cases the share sale has no implications for control of the company. But the legal technique does not alter if acquisition is intended to shift control. If control is acquired from a single shareholder all that is necessary is one contract for the sale of shares. Where control is acquired from multiple non-controlling shareholders, mechanisms for coordinating the offers and acceptances need to be put in place, but at root there is simply a set of conditional contracts between acquirer and shareholders. It might thus be thought that the law of contract provides all the regulation that is necessary.

However, takeover regulation around the world recognizes three principal areas where contract may need to be supplemented by takeover-specific rules. In each case, the underlying question is whether the control-shift by share acquisition should be regulated simply as a series of parallel contracts (implying little or perhaps no supplementation of the contractual rules) or whether it should be regulated by analogy with a corporate transaction (i.e., a decision binding on the company taken by the shareholders in general meeting or a board decision), which might imply a substantial supplementation of the contractual rules. As we shall see, the salience of each of the three potential areas of regulation depends to a significant extent on whether the shareholding structure of the target company is concentrated or dispersed.

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

(p. 534) 2.1 Coordination Costs of Target Shareholders

With multiple shareholders in the target company, coordination among those shareholders may be costly and thus found only at a low level. Contract law has some techniques for generating coordination. For example, the acquirer may make its commitment to buy any shares offered to it conditional upon receiving offers to sell covering in total a certain proportion of the voting rights in the target (e.g., 50%, 75%, or even 90%),⁵ so that the acquirer either obtains control or no shares are transferred. However, a widely recognized problem, which takeover-specific laws seek to address, is the ability of the acquirer to exploit target shareholders' coordination problems so as to enable it to acquire the target at a price which, overall, does not reflect its true value. A classic example was the "Saturday night special," i.e., an offer, open only for a short period, to acquire shares at an attractive price, which offer would be shut off once the acquirer had obtained de facto control (say around one-third of the voting rights) of the company. Non-accepting shareholders would later receive offers for their shares at a much lower price (if they received an offer at all), reflecting the absence now of a control-shift premium and, perhaps, the market's adverse assessment of the acquirer's plans for the company. The impact of the scheme is to incentivize shareholders to be quick to tender all their shares into the offer, even though collectively they would likely be better off not accepting the offer but negotiating a uniform price with the acquirer as if they were a single shareholder.

Where all or a controlling block of shares are held by one or a coherent group of shareholders, the target shareholders' coordination costs are substantially reduced, perhaps even eliminated. Nevertheless, provisions addressing target shareholders' coordination problems are widely found in takeover regimes around the world, even in jurisdictions characterized by controlling shareholders. This is probably because even those jurisdictions contain (or may contain in the near future) some companies with dispersed shareholdings and because the arguments for permitting acquirers to exploit target shareholders' coordination problems seem weak. Exploitation is likely to result in inefficient transfers of control as companies are transferred at less than their fundamental value, perhaps to acquirers who intend to 'loot' the target. Acquirers may thus be motivated by the goal of acquiring assets cheaply, not by the goal of operating the acquired company more efficiently. Wealth is transferred from existing shareholders to the acquirer, but no societal benefit occurs in the shape, for example, of increased operating efficiencies. Addressing target shareholders' coordination problems is thus a method of maximizing the number of efficient control shifts by eliminating competition from one set of inefficient acquirers (or acquirers no more efficient than the existing controllers).⁶

The analogy with a corporate decision (e.g., a decision by the shareholders in general meeting to remove the members of the board or to instruct the board to adopt a new strategy, to which a takeover is often the functional equivalent) suggests various ways of addressing these coordination problems. Procedurally, takeover rules might seek to impose minimum (p. 535) periods during which the offer must remain open (so that target shareholders have the opportunity to analyze it properly) and require that information should be disclosed about the offer by both acquirer and target (to the same end). Sub-

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

stantively, the corporate decision analogy suggests that all accepting shareholders should receive the same price (i.e., they should all be “voting” on the same proposition). Thus, purchases from shareholders who sell in the market to the acquirer at a higher price or from shareholders who accept the offer late in the process after the acquirer has raised the level of its offer should cause the price available to all shareholders to be revised upwards. The provisions mentioned in this paragraph are widely found in takeover rules around the world.

It may even be that the corporate decision analogy is taken to the point of making a majority acceptance of the offer binding on all the target shareholders. This means the acquirer is entitled to squeeze out non-accepting shareholders at the offer price. Often squeeze out is available only at a very high level of acquirer post-bid shareholding (e.g., 90% of the voting rights),⁷ but some jurisdictions are more open to squeeze out at lower levels of post-bid share ownership.⁸ Where squeeze out is available, it can be said to address the target shareholders’ coordination problems from the acquirer’s perspective. A shareholder may refuse an offer from an efficient acquirer even when it is pitched above the pre-bid market price because she calculates that she will be even better off if the bidder acquires control but she remains in the company. If enough shareholders take this view, insufficient shareholders will accept the offer for control to pass. The bidder may have to offer nearly the whole of its expected gains from the transaction to the target shareholders to persuade them to accept its offer—but this will substantially reduce the incentives for potential acquirers to put offers on the table.⁹ One way to break out of this vicious circle may be to provide acquirers with rights to squeeze out non-accepting minorities at the same price as was accepted by the majority, so that the option of staying in and benefiting from the acquirer’s control is taken off the table.

2.2 Centralized Management

Control of the company or its assets can be shifted to another in many ways other than through an acquisition of the company’s shares directly from their existing holders. A company may engage in a statutory merger which, provided the jurisdiction’s merger procedure permits cash to be used as merger consideration, can be used to replicate almost exactly the (p. 536) result of a cash or share (or combined) takeover offer.¹⁰ Or the company may simply sell the assets it owns rather than the acquirer buying the shares in the company holding the assets in question. Or a company may issue or repurchase shares with a consequent impact on control of the company. All these transactions, however, involve a corporate decision, often more than one. In particular, in all the above transactions the incumbent management of the target company has, de jure or de facto, a veto over the transaction. This veto right may arise because only the board may initiate the transaction (as with a statutory merger in many jurisdictions) or because, even where the decision could be initiated by the shareholders alone, the coordination problems of dispersed shareholders make it difficult for them to secure the necessary level of shareholder agreement. Of course, shareholder consent may be required for these transactions as well (jurisdictions tend to vary quite considerably on this matter),¹¹ but the crucial

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

point is that, one way or another, the consent of the target board is at least a precondition of the transaction.

The contrast with the takeover is stark, since that transaction is formally between acquirer and target shareholders. The incumbent management appears to be sidelined. However, the formal position is highly misleading. Management is in fact in a strong position to protect itself by self-help: its powers of centralized management will often permit it to take action which renders a takeover offer unattractive to the acquirer, so that management may be in a good position to derail a bid it does not favor. For example, it may issue new shares to a friendly investor or conditionally dispose of the assets the acquirer is keen to obtain. Thus, in relation to target management, the core issue for takeover regulation is whether the standard powers routinely conferred upon the boards of public companies should be constrained during takeover offers precisely in order to allow shareholders to contract freely with the acquirer. Should takeover rules ensure that the transaction is in fact, as well as formally, one subject solely to the joint decision of the acquirer and target shareholders? More colloquially, should the rules facilitate “hostile” bids¹² (i.e., offers to which the incumbent management objects) or only “friendly” bids (i.e., those supported by incumbent management)?

There is a linkage between the first and second areas of potential takeover regulation. Management, if allowed to insert itself into the takeover process, might operate so as to protect dispersed shareholders against bidder exploitation. Management might act as the single counter-party, on behalf of all shareholders, with whom the acquirer has to deal. There is a potential trade-off here, but the trade-off is more apparent than real if effective and low-cost protection against bidder opportunism can be provided directly and without relying on target management.

It will be apparent that the centralized management point, like the coordination problems of target shareholders, is highly sensitive to the shareholder structure of the target company. (p. 537) Where there is a single or cohesive group of shareholders with a controlling block in the target, the debate about centralized management is largely irrelevant. The board of such a company are highly unlikely to exercise their powers to block an offer the controlling shareholder is minded to accept, since they will owe their positions on the board to election by the controlling shareholder.¹³ On the other hand, the controlling shareholder is less reliant on the governance benefits of a takeover than are dispersed shareholders. The controller can make use at low cost of the standard corporate law governance mechanisms (most obviously, dismissal of the board) to remove underperforming management, without relying on an acquirer to do this job. Equally, if the controlling shareholder concludes it is in her interest to merge the company with another, she is well placed to hire an investment bank to seek out a company which might want to bid for her company.¹⁴

From this it is sometimes concluded that this second area of takeover regulation is important only for dispersed shareholding companies (or jurisdictions). However, this is not the case. Assume the controller (or controlling group) does not have de jure control of the

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

company (more than 50% of the votes) but only de facto control (e.g., 20–30% of the votes)—the remainder of the votes being dispersed. Absent a takeover offer, a de facto controller relies on the apathy or lack of coordination among the majority shareholders to sustain her control of the company in the general meeting. A takeover offer, however, may generate very different decision dynamics from those in play at a general meeting. At a meeting the de facto controller's position ultimately turns on the dispersed shareholders' assessment that the certain costs of trying to coordinate with the other non-controlling shareholders so as to outvote the de facto controller outweigh the uncertain gains from taking control and implementing a new business strategy for the company. A takeover offer, by contrast, quantifies the benefits of the new strategy (in the shape of the offer consideration) and removes the need for the shareholders to coordinate amongst themselves as against incumbent management in order to produce a control shift. Thus, there can be no guarantee for the de facto controller that the acceptance patterns in relation to the takeover offer will reflect the voting patterns at a general meeting; in fact, an attractive offer is likely to secure acceptance from the majority, especially if the de facto controller had been extracting private benefits of control. Consequently, the rules on the involvement of management in the bid process may be crucial for the de facto controller who, through the management she has appointed, may wish to take action aimed at derailing the bid.

A challenge to the de facto control of the company may be even more plausible if that control is held, not by a single shareholder, but by a coordinated group of large shareholders. The acquirer may be able to detach one of those shareholders from the group and thus increase its chances of success with the offer—assuming that that shareholder is not effectively bound by contract with the other group members not to defect. By extension, a takeover offer could be used to make even de jure control contestable where that control is held by a group of shareholders, one or more of whom can be induced to defect from the controlling group.

Contrary to what is sometimes argued, it follows that restrictions on the use of the powers of centralized management during a takeover may operate, not only to make (p. 538) managerial control contestable in a wholly dispersed shareholding environment, but also to make de facto control and even de jure control by a group of shareholders contestable. Whether to inhibit the use of the powers of centralized management becomes a salient issue, not only for dispersed shareholding jurisdictions, such as the US and the UK, but also for jurisdictions where block-holding is more common. Thus, Professor Culpepper concludes, on the basis of a cross-country examination of patterns of shareholdings and hostile bids,¹⁵ that “some [shareholding] concentration is not inconsistent with an active market for corporate control.”¹⁶ He points particularly at Australia and Canada as countries with a higher percentage of hostile bids as a proportion of overall deal activity than the US and the UK despite moderately high levels of shareholder concentration. One might also point to France as a country with shareholder concentration around the Canadian/Australian level where (see section 3.2.1) the regulatory constraints on management intervention in takeover offers have recently been almost completely relaxed for fear of unwelcome foreign takeover offers succeeding. Unless irrational, this legislative reaction

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

suggests that hostile bids are feasible in that country, at least for a significant proportion of domestic companies.¹⁷

Of course, the self-interest of the incumbent management may not lie in blocking a bid but in promoting it to the shareholders, for example, in a management buy-out or a private equity buy-out where the acquirer intends to keep on the incumbent management and give them a higher economic stake in the business than was available to them when the target was in public ownership. Incumbent management cannot force the shareholders to accept a bid they regard as suboptimal, but they may recommend them to do so, a recommendation which may carry considerable weight with the shareholders given management's access to "soft" inside information. The standard remedies against bias in this context are disclosure of potential conflicts of interest and, possibly, third-party opinions on the fairness of the proposed transaction, to be disclosed along with recommendation.

(p. 539) 2.3 Agency Costs of Non-Controlling Shareholders

We have just seen that debates about shareholders' coordination costs and the exercise of management powers arise most strongly in dispersed shareholding contexts. By contrast, non-controlling agency costs arise, as the term implies, where there is a controlling shareholder. Assuming the controlling shareholder(s) have enough voting shares to pass control to the acquirer, the deal will occur whether the non-controlling shareholders are in favor of it or not, provided that the controlling shareholder is in favor.¹⁸ No powers of centralized management will be deployed to block the deal and the controlling shareholders who negotiated the deal will not be subject to significant coordination costs. The central questions for the non-controlling shareholders are: (1) are they entitled to receive an offer at all where control is transferred from an existing controller to a new one (i.e., do they receive an exit right) and (2) if so, is the offer to be on the same terms as those offered to the controllers?

Standard contract law does not require the acquirer to make an offer to all the holders of the shares carrying voting rights in the company. If a deal with one or some shareholders gives the acquirer control, it may choose not to offer for the remainder of the shares. Nor does standard contract law require the same price to be offered to all those who own the same good. By contrast, an analogous corporate transaction (e.g., sale of corporate assets) would see the consideration received by the company and the rules on distributions would normally follow an equality principle, i.e., all shareholders participate in the distribution pro rata to their economic interest in the company.¹⁹ If this analogy were followed, non-controlling shareholders would have the right to exit the company on the same terms as had been made available to the controlling shareholder, i.e., the premium attaching to the controlling shares would be shared among all the target shareholders.

3 The Goals of Takeover Regulation

The previous section has shown the tension between the purely contractual mechanism of the takeover offer and the different rules that would apply if an equivalent transaction were effected through the corporation. The position of the target shareholders as a group, of incumbent management and of non-controlling shareholders would be regulated in a significantly different way according to the regulatory model chosen. The purpose of using the device of the analogous corporate transaction was to illuminate the central choices that need to be made in takeover regulation. The purpose was not to argue that the corporate analogy should trump the contractual analysis, either wholly or partly, or vice versa. Except in relation to target shareholders' coordination costs, where the corporate analogy has gained traction with rulemakers for the reasons pointed out above, the debate between the (p. 540) contractarians and the corporatists has not resulted in a clear victory for either side. Nor is it the case that in relation to centralized management and non-controlling shareholders' agency costs that jurisdictions have ended up in the same mode on both questions. The UK, for example, is contractarian in relation to centralized management (target board excluded from exercising its powers to frustrate an offer) but corporatist in relation to non-controlling shareholders (exit opportunity on the same terms as the controlling shareholder). Delaware is similarly eclectic, but the other way around: allowing the incumbent management to "just say no" but more respectful of the principle that a controlling shareholder should be able to sell her shares without sharing the control premium with other shareholders.

In order to make choices between the contractarian and the corporate approaches some higher level of theory is required. In line with modern corporate law scholarship, one might say that the goal of takeover regulation should be to maximize the number of efficient shifts of control and to minimize the number of inefficient shifts. A rule which produces the best combination of these two objectives is thus to be preferred. Also in line with that scholarship, an efficient shift of control can be said to be one that reduces the costs of production through the corporate form. Reducing production costs is the general societal interest which company law serves.²⁰

Operationalizing this general principle through detailed takeover rules is, however, far from straightforward. A starting point might be to test the efficiency of takeover rules by reference to their impact on the share price of target and acquiring companies. If the joint value of target and acquirer companies is maximized, the above principle might be said to be satisfied. In fact, the empirical evidence, mainly from the US, has long shown that the value of the target company is enhanced by a takeover (comparing the pre-bid price with the level at which the deal is consummated),²¹ whilst the evidence on the post-bid value of the acquirer has been mixed. More recent research suggests that the gains to the acquirer have been underestimated in the past.²² Even on the more pessimistic assessment of the gains, the joint wealth of the acquirer and target shareholders is maximized.²³

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

3.1 Efficiency Arguments for Takeovers

As Romano pointed out some time ago,²⁴ takeovers may operate to increase the value of the companies involved for their shareholders for reasons which are linked to reduced costs of production but also for reasons which are not. In the former case, increased shareholder value correlates with society's interest in takeovers; in the latter case, it does not. Let us look at the efficiency arguments first.

(p. 541) The principal arguments in favor of takeovers from an efficiency perspective relate to the reduction of agency costs (for dispersed shareholders)²⁵ and synergy gains. The threat of a takeover can operate as a powerful incentive to management to promote the interests of the shareholders and one that operates at low cost for the shareholders. The takeover threat will be there at all times, it is argued, and not just when an offer is imminent. This is an argument in favor of preserving the contractual stance of the law in relation to takeovers, for a management which can derail a bid aimed at displacing it will feel less exposed to takeover threat than one which cannot. Ensuring that an acquirer can effectively appeal over the heads of the incumbent management to the shareholders (in a "hostile" bid) maximizes the disciplinary impact of the takeover. However, the intensity of the takeover threat is not a function simply of the rules regulating it (notably rules restraining the exercise of powers of management during the takeover process), but also of the incentives for bidders to launch takeovers. There is some evidence that very poorly performing companies are not attractive targets²⁶ and clear evidence that takeover activity is highly correlated with the business cycle.²⁷ So the disciplinary threat of the takeover may not operate perfectly, but it does not look as if it can be written off completely.

The synergy gains from a takeover flow from the economies of scale or scope which result from redrawing the boundaries of the firm. Management's reasons for opposing a disciplinary takeover are clear (the purpose of the takeover is to remove the incumbent management team). They are likely as well to oppose a takeover driven by synergies, since in that situation too they risk being replaced by the bidder's team or being demoted from running their own show to being subordinate to a higher level of management.²⁸

However, managerial opposition to a synergistic bid is not inevitable: an MBO is defined by its retention of the incumbent management team whilst we noted above that a private equity acquirer might wish to keep on the existing team and in fact offer them financial incentives which compensate for their newly subordinate position, or the CEO and other senior managers of the target may have the opportunity to move into equivalent positions in the combined group. Nevertheless, in the absence of such options, the self-interest of the incumbent management is likely to prejudice them against the acquisition.

In consequence, whether the bid rules permit incumbent management to exercise their powers so as to derail a bid of which they disapprove becomes an important question—perhaps the central question in takeover regulation. Preserving the contractual nature of the takeover offer permits a potential acquirer to appeal, via a "hostile" takeover, over the heads of the incumbent management, when it is conflicted, to the shareholders of the target. This policy also permits the shareholders of the target to vote on a business plan

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

for the company (p. 542) that represents an alternative to the plan being pursued by incumbent management, but without the target shareholders having to incur the cost of developing or implementing that alternative. In somewhat the same way as activist shareholders, seeking a change of management policy without a change of control, the takeover can operate as a method of putting alternative investment propositions before the shareholders in a manner that neatly sidesteps their coordination costs.²⁹

As we noted in section 2, the hostile takeover is a mechanism of potential benefit not only to shareholders in dispersed shareholding companies, but also to non-controlling shareholders where the company has a de facto controller or even where the company has a de jure controlling group, provided the solidarity of the group is open to question. The threat of the takeover may make the controlling group more respectful of the interests of the non-controlling shareholders. However, one may wonder why controlling shareholders would not accept a synergy-driven offer from an acquirer since the target shareholders' gains from such an acquisition would go predominantly to its controlling shareholders and the controlling shareholders would be well-placed to negotiate effectively with the potential acquirer. If the controlling shareholders would typically accept an efficient offer, regulating the exercise of managerial powers in relation to a synergistic bid in order to facilitate an acquisition would be a much less important question for controlled companies.

The controller's behavior is likely to be conditioned on whether her controlling position gives her access to benefits which are not available to the non-controlling shareholders ("private benefits of control"—pbc). Where this is not the case, the financial incentives of the controller are aligned with the incentives of the non-controllers and there is little reason to fear that the controller will use her influence over the management of the company to block an efficient bid. Where pbc are being extracted, this argument cannot be relied on. If the pbc are financial (i.e., the controller is diverting more than her pro-rata share of the firm's revenues to herself), the controller may calculate that her currently enhanced share of the smaller pie is worth more to her than her pro-rata share of the bigger pie resulting from the control shift. Where the pbc are non-financial (e.g., the prestige and social recognition flowing from controlling an important company), the controller may attach a very high price to that benefit—a sort of controller's "consumer surplus." In either case, the controller will be disposed to block the takeover offer.³⁰

There are two legal strategies which could be deployed to induce takeovers in this situation, both involving insistence on the contractarian model. One would be to sideline management in the acquisition process, so that the controller cannot deploy her influence over (p. 543) management to block the bid. This might be effective where the control is de facto or is held de jure by an unstable group of shareholders. Alternatively, the controller could be permitted to sell her shares at the price which reflects her pbc. This strategy might induce control shifts even in the case of secure de jure control. In order to make the acquisition of the target financially viable from the bidder's point of view, the acquirer would need to be left free not to offer the same level of consideration to the non-controlling shareholders and perhaps even not to offer to acquire their shares at all. The

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

mandatory bid rule (MBR—required of European Union (EU) states by the Takeover Directive),³¹ would become suspect in this analysis, for that rule requires a person acquiring de facto control to offer an exit right to all the other shareholders at an “equitable” price, defined as a price at least equal to the highest price paid over the previous six to twelve months in the acquisition of the controlling shares. In most cases, therefore, under the MBR the acquirer will not be able to engage in price discrimination.³² The tendency of the MBR is thus to inhibit transfers of control by controllers who extract pbc. Where the acquirer intends to earn a return on the investment involved in the takeover by increasing the operating efficiency of the target, then the societal interest in control shifts is harmed. Where, on the other hand, the bid is motivated by a plan to extract even higher pbc than currently, the inhibition is to be welcomed from a societal point of view, as we see below.

3.2 Inefficient Takeovers

Takeovers may be inefficient for three main reasons. First, the joint wealth of target and acquirer shareholders may be increased but for reasons which are unrelated to any increase in the productive efficiency of the target. Second, the joint value of the two companies may not be expected to increase, but the acquirer’s management nevertheless have an incentive to launch the takeover and the target’s shareholders an incentive to accept it. Third, those responsible for making the takeover decision may aim to bring about only efficient transfers of control and to block inefficient ones, but their decision making is poor so that they achieve their aim with only a low level of accuracy.

3.2.1 Wealth Transfers

In the first case, the gains to acquirer and target shareholders are achieved, not by increased operating efficiencies in the target, but by a wealth transfer from some other group to (p. 544) those shareholders.³³ Since there are no gains to productive efficiency, the societal case for facilitating the takeover disappears. In fact, the prospect of redistribution may have an adverse effect on the target’s current productive efficiency, so that there may be efficiency gains from blocking such takeovers.

The range of candidates which has been put forward as likely to suffer adverse redistribution is wide: target employees, target creditors, consumers of the target’s products, taxpayers of the jurisdiction in which the target is located, even citizens generally in the target’s jurisdiction. In principle, most of these inefficient transfers can be addressed by rules separate from those which deal with the three areas identified above. All jurisdictions have some rules which constrain the bidder from initiating an offer for certain categories of target, either at all or without the consent of some governmental agency. All countries have put in place controls over the acquisition of targets which are particularly important for the polity in question, for example, defense contractors, banks, crucial infrastructure suppliers. Sometimes, these controls are overtly discriminatory against foreign acquirers; and sometimes the claims of the target to “public interest” protection seem rather weak. Sometimes the rules apply to wide swathes of the domestic economy,

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

sometimes to only narrow sectors. Whenever these rules apply, the acquirer ends up dealing with the state before it can talk effectively to the shareholders of the target.

In these cases regulation of the takeover process is driven by, often ill-articulated, notions of national security or of sovereignty. So the implementation of these policy concerns via rules separate from the formal takeover rules seems sensible. Nevertheless, there is a tendency for states to buttress these separate rules when configuring their takeover laws. Thus, in 2014 the French legislature made a number of important changes to the French takeover laws, including the removal of a “no frustration” rule which had previously applied to the management of target companies, in large part because of what was seen as a threat of takeovers from foreign acquirers who would reduce jobs and investment in France.³⁴ Improving target management’s freedom to “just say no” was seen as a way of reducing foreign takeovers which, it was claimed, would leave French citizens less well off.

Tax-driven takeovers are a more obvious form of wealth transfer, i.e., from taxpayers to the shareholders of the acquiring and target companies, which may be accompanied by no improvements in productive efficiency. However, the legislature is in a good position to combat through the tax code control shifts driven by tax consideration. Tax law can set the incentives for takeovers, for example, through rules relating the deductibility of interest on loans taken out to finance takeover or rules on the availability of target tax losses to acquiring companies or which discourage companies from altering their tax domicile through a takeover in order to achieve a lower tax burden.³⁵ Using takeover rules to this end appears unnecessary.

(p. 545) The consumer interest in competitive markets is normally addressed through competition (antitrust) law separate from takeover regulation. Within a contractual model of takeover regulation the shareholders of the target might well accept a competition-reducing offer, because the acquirer would be able to finance an attractive offer for the target’s shares on the back of its expected monopoly or oligopoly rents. In a corporatist model, the self-interest of the managers in blocking a control shift might be better aligned with the interests of consumers, but this cannot be relied on, for example, where the management of the target are offered attractive positions with the acquirer. Separate competition regulation also seems sensible since anti-competitive moves can result from transactions other than control shifts via share acquisitions, for example, through the acquisition of assets from a competitor which is seeking to exit that particular line of business. From a competition standpoint these transactions should be treated equally.

Specific takeover regulation might be thought to have a bigger role to play in protecting corporate constituents (i.e., creditors and employees) against wealth-transfers via takeover bids. Creditors in fact feature rarely in takeover regulation, even though a control shift which lowers the credit-rating of the target (e.g., where its assets are used as security for loans taken out to fund the acquisition) reduces the value of the loan to the lender. Probably, this is because financial creditors are thought well positioned to protect themselves through contract, for example, a change of control clause in the initial loan

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

contract that permits the lender to recall the loan when a control shift occurs. The lender can then decide whether to recall the loan or seek to renegotiate the terms of the loan under the threat of recall (or, of course, do neither of these things).³⁶

3.2.2 Wealth Transfers and Employees

Employees, by contrast, do receive explicit recognition in at least some takeover codes. In the EU the Takeover Directive requires the provision of information to employees or their representatives and gives some opportunity for the employee representatives to make their views on the proposed acquisition known.³⁷ Some national laws go further: the French reforms referred to above extend the information right into a consultation right and make the receipt of the works council's opinion³⁸ a precondition (usually) for the distribution to the shareholders of the target board's opinion on the offer, which is itself a mandatory step in the bid process.³⁹ This requirement has some potential for slowing down the acquisition (p. 546) process and for giving target management more time to set up defenses against the bid or to seek an alternative acquirer whom the incumbent management regards more favorably. The French reforms also require the acquirer post-bid to report to the works council at intervals over the following two years on its implementation of any commitments made to the employees in the bid process. The UK Takeover Code now also contains a somewhat similar post-bid requirement, introduced as a result of the decision by a foreign bidder to reverse its commitment not to close a particular plant after it had acquired control of the target.⁴⁰ Such rules are likely somewhat to constrain acquirer opportunism in relation to statements made about employment matters in the acquisition process.

The obvious objection to such rules in takeover codes is that a takeover is only one of a number of corporate events which might have an adverse impact on the employees. A transfer of assets or simple competition in the product market might produce similar management decisions adverse to the interests of the employees. Therefore, employee protections, it could be argued, should be general, if they are deployed at all, and, in particular, are difficult to justify if confined to takeovers. In fact, the EU does have information and consultation requirements in these additional areas,⁴¹ so that the objection is not so much to the substantive scope of the EU rules as to the legislative technique of generating multiple, but not identical, information and consultation requirements rather than a single overarching regime.

The utility of information and consultation rights is open to question, even from the point of view of the employees themselves. It is not clear why target shareholders should be influenced by the adverse impact of the offer on the employees, at least in a cash offer. It is possible that the information disclosed could be used to bolster the possibilities available to employee organizations outside the offer process itself, for example, to deploy more effectively industrial or political resources against the offer.⁴² And, as indicated, within the offer process consultation rights may have a limited hold-up value for the employees.

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

From our point of view, the more salient question is how the objective of avoiding wealth transfers from the employees impacts on the configuration of takeover rules in the core areas identified above. A strategy, often advocated, is to allow target management freedom to take defensive measures, thus relying on the self-interest of management in blocking bids to act as a proxy for the protection of employee interests. A weak version of this strategy can be found in US “constituency statutes” which permit or require target boards to take into (p. 547) account non-shareholder interests when formulating their response to the offer. The utility of such statutes depends, for employees, on how closely aligned the incentives of managers and employees are in fact and, for society, on how closely those interests are aligned with societal interests. In the absence of alignment, such statutes could operate so as to increase the discretion of management by diluting their accountability to the shareholders without any clear gain to the employees or to society.⁴³

A stronger version of this strategy would be to institutionalize employee voice within the acquisition process, perhaps via employee representation at board level or via a strong role for the works council⁴⁴ in the acquisition process. It is important to be clear what the societal interest in such employee voice mechanisms might be. The mere fact that takeovers are often associated with job loss as the acquirer implements its plans post-acquisition seems a poor basis for giving employees a voice in the control-shift decision itself (as opposed to laws which seek to mitigate the adverse impact of the subsequent restructuring on the employees). The societal interest in takeovers, it is suggested in this chapter, lies in their potential to increase the productive efficiency of companies. Short-term losses to employees are not decisive evidence of an inefficient transfer of control.⁴⁵ Such losses are not even inconsistent with the view that, in the longer term, employees gain from higher productive efficiency (e.g., because the company will fail completely in the medium term if it does not adapt to competitive pressures or because, again in the medium term, the target company will end up employing more workers than at the time of its acquisition).

For the employee voice argument to be convincing it needs to be shown that takeovers (or a certain class of takeovers) are routinely driven by wealth transfers from employees even where the prior arrangements with the employees are productively efficient (and, ideally, that there are no or only limited offsetting efficiency gains from takeovers in such cases). An early statement of such a theory was provided by Shleifer and Summers⁴⁶ on the basis of firm-specific human capital investment by employees in return for implicit⁴⁷ promises by management to exercise their discretion (especially in relation to the maintenance of employment) in a way that favors employee interests. Although this theory was described in the US context as “clever but not convincing,”⁴⁸ the subsequent development of the “varieties of capitalism” literature⁴⁹ suggests that in “coordinated market” economies the story of transfer of wealth from employees in a takeover is a plausible one. In a “liberal market” economy, such as the US, coordination of the inputs necessary for production occurs, both within and outside firms, mainly across markets, i.e., principally by explicit contract. In coordinated market economies, such as Germany and Japan, there is strategic coordination of those contributing to the productive process through institu-

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

tions operating to some extent (p. 548) independently of markets. Although the coordinated market analysis has implications for a wide range of policies and institutions in society, in terms of labor contracting and takeovers it follows quite closely the Shleifer and Summers argument. For example, a somewhat idealized picture of Germany, a prototypical coordinated economy, is one in which adversarial, distributional issues are handled largely outside the firm—through multi-employer collective bargaining—leaving scope for firm level labor representation bodies, notably works councils, to develop informal arrangements over efficient working practices and skill acquisition in exchange for greater security of employment and greater promotion opportunities. Board-level representation in Germany functions as a way of verifying that the management of the company has stuck to its promises, i.e., it functions as a governance substitute for the unavailable direct enforcement of implicit contracts.⁵⁰

In this analysis, the takeover appears as a threat to the informal arrangements put in place by incumbent management. The new management team might renege on the informal commitments made by the previous management team in pursuit of short-term shareholder gain. The risk of this outcome would reduce generally the credibility of management promises made as part of cooperative deals and so thus reduce also the ex ante incentives for employees to enter into such deals. Of course, the new management team might be as committed as the previous team to the high-level coordination of corporate strategy and human resources policy. The acquirer might be expecting to gain from the takeover through productive efficiencies in an entirely different area of corporate strategy than the terms and conditions, explicit and implicit, upon which the workers are employed. These arguments point in the direction, not of prohibiting takeovers, but of creating a space for strong employee voice in the selection of offers which will proceed and those which will be blocked. In Germany this is achieved by permitting the management board to exercise its powers of centralized management to discourage takeovers, provided the management's action is approved, post-bid, by the supervisory board, upon which the employees are represented, perhaps to the extent of half the seats.⁵¹

I am not aware of direct evidence about the capacity of codetermined boards to distinguish between efficient and inefficient takeover offers in coordinated market economies, as compared to boards with no employee representation. However, there is evidence that coordinated market economies and liberal market economies are equally good at generating economic growth,⁵² and that the reduced costs of labor contracting under the German system are considerable and may outweigh the additional costs in that system of contracting for equity capital.⁵³

Finally, it should be noted that the mechanism for giving employees voice in takeover decisions in Germany is not one developed ad hoc for the takeover situation. Board representation is an integral part of the corporate governance system of that country and operates (p. 549) in relation to all aspects of corporate strategy setting. The same is true of other European countries which use board-level representation or works council input to provide employee voice in takeovers. Employee voice is not just a device for preventing wealth transfers from employees to shareholders in takeovers but an integral part of the

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

arrangements which, at least in association with certain productive technologies, generate and reinforce the company's productive efficiency.

3.2.3 Inefficient Transfers of Control Involving Wealth Transfers between or within Acquirer and Target Shareholders

In all the above cases the transfer of control is inefficient because there may be little or no increase in productive efficiency, but the joint wealth of the shareholders of the acquirer and target is increased because of a transfer of wealth to them from non-shareholder groups. In these cases, it is likely that control shifts will occur if the decision is left wholly to the target shareholders. In this section we consider cases where the joint wealth of the shareholders of the acquirer and the target shareholders is not increased, but, nevertheless, the acquisition occurs because there is a wealth transfer between acquirer and target shareholders or within those groups. Since these transfers are also financed by a redistribution of wealth rather than by an increase in wealth resulting from greater operational efficiency, there is no public policy reason to facilitate such acquisitions.

3.2.3.1 Acquirer Empire Building

First, there will be a transfer of wealth from bidder to target shareholders where the bidder offers a premium price to the shareholders of the target company but has no realistic prospect of obtaining synergies from the control shift or better management performance in the target to recoup the money spent on paying the target shareholders above the pre-bid, undisturbed price of their shares. In effect, there is a wealth shift from bidder shareholders to target shareholders.⁵⁴ Such acquisitions may occur because the management of the bidder is more incentivized to increase the size of the acquirer than its profitability, perhaps because their pay packets are tied more to the size than to the profitability of the enterprise or because they obtain significant reputational rewards from running bigger companies or because the bankruptcy risk of the company is reduced if its operations are diversified. Such behavior is perhaps particularly likely where the bidder has a large free cash flow and so can easily finance an acquisition, and the management prefers to engage in such action rather than return the surplus to the acquirer's shareholders.⁵⁵

Acquirer management behavior of this type tends not to be covered in takeover-specific rules, probably because expansion of the enterprise can take many forms other than a takeover offer. Consequently, this problem is usually addressed through the general corporate governance rules applying to the acquirer. Where shareholding in the acquirer is concentrated, management aggrandisement is unlikely, but it may be replaced by acts of controlling shareholder aggrandisement, which general corporate governance rules may find difficult (p. 550) to control.⁵⁶ Where shareholding is dispersed, sophisticated institutional shareholders may have been able to lobby for rules that require acquirer management explicitly to obtain shareholder consent for large transactions.⁵⁷ Alternatively, the applicable governance rules may make it feasible for shareholders to respond effectively to a drop in the price of the acquirer's shares on the announcement of an inefficient offer by the acquirer, for example, by credibly threatening the removal of the management if they proceed without informal shareholder approval.

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

A variation of this problem is where the offer is initially wealth enhancing, but the offer is amended in the course of the takeover process so as to involve overpayment for the target's shares. This is a particular risk where competitive bidding occurs and is sometimes referred to as the "winner's curse," i.e., bidder management gets carried away with enthusiasm for winning the auction without noticing that the price offered is destroying the financial foundation of the acquisition. However, the winner's curse is not to be explained entirely by the dysfunctional psychology of auctions. The initial bidder will have incurred substantial sunk costs in identifying the target and launching the offer. Those costs are likely to be thrown away if a competitor succeeds, as will be clear to the shareholders. Whether the costs of the acquisition are recoverable within a reasonable time-frame, by contrast, may not become clear until sometime in the future, so that management may think it will have an easier time with its shareholders if it pursues the course of winning the auction. Much depends on the ability of the market to identify overpayment at the time of the offer (and then mark down the price of the acquirer's shares) and on the intensity of the accountability of acquirer management to shareholders under the general corporate governance rules.

However, some rules specific to takeovers (or to mergers and acquisitions more generally) may help to moderate the winner's curse. "Break fees," i.e., payments by the target company to the initial offeror if the deal is ultimately completed with an alternative offeror, may, if substantial, recompense the initial bidder for its search and launch costs, and thus reduce the incentive to participate over-actively in an auction. On the other hand, such arrangements tend to reduce the incidence of competitive bidding (because the target is worth less in the hands of a subsequent bidder, to the extent of the break fee) but equally to increase the probability of the bid being completed. Because the break fee is part of an agreement between target management and acquirer, break fee agreements tend to be strictly controlled in systems which place the bid decision in the hands of the target shareholders, because they reduce shareholder choice, but approached more favorably in systems which allow target management a substantial role in the acceptance decision.⁵⁸

(p. 551) An alternative technique to reduce the incentive to pursue an auction to the bitter end, which has less impact on the incidence of auctions, is to facilitate pre-bid acquisition of shares of the target by the bidder. These can then be sold into the winning bidder's offer at a substantial profit, if it loses out in the auction.⁵⁹ Insider dealing rules tend to facilitate such precautionary action by not requiring a prospective bidder to reveal its intentions prior to dealing in the market.⁶⁰ On the other hand, disclosure requirements for "large" shareholdings put a cap on the size of the stake a potential acquirer can build up before the market becomes aware of its existence and the price of the target's shares increases. Sometimes the disclosure rules are supplemented by rules enabling companies to take the initiative to demand information of a suspected investor about its stake in the company, if any.⁶¹

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

More generally, competitive bidding raises the price paid to target shareholders, conditional on a bid being made, but the extent to which the prospect of an auction discourages the launching of bids in the first place and the impact of reduced bidding activity on shareholder wealth is unclear.⁶²

3.2.3.2 Controlling and Non-Controlling Shareholders

A second form of wealth transfer may occur where there is a controlling shareholder in the target company. In this case, there may be a transfer of wealth from the non-controlling shareholders in the target to the controlling shareholder and the shareholders of the acquirer. The controller may agree to sell her stake to the acquirer who intends to extract pbc—or to extract a higher level of pbc than the existing controller. Since such an acquisition will depress the price of the non-controlling shares, a wealth transfer occurs. In egregious cases of post-acquisition behavior by the acquirer (“looting”), liability may be imposed on the selling controlling shareholder to share her control premium with the non-controlling shareholders, thus incentivizing the selling controller to do some investigation of the acquirer’s intentions.⁶³ More generally, the mandatory bid rule, imposing an obligation (p. 552) on the buyer of the controlling block, may help to reduce the incidence of wealth-shifting transfers of control. Assume that the potential acquirer intends to gain from the transaction by extracting greater pbc than the seller currently extracts and to run the company less efficiently than the current controller. If this acquisition succeeds and the non-controlling shareholders remain in the company, they will be much worse off, because the post-bid share price of the company will reflect both the higher pbc of the new controller and the less efficient operation of the company. However, in order to secure the current controller’s acceptance of the offer, the potential acquirer will have to pay the existing controller a price which at least reflects that controller’s pbc as well as the pre-bid market price of the shares. Given that the acquirer will run the company less efficiently, so that its overall value is less post the acquisition than before it, the transaction will not occur if the price the existing controller will demand has to be extended to all the shareholders. Without that extension, the acquisition will likely go ahead provided the pbc of the new controller plus the post-bid market price of the acquired shares exceed the existing controller’s reservation price. Unlike in the situation discussed in section 2, where the MBR potentially blocked efficient sales of control, here it operates to block (or reduce the likelihood of) inefficient sales of control.⁶⁴

3.2.4 Inefficient Sales of Control Resulting from Intended Efficient Control Shifts

In this section we consider cases where the parties to the acquisition intend to produce an efficient control shift but they end up with an inefficient result. Operating efficiencies rather than wealth shifts motivate the acquisition, but the result is not efficient. There are two reasons why this may occur. First, the market value of acquirer and bidder companies may fail to reflect their fundamental value. Consequently, efficient companies may be undervalued and become takeover targets whilst overvalued acquiring companies may be in a position to make offers (especially share offers) which do not reflect their true value. Second, whether a particular acquisition pays off is determined only after the acquisition

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

(ex post), whilst those deciding whether to make the acquisition have to decide ex ante, normally in the absence of full information about the target. If acquirers are not good at distinguishing takeovers likely to be efficient from those likely to be inefficient, then an inefficient (p. 553) takeover may result in a high number of cases even if all those involved are trying to avoid this result.

The first argument obviously raises very fundamental questions about the utility of stock prices, which affects not just takeover regulation, but the whole question of the appropriate level of accountability of management to shareholders. The most common argument that markets misprice companies is that securities markets take a short-term approach to company valuation. Investments that pay off in the short term are more highly valued by investors than investments that pay off in the long term, whilst there is no reason to equate the societal interest in corporate development with short-term payoffs. This is a long-standing debate,⁶⁵ which is still not close to being resolved. It is clearly a debate of relevance mainly to dispersed shareholding companies, since controlling shareholders are necessarily there for the long term. It is plausible that a market populated by “speculators,” i.e., those interested only in short-term gains, would operate so as inappropriately as to discount long-term increases in share value. However, in both the US and the UK, the major dispersed shareholding jurisdictions, the biggest section of the market is held by institutional shareholders—pension funds, insurance companies, mutual funds—which do not have short-term goals. Often their holdings reflect an underlying drive to provide income in old age. So it is a puzzle why investors with a long-term investment horizon should be thought to be driven by the acquisition of short-term gains.

There are possible explanations for the puzzle, arising out of the relations between the institutional shareholders and their asset managers or the way in which asset owners are regulated. These explanations suggest that the market valuation of shares is not inevitably short termist. Indeed, the current fashion for investor “engagement” in the UK and the EU is premised upon the notion that the long-term interests of institutional shareholders and managers in the development of companies would be aligned, if only they could concentrate on them.⁶⁶ The implications of this debate for takeover regulation are clear: for those who think the market misvalues companies, especially targets, giving target management a veto over takeover offers is the preferred strategy, because of management’s greater information about the company,⁶⁷ whilst those who think the market does not misprice are anxious to take advantage of the hostile takeover to reduce shareholders’ managerial agency problems.⁶⁸

(p. 554) The second suggested way in which misvaluation occurs builds on information asymmetry. The bidder lacks full information about the target and so may be prone not to bid when an acquisition would be efficient or to bid when it would not. One potential legal strategy would be to require potential targets to make information available to potential bidders, but, given the opportunistic behavior by competitors which this might engender, the decision whether to provide a “data room” is invariably left to target management, not something required of them. This creates an incentive for bidders proposing particularly risky acquisitions—for example, a highly leveraged acquisition by a private

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

equity company—to proceed only via a friendly takeover, which includes some access to the target’s books before an offer is made.⁶⁹ If the proposed acquisition is on a share-exchange basis, then the risks of an inefficient transfer of control fall in part on target shareholders as well. It is unlikely that dispersed target shareholders are better placed than the bidder to evaluate the offer, and so this may be an argument in favor of a role for target management in deciding whether the acquisition goes ahead, but only where the information the target management holds cannot credibly be communicated to target shareholders.

4 Some National Systems

Having identified the crucial areas for takeover regulation (section 2) and the (conflicting) policy objectives which determine how these areas could be regulated (section 3) we now turn in section 4 to analysis of choices made by selected jurisdictions. We will examine the UK, the US (focusing on Delaware for state law), Germany, and Japan, focusing, for want of space, mainly on the second principal issue in takeover regulation, i.e., the role of target management and the hostile bid. In each case it is important to view takeover regulation in the context of the corporate governance system of the jurisdiction as a whole. Placing takeover regulation in context will help us to see (1) whether different formal systems are functionally equivalent⁷⁰ and (2) whether even functionally different systems are equally efficient because of complementarities.⁷¹

4.1 The United Kingdom

We start with the UK, because it is in many ways a straightforward system. The principal, but not exclusive, body of rules, is the Takeover Code, which now has a statutory basis.⁷²

(p. 555) Its central feature is the allocation of the decision on the bid wholly to the shareholders of the target company. Once the board has reason to believe that an offer might be imminent, it needs the consent of the shareholders in general meeting to take any action “which may result in any offer or bona fide possible offer being frustrated or in shareholders being denied the opportunity to decide on its merits.”⁷³ This is a strong effects-based rule which reverses the normal allocation of powers between board and management during the bid. Management good faith is not a defense if the action frustrates the bid. The rule extends to the initiation of litigation to defend the company’s interests. Prior shareholder approval before the bid emerges is not enough to satisfy the rule. In short, hostile bids are facilitated. In addition, by imposing minimum periods during which the offer must be open, the Code encourages the emergence of competing offers. The competitor has an equal information right with the initial (and perhaps preferred) bidder⁷⁴ and break fees and other arrangements designed to reduce shareholder choice are normally not allowed.⁷⁵

Having side-lined target management, the UK Code is unable to rely on that source to protect target shareholders and so needs to address directly the issue of coercive offers. The Code contains a wide range of rules requiring disclosure of information (by the man-

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

agement of both target and acquirer), laying down timetables with minimum offer periods, and requiring equal treatment of those who accept early with those who accept late in the offer period or outside the offer, even before it was launched, including a mandatory bid rule.⁷⁶ Particularly important is Rule 31.4. This provides that, even after the acquirer has received the level of acceptances which it requires, the offer must remain open to non-accepting shareholders for a further 14 days. Target shareholders who regard the offer as inadequate and so do not want to accept it but are even less enamored of becoming minority shareholders in a company controlled by the acquirer can thus order their preferences by (1) not initially accepting the offer and (2) changing their minds when it becomes clear that a majority of fellow shareholders have accepted it.⁷⁷

Finally, the UK Code contains a mandatory bid rule, though it was not initially part of the Code. In a dispersed shareholder setting, the MBR does not function so as to block (or discourage) sales of control by existing controlling shareholders, whether those sales are efficient or inefficient. Its function appears to be to control bidder coercion as against the shareholders as a class.⁷⁸ Without it, the acquirer could carry out a market raid at a high price, but not offer for the shares of those who did not respond to the market raid. If this is its function, it is not clear that the trigger is set at the right level: in a dispersed context, a holding of less than 30% may well be enough to give the holder de facto control of the company.⁷⁹

Overall, the UK Code is target shareholder friendly, in a way that maximizes shareholder wealth conditional on a bid being made, rather than by maximizing the number of offers. An acquirer who is not in a position to offer for all the shares in the target company at the highest (p. 556) price paid for any of them is likely to find the UK rules discouraging. Furthermore, the UK rules, whilst sidelining management in relation to defensive measures, nevertheless permit target management to negotiate on behalf of target shareholders. Partly through the force of their recommendations to shareholders and partly by permitting or denying the acquirer access to the target's books, the management of UK target companies can play an active role in the takeover process even though subject to the "no frustration" rule. Thus, bid premiums in the UK and the US, which allows target management a significant role in the takeover decision, are not significantly different.⁸⁰

There is a convincing political economy cum method-of-rulemaking story to explain the orientation of the UK Code. The adoption of the Code in 1968, after a series of fiercely contested takeovers when target management freely exercised their powers in attempts to block bids, occurred at a time when pension funds and insurance companies had acquired commanding share of the UK public market. The institutions' interest in investee companies was primarily financial, unlike that of the controlling families whom they were replacing, and so they had an interest in promoting rules likely to generate high-premium takeovers. As important, the UK government decided not to legislate on takeover rules but to leave that matter to a self-regulatory exercise by a group of financial interests coordinated by the Bank of England.⁸¹ This gave institutional shareholders more influence over the setting of the rules than management or other groups, such as employees, who might have been more effective in a standard legislative process.⁸² The "no frustration"

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

rule was adopted from the beginning and has retained its place despite its adverse impact on non-shareholder interests in a number of cases.⁸³ The choice of rules which maximize target shareholder wealth conditional upon a bid being made (rather than to maximize the number of offers) is probably explicable by the desire of the institutions' representative bodies (which did the negotiating) to avoid a situation where one institution did better out of an acquisition than the others.

The role of the institutions is also crucial in explaining one other mystery about UK takeover rules. If the Code is so strong at ruling out post-bid takeover defenses, why does this not push management into adopting pre-bid shareholder defenses, such as non-voting or weighted voting shares or voting cap arrangements, all of which general UK corporate law permits and which the Code does not control because the defenses are put in place before a bid is imminent? If companies take this step, the ban on post-bid defensive measures becomes an irritation rather than a real block on effective defenses.⁸⁴ Such arrangements might be put in place at the point at which the company goes public, thus giving investors the option of buying on this basis or not buying at all. Offers of this type are common in New York; rare in London. The answer seems to be the strong opposition of UK institutions to departures from "one share, one vote." The opposition of the UK institutions to non-voting (p. 557) shares is legendary and of long standing. The position is not that they discount the price of shares which do not carry equal voting rights, but that they will not buy them at all.⁸⁵ Coordination amongst the UK institutions thus extends beyond lobbying for rules they favor to establishing market practice.⁸⁶

Finally, the shareholder friendly approach of the Code fits in well with the general orientation of UK corporate law, which retains its classical, nineteenth-century position of giving shareholders strong governance rights over management.⁸⁷ Shareholders by ordinary majority vote at any time may remove all or any of the directors from office without cause and 5% of the shareholders may convene a meeting, whether the board agrees or not, to put such a resolution before the shareholders. As the prehistory of the Code showed, however, the governance rights were not enough to dissuade management from the use of their powers to block bids.⁸⁸ Managers may have reasoned that the opportunity to argue things out later with the shareholders was more attractive than certain execution now in the hands of the acquirer. In any event, the "no frustration" rule shifts the burden of action from shareholders (to remove managers who blocked bids) to management (wishing to take defensive action) and moves the decision from the future (when passions may have cooled) to the present (when a bid is on the table).

However, David Kershaw has argued that the "no frustration" rule adds nothing to what the English common law fiduciary duties of directors would have required—other than, one might suggest, a much more effective enforcement mechanism via the Takeover Panel.⁸⁹ This is a very difficult argument to assess, since there was only one English case applying the fiduciary "proper purposes" rule to defensive measures by target management before common law decision making was overtaken by the Panel. This was the first-instance decision in *Hogg v. Cramphorn*,⁹⁰ which did indeed decide that the defensive tactics adopted in response to a non-coercive bid without shareholder approval constituted a

breach of that rule. How the courts would have further developed the proper purposes doctrine in the takeover context is a highly speculative question, especially as the counterfactual could take more than one form. In the complete absence of a takeover code it seems likely that the English courts would have been forced, as with the courts in Delaware and Japan, to use fiduciary duty law to distinguish between “legitimate” and “illegitimate” offers, rather than to impose a blanket ban on defensive action, as the UK Code does, for that would have left target shareholders unprotected against bidder opportunism. As we shall see below, however, the (p. 558) courts in those two jurisdictions draw the line between legitimacy and illegitimacy in rather different ways, so there would have been a range of choices for the English courts to make when fashioning a full set of takeover rules on the back of fiduciary duties law. In any event, a simple “no frustration” rule is unlikely to have resulted. If the counterfactual is the Takeover Code and Panel, as they stand, except for the absence of a “no frustration” rule, the English courts would have had to puzzle out whether the omission of that rule from an otherwise target-shareholder friendly set of rules represented a deliberate decision to permit defensive measures or whether a “no frustration” rule was implicit in the Code’s structure. In either case, there is good reason to think that the institutional shareholders had more success in shaping the rules of the Code than they would have had in influencing court decisions, where lobbying is not an accepted part of judicial decision making.⁹¹

The Takeover Code’s “no frustration” rule thus adds materially to the power of target shareholders in takeovers, albeit by way of extension of characteristics already present in the UK corporate governance system rather than by way of a novel addition.

4.2 The United States

The US takeover rules are an almost complete contrast with those in the UK, but the practical results of their operation seem not to be as different as the contrast at the level of the formal rules would suggest. Let us look first at the formal rules.

The Williams Act 1968⁹² contains provisions which inhibit the acquirer to a significant extent from taking advantage of the coordination problems of dispersed shareholders—though the Act stops short of a mandatory bid rule. The other two major areas of takeover regulation (defensive measures, minority protection against controlling shareholders) have been left to state law. State legislation, which has been partial rather than comprehensive, has generally favored defensive measures, sometimes through constituency statutes⁹³ and sometimes through more robust measures.⁹⁴ However, these legislative provisions have been superseded in fact by a remarkable piece of private ordering (the shareholder rights plan—hereafter the “plan”—or “poison pill”) which has provided target management with a high level of input into the takeover decision.⁹⁵ Where the plan has been accepted by the courts, as it has in Delaware and most other states, it has become the primary mechanism for forcing acquirers to deal with the management of the target company rather than appeal over their heads to the target shareholders in a hostile bid.

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

(p. 559) The plan, in its dominant “flip in” version,⁹⁶ provides for the issue of warrants to subscribe for shares at an attractively low price when an investor acquires a proportion of the company’s voting rights which is set out in the plan (e.g., 15%). The warrants are made available to all shareholders except the one who has crossed the threshold. Where the acquirer obtains the shares by purchases in the market or by private treaty with a large shareholder, the impact of the plan, if triggered, is to dilute the acquirer’s holding (in both voting and financial terms) below the threshold and to do so whenever the threshold is crossed. The acquirer might seek to avoid this “show stopper” by making an offer for shares conditional upon a high percentage of the target shareholders accepting the offer, so that the dilution will apply only to the small percentage of non-accepting shares.⁹⁷ However, if the plan is triggered also by an offer for more than a certain percentage of the voting shares, the target shareholders will have every incentive to exercise their rights and then assent them to the offer, thus destroying the financial basis of the acquirer’s offer of so much per share.⁹⁸ In either case, proceeding is too risky a business for the acquirer. No acquirer is known to have launched and succeeded in a bid in the face of a plan. Instead, it needs to get the rights removed, which the plan will provide can be done by the directors of the target company at low or no cost to the company, thus forcing the acquirer to deal with target management as well as target shareholders.

The second crucial feature of the shareholder rights plan is the ease with which it can be adopted. Under Delaware law⁹⁹ the adoption of a plan is within the powers of the board, so that no shareholder consent is required.¹⁰⁰ Not only is the decision within the unilateral control of the board, but it can be taken speedily, since only a board resolution is needed.¹⁰¹

(p. 560) However, the effectiveness of this piece of private ordering depends crucially on the courts’ view of its relationship to the fiduciary duties of directors. The Delaware courts easily accepted that for the directors, by adopting a plan, to put themselves in a position where they could decide whether or not to block an offer, if one were made, was not a breach of fiduciary duty.¹⁰² So the question became whether failure to redeem a plan in the face of a particular offer, so as to permit the bid to proceed, was a breach of fiduciary duty. This decision of the board has always been subject to court review. It was relatively easy for the courts to conclude that it was legitimate for the board to stymie a bid which was structurally coercive of target shareholders, because the shareholders’ decision in that situation could not be regarded as a reliable expression of their wishes.¹⁰³ Absent coercion, the analogy with the UK approach would indicate that the pill should routinely be redeemed. The Delaware courts never adopted this approach. In fact, as time went on, although the standard of court review was always formally more exacting than a business judgment rule,¹⁰⁴ the courts became increasingly deferential to the board’s views.¹⁰⁵ The board could refuse to redeem if this were necessary to protect their existing business strategy (even though productive efficiencies might indicate a change of strategy)¹⁰⁶ and, more recently, if the board thought the offer “substantively” coercive (apparently meaning that the shareholders might take a lower view of the company’s value than the directors thought appropriate).¹⁰⁷ The only serious qualification to the courts’

deference to management was the duty imposed on the board to seek out the highest bidder for the company if the board had in fact decided to sell the company.¹⁰⁸

As might be expected, the very different UK and US rules produced different experiences in relation to hostile bids. In both jurisdictions hostile bids are uncommon, but they are more common and more likely to succeed in the UK than in the US. Armour and Skeel report that “in the United Kingdom, 0.85% of takeovers announced during the period 1990–2005 were hostile, compared with 0.57% in the United States. Of these hostile bids, 43% were successful in the United Kingdom, as opposed to just 24% in the United States.”¹⁰⁹ More striking, however, is their assessment that “in the United States, the overall level of takeover activity, adjusted for the size of the economy, actually seems slightly higher than in the United Kingdom, even during the 1990s.”¹¹⁰ This is surprising because, if the thesis about (p. 561) managerial hostility to disciplinary and synergistic control shifts is correct, one would expect target management to use the power given to them by the plan to reduce substantially the incidence of takeovers.¹¹¹

There are two broad categories of explanation of this fact. The first is that the plan simply diverted acquirers into another method of obtaining control, i.e., a proxy fight to replace the directors with the acquirer’s nominees, who would repeal the plan. Given that under Delaware law directors can normally be removed by shareholders only at the annual meeting through a failure to re-elect (not at any time, as in the UK), even this change of procedure would seem to imply some significant costs for the acquirer.¹¹² For most of the recent period, however, even this opportunity has not been available, because boards were “classified” or “staggered” (only one-third of the board retiring each year), so that a proxy victory in two successive general meetings would be necessary to pass control. The combination of the plan and the staggered board made this alternative route impassable.¹¹³

The alternative explanation is that the corporate governance system in the US adapted to this grant of power by the plan to target boards by developing mechanisms to influence the way in which directors exercise the power. “Just say no” may be an accurate description of the formal power held by target directors under the plan, but “just say no” did not become an accurate description of how target directors behaved. Two developments in US corporate governance, occurring at the same time as the plan became widespread, but not necessarily because of the prevalence of the plan, altered the incentives of target management directors in a direction more friendly to the interests of target shareholders. One development, high-powered share-based remuneration schemes for executive directors and top managers, re-channeled the self-interest of executives in the direction of accepting bids which were wealth-enhancing for target shareholders. Such schemes might provide handsome recompense for an executive who lost his job in a control shift, especially if the normal vesting period requirements were waived on the takeover, and generate an incentive for that executive to negotiate the best price for the target shares which could be obtained. At the same time the arrival of the independent non-executive director as the dominant type of board member (at least in numerical terms) generated pressure in the same direction, since the incentives of the non-executives were to be seen to do a

Control Shifts via Share Acquisition Contracts with Shareholders (Takeovers)

good job for target shareholders in order to enhance their reputation and increase the likelihood of higher-status non-executive positions in the future. The combined effect of these two developments was to change “just say no” into “just say yes, if it is a good price.”¹¹⁴

(p. 562) Does this mean that the UK and the US have ended up in the same place (at least in relation to Delaware corporations)? There is one potentially important difference. If the management of the Delaware target company genuinely believe¹¹⁵ that the value of the company in their hands is greater than its value in the hands of the acquirer and they can convince another set of corporate insiders (the independent directors) that this is the case, but it is difficult for them to convey that argument credibly to outsiders (target shareholders), then they have a greater possibility of keeping the target independent in the US than in the UK. Under a “shareholders decide” rule, target management runs the risk of being misunderstood by the investors or, what is usually the same thing, the market. Since the most plausible version of the efficient capital market hypothesis (the semi-strong version) accepts that sometimes there is information available to insiders which is not available to the market and a more skeptical view might be that there are periods when the market suffers from failures to value companies accurately,¹¹⁶ the Delaware arrangement might be thought to have advantages.¹¹⁷

Another potential advantage of the Delaware arrangement is that it relies heavily on private ordering, i.e., decisions taken at company level rather than by legislatures or other general rulemakers. The plan, the staggered board and the incentive remuneration system are all examples of private ordering; only the independent director requirements result from regulation. Enriques, Gilson, and Paces¹¹⁸ have argued that, in general, firm-level decision making on the role of management in the takeover is to be preferred. Whether protection of the existing strategy of the company or exposing target board management to the risk of removal if they perform badly will better promote the wealth of target shareholders depends heavily upon the circumstances of each company and, within a company, may vary from time to time.¹¹⁹ A mandatory exclusion, as under the UK Code, prevents shareholders from committing themselves not to assent to a takeover offer for a period of time, as the newly fashionable policy of engagement might be thought to require from time to time.¹²⁰ However, the Delaware arrangements do not fully measure up to the default model proposed by these authors. They propose that the default should be that shareholders decide, both because on average shareholder decision making is more likely to be wealth-enhancing than (p. 563) board decision making, and because a shareholder default means that it can be altered only with shareholders’ consent. It is the management’s burden to persuade the shareholders to alter the default rather than the other way around. This is likely to be the better arrangement because the burden of persuasion is more easily discharged by management than dispersed shareholders.¹²¹ On this view, the shareholder rights plan places the burden of action the wrong way around.

4.3 Germany

The formal rules in Germany look very much like the US ones where there is a plan in place, except that the rules result from legislation rather than private ordering. Under the relevant statute, the management board may take defensive measures provided the supervisory board approves, subject to their fiduciary duties and their obtaining shareholder approval where the measure is one which, if taken outside a takeover bid, would require shareholder approval.¹²² Scrutiny by reference to directors' duties is likely to be light, as in Delaware, but in this case for the reason that German company law does not equate corporate value with shareholder value. The board is free, even obliged, routinely to consider a range of "stakeholder" interests, so that the fact that the directors' decision does not and is not intended to maximize shareholder wealth does not of itself render that decision suspect.
